Protocol Engine Hash Table Entry	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the PE Hash Table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the hash table entry are dropped. Protocol Engine Asynchronous Events are not reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the PE Hash Table entry object is reported in the PFHMC_ERRORDATA register. Packets associated with the hash table entry are dropped. Protocol Engine Asynchronous Events are not reported.
ARP Table Entry	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the ARP Table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the ARP table entry are dropped. Protocol Engine Asynchronous Events are not reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the ARP Table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the ARP table entry are dropped. Protocol Engine Asynchronous Events are not reported.
Accelerated Port Bit Vector In-Use	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the APBVT entry is reported in the PFHMC_ERRORDATA register. Packets associated with the APBVT entry are dropped. Protocol Engine Asynchronous Events are not reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the APBVT entry is reported in the PFHMC_ERRORDATA register. Packets associated with the APBVT entry are dropped. Protocol Engine Asynchronous Events are not reported.
Memory Region Table Entry (MRTE)	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the MRTE is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the MRTE object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Xmit FIFO	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Xmit FIFO entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Xmit FIFO entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Xmit FIFO Free List	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Xmit FIFO Free List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Xmit FIFO Free List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.

Table 9-20. HMC Errors [continued]

HMC Object	Error Type(s)	Error Behavior
Inbound RDMA Read Queue (IRRQ or Q1)	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the IRRQ entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the IRRQ entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Inbound RDMA Read Queue (IRRQ or Q1) Free List	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the IRRQ Free List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the IRRQ Free List entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Multicast Group	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Multicast Group entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Multicast Group entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Address Handles	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Address Handle entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Address Handle entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Physical Buffer List Entry (PBLE)	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the PBLE entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the PBLE entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Read Response FIFO	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Read Response FIFO List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Scatter Element List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.

Table 9-20. HMC Errors [continued]

HMC Object	Error Type(s)	Error Behavior
Read Response FIFO Free List	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Read Response FIFO Free List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the STag Free List entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Header	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Header object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• Invalid LAN Queue Index	Not Applicable to this object type.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Header object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Metadata	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Metadata object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• Invalid LAN Queue Index	Not Applicable to this object type.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Metadata object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Out-of-Order Send Completion (OOISC) FIFO	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Out-of-Order Send Completion (OOISC) is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• Invalid LAN Queue Index	Not Applicable to this object type.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Out-of-Order Send Completion (OOISC) object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
Out-of-Order Send Completion (OOISC) FIFO Free List	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the Out-of-Order Send Completion (OOISC) FIFO Free List entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.
	• Invalid LAN Queue Index	Not Applicable to this object type.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the Out-of-Order Send Completion (OOISC) FIFO Free List entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A Protocol Engine Asynchronous Event for the QP is reported.

9.4 Quad Hash Host Memory Cache

9.4.1 Cache Replication

The HMC for RDMA contains all the RDMA objects. This cache is partially replicated to another cache. The Quad Hash objects are duplicated for packet filtering to use. No other objects are duplicated.

When Quad Hash objects are added or deleted, the RDMA firmware is responsible for keeping the Quad Hash objects in sync for both caches. This includes populating, de-populating, and removing backing pages in both caches.

The duplicate of the Quad Hash objects cache is implemented as a separate caching block. The two caching controllers are identical design blocks. Therefore, their configuration and operation is identical as well. A separate set of registers is used for those caching blocks. Table 9-21 provides the register names of each one of those blocks.

9.4.2 Function Private Memory Space Configuration

The Quad Hash HMC configuration principles are similar to the RDMA block HMC configuration. The main difference is that Quad Hash HMC manages only one type of caching data elements. Once NVM has set the default profile or the profile was changed during the Create Control Queue Pair (Section 11.5.2.1) operation, the driver can then continue on with the second step of HMC configuration, which is to break down the FPM space into individual object regions. To do this, the driver must perform the following steps:

1. Determine the HMC function index to be configured. In the case of a PF, the HMC function number is equal to the PCI function number.
2. Read the current HMC configuration information to determine how to calculate the numbers of each HMC object that need to be requested.
    a. The GLHMC_SDPART_FPMAT[n] (or GLHMC_VFSDPART_FPMAT[n] in the case of a Protocol Engine enabled VF) register associated with the HMC FPM reports the currently available SDs for a given PCI function, which can be used to calculate the maximum FPM space.

Table 9-21 describes all the Quad HASH HMC objects and the registers used to determine the object location within Function Private Memory space, the size and limit of each object.

Table 9-21. FPM Object Registers

HMC Object	Base Register Array	Object Counter Register Array	Maximum Object Count Register	Object Element Size Register
Quad Hash Table Entry	GLHMC_PEHTEBASE_FPMAT GLHMC_VFPEHTEBASE_FPMAT	GLHMC_PEHTCNT_FPMAT GLHMC_VFPEHTCNT_FPMAT	GLHMC_PEHTMAX_FPMAT	GLHMC_PEHTEOBJSZ_FPMAT

9.4.2.1 Programming the HMC FPM Base Registers

All settings of FPM registers impact only the function associated with the registers. In other words, the driver on a given PCI function must program only the GLHMC_{object}CNT and GLHMC_{object}BASE registers for HMC PMs that are owned by that same PCI function, or HMC PMs that are associated with Protocol Engine enabled VFs that the PF owns. The FPM base of the first HMC object for each PCI function is always 0. The FPM base of subsequent HMC objects increment from previous HMC object base, the number of elements for the previous HMC object, and the size of the previous HMC object element. Additional rounding is necessary to get to the next FPM address that is properly aligned for the HMC object under consideration.

The alignment required for Hash table entry is 512B.

9.4.3 Populating HMC Backing Pages

Once the Quad Hash HMC resource profile has been picked (field) and the Function Private memory space has been programmed (Section 9.4.2), the driver must populate the HMC backing pages for the PCI function that it is initializing. The first step in this phase of initialization is to allocate 4KB pages for the PDs. Each 4KB PD page holds 512 PDs and occupies a single SD entry. Once a 4KB page has been allocated, initialized to zero, and pinned by software, the PFHMC_SDCMD_FPMAT, PFHMC_SDDATALOW_FPMAT, and PFHMC_SDDATAHIGH_FPMAT registers are used to populate the SD table for the PCI Function. Protocol Engine enabled VFs use the GLHMC_VFSDCMD_FPMAT[n], GLHMC_VFSDDATALOW_FPMAT[n], and GLHMC_SDDATAHIGH_FPMAT[n] registers, where n is the HMC Virtual Function index. Protocol Engine related SDs are programmed using the Update Protocol Engine SDs CQP operation.

Refer to the following sections:

- Section 9.3.7, “Populating HMC Backing Pages”
- Section 9.3.8, “De-Populating HMC Backing Pages”
- Section 9.3.8.1, “Removing a Backing Page”
- Section 9.3.8.2, “Removing a Page Descriptor Page”
- Section 9.3.10, “HMC Error Reporting”

9.4.4 Register Naming in Quad Hash HMC Relative to PE HMC

Table 9-22 provides control registers naming for PE HMC and Quad Hash HMC. Red text signifies the difference.

Table 9-22. Control Registers Naming

PE HMC Control Register	Quad Hash HMC Control Register
GLHMC_FWPDINV	GLHMC_FWPDINV_FPMAT
GLHMC_FWSDCMD	GLHMC_FWSDCMD_FPMAT
GLHMC_FWSDDATAHIGH	GLHMC_FWSDDATAHIGH_FPMAT
GLHMC_FWSDDATALOW	GLHMC_FWSDDATALOW_FPMAT

9.5 Control Queues

9.5.1 Preface

The Control Queue is designed with the following goals:

- Abstract firmware interface so that firmware can be changed, whether for added functionality or bug fixes, without changing the driver. Further extension of the firmware can allow changing parts of the hardware without modifying the driver.
- Remove MMIO access from all non-essential driver paths.
- Incorporate the VF-to-PF and function-to-function mailboxes into a single, extensible interface. Shared resources should be accessed through the Control Queue.
- It is possible to write one driver that works both on a primary function and on a virtual function.
- A low resource driver, such as a pre-boot driver or an out-of-the-box driver, can use the Control Queue for limited transmit and receive.

The E810 provides three types of Control Queues:

- **Firmware Admin Queues** — For communication between the software PF driver and the the E810's firmware engine.
- **Mailbox Queues** — For communications between software drivers, either two different drivers running on the same function (PF/VF), or a PF driver communicating with its corresponding VF driver. In this case, the E810's mailbox transfers the data between the respective host memory buffers.
- **Sideband Queues** — For communications between software driver and its hardware. In this case, the E810's mailbox transfers the data between the host memory and the connected hardware device.

The E810 provides the following sets of Control Queues:

- One firmware Admin Queue per PF, used for software (E810 driver)-to-firmware communication, exposed in the PF memory BAR.
- One mailbox queue at the single PF, used for the PF-to-VF. Each mailbox queue can be used by different driver on a separate 4K memory space.
- One sideband queue per PF for the E810 driver. Sideband queues are used for the neighbor IP communication and are exposed in the PF memory BAR. Each sideband queue that can be used by a different driver is allocated with a separate 4K memory space.
- One mailbox queue per VF, used for the PF-to-VF communications and exposed in the VF memory BAR. Each mailbox queue can be used by a different driver on a separate 4K memory space.

Assumptions:

- Currently, firmware does not maintain context for any driver operation, except for the state of the queue itself.
- Firmware deals with one command at a time and does not start working on a new command before finishing its current task. This might change in a future version of the firmware, so the queue mechanism must allow for it today to avoid the need for driver modification if this happens. Firmware does, however, pipeline descriptor and data fetches to optimize execution latency.
- Mailbox queues and sideband queues are handled by hardware mailbox.

Figure 9-10 describes the control queues organization. Each queue type is represented by a colored box, with the number of instances on its right.

Rows represent the different queue types. The first row are firmware Admin Queues, the second are mailbox queues, and the third are sideband queues.

Columns represent the different functions and drivers, where each driver has its own color. We have four drivers running at the PF space and four drivers running at the VF space.

Colored lines represent messages that might pass between the mailbox queues.

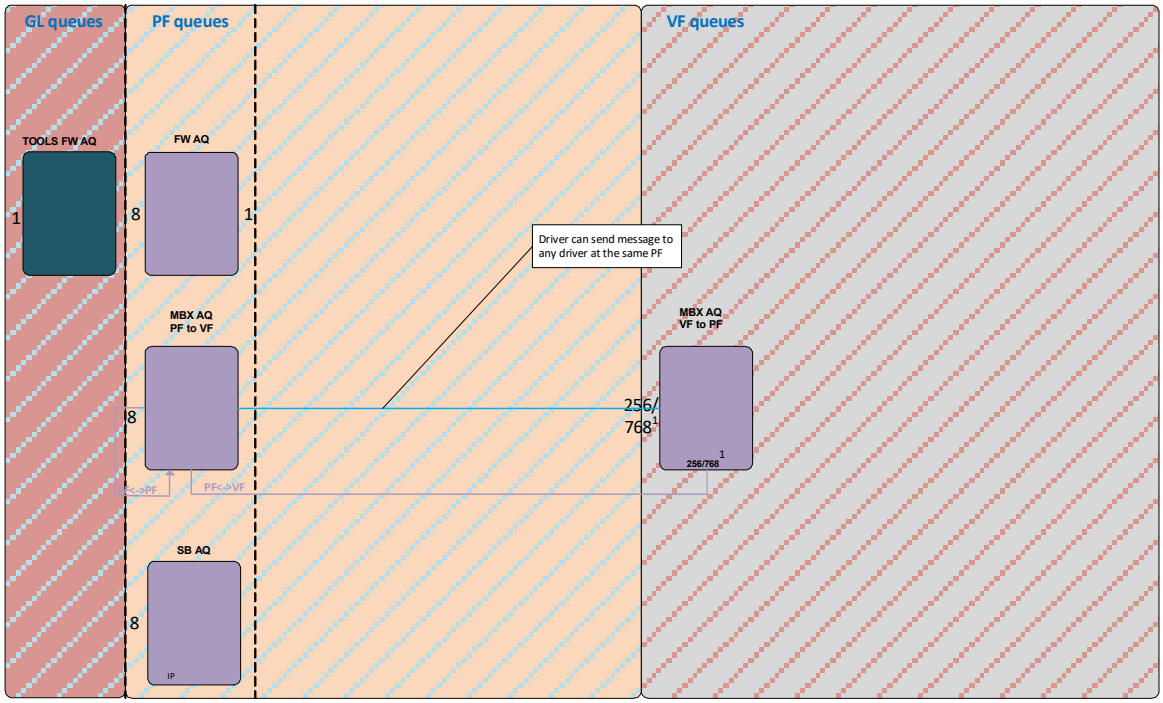

Figure 9-10. Control Queues Organization[1]

1. 768 VF queues are supported in PASID mode (GL_MBX_PASID.*PASID_MODE*).

9.5.2 Queue Structure

The Control Queue is comprised of a pair of Control Transmit Queue and Control Receive Queue. Driver commands are posted on the Control Transmit Queue (ATQ). Mailbox/Firmware completes driver commands by writing back onto the command descriptor. Events that are not an immediate result of a command are written to the Control Receive Queue (ARQ). The driver posts empty buffers to the ARQ, and the mailbox/firmware fills them with events.

Both ATQ and ARQ support direct and indirect commands, where they function as firmware or mailbox queues. Sideband ATQ queues only support indirect, as their purpose is to take the message within the buffer and send it over SB-IOSF. Sideband ARQ queues support only direct commands.

The Control Queue direct command is one that fits entirely in the queue descriptor, while an extended or indirect command is one that uses an additional buffer, which is specified in the descriptor. When a command needs an additional external buffer, it marks the *BUF* flag. If the buffer contains data that the mailbox/firmware needs to read, the *RD* flag is used. A buffer bigger than 512 bytes (AQ_LARGE_BUF) must have the *LB* flag set.

The maximum buffer size supported in this version of the queues is 4096 bytes for firmware and mailbox queues, and 512 bytes for sideband queues.

Both queues use the same descriptor structure. All descriptors and commands are defined using Little Endian notation with 32-bit words. Drivers using other conventions should take care to do the proper conversions.

Table 9-23. Control Queue Descriptor Structure (in LE 32 Order)

+3								+2								+1								+0							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

Param1																															
Data Address High																															
Data Address Low																															

Table 9-24. Control Descriptor Field Descriptions

Name	Byte.Bit	Description
Flags.DD	0.0	Set by mailbox/firmware to mark entry done.
Flags.CMP	0.1	Set by mailbox/firmware to mark entry as completion.
Flags.ERR	0.2	Set by mailbox/firmware to mark entry as an error indication.
Flags.VFE	0.3	Set by mailbox/firmware to mark entry as an event forwarded from a VF driver.
Flags.Reserved	0.4-1.0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Set by driver to indicate that indirect buffer is longer than AQ_LARGE_BUF.
Flags.RD	1.2	Set by driver to indicate that mailbox/firmware needs to read indirect buffer.
Flags.VFC	1.3	Set by driver to indicate command on behalf of a VF.
Flags.BUF	1.4	This command uses additional data.
Flags.SI	1.5	Do not interrupt when this command completes[1]
Flags.EI	1.6	Interrupt on error. Supersedes *Flags.SI* in case of an error.
Flags.FE	1.7	If previous command completed in error, flush this one.
Opcode	2-3	Command opcode. See Table 9-35.
Datalen	4-5	Indirect data length in bytes (can be used for other purposes if *Flags.BUF* is unset).

Table 9-24. Control Descriptor Field Descriptions [continued]

Name	Byte.Bit	Description
Return Value/VFID/ PFID/DRID	6-7	Return Value / VF ID / PF ID / DR ID for command or event. It is used by mailbox/firmware as a return value and reflects the error code as described in Section 9.5.9 and Table 9-34. When the command is used for mailbox or sideband queue, this parameter reflects the destination PF/VF/ driver ID on outgoing messages or the source PF/VF/driver ID on incoming messages.
Cookie High	8-11	Opaque data, echoed by receiver, high half.
Cookie Low	12-15	Opaque data, echoed by receiver, low half.
Param0	16-19	First general use parameter.
Param1	20-23	Second general use parameter.
Data Address High	24-27	Indirect data pointer (can be used for other purposes if *Flags.BUF* is unset).
Data Address Low	28-31	Indirect data pointer (can be used for other purposes if *Flags.BUF* is unset).

1. *Flags.SI* is not applicable for sideband ARQ.

See Section 9.5.5 for details on the different command types.

9.5.2.1 Control Queue CSRs

The Control queues have 32 byte descriptors. They are serviced by the following registers (Table 9-25).

{PFX} denotes the register scope prefix:

- For VFs, it is "VF_"
- For PFs, it is "PF_" or "PF0_"
- For VSIs, (PASID_MODE), it is "VSI_"

Except for the name prefix the PF and VF registers are exactly the same.

There might be several control queues at the PF or at the VF context. The PF or the VF might have up to three different types of control queues (firmware, mailbox, and sideband) and up to four different queues from the same type that belong to different drivers. The queue type is added to the register name with {TYP} as follows:

- For firmware queue, it is "FW_"
- For mailbox queue, it is "MBX"
- For sideband queue, it is "SB_"

Table 9-25. Control Queue Registers

Name	Width (Bits)	Comments
{PFX}{TYP}ATQBAH	32	High bytes of ATQ base address.
{PFX}{TYP}ATQBAL	32	Low bytes of ATQ base address. Address must be 64-byte aligned.
{PFX}{TYP}ATQLEN	10 + 4	ATQ length in descriptors. MSB is set for queue enable. Three error bits (critical error, overflow error, and VF error) are set by mailbox/firmware to indicate error conditions. See Section 9.5.10.1, "Critical Error Indication" for more information.
{PFX}{TYP}ATQH	10	ATQ head pointer (mailbox/firmware updates).
{PFX}{TYP}ATQT	10	ATQ tail pointer (driver updates).
{PFX}{TYP}ARQBAH	32	High bytes of ARQ base address.

Table 9-25. Control Queue Registers [continued]

Name	Width (Bits)	Comments
{PFX}{TYP}ARQBAL	32	Low bytes of ARQ base address. Address must be 64-byte aligned.
{PFX}{TYP}ARQLEN	10 + 4	ARQ length in descriptors. MSB is set for queue enable. Three error bits (critical error, overflow error, and VF error) are set by mailbox/firmware to indicate error conditions. See Section 9.5.10.1, "Critical Error Indication" for more information.
{PFX}{TYP}ARQH	10	ARQ head pointer (mailbox/firmware updates).
{PFX}{TYP}ARQT	10	ARQ tail pointer (driver updates).

9.5.2.1.1 Control Queues CSRs Mapping

At the PF space, Control Queues targeted for different PF drivers are mapped in separate 4K pages. However, several Control Queues (for example the firmware Admin Queue and the mailbox, sideband queues) that are targeted for the same driver might be mapped on the same page. In PASID mode (set by GL_MBX_PASID.*PASID_MODE*), the control queues targeted for VSIs are mapped in separate 4K pages per VSI, at the PF space.

In non PASID mode, the same queues that were targeted for VSI are used for the virtual functions (VF). However up to 256 queues out of the 768 are in use.

See Section 13.1.2 for the exact mapping of the control queues CSRs.

9.5.2.2 Control Queue Interrupts

Firmware, mailbox, and sideband queues trigger an interrupt when they complete descriptors on the Transmit Queue or when they post events to the Receive Queue. There is a different interrupt mapping register to map the interrupts coming from firmware, mailbox, and sideband queues per driver type. Interrupts are mapped according to the following:

- Type of the control queue: firmware, mailbox, or sideband.
- The function type: PF or VF.
- The driver queue — Up to 4 different drivers, depending on the queue type and function type.

For additional details, see Section 9.1.2.5.

9.5.3 Initialization

When initializing the queue, the driver must do the following:

- The driver allocates and sets up appropriately-sized host memory for the queues.
- The driver must post initialized buffers to the Receive Queue before it can use the Transmit Queue (see Section 9.5.3.1 for Receive Queue element initialization).
- The driver clears the head and tail registers for each queue.

  Head registers are:

  {PFX}{TYP}{DRV}ATQH and {PFX}{TYP}{DRV}ARQH

  Tail registers are:

  {PFX}{TYP}{DRV}ATQT and {PFX}{TYP}{DRV}ARQT

- Then, the driver programs the base and length registers for each queue ({PFX}{TYP}{DRV}ATQBAL, {PFX}{TYP}{DRV}ATQBAH, {PFX}{TYP}{DRV}ATQLEN, {PFX}{TYP}{DRV}ARQBAL, {PFX}{TYP}{DRV}ARQBAH, and {PFX}{TYP}{DRV}ARQLEN), and sets *legnth.enable* to 1 to inform mailbox/firmware that the queue is now enabled.
- For a firmware Admin Queue, the driver must then issue a Get Version admin command and check the queue and firmware major version numbers before it can use the queue for anything else. If the major versions does not match what the driver expects, the driver reports the mismatch and fails to load. For details and current queue version number see Section 9.5.13.1, "Get Version (0x0001)".
- For a firmware Admin Queue, after the driver has verified the queue version, it sends a Driver Version command to the device. The device then sends an indication to the BMC that the PF driver is present. This is done using Host NC Driver Status Indication in NC-SI Get Link command or via the Host Network Controller Driver Status Change AEN.
- A PF driver must have at least one buffer posted to the receive queue for each VF that is currently running. This can never be greater than the number of logical cores in the system. This must be done before enabling VFs.
- A PF can disable a mailbox queue that belongs to a VF that is associated with the PF. This is done with clearing the *QUEUE_EN* bit of the relevant PF VF control register. The *QUEUE_EN* bit is allocated for each mailbox queue and there is a mailbox queue allocated for different drivers (using register name: PF_VF_MBX_CTRL, so different PF drivers can enable or disable messages from the corresponding VF driver.

9.5.3.1 Receive Queue Element Initialization by Driver

The driver must clear any unused fields (including unused flags), and set data pointers and data length to a mapped DMA pointer.

The driver can set the *SI* and the *EI* flags in the receive queue element. The driver must not set the *FE* flag on receive queue elements.

Table 9-26. Receive Queue Element - Initial Values

Name	Byte.Bit	Value	Description
Flags.DD	0.0	0	Driver must clear.
Flags.CMP	0.1	0	Driver must clear.
Flags.ERR	0.2	0	Driver must clear.
Flags.VFE	0.3	0	Driver must clear.
Flags.Reserved	0.4-1.0	0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Driver can set	Set by driver if buffer is longer than AQ_LARGE_BUF (512 bytes).
Flags.RD	1.2	0	Not applicable to receive queue.
Flags.VFC	1.3	0	Driver must clear.
Flags.BUF	1.4	1	Receive queue elements always have an additional buffer.
Flags.SI	1.5	Driver can set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver can set	Interrupt on error. Supersedes *Flags.SI* in case of error.
Flags.FE	1.7	0	Driver must clear.
Opcode	2-3		Driver must clear.
Datalen	4-5	Buffer Length	Additional data length in bytes.

Table 9-26. Receive Queue Element - Initial Values [continued]

Name	Byte.Bit	Value	Description
Return Value/VFID/ PFID/DRID	6-7		Driver must clear.
Cookie High	8-11		Driver must clear.
Cookie Low	12-15		Driver must clear.
Param0	16-19		Driver must clear.
Param1	20-23		Driver must clear.
Data Address High	24-27	Buffer Address	Indirect data pointer.
Data Address Low	28-31	Buffer Address	Indirect data pointer.

The values written by the mailbox/firmware when it uses the EAQ element are discussed in the following paragraphs.

9.5.4 Driver Unload and Queue Shutdown

When shutting down the Control Queue, the driver (both for PF and VF) does the following:

- Posts a Queue Shutdown admin command (0x0003) (Section 9.5.13.3). In this command, the driver sets the "Driver Unloading" flag if it intends to unload.
- Software must not send any additional commands on the queue until the flow is completed.

Firmware/mailbox does the following:

- Waits for any pending DMA transactions from firmware/mailbox to be acknowledged by hardware.
- Closes the Rx-Queue by clearing its "enable" bit.
- Sends a completion to the driver as usual, honoring all the interrupt control bits in the descriptor.

Software then closes the Tx-Queue by clearing its "enable" bit. (this is the *ATQENABLE* bit in the {PFX}{TYP}{DRV}_ATQLEN register).

If the driver is unloading, it issues a function reset (PFR or VFR) to the device.

If the driver is unloading, firmware informs the BMC. This is done using Host NC Driver Status Indication in NC-SI Get Link command or via the Host Network Controller Driver Status Change AEN.

- Only for a PF driver posting the Queue Shutdown command on a firmware Admin Queue.

Note: Before the Control Queues are re-enabled, software should clear the head and tail registers of the transmit and receive Control Queue.

9.5.5 Command Descriptions

9.5.5.1 Direct Command

9.5.5.1.1 Direct Admin Command

The template for a command that is fully contained in the descriptor and does not need an additional data buffer.

Table 9-27. Direct Admin Command Template

Name	Byte.Bit	Value	Description
Flags.DD	0.0	0	Driver must clear.
Flags.CMP	0.1	0	Driver must clear.
Flags.ERR	0.2	0	Driver must clear.
Flags.VFE	0.3	0	Driver must clear.
Flags.Reserved	0.4-1.0	0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	0	A direct command has no additional buffer.
Flags.RD	1.2	0	A direct command has no additional buffer.
Flags.VFC	1.3	0	Driver must clear.
Flags.BUF	1.4	0	A direct command has no additional write buffer.
Flags.SI	1.5	Driver can set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver can set	Interrupt on error. Supersedes *Flags.SI* in case of error.
Flags.FE	1.7	Driver can set	If set, command is flushed if the preceding command resulted in an error.
Opcode	2-3	Opcode	Command opcode. See Table 9-35.
Datalen	4-5	0	
Return Value/VFID/ PFID/DRID	6-7		Mailbox messages use this field for the source/destination PF/VF/driver ID.
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.
Data Address Low	28-31		Can be used for an additional command parameter.

9.5.5.1.2 Direct Command Completion

Table 9-28. Direct Command Completion Event Template

Name	Byte.Bit	Value	Description
Flags.DD	0.0	1	Mailbox/Firmware must set.
Flags.CMP	0.1	1	Mailbox/Firmware must set.
Flags.ERR	0.2	0 or 1	Mailbox/Firmware must set only if it is reporting an error.
Flags.VFE	0.4	0	Mailbox/Firmware must clear.
Flags.Reserved	0.4-1.0	0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	echo	Mailbox/Firmware copies value from command.
Flags.RD	1.2	echo	Mailbox/Firmware copies value from command.
Flags.VFC	1.3	echo	Mailbox/Firmware copies value from command.
Flags.BUF	1.4	echo	Mailbox/Firmware copies value from command.
Flags.SI	1.5	echo	Mailbox/Firmware copies value from command.
Flags.EI	1.6	echo	Mailbox/Firmware copies value from command.
Flags.FE	1.7	echo	Mailbox/Firmware copies value from command.
Opcode	2-3	Opcode	Command opcode. See Table 9-35.
Datalen	4-5		Can be used for an additional command parameter.
Return Value/VFID/ PFID/DRID	6-7		Mailbox/Firmware return value 0=no error (for error codes see Table 9-34).
Cookie High	8-11	echo	Opaque value copied by the mailbox/firmware from the command.
Cookie Low	12-15	echo	Opaque value copied by the mailbox/firmware from the command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.
Data Address Low	28-31		Can be used for an additional command parameter.

9.5.5.2 Indirect Command

9.5.5.2.1 Indirect Admin Command

An indirect write command uses an additional DMA buffer specified in the descriptor.

The *BUF* flag must be set by the driver. If the buffer is larger than 512 bytes, the *LB* flag must be set.

This version of the queue is limited to buffers up to 4096 bytes. If the command uses the buffer to pass data, the *RD* flag must be set.

Table 9-29. Indirect Admin Command Template

Name	Byte.Bit	Value	Description
Flags.DD	0.0	0	Driver must clear.
Flags.CMP	0.1	0	Driver must clear.
Flags.ERR	0.2	0	Driver must clear.
Flags.VFE	0.3	0	Driver must clear.
Flags.Reserved	0.4-1.0	0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Driver can set	Set by driver if buffer is longer than AQ_LARGE_BUF (512).
Flags.RD	1.2	Driver can set	Set by driver to indicate that mailbox/firmware needs to read indirect buffer.
Flags.VFC	1.3	0	Driver must clear.
Flags.BUF	1.4	1	This command uses additional data buffer. Driver must set this flag on an indirect command.
Flags.SI	1.5	Driver can set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver can set	Interrupt on error. Supersedes *Flags.SI* in case of error.
Flags.FE	1.7	Driver can set	If set, command is flushed if the preceding command resulted in an error.
Opcode	2-3	Opcode	Command opcode. See Table 9-35.
Datalen	4-5	Buffer Length	Usable length of additional buffer in bytes.
Return Value/VFID/ PFID/DRID	6-7		Mailbox messages use this field for the source/destination PF/VF/driver ID.
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

9.5.5.2.2 Indirect Command Completion

When completing an indirect command, the firmware overwrites the *Datalen* with the actual length of data returned by the command.

Table 9-30. Direct Command Completion Event Template

Name	Byte.Bit	Value	Description
Flags.DD	0.0	1	Mailbox/Firmware must set.
Flags.CMP	0.1	1	Mailbox/Firmware must set.
Flags.ERR	0.2	0 or 1	Mailbox/Firmware must set only if it is reporting an error.
Flags.VFE	0.3	0	Mailbox/Firmware must clear.
Flags.Reserved	0.4-1.0	0	Reserved. Must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	echo	Mailbox/Firmware copies value from command.
Flags.RD	1.2	echo	Mailbox/Firmware copies value from command.
Flags.VFC	1.3	echo	Mailbox/Firmware copies value from command.
Flags.BUF	1.4	echo	Mailbox/Firmware copies value from command.
Flags.SI	1.5	echo	Mailbox/Firmware copies value from command.
Flags.EI	1.6	echo	Mailbox/Firmware copies value from command.
Flags.FE	1.7	echo	Mailbox/Firmware copies value from command.
Opcode	2-3	Opcode	Command opcode. See Table 9-35.
Datalen	4-5	echo	Mailbox/Firmware copies value from command.
Return Value/VFID/ PFID/DRID	6-7		Mailbox/Firmware return value 0=no error (for error codes see Table 9-34).
Cookie High	8-11	echo	Opaque value copied by the mailbox/firmware from the command.
Cookie Low	12-15	echo	Opaque value copied by the mailbox/firmware from the command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.
Data Address Low	28-31		Can be used for an additional command parameter.

9.5.6 Firmware Command Fetch and Verification

When a command is posted, firmware looks it up in an internal permission table to decide if the request should be honored. Possible actions are:

- **Allow** — Firmware acts upon the command.
- **Forward** — Firmware halts the queue and forwards the command to the PF driver. A completion for this command is initiated by the PF driver when it finishes i. Only then is further processing of commands from this queue allowed. (The PF driver must re-enable the queue after it deals with the command.)
- **Error** — Firmware completes the action by returning the error specified in the table.
- **Drop** — Firmware behaves as if the command succeed but does nothing.

9.5.7 Mailbox and Sideband Command Fetch and Verification

When a command is posted at a mailbox queue or at a sideband queue, the hardware mailbox verifies permission for the command to decide if the request should be honored. Possible actions are:

- **Allow** — Mailbox acts upon the command. In other words, it forwards the command to the relevant mailbox queue or executes the SB-IOSF transaction.
- **Error** — Mailbox completes the action by returning the error specified in the table.

Table 9-31 specifies the commands allowed in a mailbox queue and the commands allowed in a sideband queue. A PF driver is allowed to execute a richer set of commands than a VF driver. In addition, commands that deal with PF-to-VF communications are only allowed on a mailbox queue, while commands that deal with SB-IOSF are allowed on the sideband queue. If any other command is posted, the mailbox returns the EPERM (operation not permitted) error code.

Table 9-31. Commands Allowed for Mailbox and Sideband Queues

Opcode	Command	Function Allowed	Queue Type	Section Reference
0x0801	Send to PF	VF	Mailbox	9.5.14.1
0x0802	Send to VF	PF	Mailbox	9.5.14.2
0x0C00	Neighbor Device Request	PF, VF	Sideband	
0x0C01	Neighbor Device Event	PF, VF	Sideband	
0x0003	Queue Shutdown	PF, VF	Mailbox	9.5.13.3

A VF driver is only allowed to post commands at the mailbox queue, or at the sideband VF queue. Those queues are processed by the hardware mailbox. Sideband queue accepts only the Neighbor Device Request and Neighbor Device Event commands listed in Table 9-31. If any other command is posted by a VF, the mailbox returns the EPERM (operation not permitted) error code.

A PF driver can post commands at the firmware Admin Queue, Mailbox Queue, or Sideband Queue. Each queue type supports specific commands. When the command does not match the queue type, an EPERM error code is returned.

A "Queue Shutdown" command posted to a sideband queue without a buffer attached will result in an error code of EINVAL. When a buffer is attached to the "Queue Shutdown" command, the hardware will shutdown the queue.

9.5.8 Non-Completion Events

Events that are not an immediate result of a command completion are posted by the mailbox/firmware onto the receive queue.

Table 9-32 lists the currently-defined events. Note that whenever possible, the same number is used for the opcode that generates the event and for the event ID.

Table 9-32. Non-Completion Events

Opcode	Command	Type	Section Reference
0x0801	Send to PF	Indirect/Direct	9.5.14.1
0x0802	Send to VF	Indirect/Direct	9.5.14.2

9.5.9 Error Handling

When mailbox/firmware encounters an error, it uses the *Return Value* field to indicate the type of error. The error code is comprised of two bytes. The lower byte is a user-visible code from Table 9-34, and the higher byte can be used by mailbox/firmware to report internal state or debug information. The driver must log this information. Mailbox/Firmware might change this value from release to release. It is not to be reported to the user and no other action is to be taken upon this data. When the *Return Value* is 0 (“no error”), mailbox/firmware must not set the high byte.

Table 9-33. Control Queue Return Value Fields

Name	Bytes	Comment
Code	0-7	Return value from Table 9-34.
Mailbox/Firmware Internal Code	8-15	Mailbox/Firmware internal code. Must be 0 if *Code* field is 0.

9.5.10 Error Codes

When mailbox/firmware completes a command, it must use the following error codes.

Table 9-34. Control Queue Return Values and Error Codes

Error Code	Value	Meaning
(No Error)	0	No error (success).
EPERM	1	Operation not permitted. For mailbox queue: VF not allowed to access the PF. For sideband queue: Driver not allowed to access the sideband IP, or the driver is not allowed to send the sideband opcode.
ENOENT	2	No such element.
ESRCH	3	Bad opcode. For mailbox queue: Not a mailbox queue opcode, or incorrect use of opcode (e.g. VF uses the Send-to-VF opcode). For sideband queue: Not a sideband queue opcode.
EINTR	4	Operation interrupted.
EIO	5	I/O error.
ENXIO	6	No such resource.
E2BIG	7	Argument too long. For mailbox queue: Buffer longer than 4K bytes For sideband queue: Buffer longer than 512 bytes.
EAGAIN	8	Try again.
ENOMEM	9	Out of memory.
EACCES	10	Permission denied.

Table 9-34. Control Queue Return Values and Error Codes [continued]

Error Code	Value	Meaning
EFAULT	11	Bad address.
EBUSY	12	Device or resource busy.
EEXIST	13	Attempt to create something that exists.
EINVAL	14	Invalid argument. For mailbox queue: *Flags.BUF* and *Flags.RD* are set, but *Datalen* is equal to zero. For sideband queue: The descriptor is shorter than 8 bytes.
ENOTTY	15	Not a typewriter.
ENOSPC	16	No space left or allocation failure. For mailbox queue: No valid descriptor at the destination queue or the source buffer is bigger than the destination buffer.
ENOSYS	17	Function not implemented. For mailbox queue: Destination queue is disabled or the destination function is disabled.
ERANGE	18	Parameter out of range.
EFLUSHED	19	Command flushed because a previous command completed in error.
BAD_ADDR	20	Internal error. Descriptor contains a bad pointer.
EMODE	21	Operation not allowed in current device mode. For mailbox queue: VF greater than max supported by this function.
EFBIG	22	File too big.
ESBCOMP	23	Cannot find enough space for the message in the sideband or mailbox queue. For sideband queue: This error is flagged when the completion message from the neighbor IP was longer than 512 bytes. This error can be flagged also for sideband queues when the SB-IOSF completion from the neighbor IP was unsuccessful, or when the SB-IOSF completion contains data that could not fit the buffer size in the sideband queue buffer.
RC_ENOSEC	24	Missing security manifest.
RC_EBADSIG	25	Bad RSA signature.
RC_ESVN	26	SVN number prohibits this package.
RC_EBADMAN	27	Manifest hash mismatch.
RC_EBADBUF	28	Buffer hash mismatches manifest.
EACCES_BMCU	29	BMC update in progress. Returned when NVM ownership is required during PLDM firmware update.

9.5.10.1 Critical Error Indication

On any error that prevents data placement to a queue, the ATQLEN.*ATQCRIT* (or ARQLEN.*ARQCRIT*) bit is set by mailbox/firmware and the queue is stopped (by clearing its enable bit), then an interrupt is sent by mailbox/firmware to the driver.

Software reads and reports the error, and then resets the queue.

If an overflow occurs and a message to the queue is dropped because the queue is full, mailbox/firmware sets the ARQLEN.*ARQOVFL* bit and interrupts the driver. (Mailbox/Firmware does not stop the queue since, depending on the driver mode, this can be a recoverable error.)

Note: This error can currently only happen on the receive queue, but to simplify the hardware design, the bit is present on both queues.

When a VF has an event that causes mailbox/firmware to set an error bit in its receive queue. Mailbox/Firmware sets the ARQLEN.*ARQVFE* bit in the corresponding PF's queue and interrupts it. (Mailbox/Firmware does not stop the PF queue in this case.)

Note: Events and completions that have already been posted before the error are still readable and can be handled by software.

9.5.11 Command Opcodes

Opcodes are 16 bits. The upper eight bits designate the group of the opcode, and the lower eight bits are the command in the group. Each group is described in its relevant chapter.

Table 9-35. Opcode Groups

Name	Opcode(s)	Section Reference/Remarks
Generic	0x00xx	Section 9.5.13 and Table 9-39
MAC Address	0x0100	Section 4.2.1.3
PXE Mode	0x0110	Section 10.4.3.2
Switch	0x02xx	Section 7.8.12 and Table 7-21
DCB	0x03xx	Section 8.2.5
Scheduler	0x04xx	Section 8.3.4.3.6
RESERVED	0x05xx	Reserved.
Link	0x06xx	Section 3.2.4 and Section 3.3.8 (0x06E0:0x06F0 is dedicated to link topology commands.)
NVM	0x07xx	Section 3.4.10
Mailbox	0x08xx	Section 9.5.14
Alternate Structure	0x09xx	Section 4.3.2.2
LLDP	0x0Axx	Section 9.8.5.2.2
Receive Filters	0x0Bxx	Section 7.10.11
Sideband Control Interface	0x0C00:0x0C0F	
ACL Block	0x0C10:0x0C2F	Section 7.9.3.4
Queue Handling	0x0C30:0x0C3F	Section 10.5.5.8
Profiles Handling	0x0C40:0x0C5F	Section 7.11.9 and Section 7.11.12

9.5.12 CSR-Based Firmware Admin Queue for Tools

The E810 implements a CSR-based firmware admin queue for the use of tools. The CSR-based firmware admin queue implements a single command interface to firmware, which is CSR-based. The E810 implements a memory space, including a 32-byte descriptor for Tx and for immediate response, a 32-byte descriptor for events, and a 4KB buffer mapped into the CSR space. This area is directly accessible by the user mode tools software.

The GL_HICR and GL_HICR_EN registers are used to control the usage of this mechanism.

9.5.12.1 CSR-Based Firmware Queue Hardware Implementation

The tools software writes a single admin queue command into the 32-byte descriptor space using the same format of the admin queue command. It uses the 4K buffer as the buffer needed for the indirect command. Then, it signals the firmware using a GL_HICR CSR (as defined below) that it wrote for command execution. The firmware reads the command, executes it, and uses the same memory space to send back the answer from the admin command.

Note: No asynchronous events can be used by the tool queue (e.g. link change event), except asynchronous events that are caused by delayed response to a command.

Note: The CSRs are accessible to all PFs, but the assumption is that only PF0 will access it.

The CSR-based firmware admin queue implements:

- 64 bytes of descriptor area.
- 4K bytes of buffer area.

Those areas are accessible for software reads and writes only if the GL_HICR.*EN* bit is set. Write access is also limited by GL_HICR.*C* being zero.

Those areas are also mapped as Aux registers - though aux, the memory is always accessible.

Table 9-36. CSR-Based Firmware Admin Queue Areas

Area	CSR Name	Size	Offset CSR	Usage in Command	Usage in Response
Data Buffer	GL_HIBA	4K bytes	0x81000	Command Buffer	Event Response Buffer
1st Descriptor	GL_HIDA	32 bytes	0x82000	Command Descriptor	Sync Response
2nd Descriptor	GL_HIDA+0x20	32 bytes	0x82020	N/A	Async Response

The CSR-based firmware admin queue also implements the GL_HICR and GL_HICR_EN registers.

Table 9-37. GL_HICR

Field	Bits	Init Value	Firmware (Aux) Access	Software (CSR) Access	Description
Reserved	0	0b	RW	RW	Reserved.
C	1	0b	RW1C	RW[1]	**Command** The tool sets this bit when it has finished putting a command block in the command buffer. This bit should be cleared by the firmware when the command's processing is completed. Setting this bit causes an interrupt to the firmware. This bit can be only set through the CSR (software) interface and can be cleared through the AUX (firmware) interface. While this bit is set, the memory is RO to software.
SV	2	0b	RW	RW	**Status Valid** Indicates that there is a valid status in the 1st descriptor that the device driver can read. If Flags.*BUF* is set in the 1st descriptor, the buffer is valid. 0b = Status not valid. 1b = Status valid.

Table 9-37. GL_HICR [continued]

Field	Bits	Init Value	Firmware (Aux) Access	Software (CSR) Access	Description
EV	3	0b	RW	RW	**Event Valid** Indicates that there is a valid status in the 2nd descriptor that the device driver can read. If Flags.*BUF* is set in the 2nd descriptor, the buffer is valid. 0b = Status not valid. 1b = Status valid.
RESERVED	31:4	0x0	RSV	RSV	Reserved.

1. Changing the *C* bit from 0b to 1b in this CSR create an interrupt to firmware. The firmware implements an interrupt routine, which reads the admin queue command from the internal memory and executes it, in a similar fashion as it executes any other admin command. The results of the admin command, is written back to the same memory.

Table 9-38. GL_HICR_EN

Field	Bits	Init Value	Firmware (Aux) Access	Software (CSR) Access	Description
EN	0	0b	RW	RO	**Enable** When set, indicates that the buffer is accessible for the device. ***Note:*** This bit is common to all functions.
RESERVED	31:1	0x0	RSV	RSV	Reserved.

9.5.12.2 Firmware and Software Interaction Using the CSR-Based Admin Queue

The following interaction is expected:

1. Firmware must register to an interrupt, which is triggered when software writes to the GL_HICR register. The mechanism is enabled by setting the GL_HICR.*EN* bit (GL_HICR.*EN* = 1).
2. Software fills the descriptor + buffer, sets the GL_HICR.*C* bit, and clears the GL_HICR.*SV* and GL_HICR.*EV* bits.
3. Once the GL_HICR.*C* bit is set, the firmware on the main CPU reads the data (descriptor + buffer), parses the packet, and checks the command parameters correctness.

   Note: All the commands reach the main CPU, and if needed, it should distribute them to other CPUs.
4. Firmware executes the command (arbitration with other commands is left to firmware).
5. Firmware then writes a response in the 1st descriptor and optionally to the buffer, and sets the GL_HICR.*SV* bit. If there is an error, or the command is completed (synchronous command), it also clears the GL_HICR.*C* bit
6. If Flags.BUF is set in the 1st descriptor, the buffer is valid and the SW should process it.
7. If GL_HICR.*C* bit is cleared, software stops the flow.
8. If the command is asynchronous, firmware waits for the command to complete. It does not process additional commands.
9. Firmware responds using the same 4KB buffer and the 32-byte 2nd descriptor, clears the GL_HICR.*C* bit, and sets the GL_HICR.*EV* bit.

10. If Flags.*BUF* is set in the 2nd descriptor, the buffer is valid and the software should process it.

Note: The buffer may be used for the 1st or 2nd response, but not for both.

Note: The mechanism mimics the synchronous and asynchronous flows used in regular event queues, but the command buffer and completion buffer are shared. The tool should not post new commands until the GL_HICR.*C* bit is cleared.

Note: When the GL_HICR.*C* bit is set, the entire memory (buffer and descriptors) is RO to software.

9.5.13 Generic Firmware Admin Commands

Table 9-39. Generic Commands

Name	Opcode	Type	Section Reference
Get Version	0x0001	Direct	9.5.13.1
Driver Version	0x0002	Indirect	9.5.13.2
Queue Shutdown	0x0003	Indirect	9.5.13.3
Set PF Context	0x0004	Direct	9.5.13.4
Get Expanded AQ Error Reason	0x0005	Direct	9.5.13.5
Request Resource Ownership	0x0008	Direct	9.5.13.6
Release Resource Ownership	0x0009	Direct	9.5.13.7
Discover Function Capabilities	0x000A	Indirect	9.5.13.8
Discover Device Capabilities	0x000B	Indirect	
VM/VF Reset	0x0C31	Indirect	9.5.13.9

9.5.13.1 Get Version (0x0001)

This must be the first command that the driver issues before it can use the queue for other purposes. The driver must inspect the reply to ensure that the firmware version is compatible. If firmware is still initializing, it can delay response until it is done.

Both the firmware and the API have two unassigned 16-bit values as minor and major version. The driver must not continue loading if the major version mismatches. Minor versions are for tracking changes that do not need driver modifications.

Table 9-40. Get Version Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0001	Command opcode.
Datalen	4-5	0	No external response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
ROM Build ID	16-19		Device ROM build version.
FW Build ID	20-23		Device firmware build version.

Table 9-40. Get Version Command [continued]

Name	Byte.Bit	Value	Remarks
FW Branch	24		Firmware branch identifier (unsigned 8-bit integer).
FW Major Version	25		Firmware major version (unsigned 8-bit integer).
FW Minor Version	26		Firmware minor version (unsigned 8-bit integer).
FW Patch Version	27		Firmware patch version (unsigned 8-bit integer).
AQ API Branch	28		AQ API branch identifier (unsigned 8-bit integer).
AQ API Major Version	29		AQ API major version (unsigned 8-bit integer).
AQ API Minor Version	30		AQ API minor version (unsigned 8-bit integer).
AQ API Patch Version	31		AQ API patch version (unsigned 8-bit integer).

9.5.13.2 Driver Version (0x0002)

This command is used by the driver to report the driver version. The firmware should use the driver version to report it to the BMC. See Section 9.5.3.

Table 9-41. Driver Version Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0002	Command opcode.
Datalen	4-5		Buffer Length. Can be up to 32.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Driver Version	16-19	Version	Byte 16 = Major version Byte 17 = Minor version Byte 18 = Build version Byte 19 = Sub-build version
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address or response buffer.
Data Address Low	28-31		

Table 9-42. Driver Version Buffer

Name	Length	Description
Driver Version	Datalen	Driver string (not null terminated) as reported by driver.

9.5.13.3 Queue Shutdown (0x0003)

This is the final command posted to the queue, closing the queue as described in Section 9.5.4. When this command completes, the driver is allowed to free any host resources associated with the Control Queue.

If the driver is going to unload, it must set the *Driver Unloading* flag to inform firmware.

Once this command is posted, the driver is not allowed to issue any more commands on the queue before a reset is done.

Note: Interrupt generation and the interrupt control flags in this command are handled as usual by firmware. This means that if an interrupt was not inhibited by setting the *SI* flag, it happens. If the driver is in polling mode and can not handle an interrupt, it needs to either inhibit the interrupt or have interrupts disabled through the interrupt control registers.

Table 9-43. Queue Shutdown Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0003	Command opcode.
Datalen	4-5	0	No external data.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Driver Unloading	16.0		1b if the driver intends to unload. 0b otherwise.
Reserved	16.1-31	0x0	Reserved.

9.5.13.4 Set PF Context (0x0004)

This admin command is used to set explicit PF ID number. It is needed for some admin commands that require control on specific PF contexts regardless of the PF from which the admin command is initiated.

Table 9-44. Set PF Context Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0004	Command opcode.
Datalen	4-5	0	No external data.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
PF ID	16		Physical function ID.
Reserved	17-31	0x0	Reserved.

9.5.13.5 Get Expanded AQ Error Reason (0x0005)

This command is used by the software to retrieve an expanded error reason for a previous AQ command failure. This command always returns the expanded error reason for the last failed firmware Admin Queue command. This value only changes if another command fails. An additional successful command after the failed one does not change the returned value. The Get Expanded AQ Error Reason command itself does not affect the value, regardless of its success or failure. The software driver must query the firmware for the expanded error code if an AQ command returns an error and logs the *Error Reason* and *Error Identifier* values.

Table 9-45. Get Expanded AQ Error Reason Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0005	Command opcode.
Datalen	4-5	0	No external data.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Error Reason	16-19		Error reason code. 0xFFFFFFFF indicates no additional reason specified beyond the original AQ return value.
Error Identifier	20-23		Error identifier. A zero is returned if no *Error Reason* is specified.
Reserved	24-31	0x0	Reserved.

9.5.13.6 Request Resource Ownership (0x0008)

This command is used by the driver to request ownership of a shared resource. The driver specifies the resource and the type of access it requests (listed in Table 9-46). On success, the command returns a returns value of 0. The completion specifies in the *Timeout* field the maximum time in milliseconds that the driver can hold the resource. The driver must free the resource before that time. The driver must free a resource before asking for it again. A request for a resource that is already held by this driver fails with the EACCESS error code. A timeout value of zero means no timeout.

If the resource is held by someone else and the resource is different from "Global Config Lock", the command completes with a EBUSY return value, and the *Timeout* field indicates the maximum time the current owner of the resource has to free it. For the "Global Config Lock" resource, the command always completes successfully, while the status is reflected in the *Status* field of the command.

Firmware implements a timeout mechanism, taking back the ownership if the driver hangs. Any further commands by this driver that attempt to access this resource will fail with the EPERM error code until the driver frees the resource and requests it again.

Table 9-46. Shared Resources

Resource	ID	Supported Modes	Default Timeout
NVM	0x0001	1=read, 2=write	3000 ms for read, 180000 ms for write
SDP	0x0002	1=read, 2=write	0 (no timeout)
Change Lock[1]	0x0003	1=read, 2=write	1000 ms
Global Config Lock[1]	0x0004	1=read, 2=write	3000 ms

1. This resource is used by the Download Package admin command.

Table 9-47. Request Resource Ownership Command)

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0008	Command opcode.
Datalen	4-5	0	No external buffer for this command.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Resource ID	16-17	ID	See Table 9-46 for list of IDs.
Access Type	18-19	Type	See Table 9-46 for list.
Timeout	20-23	Timeout	Timeout in milliseconds. For specific resources, such as Change Lock (0x0003) and Global Config Lock (0x0004), this field is used by software to override the default timeout for the operation, and also to specify the timeout used for this operation. As an input, the software might specify timeout longer than the default taken for this resource, and up to one minute. As an output, this field is returned in the firmware response structure and indicates the timeout used for the specific resource.
Resource Number	24-27	Number	For an SDP, this is the pin ID of the SDP.
Status	28-29	Status	Written by firmware. Used for Global Config Lock (0x0004), reserved for others. 0x0000 = Global Config Lock acquired successfully (STAT_SUCCESS). 0x0001 = Global Config Lock acquired by another driver, configuration is in progress (STAT_INPROGRESS). 0x0002 = Global Lock could not be acquired, configuration was already completed (STAT_COMPLETED).
Reserved	30-31		Reserved.

Notes:

- Global Config Lock (0x0004) always returns success. Command status is reflected by the *Status* field.
- If Global Config Lock was not released and a timeout occurs, firmware issues a CORER to load working configurations from NVM.
- A software driver that successfully acquired Global Config Lock, can use only the following admin commands: Download Package, Get Version, Get Package Info List, and Release Resource Ownership with Resource ID = 0x0004. All the other commands should not be used until Global Config Lock release.
- The rest of the drivers can use Request Resource Ownership with Resource ID = 0x0004 admin command only, until getting STAT_COMPLETED status.
- Global Config Lock could be successfully acquired only once after CORER/GLOBR or after the last driver goes down, to the first driver asking for the lock for the first time.
- The Request Resource Ownership admin command might return additional error code. EACCES_BMCU (0x24) - BMC update in progress. Returned when NVM ownership is required during PLDM firmware update.

9.5.13.7 Release Resource Ownership (0x0009)

This command is used to return ownership of a shared resource to the firmware. The driver specifies the ID of the resource it is releasing in the *Resource ID* field.

Table 9-48. Release Resource Ownership Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0009	Command opcode.
Datalen	4-5	0	No external buffer for this command.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Resource ID	16-17	ID	See Table 9-46 for list of IDs.
Reserved	18-23		Reserved.
Resource Number	24-27	Number	If a resource number was specified in the request, it needs to be specified here too.
Reserved	28-31		Reserved.

9.5.13.8 Discover Function/Device Capabilities (0x000A/ 0x000B)

This command is used to request the list of capabilities of the device or the function. The firmware fills in the capabilities structure and returns the length to the driver. If the buffer size is not big enough for the whole structure, the firmware returns ENOMEM (at the return value), writes the number of capabilities that should be returned by the command to the *Cap Count* field, and resets the *Length* field to zero. This can be used to discover the number of capabilities returned, and the structure size can be calculated by software using the known size of the capability structure.

Capabilities are described using the structure in Table 9-50. The list of resources recognized by this version of the command are in Table 9-51.

Additional capabilities can be retrieved using the Get PHY Abilities command (0x0600) and the Get Resource Allocation command (0x0204), described in Section 3.2.4.1.4 and Section 7.8.12.2.3, respectively.

Note: Unsupported capabilities are not reported.

Table 9-49. Discover Function/Device Capabilities Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x000A or 0x000B	Command opcode. 0x000A = Function 0x000B = Device
Length	4-5	Buffer Length	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-19		Reserved.
Cap Count	20-23		Number of capability records returned. Zeroed by driver. Written by firmware.
Data Address High	24-27	0x0	Address of response buffer.
Data Address Low	28-31	0x0	

Table 9-50. Capability Structure

Name	Length (Bits)	Remarks
Capability	16	See Table 9-51 for list of capabilities.
Major Version	8	
Minor Version	8	
Number	32	Number of resources described by this capability.
Logical ID	32	Only meaningful for some types of resources.
Physical ID	32	
Additional Data1	64	In the E810, these field are used in the Logical-to-Physical Port Mapping (0x0073) capability structure.
Additional Data2	64	

Table 9-51. Resources Recognized by This Version of the Command

Name	Capability	Ver	Number	Logical ID	Physical ID
Switching Mode	0x0001	1.0	Returns the switching mode supported: 0 = EVB switching (including cloud) All other values are reserved.		
Manageability Mode	0x0002	2.0	**Bits 3:0:** Returns the value of the *Manageability Pass-Through Mode* field in the NVM. **Bits 7:4:** Returns the value of the *Control Interface* field in the NVM. **Bits 11:8:** Returns the value of the *Redirection Sideband Interface* field in the NVM. **Bits 31:12:** Reserved.	Supported Protocols over MCTP: **Bit 0:** Reserved **Bit 1:** PLDM **Bit 2:** OEM commands **Bit 3:** NC-SI **Bits 31:4**: Reserved	Supported Protocol over PLDM (relevant only in PLDM is supported): **Bit 0:** PLDM base (always set if PLDM supported) **Bit 1:** Reserved **Bit 2:** PLDM for Platform Monitoring and Control **Bit 3:** Reserved **Bit 4:** Reserved **Bit 5:** PLDM FW update **Bit 6:** Reserved (RDE)
OS2BMC Capable	0x0004	1.0	Returns the value of the *OS2BMC Capable* field in the NVM.		
Functions Valid	0x0005	1.0	**Bits 7:0:** Each corresponds to a PFPCI_STATUS1.*FUNC_VALID* bit for PFs 0,…,		
Alternate RAM Structure	0x0006	1.0	1		
WoL and Proxy Support	0x0008	1.0	Number of ACPI supported filters = 8 if supported, 0 otherwise. In the E810 it is equal to 0, excluding Magic Packet filters, which are always supported. Same value for all ports and for the device command. For the device, return the total number of filters across all supporting functions.	SEID of WoL and Proxy VSI of the port. N/A if programming method is hardware. N/A for device.	**Bit 0:** APM WoL is supported (based on PFPM_APM.*APME* bit. For Device command - OR of all the PFs bits. **Bit 1:** ACPI Programming Method (relevant only if number of ACPI supported filters is not zero). 0b = HW 1b = AQC **Bit 2:** Proxy Support 0b = Disabled 1b = Enabled For Device command - OR of all the PFs bits. **All other bits** = Reserved.
SR-IOV	0x0012	1.0	Set to one if enabled in config space. For device, should be set if set in any of the functions.	SR-IOV version (1.1).	
Virtual Function	0x0013	1.0	Function: Number of allocated VFs. Device: Total number of VFs exposed to all functions.	Logical ID of first VF.	
VMDq	0x0014	1.0	Set to one.		
802.1Qbg	0x0015	1.0	One if enabled.		

Table 9-51. Resources Recognized by This Version of the Command [continued]

Name	Capability	Ver	Number	Logical ID	Physical ID
VSI	0x0017	1.0	Function: Number of guaranteed VSI as read from PF allocations structure for PFs. Device: Number of VSIs allocated to the host (not including EMP VSIs).		
DCB	0x0018	1.0	One if enabled.	Device = 0: Bitmap of active TCs.	Max number of TCs. (8 TCs when the device is configured to 1, 2 or 4 ports. 4 TCs when the device is configured to more than 4 port.)
Reserved	0x0021	1.0	Reserved 0x0.	Reserved.	Reserved.
iSCSI	0x0022	1.0	0x1 if iSCSI is enabled. 0x0 if not enabled. For a device capability it is always set. For a function capability it is a reflection of the PFGEN_STATE.*PFSCEN* flag.		
RSS	0x0040	1.0	Table size: 2048 for PFs.	Entry width in bits. 8 for PFs.	
Rx-Queues	0x0041	1.0	Function: Number of queues allocated to the PF. Device: Total number of queues available to the device.		ID of first queue.
Tx-Queues	0x0042	1.0	Function: Number of queues. Device: Total number of queues available.		ID of first queue.
MSI-X	0x0043	1.1	Number of vectors. For functions: PFINT_ALLOC[PF#].*LAST* - PFINT_ALLOC[PF#].*FIRST* + 1 For the device: 2048		First allocated vector: PFINT_ALLOC[PF#].*FIRST*
VF-MSIX[1]	0x0044	1.0	Number of MSIX vectors available to VFs of this PF		
Flow Director	0x0045	1.0	Function: Number of filters guaranteed to this PF. Device: Number of filters available in device (8192).	Function: Number of best effort filters. Device: Number of filters available in device (8192).	

Table 9-51. Resources Recognized by This Version of the Command [continued]

Name	Capability	Ver	Number	Logical ID	Physical ID
1588	0x0046	1.1	Function: **Byte 0 (LSB)** - Timer info: **Bit 0:** TimeSync is enabled on the port on which this function runs. **Bit 1:** A master timer is owned by this function. **Bit 2:** Timer enabled (GLTSYN_ENA). **Bit 3:** Reserved. **Bit 4:** Timer index owned by the function (0/1). (Note that this bit defaults to 0, in the case that the function owns both timers.) **Bits 7:5:** Reserved. **Byte 1** - GPIOs association with the timer owned by the function: **Bit 8:** SDP_TIMESYNC[0] **Bit 9:** SDP_TIMESYNC[1] **Bit 10:**SDP_TIMESYNC[2] **Bit 11:** SDP_TIMESYNC[3] **Bit 12:** 1PPS (output) **Bit 13:** TIME_SYNC (input) **Bit 14:** CLK_SYNCE (output) **Bit 15:** Reserved **Byte 2** - Clock source info: **Bits 18:16:** Clock frequency report from CGU. **Bit 19:** Reserved. **Bit 20:**Clock source selection report from CGU. **Bits 23:21:** Reserved. **Byte 3 (MSB)** - PHY association with timers: **Bit 24:**Timer index associated with the port on which the function runs. **Bits 31:25:** Reserved. Device: **Byte 0 (LSB)** - Timer ownership: **Bits 2:0:** PF owning timer 0. **Bit 3:** Timer 0 owned by a PF. **Bits 6:4:** PF owning timer 1. **Bit 7:** Timer 1 owned by a PF. **Byte 1** - GPIOs associated with any of the timers (same structure as Byte 1 in function response). **Byte 2** - 1588 Clock source info (same as Byte 2 in function response). **Byte 3** - General info: **Bit 24:**TimeSync enabled on any of the ports. **Bit 25:**Timer 0 is enabled. **Bit 26:**Timer 1 is enabled. **Bits 31:27:** Reserved.	Function: N/A. Device: A bitmap of the enabled ports.	Function: N/A. Device: Timer ownership bitmap of the enabled ports (each bit value must hold the timer index for the port).

Table 9-51. Resources Recognized by This Version of the Command [continued]

Name	Capability	Ver	Number	Logical ID	Physical ID
MaxMTU	0x0047	1.0	Function: Max MTU of the function. Device: Max MTU of the hardware (9728).		
NVM Versions[2]	0x0048	1.0	1st word: NVM word address. 2nd word: NVM value.	1st word: NVM word address. 2nd word: NVM value.	1st word: NVM word address. 2nd word: NVM value.
NVM Pending Versions[3]	0x0048	1.3	1st word: NVM word address. 2nd word: NVM value.	1st word: NVM word address. 2nd word: NVM value.	1st word: NVM word address. 2nd word: NVM value.
OROM Version	0x004A	1.3	2 words - OROM version.		
OROM Pending Version[4]	0x004A	1.3	2 words - OROM version.		
Netlist Version	0x004C	1.3	BaseReleaseVersion.Major	BaseReleaseVersion.Type	BaseReleaseVersion.IANA + CustomerNetlistVersion
Netlist Pending Version[4]	0x004C	1.3	BaseReleaseVersion.Minor	BaseReleaseVersion.Type	BaseReleaseVersion.IANA + CustomerNetlistVersion
iWARP	0x0051	1.0	One if enabled		
LED[5]	0x0061	1.0	Always 1.	Action.	Pin number (GPIO Index).
SDP[6]	0x0062	1.0	Always 1.	Action.	Pin number (GPIO Index).
MDIO[7]	0x0063	1.0	Only if enabled.		The interface used to control this port.
Drop/No Drop Policy[8]	0x0065	1.0	Returns the value of the PXE Mode No-Drop Policy supported NVM bit.	Function: 0x1 if No-Drop policy is enabled on the port used by the current PF. 0x0 if No-Drop policy is not enabled on the port used by the current PF. Device: N/A	
Reserved	0x0071 - 0x0073	1.0	Reserved.	Reserved.	Reserved.
SKU	0x0074	1.0	Returns the SKU as described in register GL_UFUSE_SOC[15:0].	Reserved.	Reserved.
Port Mapping[9]	0x0075	1.3	Reserved	Function Number	Port Number

1. This capability is not available in the E810, as any vector can be assigned to a VF, and each VF can get a different number of vectors
2. The NVM Versions capability is used to return NVM version data to software in a centralized location. It appears multiple times, reporting three NVM versions per entry. The following NVM words are returned as versions: 0x18-0x2E (inclusive) 0x34, and 0x35. An NVM word address of 0xFFFF indicates an invalid field.
3. This capability takes the same format as in NVM versions capability. This capability appears only if pending image exists.
4. This capability appears only if pending image exists.
5. Repeat this entry for each assigned LED. In the E810, LEDs are not assigned to functions and therefore this capability is not returned if called at the context of a function. If Device = 1, returns an entry for each LED in the device, in the E810 returns an entry for each GPIO in the I/O widget, which is defined as LED in the link topology.
6. Repeat this entry for each assigned pin. In the E810, SDPs are not assigned to functions and therefore this capability is not returned if called at the context of a function. If Device = 1, returns an entry for each SDP in the device, in the E810 returns an entry for each GPIO in the I/O widget, which is defined as SDP in the link topology.
7. This entry is not relevant for the E810 and is not returned.
8. The values in this capability are based on the PXE Mode *No-Drop Policy Supported* NVM bit and on variable sw_force_no_drop.
9. For Discover Device Capabilities, this entry is returned for each enabled function. For Discover Function Capabilities it is returned only for the current function.

Notes:

- Fields that are not applicable (empty in the table) are set to zero by the firmware.
- When device capabilities are requested, total numbers for the whole device should be returned.

9.5.13.9 VF/VM Reset (0x0C31)

In this command, software provides a list of Tx-Queue or RDMA QSet IDs that need to be closed. The AQ must be called after software stops feeding the closed queues (stop sending doorbells). RDMA QSet can be closed only when it is not associated with any QP.

The command gets the following parameters as input:

- Number of Disabled Queues/QSets
- List of Queue or QSet IDs (in the PF space)

This command deallocates nodes (in leaf layer and possibly in intermediate layers as well) in the Tx-Scheduler.

Inside the command structure, the disabled queues are organized in groups. Each group includes queues belonging to one parent node in the Tx-Scheduler structure. This organization in groups is added to ease the interface between the software and the firmware. It is not required to disable all the queues belonging to a parent in one call.

This command is called by software as part of VM/VF reset flow. When it is called as part of VM/VF reset flow, it is used for a single VM/VF per call. As part of this command flow, the EMP firmware drains the Tx-Pipe from any in-flight packets (packets scheduled for transmission by the Tx-Scheduler but have not yet been transmitted) of all disabled Tx-Queues or RDMA QSets. This is required to verify that no Tx completion is posted to software after the queue resources are released, or even re-used.

Normally, the pipe draining flow requires a very short delay. A long (or endless) Flow Control event that blocks the transmit of one or more TC's or even the entire port transmit, affects the pipe draining flow as well.

This command is completed when all in-flight packets belonging to the Disabled LAN Queues or RDMA QSets have left the Tx-Pipe. Alternately, the command is called with a timeout parameter. If the EMP firmware waits more than the timeout time, it responds with an EAGAIN error code. With the EAGAIN error code, firmware also provides a bitmap that marks which of the Congestion Domains is blocked by the long Flow Control.

Software must recall this command (with *Call-Again* flag set) prior to releasing and reusing of any of the Tx-Queues that are associated with the blocked Congestion Domains.

This command must be fully completed (all Tx-Queues or RMDA QSets released) prior to any other calling to it for other queues, and prior to calling that Move/Reconfigure Tx LAN Queues AQC.

The command's timeout is posted by software as part of the command's parameters.

Software can also instruct the EMP firmware to force the Tx-Pipe and Rx-Pipe to flush out and drop all packets from the blocked Congestion Domain. It is the PF's responsibility and authority to make the decision when to consider a long Flow Control as a malicious link partner behavior.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 9-52 describes command format and defines command-specific fields.

Table 9-52. VM/VF Reset Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C31	Same as LAN Transmit Queue Disable command (see Section 10.5.5.8.3)
Datalen	4-5		Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Type and Flags	16		**Bits 0:1:** 00b = Reserved. 01b = VM Reset operation. 10b = VF Reset operation. 11b = Reserved. **Bit 2:** 0b = This is an initial call. 1b = This is a subsequent call. **Bit 3:** 0b = Return EAGAIN on timeout. 1b = Flush pipe on timeout. **Bits 4:7:** Reserved. Must set to zero. ***Note:*** Bits 2 and 3 are **NOT** mutually exclusive.
Number of Queue Groups	17		In the command: Number of Disabled Queue Groups (1..127) involved in the Q disable flow. In the response: Number of fully-processed groups.
VMVF_NUM	18-19.1		Used when the *Command Type* (Bits 0-1) is VM Reset (01b) or VF Reset (10b). Bits 0 and 1 of Byte 19 contain the MSB of the *VMVF_NUM*. This is the absolute VM or VF numbers, not relative to PF.
Timeout Time	19.2-19.7		Command timeout in units of 100 micro seconds. Valid values are 0-50.
Blocked CGDs	20	0	Zeroed by the driver. A bitmap of blocked CGDs. Set by EMP firmware when returns with EAGAIN.
Reserved	21-23		Reserved.
Data Address High	24-27	0x0	Address of buffer.
Data Address Low	28-31	0x0	

Table 9-53 describes format of the data buffer carrying additional command attributes.

Table 9-53. VM/VF Reset Command Buffer[1]

Category	Byte.Bit	Field	Description
Group #1	0-3	Parent's TEID	The TEID of the parent node to which leaves are involved.
	4	Number of Queues	(1...128).
	5	Reserved	Reserved.
	6-7.6	Queue #1	Tx-Queue ID in PF space of the first queue to be closed.
	7.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	8-9.6	Queue #2	Tx-Queue ID in PF space of the second queue to be closed.
	9.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	. . .		
		Queue #N	Tx-Queue ID in PF space of queue N to be closed.
		QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
		Padding	Alignment to 4-byte units.
. . .			
Group #N	0-3	Parent's TEID	The TEID of the parent node to which leaves are involved.
	4	Number of Queues	(1...128).
	5	Reserved	Reserved.
	6-7.6	Queue #1	Tx-Queue ID in PF space of the first queue to be closed.
	7.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	8-9.6	Queue #2	Tx-Queue ID in PF space of the second queue to be closed.
	9.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	. . .		
		Queue #N	Tx-Queue ID in PF space of queue N to be closed.
		QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.

1. The command buffer includes a structure per involved Queues group.

9.5.13.9.1 Software Activities Prior to Calling VM/VF Reset

- Software must stop sending doorbells to the disabled queues before closing them.
- For Tx-Queues that are associated with the Doorbell Queue, the Doorbell Queue must be drained from any doorbell message of the disabled queues.
  - This is done by sending a draining marker through the Doorbell Queue. A Doorbell Queue descriptor with *Dummy* and *RS* bits set acts as a drain marker.
- Stop getting interrupts for the disabled queue(s)
  1. Software clears the *CAUSE_ENA* bit in the QINT_TQCTL register for all disabled queues.
  2. Software waits 100 ns.
  3. Software sends software interrupt for the vector associated with the queue.
  4. When interrupt arrives, software can continue.
- In case of an VM reset or multiple queues disable, software does Step 1 for all disabled queues and Step 3 for all vectors associated to the queues.

9.5.13.9.2 Software Activities After VM/VF Reset AQ Completed

- Once the whole operation is complete and the pipe is cleaned from the disabled queues (EMP firmware responses with "No Error"), software can re-use all involved resources.
- Software can post a VM reset notification via the Completion Queue. This is done directly to each involved Completion Queue using CSRs GLCOMM_CQ_CTL[512].

9.5.14 Mailbox Commands

Table 9-54. Virtualization Admin Commands

Name	Opcode	Type	Section Reference
Send to PF	0x0801	Indirect/Direct	9.5.14.1
Send to VF	0x0802	Indirect/Direct	9.5.14.2

9.5.14.1 Send Message to PF (0x0801)

This command, together with the next one, implements a communication channel between PFs and their VFs. The data in the external buffer is copied into an event on the PF receive queue. The command completes once the data is copied. The contents of the messages are defined by software.

Since the value of the cookie is copied to the event, if eight bytes are enough for the needed message, the driver can specify a length of zero, and not use an external buffer. In this case, it should also not set the *BUF* flag.

Note: This version of the queues supports messages of up to 4096 bytes.

Table 9-55. Send to PF Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 and Section 9.5.5.2.1 for details.
Opcode	2-3	0x0801	Command opcode.
Length	4-5	Buffer Length	Length of message.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by mailbox.
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command. It is also copied to the descriptor of the target mailbox queue.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command. It is also copied to the descriptor of the target mailbox queue.
Reserved	16-23		
Data Address High	24-27	0x0	Address of data buffer
Data Address Low	28-31	0x0	

After posting the event to the PF admin receive queue, the mailbox completes this command by updating the flags and return value (0 for success).

Table 9-56. Message from VF Event

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 and Section 9.5.5.2.1 for details.
Opcode	2-3	0x0801	Event code.
Length	4-5	Buffer Length	Length of message.
Return Value/VFID	6-7	VFID	ID of sending VF. (In non-PASID mode, this is the relative virtual function ID, starting from 0 for each PF. In PASID mode, this is the absolute VSI number).
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware from the source descriptor.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware from the source descriptor.
Reserved	16-23		
Data Address High	24-27	0x0	Address of data buffer
Data Address Low	28-31	0x0	

9.5.14.2 Send Message to VF (0x0802)

This command, together with the previous one, implements a communication channel between PFs and their VFs. The data in the external buffer is copied into an event on the VF receive queue. The command completes once the data is copied. The contents of the messages is defined by software. A PF can only send messages to one of its VFs.

Since the value of the cookie is copied to the event, if eight bytes are enough for the needed message, the driver can specify a length of zero, and not use an external buffer. In this case, it should also not set the *BUF* flag.

Note: This version of the queues supports messages of up to 4096 bytes.

Table 9-57. Send to VF Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 and Section 9.5.5.2.1 for details.
Opcode	2-3	0x0802	Command opcode.
Length	4-5	Buffer Length	Length of message.
Return Value	6-7		Return value. Zeroed by driver. Written by mailbox.
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command. It is also copied to the descriptor of the target mailbox queue.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware into the completion of this command. It is also copied to the descriptor of the target mailbox queue.
VFID	16-19	VFID	ID of VF. (In non-PASID mode, this is the relative virtual function ID, starting from 0 for each PF. In PASID mode this is the absolute VSI number).
Reserved	20-23		
Data Address High	24-27	0x0	Address of data buffer
Data Address Low	28-31	0x0	

After posting the event to the VF admin receive queue, the mailbox completes this command by updating the flags and return value (0 for success).

Table 9-58. Message from PF Event

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 and Section 9.5.5.2.1 for details.
Opcode	2-3	0x0802	Event code.
Length	4-5	Buffer Length	Length of message.
Return Value/VFID	6-7		Reserved.
Cookie High	8-11	Cookie	Opaque value copied by the mailbox/firmware from the source descriptor.
Cookie Low	12-15	Cookie	Opaque value copied by the mailbox/firmware from the source descriptor.
Reserved	16-23		
Data Address High	24-27	0x0	Address of data buffer
Data Address Low	28-31	0x0	

9.5.15 Software Assist Commands

9.5.15.1 Set/Get Shared Driver Parameters (0x0C90)

The Set/Get Shared Driver Parameters admin command is used by the software driver to set (write) firmware opaque parameters and get (read) them back when needed. The parameters are shared between PFs, (that is, all PFs see the same parameters).

Table 9-59. Set Shared Driver Parameters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C90	Command opcode.
Datalen	4-5	0	Direct command. No external buffer should be attached.
Return Value	6-7		Return value. Zeroed by driver. Written by Firmware. 0 = Success 18 = ERANGE — When the Parameter index is out of range.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command
Set/Get Opcode	16		**Bit 16.0:** Set / Get opcode 0b = Set 1b = Get **Bits 16.1-16.7:** Reserved
Parameter Index	17		Firmware maintains up to 16 32-bit wide parameters for the driver. Software should range this index between 0 and 15.
Reserved.	18-19		Reserved.
Parameter Value	20-23		32-bit value for the parameter. When the command is *Set*, software should give the value here. When the command is *Get*, the value is set by firmware at the returned descriptor.
Data Address High	24-27	0x0	Address of data buffer. Not used in this command.
Data Address Low	28-31	0x0	

Notes:

1. 1.At CORER and above, firmware initialize all parameters to 0.
2. The firmware does not maintain any lock/synchronization between PFs. The parameter holds the value set by the last *Set* command that was executed. If a *Get* is executed before any *Set*, firmware returns the initialization value (0).
3. The admin command is not provided by firmware during Firmware Recovery mode.
4. It is expected that the PF that owns the parameter resets its value in its reset flow when it goes down.
5. The *Set* command can arrive from any PF. Firmware does not limit that.

9.6 Statistics

The E810 provides statistics for the following interfaces:

- Physical ports.
- Virtual switch elements: VEBs and VSIs.
- PE statistics, some of which are global and some are per VSI.
- ACL statistics.
- Flow Director statistics.
- Host Interface statistics.

A minimal set of Ethernet interface group statistics (RFC 2863) is provided by the E810 at the switch sampling points, while a fuller set of statistics is provided for physical ports.

The prefixes for the statistics counter names are listed in Table 9-60.

Table 9-60. Counter Name Prefixes

Element	Register Prefix	Instances	Remarks
Port	GLPRT	8	
VEPA or VEB	GLSW	32	
VEB per VLAN	GL_STAT_SWR	128	
VEB per UP	GLVEBUP	32x8	Two dimensional array of 8 UPs for 32 VEBs.
VSI	GLV	768	
Switch ID	GLSWID	256	
ACL	GLSTAT_ACL	2048	
FD	GLSTAT_FD	8192	

9.6.1 Counter Implementation

Most of the counters in the E810 are used by more than one entity. For example, VSI counters are both a virtual switch port (hence used by a switch monitor agent) and a driver interface. The E810 does not provide clear-on-read statistics counters, since these would need to be duplicated per client.

As a general rule, E810 statistics counters should not be reset by software, because they are shared between more than one owner. Software must maintain a delta from the first value seen. If a software device driver needs the ability to reset counters, this should be implemented by updating the delta reference value.

To allow firmware to reset counters when a switching element is allocated, or for debug, the counters are implemented as clear-on-write, meaning that writing any value clears the counter.

The E810 provides 40-bit counters for byte and packet counters, and 32-bit counters for errors and discard events. Software should maintain counters that are appropriate in size for the OS and MIB requirement.

40-bit counters are implemented as two registers, whose names end with “high” and “low”, containing the upper eight bits and lower 32 bits, respectively.

When accessed using a 64-bit operation from PCI, these accesses are guaranteed by design to be atomic. They are internally converted to two 32-bit accesses that are always consecutive, with no interleaving between reads from different drivers. A special hardware indication tells the statistics block that this is the case. The statistics block performs one read of the counter memory to satisfy both requests, thus providing atomicity.

When 32-bit accesses are used to read the counters, each of them cause a separate read from the statistics block. Therefore, care must be taken to properly handle the possibility of one half around between the reads, since atomicity is not guaranteed.

VFs have no access to statistics registers. They should query the PF through the VF-to-PF virtual channel for their statistics.

9.6.2 Statistics Sample Points

Figure 9-11 and Figure 9-12 show sample points for Tx and Rx statistics, respectively. Error counters are in red. The figures show the processing stages in which counters are updated.

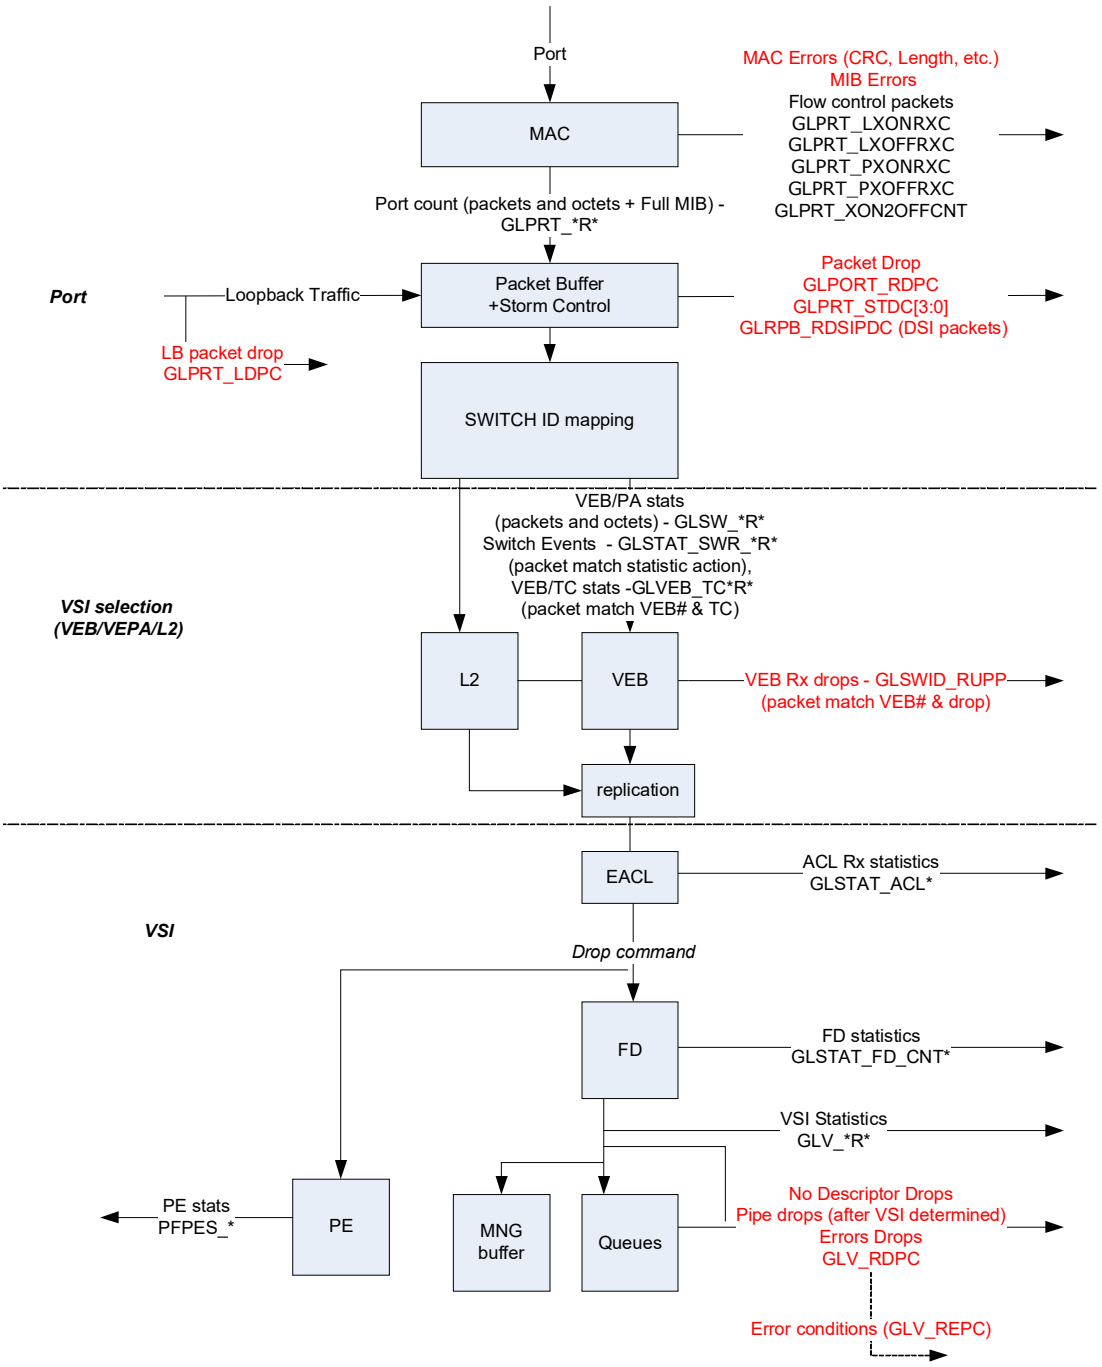

Figure 9-11. Rx Statistics Sampling Points

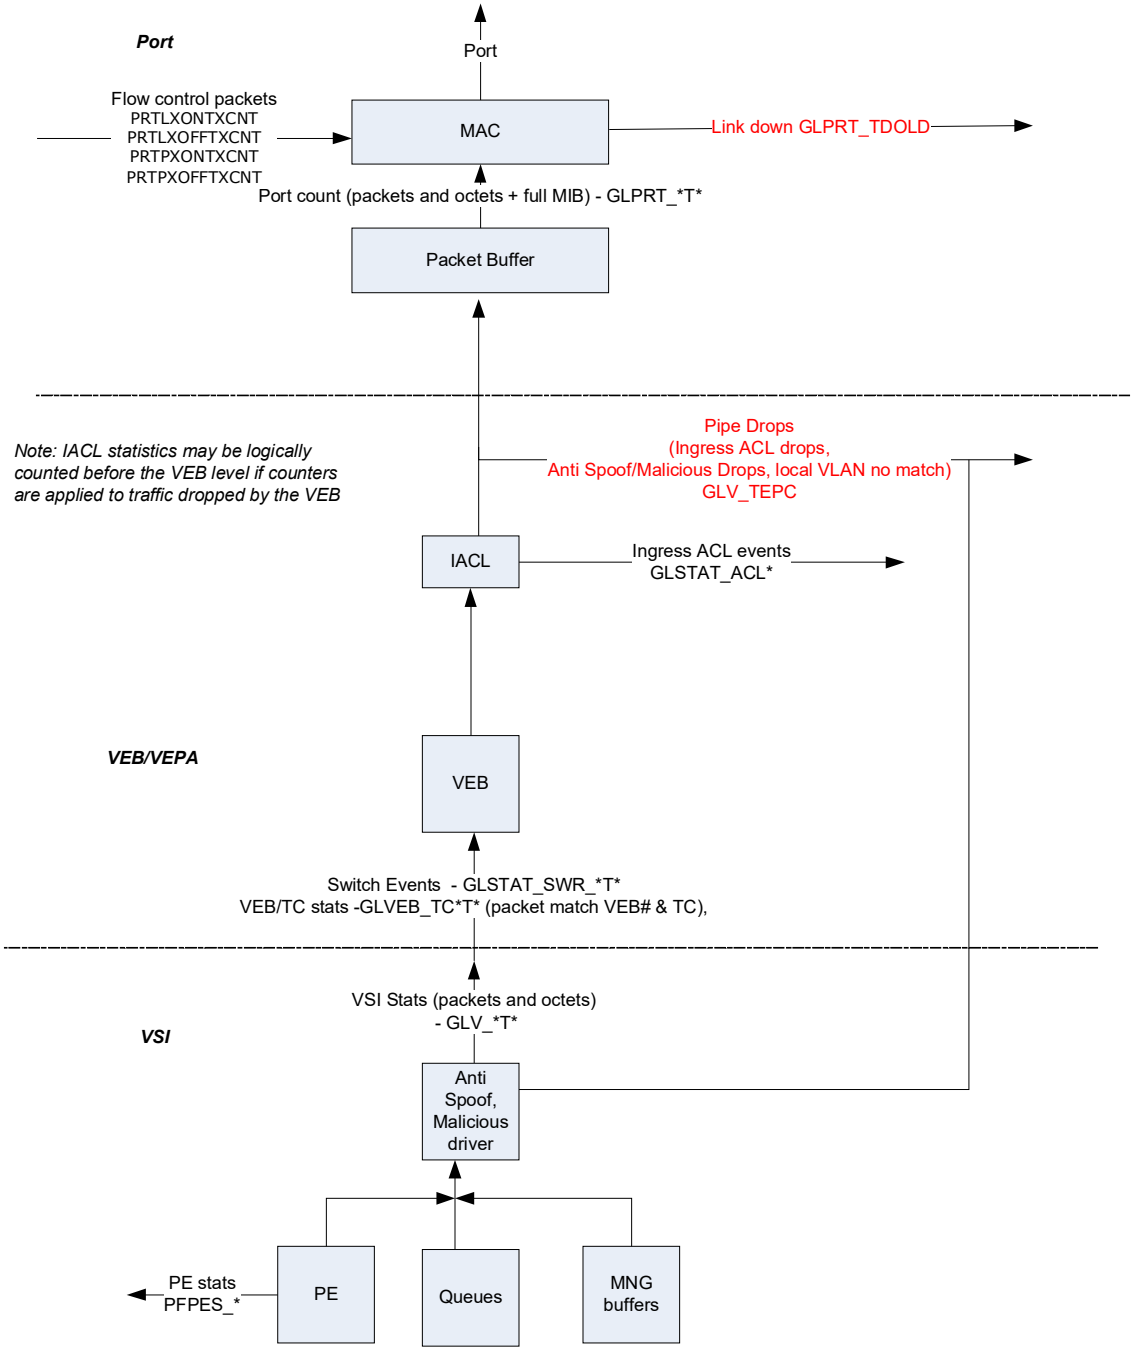

Figure 9-12. Tx Statistics Sampling Points

9.6.3 Statistics Consistency Rules

- At each switch sample point, a packet is either good or error. This means that when a packet is discarded, it is not counted in any of the non-error counters. It is also never counted by any of the next processing stages.
- All drops are counted. A packet with an error is only counted in one counter. An exception to this rule is that some debug counters are not mutually exclusive with error counters. For example, GLPRT_ERRBC and GLPRT_MSPDC are also counted as CRC errors and undersize errors, respectively.
- Ethernet octet counters count the packet as seen on the wire, from the Ethernet header up to and including the CRC (for both Rx and Tx). This means that even though an Rx packet might be stripped of tags before placement, the byte counters record the original size. Tx packets are counted after all offloads and insertions.
- Flow control packets are only counted in the flow control counters.
- Statistics specific to iWARP/RoCE count packets as they are delivered to the offload engine on Rx, and as they leave the engine on Tx. This applies to both packet lengths and packets that were merged or split. For example, packets merged by LRO are counted before the aggregation.
- Maximum lengths are adjusted to accommodate added tags. For example, the highest histogram bin MIB counter GLPRT_PTC9522 also counts any packet that would have fit in it without the added STags and VLANs.

9.6.4 Supported MIBs

The E810 supports different statistic counters as described in this chapter. The statistic counters can be used to create statistic reports as required by different standards. The E810 statistic counters allow support for the following standards:

- IEEE 802.3 clause 30 management – DTE section
- NDIS 6.0 OID_GEN_STATISTICS
- RFC 2819 – RMON Ethernet statistics group, for ports and VSIs.
- RFC 2863 – SMON Ethernet statistics group, for various switch elements.
- Linux Kernel
- net_device_stats

The following section describes the match between the internal E810 statistic counters and the counters requested by the different standards.

9.6.5 Interface Statistics at VSIs and Logical Interfaces

The E810 provides Ethernet interface group statistics per RFC 2863 on each of the Virtual Station Interfaces (VSIs), port aggregators, and virtual bridges. Table 9-61 provides an illustration of interface counters in the E810 and their sizes.

VF and PF VSIs have the same counter set. The only difference between the counter set for VSIs and the one for other switch elements is that the RUPP (unknown protocol) counter is replaced by a missed packet counter RMPC.

Note: The counter names repeat themselves with a different prefix for the element type. See Table 9-60 for the list of prefixes.

The width of the counters that are provided, is calculated to allow ample time for software to get the statistics before they wrap around. The 48-bit counters are a pair of registers, one ending with an "L" that holds with the lower 32-bits of the counter, while the higher 12 bits are in a register ending with an "H" (denoted in Table 9-61 as {H,L}). Not all counters are implemented for all prefixes. See Table 9-64 to Table 9-67 for implementation for specific prefixes.

Table 9-61. Ethernet Interface Group Statistics Counters

Register Name	Width	Description
[PFX]GORC{H,L}	40	Incoming packet octets.
[PFX]UPRC{H,L}	40	Incoming number of unicast packets.
[PFX]MPRC{H,L}	40	Incoming number of multicast packets.
[PFX]BPRC{H,L}	40	Incoming number of broadcast packets.
[PFX]RDPC	40	Incoming packet discards.
[PFX]RUPP	32	Incoming unknown protocol packets.
[PFX]GOTC{H,L}	40	Outgoing packet octets.
[PFX]UPTC{H,L}	40	Outgoing number of unicast packets.
[PFX]MPTC{H,L}	40	Outgoing number of multicast packets.
[PFX]BPTC{H,L}	40	Outgoing number of non-unicast packets.
[PFX]TDPC	32	Outgoing number of discards.
[PFX]TEPC	32	Outgoing packet errors.

Some error counters are not implemented at specific switch elements because they cannot happen at those elements in the current switch design. If software is queried about the value of these counters, it should return zero (see Table 9-62).

Table 9-62. Error Counters Not Implemented in Current Design

Counter Name	Switch Element	Description
GLPRT_XEC	Port	Port XSUM error count.
GLPRT_TEPC	Port	Port transmit error packet count (GPLRT_TDOLD counts drops due to link down).
GLV_TDPC	VSI	VSI transmit packets discarded count.
GLSW_RDPC	PA or VEB	Switch receive packets discarded count (Replaced by GLSWID_RUPP).
GLSW_TEPC	PA or VEB	Switch transmit error packet count.
GLPRT_TDPC	Port	Packets that were discarded on transmit while link was down.

9.6.5.1 MAC or Physical Uplink Interface Statistics

The MAC or Physical Uplink Interface statistics counters are accessible to the device management/ control entity in VMM or IOVM through the PF. The MAC or Physical Uplink Interface statistics use the counters defined in Table 9-63. The only exception is the Unknown Protocol Packet counter, which has no meaning in the case of the physical port and is therefor absent.

In addition, the E810 provides per MAC port some of the statistics out of the IEEE 802.3 clause 30 management counters, as well as part of the RMON Ethernet statistics group as defined by IETF RFC 2819. See Table 9-63.

Table 9-63. Additional per-Port Counters

Register Name	Width	Description
GLPRT_PRC64{H,L}	40	Packets Received [64 Bytes] Count
GLPRT_PRC127{H,L}	40	Packets Received [65–127 Bytes] Count
GLPRT_PRC255{H,L}	40	Packets Received [128–255 Bytes] Count
GLPRT_PRC511{H,L}	40	Packets Received [256–511 Bytes] Count
GLPRT_PRC1023{H,L}	40	Packets Received [512–1023 Bytes] Count
GLPRT_PRC1522{H,L}	40	Packets Received [1024 to 1522] Count
GLPRT_PRC9522{H,L}	40	Packets Received [1523 to Max Bytes] Count
GLPRT_PTC64{H,L}	40	Packets Transmitted [64 Bytes] Count
GLPRT_PTC127{H,L}	40	Packets Transmitted [65–127 Bytes] Count
GLPRT_PTC255{H,L}	40	Packets Transmitted [128–255 Bytes] Count
GLPRT_PTC511{H,L}	40	Packets Transmitted [256–511 Bytes] Count
GLPRT_PTC1023{H,L}	40	Packets Transmitted [512–1023 Bytes] Count
GLPRT_PTC1522{H,L}	40	Packets Transmitted [1024 to 1522] Count
GLPRT_PTC9522{H,L}	40	Packets Transmitted [1523 to Max Bytes] Count
GLPRT_LXONRXC{H,}	40	Link XON Received Count
GLPRT_LXOFFRXC{H,}	40	Link XOFF Received Count
GLPRT_LXONTXC{H,}	40	Link XON Transmitted Count
GLPRT_LXOFFTXC{H,}	40	Link XOFF Transmitted Count
GLPRT_PXONRXC{H,}[n]	40	Priority XON Received Count
GLPRT_PXOFFRXC{H,}[n]	40	Priority XOFF Received Count
GLPRT_PXONTXC{H,}[n]	40	Priority XON Transmitted Count
GLPRT_PXOFFTXC{H,}[n]	40	Priority XOFF Transmitted Count
GLPRT_CRCERRS{H}	40	CRC Error Count
GLPRT_ILLERRC{H,}	40	Illegal Byte Error Count
GLPRT_MLFC{H,}	40	MAC Local Fault Count
GLPRT_MRFC{H,}	40	MAC Remote Fault Count
GLPRT_RLEC{H,}	40	Receive Length Error Count
GLPRT_RUC{H,}	40	Receive Undersize Count
GLPRT_RFC{H,}	40	Receive Fragment Count
GLPRT_ROC{H,}	40	Receive Oversize Count
GLPRT_RJC{H,}	40	Receive Jabber Count
PRTRPB_RDPC	32	Received packets from the network that are dropped in the receive packet buffer. The packets are dropped due to possible lack of bandwidth on the PCIe or total bandwidth of the internal data path.
PRTRPB_LDPC	32	Same as the PRTRPB_RDPC for VM-to-VM loopback packets.
GLPRT_STDC	32	Port Storm Control Discard Count
GLPRT_TDOLD{H,}	40	Transmit Packets Dropped on Link Down

9.6.5.2 VEB Statistics

The E810 supports SMON statistics per RFC 2613 (Table 9-64) and smonPrioStats counters per priority (Table 9-65) for up to 32 VEBs. The E810 supports a set of smonVlanStats counters for up to 128 802.1Q VLANs listed in Table 9-66.

Notes:

- These VEB per VLAN counters are implemented by assigning a statistic action to a VLAN entry, and can also be used to count other types of traffic.
- When a port is using DSCP as the TC indicator, the VEB per UP counters reflects the DSCP to UP translation.
- Packets replicated by the switch are counted only once.

Table 9-64. Per-VEB Statistics Counters

Register Name	Width	Description
GLSW_GORC{H,L}	40	Incoming packet octets.
GLSW_UPRC{H,L}	40	Incoming number of unicast packets.
GLSW_MPRC{H,L}	40	Incoming number of multicast packets.
GLSW_BPRC{H,L}	40	Incoming number of broadcast packets.
GLSW_GOTC{H,L}	40	Outgoing packet octets.
GLSW_UPTC{H,L}	40	Outgoing number of unicast packets.
GLSW_MPTC{H,L}	40	Outgoing number of multicast packets.
GLSW_BPTC{H,L}	40	Outgoing number of non-unicast packets.

The following counters are available per VEB/UP:

Table 9-65. VEB per UP Counters

Register Name	Width	Description
GLVEBUP_RPC{H,L}	40	Total number of packets received per priority.
GLVEBUP_RBC{H,L}	40	Total number of octets received per priority.
GLVEBUP_TPC{H,L}	40	Total number of packets transmitted per priority.
GLVEBUP_TBC{H,L}	40	Total number of octets transmitted per priority.

Table 9-66. Event Counters

Register Name	Width	Description
GL_STAT_SWR_GORC{H,L}	40	Incoming packet octets.
GL_STAT_SWR_GOTC{H,L}	40	Outgoing packet octets.
GL_STAT_SWR_UPC{H,L}	40	Number of unicast packets
GL_STAT_SWR_MPC{H,L}	40	Number of multicast packets.
GL_STAT_SWR_BPC{H,L}	40	Number of broadcast packets.

Table 9-67. Per VSI Counters

Register Name	Width	Description
GLV_TEPC	32	Transmit error packet count.
GLV_GOTC{H,L}	40	Transmit octet count. Counts number of bytes transmitted by this VSI.
GLV_GORC{H,L}	40	Receive octet count. Counts number of bytes received by this VSI. Will count packets forwarded by switch even if dropped by later stages like ACL or Flow Director.
GLV_UPRC{H,L}	40	Receive unicast packet count. Counts number of unicast packets received by this VSI. Will count packets forwarded by switch even if dropped by later stages like ACL or Flow Director.
GLV_BPTC[H,L}	40	Transmit Broadcast packet count. Counts number of broadcast packets transmitted by this VSI.
GLV_MPTC{H,L}	40	Transmit multicast packet count. Counts number of multicast packets transmitted by this VSI.
GLV_MPRC{H,L}	40	Receive multicast packet count. Counts number of multicast packets received by this VSI. Counts packets forwarded by switch even if dropped by later stages like ACL or Flow Director.
GLV_BPRC{H,L}	40	Receive Broadcast packet count. Counts number of broadcast packets received by this VSI. Counts packets forwarded by switch even if dropped by later stages like ACL or Flow Director.
GLV_UPTC{H,L}	40	Transmit unicast packet count. Counts number of unicast packets transmitted by this VSI.
GLV_RDPC	32	Counts (per VSI) packets that were drop due to no descriptors in host queue or other drops in the pipe[1].
GLV_REPC[2]	16	*NO_DESC_CNT*[3,4] Counts drops due to no available descriptors (stuck at 0xFFFF).
	16	ERROR_CNT[3] Counts the following four error cases (stuck at 0xFFFF): 1. Packet size is larger than RXMAX of the queue. 2. Receive descriptor Unsupported Request on the PCI or internal Dummy completion. 3. Packets directed to disabled receive queues. 4. Packets dropped due to VM reset, VF reset or PF reset.

1. Pipe drops includes, for example, Flow Director, ACL, and Packets directed to invalid receive queues drops.
2. Packets dropped due to the following reasons, are not counted by REPC even if it matches one of its criteria: dropped by ACL, dropped by FD, dropped due to invalid queue.
3. These are also counted by GLV_RDPC.
4. Packets dropped and counted in GLV_REPC.*ERROR_CNT* are not counted in this counter even if descriptors are not available.

The E810 provides virtual bridge port or interface statistics counters for VSIs and uplinks associated with a VEB instance. See Section 9.6.5 for additional details on VSI and uplink interface statistics.

Notes:

- VEB statistics and VEB/TC statistics includes action-based mirror packets and manageability packets passing through this VEB. For example, traffic from BMC to host is counted both in Tx (from BMC) and Rx (to host) counters of the VEB. Port/VSI-based mirror packets are not counted in the VEB, VEB/TC counters.
- Transmits counters usually count only packets that are sent either to the LAN or to the loopback. In some cases, it might count packets that are dropped later when the packet is sent back to the receive. For example, a valid transmit packet dropped in receive due to VSI source pruning is counted in Tx counters.

9.6.5.3 ACL Statistics

The E810 provides 2048 ACL statistic counters to collect statistics based on ACL policy. ACL statistics are updated when a packet matches the ACL rule. If it matches more than one rule, only the first rule is counted as a match. ACL statistics can be used for collecting flow base statistics for accounting or billing purposes, and also to monitor network policy violations. The ACL counters are created by creating a statistic action in an ACL entry. See Section 7.9.1.6 for further details on ACL counter actions.

ACL counters are accessible via GLSTAT_ACL_CNT_n_L/H[bank_offset] registers. See Section 7.9.1.6.4 for details.

9.6.5.4 Flow Director Statistics

The E810 provides 8192 Flow Director statistic counters to collect statistics based on Flow Director actions. Flow Director statistics are updated when a packet matches a Flow Director filter and can count bytes and/or packets. Flow Director statistics can be used for collecting flow base statistics for accounting or billing purposes and also to monitor network policy violations. The Flow Director counters are addressed by creating a statistic action in an Flow Director filter. See Section 7.10.8 for further details on Flow Director counter actions.

Flow Director counters are accessible via GLSTAT_FD_CNT_L/H registers. See Section 7.10.8.1 for details.

9.6.5.5 Statistics Resources

Almost all statistic counters are statically-allocated. This means that for each element type there is a 1:1 ratio between the number of elements and the number of counter sets. The only two exceptions to this are VEB and VEB per VLAN statistics. There can be up to 256 VEBs (switch IDs), but only 32 of these can be allocated a statistic block. The total number of VLAN x VEB combinations in the system can exceed the number of counter sets.

For statically-allocated counters, the admin command allocating the object returns the offset in the counter array of the counters for this entity. For dynamically-allocated counters, the allocator must request statistics counters for the object. If statistics counters are not available, the allocation fails. In that case, the allocating driver can retry the operation without requesting statistics.

9.6.6 RDMA/RoCE Statistics

Protocol Engine (PE) statistics are defined in Section 11.9. Note that switch VSI statistics are counted for PE VSIs at PE ingress. That is, before any PE processing.

9.7 TimeSync (IEEE1588 and 802.1AS)

9.7.1 Overview

Measurement and control applications are increasingly using distributed system technologies such as network communication, local computing, and distributed objects. The 1588 standard enables accurate synchronization between clocks on distributed systems.

The E810 supports two 1588 master timers that can be synchronized to two separate 1588 time domains. The master timers are synchronized to additional 1588 timers on the PHY units. Figure 9-13 shows a top-level diagram of the 1588 logic.

PHY Timers:

The timers on the PHY units do the actual time sampling of the packets. The timers in the PHYs are synchronized to one of the two master timers by the *master_timer* parameter in the rx_timer_cmd and tx_timer_cmd PHY registers. PHY setting is per LAN port.

Master Timers:

The master timers synchronize all the timers in the PHYs. It is used by software to synchronize the time to the network time. It is used to sample and drive GPIO signals synchronized to the timer.

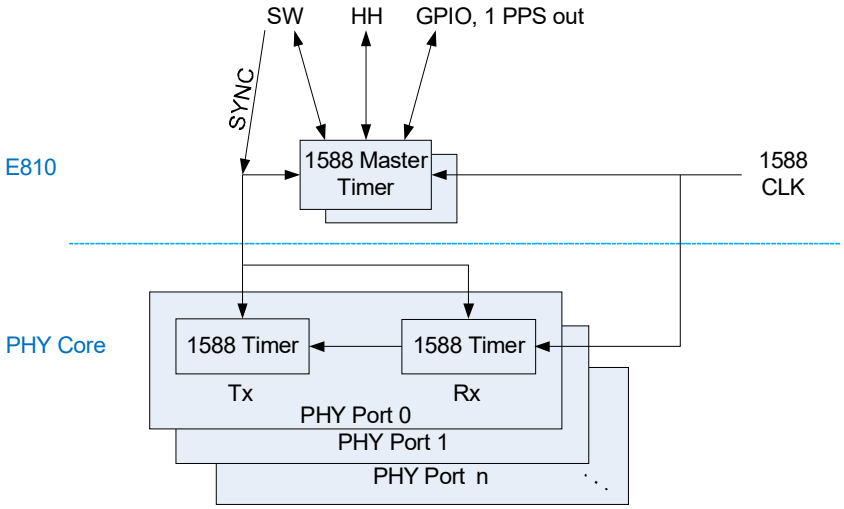

Figure 9-13. 1588 Logic - Top-Level Diagram

9.7.2 Time Synchronization - Background

9.7.2.1 Time Synchronization Flow

The operation of a 1588 logic is based on Precision Time Protocol (PTP). This protocol is composed of two stages: initialization and time synchronization. These stages are described below, emphasizing hardware and software roles.

9.7.2.2 Initialization Phase

If enabled as a potential master (by a software setting), the software periodically transmits sync packets that include the master's clock parameters. Upon receipt of a sync packet, the software on any potential master compares the received clock parameters to its own parameters. If the received parameters are better, the software transitions to a slave state and stops sending sync packets.

While in slave state, the software selects a particular master. The software continuously compares the received sync packet to its selected master. If the received sync packet belongs to a different master with better clock parameters, the software switches to the new master. Eventually only one master (with the best clock parameters) remains active, while all other nodes act as slaves listening to the single master.

Every node has a defined time-out interval. If no sync packets are received from the selected master, software on each slave switches back to the initialization phase until a new master is chosen.

Note: There is more than one option for the above flow while there are other flows that are based on static master setting. The node can be set statically to master or slave modes. While in a slave mode, the node can be tuned statically to a specific master.

9.7.2.3 Time Synchronization Phase

There are two phases to the synchronization flow: (1) the slave calibrates its clock to the master, and then (2) the master performs complete synchronization.

9.7.2.3.1 Clocks Calibration

The master sends sync packets periodically (about of 10 packets per second and up to 128 packets per second according to ITU requirements). These packets are followed by *Follow_UP* packets that indicate the transmission time. The slave captures the reception time of the sync packet, so it holds the packet transmission time at the master and its reception time at the slave.

Receiving consecutive sync packets, the slave gets the delta T of the master and can calibrate its timer to get the same delta T. During this phase, the slave adjusts the INCVAL of its 1588 timer. It can also calibrate its 1588 timer at limited accuracy in the order of the transmission delay between the master and the slave. This process is illustrated in Figure 9-14.

To minimize sampling inaccuracy, both master and slave sample the packet's transmission and reception time at a location in the hardware that has as much as possible deterministic delay from the PHY interface.

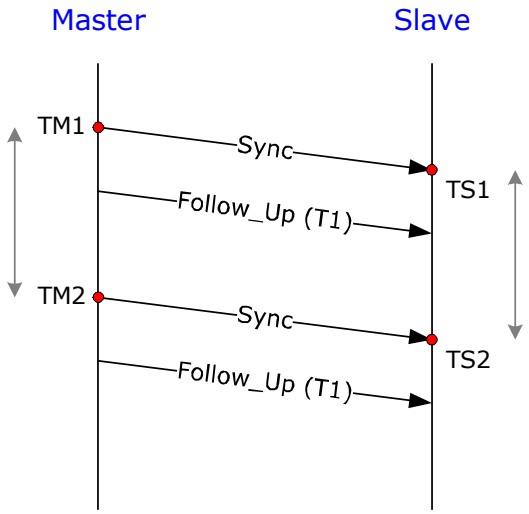

Figure 9-14. Clocks Calibration

9.7.2.3.2 Time Synchronization Phase

The complete synchronization scheme is illustrated in Figure 9-15. It relies on measured timestamp of sync packets transmission and reception by the master and the slave. The scheme is based on two assumptions:

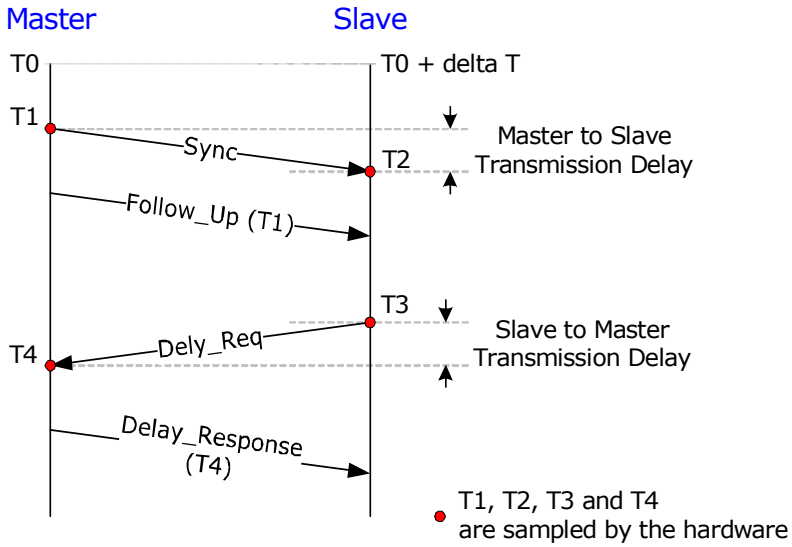
- The clocks at both nodes are almost identical (achieved in the first step).
- Transmission delays between the master to the slave and backward are symmetric. If this assumption does not hold, the software on the master as well as the slave(s) should compensate it by adjusting the sampled time of the sync packets.

The master's software sends periodic sync packets to each slave followed by a *Follow_Up* packet (as explained in Section 9.7.2.3.1). The slave samples the sync packet reception time. The slave responds back, sending a *Delay_Req* packet to the master and samples its transmission time. The master samples its reception time and reports it to the slave by a *Delay_Response* packet. At this point, the slave has all the following parameters (the notations below match the notations used in Figure 9-15):

- **T1** — *Sync* packet transmission time in the master (based on master clock)
- **T2** — *Sync* packet reception time in the slave (based on slave clock)
- **T3** — *Delay_Request* transmission time in the slave (based on slave clock)
- **T4** — *Delay_Request* reception time in the master (based on master clock)

The Slave can adjust its clock using the following equation:

Slave Adjust Time = [(T4-T3) - (T2-T1)] / 2



Calculated delta T = [(T2-T1)-(T4-T3)]/2 // assuming symmetric transmission delays

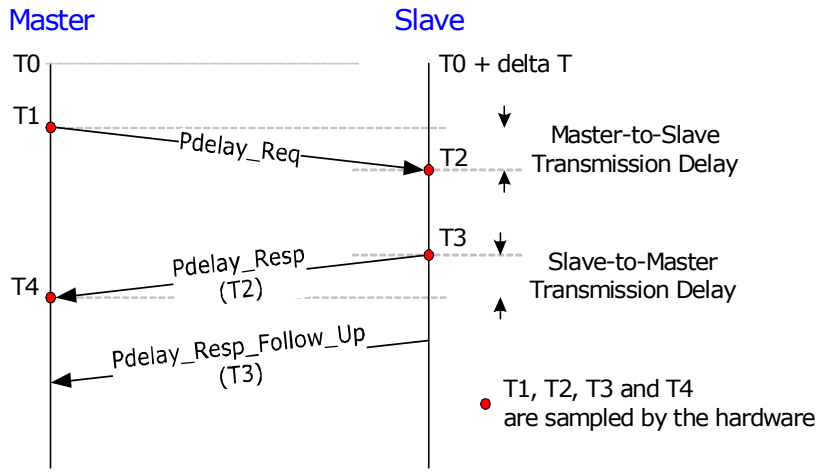
Slave Adjust Time = - delta T

Figure 9-15. Sync Flow and Offset Calculation

9.7.2.3.3 PDelay Flow for Dynamic Master Selection

The master sends a *Pdelay_Req* packet to the slave, and the slave response by sending back a *Pdelay_Resp* packet followed by a *Pdelay_Resp_Follow_Up* packet. The master uses these packets to calculate the link delay. This process is also used for fast recovery when the master is changed.

The process is usually activated when dynamic master selection is enabled. It can operate asynchronous to the "Time Synchronization" flow described in Section 9.7.2.3.2. The PDelay flow is shown in Figure 9-16.



Calculated Transmission Delay = [(T2-T1) + (T4-T3)] / 2 // assuming symmetric

Figure 9-16. PDelay Flow

9.7.3 1588 Clock and Timer Registers

9.7.3.1 1588 Master Timer Enable

The 1588 master timers are enabled by the GLTSYN_ENA register per master. When the master is not enabled, it does not increment.

9.7.3.2 Initialization

9.7.3.2.1 Firmware-Related Initialization

The EMP firmware is responsible for determining the configuration specified in this section and reflecting it to software using the Discover Function/Device Capabilities admin command (see Section 9.5.13.8). The EMP firmware must determine the mentioned configuration following each boot or following an adaptive NVM change.

9.7.3.2.1.1 Timer Ownership

Each of the two 1588 masters can be controlled by a single PF driver. The ownership is determined by an NVM-loaded configuration that can be modified by the adaptive NVM procedure (see Section 6.1.6).

9.7.3.2.1.2 Association of Timer to PHY(s)

Each PHY can be associated to one of the two master timers. The ownership is determined by an NVM-loaded configuration that can be modified by the adaptive NVM procedure (see Section 6.1.6).

9.7.3.2.1.3 Association of GPIOs to Timers

As mentioned in Section 9.7.6.1, each master timer can be associated with GPIOs. The ownership is determined by an NVM-loaded configuration.

9.7.3.2.1.4 1588 Source Clock

The 1588 timers in the E810 and the PHYs operate on the same clock of 812.5 MHz.

9.7.3.2.2 Software-Related Initialization

As mentioned in Section 9.7.3.2.1, the PF driver gets the following information using the Discover Function/Device Capabilities admin command (see Section 9.5.13.8):

- The PF driver ownership on 1588 master timers (see Section 9.7.3.2.1.1).
- The association of 1588 timers to PHY(s) (see Section 9.7.3.2.1.2).
- The association of GPIOs to 1588 master timers (see Section 9.7.3.2.1.3).
- Information about the 1588 source clock (see Section 9.7.3.2.1.4).

The PF driver that owns a 1588 master is expected to initialize and program during run time the 1588 master timer and its associated PHYs. As part of the PF initialization sequence, the driver of the PF that owns the 1588 master initializes the clock logic in the PHYs that it controls. The driver reports the PLL clock frequency to the PHYs.

The PF driver also sets the *SEL_MASTER* to one of the two 1588 masters.

9.7.3.3 1588 Timer Registers

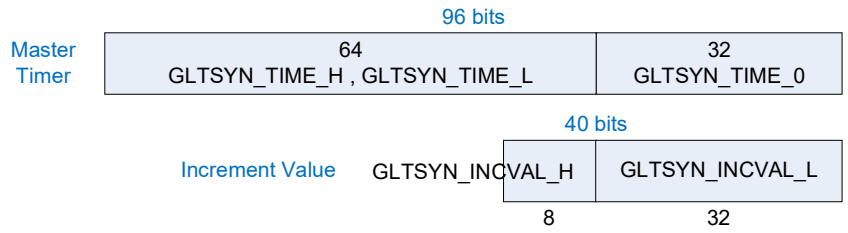


Figure 9-17. 1588 Timers

As shown in Figure 9-17, the 1588 timers are composed of two sets of registers: the timer registers and the step registers:

GLTSYN_TIME:

The E810 has two 1588 master timers, each of them is a 96-bit counter: GLTSYN_SHTIME_H, GLTSYN_SHTIME_L, and GLTSYN_SHTIME_0. Each 1588 clock, the 1588 timers are increment by a programmable "step" called INCVAL. Setting the INCVAL as specified in Table 9-68, the upper 64 bits of the timer represent the time in nanosecond units.

The PHYs have dedicated timer registers for each transmit and each receive port. The timers in the PHYs are 64-bit registers that match the lower 64-bits of the master timer in the E810.

During nominal operation, the timers in the PHYs always show the exact values as its master timer in the E810. This synchronization is achieved by initializing the master timer and the PHY's timers, including its INCVAL registers, to the same values at the same time. Setting the master timer and the PHY timers with the same values is done using the Read/Write 1588 PHY sideband admin command (the setting flows are detailed in the following sections).

The software can read the master timer value(s) by the Read 1588 PHY sideband admin command. It can also read the upper 64 bits of the timer by a direct access to the timer registers in the E810 in the following order: Read first the GLTSYN_TIME_L register and then the GLTSYN_TIME_H register. The software should re-read the GLTSYN_TIME_L register to ensure that it was not wrapped around before the read of the GLTSYN_TIME_H register. If it does wrap around, software should start the read process again.

GLTSYN_INCVAL:

As indicated above, at each 1588 clock pulse the 1588 timers are increment by a programmable "step" called INCVAL. The INCVAL is a 40-bit field. The E810 contains the INCVAL in the GLTSYN_INCVAL_L and GLTSYN_INCVAL_H registers per master timer. The PHYs also have the same 40-bit INCVAL registers per transmit and receive timers per port.

During nominal operation, the software programs the INCVAL of the master timer and the INCVAL of the PHYs together by the Read/Write 1588 PHY sideband admin command.

1588 Clock Frequencies and Its Matched INCVAL:

Table 9-68 shows the INCVAL settings by which the upper 64-bits of the timer represent the time in nanosecond units. These settings (done by the software) are just an example for the INCVAL values if the timer operates as asynchronous timer. When the 1588 timer is synchronized to another timer, the INCVAL is adjusted during time according to the difference between the local clock frequency relative to the clock frequency of the other timer.

Note: There are applications on which the timer represents the time in units of its input clock. In this case, the INCVAL in the master node in the network is set to 0x100000000 and there is no need for any adjustment as indicated in the last column in Table 9-68.

Table 9-68. Recommended INCVAL for a Given PLL Frequency

Source Clock	Source Clock Frequency (MHz)	Matched PLL Frequency (MHz)	INCVAL for Getting a Timer in Nanosecond units	Time Adjust in Sub-Nanosecond Units for Accurate Asynchronous Clock
TIME_REF	812.5 MHz	812.5 MHz	1	0x13B13B13B

Time Adjustment and GLTSYN_SHADJ:

Adjusting the timer by 'N' or by +-1: On each 1588 clock, the timer is incremented by INCVAL. When adjusting the timer by 'N' or by +-1, the timer is incremented by the INCVAL + ('N' or +-1) for one 1588 clock and then it reverts back to incremental step of INCVAL.

Note that +- 1 equals to +- 0x100000000 (one and 32 hex zero's).

Note: The 'N' in the equation above is the value of the *ADJUST* field in the GLTSYN_SHADJ registers. Negative numbers are represented in 2's complement.

9.7.4 Programming the 1588 Timers

As indicated, the E810 supports two 1588 master timers, plus the timers in the PHYs that are synchronized to one of the master timers. This section describes how the software sets the timer registers and the mechanism by which the PHY timers are synchronized to one of the master timers.

The synchronization mechanism is based on two pillars:

- All timers (master and PHY timer) operate on the same clock.
- The registers of all timers are programmed to the same values at the exact same clock.
  - All the timers that should be programmed by a specific parameter are pre-armed by the required instruction.

Then the *SYNC* signals are driven, which executes the pre-armed instruction to all selected timers on the same clock. See the timing diagram in the Figure 9-18.

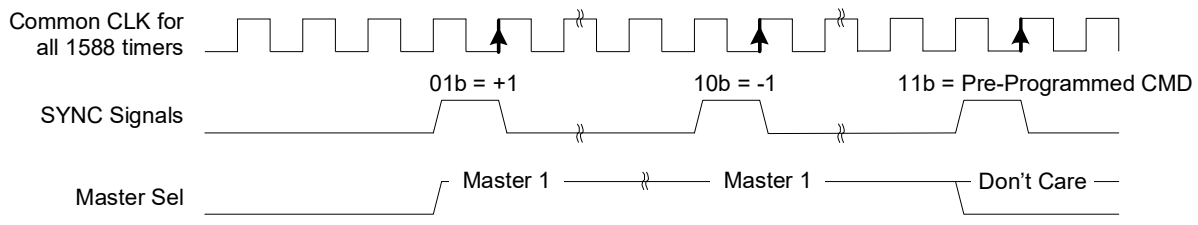

Figure 9-18. SYNC Timing Diagram

It is assumed that only one PF manages one of the 1588 masters and the timers in the PHYs that should be synchronized to that master. Programming or reading some parameters are composed of a sequence of steps. The whole sequence should be executed as an atomic action. Otherwise, possible interleaved sequences would result in an unexpected response. The atomic operation is achieved by using a semaphore scheme explained in Section 9.7.4.1.

Table 9-69 lists the timers' programming primitives that the master timer and PHY timers support:

Table 9-69. Programming the 1588 Timer Primitives

Programming Primitive Supported by the PHYs Controlled by the Sideband Messages		
No action	Init Value of the Inc Value / Timer Value	Adjust the Timer by 'N'
Sample the Timer and the Inc Value	Increment / Decrement the Timer by 1	Adjust the Timer by 'N' at a specific time

9.7.4.1 Semaphore Scheme Enabling Atomic Sequences

The E810 includes a *BUSY* flag in the PFTSYN_SEM register that can be used to gain control of a shared hardware resources. It can be used by a software driver to access the device for a sequence of actions without possible interference by other software drivers (possibly on other PFs).

1. Software should read the PFTSYN_SEM.*BUSY* flag.
2. Reading a *BUSY* flag value of zero (0b) means that the software can access the hardware.
3. Following this read access, the *BUSY* flag is auto-set by the hardware and the PF index (that initiated the read access) is captured in the PFTSYN_SEM.*PF_OWNER* field.
4. Any following read access to the register shows an active *BUSY* that tells the software it cannot access the shared hardware resource.
5. It is the responsibility of software to keep the *BUSY* active as short as possible. Once the software completes the sequence that must be atomic, it should write to clear the *BUSY* flag.
6. On a PF reset event, the EMP firmware must read the PFTSYN_SEM register and, in case of a PF reset to the PF whose index is captured in PFTSYN_SEM.*PF_OWNER* and while the *BUSY* indication is set, the EMP firmware must automatically clear the BUSY indication to allow other PFs to access the registers.

9.7.4.2 Shadow Registers for Timer Programming

Table 9-69 lists the timers' programming primitives. Supporting these primitives, each timer (masters and slaves) holds the following shadow registers.

- **Shadow Time** — These registers are used for one of the following actions:
  - — Set initial value of the timer.
  - — Sample the timer registers.
  - — Set the time for the "Adjust the Timer by 'N' at a specific time" command.

  In the E810, it is a 96-bit register per timer, called GLTSYN_SHTIME. In the PHY Core, these registers are 64 bits long (two sets of registers in the PHY Core: for the Tx and Rx data paths).
- **Shadow Adjust** — These registers are used for one of the following actions:
  - — Set initial value of the INCVAL registers.
  - — Sample the INCVAL registers.

— Adjust the timer registers.

In the E810, it is a 48-bit register per timer, called GLTSYN_SHADJ. Same register size in the PHY Core (two sets of registers in the PHY Core: for the Tx and Rx data paths).

- **CMD Register 1** — The PHY Core has two sets of command registers: rx_master_timer and tx_master_timer. These registers are programmed by the command to be executed at *SYNC* pulse. It contains the 3-bit opcode and one bit selecting the 1588 master timer. At any write access, the associated master timer should be set (not indicated explicitly in the following subsections).
- **CMD Register 2** — The E810 have two command registers used to control the 1588 timers:
  - **GLTSYN_CMD** — Contains the command to be executed and a select the master timer flag.
  - **GLTSYN_CMD_SYNC** — Writing to this register generates the *SYNC* pulse.

9.7.4.3 Initializing the 1588 Timers and the INCVAL

This sequence is useful mainly at timer initialization. It makes sense to initialize both the timer values and its INCVAL in the same step, as shown below. This is the first step that group a set of PHYs with one of the two master timers in the E810.

1. Read the PFTSYN_SEM.*BUSY* flag until it is zero (0b).
2. Program the CMD registers and the shadow registers of all the relevant PHY ports that should be tied to the selected master using the Read/Write 1588 PHY sideband Admin Queue command with the following parameters (both the Tx and Rx PHY registers):
   a. CMD register = INIT INCVAL + TIMER at SYNC
   b. Set the SHTIME_L register (32 bits) // Equivalent to GLTSYN_SHTIME_0 of the master.
   c. Set the SHTIME_H register (32 bits) // Equivalent to GLTSYN_SHTIME_L of the master.
   d. Set the SHADJ_L register (32 bits) // Same as GLTSYN_SHADJ_L of the master.
   e. Set the SHADJ_H register (32 bits) // Same as GLTSYN_SHADJ_H of the master.
3. Set the GLTSYN_SHTIME (0, L, and H) and GLTSYN_SHADJ (L and H) registers of the master timer in the E810.
4. Set the *CMD* to INIT INCVAL + TIMER and the *SEL_MASTER* as needed in the GLTSYN_CMD register in the E810. The *Sel_Master* signal is driven to the master and the PHYs.
5. Set the *SYNC* field in the GLTSYN_CMD_SYNC register to 11b.
   a. As a response, the E810 drives the sync signals to the masters and the PHYs.
   b. The programmed values are loaded to the master timer and the PHY timers: The SHTIME registers are loaded to the TIME registers and the SHADJ registers are loaded to the INCVAL registers.
   c. After the sync signals are generated, the *SYNC* field is auto-cleared in the GLTSYN_CMD_SYNC register.
6. Clear the PFTSYN_SEM.*BUSY* flag, enabling other software drivers to access the 1588 logic.

Note: In Step 2, the software can indicate the admin commands for all registers of all the relevant PHYs by a single tail bump of the sideband AQ. The E810 drives these sideband commands to the PHYs one-by-one, driving the next command in line only after the previous one is completed. This comment is relevant to all the following flows accessing the PHYs.

9.7.4.4 Adjust the Timer by 'N'

This step is useful at run time when the timer should be adjusted by a larger value than one LS bit of the GLTSYN_TIME_L or more granular value.

1. Read the PFTSYN_SEM.*BUSY* flag until it is zero (0b).
2. Program the CMD registers and the shadow registers of all the relevant PHY ports that should be tied to the selected master using the Read/Write 1588 PHY sideband Admin Queue command with the following parameters (both the Tx and Rx PHY registers):
   a. CMD register = ADJUST at SYNC
   b. Set the SHADJ_L register (32 bits).
   c. Set the SHADJ_H register (32 bits).
3. Set the GLTSYN_SHADJ registers of the master timer in the E810.
4. Set the *CMD* to ADJUST and set the *SEL_MASTER* as required in the GLTSYN_CMD register in the E810. The *Sel_Master* signal is driven to the master and the PHYs.
5. Set the *SYNC* field in the GLTSYN_CMD_SYNC register to 11b.
   a. As a response, the E810 drives the sync signals to the masters and the PHYs.
   b. The TIME registers are updated by the SHADJ value (on top of the INCVAL) in the master timer and the selected PHYs.
   c. After the sync signals are generated, the *SYNC* field is auto-cleared in the GLTSYN_CMD_SYNC register.
6. Clear the PFTSYN_SEM.*BUSY* flag, enabling other software drivers to access the 1588 logic.

Notes: See note in Section 9.7.4.3 for possible tail bump of the sideband AQ.

This command can only be used to increment the timer. When decrementing the timer is required, the software should set the SHADJ value to the 2's complement value of the requested decrement operand.

9.7.4.5 Adjust the Timer by 'N' at Time

This step is very similar to the adjust time sequence, plus an option to execute this step at a specific time (when the timers cross the value defined by the time parameter).

Note: This timer manipulation action is designed to be performed in a future time (hence the "at time" term). The hardware assumes that a new operation for the timer is not performed until this action is executed. Furthermore, if any of the CSRs holding settings mentioned in the flow below are changed before the timer manipulation executes, the new values are used.

1. Read the PFTSYN_SEM.*BUSY* flag until it is zero (0b).
2. Program the CMD registers and the shadow registers of all the relevant PHY ports that should be tied to the selected master using the Read/Write 1588 PHY sideband Admin Queue command with the following parameters (both the Tx and Rx PHY registers):
   a. CMD register = ADJUST at Time after SYNC
   b. Set the SHTIME_L register to the target time low // Equivalent to GLTSYN_SHTIME_0.
   c. Set the SHTIME_H register to the target time high // Equivalent to GLTSYN_SHTIME_L.
   d. Set the SHADJ_L register (32 bits).

e. Set the SHADJ_H register (32 bits).

3. Set the GLTSYN_SHTIME and GLTSYN_SHADJ registers of the master timer in the E810:
   a. Set the target time to the GLTSYN_SHTIME_0 and GLTSYN_SHTIME_L registers. The hardware ignores the value of the 32 MS bits of the timer and the GLTSYN_SHTIME_H register in this command.
   b. Set the adjust value to the GLTSYN_SHADJ_L and GLTSYN_SHADJ_H registers.
4. Set the *CMD* to ADJUST at time and set the *SEL_MASTER* as required in the GLTSYN_CMD register in the E810. The *Sel_Master* signal is driven to the master and the PHYs.
5. Set the *SYNC* field in the GLTSYN_CMD_SYNC register to 11b.
   a. As a response, the E810 drives the sync signals to the masters and the PHYs.
   b. The TIME registers are updated by the SHADJ value (on top of the INCVAL) in the master timer and the selected PHYs, one clock after the TIME registers cross the SHTIME registers. Note that if the TIME registers are exactly equal to the SHTIME registers at sync time, the TIME is updated by the SHADJ value only after the next time it cross the SHTIME registers.
   c. After the sync signals are generated, the *SYNC* field is auto-cleared in the GLTSYN_CMD_SYNC register.
6. Clear the PFTSYN_SEM.*BUSY* flag, enabling other software drivers to access the 1588 logic.

Notes: See note in Section 9.7.4.3 for possible tail bump of the sideband AQ.

This command can only be used to increment the timer. When decrementing the timer is required, the software should set the SHADJ value to the 2's complement value of the requested decrement operand.

Once the shadow time registers are set using this flow, wait for this flow to complete and for the timer to be updated before overriding the shadow time registers. That is, the shadow time registers should not be overridden before the timer update time occurs.

9.7.4.6 Read the Timer Values

Software on any PF can read the master timer and its INCVAL by direct read access to the GLTSYN_TIME and GLTSYN_INCVAL registers. Furthermore, the software driver that controls the timer can sample the timer and its INCVAL of both masters and the PHY timers. Checking the PHY timers against their master can be useful for debug purposes.

Software can also sample both master timers. It can be useful for applications that care about 2x 1588 time domains and the time delta between the two domains.

The following flow describes the steps to sample the time and INCVAL of the timers.

1. Read the PFTSYN_SEM.*BUSY* flag until it is zero (0b).
2. Optional: Program the CMD registers of all the relevant PHY ports that should be sampled by the Read/Write 1588 PHY sideband Admin Queue command with the following parameters:
   a. CMD = SAMPLE TIME at SYNC and SEL_TX_RX (selecting the Tx or Rx timer to be sampled)
3. Set the *CMD* to READ_TIME in the GLTSYN_CMD register. The *SEL_MASTER* field value is don't care.
4. Set the *SYNC* field in the GLTSYN_CMD_SYNC register to 11b.
   a. As a response, the E810 drives the Sync signals to the masters and the PHYs.

b. The 1588 timers and the INCVAL of the selected PHYs are sampled by their SHTIME and SHADJ registers, respectively. The master timers and INCVAL are sampled by their GLTSYN_SHTIME and GLTSYN_SHADJ registers, respectively.

5. Software can read the sampled TIME of both masters in their GLTSYN_SHTIME registers, and read the sampled INCVAL in their GLTSYN_INCVAL registers.
6. Software can read the sampled TIME and INCVAL registers of the PHYs that are tied to the selected master by the Read 1588 PHY sideband Admin Queue command.
7. Clear the PFTSYN_SEM.*BUSY* flag, enabling other software drivers to access the 1588 logic.

Note: See note in Section 9.7.4.3 for possible tail bump of the sideband AQ.

9.7.5 Timestamp Indication

Packet transmission time is sampled by the PHY logic at a deterministic as possible affinity to the link interface. The sampled time is taken at the beginning of the packet, as shown in Figure 9-19.

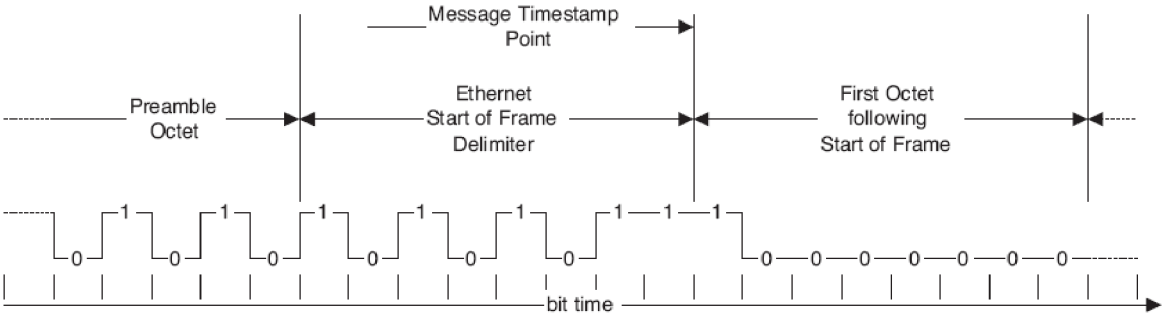

Figure 9-19. Timestamp Point

The sampled time in the PHY is a 39-bit word plus a valid indication. These 39 bits are composed of the PHY_TIME_H value plus the seven MS bits of the PHY_TIME_L (usually the sub-nanosecond units). It is illustrated in the Figure 9-20.

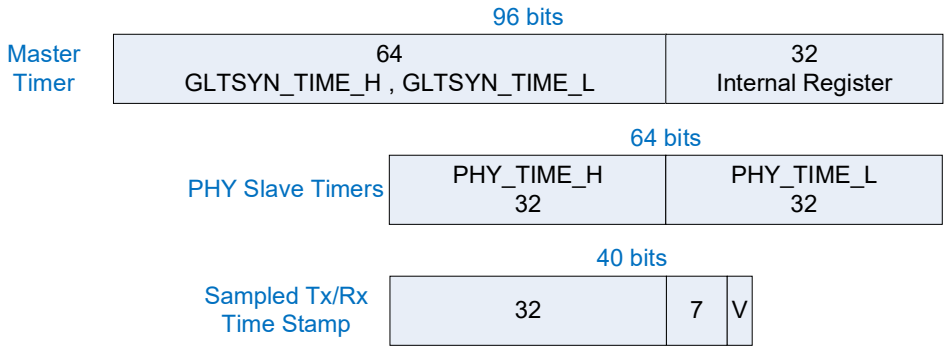

Figure 9-20. Sampled Timestamp

9.7.5.1 Transmit Timestamp

Software indicates to the hardware the packets to be sampled by setting the *TSYN* flag and the *TSYN_REG* field in the transmit context descriptor (see Section 10.5.3.2). The hardware samples the transmission time of packets with an active *TSYN* bit. Setting the *TSYN* flag in the context descriptor is meaningful only from those queues that are enabled for time sampling. A queue is enabled to use the TimeSync features using the *TSYN_ENA* flag in the transmit queue context (see Section 10.5.5.2.1).

Transmit packets are forwarded to the PHY with the *TSYN* flag and the *TSYN_REG* field as part of the packet metadata. The PHY samples the packet transmission time in a register index equals *TSYN_REG*. Once the packet is transmitted and its time is sampled, the PHY triggers a *Tx_Sample* pulse. If the specific PHY is enabled for the PF by the PFINT_TSYN_MSK register, the *1588_TX* flag in the other cause interrupt register is set, generating an interrupt to the software.

Then, the software can read the timestamp registers of all its transmitted packets that might be completed (as shown in Figure 9-21). Software reads the sampled timestamps by the Read 1588 PHY admin command (reading the low and high portions of the sampled time registers in the PHY).

Note: It is software's responsibility to read the sampled time before overriding these values by new packets. The PF driver should enable time sampling for those transmit queues on which it is guaranteed that the software is well behaved so the above rule is kept.

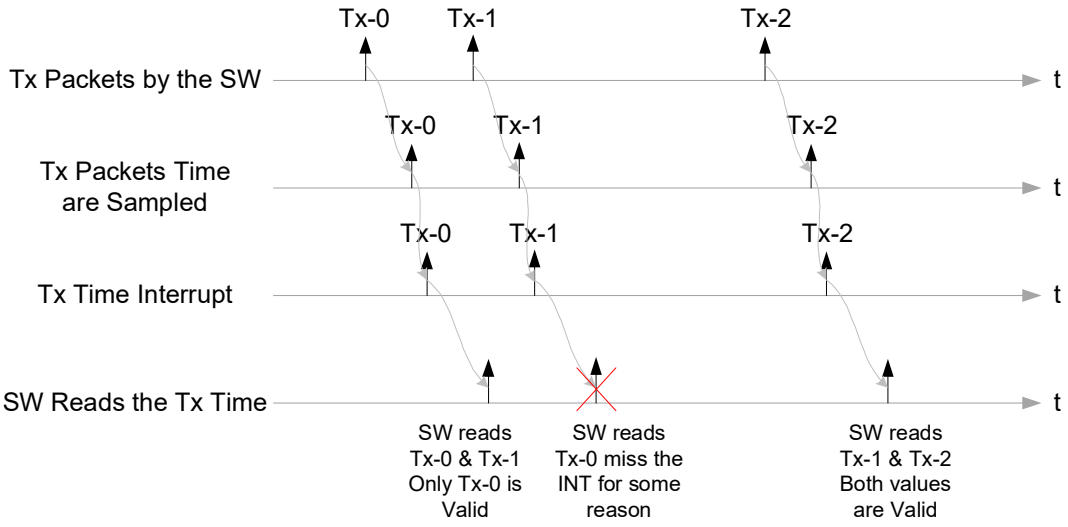

Figure 9-21. Sampled Timestamp

9.7.5.2 Receive Timestamp

The E810 samples the reception time of all packets in the PHY. The sampled time is forwarded from the PHY to the E810 as part of the packet's metadata. It is then posted with the packets in the receive descriptor if enabled in the queue context by the relevant QRXFLXP_CNTXT.*TS* flag. This option is valid only when using 32-byte descriptors.

9.7.6 Synchronized Auxiliary Events

The E810 supports the following global auxiliary events:

- Synchronized events to global I/O signals are described in Section 9.7.6.1.
- Synchronized events to PCI slave access are described in Section 9.7.7.1.

9.7.6.1 Auxiliary 1588 I/O Signals

The E810 supports a total of four single-ended GPIO signals (SDP[20:23]) plus one differential GPIO signal (CLK_OUT_P/N), which is configured by default as 1PPS (out). The functionality of these GPIOs is controlled by the GLGEN_GPIO_CTL[x] registers (expected to be loaded from the NVM). These GPIO pins are associated to the 1588 logic by the *PIN_FUNC* fields in the GLGEN_GPIO_CTL[x] registers.

The GPIO signals are set to input or output by the *PIN_DIR* field in the GLGEN_GPIO_CTL registers. When set to input signal, the sampling event can be sampled by one of the GLTSYN_EVNT registers (as programmed by the *PIN_FUNC* field). When set to output signal, the output event time is defined by one of the GLTSYN_TGT registers (as programmed by the *PIN_FUNC* field). The following settings should be loaded from the NVM and must not be modified by the software:

- GLGEN_GPIO_CTL[5] - CLK_OUT_P/N (out): *PIN_DIR* must be set to output.

There are several output modes of operation described below. In any of them, the initial state of the GPIO pins can be set by the GLGEN_GPIO_CTL registers. The output modes related to the 1588 timers are enabled by the *OUT_ENA* flag in the GLTSYN_AUX registers.

Note: Though the system configuration allows outputting high-frequency signals using the single-ended GPIO signals, the maximum, output frequency supported by the system for these GPIO signals is 20 MHz with a minimum duty cycle of 10%.

- **Synchronized Level Output** — Software should set the event time in the matched GLTSYN_TGT registers. Then set the *OUT_ENA* flag to one and the *OUTMOD* field to "Output Level Mode" (00b) in the GLTSYN_AUX_OUT registers. When the upper 64 bits of the GLTSYN_TIME crosses the value of the GLTSYN_TGT, the assigned GPIO transits to the programmed output level.

  Note: The output level is set by the TimeSync logic only once (when reaching or passing the time specified in GLTSYN_TGT.

- **Synchronized Flipped Output Signal** — Same flow as the Synchronized Level Output, except set the *OUTMOD* field to "Flipped Output Mode" (01b) in the GLTSYN_AUX_OUT registers. When the upper 64 bits of the GLTSYN_TIME crosses the value of the GLTSYN_TGT the GPIO flips its output level.

  Note: The output is flipped by the TimeSync logic only once (when reaching or passing the time specified in GLTSYN_TGT.

- **Synchronized Output Pulse** — Same flow as the Synchronized Level Output, except set the *OUTMOD* field to "Output Pulse Mode" (10b) and the *PULSEW* field to the required pulse width in the GLTSYN_AUX_OUT registers. Doing so, when the upper 64 bits of the GLTSYN_TIME crosses the value of the GLTSYN_TGT, the GPIO signal flips its output state for {16 x (*PULSEW* + 1)} x 1588 clocks and then reverts back to its previous level.

  Note: The output is pulsed by the TimeSync logic only once (when reaching or passing the time specified in GLTSYN_TGT.

- **Synchronized Clock Output** — This mode is selected by setting the *OUT_ENA* flag to one and the *OUTMOD* field to "Output Clock Mode" (11b) in the GLTSYN_AUX_OUT register. The matched GLTSYN_CLKO registers should be set to 50% of the required output clock duration, and the GLTSYN_TGT registers should be set to the time on which the output clock should start. Each time the upper 64 bits of the GLTSYN_TIME crosses the value of the GLTSYN_TGT the GPIO signal flips its output level. Then, the GLTSYN_TGT register is reloaded by the hardware to GLTSYN_TGT plus GLTSYN_CLKO (while GLTSYN_CLKO is padded by 32 MS bit zero's).

  Note: For proper operation, the GLTSYN_CLKO must be larger than twice the value of GLTSYN_INCVAL, and for reasonable accuracy, GLTSYN_CLKO should be significantly larger than twice the value of GLTSYN_INCVAL.

  Software can set the initial state of the output signal by direct setting of the GPIO level.

- **Sampling Input Event** — The E810 can capture the time on which a level transition is sensed on the 1588 auxiliary signals. The event time is captured by one of the 64 bit GLTSYN_EVNT registers. The sampled input event type is defined by the *EVNTLVL* field in the GLTSYN_AUX_IN registers, equal to one of the following options:

  — Disable (00b)

  — Rising Edge (01b)

  — Falling Edge (10b)

  — Any Transition (11b)

  When the defined transition is sampled by the hardware (synchronized to the 1588 clock), the upper 64 bits of the GLTSYN_TIME are latched by the matched GLTSYN_EVNT registers.

9.7.7 Synchronization with Host Timer

The time relationship between the CPU time and devices within the system is a key element in many applications. Specifically, the relationship with the 1588 clock is critical. The following subsections describe mechanisms to measure this relationship.

9.7.7.1 Reading and Sampling the 1588 Master Timers

Reading and sampling the 1588 master timers is described in Section 9.7.4.6. Software can use the "sample time" flow described in Section 9.7.4.6 to get the time delta between the two 1588 master timers.

9.7.8 Interrupts

The E810 can generate a 1588 interrupt for one of the following events if the interrupt is enabled by the *TSYN* flags in the PFINT_OICR_ENA register.

- The PHY asserts an interrupt signal to the E810 for each transmit packet that is time sampled. Packet on port 'n' asserts bit 'n' in the GLINT_TSYN_PHY register. The PF that owns the port as programmed by the PFINT_TSYN_MSK register gets an interrupt if enabled by the *TSYN_TX* flag.
- Input event is latched by one of the GLTSYN_EVNT registers while the interrupt is enabled by the *TSYN_EVNT* flag. The interrupts is asserted to the PF defined by the *PF_MASTER* field in the GLINT_TSYN_PFMSTR0 and GLINT_TSYN_PFMSTR1 registers for an event that is generated by the 1588 master timer 0 and 1, respectively.

- One of the target time registers has expired while the interrupt is enabled by the *TSYN_TGT* flag. See above for PF *PF_MASTER* impact.

Regardless if the interrupt is enabled, the above AUX events are reported in the applicable PFINT_OICR register.

9.7.9 1588 Initialization Flow

This section describes the PF software initialization flow required to activate the 1588 logic.

1. Check the *PF_MASTER* field in the GLINT_TSYN_PFMSTR register if the PF is expected to control the 1588 logic.
2. The 1588 CSRs in the PHYs are initialized by global reset, which might not be triggered by a PCI reset. Therefore, PF software is required to initialize most of the 1588 registers listed in the "TimeSync (IEEE 1588) Registers" section:
   a. Clear any optional residuals reported in the GLTSYN_STAT register and the GLINT_TSYN_PHY register.
   b. Read all transmit timestamps in the PHYs clearing its possible valid indication.
   c. Set the GLTSYN_AUX register as required for the AUX functionality.
   d. The timer and the increment values are expected to be programmed as part of the nominal operation (GLTSYN_TIME and GLTSYN_INCVAL registers).
3. Assign a transmit queue for 1588 transmission and enable *TSYN_ENA* flag in its queue context.
4. Set the relevant QRXFLXP_CNTXT.*TS* flag in those receive queues that should get the receive timestamps.

9.7.10 Software Timer

The E810 includes a 32-bit counter in GLVFGEN_TIMER register, which is based on a free running 1 μs clock. The counter is cleared by Power On Reset (POR) and increments after being cleared. The timer wraps around in about 70 minutes.

9.8 LLDP Protocol

9.8.1 Introduction

The E810 supports the IEEE Data Center Bridging standards such as:

- IEEE 802.1Qaz — Enhanced Transmission Selection (ETS)
- IEEE 802.1Qbb — Priority based Flow Control (PFC)
- IEEE 802.1Qbg — Edge Virtual Bridging (ECB)

Devices that support these standards use IEEE 802.1AB Link Layer Discovery Protocol (LLDP) to exchange configuration information with their network link partner.

LLDP is a link layer protocol that allows a LAN station to advertise capabilities and status of the system. An LLDP agent transmits and receives information to and from the LLDP agents of other stations attached to the same LAN. The information distributed and received in each LLDP Data Unit (LLDPDU) is stored in two Management Information Bases (MIBs) per physical LAN port, one for Nearest Bridge and the other for non-TPMR.

9.8.2 Scope

The E810 supports an embedded LLDP agent that runs on the Embedded Management Processor (EMP).

This section describes implementation of the embedded LLDP agent. It describes the agents operational modes, supported TLVs, configuration, and run time operation of LLDP.

9.8.3 LLDP Agent

The following IEEE standards have configuration parameters and use LLDP to exchange configuration parameters with the link partner.

- Data Center Bridging (DCB).

The DCB features (PFC, ETS, DCBX, App TLV) are defined as requirements for a VLAN aware bridge component. Both C-components and S-components are VLAN-aware bridge components. The E810 supports a single instance of DCB logic per physical LAN port. Therefore, the E810 DCB logic is associated with the component connected to the physical LAN port, either C or S depending on the use case/configuration.

The E810 supports an LLDP agent that exchanges LLDP MIB with its peer. The LLDP agent exchanges the LLDP MIB with either an S-VLAN bridge or C-VLAN bridge depending on mode of operation.

The LLDP agent is active under the following conditions

- During pre-boot operations, including S5 (D0u and D0a).
- During OS present mode, unless software explicitly turns off the agent using the Stop LLDP Agent AQ command.

The LLDP agent is enabled during power-on by setting the LLDP Admin Status word in NVM, (enabled separately per Ethernet port). It is disabled when the Stop LLDP Agent AQ command is executed (per Ethernet port). Software can transfer ownership of LLDP processing back to the device by issuing a Start LLDP Agent AQ command.

9.8.4 LLDP Processing

9.8.4.1 LLDPDU Addressing and Forwarding

9.8.4.1.1 Egress Rules

On the egress side, the LLDP agent uses the appropriate group MAC Address as destination MAC and with EtherType 0x88CC:

- **DCB** — Nearest bridge address.

When an LLDP agent is enabled in the device, the following forwarding rules apply for untagged LLDP packet originating in the host:

- Packets with a Nearest Bridge destination MAC Address are forwarded to the internal control port.
- Packets with Nearest Customer Bridge destination MAC Address are dropped.
- Packets with a non-TPMR destination MAC Address are forwarded to the internal control port.

A control port that wants to send control packets overriding these rules should use the *SWTCH* field in the transmit context descriptor of the control packet. Tagged (802.1Qbg) LLDP packets are forwarded like regular packets. The driver can define different rules (forward to control VSI or drop) using the Add Switch Rules admin command (Section 7.8.12.6.1).

9.8.4.1.2 Ingress Rules

When an LLDP agent is enabled in the device, the following forwarding rules apply for Rx LLDP packets:

Table 9-70. Forwarding Rules for Rx LLDP Packets

Destination MAC Address	STagged LLDP Packets	Untagged LLDP Packets
Nearest Bridge Address	Forward to the PF if programmed so by the PF. Drop otherwise	Forward to EMP.
Non-TPMR Address	Forward to the PF if programmed so by the PF. Drop otherwise	Forward to EMP.
Nearest Customer Bridge Address	Forward to the PF if programmed so by the PF. Drop otherwise	Forward to the PF if programmed so by the PF. Drop otherwise

9.8.4.2 Supported TLV

The LLDP agent should include following TLV as part of the LLDPDU.

- **Chassis ID TLV** — One of four mandatory TLVs. Uses *TLV Type* value of 1 and subtype value of 4 (MAC Address). This TLV contains the permanent/factory-assigned MAC Address of the LAN port.
- **Port ID TLV** — One of four mandatory TLVs. Uses *TLV Type* value of 2 and subtype value of 3 (MAC Address). This TLV contains MAC Address of any physical function. If there is none assigned to a physical function, this TLV contains the permanent/factory-assigned MAC Address of the LAN port.
- **TTL TLV** — One of four mandatory TLVs. Uses *TLV Type* value 3. This TLV contains time-to-live value and is the lower between ((*msgTxHold* * *msgTxInterval*) +1) and 65535. Default *msgTxHold* and *msgTxInterval* are defined in NVM and are loaded by the agent during initialization. See Section 9.8.5.2 for default values.
- **End of LLDPDU TLV** — One of four mandatory TLVs. Uses *TLV Type* value 0. This TLV does not contain any information and sets the TLV information string length to 0.

  Note: Although this is a mandatory TLV, there are apparently some implementations out there that do not send it. Therefore, the device does not require that an LLDPDU ends with this TLV.
- **OEM Device type TLV** — One of the three OEM required TLVs. This TLV uses *TLV Type* value of 127 with subtype of 1. For more information, refer to OEM-specific LLDP specifications for OUI and contents of the TLV.
- **OEM Firmware Version TLV** — One of the three OEM required TLVs. This TLV uses *TLV Type* value of 127 with subtype of 3. For more information, refer to OEM-specific LLDP specifications for OUI and contents of the TLV.
- **OEM Port Capabilities TLV** — One of the three OEM required TLVs. This TLV uses *TLV Type* value of 127 with subtype of 4. For more information, refer to OEM-specific LLDP specifications for OUI and contents of the TLV.
- **DCBX ETS Configuration TLV** — This TLV uses *TLV Type* value of 127 with OUI of IEEE 802.1, which is 0x0080C2. Subtype is 0x09.

  This TLV information string uses the following default values:

  — *Willing* bit set to 1 (unless the software decides to take control by calling Set Local MIB and setting the *willing* bit to 0), indicating that this station is willing to accept configuration from remote station.

  — *CBS* bit is set to 0, indicating that this station does not support credit based shaper.

  — Maximum traffic classes.

  — *Priority Assignment Table* is a four octet string with four bits per entry.

  — *Bandwidth Table* is a string of eight octets with each octet defining the bandwidth percentage for traffic classes. Octet 0 specifies bandwidth percentage of Traffic Class 0, octet 1 for Traffic Class 1, and so on.

  — *TSA Assignment Table* is a string of eight octets with an 8-bit value specifying Transmission selection algorithm per traffic class.

- **DCBX PFC Configuration TLV** — This TLV uses type value of 127 with OUI of IEEE 802.1, which is 0x0080C2. Subtype is 0x0B.

  This TLV information string uses the following default values:

  — *Willing* bit set to 1 (unless the software decides to take control by calling Set Local MIB and setting the *willing* bit to 0), indicating that this station is willing to accept configuration from remote station.

  — *MBC* bit is set to 0 since MACsec is not processed by the E810.

  — *PFC Capability* is a 4-bit unsigned integer indicating the number of traffic classes that simultaneously support PFC. Default value is 8.

  — *PFC Enable* is a 8-bit vector that indicates which traffic classes have PFC enabled. Default value is zero. None of the traffic call uses have PFC enabled by default.

- **DCBX Application Priority Configuration TLV** — This TLV uses type value of 127 with OUI of IEEE 802.1, which is 0x0080C2. Subtype is 0x0C.

  By default, this optional TLV is not transmitted by the LLDP agent, but the agent reflects the table received from peer network port if the agent receives LLDPDU with remote link partner.

9.8.4.3 LLDPDU Transmission and Reception

First LLDP transmission is immediate after the LLDP agent reaches ready state and link is up. This first transmission populates the LLDPDU with default TLV values.

The LLDP agent enters Fast transmission state/period whenever the LLDP agent detects a new neighbor. The LLDP agent enters new neighbor detected state (Fast transmission period) when an IEEE 802.1az Link Layer LLDP frame with new Chassis and Port ID is received. Fast transmission state exited after transmitting *txFastInit* number of LLDPDUs. Default value of *txFastInit* is 4.

When not in Fast transmission mode, the LLDP agent transmits every *msgTxInterval*, unless there is change in local LLDP MIB variables. LLDPDU is transmitted immediately, without waiting for *msgTxInterval* when there is a change in local MIB variables.

The E810 supports a single LLDP neighbor per supported destination LLDP address per port. (that is, two total neighbors – one for Nearest Bridge and one for Nearest non-TPMR per port). LLDPDUs with other addresses are ignored.

The transmission and reception flow is interrupted by several events, each causing a disruption in the normal flow. The behavior in such cases is as follows:

- LLDP events visible to both ends:
  — Aging of the LLDP timer or LLDPDU is received with a TTL value of zero (for example, Shutdown LLDPDU).
    - Delete all information in the LLDP remote systems MIB associated with the respective MSAP identifier.
    - EMP reconfigures device based on the local defaults.
  — Missing TLV in a received LLDPDU.
    - Delete all information for the missing TLV in the LLDP remote systems MIB associated with the respective MSAP identifier.
    - EMP reconfigures device based on the local defaults of this TLV.

- Events that cause a link down:
  - Link Down event (only if LLDP timer has not expired).
    - When link is back up, delete all information in the remote systems MIB associated with the LLDP agent(s) for this link.
    - EMP reconfigures device based on the local defaults.
  - Device Resets that causes Link Down (in other words, EMP Reset, Global Reset, PCI Resets that causes Link Down)
    - Device performs an Internal GLOBR that brings the link down momentarily.
    - Continue as in Link Down case.
  - LLDP ownership transfer from software to firmware.
    - Software issues a Global Reset to the device.
    - Software sends a Start LLDP Agent AQ command to start LLDP agent in firmware.
    - Continue as in Link Down case.
- Events not visible to other end:
  - LLDP ownership transfer from firmware to software.
    - LLDP agent terminated in device.
    - No automatic change in device configuration.
    - EMP waits for software commands.
  - Device resets that do not cause Link Down (like Core Reset, PCI Resets that do not cause link down, function-level resets).
    - Device performs an internal CORER.
    - EMP reconfigures core based on the LLDP MIBs.

      Note: No change in MAC/PHY state, including Flow Control configuration and operation.

      LLDP reception and transmission continues once the above configuration is done. Configuration is estimated to take milliseconds, well below the LLDP timeout values (usually in seconds).

9.8.4.4 LLDP Protocol Variables

Unless otherwise specified, the LLDP agent operational state variables are set to values recommended in Section 9.2.2 of the IEEE 802. AB - 2009 standard. However, certain values can be configured via NVM, and are loaded from NVM when the LLDP agent reaches operational state; this occurs after a power-up or a device reset. Refer to Section 9.8.5.2 for a list of LLDP protocol variables that can be configured via NVM.

9.8.4.5 LLDP Data Store

The LLDP agent maintains sufficient information to enable a host software based management agent to support basic LLDP MIB and organizationally-specific LLDP MIB extensions.

The following basic variables are maintained by the LLDP agent:

- ***msgTxInterval*** — Defines the time interval in timer ticks between transmissions during normal transmission periods.
- ***msgTxHold*** — Used, as a multiplier of *msgTxInterval*, to determine the value of txTTL that is carried in LLDP frames transmitted by the LLDP agent.
- ***reinitDelay*** — Indicates the amount of delay from when *adminStatus* becomes "disabled" until re-initialization is attempted.
- ***txCreditMax*** — Maximum number of consecutive LLDPDUs that can be transmitted at any time.
- ***msgFastTx*** — Defines the time interval in timer ticks between transmissions during Fast transmission periods.
- ***txFastInit*** — Determines the number of LLDPDUs that are transmitted during a Fast transmission period.
- ***adminStatus*** — Indicates whether or not the LLDP agent is enabled. The defined values for this variable are as follows:
  - Integer value of 3 means the LLDP agent is enabled for reception and transmission of LLDPDUs.
  - Integer value of 2 means the LLDP agent is enabled for transmission of LLDPDUs only.
  - Integer value of 1 means the LLDP agent is enabled for reception of LLDPDUs only.
  - Integer value of 0 means the LLDP agent is disabled for both reception and transmission.

The LLDP agent maintains last received LLDPDU per port. Upper bound for size of LLDPDU is 1500 bytes. Details of data structure used for information store is implementation specific and beyond scope of this document.

The E810 provides LSAP services to the OS provided MSAP services that are used by LLDP agents hosted by system processors.

9.8.5 Initialization and Configuration

9.8.5.1 Initialization

As part of EMP initialization, an the LLDP agent is loaded and initialized by EMP. The LLDP agent loads default values for TLVs from the NVM. The LLDP agent transitions to "ready" state and waits for LAN link up before transmitting the first LLDPDU.

DCBX agent operates in slave mode, sets the *Willing* bit, and accepts recommendations from the link partner (unless the software decides to take control by calling Set Local MIB and setting *willing* bit to 0).

9.8.5.2 LLDP Configuration

9.8.5.2.1 LLDP Protocol Variables

The following LLDP timers can be configured via NVM:

- ***msgFastTx*** — Defines the time interval in timer ticks between transmissions during Fast transmission periods. The default value of *msgFastTx* is 1. This value can be changed by management to any value in the range 1 through 3600.
- ***msgTxInterval*** — Defines the time interval in timer ticks between transmissions during normal transmission. The default value for *msgTxInterval* is 30 seconds. This value can be changed by management to any value in the range 1 through 3600.
- ***msgTxHold*** — Used as a multiplier of *msgTxInterval*, to determine the value of txTTL that is carried in LLDP frames transmitted by the LLDP agent. The recommended default value of msgTxHold is 4. This value can be changed by management to any value in the range 1 through 100.
- ***txCreditMax*** — Determines maximum number of LLDPDUs that can be sent per second. The default value of *txCreditMax* is 5. This value can be changed by management to any value in the range 1 through 10.
- ***txFastInit*** — Determines the number of LLDPDUs that are transmitted during a Fast transmission period. The default value of *txFastInit* is 4. This value can be changed by management to any value in the range 1 through 8.
- ***reinitDelay*** — Indicates the amount of delay from when *adminStatus* becomes "disabled" until re-initialization is attempted. Default value of *reinitDelay* is 2.

9.8.5.2.2 LLDP Admin Queue Commands

The following commands are supported by the E810 to manage the LLDP agent and provide information to the drivers.

Table 9-71. LLDP Admin Queue Commands

Command	Opcode	Type	Description	Section Reference
Get LLDP MIB	0x0A00	Indirect	Fetch latest LLDP MIB.	9.8.5.2.2.1
Configure LLDP MIB Change Event	0x0A01	Direct	Request and deliver a notification that the peer has sent an updated LLDP MIB.	9.8.5.2.2.2
Add LLDP TLV	0x0A02	Indirect	Add a new TLV to the local LLDP MIB.	9.8.5.2.2.3
Update LLDP TLV	0x0A03	Indirect	Update an existing TLV in the local LLDP MIB.	9.8.5.2.2.4
Delete LLDP TLV	0x0A04	Indirect	Delete a TLV from the local LLDP MIB.	9.8.5.2.2.5
Stop LLDP Agent	0x0A05	Direct	Used to stop or shutdown LLDP agent.	9.8.5.2.2.6
Start LLDP Agent	0x0A06	Direct	Start an LLDP agent running.	9.8.5.2.2.7
Get CEE DCBX CFG	0x0A07	Indirect	Retrieves the CEE configuration.	9.8.5.2.2.8
Set Local LLDP MIB	0x0A08	Indirect	Load the DCBX configuration.	9.8.5.2.2.9
Stop/Start a Specific LLDP Agent	0x0A09	Direct	Stop and restart the firmware DCBX agent.	9.8.5.2.2.10
LLDP Filter Control	0x0A0A	Direct	Request forwarding of LLDP traffic to host.	9.8.5.2.2.11

9.8.5.2.2.1 Get LLDP MIB (0x0A00)

This command, posted on the ATQ, is an indirect AQ command. The driver requests the complete LLDP MIB, providing a response buffer (address/length pair) and the type of LLDP MIB requested. The LLDP MIB is associated with a physical LAN port. Instead of formatting the LLDP MIB in any particular way, firmware should write the entire packet (including headers) that was sent/received on the wire for the particular MIB type specified. The MIB is guaranteed to fit in a 1.5K packet, so there is no need to use a "large buffer". For a particular Bridge Type, software can request the local MIB, the remote MIB, or both MIBs.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ. It writes the status of the request in the *Return Value* field. For the case where both MIBs are returned, firmware always writes the Local MIB first and the Remote MIB immediately following the Local MIB.

Table 9-72. Get LLDP MIB Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0A00	Command opcode.
Datalen	4-5		Length or response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Type	16	MIB Type	**Bits 0:1:** Direction 00b = Local MIB (sent by device) 01b = Remote MIB (received by device) 10b = Both Local and Remote MIBs 11b = Reserved **Bits 2:3:** Bridge Type 00b = Nearest Bridge 01b = Non-TPMR Bridge 10b = Reserved 11b = Reserved **Bits 4:7:** Reserved
Reserved.	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

Table 9-73. Get LLDP MIB Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0A00	Command opcode.
Datalen	4-5		Length of LLDP MIB if Status==Success. In bytes.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Status of request. A value of SUCCESS means that command was performed successfully. Error Codes: ENOENT = Firmware returns this value if any requested LLDP MIB does not exist. EPERM = Firmware returns this value if software has taken control of LLDP processing. EFBIG = Firmware returns this value when size of LLDPDU is larger than size of the response buffer. EINVAL = Firmware returns this value when software asks for a bad request (for example, invalid bridge type or direction).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Type	16	MIB Type	**Bits 0:1:** Direction 00b = Local MIB (sent by device) 01b = Remote MIB (received by device) 10b = Both Local and Remote MIBs 11b = Reserved **Bits 2:3:** Bridge Type 00b = Nearest Bridge 01b = Non-TPMR Bridge 10b = Reserved 11b = Reserved **Bits 4:7:** Reserved
Reserved	17	Reserved	Reserved.
Local MIB Length	18-19	Length	If the response buffer contains a Local MIB, this field reports its length. If no Local MIB is present, this field is written with a value of 0.
Remote MIB Length	20-21	Length	If the response buffer contains a Remote MIB, this field reports its length. If no Remote MIB is present, this field is written with a value of 0.
Reserved	22-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

Note: If only one MIB is present, it is written to the response buffer beginning at the first byte of the response buffer (i.e. offset=0). If two MIBs are present, the Local MIB is always written first (i.e. offset=0), and the Remote MIB is written immediately following the Local MIB (i.e. offset=*LocalMIBLength*).

9.8.5.2.2.2 Configure LLDP MIB Change Event (0x0A01)

This command, posted on the ATQ, is a direct AQ command. The driver uses this command to request that firmware post an event on the ARQ when the LLDP MIB associated with this interface changes. The driver can also use this command to request that firmware stop posting this event to the ARQ.

Firmware writes back the status of the request to the *Return Value* field.

Table 9-74. Configure LLDP MIB Change Event Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0A01	Command opcode.
Datalen	4-5	0	Direct command. No response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command	16	Command	**Bit 0:** Command 0b = Enable event 1b = Disable event **Bits 1:7:** Reserved
Reserved	17-31	Reserved	Reserved.

Table 9-75. Configure LLDP MIB Change Event Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0A01	Command opcode.
Datalen	4-5	0	Direct command. No response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Status of request. A value of SUCCESS means that command was performed successfully. Error Codes: EPERM = Firmware returns this value if software has taken control of LLDP processing.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	Reserved	Reserved.

9.8.5.2.2.2.1 LLDP MIB Change Event

This event is posted on the ARQ to indicate to software that any LLDP MIB associated with the physical interface has changed. The LLDP MIB change event is also posted if a multiple-peers condition is detected or if a TLV is aged out.

Firmware provides the status of the event, the length of the LLDP MIB in bytes, and the type of LLDP MIB that has changed, and copies the *Cookie* value from the associated Configure LLDP MIB Change Event.

The response buffer includes the entire MIB that has changed. The formatting is identical to the response for the Get LLDP MIB command.

Note: The opcode for this event is the same as the opcode for the related command on the ATQ that enabled this event to be sent to software.

Table 9-76. LLDP MIB Change Event

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0A01	Event code.
Datalen	4-5	0	Length of LLDP MIB if Status==Success. In bytes.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Status of request.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Type	16	MIB Type	**Bits 0:1:** Direction 00b = Local MIB (sent by device) 01b = Remote MIB (received by device) 10b = Reserved 11b = Reserved **Bits 2:3:** Bridge Type 00b = Nearest Bridge 01b = Non-TPMR Bridge 10b = Reserved 11b = Reserved **Bits 4:5:** Miscellaneous 00b = Port's Tx active 01b = Port's Tx suspended and drained. 10b = Reserved 11b = Port's Tx suspended and drained. Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

9.8.5.2.2.3 Add LLDP TLV (0x0A02)

This command, posted on the ATQ, is an indirect AQ command. The driver provides the type of MIB to be updated, the TLV to be added, and the address/length of the buffer containing the TLV. Software is responsible for guaranteeing that the TLV to be added does not already exist in the MIB, or follows the TLV usage rules for TLVs that allow multiple instances. Software can only add TLVs to the Local LLDP MIB.

Firmware adds the new TLV to the Local LLDP MIB just before the "End of LLDPDU TLV". Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 9-77. Add LLDP TLV Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0A02	Command opcode.
Datalen	4-5	Length	Length of indirect buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.

Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

9.8.5.2.2.4 Update LLDP TLV (0x0A03)

This command, posted on the ATQ, is an indirect AQ command. The driver provides the bridge type of the MIB to be updated, the TLV to be updated (both original and updated versions), the offset/length of both TLVs in the indirect buffer, and the address/length of the indirect buffer. Software is responsible for guaranteeing that the TLV to be updated does already exist in the MIB. Only a local MIB can be updated by the driver.

Firmware must match the entire original TLV in the MIB before performing an update. There are some TLV types that can appear more than once. Therefore, matching based only on Type/Subtype is not sufficient.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 9-79. Update LLDP TLV Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.

9.8.5.2.2.5 Delete LLDP TLV (0x0A04)

This command, posted on the ATQ, is an indirect AQ command. The driver provides the type of MIB to be updated and a copy of the TLV to be deleted. Software is responsible for guaranteeing that the TLV to be deleted does already exist in the MIB.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 9-81. Delete LLDP TLV Command

9.8.5.2.2.6 Stop LLDP Agent (0x0A05)

This command, posted on the ATQ, is a direct AQ command. The driver uses this command to request that firmware stop or shutdown the LLDP agent on the port.

If *Stop* is specified, the device stops the LLDP agent on the port and directs all untagged ingress LLDP frames received on the port to the default queue of the Control VSI associated with the Port aggregator or Port extender.

If *Shutdown* is specified, the device stops the LLDP agent on the port and sends a last LLDP PDU on the wire with TTL=0 and with Nearest Bridge and non-TPMR destination address. Firmware then directs all untagged ingress LLDP frames received on the port to the default queue of the S-Component Control VSI.

When *Command* Bit 1 is set to 1b to indicate disabling LLDP Agent persistently, it sets the *Current LLDP AdminStatus* for the given Port to 0x0. EMP firmware does not attempt to stop the LLDP Agent on that port if the agent is already disabled.

Firmware writes back the status of the request.

Any preceding registration to events on the port (via the Configure LLDP MIB Change Event command) is discarded. Software should register for events again once the LLDP agent in the device is active again.

After the response, the driver should route the LLDP flows to a control VSI using the Add Switch Rules admin command (Section 7.8.12.6.1).

Table 9-83. Stop LLDP Agent Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0A05	Command opcode.

Reserved	16-31	Reserved	Reserved.

9.8.5.2.2.7 Start LLDP Agent (0x0A06)

It is expected that CORER has occurred before this command is issued. CORER causes the EMP to reload LLDP forwarding rules from NVM default or based on the *Current LLDP AdminStatus* and re-initialize based on those settings.

This command, posted on the ATQ, is a direct AQ command. In response to this command EMP re-enables LLDP agent over a given port and treats the command as a request to set the LLDP Configuration variable *AdminStatus* that indicates the LLDP Agent is enabled for "Both Tx and Rx enabled". EMP firmware starts the firmware-based LLDP Agent regardless of the NVM settings in either default *LLDP Admin Status* or the *Current LLDP AdminStatus* fields.

When *Command* Bit 1 is set to 1b to indicate disabling LLDP Agent persistently, it sets the *Current LLDP AdminStatus* for the given Port to 0x3 indicating the LLDP Configuration AdminStatus is set to "Both Tx and Rx enabled" mode. EMP firmware does not attempt to stop the LLDP Agent on that port if the agent is already disabled.

If the driver defined LLDP forwarding rules previous to sending this command, these rules should be removed using the Remove Switch Rules admin command (Section 7.8.12.6.3) before sending this command.

Table 9-85. Start LLDP Agent Command

9.8.5.2.2.8 Get CEE DCBX OPER CFG (0x0A07)

This command, posted on the ATQ, is an indirect AQ command. The driver requests the operational configuration of CEE/DCBX. The driver provides a response buffer (address/length pair).

EMP writes back the CEE/DCBX configuration to the response buffer.

Table 9-87. Get CEE DCBX OPER CFG Command

Name	Byte.Bit	Value	Remarks

Table 9-89. Get CEE DCBX OPER CFG Response Buffer Format

Offset (Bytes)	Description
0	**Local Oper Num Traffic Class Supported** Returns a value between 1-8 for the number of TCs supported locally.
1-4	**Local Oper Priority Assignment** For each UP a 4-bit for the TCID. Available value is 0-7. Upper bit == 0 Bits 0:3 assigned for up 0. Bits 4:7 assigned for up 1. . . . Bits 27:31 assigned for up 7.
5-12	**Local Oper TCB Bandwidth** An 8-byte field. Each byte represents the relative bandwidth allocation of one enabled TC. Byte 7 assigned for TC 0. Relative bandwidth allocation is a value 0-100, and represents the percentage of the available bandwidth this TC is allocated with. The sum of the bandwidth allocated for all TC equal to 100%
13	**Local Oper PFC Enable** A bitmap containing a PFC-enable flag for each UP. Bit 0 concerns UP 0.
14-15	**Local Oper Application Priority** Indicates the Application TLV negotiated for FCoE, iSCSI, and FIP (encoded in three bits) Bits 14.0-14.2: FCoE Application priority. Bits 14.3-14.5: Reserved for iSCSI Application priority. Bits 14.6-14.7: Reserved. Bits 15.0-15.2: Reserved for FIP Application priority. Bits 15.3-15.7: Reserved.
16-19	**Status flags for DCBX TLVs** For each TLV, indicates the status of the TLV (1 = True, 0 = False): Bit 0 = Operational Mode. Bit 1 = Synced. Bit 2 = Error Bits 16.0-16.2: Status bits for PG. Bits 16.3-16.5: Status bits for PFC. Bits 16.6-16.7: Reserved. Bits 17.0-17.2: Status bits for FCoE Application Priority. Bits 17.3-17.5: Status bits for iSCSI Application Priority. Bits 17.6-17.7: Reserved. Bits 18.0-18.2: Status bits for FIP Application Priority. Bits 18.3-18.7: Reserved. Bits 19.0-18.7: Reserved.
20-31	Reserved. Return 0.

9.8.5.2.2.9 Set Local LLDP MIB (0x0A08)

This command, posted on the ATQ, is an indirect AQ command. The driver configures the complete DCBX MIB, providing a response buffer (address/length pair). The DCBX MIB is associated with a physical LAN port and is expressed in IEEE format even though firmware finally sends it as CEE TLVs on the wire, if needed. The MIB is guaranteed to fit in a 1.5K packet, so there is no need to use a "large buffer". Once DCBX negotiation with the peer completes, the local DCBX MIB returned by the Get LLDP MIB command reflects the final resolved values. In the future, the command could be extended to support more other LLDP MIBs.

This command is useful to configure the local DCBX agent into the non-willing mode (a.k.a. master mode), and to set the DCB configuration to be pushed to the peer.

Firmware writes back the status of the request in the *Return Value* field.

If the *Willing* bit is set in a DCBX TLV, the DCBX agent should take it in account when resolving DCBX with the peer, as per the rules defined in the IEEE/CEE standard.

Firmware can change the local configuration twice, once upon reception of the AQ command to align default configuration to what is published in the TLVs sent to the peer, and once upon reception of the peer's TLV when resolving DCBX. These two steps can be collapsed into one single configuration change in case peer's TLV is received within short delays. The new default configuration is maintained until the next GLOBR event or until a Stop DCBX Agent AQ command is received.

If the command is received while the firmware DCBX agent is disabled or stopped, the MIB is parsed by firmware and used to configure the local DCB settings of the port, with no DCB TLV exchange with the peer performed by firmware. Firmware drains the Tx-Pipe if TC or PFC changes were pushed, as if it was resulting from a regular DCBX negotiation flow.

Table 9-90. Set Local LLDP MIB Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.

Reserved	20-23	Reserved	Reserved.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

Table 9-91. Set Local LLDP MIB Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0A08	Command opcode.
Datalen	4-5		Length of LLDP MIB if Status==Success. In bytes.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Status of request. A value of SUCCESS means that command was performed successfully. Error Codes: EPERM = If any local LLDP MIB set in the command does not exist (e.g. if the specific agent was stopped). EINVAL = If a DCBX TLV is missing in the pushed MIB or if the TLV's pushed are not consistent or illegal.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Type	16	MIB Type	**Bit 0:** 0b = MIB is Silently Changed. Event to software is not required. 1b = MIB is Changed. MIB change event is triggered. **Bits 1:7:** Reserved
Reserved	17-31	Reserved	Reserved.

9.8.5.2.2.10 Stop/Start a Specific LLDP Agent (0x0A09)

This command, posted on the ATQ, is a direct AQ command. The driver uses this command to request that firmware stop or (re-)start the DCBX agent on the port. In the future, the command could be extended to support more specific agents.

Stopping the DCBX agent on the port means the following:

1. When parsing the LLDP TLVs received from the peer, the LLDP agent skips over all DCBX TLVs.
2. The LLDP agent does not send DCBX TLVs to the peer.
3. Local DCB configuration is returned to the hardware default (single TC, no PFC).
4. Get LLDP MIB still returns the remote DCBX MIBs if such are received from the peer.

(Re-)Starting the DCBX agent on the port means the following:

1. The LLDP agent parses and processes the DCBX TLVs received from the peer.
2. The LLDP agent sends DCBX TLVs to the peer.
3. Local DCB configuration is modified according to the DCBX negotiation with peer.

Firmware writes back the status of the request.

Table 9-92. Stop/Start a Specific LLDP Agent Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.

9.8.5.2.2.11 LLDP Filter Control

Upon reception of this command, the firmware adds a new filter with the requested VSI as destination.

The following resources are reserved for this command: One forwarding rules and one VSI list per port. These resources are accounted as firmware resources.

Note: A Start LLDP command should be preceded by a LLDP Control command with a "delete" action to remove the filters used by software.

Table 9-94. LLDP Filter Control Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0A0A	Command opcode.
Datalen	4-5	0	Direct command. No response buffer.

VSI	18-19		VSI to send the LLDP traffic to (relevant for Add or Update actions),
Reserved	20-31	Reserved	Reserved.

Table 9-95. LLDP Filter Control Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0A08	Command opcode.
Datalen	4-5		Direct command. No response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Status of request. A value of SUCCESS means that command was performed successfully. Error Codes: EPERM = When the command is sent while LLDP is owned by firmware. EACESS = When the requested VSI is not owned by the PF. EINVAL = When there is an attempt to update or remove a non existing filter or add an existing filter.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	Reserved	Reserved.

Chapter 10 LAN Engine

10.1 Introduction

This section describes the hardware/software interfaces for transmit and receive LAN functionality. Details include:

- Associated device registers.
- Device descriptor formats.
- Initialization and run-time flows illustrating the use of the registers and descriptors.
- Stateless offloads in Rx and Tx data path.

10.2 Queues Allocation and Management

10.2.1 LAN Receive Queue Allocation

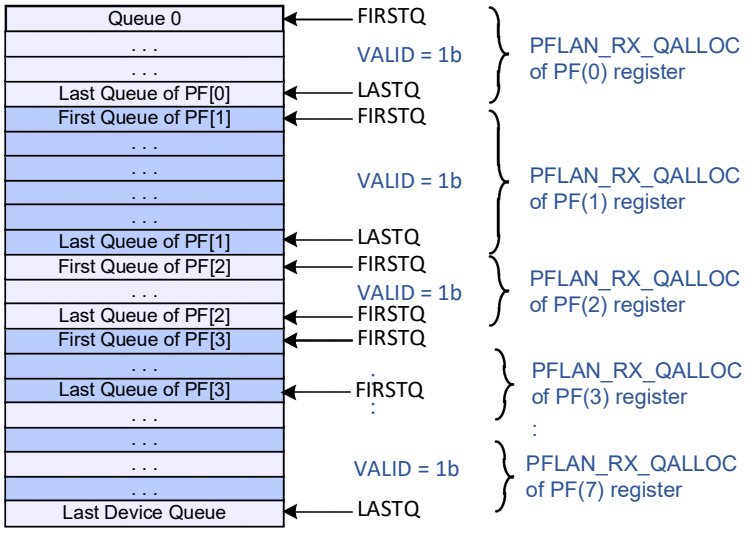

Figure 10-1. LAN Queues Allocation Example of 8 PFs

The PF software device driver is expected to read the values of the PFLAN_RX_QALLOC register (auto-loaded from NVM at reset) to determine the receive queues it owns. The PF allocates these receive queues to VFs by programming the VPLAN_RX_QTABLE and VPLAN_RX_QBASE registers and to VSIs by the Add VSI Admin Queue command, which programs the VSILAN_QTABLE and VSILAN_QBASE registers.

The implementation has the following configuration notes:

- VFs used by the VMM are expected to be statically allocated and therefore could be contiguous. Contiguous space is defined by the *VFFIRSTQ* and *VFNUMQ* fields in the VPLAN_RX_QBASE register. VFs that are allocated contiguous receive queues in the PF space can get up to 256 receive queues.
- Non-statically allocated VFs and VMDq2 VSIs are allocated up to 16 "scattered" receive queues in the PF space by the VPLAN_RX_QTABLE, and VSILAN_QTABLE registers. The VSILAN_QTABLE registers enable scattered receive queue allocation useful for dynamic VM motion.
  - For VFs, the VSILAN_QTABLE of all its VSIs must be set to the same indexes assigned to the VF by the VPLAN_RX_QTABLE.
  - These tables are not readable for the VFs. Instead, the VF is notified by the PF about the number of its allocated receive queues (using a software API or the mailbox). The PF on its side, must allocate the receive queues starting at receive queue zero and setting contiguous entries in these tables.
- VSIs allocated to nominal PF traffic or PF control ports are expected to be statically allocated and therefore could be contiguous. Contiguous space is defined by the *VSIBASE* field in the VSILAN_QBASE register. VSIs that are allocated contiguous receive queues in the PF space can get any number of receive queues.
  - The size of the contiguous VSI is not enforced by hardware setting; it is the responsibility of software to keep within the VSI boundaries.
  - During reception, hardware checks that the queue index generated by the receive classification filters does not exceed the PF queue range. However, it does not check if the queue index exceeds the VSI range. It is the responsibility of PF software to define the receive classification filters so that the queues do not exceed the VSI space.
- Contiguous versus "scattered" VSI is controlled by the *VSIQTABLE_ENA* flag in the VSILAN_QBASE register.
- It is the responsibility of PF software to define "free" receive queues that are within the space of the PF.

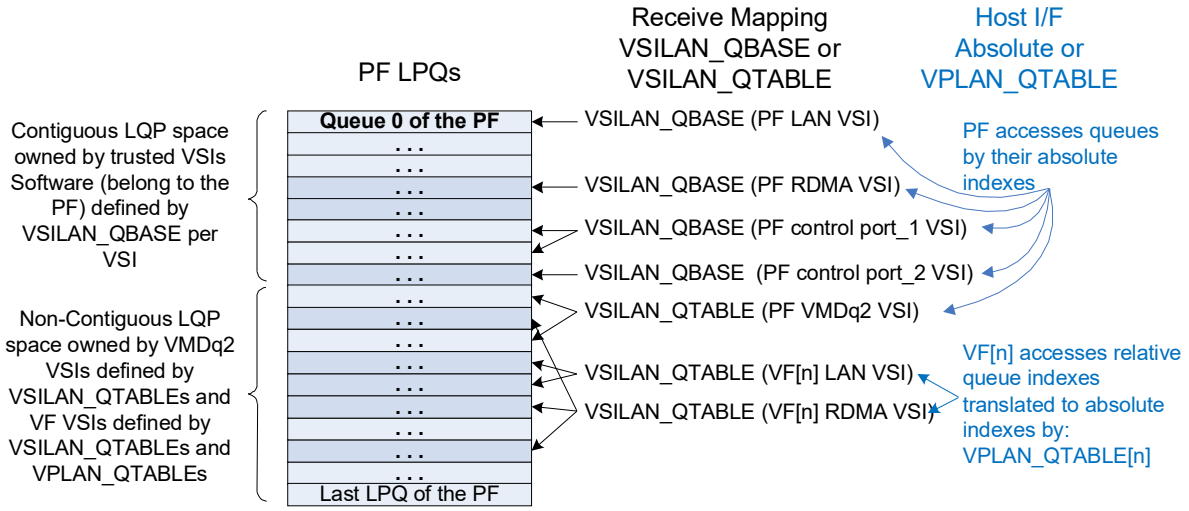

Figure 10-2. PF Queues (Example)

10.2.1.1 Software Access to the Queues of the Functions

PF software accesses its receive queues by their index within the PF space. Queue index "m" of PF "n" equals "m + PFLAN_RX_QALLOC[n].*FIRSTQ*" in the device space. Accessing receive queues outside the PF space does not impact device functionality. Write accesses are terminated successfully on the PCIe bus with no impact on the hardware, while read accesses provide meaningless data.

VF software accesses its receive queues using an index within the VF space. Receive queue indexes are translated to indexes in the PF space by the VPLAN_RX_QTABLE and VPLAN_RX_QBASE registers. The VPLAN_RX_QTABLE supports up to 16 receive queues. When using a contiguous allocation via the VPLAN_RX_QBASE, up to 256 queues can be accessed. A VF might get less than the maximum number of receive queues. The selection between contiguous and scattered is done through the VPLAN_RX_QBASE.*VFQTABLE_ENA* bit. The mapping for a VF in both modes is set through the VPLAN_RXQ_MAPENA.*RX_ENA* bit. A VF software attempt to access receive queues above the allocated ones does not impact device functionality (the same as described above for the PF).

Note: A function (PF or VF) might have multiple VSIs. Still, software accesses all receive queues by their index in the function space rather than index in the VSI spaces.

10.2.1.2 Associating Received Packets to VSI Queues

The E810 associates received packets to VSIs by the embedded switch/ACL as described in Section 7.8. It then associates packets to queues using the classification filters described in Section 7.10.

- As opposed to the software interface, the classification filters assign a queue index in the VSI space. The queue index "n" is mapped to the PF space as follows:
  - Queue index "n" of a contiguous VSI is mapped to queue index "n + VSILAN_QBASE.*VSIBASE*"
  - Queue index "n" of a "scattered" VSI is mapped as follows:
    - For an even "n" it is mapped to VSILAN_QTABLE[n/2].*QINDEX_0*.
    - For an odd "n" it is mapped to VSILAN_QTABLE[(n-1)/2].*QINDEX_1*.
- Invalid receive queues:
  - An invalid queue for contiguous VSI is identified if "n + VSILAN_QBASE.*VSIBASE*" exceeds the PF queue space.
  - An invalid queue "n" for "scattered" VSI is identified if its *QINDEX* in the VSILAN_QTABLE equals 0x3FF, or if "n" is greater than or equal to 16.
- Packets received to invalid queues are dropped and counted by the GLV_RDPC counter of the VSI.

10.2.1.3 LAN Receive Queue Allocation Example

Allocate the receive queues to the VSIs of the PF by setting the VSILAN_QBASE registers, VSILAN_QTABLE and VPLAN_RX_QTABLE. The table below shows an example of five VSIs, where the PF owns 128 receive queues (as configured by PFLAN_RX_QALLOC.*FIRSTQ* = 128 and PFLAN_RX_QALLOC.*LASTQ* = 255):

Table 10-1. Example Receive Queue Allocation

VSI No.	VSI Usage	Requirement	Setting
None	N/A	1 LQP	Allocating dedicated receive queue for the Flow Director Filter Programming Status Descriptors. Queue index 0 in the PF space is absolute queue index 128.
0	PF control port	1 LQP	VSILAN_QBASE[0].*VSIQTABLE_ENA* = 0 // contiguous range VSILAN_QBASE[0].*VSIBASE* = 1 Queue index 1 in the PF space is absolute queue index 129.
1	PF LAN and its VMDq1 VMs	64 LQPs	VSILAN_QBASE[1].*VSIQTABLE_ENA* = 0 // contiguous range VSILAN_QBASE[1].*VSIBASE* = 2 Queue indexes 2...65 in the PF space are absolute queue index 130...193.
2	PF traffic	16 LQPs	VSILAN_QBASE[2].*VSIQTABLE_ENA* = 0 // contiguous range VSILAN_QBASE[2].*VSIBASE* = 66 Queue indexes 66...81 in the PF space are absolute queue index 194...209.
10	VMDq2	2 LQPs	VSILAN_QBASE[10].*VSIQTABLE_ENA* = 1 // scattered range VSILAN_QTABLE[10,0].*QINDEX_0* and *QINDEX_1* = 100 and 102 *QINDEX_0* and *QINDEX_1* in VSILAN_QTABLE[10,1...7] = 0x7FF Queues 100 and 102 in the PF space are absolute queues 228 and 230.
100	VF[20]	4 LQPs	VSILAN_QBASE[100].*VSIQTABLE_ENA* = 1 // scattered range VSILAN_QTABLE[100,0].*QINDEX_0* and *QINDEX_1* = 90 and 98 VSILAN_QTABLE[100,1].*QINDEX_0* and *QINDEX_1* = 110 and 112 *QINDEX_0* and *QINDEX_1* in VSILAN_QTABLE[100,2...7] = 0x7FF VPLAN_RX_QTABLE[20; 0,1,2,3,4:15].*QINDEX* = 90, 98, 110, 112, 0x7FF Queues 90, 98, 110, and 112 in the PF space are absolute queues 218, 226, 238, and 240.

10.2.1.4 LAN Receive Initialization Flow

This section describes the LAN engine initialization flow executed by the PF software driver. It is assumed that a PF reset (PFR) was initiated by the software prior to this flow:

1. The LAN receive queues are allocated to the PF by NVM setting loaded to the PFLAN_RX_QALLOC registers following a core reset (CORER).
2. The statistic counters are cleared only at Power On Reset (POR). As part of the PF driver initialization, the software should read all the PF and its VF statistic counters. The values of these counters is the baseline for any statistics collected later.
3. OS driver only step: Transit the device to non-PXE mode by initiating the Clear PXE Mode admin command. See the command description in Section 10.4.3.2.
4. Most of the LAN engine logic is cleared by the hardware by core reset signal (CORER). If it is not guaranteed that a CORER was initiated, the software should clear the following control registers (listed in the "LAN Transmit Receive Registers" section) of the PF and its VFs. Mapping of receive queues is as follows:
   a. Clear the QRX_CTRL and QRX_TAIL registers of all the PF and its VFs LAN receive queues.

      Note: Writing the value "0'" to the QRX_CTRL register does not clear it. The *Fast_QDIS* and *CDS* bits are zeroed by writing a value of "1" to them.

   b. Initialize LAN port parameters using the Set Port Parameters admin command (setting "save bad packet", default VSI and more). In a single VSI per port, the VSI parameters are loaded from the NVM, while software could execute this step only if it requires other setting then the NVM image.

5. Allocate the receive queues to VFs and VSIs of the PF or each assigned VSI do the following as part of "create VSI" procedure:
   a. Allocate the receive queues to the VSI (see programming example in Section 10.2.1.3).
   b. Program the VSILAN_QBASE and VSILAN_QTABLE (use QBASE option for "contiguous" receive queues or the QTABLE option for "scattered" receive queues).
   c. Program the VPLAN_RX_QTABLE and VPLAN_RX_QBASE of each assigned VF.
6. Enable individual receive and transmit queues of the PF and its VFs following the flow described in Section 10.4.3.1.1 and Section 10.5.5.1, respectively.

10.2.2 LAN Transmit Queue Allocation

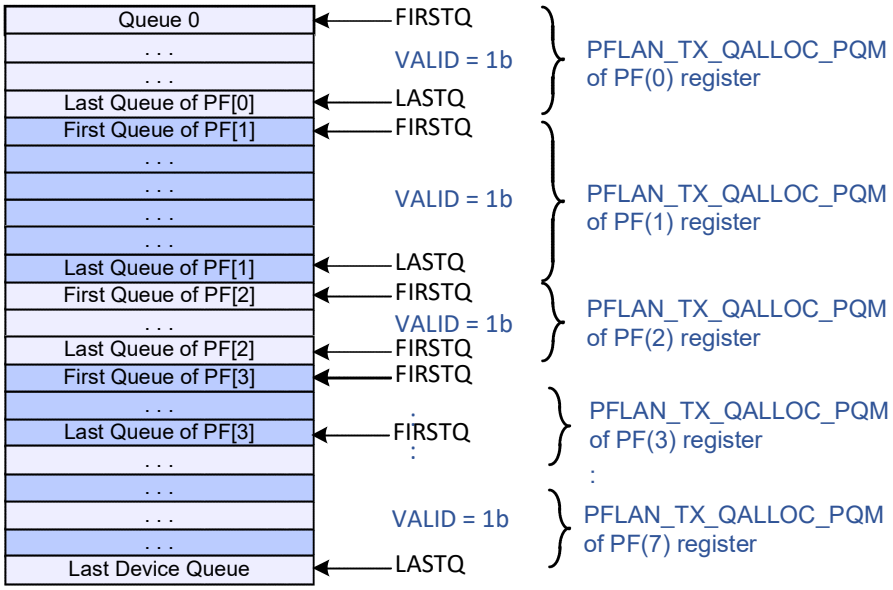

Figure 10-3. LAN Transmit Queues Allocation Example of 8 PFs

The PF software device driver is expected to read the values of the PFLAN_TX_QALLOC register (auto-loaded from NVM at reset) to determine the transmit queues owned. The PF allocates these transmit queues by programming the VPLAN_TX_QTABLE and VPLAN_TX_QBASE registers. Note the following:

- VFs used by the VMM are expected to be statically allocated and therefore could be contiguous. Contiguous space is defined by the *VFFIRSTQ* and *VFNUMQ* fields in the VPLAN_TX_QBASE register. VFs that are allocated contiguous transmit queues in the PF space can get up to 256 transmit queues. The selection between contiguous and scattered is done through the VPLAN_TX_QBASE.*VFQTABLE_ENA* bit. The mapping for a VF in both modes is set through the VPLAN_TXQ_MAPENA.*TX_ENA* bit.

- Non-statically allocated VFs are allocated up to 16 "scattered" transmit queues in the PF space by the VPLAN_TX_QTABLE registers.
  - These tables are not readable for the VFs. Instead, the VF is notified by the PF about the number of its allocated transmit queues (using a software API or the Mailbox). The PF on its side, must allocate the transmit queues starting at transmit queue zero and setting contiguous entries in these tables.
- It is the responsibility of PF software to define "free" transmit queues that are within the space of the PF.

10.2.2.1 Software Access to the Queues of the Functions

PF software accesses its transmit queues by their index within the PF space. Queue index "m" of PF "n" equals "m + PFLAN_TX_QALLOC[n].*FIRSTQ*" in the device space. Accessing transmit queues outside the PF space does not impact device functionality. Write accesses are terminated successfully on the PCIe bus with no impact on the hardware while read accesses provide meaningless data.

VF software accesses its transmit queues using an index within the VF space. Transmit queue indexes are translated to indexes in the PF space by the VPLAN_TX_QTABLE and VPLAN_TX_QBASE registers. The VPLAN_TX_QTABLE supports up to 16 transmit queues. When using a contiguous allocation via the VPLAN_TX_QBASE, up to 256 queues can be accessed. A VF might get less than the maximum number of transmit queues. A VF software attempt to access transmit queues above the allocated ones does not impact device functionality (the same as described above for the PF).

Note: A physical function might have multiple VSIs. Still, software accesses all transmit queues by their index in the function space rather than index in the VSI spaces.

10.2.3 Dynamic Queue Allocation in Rx and Tx

The E810 supports dynamic queue allocation between VSIs of each PF. Dynamic queue allocation is mainly aimed to support dynamic load balance of VFs according to needs due to VM motion or any other queuing load balancing scheme. Queues can be deallocated from an active VSI during run time. These queues can then be allocated to another VSI of the same VF or to another VF. The whole flow is managed by the PF as detailed below.

Both receive and transmit queues can be dynamically and independently allocated.

The following steps relate to receive queues of VFs while it is similar to receive queues of VMs:

1. PF software communicates to the VF that it needs to give up a specific receive or transmit queue(s).
2. The PF removes the queue(s) from the VF/VM by updating VPLAN_RX_QTABLE(VF), VPLAN_RX_QBASE(VF).*VFNUMQ* for Rx VF queues, calling Update VSI (Section 7.8.12.3.2) for Rx VM queues, or by updating VPLAN_TX_QTABLE and VPLAN_TX_QBASE(VF).*VFNUMQ* for the VF transmit queue case. As a result, the VF/VM can no longer access the queue(s).

   Note: The fields *VFNUMQ* and *VFQTABLE_ENA* of registers VPLAN_RX_QBASE(VF) and VPLAN_TX_QBASE(VF) must not be changed dynamically. Their setting is done only as part of the VF establishment flow.
3. PF software disables the relevant queues, following "queue disable" flow described in Section 10.4.3.1.2 for receive queues, or in Section 10.5.5.8.3 for transmit queues. As part of the flow, the PF waits for the hardware indication that the queues are disabled with no further activity to host memory.
4. The PF notifies the VF that it can release the host memory structures of the removed queue(s).

5. The PF remaps these queue(s) to another VF as follows:
   a. It programs the new queue and enables these queues (see Section 10.4.3.1.1 for receive queue enablement flows, and Section 10.5.5.8.1 for transmit queue enablement flows).
   b. It maps the queue(s) to the new VF or VM by updating VPLAN_RX_QTABLE(VF), VPLAN_RX_QBASE(VF).*VFNUMQ* for Rx VF queues, calling Update VSI (Section 7.8.12.3.2) for Rx VM queues, or by updating VPLAN_TX_QTABLE and VPLAN_TX_QBASE(VF).*VFNUMQ* for the VF transmit queue case.

      Note: The fields *VFNUMQ* and *VFQTABLE_ENA* of registers VPLAN_RX_QBASE(VF) and VPLAN_TX_QBASE(VF) must not be changed dynamically. Their setting is done only as part of the VF establishment flow.

   c. The PF informs the VF or VM about this action.
6. The queues are ready to be used by the VF.

10.2.4 LAN Transmit Completion Queue and Doorbell Queue Allocation

Completion Queues and Doorbell sharing among PF mechanism is similar to Transmit and Receive Queue allocation mechanism. The PF software device driver is expected to read the values of the PFLAN_CP_QALLOC and PFLAN_DB_QALLOC registers (auto-loaded from NVM at reset) to determine the Completion and Doorbell Queues owned.

The PF can allocate those Completion Queues and Doorbell Queues or part of them for VFs usage. Allocating of a Completion Queue to a VF does not require any special Hardware CSR setting, since Completion Queue run time operation does not include doorbell.

Doorbell Queues allocation to VFs is programmed in CSR VPLAN_DB_QTABLE. Up to four Doorbell Queues can be associated with a VF.

10.2.4.1 Software Access to the Queues of the Functions

PF software accesses its Completion and Doorbell Queues by their index within the PF space. Completion Queue index "m" of PF "n" equals "m + PFLAN_CP_QALLOC[n].*FIRSTQ*' in the device space. Accessing Completion or Doorbell Queues outside the PF space does not impact device functionality. Write accesses are terminated successfully on the PCIe bus with no impact on the hardware, while read accesses provide meaningless data.

VF software accesses its Doorbell Queues using an index within the VF space. Doorbell Queue indexes are translated to indexes in the PF space by the VPLAN_DB_QTABLE registers. The VPLAN_DB_QTABLE supports up to four Doorbell Queues. A VF software attempt to access Doorbell Queues above the allocated ones does not impact device functionality (the same as described above for the PF).

Note: A function might have multiple VSIs. Still, software accesses all transmit queues by their index in the function space rather than index in the VSI spaces.

10.3 Steering Tag and Processing Hint Support for LAN Engine Traffic (TPH)

See Section 3.1.2.6.2 for information on TLP processing hint support.

Table 10-2 describes how steering tag and processing hints are generated and how TPH operation is enabled for types of DMA traffic associated with the LAN queues.

Table 10-2. Steering Tag and Processing Hint Programming by the LAN Engine

Traffic Access	Steering Tag Value and TPH Enablement	PH Value
Read Receive Descriptor	CPUID and TPHRDesc in the Rx-Queue Context	Desc_PH in GLTPH_CTRL register
Write-Back Receive Descriptor	CPUID and TPHWDesc in the Rx-Queue Context	Desc_PH in GLTPH_CTRL register
Write Receive Packet Payload	CPUID and TPHData in the Rx-Queue Context	DATA_PH in GLTPH_CTRL register
Write Receive Packet Header	CPUID and TPHHead in the Rx-Queue Context	DATA_PH in GLTPH_CTRL register
Read Transmit Descriptor and Quanta Descriptor	CPUID and TPHRDesc in the Tx-Queue Context	Desc_PH in GLTPH_CTRL register
Write-Back Transmit Descriptor	CPUID and TPHWDesc in the Tx-Queue Context	Desc_PH in GLTPH_CTRL register
Transmit Head Write-Back	CPUID and TPHWDesc in the Tx-Queue Context	Desc_PH in GLTPH_CTRL register
Read Transmit Packet	CPUID and TPHRPacket in the Tx-Queue Context	DATA_PH in GLTPH_CTRL register
Read Doorbell Queue Descriptor	CPUID and TPHRDesc in the Doorbell Queue Context	Desc_PH in GLTPH_CTRL register
Write-Back Doorbell Queue Descriptor	CPUID and TPHWDesc in the Doorbell Queue Context	Desc_PH in GLTPH_CTRL register
Write to Completion Queue Descriptor	CPUID and TPHWDesc in the Completion Queue Context	Desc_PH in GLTPH_CTRL register

10.4 LAN Receive Data-Path

The LAN Receive Data-Path sections includes the following major topics:

- Receive packets stored in system memory.
- Indicating free descriptors to the hardware and indicating completed descriptors back to the software.
- Receive descriptor queues which are called also “descriptor ring”.
- Receive arbitration (covered in Section 8.2.1.2.3).
- Stateless receive offloads.

10.4.1 Receive Packet in System Memory

Receive packets are posted to system (host) memory buffers indicated to the hardware by descriptors. There are several types of descriptors detailed in Section 10.4.2; these include pointers to the data buffers and status indications of the received packets. Figure 10-4 shows two examples of receive packets in host memory composed of two buffers (indicated by two matched descriptors). The E810 fetches the receive descriptors (on demand) to an internal cache.

A few rules relating receive packet posting to host memory are:

- Receive packets can span one to five buffers (descriptors).
- Receive packets shorter than 64 bytes are never posted to host memory (even in save bad frame mode - enabled by the *SBP* flag in the PRT_SBPVSI register).

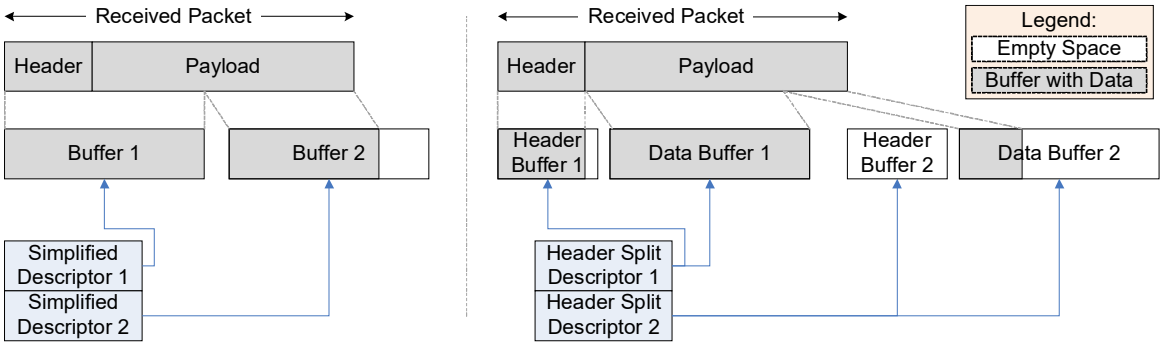

Figure 10-4. Receive Packet in System Memory

10.4.1.1 Receive Descriptor Cache

10.4.1.1.1 Descriptor Fetch Policy

The E810 fetches multiple receive descriptors at a time to minimize PCIe and memory bandwidth overhead; 8 or 4 descriptors when using 16-byte or 32-byte descriptors, respectively. New descriptors are fetched to the cache when there are fewer descriptors than incoming packets require, or the last free descriptor is used for a received packet.

Note the following rules relating descriptor fetch policy:

- Following a CORE Reset, the hardware wakes up in "PXE" mode (the *PXE_MODE* flag in the GLLAN_RCTL_0 register is set (1b)). PXE mode functionality and limitations are:
  - Receive queue length restrictions are detailed in Table 10-12, "LAN Rx-Queue Context (256 Bits = 32 Bytes)" in the *QLEN* field.
  - Software can bump the tail at descriptor granularity. Hardware fetches and writes back these descriptor at descriptor granularity as well.
  - Each packet can span only on a single buffer (in a single descriptor). A receive packet that is larger than a single buffer is reported as "OVERSIZE" in the receive descriptor.
- During nominal performance operation mode, the *PXE_MODE* flag must be cleared by the software by calling the Clear PXE Mode AQ command (0x110). This step is expected to occur during the PF software initialization procedure. In the case of multiple active PFs, only the first PF affects the device setting, while the others do nothing.
- When the *PXE_MODE* flag is cleared (0b), software should bump the tail at whole 8 x descriptors granularity.

10.4.2 LAN Receive Descriptors

10.4.2.1 Receive Descriptor - Read Format

10.4.2.1.1 16-Byte Receive Descriptors Read Format

Described below is the 16-byte receive descriptor read format prepared by the software.

Table 10-3. 16-Byte Receive Descriptors Read Format

Quad Word	63 ... 0
0	Packet Buffer Address
1	Header Buffer Address
	63 ... 0

Packet Buffer Address (Quad Word 0, Bits 0:63, 64 bits)

The physical address of the packet buffer defined in byte units. The packet buffer size is defined by the DBUFF parameter in the receive queue context.

Header Buffer Address (Quad Word 1, Bits 0:63, 64 bits)

The physical address of the header buffer defined in byte units. The header address should be set by the software to an even number (word-aligned address). The *Header Buffer Address* is meaningful only for Header Split queues and Split Always queues as defined by the DTYPE field in the receive queue context. If a received packet spans across multiple buffers, only the first descriptor's header buffer is used. The header buffer size is defined by the HBUFF parameter in the receive queue context.

Note: The LS bit should be set to zero regardless of header split enablement, since it is used for Descriptor Done (DD) indication to the software (as described in the descriptor write-back format).

10.4.2.1.2 32-Byte Receive Descriptors Read Format

Described below is the 32-byte receive descriptor read format prepared by the software.

Table 10-4. 32-Byte Receive Descriptors Read Format

Quad Word	63 ... 0
0	Packet Buffer Address
1	Header Buffer Address
2	Reserved (0x0)
3	Reserved (0x0)
	63 ... 0

The fields in first 16 bytes are Identical to the 16 Byte descriptors described in Section 10.4.2.1.1.

10.4.2.2 Receive Descriptor - Write-Back Format

The following subsections describe the fields of Receive Descriptor write-back when using 16-byte and 32-byte descriptors. In both cases, a single packet might span on a single buffer or multiple buffers reported by their matched descriptors. If a packet is described by a single descriptor, all the fields are valid.

Following are some rules that apply for a packet that is described by multiple descriptors:

- The following fields are valid in all descriptors of a packet:
  - DD flag (Done)
  - EOP flag (End of Packet)
  - PKTL field (Packet content length)
- The following fields are valid only in the first descriptor of a packet:
  - HDRL (Packet content length in the header buffer)
  - SPH (Header is identified for header split functionality)
  - HBO (Header Buffer Overflow)
- All other fields are valid only in the last descriptor of a packet.

10.4.2.2.1 16-Byte Legacy Receive Descriptors Write-Back Format

Described below is the 16-byte receive descriptor write-back (WB) format.

Table 10-5. 16-Byte Receive Descriptors Write-Back Format

Quad Word	63 … 32	31 … 16	15	14	13 … 8	7 … 0
0	Filter Status	L2TAG1	RSV	MIRR	RXDID	
1	Length	PTYPE	RSV	Error	Status	

Quad Word	63 … 38	37 … 30	29	27	26 … 19	18 … 0
0						
1						

RSV (Quad Word 0, Bits 14:15, 2 bits; Quad Word 1, Bits 27:29, 3 bits)

Reserved.

Status (Quad Word 1, Bits 0:18, 19 bits)

Bit(s)	Name	Description
0	DD	Descriptor done indication flag.
1	EOP	End of packet flag is set to 1b indicating that this descriptor is the last one of a packet.
2	L2TAG1P	L2 TAG 1 presence indication while the L2 Tag is stripped from the packet and reported in the L2TAG1 field in the descriptor. The type of the Tag is defined by the *L2TSEL* flag in the queue context. The *L2TSEL* flag selects between the first or second active flags in the *SHOWTAG* field in the VSI_TSR register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAG*xxx* registers. If the specified L2 tag is not present in the packet the *L2TAG1P* flag is cleared.
3	L3L4P	For IP packets, this flag indicates that detectable L3 and L4 integrity check is processed by the hardware. See Section 10.4.4.3 for details on which headers are processed and how.

Bit(s)	Name	Description
4	CRCP	CRCP indicates that the Ethernet CRC is posted with data to the host buffer. ***Note:*** Strip CRC is enabled by the *CRCStrip* flag in the queue context. If the *RXE* error flag is set, the CRC bytes are not stripped regardless of the *CRCStrip* flag in the queue context. Loopback packets originated by another local VSI for which the hardware computes the CRC are never posted with the CRC bytes regardless of the CRCStrip setting in the queue context.
5:7	Reserved	Reserved. Set to "0" by hardware.
8	EXT_UDP_0	This flag is set for received tunneled packets with outer UDP header on which the outer UDP checksum word equals to zero. ***Note:*** UDP checksum zero is an indication that there is no checksum. This option is valid only for IPv4 packets and considered an exception error for IPv6 packets (reported to the stack by the driver).
9:10	UMBCAST	Destination Address can be one of the following: 00b = Unicast 01b = Multicast 10b = Broadcast 11b = Mirrored Packet
11	FLM	Flow Director filter match indication. This flag is set if the received packet matches any of the Flow Director (FD) filters that direct the packet to a specific receive queue. See also the description of the *FLTSTAT* field below.
12:13	FLTSTAT	The *FLTSTAT* indicates the reported content in the "Filter Status" field (see conditions in the "Filter Status" field): 00b = No Data in the filter status field (The packet does not meet any of the cases below). 01b = FD filter ID (this option is valid only for 16B descriptor while in 32B it is reported elsewhere). 10b = Reserved. 11b = Hash filter signature (RSS).
14	LPBK	Loopback indication, which means that the packet is originated from this system rather than the network.
15	IPV6EXADD	Set when an IPv6 packet contains a Destination Options Header or a Routing Header. If the packet contains two IPv6 headers (tunneling), the *IPV6EXADD* is a logic 'OR' function of the two IP headers.
16:7	Reserved	Reserved.
18	INT_UDP_0	This flag is set for received UDP packets on which the UDP checksum word equals zero. ***Note:*** UDP checksum zero is an indication that there is no checksum. This option is valid only for IPv4 packets and considered an exception error for IPv6 packets (reported to the stack by the driver). ***Note:*** For tunneled packets with UDP header, this flag relates to the checksum field in the inner UDP header.

Error (Quad Word 1, Bits 19:26, 8 bits)

Bit(s)	Name	Description
0	RXE	The *RXE* error bit is an indication for any of the following MAC errors: • CRC error. • Alignment error. • Oversize error. • Undersizes error. • Length error. Packets with *RXE* are posted to host memory to Rx-Queue 0 of the VSI defined by the PRT_SBPVSI register if enabled by the *SBP* flag in the same register. If the *RXE* flag is set then any other status fields reporting the content of the packet are meaningless.
1	Reserved	Reserved.

Bit(s)	Name	Description
2	HBO	Header Buffer Overflow. This flag is set when using Header split buffers or Split Always buffers and the identified packet header is larger than the header buffer.
3:5	L3L4E / FCE	For IP packets processed by the hardware, the *L3L4E* flag has the following encoding: Bit 3 = IPE: IP checksum error indication (for tunneled packets it is the most inner IP header indication). Bit 4 = L4E: L4 integrity error indication (most inner L4 header in case of UDP tunneling). Bit 5 = EIPE: External (most outer) IP header or UDP checksum error. ***Note:*** For the purpose of these bits, a tunneled packet is a VXLAN/GRE/Geneve packet.
6	OVERSIZE	Oversize packet error indicates that the packet is larger than 5 descriptors in nominal operation or larger than 1 descriptor in PXE mode. In this case, the portions of the packet that exceeds the permitted number of descriptor(s) is not posted to host memory.
7	Reserved	Reserved.

RXDID (Quad Word 0, Bits 0:7, 8 bits)

Rx Write-Back Descriptor Type ID:

0x00 - 0x01 = Legacy Descriptor
0x02 - 0x06 = Flexible Descriptor
0x07 - 0x07 = Mirrored Packet
0x08 - 0x3F = Flexible Descriptor
0X40 - 0x7F = Reserved

MIRR (Quad Word 0, Bits 8:13, 6 bits)

Matched Mirror Rule ID that directed the packet to this queue. If the packet is not mirrored, this field equals zero.

L2TAG1 (Quad Word 0, Bits 16:31, 16 bits)

Stripped L2 Tag from the receive packet. This field is valid if the *L2TAG1P* flag in this descriptor is set (see additional description of the *L2TAG1P* flag in the *Status* field).

Filter Status (Quad Word 0, Bits 32:63, 32 bits)

Multiplexed field between RSS (hash filter), FD Filter ID as indicated by the *FLTSTAT* field. Note that the FD filter ID is reported in this field only in 16-byte descriptors. In 32-byte descriptors, the data is reported in a different field.

- If the packet matches a FD filter that enables its FD filter ID reporting while using a 16-byte descriptor, *FLTSTAT* equals 01b and this field contains the programmed FD filter ID.
- Else, if the packet matches the Hash filter, *FLTSTAT* equals 11b and this field contains the hash signature (RSS).
- Else, *FLTSTAT* equals 00b and this field is set to zero.

Length (Quad Word 1, Bits 38:63, 26 bits)

Bit(s)	Name	Description
0:13	PKTL	Packet content length in the packet buffer defined in byte units.
14:24	HDRL	Packet content length in the header buffer defined in byte units.
25	SPH	The Split Header flag is an indication that the device identified the packet header. See Section 10.4.4.2 for a complete description of packet types identified for header split and conditions for usage of the header and data buffers.

PTYPE (Quad Word 1, Bits 30:37, 8 bits)

Packet Type field encode supported packet types as listed in Table A-1.

Note: For Packet Types 256 and above, Flexible descriptors must be used. See Section 7.6.

10.4.2.2.1.1 Dummy Receive Descriptors

In some cases, the hardware might reserve one more descriptor than needed for a given packet. In this case, this dummy descriptor is written back as the last descriptor of the packet with a data length field == 0. For this packet, the dummy descriptor carries all the flags that are normally written at the last descriptor of a multi-descriptors packets.

10.4.2.2.2 32-Byte Receive Descriptors Write-Back Format

The 32-byte descriptor is composed of four quad words. The first two quad words are identical to the 16-byte descriptor write-back other than the Flow Director Filter ID that is moved from the "Filter Status" field to the "FD Filter ID / Flexible Bytes High" field.

Section 10.4.2.2.1.1 describes to concept of Dummy Descriptor in 16-byte descriptor format. Dummy Descriptor is relevant to 32-Byte descriptor write-back as well.

Table 10-6. 32-Byte Receive Descriptors Write-Back Format

Quad Word	63:48	47:38	37:32	31:30	29:26	25:19	18:16	15	14:13	12:8	7:0
0	Filter Status			L2TAG1				RSV	MIRR		RXDID
1	Length			PTYPE		RSV	Error		Status		
2	L2TAG2 (2nd)			L2TAG2 (1st)			Reserved				Ext_Status
3	FD Filter ID						Reserved				

	63:48	47:32	31:18	17:12	11:0

Ext_Status (Quad Word 2, Bits 0:11, 12 bits)

Bit(s)	Name	Description
0	L2TAG2P	L2 TAG 2 presence indication while the L2 Tag is stripped from the packet to the *L2TAG2 (1st)* field in the descriptor. The type of the Tag is defined by the *L2TSEL* bit in the queue context. This flag selects between the first or second active flags in the *SHOWTAG* field in the VSI_TSR register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAG*xxx* registers. If the stripped tag is larger than one word, the first word is posted to the *L2TAG2 (1st)* field and the second word is posted to the *L2TAG2 (2nd)* field. If it is a single word, it is stored in the *L2TAG2 (2nd)* field. If the specified L2 tag is not present in the packet the *L2TAG2P* flag is cleared.
1:3	Reserved	Reserved.
4:5	FLEXBH_STAT	The *FLEXBH_STAT* field indicates the content of the *FD Filter ID/Flexible Bytes High* field as follows: 00b = The field is set to zero. 01b = FD filter ID is reported in the *FD Filter ID* field. 10b = Reserved. 11b = Reserved.
6:8	Reserved	Reserved.

Bit(s)	Name	Description
9	FDLONGB	The *FDLONGB* flag is set if the matched FD filter's index within its bucket is above threshold. If the packet is searched in the FD filter and it is not found, the *FDLONGB* represents the bucket length relative to the same threshold. The threshold is defined by the *FDLONG* parameter in the GLQF_FD_CTL register.
10:11	Reserved	Reserved.

L2 Tags (Quad Word 2, Bits 32:63, 32 bits)

Bit(s)	Name	Description
0:15	L2TAG2 (1st)	Extracted L2 Tag 2 from the packet (see *L2TAG2P* flag in the *Ext_Status* field).
16:31	L2TAG2 (2nd)	Extracted second word of the L2 Tag 2 from the packet (see *L2TAG2P* flag in the *Ext_Status* field).

FD Filter ID (Quad Word 3, Bits 32:63, 32 bits)

If the packet matches a FD filter that enables reporting the *FD filter ID*, then *FLEXBH_STAT* equals 01b and this field contains the programmed FD filter ID. Otherwise, *FLEXBH_STAT* equals 00b and this field is set to zero.

10.4.2.2.3 Programming Status Descriptor Write-Back Format

The programming status descriptor provides an indication of FD filter programming.

Quad Word 0

Bit(s)	Name	Field Size	Description
0:7	RXDID	8	Descriptor Type. For Filter Programming WB it equals 0x40
8:27	Reserved	1	Reserved. Set to 0x0.
28:31	Bucket_LEN	4	The filter location within the bucket capped at 15.[1]
32:63	Filter_Status	32	The *Filter_Status* reports back the programmed FD filter ID.

1. The Bucket_LEN parameter is reported only if enabled by CSR GLQF_FD_CTL. In addition, the Bucket_LEN parameter is reported only for programming or removal requests that are completed successfully.

Quad Word 1

Bit(s)	Name	Field Size	Description
0	DD	1	Descriptor Done flag.
1:2	PROG_ID	2	The *PROG_ID* indicates the status reported by this descriptor as follows: 00b = FD filter add status. 01b = FD filter remove status. 10b = Reserved. 11b = Reserved.
3	Reserved	1	Reserved.
4	FAIL	1	FD filter programming failed due to no space in the table or the function exhausted its quota. Or, FD filter removal failed that could be a result of an attempt to remove non-existent filter entry.
5	FAIL_PROFILE		FD filter programming failed due to no matched profile or profile with an empty Field Vector.

Bit(s)	Name	Field Size	Description
6:7	Reserved	2	Reserved.
8:21	FLT_Addr	14	Filter entry address in the FD table (measured in filter entry units).[1]
22:27	Reserved	6	Reserved.
28:34	PKT_PROF	7	The packet profile that was identified by the device at filter programming.
35:37	Reserved	3	Reserved.
38:63	Bucket_HASH	26	26 LS bits of the hash function on the input set that is used for bucket index.[1]

1. The Bucket_HASH and the FLT_Addr parameters are reported only if enabled by CSR GLQF_FD_CTL. In addition, the FLT_Addr parameter is reported only for programming or removal requests that are completed successfully.

Note: If the queue is configured for 32-byte descriptors, this descriptor is padded by all zero two quad words.

10.4.2.2.4 Receive Flexible Advanced Descriptors Format

The flexible descriptor format is and its programming are detailed in Section 7.6.

10.4.3 LAN Receive Queue (Ring)

Received packets are posted to host memory through a set of queues. Each queue is a cyclic ring made of a sequence of receive descriptors in contiguous memory. These queues are also called "descriptor rings". The E810 supports up to 2048 receive queues allocated to PFs and VFs.

Receive queues are defined by a set of parameters called the "queue context". The main parameters are the queue pointers presented in Figure 10-5. The queue context includes additional parameters that define the queue functionality, as detailed in Section 10.4.3.6. All context parameters are kept in device registers accessible to the PF, while only the Tail registers (needed at run time) are accessible to the VFs.

The software interface to the queue for its initialization, during nominal operation as well as queue disable flow, is described in Section 10.4.3.1. The E810 includes additional global setting option parameters for the whole device or per function that affect multiple queues described in Section 10.4.3.1.

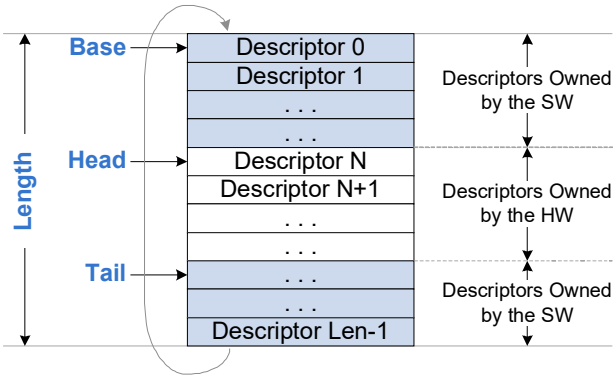

Figure 10-5. Receive Descriptor Ring Structure

10.4.3.1 Receive Queue Programming

Queue enable and disable flows are described in the following subsections.

10.4.3.1.1 Receive Queue Enable Flow

Table 10-7. Receive Queue Enable/Disable Flags

QRX_CTRL[n] Register QENA_* Bits		Receive Queue State
QENA_REQ	QENA_STAT	
0	0	Queue is not enabled.
1	0	Queue Enable request by the software.
1	1	Queue is enabled.
0	1	Queue Disable request by the software.

Queue enable flow is executed by the PF software for PF queues as well as for the queues of its VFs. The flow below assumes that the queue is already allocated as detailed in Section 10.2.

Software steps:

1. The function that owns the queue (PF or VF) allocates contiguous memory in its own memory space for the receive ring. It then program the receive descriptors in the ring so they are ready for new packet reception.
2. Program the Rx-Queue context parameters in both RLAN and RCB structures. Receive queue context structures are detailed in Section 10.4.3.6.
3. Clear the Tail pointer in the QRX_TAIL[n] register (in RLAN Queue Context) and then set the Tail pointer to the end of the descriptor ring, where "n" is the queue index within the PF space.
4. Set the *QENA_REQ* flag in the QRX_CTRL[n] register, where "n" is the queue index within the PF space (in RCB Queue Context).
5. If the Rx-Queue is associated with a No-Drop TC, then:
   a. Set *CDS* bit as well. This resets its state to init state.
   b. Set or reset the *CDE* bit according the queue's fast response policy.
      - QRX_CTRL register structure bits *CDE* and *CDS* are used for a QoS configuration of the queue.
6. As a response, the hardware sets the *QENA_STAT* flag in the QRX_CTRL[n] register. The *QENA_STAT* follows the *QENA_REQ* almost instantly and not more than 10 μs after that. Once the *QENA_STAT* flag in the QRX_CTRL[n] register is set, software can start using the queue.
7. If the queue is targeted for a VF, PF software should also program the matched entry in the VPLAN_RX_QTABLE. Then it is expected to inform the VF software that the queue is enabled.

10.4.3.1.2 Receive Queue Disable Flow

Queue disable flow is executed by PF software for PF queues as well as for the queues of its VFs.

1. Remove any filtering or switching rule which directs packets to this queue (e.g. RSS, Flow Director, and so on).
2. Wait for configuration completion.
3. Remove the queue from the interrupt linked list as described in Section 9.1.3.1.2.
4. The PF software clears the *QENA_REQ* flag in the QRX_CTRL[n] register, where "n" is the queue index within the PF space.
5. The hardware generates a "queue disable" marker to the receive "pipe".
6. Eventually, the "queue disable" marker gets to the top of the "pipe". At this point, it is guaranteed that the "pipe" does not contain any additional receive packets for the specific queue.
7. The hardware waits for completion of all outstanding requests from the specific queue on the PCIe bus.
8. The RCB queue context *QENA_STAT* flag in the QRX_CTRL[n] register is cleared.
9. Once the *QENA_STAT* flag in the QRX_CTRL[n] register is cleared, software can release all memory structures of the queue.

10.4.3.1.2.1 Fast Receive Queue Disable Flow

Fast queue disable flow should be executed by software only as part of a VF reset flow (or VM reset flow). Following a PFR, the device does all this automatically.

1. It is assumed that a VFR was initiated by the PF software and the matched *VFRD* flag in the register is already active. Or, a VMR was initiated by PF software and the matched VMRD flag in the VSIGEN_RSTAT register is already active.
2. The PF software sets the *FAST_QDIS* flag (and clear the *QENA_REQ* flag) in the QRX_CTRL[n] register, where "n" is the queue indexes in the PF space for all VF or VM queues.
3. The RCB queue context *QENA_STAT* flag in the matched QRX_CTRL[n] register is cleared.

10.4.3.2 Clear PXE Mode Admin Command (0x0110)

The Clear PXE Mode admin command transits the device from PXE to non-PXE mode. The structure of the admin command and its completion are shown below.

Table 10-8. Clear PXE Mode Admin Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0110	Command opcode.
Datalen	4-5	0x00	N/A (reserved zero).
Return Value/VFID	6-7	0x00	N/A (reserved zero).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16	0x2	Reserved. Set to 0x2.
Reserved	17-31		Reserved.

Table 10-9. Clear PXE Mode Admin Command Completion

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0110	Command opcode.
Datalen	4-5	0x00	N/A
Return Value/VFID	6-7		Some comments on specific errors (see Section 9.5.10 for the errors encoding): 0x0 = No error. 0xD = EEXIST (no action, the device is already in non-PXE mode).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

10.4.3.3 Configure No-Drop Policy Admin Command (0x00112)

The Configure No Drop Policy admin command configures the device to use the "No Drop" policy, and it might be used at PXE mode. The structure of the admin command and its completion are as follows:

Table 10-10. Configure No-Drop Policy Admin Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0112	Command opcode.
Datalen	4-5	0x00	Must be zero. Value is ignored.
Return Value/VFID	6-7	0x00	Must be zero. Value is ignored.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Force No-Drop	16	0x2	Sets the No-Drop/Drop policy: 0b = Remove the force and return to normal firmware behavior. 1b = Force No-Drop. ***Note:*** At the admin command response for this bit is defined as reserved, making all of Byte 16 reserved at the response buffer.
Reserved	16.1-31		Reserved.

Table 10-11. Configure No-Drop Policy Completion Buffer

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0112	Command opcode.
Datalen	4-5	0x00	N/A
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware. 0x0 = Command success EPERM is returned if the command was called while not in PXE mode. EPERM is returned if software control of the drop/no-drop policy is locked by NVM setting.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

Command Operation:

1. The Configure No-Drop Policy AQ command is executed only when the hardware is in PXE mode (GLLAN_RCTL_0.*PXE_MODE* is 0x1), and when the PXE Mode *No-Drop Policy Supported* NVM bit is 1b. Otherwise, the firmware returns EPERM error code.
2. The firmware must maintain an internal variable per port (sw_force_no_drop) that holds the requested No-Drop policy from software. The internal variable is updated as follows:
   a. Initial value, set also after CORER, must be 0.
   b. When the Configure No-Drop Policy AQ command is called, the variable is updated to the received *No-Drop Policy* field.

      Note: The software can disable the No-Drop policy by setting this field to 0.

   c. When a Clear PXE Mode AQ command is called, the variable is set to 0 for all ports.

3. Configure No-Drop Policy AQ command execution:
   a. If Force No-Drop is 1 and sw_force_no_drop is currently 0:
      - Firmware sets the corresponding bits of the port in GLDCB_RTC2PFC_RCB.*TC2PFC* (4 bits or 8 bits according to the link topology). In LFC mode, only the bits that correspond for TC0 should be set.
      - Firmware changes GLDCB_RSPMC.*PFCTIMER* to pxe_pfc_timer.
   b. If Force No-Drop is 0 and sw_force_no_drop is currently 1:
      - Firmware reads the bits of current port from GLDCB_TC2PFC and copies them to the corresponding bits in GLDCB_RTC2PFC_RCB.*TC2PFC*. and then writes the value to GLDCB_RTC2PFC_RCB to align all Rx copies of the CSR.
      - Firmware restores GLDCB_RSPMC.PFCTIMER to the NVM default value.
4. After any update of GLDCB_TC2PFC (the master), if sw_force_no_drop is set for this port, the firmware sets the corresponding bits of the port in GLDCB_RTC2PFC_RCB.*TC2PFC* (4 bits or 8 bits based on link topology).
5. When executing the Clear PXE Mode AQ command, firmware applies (3b) to all ports for which sw_force_no_drop is currently 1.

10.4.3.4 Transitioning Flow to non-PXE Mode

10.4.3.4.1 Device Response to Clear PXE Mode Admin Command

1. When the Clear PXE Mode admin command is initiated, the device checks the value of the *PXE_MODE* flag in the GLLAN_RCTL_0 register.
2. If the *PXE_MODE* flag is found cleared then:
   a. Return a command completion with “EEXIST” indication.
3. Else, the *PXE_MODE* flag is active:
   a. Disable Rx-Queue 0 and Rx-Queue 1 of all enabled PFs by clearing the *QENA_REQ* flag in the QRX_CTRL[0] and QRX_CTRL[1] registers of the PFs.
   b. Wait until all receive queues are disabled by polling the *QENA_STAT* flag in the QRX_CTRL registers of all above Rx-Queues. It is expected that all Rx-Queues are disabled within a few microseconds.
   c. Clear the *PXE_MODE* flag in the GLLAN_RCTL_0 register.
   d. Flow is completed by posting a command completion with “No Error”.

10.4.3.4.2 Software Steps Transitioning to non-PXE Mode

1. The Admin Queue must be active before the following steps.
2. Software initiates the Clear PXE Mode admin command and waits for its completion.
3. Proceeds with the software initialization flow.

10.4.3.5 Receive Queues Doorbells and Completions

10.4.3.5.1 Receive Descriptors and Tail Bump

During nominal operation, the function that owns the queue (PF or VF) accesses the hardware directly.

- Prepare receive descriptors by clearing the *DD* bit and setting the buffer pointer(s). Start at the descriptor indicated by the *TAIL* pointer in the relevant QRX_TAIL register.
- The software should never set the *TAIL* to a value above the descriptors owned by the hardware minus 1. The descriptors considered as "owned by the hardware" are those ones already indicated to the hardware but not yet reported as completed.
- Bump the *TAIL* to the last prepared descriptor plus one.
- The number of "free" descriptors owned by the hardware is defined by *TAIL* minus the *HEAD*. If the number of "free" descriptors becomes lower than *LRXQTRESH*, then an immediate interrupt is triggered. The *HEAD* and *LRXQTRESH* are listed in the Rx-Queue context detailed in Section 10.4.3.6.

10.4.3.5.2 Receive Descriptor Reporting (Descriptor Write-Back)

The E810 reports a completion of receive packet in host memory by status indication in the receive descriptor(s) of the packet - descriptor write-back (WB). The E810 writes back completed descriptor status in one of the following cases:

- Whole line of descriptors (4x32-byte descriptors or 8x16-byte descriptors) are completed.
- All completed descriptors of a queue are evicted from the internal cache.
- Upon assertion of the interrupt associated with the queue.
- If queue is configured for "No Expire" (as explained in Section 10.4.3.6.1), every completed descriptor is written back immediately.

Most applications use interrupts to invoke the driver. Before initiating the interrupt, the E810 posts all completed descriptors of the queue that might be kept in the device caches. Following an interrupt assertion, the device masks any further interrupts preventing interrupt nesting (as explained in Section 9.1.1.3). When the interrupts are re-enabled (by the software), further interrupts that trigger additional write-back of completed descriptors can be initiated.

In some applications, the E810 is activated in polling mode (with no interrupts). Configuring this option is done by following the "WB ON ITR" option in Table 9-1 on page 1155.

10.4.3.6 Receive Queue Context Parameters

This section describes the setting options of the LAN receive queue parameters named as "queue context". The receive queue context is an on-die structure that contains the configuration, state, and internal scratch pad of each one of the receive queues. The receive queue context is used and managed by several blocks in the Rx-Pipe. For easy access of each block, the Rx-Queue context is divided into two sections, the Receive Queue Context section and the Receive Misc. section.

10.4.3.6.1 Receive Queue Context

Receive queue context parameters are initialized by software and then managed by hardware.

The Rx-Queue context consists of two major sections:

- Queue Configuration section.
- Dynamic section.

The first one is programmed by software during the queue init flow. Software does not access this section on runtime. The dynamic section is accessed by software on runtime and therefore it is implemented as dedicated registers vectors.

10.4.3.6.1.1 Receive Queue Context - Static Section

The queue configuration section parameters reside in the QRX_CONTEXT[n, 0...7] registers and are detailed in Table 10-12. The dynamic section is detailed in Section 10.4.3.6.1.2.

The queue context is a set of 256 bits (32 bytes), where bit "i" in the vector is mapped to - bit number {"i" modulo 32} in QRX_CONTEXT register index {Whole number of ("i"/32)} of the queue. For example, the *QLEN* parameter in bits 89 to 101 of the queue context is stored in bit number 25 in QRX_CONTEXT register index 2 to bit number 5 in QRX_CONTEXT register index 3 of the queue.

Table 10-12. LAN Rx-Queue Context (256 Bits = 32 Bytes)

Alias	Width (bits)	LS Bit	MS Bit	Type	SW Init	Description
HEAD	13	0	12	Dynamic	0x0	**Receive Queue Head** An index relative to the beginning of the queue that defines the next descriptor to be used. During idle time, all descriptors starting by the HEAD up to (excluding) the RTAIL are owned by the hardware and the rest are owned by software. During dynamic operation it is not guaranteed that all descriptors below the HEAD are completed.
CPUID	8	13	20	Dynamic	0x0	**CPU Socket ID for TPH** The CPU socket ID is updated by the hardware.
Queue_Block Indication	1	21	21	Dynamic	0b	**Queue Block** When set, the device silently drops packets that arrive to this queue. This bit is set by hardware as a response to a malicious event or during Function Reset flow. This bit must be cleared by the PF before the queue is reused.
Reserved	11	22	31	N/A	0x0	Reserved. Must be set to zeros.
BASE	57	32	88	Static	BASE	**Receive Queue Base Address** Indicates the starting address of the descriptor queue defined in 128-byte units.
QLEN	13	89	101	Static	QLEN	**Receive Queue Length** Defines the size of the descriptor queue in descriptors units from eight descriptors (*QLEN*=0x8) up to 8K descriptors minus 32 (*QLEN*=0x1FE0). QLEN Restrictions: When the *PXE_MODE* flag in the GLLAN_RCTL_0 register is cleared, the *QLEN* must be whole number of 32 descriptors. When the *PXE_MODE* flag is set, the *QLEN* can be one of the following options: Up to 4 PFs, QLEN can be set to: 8, 16, 24 or 32 descriptors. Up to 8 PFs, QLEN can be set to: 8 or 16 descriptors.

Table 10-12. LAN Rx-Queue Context (256 Bits = 32 Bytes) [continued]

Alias	Width (bits)	LS Bit	MS Bit	Type	SW Init	Description
DBUFF	7	102	108	Static	DBUFF	**Receive Packet Data Buffer Size** The Packet Data Buffer Size is defined in 128-byte units. Must be at least 1 KB and up to 16 KB minus 128 bytes.
HBUFF	5	109	113	Static	HBUFF	**Receive Packet Header Buffer Size** The Header Buffer Size is defined in 64-byte units enabling buffer size up to 2 KB minus 64 bytes.
DTYPE	2	114	115	Static	DTYPE	**Descriptor Type** Descriptor Type as defined in Table 10-13.
DSIZE	1	116	116	Static	DSIZE	**Descriptor Size** 0b = 16-byte descriptors. 1b = 32-byte descriptors.
CRCStrip	1	117	117	Static	CRCStrip	**CRC Strip** Strip the Ethernet CRC bytes before the packet is posted to host memory. ***Note:*** The CRC Strip option works properly only if the whole packet is posted to the data buffer(s) in host memory with no other strip option.
Reserved	1	118	118	Static	0b	Reserved. Must be set to 0b.
L2TSEL	1	119	119	Static	0b	**L2 Tag Select** The *L2TSEL* bit defines the reported L2 Tags in the receive descriptor. 0b = The second L2 Tag defined by the *SHOWTAG* field in the VSI_TSR register of the VSI is posted to the *L2TAG1* field. The first tag is reported in the *L2TAG2* field. 1b = The above L2 tags are switched between the *L2TAG1* and *L2TAG2* fields.
HSPLIT_0	4	120	123	Static	HSPLIT_0	**Header Split 0** Header Split 0 control as described in Table 10-14.
HSPLIT_1	2	124	125	Static	HSPLIT_1	**Header Split 1** Header Split 1 control as described in Table 10-15.
Reserved	1	126	126	Static	0b	Reserved. Must be set to 0b.
SHOWIV	1	127	127	Static	SHOWIV	**Show Inner VLAN** The VLAN in the inner L2 header is stripped to the receive descriptor if enabled by this flag.
Reserved	46	128	173	Static	0x0	Reserved.
RXMAX	14	174	187	Static	RXMAX	**Max Packet Size** Max packet size for this queue defined in byte units. The *RXMAX* parameter defines the whole packet size starting at the L2 header up to and including the Ethernet CRC. The *RXMAX* must not be set to a larger value than 5 x *DBUFF* (since receive packet must never span on more than five buffers). Received packets larger than *RXMAX* are dropped and counted by the GLV_REPC counter of the VSI. ***Note:*** Packets larger than MFS defined per MAC are marked with l2_mac_err
Reserved	5	188	192	Static	0x0	Reserved. Must be set to zeros.
TPHRDesc	1	193	193	Static	TPHRDesc	**Read Descriptor TPH Enable** Descriptor fetch.
TPHWDesc	1	194	194	Static	TPHWDesc	**Write Descriptor TPH Enable** Descriptor write-back.
TPHData	1	195	195	Static	TPHData	**Packet Data TPH Enable**

Table 10-12. LAN Rx-Queue Context (256 Bits = 32 Bytes) [continued]

Alias	Width (bits)	LS Bit	MS Bit	Type	SW Init	Description
TPHHead	1	196	196	Static	TPHHead	**Packet Header TPH Enable**
Reserved	1	197	197	Static	0b	Reserved. Must be set to 0b.
LRXQTRESH	3	198	200	Static	LRXQTRESH	**Low Receive Queue Threshold** Defined in 64 descriptors units. When the number of free descriptors (defined by *TAIL* minus *HEAD*) "goes" below the *LRXQTRESH*, an immediate interrupt is triggered.
Reserved	55	201	255	Static	0x0...01	Reserved.

10.4.3.6.1.2 Receive Queue Context - Dynamic Section

This queue context section includes the fields frequently accessed by software. This section is organized as a set of two separate vectors, each of them indexed separately per Rx-Queue ID.

- Interrupt related registers QINT_RQCTL[n], where "n" is the queue index in the absolute Rx-Queue space.
- The *TAIL* pointer in the QRX_TAIL[n] registers for the PF and for the VFs, where "n" is the queue index of the function (PF or VF).

10.4.3.6.2 Miscellaneous Receive Queue Context

This section lists the queue context parameters that are used by the RCB block.

- Queue enablement flags in the QRX_CTRL[n] registers, where "n" is the queue index in the absolute Rx-Queue space. Queue enable and disable flow by the PF are explained in Section 10.4.3.1.
- Two additional bits to select and observe drop/no-drop traffic class behavior.
  - One bit enables a queue associated with a no-drop TC to start dropping received packets after a configurable timeout.
  - The other bit is a status bit indicating current state.

10.4.4 Stateless Receive Offloads

10.4.4.1 Strip Ethernet CRC Bytes

See Section 7.12.1.2.

10.4.4.2 Header Split

This feature consists of splitting a received packet into two separate regions based on the packet content. Splitting is usually between the packet header that can be posted to a dedicated buffer and the packet payload that can be posted to a different buffer (or multiple buffers). The sizes of these buffers are defined by the *DBUFF* and *HBUFF* parameters in the receive queue context. This kind of splitting is useful when different buffer allocation rules apply to these buffers, or there are different rules for TPH enablement.

Header split is enabled per receive queue by the *DTYPE*, *HSPLIT_0*, and *HSPLIT_1* fields in the receive queue context, as described in Table 10-13, Table 10-14, and Table 10-15, and illustrated in Figure 10-6.

Note: Figure 10-6 cannot cover all supported packet formats. but rather the most common cases that emphasize the header split functionality. For a complete set of packet formats supported by the default NVM settings, see the parse graph in Appendix A.2.

Split between the header buffer and the payload buffers and the status reporting is detailed in Table 10-16. The physical pointers to the header and payload buffers are defined in the receive descriptor.

Some rules regarding header split:

- A packet that has a MAC error (reported by the *RXE* flag) is posted as a whole to the packet buffers with no split.

  Note: Posting such packets to the host is enabled on in "Save Bad Frame" mode (enabled by the *SBP* flag in the PRT_SBPVSI register).

- For tunneled packets, the rules defined by *HSPLIT_1* parameter take precedence over those ones defined by the *HSPLIT_0* parameter. This means that if any flag in *HSPLIT_1* is enabled and the packet matches that setting, the packet is split according to *HSPLIT_1* regardless of *HSPLIT_0* settings.
- In each individual register (*HSPLIT_1* or *HSPLIT_0*), the packets are split according to the lowest matched entry in the tables below. If both *HSPLIT_0* and *HSPLIT_1* are set to zero, *DTYPE* in the receive queue context must be set to 00b. Otherwise (any header split is enabled by these registers), the *DTYPE* must be set to one of the header split options: 01b or 10b (explained below).
- If the packet is posted to multiple descriptors, only the header buffer of the first one is used.
- The packet header cannot span across multiple buffers. If the header buffer is smaller than the received header, the header is posted together with the packet payload. See Table 10-16.
- The header of a fragmented IP packet is defined up to including the IP header regardless if the fragment includes the L4 header. For IPv6 header, the IP header is defined up to and including the fragmented extension header.
- When a packet is replicated to multiple receive queues, the packet can be split differently on these queues according to their settings.
- Header split is supported for packets received from the network as well as local VM-to-VM traffic.

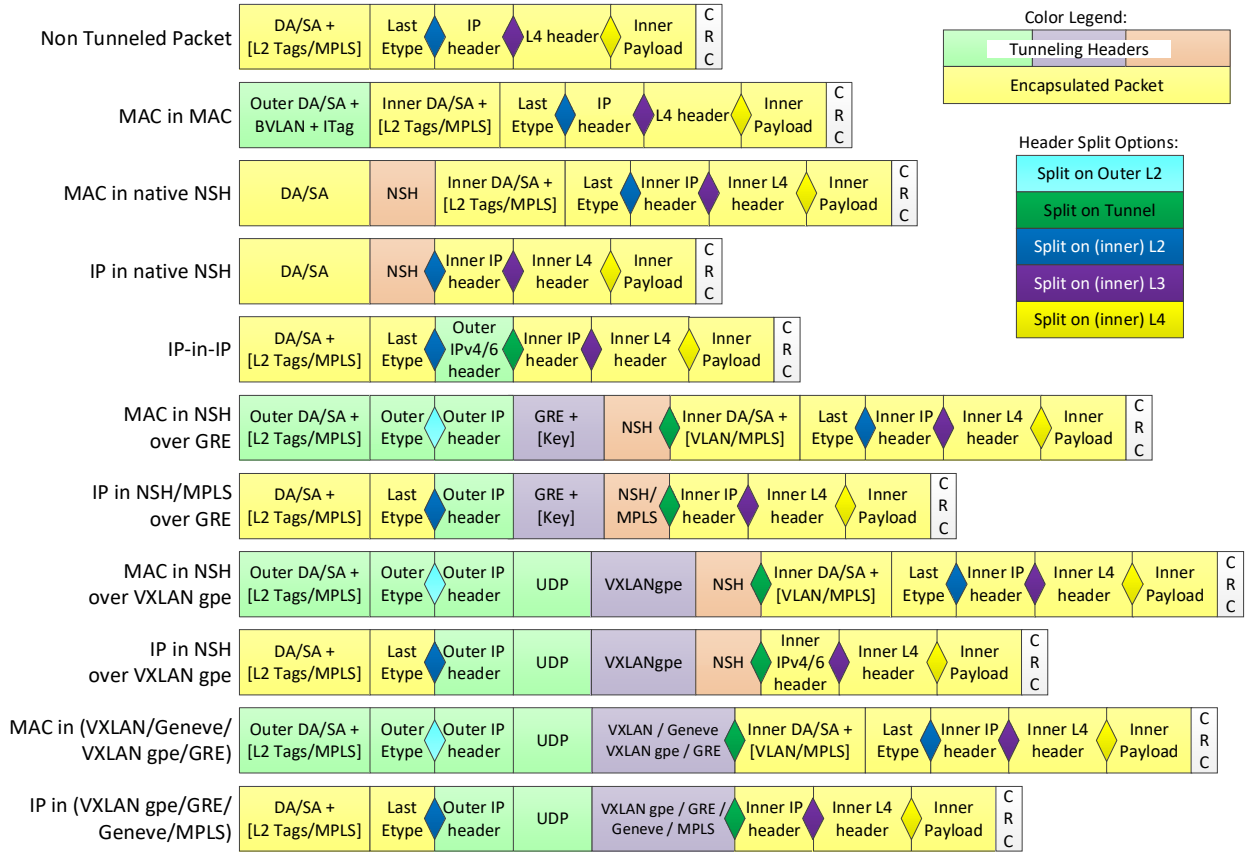

Figure 10-6. Header Split Option by Packet Formats

Table 10-13. Header Split Modes Defined by the DTYPE Field

DTYPE	Functionality
00b	**Single Buffer Descriptors** No header split mode.
01b	**Header Split Descriptors** Header split is enabled for packets that the hardware identifies their headers as enabled by the *HSPLIT* field. The packet content up to and including the most inner header enabled by the *HSPLIT* is posted to the header buffer. The rest of the packet is posted to the payload buffer. See Table 10-16 for rules of the header and payload buffers usage.
10b	**Split Always** Header split is always enabled regardless of the *HSPLIT* setting. If the packet header is identified as defined by the *HSPLIT*, the packet content up to and including the most inner header enabled by the *HSPLIT* is posted to the header buffer. See Table 10-16 for rules of the header and payload buffers usage.
11b	Reserved.

Table 10-14. Split Headers Enabled by the HSPLIT_0 Field

HSPLIT_0	Functionality
0000b	No Header are enabled by *HSPLIT_0*.
xxx1b	Enable split after L2 header. In case of L2 tunneling it is the second (inner) L2 header.
xx1xb	Enable split after the IP header. • In case of tunneling it is the second IP header. • In case of option/extension IP headers the split is after these headers. ***Note:*** If the tunneled pkt doesn't have a tunneled IP header, then split is done on the payload
x1xxb	Enable split after the UDP and TCP header (in case of UDP tunneling it is the second UDP header).
1xxxb	Enable split after the SCTP header.

Table 10-15. Split Headers Enabled by the HSPLIT_1 Field

HSPLIT_1	Functionality
00b	No split on tunneling headers.
x1b	Enable split after the outer (tunneling) L2 header. ***Note:*** Split is enabled only if inner L2 header exists.
1xb	Enable split on the entire tunneling header as follows: • Non-tunneled packet — No impact. • IP in any tunneling — Enable split before the inner IP header. It includes IP in IP, IP in GRE, IP in NSH or MPLS (w/wo prior headers), IP in any UDP tunneling. • MAC in any tunneling — Enable split before the inner MAC header. It includes MAC in any UDP tunneling or MAC in GRE.

Table 10-16. Header Split versus Packet and Buffer Sizes

DTYPE	Condition	Header and Payload DMA	SPH	HBO	PKTL[1]	HSRL[1]	Comments
00b (Single Buffer)	None.	Post the whole packet to the packet buffer(s)	0	0	Size of the whole packet	0x0	
01b (Header Split)	Header is not identified	Post the whole packet to the packet buffer(s)	0	0	Size of the whole packet	0x0	
	Header size ≤ HBUFF	Post header to header buffer and payload to the packet buffer(s)	1	0	Size of the packet payload	Header size	Packet Length calculation includes the Tags and CRC, which are striped later.
	Header size > HBUFF	Post the whole packet to the packet buffer(s)	1	1	Size of the whole packet	Header size	

Table 10-16. Header Split versus Packet and Buffer Sizes [continued]

DTYPE	Condition	Header and Payload DMA	SPH	HBO	PKTL[1]	HSRL[1]	Comments
10b (Always Split)	Packet length ≤ HBUFF	Post the whole packet to the header buffer(s)	0	0	0x0	Packet length	Packet Length calculation does not include the striped Tags and CRC.
	Header is not identified and packet length > HBUFF	Post the whole packet to the header buffer + packet buffer(s)	0	0	Size of the whole packet minus HBUFF	HBUFF	Packet Length calculation includes the Tags and CRC, which are striped later.
	Header size ≤ HBUFF	Post header to the header buffer and the payload to the packet buffer(s)	1	0	Size of the packet payload	Header size	Packet Length calculation does not include the striped Tags and CRC.
	Header size > HBUFF	Post the whole packet to the header + packet buffer(s)	1	1	Size of the whole packet minus HBUFF	Header size	

1. If the data posted to the packet buffer is larger than PKTL, multiple buffers (descriptors) are used.
   - All buffers but the last one are full (PKTL = DBUFF) while the last one contains the rest of the data.
   - Only the header buffer of the first descriptor is used.

10.4.4.3 Receive L3 and L4 Integrity Check Offload

The E810 offloads the following L3 and L4 integrity checks: IPv4 header(s) checksum, Outer UDP checksum, Inner TCP or UDP checksum, and SCTP CRC integrity (see Table 10-17). The E810 identifies the packet type and then checks the matched integrity scheme. The identified packet type is reported on the *PTYPE* field in the receive descriptor. Processing indication of the L3 and L4 headers is reported on the *L3L4P* flag in the receive descriptor. Potential IPv4 checksum error, L4 integrity error, and outer IPv4/UDP checksum error are reported by the IPE, L4E, and the EIPE error flags in the legacy receive descriptor, respectively. In the advanced receive descriptor it is reported in the flexible error flags.

Note: Outer UDP checksum is supported for all supported encapsulation over UDP (VXLAN, Geneve, and VXLAN-GPE).

Following are some rules for integrity check offload. If the following rules are not met, integrity offload is not provided and the *L3L4P* is not set.

- IPv4 header is assumed to be at least 20 bytes long (the length of the basic header).
- IPv4 headers can have any IP option headers that fit within the maximum header size (60 bytes).
- IPv6 support — The pseudo header for the L4 checksum takes into account the addresses in the IPv6 header, ignoring the optional extension headers. Packets with Routing Header type 2 and Destination Options Header with Home Address option contain an alternative IP Address in the extension header. Therefore, checksum calculation for such packets most probably results in an erroneous value. The E810 indicates the existence of a Destination Options Header or a Routing Header in the *IPV6EXADD* bit of the Rx-Descriptor. Software can then do one of the following:
  - — Ignore the checksum done by the device.
  - — Parse the extension header and identifying if it contains an IP Address, then ignore the checksum done by the device only in this case.

- Fragmented packets — The E810 parses fragmented receive packets up to and including the IP header (for IPv4) or up to and including the fragmentation extension header (for IPv6):
  - L4 checksum offload is not supported for IPv6 fragmented packets and the *L3L4P* flag in the receive descriptor is not set.
  - Fragmented IPv4 packet is offloaded up to including the IP header.
- TCP header is assumed to be at least 20 bytes long (the length of the basic header).
- The TCP header can have any option headers that fit within the maximum header size (60 bytes).
- VM-to-VM loopback traffic is processed by the hardware for L3/L4 integrity check as any other packet received from the network.

Table 10-17 lists all supported packet formats and the processed integrity. The table uses the following notations:

- IP is a generic term for IPv4 header or IPv6 header. The IPv4 header can have IP option headers and the IPv6 header can have IPv6 extension headers.
- L4 is a generic term for UDP, TCP, or SCTP headers.
- IP checksum is meaningful only for IPv4.
- Checksum is a generic term for UDP and TCP checksum, as well as SCTP CRC integrity.
- Zero UDP checksum — Zero UDP checksum for IPv4 packet is treated as no checksum and is reported by the hardware as "no error" and "done". Zero UDP checksum for IPv6 packet is illegal and is reported by the hardware as L4 checksum error.

Table 10-17. Integrity Offload Check for Receive Packet Types

Packet Type	Supported Integrity Offload	Reported L3L4P
IP -> [data / Unknown / fragmented]	IP checksum offload.	L3L4P is set if any header in the packet is checked for integrity. Note that IP checksum offload is true only for IPv4 header.
IP -> L4	IP and L4 checksum offload.	
IP -> IP -> [data / Unknown / fragmented]	2 x IP checksum offload.	
IP -> IP -> L4	2 x IP and L4 checksum offload.	
IP -> [tunnel header] -> IP -> data / Unknown / fragmented	Only 2 x IP checksum offload and tunneling UDP checksum (for UDP tunneling).	
IP -> [tunnel header] -> IP -> L4	2 x IP checksum, tunneling UDP checksum, and L4 checksum offload.[1]	
IP -> [tunnel header] -> data and IP -> [tunnel header] -> MAC -> data	IP checksum and tunneling UDP checksum offload.	
IP -> [tunnel header] -> MAC -> IP -> data	2 x IP checksum (relevant only for IPv4) and tunneling UDP checksum offload.	
IP -> [tunnel header] -> MAC -> IP -> L4	2 x IP, tunneling UDP, and L4 checksum offload.[1]	

1. The L4 checksum offload relates to the inner header:
   - For UDP or TCP protocols, the hardware calculates the expected checksum including the pseudo IP header.
   - For SCTP protocol, the hardware calculates the expected SCTP CRC.

10.5 LAN Transmit Data-Path

10.5.1 LAN Transmit Introduction

The following sections describe the initialization, configuration, data handling, disable and reset flows related to the LAN transmit functionality. This section covers the following major topics:

- A review of the transmit packet data stored in system memory, and the various assorted queue structures managed by software and used by hardware to perform data transmission.
- A discussion about the intended usage models, and the application of various features to these usage models.
- Initialization and configuration flows.
- Various packet transmission flows.
- Queue disable and reset flows.
- Error handling and additional considerations for software.

10.5.2 Transmit Packets in System Memory

Transmit packets are possibly multiple data non-contiguous buffers in host memory posted by software to hardware for transmission using descriptors (16-byte structures described in Section 10.5.3.2). These descriptors include pointer and length pairs to the data buffers, as well as control fields for the transmit data processing. In some cases, additional control parameters that cannot fit within the data descriptors are needed to process the packet(s). In this case, additional context descriptor(s) are posted by software to hardware prior to posting the data descriptors. A few common examples for context descriptor(s) are transmit segmentation (TSO) and Flow Director (FD) filter programming.

Figure 10-7 shows an example of a transmit packet in host memory composed of two buffers (header buffer and payload buffer), indicated by two matched "data descriptors" and an optional context descriptor.

The following rules are related to the transmit packet in host memory:

- The total size of a single packet in host memory must be at least 17 bytes and up to the "Max Frame Size" of the port as configured by the Set MAC Config admin command.
  - Packets outside this range are considered malicious. The respective queue is stopped and an interrupt is issued to the PF. The relevant event is "Bad Single Send size".
  - This rule applies for single packet send as well as any packet within a transmit segmentation (TSO).
- A single transmit packet can span up to eight buffers (up to eight data descriptors per packet including both the header and payload buffers).
  - When a packet spans on multiple buffers, all the descriptor of that packet must be filled similarly.
- The total number of data descriptors for the whole TSO (explained later on in this chapter) is considered unlimited (Limited only by Tx-Queue length) as long as each segment within the TSO obeys the previous rule (up to eight data descriptors per segment for both the TSO header and the segment payload buffers).

- If a packet or TSO spans on multiple transmit data descriptors, the fields in all the data descriptors must be valid.
- The TSO message header should not span on more than three buffers (Max three descriptors).

Enhanced Host-interface modes as explained in Section 10.5.6.2 places additional restrictions on the maximum number of descriptors, maximum number of descriptors per quanta, maximum commands per quanta, and the offload commands that can be used.

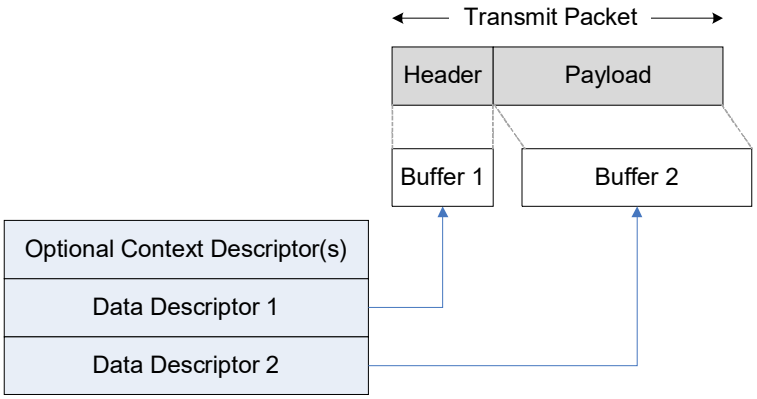

Figure 10-7. Transmit Packet in System Memory (Example Using Two Buffers)

10.5.3 Descriptors and Doorbells

The software prepares structures for transmission in system memory indicated to hardware by a list of consecutive descriptors. These descriptors are organized in a contiguous memory handled as a cyclic queue, which is also called a Transmit Descriptor Ring (TDR). Descriptors are initialized by software, and posted to hardware for processing via a write to a doorbell register. The E810 supports up to 16K transmit queues allocated to PFs and VFs.

Transmit queue state and behavior is initialized by software, which programs a set of parameters collectively called the *queue context*. The main parameters are the queue pointers presented in Figure 10-8. The queue context includes additional parameters that define the queue functionality as detailed in Section 10.5.5.2. The context parameters are kept in an internal memory within hardware.

The software interface to the queue for initialization, nominal operation, and queue disable is described in Section 10.5.5.1. The E810 has additional global parameters for the whole device or per function parameters that affect multiple queues.

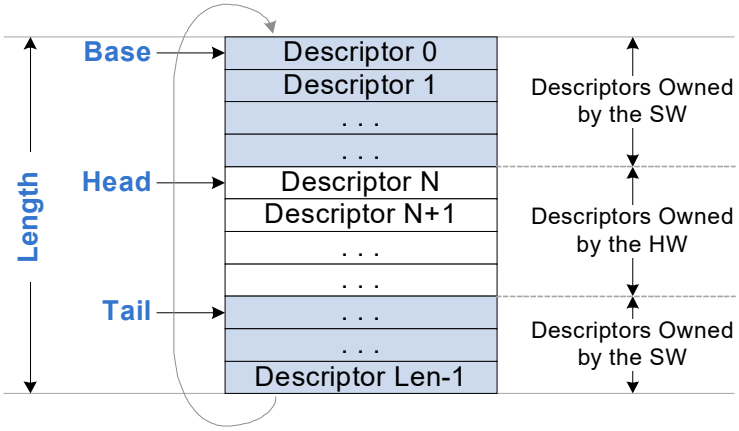

Figure 10-8. Transmit Descriptor Ring Structure

When software posts a packet for transmission, it can add some specific rules and commands per the transmitted packet. This is done by adding extra descriptors on top of the Data descriptors that point to the transmitted packet.

The following subsections describe the various descriptor types.

10.5.3.1 General Descriptors

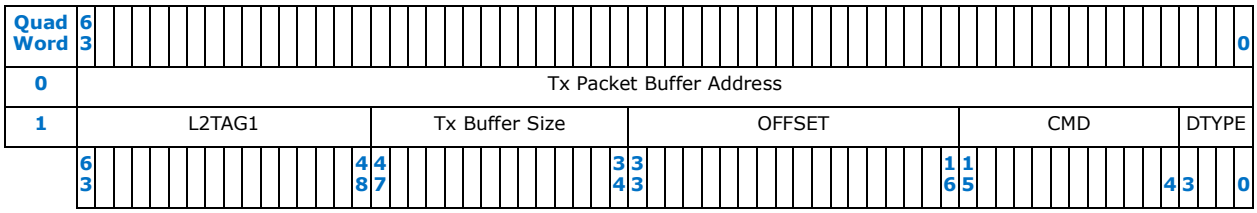
Table 10-18. LAN Descriptor Types

Descriptor Type	DTYPE Value	Description	Section Reference
NOP (optional)	0x1	NOP descriptors can be used to align descriptors to cache lines (optional usage).	10.5.3.1.2
LAN Transmit Context	0x1	Used as a companion to the Transmit Data descriptor to provide more information on the packet.	10.5.3.2
FD Filter Programming	0x8	Used to program Flow Director filters.	10.5.3.3
Transmit Data	0x0	Regular data descriptor used to send LAN packets	10.5.3.1.1

Notes:

- For all descriptors, fields indicated as "RSV" (reserved) should be set to zero by the software at programming time.
- Descriptor type 0x8 is excluded in a single packet transmit.
- Software can use multiple descriptors for a single packet transmission. For example, a transmission of a single LSO message. For this type of packet, software is required to post a Context Descriptor (0x1) followed by one or more Data Descriptors (0x0). In any case multiple descriptors are used for a transmitted packet, software must place them into the Tx-Queue in the order they are documented in Table 10-18.

10.5.3.1.1 Transmit Data Descriptor



Descriptor Type - DTYPE (Quad Word 1, Bits 0:3, 4 bits)

0x0 stands for a Transmit Data Descriptor.

Command Field - CMD (Quad Word 1, Bits 4:15, 12 bits)

Bit(s)	Name	Description
0	EOP	End of Packet. The EOP flag is set in the last descriptor of a packet or TSO.
1	RS	Report Status. When set, the hardware reports the DMA completion of the transmit descriptor and its data buffer. Completion is reported by Completion Queue or by descriptor write-back as configured by the *HEAD_WBEN* flag in the transmit context. When it is reported by descriptor write-back, the *DTYPE* field is set to 0xF and the *RS* flag is set. The *RS* flag can be set only on a last Transmit Data Descriptor of a packet or last Transmit Data Descriptor of a TSO.
2	Reserved	Reserved. Must be set to 1b.
3	IL2TAG1	Insert an L2 tag from the L2TAG1 field in this descriptor. For MAC in UDP or MAC in GRE tunneling, the *L2TAG1* field is relevant to the outer L2 header. See *IL2TAG_IL2H* for VLAN tag insertion to the inner L2 header. The type of the Tag is defined by the *L2TAG1INSERTID* field in the VSI_L2TAGSTXVALID register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAG*xxx* registers. If the type of the L2 Tag requires more than two variable bytes, additional bytes are taken from the *L2TAG2* field while the *L2TAG1* is first on the wire. In this case, the *IL2TAG2* flag must be cleared.
4	DUMMY	When the *DUMMY* flag is set, the packet is not transmitted (internal and external). The *DUMMY* indication can be useful for context programming purposes: FD filters. Note that when using the *DUMMY* option, the packet does not have to have a correct checksum. Software should set all the fields in the data descriptor and context descriptors describing the packet structure as it does for nominal packets.
5:6	IIPT	The IP header type and its offload. In case of tunneling, the IIPT relates to the inner IP header. See also *EIPT* field for the outer (External) IP header offload. 00b = Non-IP packet or packet type is not defined by software. 01b = IPv6 packet. 10b = IPv4 packet with no IP checksum offload. 11b = IPv4 packet with IP checksum offload. For an IPv4 TSO message, this field must be set to 11b.
7	Reserved	Reserved.
8:9	L4T	L4T is the L4 packet type. 00b = Unknown/Fragmented packet 01b = TCP 10b = SCTP 11b = UDP When the *L4T* is set to values other than 00b, the *L4LEN* must be defined as well. When set to UDP or TCP, the hardware inserts the L4 checksum and when set to SCTP the hardware inserts the L4 CRC. ***Note:*** Requesting SCTP CRC/TCP or UDP offload for a packet that was padded by Software results in wrong SCTP CRC.

Bit(s)	Name	Description
10	RE	Report Event. When set, the hardware reports the DMA completion of the transmit descriptor and its data buffer. Completion is reported by Completion Queue or descriptor write-back as configured by the queue context parameters. When it is reported by descriptor write-back, the *DTYPE* field is set to 0xF and the *RE* flag is set. The *RE* bit setting must follow the same rules as the *RS* bit, described above.
11	Reserved	Reserved.

Header Offset Parameters - OFFSET (Quad Word 1, Bits 16:33, 18 bits)

Bit(s)	Name	Description
0:6	MACLEN	MAC Header Length defined in Words. In case of a tunnel packet, *MACLEN* defines the outer L2 header. *MACLEN* defines the L2 header length up to including the EtherType. If L2 Tag(s) are provided in the data buffers, they are included in *MACLEN*.
7:13	IPLEN	IP header length (including IP optional/extended headers) in the Tx buffer defined in DWords. In case of a tunnel packet, *IPLEN* defines the most inner IP header length. If the *IIPT* flags cleared, this field should be set to zero.
14:17	L4LEN	*L4LEN* is the L4 header length in the Tx buffer defined in DWords. In case of a tunnel packet, *L4LEN* defines the most inner L4 header length. *L4LEN* should obey the following rules: When the *L4T* field is set to 00b, *L4LEN* must be set to zero. Otherwise, it should be set to 8/12 for UDP/SCTP, respectively, and should be greater than or equal to 20 for TCP.

L2 Tag 1 - L2TAG1 (Quad Word 1, Bits 48:63, 16 bits)

A 16-bit tag to be inserted into the packet if the *IL2TAG1* flag is set. If *IL2TAG1* is cleared, *L2TAG1* should be set to zero by software.

Tx Buffer Size (Quad Word 1, Bits 34:47, 14 bits)

Bit(s)	Name	Description
0:13	BSIZE	Buffer size in byte units from 1 byte up to 16 KB minus 1.

Tx Packet Buffer Address (Quad Word 0, Bits 0:63, 64 bits)

Bit(s)	Name	Description
0:63	BADDR	Buffer address in byte granularity.

10.5.3.1.2 NOP Descriptor

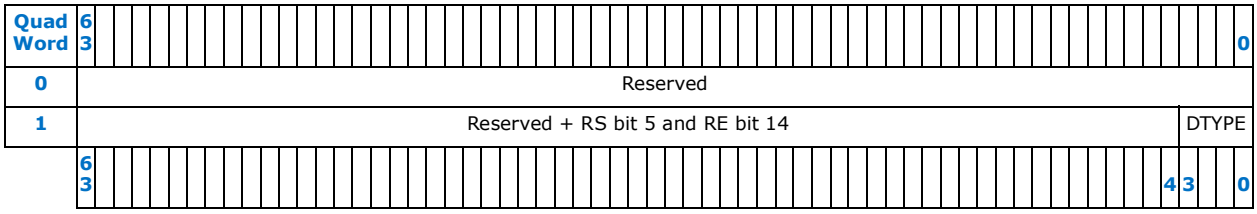
A NOP descriptor can be used for padding if software needs to align descriptors for cache alignment or other performance reasons. A NOP descriptor does not cause any activity other than processing of the descriptor. Most importantly, NOP descriptors do not generate write-backs to indicate the hardware has processed the descriptor.

NOP descriptors are implemented by the "Null" setting of a context descriptor as follows: DTYPE should be set to 0x1 (LAN Context Descriptor) and all other fields should be cleared. Note that NOP descriptors are permitted only between packets.

NOP descriptors are reported as a drop event when the queue is configured with Completion Queue and Head Drop.

When the queue is configured for advanced host interface mode, NOP descriptor can be issued only as a piggyback at end of a valid packet in a single doorbell.

10.5.3.1.3 Transmit Descriptors Write-Back Format



Descriptor Type - DTYPE (Quad Word 1, Bits 0:3, 4 bits)

The hardware indicates a completed descriptor by setting the *DTYPE* field to a value of 0xF. The write-back status is the same for all transmit descriptors used for LAN traffic, filter programming.

The hardware reports this status in the following two cases:

- For descriptors with the *RS* and/or *RE* bit set (Report Status, Report Event) while the Tx-Queue is configured for descriptor write-back completion (*WB_MODE* field in the queue context is set to 0). See rules for setting the *RS* and/or *RE* flag in the transmit descriptors in Section 10.5.3.1.1.
- For the last descriptor of a command that was executed before an interrupt of the queue is initiated.

Completion Flags - RS and RE (Quad Word 1, Bit 5 and Bit 14, respectively)

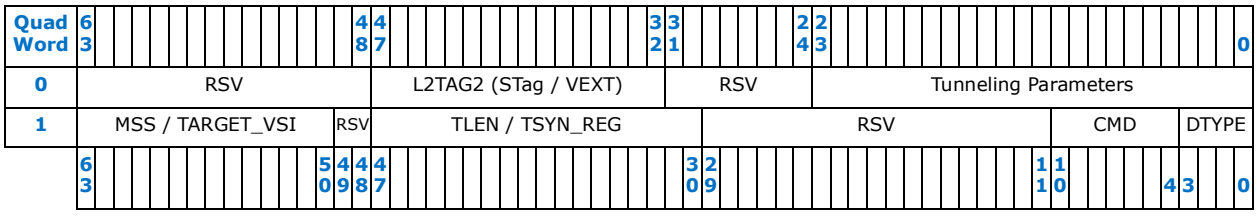
RS bit is set if it was active by software.

RE bit is set if it was active by software.

Note: The bits locations are as they are in the data descriptor.

10.5.3.2 LAN Transmit Context Descriptors

A context descriptor can contain some additional setting options for a single packet or TSO defined by the Data descriptor(s) that follows. Following the transmission of the packet or TSO, the context provided by this descriptor is “expired”.



Descriptor Type - DTYPE (Quad Word 1, Bits 0:3, 4 bits)

0x1 stands for a LAN Context Descriptor.

Command Field - CMD (Quad Word 1, Bits 4:10, 7 bits)

Bit(s)	Name	Description
0	TSO	Transmit Segmentation Offload is activated when the *TSO* flag is set. Applicable for both TCP and UDP packets.
1	TSYN	1588 Timestamp. When set, the hardware samples the packet transmission time in one of PRTTSYN_TXTIME[64] registers. The TSYN flag is processed by the device only if TimeSync is enabled by the *TSYNENA* flag in the transmit queue context. ***Note:*** The *TSYN* flag is aimed only for a single send with no TSO. When *TSYN* is set, the *TSYN_REG* field must be initialized as well.
2	IL2TAG2	Insert the L2 tag from the L2TAG2 field in this descriptor. For MAC in UDP or MAC in GRE tunneling, the *L2TAG2* field is relevant to the outer L2 header. See *IL2TAG_IL2H* for VLAN tag insertion to the inner L2 header. The type of the tag is defined by the *L2TAG2INSERTID* field in the VSI_L2TAGSTXVALID register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAG*xxx* registers. See also *IL2TAG1* in the data descriptor for 32-bit tag handling.
3	IL2TAG_IL2H	Insert VLAN to the inner L2 header from the L2TAG2 field in this descriptor. The VLAN is added after the header defined by *L4TUNLEN*. The *IL2TAG2* and *IL2TAG_IL2H* bits are mutually exclusive and the software can set only one of them. The *IL2TAG_IL2H* can be set to 1b only for L4 tunneled packets with non-zero *L4TUNLEN*. Inserting the VLAN in the inner L2 header, the hardware also updates the IP total length field in the outer IP header. It is done for Single-Send as well as for TSO.
4:5	SWTCH	Switch Control Tag (Can be set to non-zero only by control VSI as programmed by the destination override" flag per VSI): 00b = No Switch Control Tag. The packet is routed according to the hardware filters. 01b = Uplink packet. The packet is transmitted to the network bypassing hardware filters. 10b = Local packet. The packet is transmitted only to local VSIs according to the hardware filters. 11b = Target VSI. The packet is transmitted to a specific VSI defined in the MSS/VSI field in this descriptor. TSO is mutually exclusive with this option.
6	Reserved	Reserved.

Segmentation Parameters / Switching Parameters (Quad Word 1, Bits 30:47; Bits 50:63, 32 bits)

Bit(s)	Name	Description
30:47	TLEN / TSYN_REG	For a TSO message: TSO Total Length. This field defines the L4 payload bytes that should be segmented. Note that the sum of all transmit buffer sizes of the TSO should match exactly the *TLEN* plus the TSO header size in host memory. If the *TSO* flag is cleared, the *TLEN* should be set to zero by software. If the *TSO* flag is set, the *TLEN* must be set by software to a value larger than zero. For a TSYN packet: Bits 30:35 = Contain the index for TSYN_REG[64] register, which is used for this timestamp sampling. Bits 36:47 = Reserved. Must be set to zero by software.
50:63	MSS / TARGET_VSI	When the TSO flag is set, this field functions as a MSS. When the *SWTCH* field is set to 11b, this field functions as a TARGET_VSI. If the *TSO* flag is set, the *SWTCH* field should not be set to 11b and vice-versa. If both the *TSO* flag is cleared and the *SWTCH* field is not equal to 11b, then this field should be set to zero. When the TSO flag is set, the MSS field defines the Maximum Segment Size of the packet's payload in the TSO (excluding the L2, L3 and L4 headers). In case of tunneling, the MSS relates to the inner payload. The M.SS should not be set to a lower value than 88. It also must follow the rule declared in field When the *SWTCH* field equals to 11b, it is the destination VSI of the packet. This option is valid only for control VSIs on which the "Allow destination override" flag is set.

Tunneling Parameters (Quad Word 0, Bits 0:23, 24 bits)

Bit(s)	Name	Description
0:1	EIPT	The External (outer) IP header type and its offload: 00b = No External IP header. 01b = External IPv6. 10b = External IPv4 with no checksum offload. 11b = External IPv4 with checksum offload. For an IPv4 TSO message, this field must be set to 11b.
2:8	EIPLEN	External (outer) IP header length (including IP optional/extended headers) defined in DWords. When the packet has no outer IP header (EIPT equals to zero), this field must be set to zero.
9:10	L4TUNT	L4 Tunneling Type (GRE header / VXLAN header) indication: 00b = No UDP / GRE tunneling (field must be set to zero if EIPT equals to zero). 01b = UDP tunneling header (Any UDP tunneling, VXLAN and Geneve). 10b = GRE tunneling header. 11b = Reserved.
11	Reserved	Reserved. Must be set to 0b.
12:18	L4TUNLEN	L4 Tunneling Length (GRE header / VXLAN header) defined in Words (field must be set to zero if *L4TUNT* equals to zero). • If the tunneling header includes proprietary content it should be included as well. • For IP in GRE it should be set to the length of the GRE header. • For MAC in GRE or MAC in UDP it should be set to the length of the GRE or UDP headers plus the inner MAC up to including its last EtherType. ***Note:*** This field represents the length of data provided in host memory buffers. If the *L4TUNT* is cleared, this field must be set to zero. If MPLS labels exists, *L4TUNLEN* should include them as well.
19:22	DECTTL	Decrement TTL in the inner IP header by *DECTTL* and drop the packet if the original TTL was not greater than *DECTTL*. If the *EIPT* is cleared, this field must be set to zero. ***Note:*** If software attempts to transmit a packet with a value of zero in the TTL header field, the packet is dropped regardless the *DECTTL* value.
23	L4T_CS	Calculate the tunneling UDP checksum. Must be set only if *L4TUNT* = 01b and *EIPT* is not zero.

L2 Tag 2 - L2TAG2 (Quad Word 0, Bits 32:47, 16 bits)

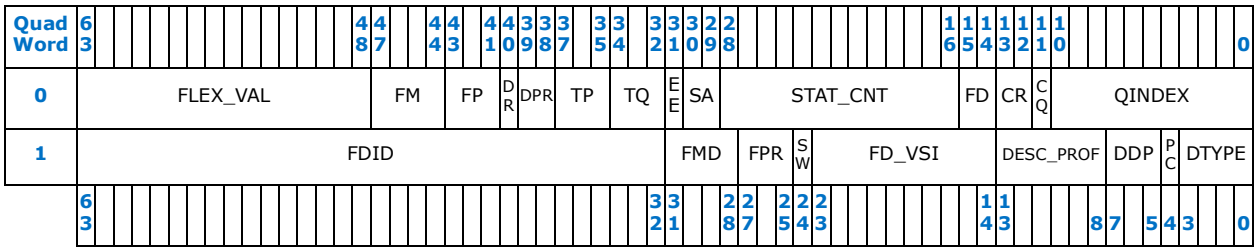
A 16-bit tag to be inserted to the packet if the *IL2TAG2* flag is set, or if *IL2TAG1* is set while L2 Tag 1 include four variable bytes, or if the *IL2TAG_IL2H* flag is set.

If the above conditions are not met, the *L2TAG2* should be set to zero by software.

RSV

Reserved bits that must be set to zero.

10.5.3.3 FD Filter Programming Descriptor



Quad Word 0

Bit(s)	Name	Field Size	Description
0:10	QINDEX	11	Destination queue index or region of queues within the VSI space. It is controlled by the *ToQueue* and *ToQueue_PRIO* parameters. The *QINDEX* must be set to zero if the *ToQueue_PRIO* equals zero.
11	COMP_QUEUE (CQ)	1	The receive queue of the programming VSI for the completion status is selected by the *COMP_QUEUE* flag: 0b = Receive queue zero. 1b = The Rx-Queue defined by the *COMP_QINDX* field in VSIQF_FD_DFLT.
12:13	COMP_REPORT (CR)	2	*COMP_REPORT* controls the completion status reported to software, as follows: 00b = No completion status is reported to software. 01b = Completion status is reported to software in the case of failed programming. 10b = Completion status is reported to software for any programming request. 11b = Reserved.
14:15	FD_SPACE (FD)	2	At programming time, software can select between best-effort and guaranteed spaces in the FD table using the *FD_SPACE* field: 00b = The FD filter is programmed only on the guaranteed space of the function. 01b = The FD filter is programmed only on the best effort space of the function. 10b = The FD filter programming starts with the guaranteed space of the function. If no space, programming is made on the best effort space of the function. 11b = The FD filter programming starts with the best effort space of the function. If no space, programming is made on the guaranteed space of the function.
16:28	STAT_CNT	13	Statistic counter(s) index(es) associated with this filter as controlled by the *STAT_ENA* field. The statistic counters are implemented in 2 "banks" with 4K counters on each bank. The MS bit of the *STAT_CNT* selects the bank and the LS bits selects the counter(s) within the bank(s). If the FD filter uses a single counter, it can be selected on any bank. If the FD filter uses both packet and byte counters, it is the same counter index in both banks. In this case, the MS bit must be set to zero.
29:30	STAT_ENA (SA)	2	The *STAT_ENA* controls the functionality of the *STAT_CNT*, as follows: 00b = No statistic counter associated with the filter. The *STAT_CNT* must be set to zero. 01b = The *STAT_CNT* defines a statistic counter that counts packets. 10b = The *STAT_CNT* defines a statistic counter that counts bytes. 11b = The *STAT_CNT* defines 2 statistic counters that counts packets and bytes. Refer Section 7.10.8.1, "Statistic Counters" for counter indexing rules.
31	EVICT_ENA (EE)	1	Filter programmed with the *EVICT_ENA* setting can be auto-evicted by FIN/RST packets.
32:34	ToQueue (TQ)	3	The *ToQueue* parameters controls the functionality of the *QINDEX,* as follows: 0 = The filter defines a target queue equal to *QINDEX*. 1-7 = The filter defines a region of queues for the hash filter. The region base equals to *QINDEX*. and the region size equals to 2^(*ToQueue*).
35:37	ToQueue_PRIO (TP)	3	To Queue priority action by the FD filter. Priority = zero means no to Queue action.
38:39	DPU_Recipe (DPR)	2	Reserved for DPU Recipe option. Must be set to 00b.
40	DROP (DR)	1	The matched packet is dropped when the *DROP* flag is set.
41:43	FLEX_PRIO (FP)	3	Flexible action priority by the FD filter. Priority = zero means no to flexible action.
44:47	FLEX_MDID (FM)	4	Flexible action type. Valid values are 0 to 4.
48:63	FLEX_VAL	16	Flexible action by the FD filter. Must be set to zero if the *FLEX_PRIO* = 0.

Quad Word 1

Bit(s)	Name	Field Size	Description
0:3	DTYPE	4	0x8 for a FD filter programming descriptor.
4	PCMD (PC)	1	Filter Programming Command: 0b = Add filter.(*) 1b = Remove filter. (*) If the filter entry does not exist, the filter is added. If the filter already exists, the filter parameters are updated. Filter is candidate for update if all the fields that are used for the packet identification match: Packet tuples, VSI, PACKET_DIR.
5:7	DESC_PROF_PRIO (DPP)	3	Receive descriptor profile priority by the FD filter. Priority = zero means no descriptor profile by the FD filter.
8:13	DESC_PROF	6	Receive descriptor profile. See Section 7.6 for supported profiles. Must be set to zero if the *DESC_PROF_PRIO* equals zero.
14:23	FD_VSI	10	Expected VSI index of the packet during reception. Note that the VSI index might be assigned by the embedded switch or any other logic that overrides it before the packet is processed by the FD filter.
24	SWAP (SW)	1	When the SWAP flag is set, "source" and "destination" fields in the Tx packet used for the filter programming are swapped. See description of the GLQF_FDSWAP register in Section 7.10.4.2.
25:27	FDID_PRIO (FPR)	3	FDID priority. Priority = zero means no FDID by the filter.
28:31	FDID_MDID (FMD)	3	FDID action type. It should be set to 0x05 for FD filter ID. Valid values are 0 to 5.
32:63	FDID	32	The functionality of the FDID is defined by the *FDID_MDID* field. It must be set to zero if the *FDID_PRIO* equals zero.

10.5.4 LAN Transmit - Advanced Features

The E810 is a device designed to support the COMMS market usage models as well. On the Tx side, this includes the COMMS Tx-Scheduler detailed in Section 8.3, "Transmit Scheduling" and the Tx advanced host interface.

10.5.4.1 Advanced Mode Host Interface

The Advanced mode host interface includes some new types of services, as follows:

- **Many Tx-Queues**

  To address fine-grained QoS in Tx, the transmits to many targets are controlled and paced separately. This is done by supporting many Tx-Queues to allow the fine distinction between targets and class of services. The E810 supports 16K transmit queues. Each one of the Tx-Queues is individually controlled by the Tx-Scheduler.

- **No Locality Assumption for COMMS Queues**

  In Enterprise and Cloud usage models, the transmitted data comes from applications running on the host platform. Those applications can be part of the PFs, and also belong to VMs or VFs in a virtualized environment. Each function is allocated with set of Tx-Queues. The amount of resources associated with a function is derived from the amount of CPU cores the function runs, and the amount of TCs it uses. For the Enterprise and Cloud usage models, the assumption is that the E810 needs 2048 Tx-Queues to address all functions Tx needs. As mentioned above, for the COMMS usage models, many Tx-Queues are required (16K in the E810).

Another difference between the Enterprise/Cloud and the COMMS usage model is the locality. In the Enterprise/Cloud usage models, not all the VMs run simultaneously on the CPU core. Rather, they are swapped in and out. Only the VMs that actively run generate Tx traffic. Hence, the assumption is that simultaneously a limited amount of Tx-Queues (256 in the E810) are active. In COMMS usage models, a small amount of software entities run on the platform anyway. Each entity uses many queues for its QoS purposes.

The E810 manages internal descriptors cache to meet the Tx performance requirements while optimizing the PCIe bandwidth. Cache helps to improve performance under some locality assumption. This works for the Enterprise/Cloud usage models.

As explained in Section 10.5.4.3, the E810 supports three types of Tx-Queues. Some of them use internal cache to accommodate device's performance requirements. The pure COMMS host interface is architected to meet the required performance without using the descriptors caching. It uses the Richer doorbell format explained below and the quanta descriptors explained in Section 10.5.4.4.

10.5.4.2 Advanced Mode Host Interface New Terms and Entities

The Advanced mode host interface includes some new type of entities, as follows:

- **Richer Doorbell Format**

  Together with quanta queue, it enables accurate scheduling, as well as accurate usage of internal resources and caches. This way, the device operates fine-grained traffic management with high performance for 16K queues with no locality assumption.

  This adds some complexity to software flows. So, pure COMMS applications are not limited for 256 locality but pay by some complexity in the Host interface.

  The Advanced Mode Doorbell is detailed Section 10.5.4.6.

- **Tx-Queue Behavior Profiles**

  The Tx-Scheduler of the X710/XXV710/XL710 worked with one fixed quanta size (4 KB) over all Tx-Queues and RDMA QSets. In the E810, each Tx-Queue can be configured to operate in different quanta size. Some other features are also profiled per Tx-Queue.

  Each Tx-Queue is assigned with three types of profiles, Quanta Profile, Packet Shaping Profile, and Cache Profile. The Tx-Queue behaves according to the profile definitions it is associated with.

- **Quanta Profile**

  Each Tx-Queue is associated with one of 16 configured quanta profiles. The quanta profile includes the following parameters:

  — **Max Descriptors in a quanta:**

    - In Legacy queue, it defines the number of descriptors fetched when the queue is scheduled according this parameter.
    - In advanced mode for TSO segments, it defines how many descriptors are fetched for each TSO quanta.

  — **Max Commands in a quanta:**

    - Similar to the previous, in Legacy queue or in LSO enabled queue, related to internal structures of packet processing. Number of commands per packet is driven from number of descriptors represent the packet.

  - **Configured quanta size:**
    - Define the quanta size used by the legacy queues or in TSO.

  The Quanta Profile structure is detailed in Section 10.5.5.3.

- **Packet Shaping Profile**

  Used in Legacy Host Interface Queue (Queue type #1 detailed in Section 10.5.4.3). The E810 Tx-Scheduler can shape and schedule traffic based on bytes-per-second, or based on packets-per-second. This feature is configurable per each scheduling group in any scheduling layer. When the queue operates in legacy host interface mode, The Packet Shaper Profile provides a predictable number of packets per scheduled quanta. Like in the regular speculative scheduling, after the queue is scheduled and the quanta is processed, an update with the real amount of packets is sent to the Tx-Scheduler to keep all further scheduling decision accurate.

  The Number of Packets Profile structure is detailed in Section 10.5.5.5.

- **Cache Profile**

  Used to fine tune quanta descriptor caching between highest single queue performance and faster response to Head Drop. Described in Section 10.5.5.4.

- **Quanta Queue**

  Quanta Queue is explained in Section 10.5.4.4.

- **Completion Queue**

  Completion Queue is explained in Section 10.5.4.5.

- **Doorbell Queue**

  Doorbell Queue is explained in Section 10.5.4.7.

- **Head Drop**

  Two types of Head Drop are explained in Section 10.5.6.2 and in Section 10.5.6.3.

10.5.4.3 LAN Transmit Queue Modes

Each queue managed by the host interface operates in one of two modes - Legacy and Advanced Transmit. The Advanced Transmit mode enables software to tightly control the burstiness of the traffic from this queue, and to interleave transmissions between multiple data sources while limiting the burst size from any one given queue.

To assist the LAN transmit scheduler to control the burst size, software provides ongoing run-time data in the form of Quanta Descriptors posted to Quanta Descriptor Rings, as well as in the doorbell writes. These scheduled quanta include the number and overall size of data posted for transmission to a given queue. The device-based transmit scheduler uses this data to schedule and pace packets.

The E810 supports two Tx-Queue host interface modes:

- **Legacy Mode (X710/XXV710/XL710 backward compatible):**

  Exposed VF interfaces are binary compatible with prior generation products. This mode supports the usage model of migrating virtual machines utilizing SR-IOV between product generations of the same family (the X710/XXV710/XL710 and the E810).

  PF managed transmit queue configuration can be changed relative to the X710/XXV710/XL710, as the PF driver must be updated to support the E810.

- **Advanced Transmit Mode:**

  A higher granularity and controlled burst size for packet transmission scheduling.

Both Legacy and Advanced queues can transmit regular packet (SSO) and TSO messages. The configuration for Legacy versus Advance Host interface is per Tx-Queue. The hardware identifies three types of behavior in Tx-Queue modes:

- **Legacy Queue** — As described above. This queue operates in legacy interface and can transmit SSO and TSO messages.
- **Advanced Mode with TSO Support** — Tx-Queue in this operation mode uses the advanced host interface and enjoys the burst control for both SSO and TSO messages. This queue type does not support backward compatibility with previous device generations.
- **Advanced Mode with 'NO' TSO Support** — This queue uses the advanced host interface with no TSO support.

The E810 supports up to 16K Tx-Queues. Each one of these 16K queues can be configured to operate in one of three above modes of operation with some limits:

- The total amount of queues that are configured for mode 1 or mode 2 must not exceed 2K at any given time.
- The performance goals of Tx are calculated under the locality assumption where no more than 256 Tx-Queues that are configured for mode 1 or for mode 2 are active simultaneously. There is no locality restriction for queues of mode 3.

In this section, where the document refers to LSO-enabled queue, it can be a mode 1 or mode 2 queue.

10.5.4.4 Quanta Descriptor

Quanta descriptors are submitted on a physically adjacent but separate queue (the QDQ) from the associated transmit queue, with an equal number of descriptors defined as the transmit queue. Quanta descriptors themselves are eight bytes in length. Two types of quanta descriptors are supported:

- Single Send (SSO)
- Transmit Segmentation Offload (TSO).

During the descriptor posting flow, when software completes a quanta, software also writes a quanta descriptor to the QDQ associated with the transmit queue.

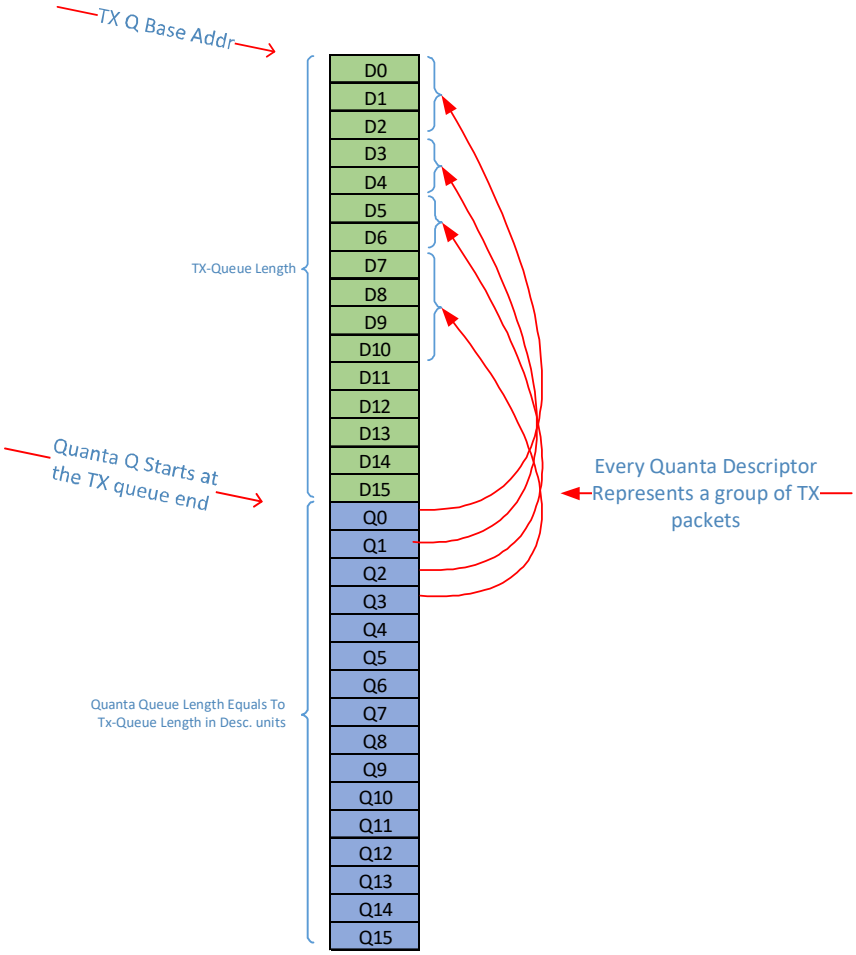


Figure 10-9. Quanta Descriptor and Data Descriptor

Every TSO message is considered as a standalone quanta in the QDQ, and the device can transmit the TSO in multiple quanta's, but software posts the TSO operation as a single standalone quanta descriptor. This means that any partially-filled quanta from previous SSOs are closed automatically by hardware before submitting the new quanta descriptor associated with the TSO. Furthermore, the quanta descriptor associated with the TSO is automatically closed and not aggregated with any later operation.

Table 10-19. SSO Quanta Descriptor Format

Field	Bit(s)	Description
Type	0	Quanta descriptor type. Set to 0b for Single Send.
Desc	6:1	Amount of data descriptors occupied by the quanta packets. Up to 63 descriptors per quanta.
Length	14:7	Data length in 64-bytes resolution - up to 16K-64 bytes.
Reserved	15	Reserved. Must be set to 0b.
Number of Packets	21:16	Number of packets incorporated in the quanta. A quanta can include 1-63 packets. Value of 0 is reserved for special cases.

Table 10-19. SSO Quanta Descriptor Format [continued]

Field	Bit(s)	Description
Reserved	31:22	Reserved. Must be set to zero.
Expire Timestamp	49:32	Expire timestamp.
Timestamp Drop Flag	50	If this bit is set to 1b, the device compares the *Expire Timestamp* field against the internal timestamp, and drops the quanta if needed.
Tx-Descriptor	63:51	Tx-Descriptor ID. Points to the first descriptor of the quanta. This data helps the device in the Head Drop implementation. If the Head Drop feature is not enabled for this queue (*drop enable* bit in queue context is cleared), this field is set to zeros.

Table 10-20. TSO Quanta Descriptor Format

Field	Bit(s)	Description
Type	0	Quanta descriptor type. Set to 1b for TSO.
Desc	13:1	Amount of descriptors occupied by the TSO message.
Length	31:14	Data length in bytes resolution - up to 256KB-1 bytes. This field defines the L4 payload bytes that should be segmented.
MSS	46:32	Maximum Segment Size (MSS) in bytes. The required maximal segmentation size. Up to 9.5KB.
Header Size	55:47	Header size. The size of the header in bytes.
Reserved	63:56	Reserved.

10.5.4.5 Completion Queue (CQ) Descriptor

After each transmit packet is fetched from host memory into device memory, or on packet transmission, a completion notification can be provided by the device. The E810 supports two completion methods

- **Descriptor write-back** — An existing feature.
- **Completion Queue** — A new feature in the E810.

Completion mode is configurable per Tx-Queue. When a Tx-Queue is configured for Completion Queue method, it is also associated with a Completion Queue.

Completion Notification is generated in three cases:

- Software marks transmit descriptors with either Report Status (RS) or Report Event (RE) request in the Tx-Descriptor.

  Note: In TSO transmits, *RS* or *RE* bit can be set only at the last descriptor of the TSO message.

- When a packet is dropped on transmit due to timestamp expiration or an explicit drop request from software, the E810 might or might not coalesce drop notifications in case of two contiguous drop events.
- When ITR expires and there are outstanding completions that have not yet been reported to software.

When a completion notification is targeted to a Completion Queue, it is not immediately written to the host memory. Each Completion Queue structure includes a 64-byte internal cache. The completion notifications are coalesced.

Completion notifications are written to host memory when:

- The internal cache is full with 16 notification (64 bytes).
- At the end of ITR expire flow, the internal completion cache is written to the host even if it is not full.
- When a Queue Disable marker or a VM reset marker is written to the Completion Queue, the internal completion cache is written to the host even if it is not full.

Table 10-21. Completion Queue Descriptor Format

Field	Bit(s)	Description
Tx Q ID / VM ID	13:0	Transmit Queue ID this completion refers to. Queue ID in the function space as configured in the Tx-Queue context field *qnum_in_func*. See Table 10-28 on page 1337. When completion type == 6 (VM reset marker), this field = *VM ID*.
Reserved	14	Reserved.
Generation	15	Completion write generation bit. This bit is flipped every wrap-around of the Completion Queue write. Software uses this bit to identify newly-written completions versus those that have already been processed.
Tx Head	28:16	Current Tx-Queue's head. Points to the next pending descriptor. Valid when *Completion Type* is one of 000b–100b.
Completion Type	31:29	Completion entry type (this is a coding of completion types): 000b = Tx Head report as part of ITR flush process (No *RS*, No *RE*). 001b = Tx completion upon *RS* bit set in the Tx-Descriptor. 010b = Tx completion upon *RE* bit set in the Tx-Descriptor. 011b = Tx completion upon *RS* + *RE* bits (both bits are set in Tx-Descriptor). 100b = Drop notification upon transmit timestamp expiration, drop doorbell request or NOP descriptor. ***Note:*** When Drop completion is about to be reported, if one or more packets are successfully transmitted and not yet reported, an unsolicited completion is reported for the prior reporting of the drop. In that case, *Completion Type* 0 (000b) is used for this unsolicited. Other Drop events, like anti-spoof, are not reported as a "Drop" completion. 101b = Queue Disable marker. Marks that Tx-Queue disable flow is flushed out via the Completion Queue. In that case, *RS* and *RE* bits from Tx-Descriptor, are not reflected. 110b = VM reset marker. When a VM reset flow is completed and any activity related to any queue of the VM is drained from the Tx-Pipe, a VM reset marker is posted in any Completion Queue that is associated with this VM. ***Note:*** This marker is triggered by EMP firmware. 111b = Reserved. Must not be used.

Unlike many other descriptors that implement a Descriptor Done (DD) bit, software identifies new Completion Queue entries by comparing the generation bit. Hardware toggles the generation bit on every wrap-around on the Completion Queue. Using this method, software can determine the old entries from the new ones by looking for mis-matches on the generation bit from one descriptor to the next.

Software must configure the Completion Queue long enough to ensure that completion is not overlapped before software processes them.

10.5.4.6 Doorbells

E810 Tx-Queues can be configured in one of two Host interface modes: Legacy and Advanced. While the doorbell registers are shared for both modes, the doorbell format is different in those two modes, Hitting a doorbell to a specific queue is done by CSR writing to its doorbell register.

10.5.4.6.1 Legacy Mode Doorbell

When a queue is used in legacy host interface mode, the doorbell format is like in legacy devices, where writes to a queue's tail register simply reflect advancing of the tail pointer in the transmit ring to post new descriptors to hardware for processing.

Table 10-22. Legacy Doorbell Format

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	The Transmit Tail defines the first descriptor that the software prepares for the hardware (it is the last valid descriptor plus one). The Tail is a relative descriptor index to the beginning of the transmit descriptor ring.
Reserved	31:13	0x0	RSV	Reserved. Must be set to zero.

10.5.4.6.2 Advanced Mode Doorbell

When a queue is configured for advanced host interface mode, writes to the queue tail register are redefined to pass additional information to control packet scheduling via quanta descriptors. Furthermore, the format of tail writes is different between Single Send (SSO) and Transmit Segmentation Offload (TSO) operations.

In addition, advanced mode supports current head-of-queue dropping based on quanta descriptors of scheduled packets via a Drop Doorbell format described below. An expected case is if the transmit backlog on a given queue grows too long, software can instruct the hardware to ignore existing packets posted on the transmit queue for transmission. Software specifies the number of quantas to drop. Hardware automatically selects the packets to drop from the current head-of-queue. Hardware then generates completion notifications to software to indicate which specific packets were dropped. Hardware accumulates the drop requests and executes the drops when the Tx-Queue is scheduled for transmission.

The internal Drop accumulator is a 7-bit counter per Tx-Queue. It can accumulate up to 127 quantas drop request. Overflow is silently ignored. When the Tx-Queue is empty, any Drop request is ignored and the accumulator is reset. Advanced Mode also includes the ability for software to specify a maximum guaranteed transmission time specified as an expiration time for transmitted packets. If packets are not transmitted in time, the packets are automatically dropped by the transmit pipeline.

The completion notification is identical to the method described above. To enable using this time based transmission, software must maintain a free running timer of 18 bits with resolution of 1 ms. Software is required to read this hardware timer from time to time and synchronize its timer.

When queuing a quanta with *Expire Timestamp*, the timestamp data is part of the quanta descriptor. When queuing it, software must keep the written timestamp to be later than current free running time and not later than 18 seconds than current time.

18-bits timer in 1 ms resolution wraps around approximately every four minutes. The assumption is that packets never wait so long in a Tx-Queue. To cover this rare case as well, it is recommended that software periodically scans the Tx-Queue. When finding a packet that pends a long time in the Tx-Queue, software can send a drop request to that Tx-Queue.

When adding a packet to the Tx-Queue with an expiration time, the delta time between the expiration time of the entered packet and the previous packet in the queue must be smaller than 22 seconds.

Note: Legacy queues or queues with TSO enabled (Mode 1 or 2) do not support "Head Drop". Queues that use drop mode must also enable Completion Queue notifications.

Table 10-23. SSO Doorbell Format

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	The Transmit Tail defines the first descriptor that the software prepares for the hardware (it is the last valid descriptor plus one). The Tail is a relative descriptor index to the beginning of the transmit descriptor ring.
DB Type	14:13	00b	RW	Doorbell Type 00b = SSO (default) 01b = LSO 10b = Drop doorbell 11b = Reserved. Hardware silently ignores this doorbell.
Reserved	15	0b	RSV	Reserved.
Data Length	23:16	0x0	RW	Data length incorporated in current doorbell in 64-byte units, rounded up. For 65-byte packet, *Data Length* field == 2.
Number of Packets	29:24	0x0		Number of packets incorporated in current doorbell. A quanta can include 1-63 packets. a value of 0 is reserved for special cases.
Quanta Completed	30	0b	RW	Set to 1b if this doorbell closes a full quanta.
Reserved	31	0b	RSV	Reserved.

Table 10-24. TSO Doorbell Format

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	The Transmit Tail defines the first descriptor that the software prepares for the hardware (it is the last valid descriptor plus one). The Tail is a relative descriptor index to the beginning of the transmit descriptor ring.
DB Type	14:13	00b	RW	Doorbell Type 00b = SSO (default) 01b = LSO 10b = Drop doorbell 11b = Reserved. Hardware silently ignores this doorbell.
Reserved	15	0b	RSV	Reserved. Must be set to 0b.
First Quanta Length	23:16	0x0	RW	Data length that is sent in each quanta during this LSO transmission. This does not include the last quanta (when the TSO spans on more than one quanta), which can be shorter and covers the tail of the LSO message. The quanta size is in 64-byte units and it is rounded up. In Queue Type #2 (LSO enabled), the max quanta size is 2 KB when transmitting TSO packets.
First Quanta Number of Segments	29:24	0x0	RW	Number of segments that are sent in each quanta during this LSO transmission. This does not include the last quanta (when the TSO spans on more than one quanta), which can be shorter and covers the tail of the LSO message.
Reserved	30	0b	RSV	Reserved. Must be set to 0b.
Single Quanta TSO	31	0b	RW	Set when first quanta is also the last quanta, in case a Large Send packet contains a single quanta.

Table 10-25. Drop Doorbell Format

Field	Bit(s)	Init.	Type	Description
Number of Quantas to Drop	6:0	0x0	RW	Drop command work in quanta granularity. This field marks how many quantas to drop. a value of 0 in this field is Illegal and is silently be ignored by hardware. Software can instruct the hardware to drop 1-127 Quanta's. If this queue is configured to Completion Queue method, the Drop Done (DD) is reported by the Completion Queues. If the queue is configured for the other completion methods, the Drop takes effect with no Done reporting. The hardware manages a Drop register per each Tx-Queue. This is a 7-bit register. When this register is saturated, the hardware uses the saturated value and drops the reminder with no overflow notification to software. It is recommended that software checks the Drop status in the Completion Queue before posting more Drop commands.
Reserved	12:7	0x0	RSV	Reserved.
DB Type	14:13	00b	RW	Doorbell Type 00b = SSO (default) 01b = LSO 10b = Drop doorbell 11b = Reserved. Hardware silently ignores this doorbell.
Reserved	31:15	0x0	RSV	Reserved.

Note: Drop commands are supported only for Tx-Queues type #3. Drop doorbell for a Tx-Queue type #1 or #2 are considered as a malicious behavior.

10.5.4.7 Doorbell Queue Descriptors

At very high packet rates, register writes for each packet to a device doorbell register becomes inefficient. A common software practice is to batch tail writes to post several packets at a time to hardware for processing. However, with high queue counts (16K transmit queues), the tail writes themselves can be spread out over a number of queues at one time, making an effective software tail batch algorithm difficult to implement. The E810 supports a mode where the individual doorbell writes, which could be posted directly to the tail register, instead are coalesced into a series of doorbell descriptors stored in a doorbell descriptor ring. From a single queue, software can advance the tail pointers on multiple queues simultaneously, effectively posting multiple packets to various queues with a single Doorbell Queue tail write.

Table 10-26. Doorbell Queue Doorbell Format

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	The Transmit Tail defines the first descriptor that the software prepares for the hardware (it is the last valid descriptor plus one). The Tail is a relative descriptor index to the beginning of the transmit descriptor ring.
Reserved	31:13	0x0	RSV	Reserved. Must be set to zero.

Table 10-27. Doorbell Descriptor Format

Field	Bit(s)	Init.	Type	Description
TXQ_ID	13:0	0x0	RW	Target Transmit Queue ID.
DD	14	0b	RW	Descriptor Done bit. Set to 0b by software, Set to 1b by hardware
RS	15	0b	RW	Report Status.
DUMMY	16	0b	RW	Used for marker. Treated as a no-op by hardware.

Table 10-27. Doorbell Descriptor Format [continued]

Field	Bit(s)	Init.	Type	Description
Reserved	31:17	0x0	RSV	Reserved.
DBData	63:32	0x0	RW	Doorbell Data. The exact format of a doorbell as it would sent in the Direct Doorbell. All three doorbell formats can be sent via the Doorbell Queue.

A single Doorbell Queue serves one and only one PF or VF. Software advances the Doorbell Queue by writing to the Doorbell Queue Doorbell CSR.

When processing a Doorbell Descriptor, if the *RS* bit is set, a descriptor write-back is required right after it was processed. The hardware writes back the value 0xFFFF_FFFF_FFFF_FFFF to the descriptor location.

10.5.4.8 Transmit During Link Down

In most usage models, when the link becomes inactive, it is not required to preserve the transmit packets that were not sent. During link down, the hardware continues to fetch transmit descriptors and data regardless of the link status. Packets directed to the network are discarded, while packets directed to local VSI port are forwarded successfully.

Note: When the link becomes inactive, PFs on this port get a link status change interrupt. It is expected that the VFs get the link status change indication from their parent PF.

10.5.5 Transmit Configuration

This section covers the various initialization and configuration requirements and examples of the following areas:

- Transmit queue context configuration.
- Quanta descriptor queue context configuration, and associated quanta profile context.
- Doorbell Queue configuration.
- Completion Queue context configuration.

10.5.5.1 Transmit Queue Programming

Queue enable and disable flows are described and summarized in Table 10-31 on page 1342.

Unlike previous products, which used host memory to cache queue contexts, the E810 implements all queue contexts in on-die internal memories. In response to an Add Queue Admin Queue command, EMP firmware uses a series of indirect register accesses (a pair of index and data registers) to program the queue contexts. The flow is described below.

10.5.5.2 Transmit Queue Context

This section describes the setting options of the LAN transmit queue parameters named as "queue context".

Transmit Q context is an on-die structure that contains the configuration, state, and internal scratch pad of each one of the transmit queues.

Context configuration change cannot be performed while the Tx-Queue is active. Configuration is allowed only when the queue is disabled or suspended (in the Tx-Scheduler).

10.5.5.2.1 Transmit Queue Context Structure

Table 10-28. LAN Tx-Queue Context in the QTXCOMM_CNTX Array

Alias	Type	Width (Bits)	LS Bit	MS Bit	Description
Queue_addr	Static	57	0	56	Descriptor queue 57 MS bits of the start address. Every queue address must be 128B-byte aligned. 7 LS bits are 0.
PORT_num	Static	3	57	59	Port number with which the queue is associated.
CGD_num	Static	5	60	64	CGD number with which the queue is associated.
PF_num	Static	3	65	67	PF number that owns this queue.
VMVF_NUM	Static	10	68	77	VF/VM index should be programmed per *VMVF_TYPE* setting: • For *VMVF_TYPE*=VF, it is the VF number between 0:256. • For *VMVF_TYPE*=VM, it is the VM number between 0:767. • For PF or EMP, this field should be set to zero.
VMVF_TYPE	Static	2	78	79	VF/VM Type 00b = Queue belongs to VF. 01b = Queue belongs to VM. 10b = Queue belongs to PF. 11b = Reserved.
SRC_VSI	Static	10	80	89	The VSI with which the queue is associated (0: 767).
TSYN_ENA	Static	1	90	90	TimeSync (1588) enabled via this queue.
Internal Usage Flag	Static	1	91	91	This Flag is reserved for internal usage. This bit must be equal to the *TSO_Enabled_Queue* flag.
ALT_VLAN	Static	1	92	92	Alternate VLAN tag select.
CPUID	Static	8	93	100	CPU ID for TPH. If enabled, it is updated by the read completion of transmit data rather than the descriptors, as implemented in the legacy LAN queues.
WB_MODE	Static	1	101	101	Select between descriptor write-back and Completion Queue write-back: 0b = Descriptor write-back. 1b = Completion Queue write-back.
TPHRDdesc	Static	1	102	102	Descriptor read TPH enable.
TPHRDdata	Static	1	103	103	Data read TPH enable.
TPHWRdesc	Static	1	104	104	Descriptor write TPH enable.
CMPQ_ID	Static	9	105	113	Completion Queue ID.
qnum_in_func	Static	14	114	127	Queue ID in PF or VF space, as reported in Completion Queue.

Table 10-28. LAN Tx-Queue Context in the QTXCOMM_CNTX Array [continued]

Alias	Type	Width (Bits)	LS Bit	MS Bit	Description
ITR Notification_Mode (Int NoExpire Mode)	Static	1	128	128	ITR Notification Mode: 0b = This queue notifies Tx state when descriptor signed with *RS* or *RE*, and also as part of ITR flow. 1b = This queue notifies Tx state only when descriptor signed with *RS* or *RE*.
adjust_profile_id	Static	6	129	134	Profile ID for packet length Adjustment. See Section 8.3.2.4.2.1 for description.
Queue_length	Static	13	135	147	Transmit Queue Length (QLEN). Defines the size of the descriptor queue in descriptors units from eight descriptors (QLEN=0x8) up to 8K-32 descriptors (QLEN=0x1FE0). QLEN restrictions: At smaller queue size than 32 descriptors, the QLEN must be whole number of eight descriptors. At larger size than 32 descriptors, the QLEN must be whole number of 32 descriptors. ***Note:*** If the queue is configured to Mode #2 or #3 (uses quanta descriptors), its length must be equal to or longer than 32 Tx-Descriptors.
Quanta_profile_idx	Static	4	148	151	Quanta Profile Index. Each Tx-Queue must be associated with one of eight quanta profiles.
TSO_Enabled_Queue	Static	1	152	152	Legacy Queue or Advanced Mode Queue. Setting this bit for Queue Type 1 or 2 enables internal usage of descriptor caching, which is required when Legacy interface or TSO are used.
TSO_Qnum	Static	11	153	163	The E810 supports up to 16K Tx-Queues. 2K of them can be TSO-enabled. Each TSO-enabled queue is associated with a TSO internal state structure. This field is the TSO state pointer. This field must be initialized for every TSO-enabled Tx-Queue. TSO structures are equally shared between the PFs (e.g., in an 8-ports configuration, each PF is associated with 256 TSO context structures). Each PF manages the TSO associating inside across the PF and VF queues. When calling the "Add Tx-Queue" AQC, the software provides a Tx-Queue context for each added Tx-Queue. inside the software structure, software provides a zero-based ID *TSO_Qnum* in the PF space. EMP firmware converts it to a physical *TSO_Qnum* and writes it to the queue context.
legacy interface	Static	1	164	164	Legacy or Advanced Host Interface: 0b = Advanced host interface. 1b = Legacy host interface.
drop enable	Static	1	165	165	When this bit is set to one, the Tx-Queue supports Head Drop feature. For those queues, software must issue the correct *Tx-Descriptor* Field with each quanta descriptor. When the queue is not configured for Drop support, the *Tx-Descriptor* field in the quanta descriptor is ignored.
cache_profile_idx	Static	2	166	167	Association of the queue to a quanta cache profile. Cache profile declare parameter can limit the number of quanta descriptors accumulated in the device cache per the Tx-Queue. This allows a per-queue fine tuning for Drop command response and single queue performance of the queue.

Table 10-28. LAN Tx-Queue Context in the QTXCOMM_CNTX Array [continued]

Alias	Type	Width (Bits)	LS Bit	MS Bit	Description
packet shaper profile idx	Static	3	168	170	Used in Legacy Host interface Queue (Queue Type #1). Some of the Tx-Scheduler nodes are configured for packet shaping. In Legacy queues, the number of packet in the quanta are not known in advance, The packet shaper profile defines a preliminary packets number. The Tx-Scheduler takes this number into consideration until the descriptors' fetch and update flow.
Internal Queue state	Dynamic	122	171	292	Internal queue state.

10.5.5.3 Quanta Profile

The E810 supports 16 quanta profile registers. Every enabled transmit queue is configured with an index to one of the 16 quanta profiles. Each quanta profile specifies resource limits each transmit queue can consume of the shared transmit pipeline. Resource limits include limiting the number of descriptors, commands, and size in bytes allowed per quanta. These limits enable the arbiter and scheduler to guarantee the desired transmit performance of high-priority queues by limiting sources of disruption from lower-priority queues.

The quanta Profiles span on 16 registers: GLCOMM_QUANTA_PROF[0..15]. The quanta profiles are auto-loaded from the NVM. They can be reconfigured by the active PFs. When reconfigured by a PF, the ownership is managed by the PFs itself.

The Field *QUANTA_SIZE* in the Profile is used to configure the quanta size in bytes. Used by hardware for LSO processing and for legacy queue. When it configures a legacy queue quanta size, the value must configured in 64-byte granularity (The five LSB must be set to 0).

The *QUANTA_SIZE* field is configured to a value between 256 bytes and 4 KB.

Notes:

- GLLAN_TCLAN_CACHE_CTL.*MIN_ALLOC_THRESH* represents descriptors fetching caching policy. This register needs to be configured to (the MAX between all Number of descriptors in a quanta from all Quanta Profiles) + 4.
- It is recommended that legacy queues will be configured to 1 KB quanta.

10.5.5.4 Quanta Descriptor Cache Profile

Cache profiles are used to fine tune quanta descriptor caching between highest single queue performance and faster response to Head Drop.

There are four quanta descriptor cache profiles used to configure the quanta descriptor cache behavior of any given transmit queue. As the case with most other descriptors, posted quanta descriptors are read ahead into local memory for fast access and processing by the scheduler. The quanta descriptor cache itself is a limited and shared resource. Cache profiles enable software to bias device processing preference to high priority queues over best effort queues.

Quanta descriptor caching has two related potential impacts to device performance. If insufficient cache is allocated to a given cache profile, single-queue transmit performance can suffer from excessive quanta descriptor fetch latency. Likewise, any queue that is subject to drop quanta doorbell commands from software should point to a cache profile that limits the number of pre-fetched quanta descriptors. Drop quanta doorbell commands can introduce unnecessary bubbles in the transmit pipeline as pre-fetched quanta must be drained from the transmit pipeline.

The Cache Profiles span on four registers: GLQDC_CFG_PRFL_1[0..3]. The cache profiles are auto-loaded from the NVM. They can be reconfigured by the active PFs. When reconfigured by a PF, the ownership is managed by the PF itself.

10.5.5.5 Packet Shaping Profile

Packet Shaping profile is used for Legacy Queues. When packet shaping is used, when queue is configured with advanced mode host interface, the number of packets in a quanta is provided by software in the doorbell and in the quanta descriptor.

If a queue is configured to legacy host interface, the number of packets is not provided by software. The queue is associated with Packet Shaping Profile, which provides a prediction per usage model queue type of the number of packets in a quanta, where its size is configured in Quanta Profile.

Packet Shaping Profile is an 8-CSRs structure: GLCOMM_PKT_SHAPER_PROF[0..7].

10.5.5.6 Doorbell Queue Configuration

Software is required to fully initialize the entire Doorbell Queue Context to zero prior to enabling the Doorbell Queue. The Doorbell Queue configuration can only be changed while the associated transmit queues are disabled. Read/Write operations to the context structure are performed via direct register access to the Doorbell Queue Configuration context QTX_COMM_DBLQ_CNTX[5][256].

The Doorbell Queue Context structure is detailed in Table 10-29.

Table 10-29. Doorbell Queue Context

Alias	Width (Bits)	LS Bit	MS Bit	Type	SW Init.	Description
Queue_addr	57	0	56	Static	Variable	Descriptor queue start address.
Reserved	7	57	63			Reserved.
Queue_length	13	64	76	Static	Variable	Queue length in descriptor units.
Reserved	3	77	79			Reserved.
PF_NUM	3	80	82			PF number.
Reserved	1	83	83			Reserved.
VF_NUM	8	84	91	Static	Variable	VF number.
Reserved	2	92	93			Reserved.
PFVF_TYPE	2	94	95			00b = Queue belongs to VF. 01b = Reserved. 10b = Queue belongs to PF. 11b = Reserved.
CPUID	8	96	103	Dynamic		
TPH Desc Rd	1	104	104	Static		
Reserved	3	105	107			Reserved.
TPH Desc Wr	1	108	108	Static		
Reserved	3	109	111	Static		Reserved.
DBL_Q_ENA	1	112	112	Static		Doorbell Queue Enable. When disabled, the queue is not scanned by the device.
Reserved	15	113	127			Reserved.

Table 10-29. Doorbell Queue Context [continued]

Alias	Width (Bits)	LS Bit	MS Bit	Type	SW Init.	Description
Read Head	13	128	140	Dynamic		Queue Head. Read by software. Written by hardware.
Reserved	3	141	143			Reserved.
Read Tail	13	144	156	Dynamic		Queue Tail. Written by software. Read by hardware.
Reserved	3	157	159			Reserved.

10.5.5.7 Completion Queue Configuration

Unlike many other queue usage models, Completion Queues are expected to be associated with a given CPU core. The expected usage model assumes that software is bound to a given CPU core, and furthermore schedules data for transmission on one or more transmit queues. The Completion Queue serves to aggregate transmit completions from multiple transmit queues to a single Completion Queue.

The Completion Queue is associated with one and only one PF or VF. All transmit queues that can post completion events must be associated with this associated PF or VF. The completions can be generated at various rates depending on the per-queue ITR settings.

Software is required to fully initialize the entire Completion Queue context structure to zero prior to enabling of the Completion Queue. The queue configuration can only be changed after all associated transmit queues are disabled. Read/Write operations to the context structure are performed via direct register access to the Completion Queue Configuration context GLTCLAN_CQ_CNTX[21][512].

The Completion Queue context structure is detailed in Table 10-30.

Table 10-30. Completion Queue Context

Field	Bit(s)	Type	Description
Queue Address	56:0	RW	Base Address of the Completion Queue. Completion Queue base must be cache-line aligned. This field does not contain the low seven bits of the address, which are always zero.
Reserved	63:57	RSV	Reserved.
Queue Length	81:64	RW	Completion Queue length in units of 16 completion descriptors. The Completion Queue length is a multiple of catch-lines. This field does not contain the low four bits of real Completion Queue length. Max Completion Queue length is 4M entries. This high number is to cover completion from multiple transmit queues in case software is delayed in completion entries processing.
Reserved	95:82	RSV	Reserved.
Generation	96	RW	Current generation bit. This bit is flipped every wraparound event.
WritePTR	118:97	RW	Current completion write pointer (0. 4M-1).
Reserved	127:119	RSV	Reserved.
PF_NUM	130:128	RW	PF number.
VMVF_NUM	140:131	RW	VM/VF number.
VMVF_TYPE	142:141	RW	00b = Queue belongs to VF. 01b = Queue belongs to VM. 10b = Queue belongs to PF. 11b = Reserved.

Table 10-30. Completion Queue Context [continued]

Field	Bit(s)	Type	Description
Reserved	159:143	RSV	Reserved.
TPH Desc Wr	160	RW	
CPUID	168:161	RW	
Reserved	191:169	RSV	Reserved.
Internal completions cache	703:192	RW	Internal cache of completions. Completions are written to the host as a full, aligned cache-line. If a write of a partial cache-line is required, the remaining bytes are padded out with zeros and with the opposite generation bit, such that software does not consider the padding as a completion.

Some other commands can be operated for a Completion Queue, like initiating VM reset marker and flushing out of internal Completion Queue cache. Those commands are operated using CSRs GLCOMM_CQ_CTL[512].

10.5.5.8 Tx-Queue Handling Admin Queue Commands

Table 10-31. Tx-Queue Handling Admin Queue Commands

Command	Opcode	Brief Description	Section Reference
Add Tx-Queues	0x0C30	This command configures queues in the PQM, configures leaf nodes in the PSM, and associates the queues with the leaf nodes. This command allocates leaf nodes. Software provides the parent node's TEID and number of queue to allocate. With the completion, a separate TEID is provided per each added queue.	10.5.5.8.1
Queues Disable	0x0C31	This command gets a list of QIDs, disables the Tx-Queues, and releases relevant Tx-Scheduler resources. This command serves both LAN queues and RDMA QSets	10.5.5.8.3
Move/Reconfigure Tx-Queues	0x0C32	This command reconfigures Tx-Queues in the E810. This AQ can be used to: 1. Restructure the Tx-Scheduler and move a leaf node or a group of leaf node from on parent to another. 2. Reconfigure the Tx-Queues' CGDs settings. 3. Both 1 and 2.	10.5.5.8.4
Add RDMA Queue Set	0x0C33	This command configures leaf nodes in the PSM and associate the queue sets with the leaf nodes. This command allocates leaf nodes. software provides the parent node's TEID and number of queue sets to allocate. With the completion, a separate TEID is provided per each added queue set.	10.5.5.8.2
Move RDMA Tx-Queue Sets	N/A	***Note:*** This is covered by Tx-Scheduler AQ command "Move Node". RDMA QSet CGD is managed inside the PE.	

10.5.5.8.1 Add Tx LAN Queues (0x0C30)

This command configures Tx-Queues in the E810, configures leaf nodes in the PSM, and associates the queues with the leaf nodes.

The command gets the following as input parameters:

- Number of added Queues Groups (a Queue Group is a group of queues that are added to a single Scheduling Parent).
- List of Parent Nodes' TEIDs. Each is the handle of the parent node of all added queues.
- Number of added queues in each Queue Group.
- List of Queue IDs (in the PF space).
- A queue context structure for each one of the queues.
- Tx-Scheduler leaf node bandwidth configuration parameters for each leaf node associated with add queue.

This command allocates leaf nodes. Software provides the parent node's TEID and number of queues to allocate. Upon completion, a separate TEID is provided per each added queue.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 10-32 describes command format and defines command specific fields.

Table 10-32. Add Tx LAN Queue Command Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C30	
Datalen	4-5		Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Queue Groups	16		Number of added queue groups. Each added queue group is associated with a structure inside the command buffer containing the parent TEID, the number of added queues in the group, and their queue IDs A maximum of 73 queue groups can be added in one AQ call. Since the command buffer containing the Queue Groups Structures is bounded to 4 KB, when adding many queues in each queue group, this number can be limited to the lower number of queue groups. 0 is an invalid value for this field. In the command response, this field returns the number of successfully-added queue groups (the first N added queue groups).
Reserved	17-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 10-33 describes format of the data buffer carrying additional command attributes and the response buffer.

Table 10-33. Add Tx LAN Queue Command and Response Buffer

Category	Byte.Bit	Field	Description
Per Queue Group Structure			Per each added queue group, a structure.
	0-3	Parent's TEID	The TEID of the parent node to which leaves are added.
	4	Number of Queues	Number of added queues (1..85).
	5-7	Reserved	Reserved.
Per-Queue Structure			Per-queue 48-byte structure.
	0-1 in per-queue structure	Tx Q ID	Tx-Queue ID in LAN space. The number is in PF space. Firmware is required to translate to global numbering.
	2-3	Reserved	Reserved. Must be set to 0.
	4-7	Queue TEID	In the command: Reserved In the response: Added Tx-Queue TEID.
	8-29	Tx-Queues Context Structure	Per each added queue, raw data structure of Q context 170 bits. The "Internal Queue State" is not included. It is reset by hardware.
	30-31	Reserved	Reserved. Must be set to 0.
Tx-Scheduler Leaf Node Configuration			The flow of adding a Tx-Queue includes adding of a Tx-Scheduler leaf node associated with it. The structure below is this node's configuration. The structure is identical to the node's configuration structure in "Add Scheduling Component" AQC.
	32	Reserved	Reserved. Must be set to 0.
	33	Valid Sections	Multiple sections can be valid at a given time. **Bit(s) Description** 0 = Generic section (Must be set to 1b.) 1 = CIR BW 2 = EIR BW 3 = Shared BW 4-7 = Reserved. When only the *EIR BW* (bit 2) is set, firmware configures EIR bandwidth only. When only the *Shared BW* (bit 3) is set, firmware configures SRL ID and switch node to SRL. When both *EIR BW* and *Shared BW* are set, firmware configures EIR, SRL and switch to SRL.
	34	Generic	**Bit(s) Description** 0 = Scheduling mode BPS (0) or PPS (1). 1-3 = Priority among siblings (0-7). 4 = Single priority node (1) or WFQ (0). 5-6 = Adjustment value (0-3) used in PSM Credit Update flow. 7 = Reserved.
	35	Reserved	Reserved.
	36-37	CIR BW Profile ID	
	38-39	CIR BW WFQ Weights (1-200)	
	40-41	EIR BW Profile ID	When the valid section has *Shared BW* set, this field is treated as reserved.
	42-43	EIR BW WFQ Weight (1 -200)	
	44-45	Shared RL Profile ID	When the valid section has *EIR BW* set, this field is treated as reserved.
	46-47	Reserved	Padding.

10.5.5.8.1.1 Software Activities Prior to Calling Add Tx LAN Queues AQ

- If a queue uses Completion Queue, then:
  - The Completion Queue ID is part of Tx-Queue context.
  - Completion Queue must be initialized by software and ready prior to associating a Tx-Queue to it.
  - Configuring of a Completion Queue is implemented directly by software with no firmware involvement.
- Quanta profile, Cache profile, and Packet Shaper profile that the Tx-Queue points to must be initialized before the association. This is done by software.
  - Profile configuration is implemented directly by software with no firmware involvement.

10.5.5.8.1.2 Software Activities After Add Tx LAN Queues AQ Completed

- Interrupt association with a specific queue is detailed in Section 9.1.2.1.
- Association of a Tx-Queue to DB queue is not reflected in hardware and not part of Add Tx LAN queue flow.

10.5.5.8.2 Add Tx RDMA Queue Sets (0x0C33)

This command configures leaf nodes in the PSM and associates the queue sets with the leaf nodes.

The command gets the following parameters as input:

- Number of added Queue Sets Groups.
  - Queue Set Group is a group of Queue Sets that are added to a single Scheduling Parent.
- List of Parent Nodes' TEIDs. Each is the handle of the parent node of all added queue sets.
- Number of added Queue Sets in each Queue Group.
- List of Queue Set IDs (in the PF space).

This command allocates leaf nodes. Software provides the parent node's TEID and number of queues to allocate. With the completion, a separate TEID is provided per each added queue set.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 10-34 describes command format and defines command specific fields.

Table 10-34. Add Tx RDMA Queue Sets Command Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C33	
Datalen	4-5		Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.

Table 10-34. Add Tx RDMA Queue Sets Command Fields [continued]

Name	Byte.Bit	Value	Remarks
Number of Queue Set Groups	16		Number of added queue set groups. Each added queue set group is associated with a structure inside the command buffer containing the parent TEID, number of added queue sets in the group, and their queue IDs. Maximum 127 queue set groups can be added in one AQ call. The E810 contains maximum 512 RDMA QSets. 0 is an invalid value for this field. In the command response, this field returns the number of successfully-added queue set groups (the first N added queue groups).
Reserved	17-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 10-35 describes format of the data buffer carrying additional command attributes and the response buffer.

Table 10-35. Add Tx RDMA Queue Sets Command and Response Buffer

Category	Byte.Bit	Field	Description
Per Queue Group Structure			Per each added queue group, a structure.
	0-3	Parent's TEID	The TEID of the parent node to which leaves are added.
	4-5	Number of QSets	Number of added queue sets (1..170).
	6-7	Reserved	Padding.
Per-Queue Structure			Per-QSet 4-byte structure.
	0-1 in per-queue structure	Tx QSet ID	Tx QSet ID in RDMA space. The number is in physical space.
	2-3	Reserved	Reserved.
	4-7	Queue TEID	In the command: Reserved In the response: Added Tx-Queue TEID.
Tx-Scheduler Leaf Node Configuration			The flow of adding a Tx-Queue includes adding of a Tx-Scheduler leaf node associated with it. The structure below is this node's configuration. The structure is identical to the node's configuration structure in "Add Scheduling Component" AQC.

Table 10-35. Add Tx RDMA Queue Sets Command and Response Buffer [continued]

Category	Byte.Bit	Field	Description
	8	Reserved	Reserved. Must be set to 0.
	9	Valid Sections	Multiple sections can be valid at a given time. **Bit(s) Description** 0 = Generic section (Must be set to 1b.) 1 = CIR BW 2 = EIR BW 3 = Shared BW 4-7 = Reserved. When only the *EIR BW* (bit 2) is set, firmware configures EIR bandwidth only. When only the *Shared BW* (bit 3) is set, firmware configures SRL ID and switch node to SRL. When both *EIR BW* and *Shared BW* are set, firmware configures EIR, SRL and switch to SRL.
	10	Generic	**Bit(s) Description** 0 = Scheduling mode BPS (0) or PPS (1). 1-3 = Priority among siblings (0-7). 4 = Single priority node (1) or WFQ (0). 5-6 = Adjustment value (0-3) used in PSM Credit Update flow. 7 = Reserved.
	11	Reserved	Reserved.
	12-13	CIR BW Profile ID	
	14-15	CIR BW WFQ Weights (1-200)	
	16-17	EIR BW Profile ID	
	18-19	EIR BW WFQ Weight (1 -200)	
	20-21	Shared RL Profile ID	
	22-23	Reserved	Padding.

10.5.5.8.2.1 Software Activities Prior to Calling Add Tx RDMA Queue Sets AQ

No specific requirements from software.

10.5.5.8.2.2 Software Activities After Add Tx RDMA Queue Sets AQ Completed

- Interrupt association with a specific Q is detailed in Section 9.1.2.3.
- With the Initialized QSet ID, software uses the QSet ID when calling the related RDMA AQs to associated RDMA QPs with the Initialized QSet.

10.5.5.8.3 Transmit Queue Disable Flow - LAN and RDMA (0x0C31)

In this command, software provides a list of Tx-Queue or RDMA QSet IDs that need to be closed. The AQ must be called after software stops feeding the closed queues (stop sending doorbells). RDMA QSet can be closed only when it is not associated with any QP.

The command gets the following parameters as input:

- Number of disabled Queues/QSets.
- List of Queue or QSet IDs (in the PF space).

This command deallocates nodes (in leaf layer and possibly in intermediate layers as well) in the Tx-Scheduler. Inside the command structure, the disabled queues are organized in groups. Each group includes queues belonging to one parent node in the Tx-Scheduler structure. This organization in group is added to ease the interface between the software and firmware. It is not required to disable all the queues belonging to a parent in one call.

This command is called by software as part of the queue disabling flow. As part of this command flow, the EMP firmware drains the Tx-Pipe of any in-flight packets (packets that are scheduled for transmission by the Tx-Scheduler but have not yet been transmitted) of all disabled Tx-Queues or RDMA QSets. This is required to verify that no Tx completion is posted to software after the queue resources are released or even re-used.

Normally, the pipe draining flow requires a very short delay. A long (or endless) flow control event that blocks the transmit of one or more TCs (or even the entire port transmit) affects the pipe draining flow as well.

This command is completed when all in-flight packets belonging to the Disabled LAN Queues or RDMA QSets have left the Tx-Pipe. Alternately, the command is called with a timeout parameter. If the EMP firmware waits more than the timeout time, it responds with EAGAIN error code. With the EAGAIN error code, firmware also provides a bitmap that marks which of the Congestion Domains is blocked by the long flow control.

Software must re-call this command (with the *Call-Again* flag set) prior to releasing and reusing of any of the Tx-Queues that are associated with the blocked congestion domains.

This command must be fully completed (all Tx-Queue or RMDA QSets are released) prior to any other calling to it for other queues, and prior to calling to “Move/Reconfigure Tx LAN Queues” AQC.

The command’s timeout is posted by software as part of the command’s parameters.

Software can also instruct the EMP firmware to force the Tx-Pipe to flush out and drop all packets from the blocked congestion domain. It is the PF’s responsibility and authority to make the decision when to consider a long flow control as a malicious link partner behavior.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 10-36 describes command format and defines command-specific fields.

Table 10-36. LAN Transmit Queue Disable Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C31	
Datalen	4-5		Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Type and Flags	16		**Bits 0:1:** 00b = Queue Disable with no function reset. Must be set to 1. 01b = Reserved. Must be set to 0. 10b = Reserved. Must be set to 0. 11b = Reserved. Must be set to 0. **Bit 2:** 0b = This is an initial call. 1b = This is a subsequent call. **Bit 3:** 0b = Return EAGAIN on timeout. 1b = Flush pipe on timeout. **Bits 4:7:** Reserved. Must set to zero. ***Note:*** Bits 2 and 3 are **NOT** mutually exclusive.
Number of Queue Groups	17		In the command: Number of Disabled Queue Groups (0..127) involved in the Q disable flow. ***Note:*** For the VF/VM reset flow, there might be 0 groups for VFs without queues. In the response: Number of fully-processed groups.
Reserved	18-19.1		Reserved. Must be set to 0.
Timeout Time	19.2-19.7		Command timeout in units of 100 micro seconds. Valid values are 0-50. If this field is 0, the AQ will return “EAGAIN”.
Blocked CGDs	20	0	Zeroed by the driver. A bitmap of blocked CGDs. Set by EMP firmware when returns with EAGAIN.
Reserved	21-23	0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 10-37 describes format of the data buffer carrying additional command attributes. The command buffer includes a structure per involved Queues group.

Table 10-37. LAN Transmit Queue Disable Command Buffer[1]

Category	Byte.Bit	Field	Description
Group #1	0-3	Parent's TEID	The TEID of the parent node to which leaves are involved.
	4	Number of Queues	(1...128).
	5	Reserved	Reserved.
	6-7.6	Queue #1	Tx-Queue ID in PF space of the first queue to be closed.
	7.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	8-9.6	Queue #2	Tx-Queue ID in PF space of the second queue to be closed.
	9.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	. . .		
		Queue #N	Tx-Queue ID in PF space of queue N to be closed.
		QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
		Padding	Alignment to 4-byte units.
. . .			
Group #N	0-3	Parent's TEID	The TEID of the parent node to which leaves are involved.
	4	Number of Queues	(1...128).
	5	Reserved	Reserved.
	6-7.6	Queue #1	Tx-Queue ID in PF space of the first queue to be closed.
	7.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	8-9.6	Queue #2	Tx-Queue ID in PF space of the second queue to be closed.
	9.7	QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.
	. . .		
		Queue #N	Tx-Queue ID in PF space of queue N to be closed.
		QSet/LAN Queue	Marks if this ID points to a LAN Queue or to a RDMA QSet. 0b = LAN Queue. 1b = RDMA QSet.

1. The command buffer include a structure per involved Queues group.

10.5.5.8.3.1 Software Activities Prior to Calling Transmit Queue Disable

- Software must stop sending doorbells to the disabled queues before closing them.
- For Tx-Queues that are associated with Doorbell Queue, the Doorbell Queue must be drained from any doorbell massage of the disabled queues.
  - This is done by sending a draining marker through the Doorbell Queue. A Doorbell Queue descriptor with *Dummy* and *RS* bits set acts as a drain marker.
- Stop getting interrupts for the disabled queue(s):
  1. Software should clear the *CAUSE_ENA* bit in the QINT_TQCTL register for all disabled queues.
  2. Software waits 100 ns.
  3. Software sends software interrupt for the vector associated with the queue.
  a. When interrupt arrives, software can continue.
- In case of a VM reset or multiple queues disable, software does Step 1 for all disabled queues, and Step 3 for all vectors associated with the queues.

10.5.5.8.3.2 Software Activities After Transmit Queue Disable AQ Completed

- Once the whole operation is complete and the pipe is cleaned from the disabled queues, EMP firmware responds with "No Error" and software can re-use all involved resources.
- Software can post a VM reset notification via the Completion Queue. This is done directly to each involved Completion Queue using CSRs GLCOMM_CQ_CTL[512].

10.5.5.8.4 Move/Reconfigure Tx LAN Queues (0x0C32)

This command reconfigures Tx-Queues in the E810. This AQ can be used to:

1. Restructure the Tx-Scheduler and move a leaf node or a group of leaf nodes from on parent to another.
2. Reconfigure the Tx-Queues' CGDs settings.
3. Both 1 and 2.

The command gets the following parameters as input:

- Number of involved queues.
- Source parent node's TEID.
- Destination parent node's TEID.
- List of queue IDs (in the PF space) and their new CGDs configuration.

By this command, software can instruct the EMP firmware to move nodes belonging to one sibling group. The moved nodes can be the entire group or part of it.

This command is usually called as part of DCBX flow. It allows moving some of the queues between TCs or CGDs.

As part of this flow, the Tx-Scheduler structure is updated in parallel to changing the CGD setting of the LAN Tx-Queues. Moved RDMA QSet CGD setting is managed internally in the RDMA block. It is under software responsibility to call the RDMA CQP for the updating of the moved RDMA QSet contexts.

When CGD association of LAN queue is changed as part of this command flow, the EMP firmware drains the Tx-Pipe of any in-flight packets (packets that are scheduled for transmission by the Tx-Scheduler but have not yet been transmitted) of all updated Tx-Queues. This is required to prevent out-of-order transmission or completion.

Normally, the pipe draining flow requires a very short delay. A long (or endless) flow control event that blocks the transmit of one or more TCs (or even the entire port transmit) affects the pipe draining flow as well.

This command is completed when all in-flight packets belong to the disabled LAN queues or RDMA QSets left in the Tx-Pipe. Alternately, the command is called with a timeout parameter. if the EMP firmware waits more than the timeout time, it responds with EAGAIN error code. With the EAGAIN error code, firmware also provides a bitmap that marks which of the Congestion Domains is blocked by the long flow control.

Software must re-call this command (with the *Call-Again* flag set) prior to updating any of the Tx-Queues that are associated with the blocked congestion domains.

This command must be fully completed (all Tx-Queues drained) prior to any other calling to it for other queues, and prior to calling to "Transmit Queue Disable Flow (LAN and RDMA)" AQC.

The command's timeout is posted by software as part of the command's parameters.

Software can also instruct the EMP firmware to force the Tx-Pipe to flush out and drop all packets from the blocked congestion domain. It is the PF's responsibility and authority to make the decision when to consider a long flow control as a malicious link partner behavior.

Note: This command is an atomic command. EMP firmware must verify it can complete the entire command prior updating any Tx-Queue context or moving any element in the Tx-Scheduler hierarchy.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 10-38 describes command format and defines command specific fields.

Table 10-38. Move/Reconfigure Tx-Queues Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C32	
Datalen	4-5		Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.

Table 10-38. Move/Reconfigure Tx-Queues Command and Response Fields [continued]

Name	Byte.Bit	Value	Remarks
Command Type and Flags	16		**Bits 0:1:** 00b = Reserved. Must not be used. 01b = Move nodes with no TC change. 10b = TC change, with no nodes movement. 11b = Both nodes movement and TC change. **Bit 2:** 0b = This is and initial call. 1b = This is a subsequent call. **Bit 3:** 0b = Return EAGAIN on timeout. 1b = Flush pipe on timeout. **Bits 4:7:** Reserved. Must set to zero. ***Note:*** Bits 2 and 3 are **NOT** mutually exclusive.
Number of Queues	17		Number of moved queues. In the command response, this field returns the number of successfully-moved queues (the first N moved queues).
Reserved	18-19.1		Reserved. Must be set to zero.
Timeout Time	19.2-19.7		Command timeout in units of 100 micro seconds. Valid values are 0-50. The two LSB are unused to keep coherency with other commands.
Blocked CGDs	20	0	Zeroed by the driver. A bitmap of blocked CGDs. Set by EMP firmware when returns with EAGAIN.
Reserved	21-23	0	Reserved
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 10-39 describes format of the data buffer carrying additional command attributes and the response buffer

Table 10-39. Move/Reconfigure Tx-Queues Command and Response Buffer

Category	Byte.Bit	Field	Description
	0-3	Source TEID	Source Parent TEID. The parent of the leaf nodes before moving.
	4-7	Destination TEID	Destination Parent TEID. The parent of the leaf nodes after moving.
Per-Queue Structure			Per-queue 8-byte structure.
	0-1 in per-queue structure	Tx Q ID	Tx Q ID in LAN. The number is in PF space. Firmware is required to translate to global numbering
	2	Queue CDG	0..7
	3	Reserved	Reserved. Padding. Must be set to zero.
	4-7	Queue TEID	Tx-Queue Leaf node TEID.

10.5.5.8.4.1 Software Activities Prior to Calling Move/Reconfigure Tx LAN Queues AQ

No specific requirements from software.

10.5.5.8.4.2 Software Activities After Move/Reconfigure Tx LAN Queues AQ Completed

No specific requirements from software.

10.5.6 Packet Transmission

During nominal operation, the function that owns the queue (PF or VF) accesses the hardware directly. To transmit a packet, software prepares transmit descriptors starting at the descriptor indicated by the *TQTAIL* pointer in the relevant QTX_TAIL register. The descriptors point to the transmitted packet. After the descriptors are ready in the Tx-Queue, software notifies the hardware. This notification is called a doorbell. The doorbell flow is different between the legacy mode and the advanced mode, as detailed in Section 10.5.6.1 and Section 10.5.6.2. A doorbell can be pushed directly to the proper address in the PCIe space or to issue it into the Doorbell Queue, coalescing multiple doorbell notifications in the Doorbell Queue before issuing a Doorbell Queue doorbell to push them to the device.

10.5.6.1 Transmit Doorbell Flow in Legacy Mode

1. Software updates queue tail (*TQTAIL*) using registers QTX_COMM_DBELL [16K].
2. Software updates *TQTAIL* at whole structures boundaries. For TSO, it is the whole TSO; for a single packet, it is the whole packet; and for filter programming, it is the whole packet that is associated with the filter programming. Updating *TQTAIL* to point into the middle of a multi-descriptor operation can trigger a Malicious Driver Detection (MDD) event and halt the queue.
3. The software should never set the *TQTAIL* to a value above the descriptors owned by the hardware minus 1. Descriptors considered as "owned by the hardware" are those already indicated to the hardware, but are not yet reported as completed. Overrunning the queue triggers an MDD event.
4. The hardware reports completed descriptors only for those ones indicated by an *RS* or *RE* (or both) bit in the *CMD* field in the descriptor. As part of the ITR expire flow, hardware reports the latest head, even if it is not marked with *RS* or *RE* bits. Completion indication is provided in one of two modes as programmed by the *HEAD_WBEN* parameter in the queue context as follows:
   - Descriptor Write-Back: The hardware changes the value of the *DTYPE* field in the completed descriptor to a 0xF (*DTYPE* equals to 0xF is reserved for completed descriptor indication). Besides the *DTYPE* field, the rest of the descriptor fields can remain as is or be changed by hardware.
   - Completion Queue Event: For details of the data written back, see Section 10.5.4.5, "Completion Queue (CQ) Descriptor".

10.5.6.2 Advanced Transmit Mode

Advanced transmission is a per Tx-Queue configured mode. In advanced mode, the actual quanta request is provided by software prior to scheduling. This enables the Tx-Scheduler to make more accurate decisions and to more efficiently control this queue's burstiness.

As described in Section 10.5.4.4, quanta descriptors describing the size of a quanta are queued to the device prior to en-queuing data packets for transmission (doorbell). Software uses two interfaces to feed the scheduled quanta to the device.

- **Doorbell** — For each new packet or packets, the software writes to a CSR QTX_COMM_DBELL[16K], advancing the transmit descriptor ring tail pointer and providing additional metadata used to schedule packets.
- **Quanta Descriptor** — Detailed in Section 10.5.4.4.

The following subsections detail the Doorbell and the Quanta Descriptor.

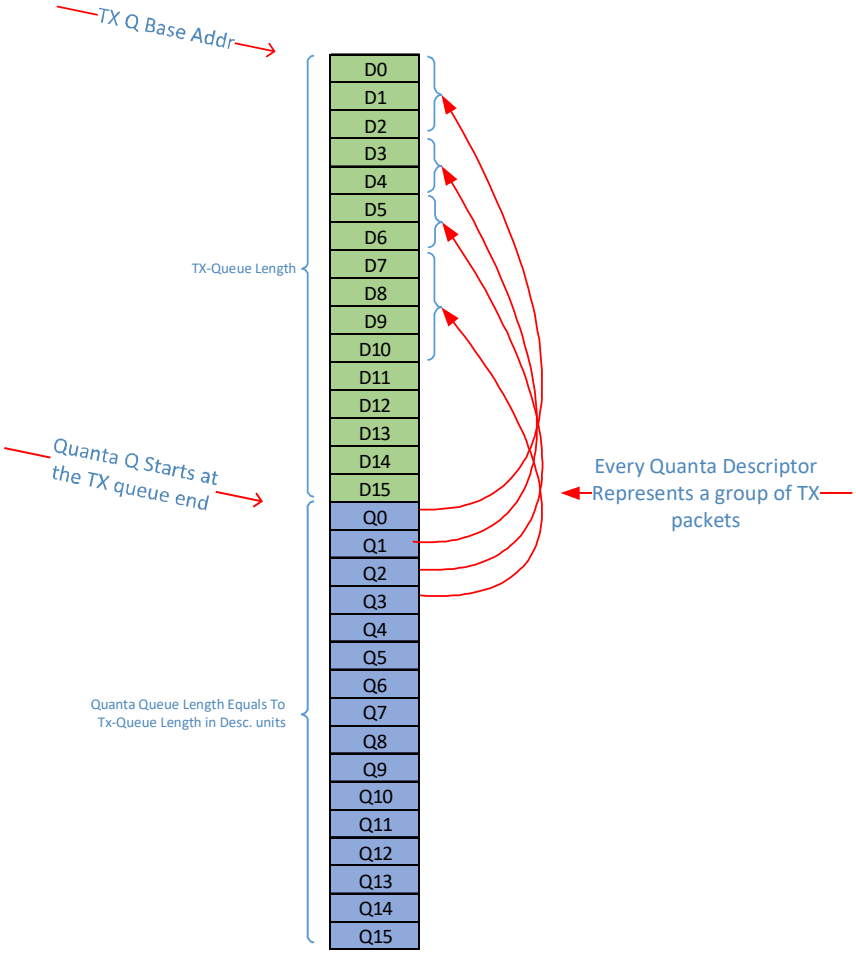

Figure 10-10. Quanta Descriptor and Data Descriptor

Note: When the transmit descriptor queue is smaller than 32, software must complete and close a quanta for every transmitted packet.

Prior to transmitting data on a transmit queue, software is assumed to have a queue-specific burst size, which is defined as the quanta size. The quanta size, in addition to the quanta profile, is used as a hint by the device to implement the WFQ transmit arbitration and scheduling algorithm. In addition, an associated Quanta Descriptor Ring (QDR) is initialized by software. The quanta queue reflects the actual transmit data posted by software to a given transmit queue.

Software allocates a Transmit Descriptor Ring (TDR), followed immediately and contiguously by the corresponding QDR. Unlike the TDR, the QDR does not have explicit head and tail pointer registers. Instead, software implicitly advances the QDR tail pointer by completing one quanta context in the TDR doorbell write. Every transmit descriptor queue, when operated in advanced transmit mode, must have a corresponding quanta descriptor ring of equal length.

As software initializes transmit descriptors in the transmit ring, software writes to the associated transmit queue doorbell register, posting one or multiple transmit descriptors. In addition, software initializes a quanta descriptor in the QDR to track the data bytes consumed per quanta.

The quanta size can change from one quanta to the next. As additional packet headers can be transparently added to transmitted packets by hardware, hardware also tracks the actual physical bandwidth used on a per packet basis when managing the posted quanta descriptors.

For SSO packets, software posts a quanta descriptor under these conditions:

- Whenever the total amount of pending transmit data equals or exceeds the expected quanta size.
- Whenever the total number of posted transmits is about to exceed 54 descriptors.
- Whenever a TCP Segmentation Offload is requested, the E810 automatically closes a previous quanta context and starts a new quanta descriptor context.

Under the expected usage model for this operating mode, software is expected to generally batch doorbell writes to the device spanning multiple transmit descriptors, and close out quanta descriptors simultaneously.

For non-TSO (SSO) packets, software would perform the following:

1. Software writes out transmit context and data descriptors to the Tx-Queue. See Section 10.5.3.1 for detailed structures.
2. Software internally accumulates the pending amount of posted transmit data and increments a pending packet count.
3. When a quanta needs to be closed (based on the above criteria), software:
    a. Rounds up total amount of pending data to the nearest 64-byte unit.
    b. Updates the current QDR entry and advances software's QDR write pointer.
    c. A transmit doorbell is sent to the device. The doorbell contains the new Tail, the amount of added data from the last doorbell (in 64-byte units rounded up), and the *Quanta Completed* bit is set to one. See Table 10-23.

Software can post a transmit doorbell without closing the current quanta (including for each and every packet) simply by not setting the *Quanta Completed* bit in the TDR doorbell write. Packets transmitted into an otherwise empty transmit queue are considered immediately for transmission based solely on the transmit doorbell contents.

For TSO messages, software would perform the following:

1. Software writes out transmit context and data descriptors to the TDR. See Section 10.5.3.1 for detailed structures.
2. If software has accumulated pending non-TSO (SSO) transmit data and has an open quanta context:

a. Software rounds up total amount of pending data to the nearest 64-byte unit.

b. Software updates the QDR entry and advance write pointer.

c. Hardware automatically closes any previous open quanta on LSO.

3. For TSO, software initializes a quanta descriptor for each TSO message:

   a. Software provides the exact number of bytes in byte-level granularity. Software updates the current QDR entry.

   b. A transmit doorbell is sent to the device. The doorbell format is detailed in Table 10-24.

Note: The minimum supported TSO MSS is 88. Whenever the supplied MSS is less than 256 bytes, the resulting TSO segments generated would be scheduled for transmission as if the MSS was 256 bytes.

- The above applies for both the TSO Quanta Descriptor and the TSO Doorbell (*First Quanta Length*).

In TSO message, a quanta must not span on more than 16 Tx-Descriptors including the context descriptor and header buffers.

10.5.6.3 Head Drop via Quanta Expiration

As software initializes SSO quanta descriptors with the associated transmit data descriptors on the transmit queue, software can specify an expiration timestamp. If the individual packets associated with the transmit quanta end up being selected for transmission later than the given timestamp, the packets are internally dropped by the transmit pipeline. Packets can be delayed for a variety of reasons, such as transient transmit scheduling contention, traffic class pause, or other.

The specific packets that are dropped are explicitly identified by Completion Queue notifications.

Note: Quanta expiration is enabled only for queue type #3 (advanced host interface with no TSO).

10.5.6.4 Head Drop via Drop Request

Software can also determine after the fact, that various packets that have been posted to the transmit queue should be dropped. One example could be either the transmit queue length has grown beyond some software-defined threshold, or other method to track forward progress of packets on a given transmit queue.

In this situation, software can utilize an explicit drop doorbell (or use the drop doorbell command) to signal hardware that one or more quanta be dropped from the head of the transmit queue. As one or more packets can be associated with a quanta, several packets can be dropped at once from the head of the queue. If the affected packets have been selected for transmission, a late drop notification is passed through the transmit pipeline.

Note: Head Drop is enabled only for queue type #3 (advanced host interface with no TSO).

If late packet transmission is an ongoing issue, the situation suggests a system configuration and usage issue. Various statistics can be queried from the various PF instances to determine the source of scheduling contention.

Hardware accumulates the drop requests and executes the drops when a Tx-Queue is scheduled for transmission. The internal drop accumulator is a 7-bit counter per Tx-Queue. It can accumulate up to 127 quantas drop request. Overflow is silently ignored. When the Tx-Queue is empty, any drop request is ignored and the accumulator is reset.

10.5.6.5 Quanta Size Selection

Quanta sizes are used in combination with the various packet scheduler rules to implement packet pacing, while simultaneously interleaving packet transmissions from other queues on the device. For legacy LAN queues with TSO enabled, the device's internal data cache is optimized for 1 KB quanta sizes. Use of larger quanta values reduces the number of simultaneously-active queues that can be in use and still meet device performance objectives.

Quanta values are further governed by the quanta profile referenced in the queue context. The quanta profile places limits on the number of descriptors as well as the number of commands per quanta. These upper bounds ensure a queue (perhaps used by an untrusted VF) cannot be used in such a manner as to deliberately skew the internal queue arbiter to service a queue more frequently than other queues. Attempts to exceed these profile thresholds triggers a malicious driver detection event to the associated PF.

10.5.7 Performance Consideration

Tx path is required to operate 80 MPPS for packets with one data descriptor with no context descriptor, or with context descriptor when the next conditions are true:

- TSO bit is cleared.
- TSYN is cleared or TSYN is disabled in queue context.
- SWICH field != TARGET_VSI

10.5.8 Stateless Transmit Offloads

10.5.8.1 Insert Ethernet CRC Bytes

See Section 7.12.1.1.

10.5.8.2 Insert L2 Tags (VLAN)

See Section 7.12.3.2 for a complete description of L2 tag insertion. This section provides some rules relating to the supported headers for which L2 tag can be inserted by the device. See Figure 10-11 for the structure of the supported packets, and Table 10-40 for the L2 tag insertion.

Table 10-40. Transmit L2 Tag Insertion Offload

Packet Type	Parsing Hints in the Transmit Descriptors	L2 Tag Insertion Supported
Non-tunneled packet	MACLEN = the length of the L2 header provided by the software.	Insert L2 tags depending on IL2TAG1 and IL2TAG2 setting. The L2 tags are inserted after.
NSH over L2 packet	MACLEN = the length of the L2 header provided by the software up to including the NSH header.	
MAC in MAC packet	MACLEN = the length of the 2 x L2 headers provided by the software.	Yes, only for the inner L2 header depending on IL2TAG1 and IL2TAG2 setting. The L2 tags are inserted after.
IP in UDP tunneling or IP in GRE	Same as non-tunneled packet.	

Table 10-40. Transmit L2 Tag Insertion Offload [continued]

Packet Type	Parsing Hints in the Transmit Descriptors	L2 Tag Insertion Supported
MAC in UDP tunneling or MAC in GRE	MACLEN = same as non-tunneled packet.	
	= The length of the tunneling UDP or GRE up to the inner IP header (including optional NSH or MPLS)	Insert VLAN after NATLEN if IL2TAG_IL2H is set. ***Note:*** The IL2TAG2 and IL2TAG_IL2H are mutually exclusive (only one of them can be set). Inner VLAN insertion offload should not be requested if MPLS follows the tunneling MAC header.

10.5.8.3 Transmit L3 and L4 Integrity Offload

The E810 can offload the following L3 and L4 integrity checks:

- IPv4 header(s) checksum for "simple" and tunneled packets.
- Inner TCP or UDP checksum.
- Tunneling UDP checksum.
- SCTP CRC integrity.

If a checksum is required, software should provide it, as well as the inner checksum value(s) that are required for the outer checksum. To request L3 and L4 integrity offloads, software should define the packet format and the required offload in the transmit descriptors as described in Figure 10-11 and Table 10-42.

Some rules for integrity offload are:

- Offloads for inner headers to an IPv6 header with fragment extension header or fragmented IPv4 packets do not make sense. Note that this rule is not enforced by the E810.
- IPv6 support: The pseudo header for the L4 checksum takes into account the addresses in the IPv6 header ignoring the optional extension headers. Packets with Routing Header type 2 or Destination Options Header with Home Address option contain an alternative IP Address in the extension header. Therefore the OS should not request checksum nor segmentation offload for packets with routing extension header type 2 or Destination Options Header with Home Address option.
- IP Header Length requirements (IPLEN and EIPLEN):
  - In case of a non-tunneled packet, the IPLEN defines the IP header length in DWord units, and the IIPT defines the IP header type.
  - In case of tunneled packets, the IPLEN defines the inner IP header length, and the EIPLEN defines the outer (external) IP header length. The IIPT defines the inner IP header type, and the EIPT defines the outer IP header type.
  - The Length field in the IP header is prepared by the software in the packet buffers. This length field includes the payload of the IP header. In MAC tunneling, the inner MAC header (including optional VLAN tag) is part of the outer IP header payload. This optional VLAN tag can be embedded in the packet buffers or by using the IL2TAG_IL2H option in the transmit context descriptor. Regardless of the above, the optional VLAN tag should be taken into account in the length field of the outer IP header.
  - For IPv4, it should be at least 20 bytes (basic header size), and not more than 60 bytes.
  - For IPv6, it should be at least 40 bytes (basic header size), and up to the maximum size enabled by the parsing fields for basic IPv6 header and its extension headers.

- L4 Header Length requirements (L4LEN):
  - For TCP, it should be at least 20 bytes (basic header size), and not more than 60 bytes.
  - For SCTP, it should be set to 12 (SCTP common header size).
  - For UDP, it should be set to 8 (UDP header size).

Table 10-42 lists all supported packet formats and the processed integrity. The table uses the following notations:

- **IP** — A generic term for IPv4 header or IPv6 header. The IPv4 header can have IP option headers and the IPv6 header can have IPv6 extension headers.
- **L4** — A generic term for UDP, TCP, or SCTP headers.
- **IP checksum** — Meaningful only for IPv4.
- **Checksum** — A generic term for UDP and TCP checksum as well as SCTP CRC integrity.

Offload details:

- IPv4 checksum calculation (both inner and outer IP header for tunneled packets):
  - The software should set the IPv4 checksum to zero.
  - The hardware calculates the IPv4 header checksum starting at the beginning of the IPv4 header up to the end of the header.
- Outer UDP checksum calculation (UDP tunneling):
  - The software provides the pseudo IP header checksum in the outer UDP header.
  - The hardware calculates the UDP checksum starting at the beginning of the tunnel header up to the end of the packet, which includes the pseudo header provided by software.
- UDP and TCP checksum calculation (inner L4 header in case of UDP/GRE tunneling):
  - The software provides the pseudo IP header checksum in the L4 header.
  - The hardware calculates the L4 checksum starting at the beginning of the L4 offset up to the end of the packet, which includes the pseudo header provided by software.
- See Table 10-41 for details of the fields that the software device driver should fill when sending a packet.
- SCTP CRC calculation (inner L4 header in case of UDP/GRE tunneling):
  - The software should set the CRC in the header to zero.
  - The hardware calculates the CRC according to SCTP standard starting at the beginning of the SCTP header up to the end of the packet.
- Tunneling UDP/GRE Header Length requirements:
  - For UDP/GRE tunneling, the header can be any value in 2-byte granularity from eight bytes (bare UDP header) and up to 254 bytes (including optional network key and optional inner L2 header up to including the last EtherType). Note that the header length includes only those bytes provided in the packet buffers in host memory.

Table 10-41. Pseudo Header Pre-Loaded Values

Field	Single Send Packet (No TSO)	Transmit Segmentation Offload (TSO)
Outer IP Length	**IPv4**: IP header +payload size **IPv6**: Payload size only, including header extensions. Should match the data size stored in host memory. (Hardware modifies it upon offloads.)	Don't care. (calculated by hardware.)
Outer L4 (UDP) Length	UDP Header size + Payload size Should match the data size that stored in host memories. (Hardware modifies it upon offloads.)	Don't care. (calculated by hardware.)
Outer L4 CS field	IP header pseudo checksum, calculated on IP header fields: **IPv4**: Source addr +Destination addr + Protocol (=0x11) + "UDP Length" **IPv6**: Source addr +Destination addr + NextHeader (=0x11) + "UDP Length" ***Note:*** UDP Length is the payload that follows the IP header. It includes the size of UDP header and data.	IP header pseudo checksum, calculated on IP header fields. Not including "UDP Length": **IPv4**: Source addr +Destination addr + Protocol (=0x11) **IPv6**: Source addr +Destination addr + NextHeader (=0x11)
Inner/Single IP Length	**IPv4**: IP header +payload size **IPv6**: Payload size only, including header extensions. Should match the data size stored in host memory. (Hardware modifies it upon offloads.)	Don't care. (calculated by hardware.)
Inner/Single L4 (UDP/ TCP) Length	Header size + Payload size Should match the data size that stored in host memories. (Hardware will modify it upon offloads.)	Don't care. (calculated by hardware.)
Inner/Single L4 CS Field	IP header pseudo checksum, calculated on IP header fields: **IPv4**: Source addr +Destination addr + Protocol + "L4 Length" **IPv6**: Source addr +Destination addr + NextHeader + "L4 Length" *Protocol* or *NextHeader* values are 0x11 for UDP and 0x6 for TCP. ***Note:*** L4 Length is the payload that follows the IP header. It includes the size of L4 header and data.	IP header pseudo checksum, calculated on IP header fields. Not including "L4 Length": **IPv4**: Source addr +Destination addr + Protocol **IPv6**: Source addr +Destination addr + NextHeader *Protocol* or *NextHeader* values are 0x11 for UDP and 0x6 for TCP.

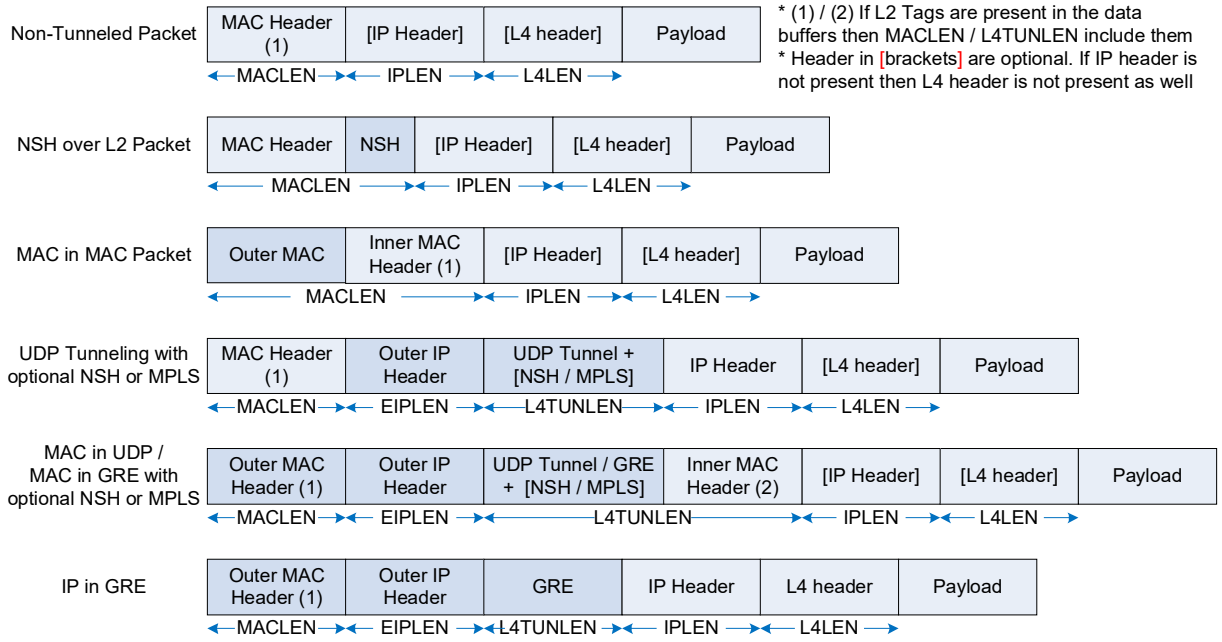

Figure 10-11. Transmit L3 and L4 Header Lengths (in Host Memory) for Integrity Offload

Table 10-42. Transmit Integrity Offload for Packet Types

Packet Type	Parsing Hints and Offload Enablement in the Transmit Descriptors[1,2]	Supported Transmit Checksum Offload
Fragmented IPv4 or IPv4 -> Unknown	IIPT = 10b or 11b. L4T = 00b (unknown).	IPv4 checksum if IIPT = 11b.
Fragmented IPv6 or IPv6 -> Unknown	IIPT = 01b. L4T = 00b (unknown).	None.
IP -> L4	IIPT = 10b or 11b for IP.v4. IIPT = 01b for IPv6 IPLEN = The length of the IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). L4LEN = L4 header length. EIPT = EIPLEN = L4TUNT = 0 (no tunneling).	IPv4 checksum if IIPT = 11b: L4 checksum if L4LEN is meaningful (i.e., L4T <> 0).
IP -> (Fragmented IP or IP -> Unknown)	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 00b (unknown). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 00b (no L4 tunneling).	Inner IPv4 checksum if IIPT = 11b. Outer IPv4 checksum if EIPT = 11b. No L4 checksum.

Table 10-42. Transmit Integrity Offload for Packet Types [continued]

Packet Type	Parsing Hints and Offload Enablement in the Transmit Descriptors[1,2]	Supported Transmit Checksum Offload
IP -> IP -> L4	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 00b (no L4 tunneling).	Inner IPv4 checksum if IIPT = 11b. Outer IPv4 checksum if EIPT = 11b. L4 checksum if L4LEN is meaningful (i.e., L4T <> 0).
IP -> (Tunneling UDP/GRE) -> IP -> L4	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 01b for UDP/GRE tunneling. L4TUNLEN = Tunneling header length.	Same as IP -> IP -> L4.
IP -> (Tunneling UDP/GRE) -> (Fragmented IP or IP -> Unknown)	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 00b (unknown). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 00b (no L4 tunneling).	Same as IP -> (Fragmented IP or IP -> Unknown).

Table 10-42. Transmit Integrity Offload for Packet Types [continued]

Packet Type	Parsing Hints and Offload Enablement in the Transmit Descriptors[1,2]	Supported Transmit Checksum Offload
IP -> (Tunneling UDP/GRE) -> [NSH/MPLS] -> MAC (w/wo VLAN) -> IP -> L4	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 01b for UDP/GRE tunneling. L4TUNLEN = UDP/GRE header length in the packet buffers up to excluding the inner IP header.	Same as IP -> IP -> L4 plus tunneling UDP checksum.
IP -> (Tunneling UDP/GRE) -> [NSH/MPLS] -> MAC (w/wo VLAN) -> (Fragmented IP or IP -> Unknown)	IIPT = 10b or 11b for inner IPv4. IIPT = 01b for inner IPv6. IPLEN = The length of the inner IP header (including IP optional or extension headers). L4T = 00b (unknown). EIPT = 10b or 11b for outer IPv4. EIPT = 01b for outer IPv6. EIPLEN = The length of the outer IP header (including IP optional or extension headers). L4TUNT = 01b for UDP/GRE tunneling. L4TUNLEN = UDP/GRE header length in the packet buffers up to excluding the inner IP header.	Same as IP -> (Fragmented IP or IP -> Unknown).

1. Common settings to all cases: When context descriptor is used, the TSO flag should be cleared.
2. When IP-IP or other supported tunneling is transmitted, a context descriptor must be used to provide the additional fields types and sizes. For non-tunneled packets, the context descriptor might be needed for other offloads than checksum. The values indicated in this table assume that the context descriptor is used.

10.5.8.4 Transmit Segmentation Offload (Also Known as TSO or LSO)

Transmit Segmentation Offload (TSO, also called Large Send Offload - LSO) enables the TCP/IP or UDP/IP stack to pass a ULP datagram larger than the Maximum Transmit Unit (MTU) size to the network device. The E810 divides the large ULP datagram to multiple segments according to the MTU size, as illustrated in the Figure 10-12. The size of the ULP datagram supported for TSO can be as small as a single byte (obviously transmitted on a single segment) and up to 256 KB (2^18) supporting TSO and “Giant” TSO.

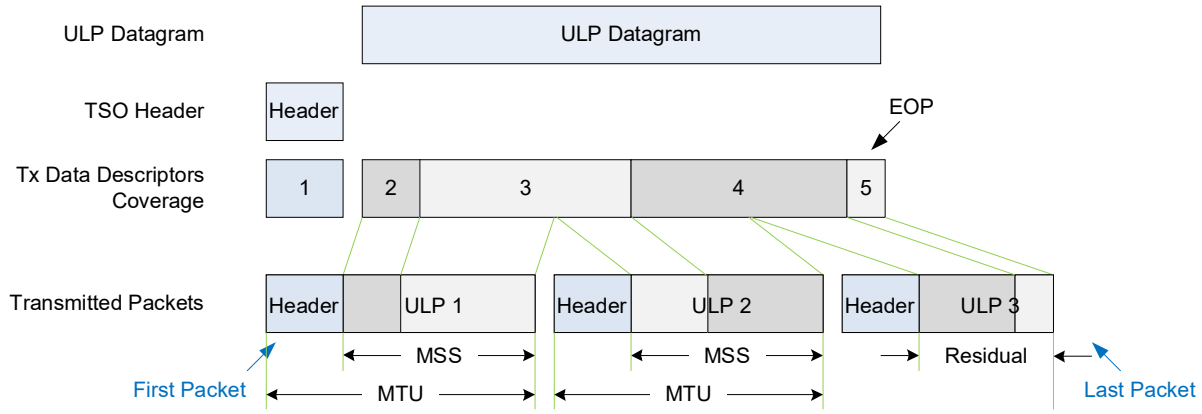

Figure 10-12. TSO Functionality (Example)

10.5.8.4.1 Frame Formats and Assumptions

The following packet formats are supported for TSO:

Note: For all the formats below, IP is IPv4 or IPv6 with/without Option/Extension headers. L4 is TCP or UDP.

- IP -> L4
- IP -> IP -> L4
- IP -> Tunneling header(s) -> IP -> L4
- IP -> Tunneling header(s) -> MAC -> [VLAN] -> IP -> L4

SNAP packet formats are not supported for TSO.

The following assumptions apply to the TCP segmentation implementation in the E810:

- TSO is activated by setting the *TSO* flag in the transmit context descriptor. On top of it, the software should follow the data and context descriptor settings for integrity offload as described in Table 10-42.
- The TSO header (L2, L3 and L4) should be provided by a maximum three descriptors, while still allowed to mix header and data in the last header buffer. The maximum size of the TSO header is 512 bytes.
- The maximum size of a single TSO can be as large as 256 KB minus 1 (defined by the *TLEN* field in the transmit context descriptor).
- The *RS* bit in the data descriptor can be set only on the last data descriptor of the TSO (on which the *EOP* bit is set).
- It is assumed that the software initializes the “pseudo header” checksum excluding the TCP length (as opposed to single send on which the pseudo header checksum includes the TCP length).

10.5.8.4.2 Transmit Segmentation Flow

The TSO flow includes the following steps:

1. The protocol stack receives from an application a ULP datagram to be transmitted.
2. The protocol stack calculates the number of packets required to be transmitted based on the MSS.
3. The stack interfaces with the device driver and passes the block down with the appropriate header information: Ethernet, IP header(s), optional tunneling headers, and the L4 header.
4. The stack interfaces with the device driver and commands the driver to send the whole datagram. The device driver sets up the interface to the hardware (via descriptors) for the segmentation.
5. The hardware fetches the segmentation parameters as well as the data and header buffers description by the transmit context and data descriptors.
6. The hardware fetches the header and data buffers and then transmits them by segments according to the TSO parameters.
7. Dynamic fields set by the software:
   - For IPv4 the IP header, checksum should be set to zero.
   - The *Total Length* field in the IP header(s) should be set to zero.
   - The IP ID of the first segment to be transmitted.
   - The pseudo header checksum of the TCP/UDP header should be calculated and placed as part of the packet data in the TCP or UDP checksum offset.
   - Initial value of the TCP flags (see later on for its value in the TSO packets).
8. Dynamic fields in the IPv4 header(s) that are modified by the hardware:
   - The *Total Length* field should reflect the IP payload size plus the IP header length. The L4 payload size is MSS for all packets but the last one, which contains the rest of the data. So for the inner IP header (in case of tunneling), it is:

     L4 Payload + L4LEN + IPLEN.

     This is the same rule for the IP header in non tunneling case. For an outer IP header (in case of tunneling) it equals:

     L4 Payload + L4LEN + IPLEN + optional L4TUNT length + EIPLEN

     Note that in case of MAC tunneling, the length of the outer IP includes the inner L2 header, including optional VLAN (updated by the hardware if the VLAN is inserted by the hardware).
   - The *Identification* field (in the IP header in non-tunneled packets, or the inner IP header in tunneled packets) is taken from the TSO header in the first segment, and is increased by one for each transmitted segment.
   - The header checksum is calculated after the other parameters in the IP header are updated.
9. Dynamic fields in the IPv6 header(s) that are modified by the hardware:
   - The *Payload Length* should reflect the payload size. It is the MSS for all packets but the last one, which contains the rest of the data. The *Payload Length* should reflect the IP payload size. Therefore, for the inner IP header (in case of tunneling) it is:

     L4 Payload + L4LEN + IP Extensions

This is the same rule for the IP header in non tunneling case. For an outer IP header (in case of tunneling) it equals:

L4 Payload + L4LEN + IPLEN + optional L4TUNT length + IP Extensions

The *IP Extensions* length equals to *IPLEN* minus 40, or *EIPLEN* minus 40 for the inner or external IP headers, respectively. Note that in case of MAC tunneling, the length of the outer IP includes the inner L2 header including optional VLAN.

10. Dynamic fields in the TCP header that are modified by the hardware:
    - The *Sequence* number in the TCP header is taken from the TSO header in the first segment. It is then incremented by MSS for each transmitted segment.
    - The TCP flags are taken from the TSO header. The header is then masked (logic AND) by the *TCPMSKF*, *TCPMSKM*, and *TCPMSKL* fields in the GLLAN_TSOMSK_F/M/L global registers. The *TCPMSKF* is used for the first segment of the TSO, *TCPMSKL* is used for the last segment of the TSO, and *TCPMSKM* is used for all other segments of the TSO. If the TSO is composed of a single segment, it is processed the same as the last segment of a multi-segment TSO.
    - The TCP checksum is calculated starting by the initial value (of the pseudo header). The checksum includes the updated TCP header, TCP payload and the calculated TCP length (equals the payload size plus the TCP header size).
11. Dynamic fields in a tunneling UDP header that are modified by the hardware:
    - The UDP length reflects the size of the tunneling UDP payload plus 8 (which is the size of the UDP header).
    - The UDP checksum is calculated starting by the initial value (of the pseudo header). The checksum includes the updated UDP length and the UDP payload.

10.5.8.4.3 Transmit Arbitration

The E810 arbitrates between transmit queues at packet boundaries while enabling each queue to transmit at least pre-defined quanta (as long as the queue is not empty). TSOs are not an exception to this rule. If the queue exhausts its quanta in the middle of a TSO, the E810 switches to the next queue in line at the end of the transmitted segment of the TSO. See Section 8.3, "Transmit Scheduling" for a description of transmit arbitration.

10.5.8.4.4 Segmentation Indication to the Hardware

Software indicates a TCP.UDP segmentation by a transmit context descriptor just before the data descriptor with the following parameters:

- TSO flag is set, indicating a TSO is requested.
- Insert STag or External VLAN can be set only by the PF (the same as a single send).
- Switch control fields must not be enabled for TSO.
- MSS should be set to the required size of the L4 payload on each segment (MTU minus the size of the headers).
  - MSS smaller than 88-bytes or larger than allowed (declared in field), are considered malicious. The respective queue is stopped and an interrupt is issued to the PF. The relevant event is "Bad LSO MSS".

- *TLEN* is the total ULP datagram length.
- Other parameters in the data descriptor(s) and the context descriptor are defined the same as a single send.

The data descriptors indicate the TSO header as well as the ULP datagram while following the frame formats and assumptions described in Section 10.5.8.4.1.

Chapter 11 Protocol Engine

11.1 Protocol Engine Overview

The Protocol Engine (PE) adds Remote Direct Memory Access (RDMA) capabilities to the traditional LAN functionality found in standard NICs. RDMA is a *networking performance optimization* that enables servers to communicate across a network using high-performance, low-latency, zero-copy DMA semantics. It is designed to reduce host CPU utilization, host memory bandwidth used for network traffic, and network latency when compared to traditional networking stacks such as sockets with TCP/IP. Here are some of the RDMA capabilities provided by the PE:

- Secure, direct access to PE hardware for userspace or kernel applications
  - — Supported in Virtual Machine environments using SR-IOV.
- Translation Protection Table (TPT)
  - — Similar to a CPU Memory Management Unit (MMU).
  - — Enables definition of > 1M Memory Regions.
  - — A Memory Region is a virtually or logically contiguous area of application address space registered with the OS. An enabled Memory Region enables the PE to perform DMA access for local and (optional) remote requests, and enables userspace applications to specify buffers in Virtual Address space.
  - — 100M+ Virtual-to-Physical page translations.
- Reliable Connection Transport
  - — 100K+ connections, analogous to a DMA engine with 100K+ channels
  - — Sequence number checks
  - — Acknowledgment
  - — Dynamic congestion control
  - — Retransmission
  - — Timers
- IP Routable RDMA

The remaining subsections in this chapter are organized as follows:

- Section 11.2, “Features” — Gives details on PE features.
- Section 11.3, “Functional Description” — Describes the hardware infrastructure external to PE that a silicon device must implement, in order to successfully integrate PE.
- Section 11.4, “Verbs Programming Model” — Defines PE implementation details related to the RDMA *Verbs* programming model.
- Section 11.5, “Resource Management” — Defines how PE hardware resources are managed by a driver.
- Section 11.6, “RDMA Functionality” — Defines RDMA-related structures a driver must program.
- Section 11.7, “UD/UDA Functionality” — Defines UD/UDA functionality.

- Section 11.8, "UDA Functionality" — Describes the PE UDA capabilities, a way to give kernel applications direct access to PE hardware to enable iWARP connection setup and error handling.
- Section 11.9, "Protocol Engine Statistics" — Describes PE hardware statistics counters.
- Section 11.10, "SR-IOV Protocol Engine Functionality" — Describes PE SR-IOV support.
- Section 11.11, "NVM RDMA Register Initialization" — Describes RDMA registers that are initialize from NVM values.

11.2 Features

Table 11-1 shows the Protocol Engine feature set.

Table 11-1. Protocol Engine Features

Category	Description
General	**RDMA Protocol Support** Simultaneous support for both iWARP and RoCE v2.
General	**PCIe Function Enabled for RDMA** All of the device's PCIe Physical Functions, and any 32 of the device's PCIe Virtual Functions can be enabled to use RDMA. The number of VFs enabled for RDMA can be reduced via resource profiles. RDMA resources can be redistributed between VFs and PFs based on resource profiles. ***Note:*** The maximum number of Physical Functions supported is 8.
General	**Ethernet Ports Supported** Support for 4 Ethernet ports with 8 TCs, or 8 Ethernet ports with 4 TCs.
General	**IP Version** Support both IPv4 and IPv6 offloaded RDMA connections.
General	**ARP Table** Supports a unique ARP Table instance with up to 65536 entries per PCI function (PF or VF). Each entry contains a 6-byte Ethernet address, plus control/status information for neighbor reachability detection. The ARP Table supplies a destination Ethernet address for all transmitted RDMA packets.
General	**RDMA-Enabled MAC Addresses** The Source Ethernet MAC Addresses are kept with the QP context. There is no table of MAC Addresses.
General	**IP Datagrams/Fragmentation** RDMA IP datagrams are never transmitted with fragmentation. RDMA IPv4 datagrams are always transmitted with the *Don't Fragment* flag set and the *Fragment Offset* field set to 0. Received RDMA IP datagram fragments are sent to the LAN stack and not processed by the RDMA offload engine.
General	**RDMA Statistics** 128 sets of RDMA statistics. Each set can be assigned to an arbitrary/programmable group of one or more Queue Pairs. Any Queue Pair can be assigned to only one stat set. A typical configuration assigns one set to each active PCIe PF and VF, with the extra sets available for assignment as requested by the OS. For example, if 8 PCIe PFs and 32 PCIe VFs are active, then 40 RDMA stat sets are assigned to these functions, with the sets remaining for allocation as requested by the OS.
QP	**Max QP Count** Supports 256K Queue Pairs for RDMA that are dynamically assigned to PCI functions at runtime by Protocol Engine firmware.

Table 11-1. Protocol Engine Features [continued]

Category	Description
QP	**Work Queue Elements (WQEs)** These WQE properties are supported: • Similar WQE format for SQs and RQs. • Each iWARP or RoCE v2 WQE can vary in size from 1 to 14 fragments, with these sizes: 32B, 64B, 96B, 128B, 160B, 192B, 224B, 256B. • Fragments are specified with virtual addresses and are virtually contiguous. • The Protocol Engine performs virtual-to-physical translation using its built-in Memory Management Unit (MMU). • An iWARP or RoCE v2 SQ WQE can (optionally) directly convey 224B of inline data for small message latency optimization. • Send Queue Push mode support is required.
QP	**Work Queues (WQs)** RDMA WQs are mapped into host memory as physically or virtually contiguous ring buffers. Maximum WQ size is 16K entries x 32B = 512 KB. Maximum WQ depth is configurable on a per-WQ basis. Supported values range from 4 to 16K 32B WQEs, in power-of-two increments. Dynamic WQ resizing is not supported.
QP	**SQ Operations (Baseline)** Support for these baseline SQ operations: • Send • Send with Invalidate • Send with Solicited Event • Send with Solicited Event and Invalidate • RDMA Write • RDMA Read (iWARP-style single local SGE) • RDMA Read with Local Invalidate (iWARP-style single local SGE) • Bind Memory Window • Fast-Register Memory Region • Invalidate Local STag. These operations work with either iWARP or RoCE v2, except the iWARP-style RDMA Reads, which are iWARP-only.
QP	**SQ Operations (RDMA Write with Immediate Data)** Support for RDMA Write with Immediate Data. CQE and SQ WQE formats enable 8B of Immediate Data for both iWARP and RoCE. For iWARP, 8B of Immediate Data is conveyed on the network. For RoCE, only 4B of Immediate Data is conveyed on the network.
QP	**SQ Operations (RDMA Read Special)** Support RDMA Read (IB-style with multiple local SGEs). For RoCE v2, this is the only form of RDMA Read. Each iWARP QP is configured by software to use either canonical iWARP-style RDMA Reads, or to use IB-style RDMA Reads. In the later mode, RDMA Read with Local Invalidate must not be considered an illegal operation, for backwards compatibility with existing iWARP applications.
QP	**SQ Operations (Send with Immediate)** For RoCE v2 Queue Pairs only, support Send with Imm, Send with SE and Imm.
QP	**Number of RDMA Reads** The number of outstanding inbound RDMA Reads, defined by Inbound RDMA Read Queue Depth (IRD) is configured independently per QP. These IRD settings are supported: 2, 8, 32, 64, 128, 256. IRD can not be modified after the QP has been created. The number of outstanding outbound RDMA Reads, defined by Outbound RDMA Read Queue Depth (ORD), is also configured independently per QP. These ORD settings are supported: 0 to 255, in single-step increments. ORD can be modified after the QP has been created, if the proper quiesce conditions are met.
QP	**Send Queue Push Mode** This device supports Send Queue *Push Mode*. In this mode, the Host CPU writes or pushes SQ WQEs with or without inline data to the device memory-mapped address space using CPU write-combining buffers. Each of the device's PCIe PFs MUST support up to 1024 separate 4KB Push Pages. Each of the device's RDMA-enabled VFs MUST support 16 4KB Push Pages. The Push Pages are typically exposed through an extension of the memory BAR that contains the CSRs. PF Push Pages MUST be assignable to VMs via device firmware in para-virtualized driver models.

Table 11-1. Protocol Engine Features [continued]

Category	Description
CQ	**Completion Queues** Supports up to 524288 CQs that are dynamically assigned to PCI functions at runtime by device firmware. A CQ/ring buffer can be either virtually or physically contiguous. CQE size is 32B for standard operations, and 64B for special cases including some Immediate Data and UD operations. 32B CQEs can optionally be padded to 64B cache-line boundary to avoid memory conflicts. Max CQ size is 1M entries x 64B = 64 MB. Supports user-defined mapping of WQs to CQs. Supports CQ resizing, CQ size can be increased or decreased while the CQ is active. Supports CQ overflow detection.
EQ	**Completion Event Queues** Supports 256 Completion Event Queues for RDMA that are dynamically assigned to PCI functions at runtime by device firmware.
EQ	**Asynchronous Event Queues** Supports 48 Asynchronous Event Queues for RDMA that are dynamically assigned to PCI functions at runtime by Protocol Engine firmware.
MMU	**Protection Domains** Each PCIe PF or VF enabled to use RDMA can define up to 256K Protection Domains.
MMU	**Memory Regions and Windows** Each PF or VF enabled to use the Protocol Engine can allocate up to 4M (i.e. 2^{22}) Memory Regions or Memory Windows. The maximum size of a standard Memory Region or Memory Window is 32TB (245 bytes). The Protocol Engine also supports a special privileged unbounded Memory Region configuration. When set to unbounded, a Memory Region is configured to register all of contiguous physical memory, and to treat Memory Region Length as "unused and unenforced".
MMU	**Wide Memory Windows** Support Wide Memory Windows for both iWARP and RoCE. Wide Memory Windows have Protection Domain scope, whereas standard iWARP Memory Windows have QP scope.
MMU	**Host Memory Page Sizes (Baseline)** Host Memory page sizes supported: 4 KB, 2 MB. Each Memory Region can be independently configured for either page size.
MMU	**Host Memory Page Sizes (Enhanced)** Includes everything in baseline, plus support for 1 GB Host Memory page size.
MMU	**Physical Buffer List (PBL)** Each RDMA Memory Region can be Physically Mapped (that is, the region is physically contiguous in Host Memory) or Virtually Mapped with a one- or two-level PBL. Each RDMA-enabled PF or VF can allocate up to 256M (2^{28}) PBL Entries. A single PBL Entry maps a single Host Memory page.
MMU	**Maximum Virtually Mapped Memory (Enhanced)** The maximum virtually-mapped memory a single PF or VF can register for RDMA depends on host page sizes used. The examples below illustrate this for different page sizes. Supported page sizes are defined elsewhere, and some of these examples might not be relevant for this device. If a PF or VF allocates its maximum limit of 256M PBL Entries, then... ...its maximum virtually mapped memory using 100% 1 GB host memory pages is: 2^{30} x 2^{28} = 2^{58} bytes = 256 PB ...its maximum virtually mapped memory using 100% 2 MB host memory pages is: 2^{21} x 2^{28} = 2^{49} bytes = 512 TB ...its maximum virtually mapped memory using 100% 4 KB host memory pages is: 2^{12} x 2^{28} = 2^{40} bytes = 1 TB
UD	**Address Handles** Supports 128K Address Handles per PCIe function.
iWARP	**Standards Compliance** IETF RFC 5040, 5041, 5042, 5044, 6580, 6581, 7306 (immediate data only, atomics are not supported) RDMA Consortium Verbs
iWARP	**Receive Window Size** Each RDMA connection has a configurable Receive Window with maximum size of 1GB-1B.
iWARP	**Non-Permissive IETF RNIC** Using a term coined in IETF RFC 5044, this device is a non-permissive IETF RNIC (an RNIC that implements the IETF protocols, but not the RDMAC protocols).

Table 11-1. Protocol Engine Features [continued]

Category	Description
iWARP	**MPA - Baseline Support** Supports all of the following: • Insertion of Transmit markers (can be enabled/disabled per QP). • MPA CRC generation for outbound iWARP packets. • Transmit up to four FPDUs in a single Ethernet packet. • Able to transmit partial FPDUs when there is outstanding (unacknowledged) data and an MSS change occurs. • MPA CRC checking on inbound packets (can be enabled/disabled per QP). • Process received Ethernet packets with any number of iWARP FPDUs (bounded by max packet size). • Support for detection/handling of received partial FPDUs. • Drop out-of-order received FPDUs without ACKing the TCP segment containing them.
iWARP	**MPA - Place Out-of-Order Received FPDUs** When Receive Markers are enabled, place out-of-order FPDUs.
RoCE	**Standards Compliance** InfiniBand Architecture Specification Volume 1 Release 1.3 (support the subset of this spec that applies to RoCE v2) InfiniBand Architecture Specification Annex A17: RoCE v2 Sept 2014

11.3 Functional Description

11.3.1 Packet Classification and the PE

The E810 provides several filtering checks that can be used to distinguish LAN traffic that should be handled by the PE from other LAN traffic. The mechanism to direct a packet to be processed by the PE is to enable the RDMA Packet Profiles for RDMA in the VSI. The internal switching components described in Section 7.10, including this special setting, are used to identify a Virtual Station Interface (VSI). Once the VSI has been identified, the checks shown in Figure 11-1 determine if a packet is processed by the PE.

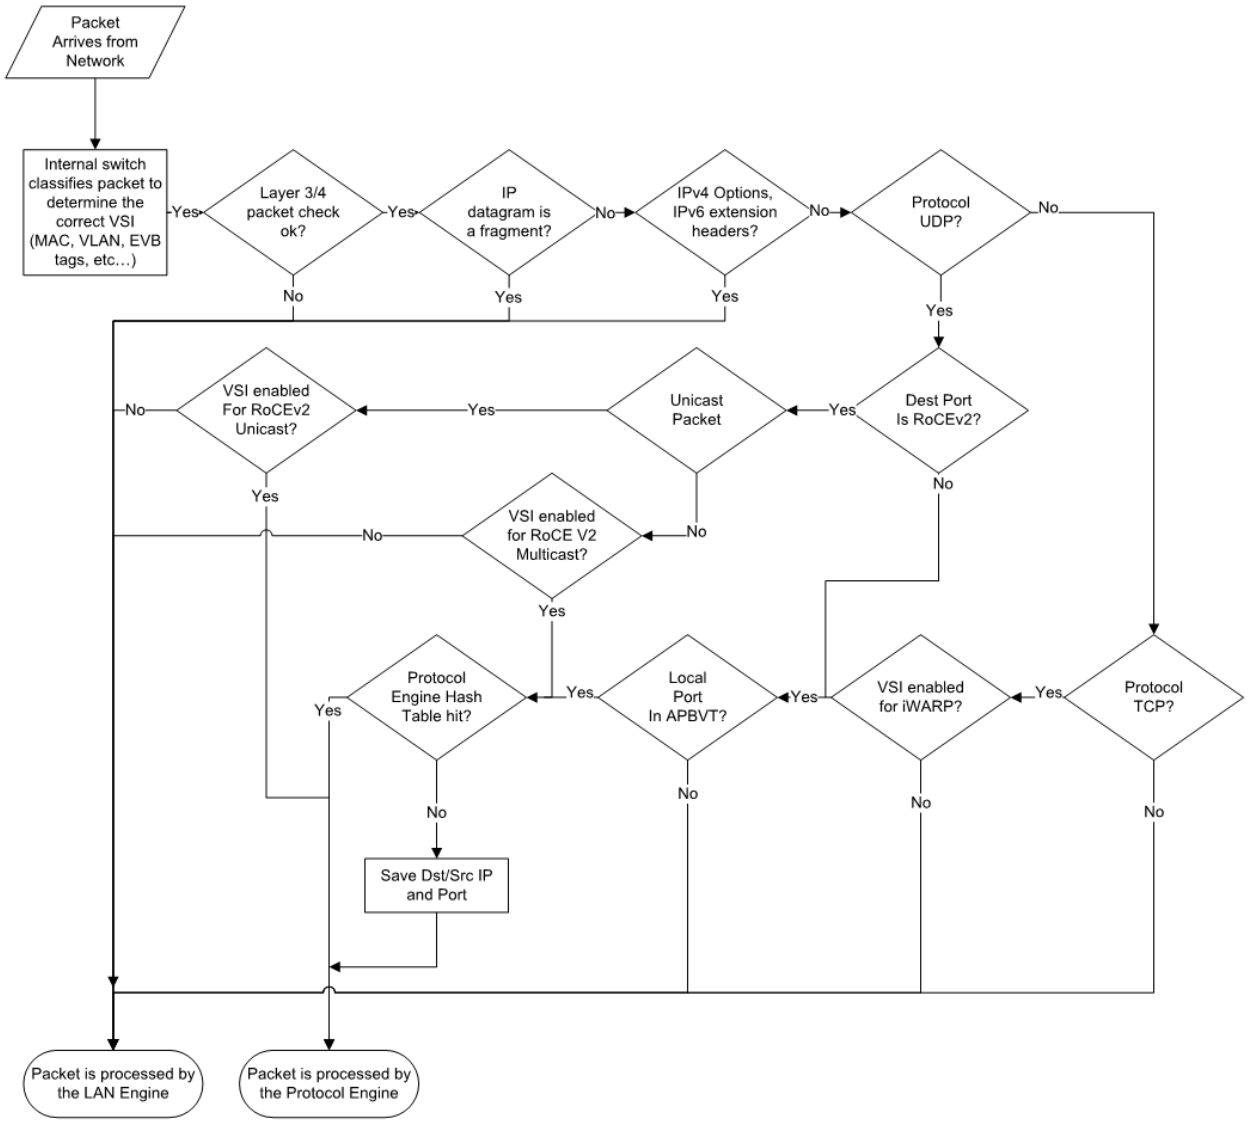

Figure 11-1. PE Packet Classification

Once the internal switch packet classification has been performed, the following checks must be passed before a packet is processed by the PE:

1. The VSI configuration option that enables traffic to be routed to the PE must be enabled.
2. The packet must be a protocol that is supported by the PE. The current protocols that the PE is capable of handling are TCP/IP and UDP/IP. Multicast and unicast packets are supported for UDP/IP.
3. Additional checks to validate the IP and TCP or UDP headers must succeed.
4. If the packet is an IP packet it must not be a fragmented IP datagram.
5. If the packet is targeted for the RoCEv2 port and is a unicast packet, it is sent to the Protocol Engine.

6. If the packet is targeted for the RoCEv2 port and is a multicast packet, it skips the next step. That is, it does not have an APBVT entry but it does go through the Protocol Engine Hash Table.
7. Otherwise, the destination port of the TCP or unicast UDP packet header must have its associated bit set in the Accelerated Port Bit Vector Table (APBVT). APBVT is described in Section 11.5.3.18.
8. The packet is then sent through a hash table lookup and must be found. The fields from the packet that are used for the lookup vary based on the packet contents. TCP/IP packets that do not have the *SYN* bit set, or have the *SYN* bit set and the *ACK* bit set, use the combination of destination MAC Address, VLAN tag (if present), source and destination IP Addresses, and the source and destination port fields. TCP/IP packets with the *SYN* bit set and the *ACK* bit clear or unicast UDP/IP packets use the destination MAC Address, VLAN tag (if present), destination IP Address and destination port. See Section 11.5.3.20 for more details on the PE hash filter. If this check fails, a bit indicating that a hit in the APBVT was found, the IP table index from check number #7 and destination TCP port number are reported in the receive descriptor as status.

7. Finally, the packet must not have IPv4 options or IPv6 extension headers.

If any of the previous checks fail, the packet is processed by the LAN engine.

The PE has some limitations regarding the packet formats that are supported with RDMA and UDA traffic. The PE supports all packet formats that are configured using the internal switch and configured for the VSI. Additional headers (such as an extra inserted IP header, IP and NAT tunneling headers, or IP and Teredo headers) that are inserted for L2 traffic on a per packet basis are not supported for PE traffic. When the VSI is not configured for handling specific header formats, the PE is capable of handling packets with up to one extra packet headers to match the L2 VLAN capability. The VLAN tag specified in QP context matches the definition for L2TAG1 for LAN descriptors.

Two different values have been used for the RoCEv2 well-known port number: 1021 (early development) and 4791 (assigned by IANA). Two port numbers per physical port are recognized by the Parse Graph as RoCEv2 well-known ports. See the section on Packet Parsing for more information on how to program the parser for these values.

11.4 Verbs Programming Model

The verbs programming model is specified for iWARP from the RDMA Consortium.

http://www.rdmaconsortium.org/home/draft-hilland-iwarp-verbs-v1.0-RDMAC.pdf

The E810 supports the verbs constructs of QPs, CQs, and events. The E810 supports verbs events by implementing CEQs and AEQs. Further description of each of these constructs in provided in the following sections. Additional information on the verbs programming model can be found in the link to the RDMA consortium website previously provided.

11.4.1 Verbs from a System View

The following sections provide an overview of each verbs construct supported by the E810 from a system view. It is expected that the user is generally familiar with the verbs programming interface.

11.4.1.1 Asynchronous Event Queue (AEQ)

The E810 supports a single AEQ per PE-enabled PCI function. AEQs are used to report status and errors associated with PE QPs, CQs, and ARP table entries.

AEQs are a packed array of AEQ entries (see Section 11.4.6 for the format of an AEQ entry) located in a virtually contiguous buffer in host memory (see Figure 11-2). AEQs should be sized to enable a two entries for every QP, CQ, and ARP table entry that is active for the PCI function. Each QP, CQ and ARP table entry ensures that it generates only a single AEQ entry at a time.

Software interaction is required for each resource to enable subsequent AEQ entries. If the AEQ is not sized appropriately, AEQ overflows can result [(Head+2)%AEQ_Size=Tail], in which case AEQ entries are lost, and the *AEQE_Overflow* bit in the AEQE is set to notify software that the overflow condition occurred. Once the AEQ has overflowed, no new AEs are delivered to that queue. The AEQ must be destroyed and recreated to resume AE processing.

The initial condition for software shown in Figure 11-2 is *AEQE_Index* set to 0b. The last valid is shown strictly for discussion purposes. The E810 first writes to the AEQE index specified by *Head*. After an AEQE is written, an interrupt is generated if AEQ interrupts are not masked. Once an interrupt has been received that indicates that a new AEQ element (AEQE) is available, software reads the AEQE at *AEQE_Index* and increments *AEQE_Index*.

Software processes all valid AEQEs until it encounters an invalid entry, and stores the index of the invalid entry in the *AEQE_Index* variable. Subsequent AEQ entries might be generated by the E810 after the entry that caused the interrupt while interrupts are masked. For each valid AEQ entry found, the PFPE_AEQALLOC register (see Section 13.2.2.28.10) must be written to notify the E810 that the AEQ entry is available for use by hardware. Writing the PFPE_AEQALLOC register causes the E810 to increment the on-chip tail context variable. The PFPE_AEQALLOC register supports batching of AEQ entry acknowledgment into a single write to enable software to minimize the number of register writes necessary to complete AEQ interrupt processing. PE enabled VF must use the VFPE_AEQALLOC registers instead of the PFPE_AEQALLOC.

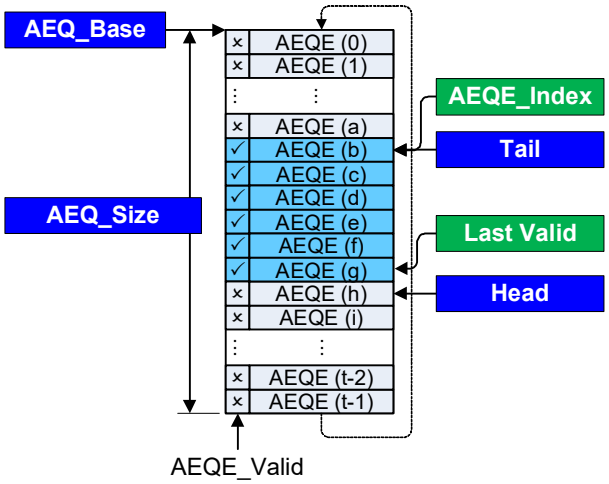

Figure 11-2. AEQ

If software stops processing the AEQ before it has consumed all valid AEQEs, software must use a software-initiated interrupt to return to processing AEQEs. Otherwise, no further interrupts are generated until a new AE is generated. Once the E810 has run through the AEQ and wrapped back to AEQ0, the polarity of the *AEQE_Valid* bit is switched to avoid the need for software to go back and clear the *AEQE_Valid* bit for each AEQE processed.

11.4.1.2 Completion Event Queue (CEQ)

The E810 supports one CEQ per MSI-X vector per PE enabled PCI function and a maximum of 768 CEQs total. HMC resource profiles are used to distribute the number of CEQs across the PE enabled PCI functions.

Software can determine the number of CEQs and the specific instances assigned to a particular PCI function by reading the GLHMC_CEQPART[n] (see Section 13.2.2.20.27) or GLHMC_VFCEQPART[n] (see Section 13.2.2.20.25) registers after the HMC profile has been selected. Each CEQ is associated with a separate interrupt cause. It is expected that the number of CEQs that software uses is the minimum of the number of MSI-X vectors available, the number of CPU cores, and the value reported from the GLHMC_CEQPART[n].*PMCEQSIZE*. Software uses multiple CEQs to distribute the completion process workload across multiple CPUs. Each CQ is individually assigned a CEQ via the CreateCQ or ModifyCQ operations defined in Section 11.5.3.3.

Figure 11-3 shows that CEQs are a packed array of CEQ elements (see Section 11.4.5 for the CEQ element definition) located in a virtually contiguous buffer in host memory. CEQs should be sized according to the maximum number of active CQs that are assigned to the CEQ. Each CQ guarantees that it generates a maximum of one CEQ entry without having software acknowledge that the CEQ entry has been consumed. CEQs are not checked for overflow conditions, so it is important that they are sized correctly or completion events are lost.

The initial conditions for software shown in Figure 11-3 is *CEQE_Index* is set to 0. The last valid is shown strictly for discussion purposes. When the E810 generates a new CE, a CEQE is written to the CEQ at index value of head with the *CEQE_Valid* bit indicating that a new event is available and an interrupt is generated. The E810 bumps *Head* as part of the CEQE generation process, and when the *Head* reaches the end of the CEQ it wraps back to 0. Software management of *CEQE_Index* must match the E810's head algorithm.

Subsequent CEQEs might be written after the entry that caused the interrupt while CEQ interrupts are masked. Software is required to process all valid CEQEs up to the point where the first invalid entry is found. If software stops processing CEQEs before it has found an invalid entry, software must force the E810 to generate a new interrupt using the *SWINT_TRIG* bit in the interrupt control registers. This is necessary since the E810 does not track a tail value for CEQs and therefore cannot determine if a new interrupt is required to process CEQEs that have already been written and not processed by software. Once software has processed a valid CEQ entry, software writes the PFPE_CQACK register (see Section 13.2.2.28.9) to enable the CE to generate new events.

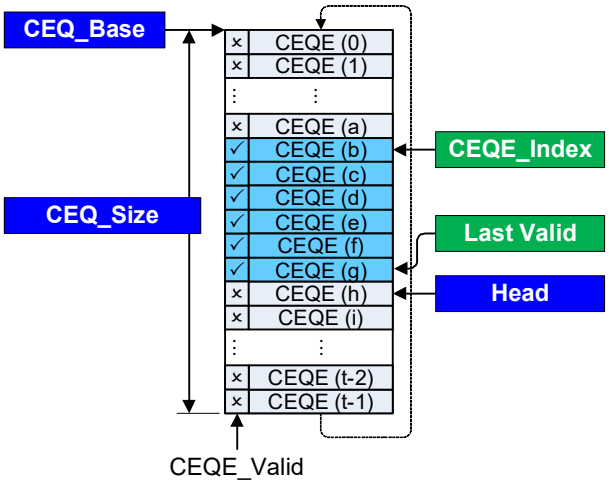

Figure 11-3. CEQ

Once the E810 has wrapped back to CEQE0, the polarity of the *CEQE_Valid* bit is switched to avoid the need for software to go back and clear the *CEQE_Valid* bit for each CEQE processed.

11.4.1.3 Completion Queues

When work requests submitted to Work Queues (WQs) complete, the E810 might post CQEs to associated CQs. Queue Pair WQs might be Send Queues (SQs) or Receive Queues (RQs). SQs and RQs are associated with their CQs at QP creation time. This association remains (and cannot be changed) until the QP is destroyed. Each SQ and RQ can be bound to same or separate CQs. CQs can also be shared by multiple WQs from different QPs.

The E810 supports up to 512K CQs that are distributed among that active PCI functions using HMC resource profiles. See Section 9.3.3 for more information on the resource distribution mechanism used with CQs. The E810 maintains the context of each Completion Queue in CQ context data structures in the HMC's function private memory space. The storage elements of CQs reside in system memory. See Section 9.3 for more information on the E810's usage of host memory for CQ context.

As shown in Figure 11-4, CQs are organized as a circular array of CQEs. Each CQE is 32 or 64 bytes in length, and the format is dependent on the type of the WQ that is associated with the CQE. CQP, RDMA, and UDA WQs all can be related to CQs. CQs are managed using the Create/Modify/ DestroyCQ operations defined in Section 11.5.3.3.

In addition to the CQ itself, software maintains a shadow area that the E810 reads when the CQ is getting low on CQEs for hardware to write, or when the CQ has been armed for event generation. The E810 supports the verbs interface calls for requesting completion notification based on the next completion or based on the next completion that is associated with an operation that is a solicited event. The shadow area contains variables that must be maintained by software in an atomic fashion, since the E810 could read that area at anytime. Specifically, the two 32-bit words (first one at byte offset 0 and second at byte offset 32) in the Completion Queue doorbell shadow area must be accessed using atomic 32-bit processor instructions. The *arm_seq_num*, *arm_next* and *arm_next_se* fields are ignored if an arm request has not been made by writing to the PFPE_CQARM register (see Section 13.2.2.28.8). The PFPE_CQARM register exists in CSR space for kernel mode drivers to access and also in the doorbell page area of the PCI function's BAR space that can be mapped directly to a userspace application's memory space for kernel bypass operation. The format of the shadow area for CQs is shown in Table 11-27 on page 1442.

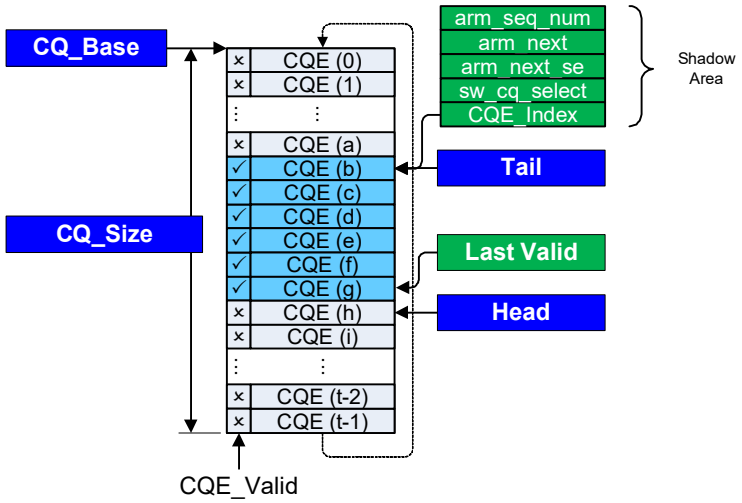

Figure 11-4. CQ

The CQ is organized as a circular queue, written by the E810 and read by the driver software. Initially, both the E810 and the driver software point to the first entry in the queue. The E810 advances the *Head* context field after it writes a CQE to the CQ. Similarly, when the driver picks up a CQE, it advances the *CQE_Index* context field in shadow area in host memory. When *Head* approaches *Tail*, the E810 reads the CQ shadow area and writes the *CQE_Index* value from the shadow area to the *Tail* context variable. If *Head* reaches *Tail*-1 when the E810 attempts to write a CQE, an overflow condition is reported and the CQ is put into the error state. CQs generate a single Asynchronous AE_CQ_OPERATION_ERROR event at this point and any further CQEs that are attempted to be generated by the E810 are lost.

Completion events are generated if the CQ is armed for the appropriate event. The E810 generates completion events under the following conditions assuming the *Tail* does not equal *Head*:

- Any CQE is written (or has been written since the last event) and the CQ is armed for the next completion.
- A CQE is written (or has been written since the last event) that is associated with a Solicited Event operation and the CQ is armed for next solicited event.
- The CQ is armed on a recently re-sized CQ and software has not moved over to the new CQ yet based on the *sw_cq_select* value in the shadow area.

Completion Events can be deferred if a Completion Event has been generated for a CQ and the PFPE_CQACK register (see Section 13.2.2.28.9) has not been written by software.

The E810 differs slightly from the verbs specification definition of generating completion events in two ways. First, the E810 generates a completion event for a CQ that is armed for next completion without waiting for a new completion to be generated if it appears that CQEs have not been processed by software (Head != Tail after reading the doorbell shadow area). Second, the E810 does not track the exact location of the solicited events that have been generated since the last completion event. The E810 generates a completion event for a solicited event operation if any solicited event completion has been generated since the last completion event was generated, and it appears that CQEs have not been processed by software.

The E810 process for arming CQs for event generation is simply to first write to the appropriate bit in the CQ shadow area to enable either next or next solicited completion notification events, increment *arm_seq_num*, and then write to the PFPE_CQARM register (see Section 13.2.2.28.8). The E810 then reads the shadow area and the CQ context is used to either immediately generate a new completion event if the CQ has unprocessed CQEs remaining, or arm the CQ to generate a new event once a subsequent CQE is written. As previously described, completion events can be deferred under certain circumstances. The E810 maintains a copy of the last *arm_seq_num* value that was read during the last arm request in CQ context. The E810 compares the value of *arm_seq_num* in CQ shadow area with the value in CQ context during arm requests and drops arm requests that have the same value in the shadow area and in CQ context. This comparison prevents CQ arm requests from rogue applications from changing the arm state of a CQ unless the application also has access to the CQ shadow area.

CQ resize operations with the E810 involve four steps.

1. Allocate a new CQ in host memory based on the new size requested by an application.
2. Issue a ModifyCQ operation to the E810. ModifyCQ operations notify The E810 to start using the new CQ for new CQEs.
3. Completely process CQEs from the old CQ.
4. Start to process CQEs from the new CQ after freeing the buffer for the old CQ. The old CQ can be considered to be completely processed when an invalid CQE has been found in the old CQ and at least a single valid CQE has been encountered on the new CQ.

When the transition to updating *CQE_Index* based on the new CQ occurs, *sw_cq_select* must be incremented. During the ModifyCQ operation, the E810 incremented its *cq_select* value and switched over to writing CQEs to the new CQ. Since there could be pending CQEs still on the old CQ, the E810 compares the CQ shadow area *sw_cq_select* to the hardware *cq_select* value during any reads of the CQ shadow area due to arms or CQ tail updates. If hardware *cq_select* does not match *sw_cq_select*, the E810 ignores *CQE_Index* and does not update CQ *Tail*, assuming that software is still working with the old CQ. Arm requests generate new events immediately, since the E810 is no longer aware of the state of the old CQ. Once software has properly set *CQE_Index* to reflect progress on the new CQ, it must also increment *sw_cq_select* so the E810 will start processing arm requests and CQ *Tail* updates based on the new CQ.

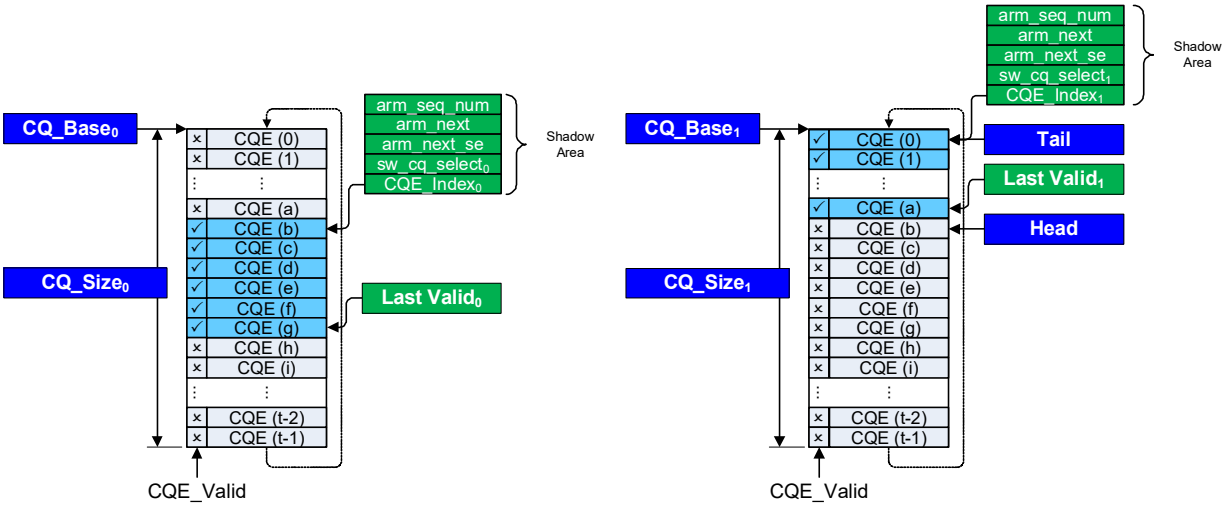

Figure 11-5. CQ Resize Operation

Figure 11-5 shows a CQ during a resize operation. The original CQ is shown on the left side of the diagram. At the time that the ModifyCQ operation occurred for the resize, the CQ had valid CQEs that had not been processed by software. The E810 switched over to the new CQ shown on the right side of the diagram at the time of the ModifyCQ and incremented its *cq_select* value. New CQEs are shown as generated on the new CQ in Figure 11-5. Any arm requests immediately generate new CEs while *sw_cq_select* does no match the hardware *cq_select* value. If the doorbell region is read during this time, the CQE_Index_0 value is ignored because $sw\_cq\_select_0$ does not match *cq_select*. Once software has found an invalid entry in the original CQ and CQE0 from the new CQ is valid, software can reset *CQE_Index* to 0, increment *sw_cq_select*, and start processing CQEs on the new CQ. At this time it is safe to free the memory used for the original CQ, since the E810 no longer writes to the old CQ. While two CQ shadow areas are shown in Figure 11-5, there is really only one. Two are shown to indicated that values of *sw_cq_select* and *CQE_Index* have changed to signal the change over to the new CQ.

11.4.1.4 Memory Registration (Translation/Protection)

In today's modern operating systems, applications running at user protection level use virtual addresses and they are not aware of their data buffers' physical addresses. However, traditional I/O devices require physical addresses to transfer data to/from system memory. This gap is typically bridged by the device driver, which runs in the kernel protection level. Transitioning from user to kernel protection level, and than back to user protection level is not only quite expensive (in terms of MIPs), but also contributes to increased latency. The RDMA architecture solves this inefficiency by:

- Using virtual data buffer addresses in the RNIC programming model.
- Servicing latency critical functions through libraries running at the user protection level

This approach requires RNICs to implement robust address translation and protection techniques. This section provides in-depth descriptions of the address translation and protection mechanism used by the E810. However, the reader is assumed to be familiar with the memory management concepts, operations, and related terms described by the RDMA specification.

The E810 uses a Memory Region Table (MRT) and Physical Buffer Lists (PBLs) to represent virtually contiguous system memory locations that are accessible for RDMA operations. The data structures in MRT are used to describe these memory locations and their protection attributes. PBLs provide the page lists that back each MRT entry. Both of the data structures are HMC objects that are described further in Section 9.3. These concepts, supporting data structures, and related operations are described in Section 11.4.1.4.1. In these sections, the actual MRT and PBL construction details through the HMC are intentionally omitted and a virtually contiguous HMC function private memory space is assumed.

11.4.1.4.1 Address Translation and Protection Overview

As shown in Figure 11-6, the E810 supports a two-level protection and translation flow. The STag and tagged offset pair define the protection attributes and physical address of the system memory being accessed.

The STag portion of the address is used to locate the Memory Region Table Entry (MRTE) in the MRT. This data structure provides the protection attributes (Type, Access Control, Protection Domain and Key), the bounds check attributes (Base Tagged Offset, Length and First Byte Offset), and the address translation attributes (Page Size, and Base PBL Index). These attributes are described in detail later in this section.

After the protection attributes are checked and the address bounds checks are performed, the address translation attributes, along with tagged offset, are used to calculate the PBL virtual address. The translation flow is explained in detail later in this section. The PBL Index portion of the PBL virtual address is used to locate the Physical Buffer List Entry (PBLE), which provides the physical page address. Finally, the page address is concatenated with the offset portion of the PBL virtual address to form the physical system address.

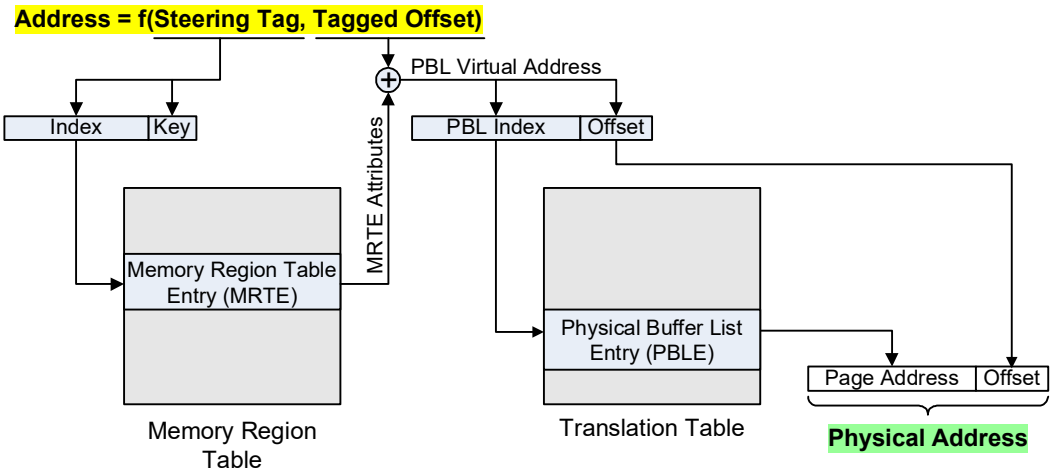

Figure 11-6. STag Decomposition to Physical Address

Depending on its size, each MRTE might be associated with multiple PBLEs. In this case, the PBLEs must be allocated consecutively to form the PBL. The PBLs can also be shared between multiple MRTEs when memory windows or shared memory regions are used. This enables efficient representation of a section of the system memory that is registered multiple times; potentially with different protection attributes.

The E810 also supports two other modes of address translation. The first is termed direct page translation, which can be used when the STag is backed by a physically contiguous buffer is depicted in Figure 11-7. In this case, the PBL translation step is skipped, which enables more efficient calculation of the physical address accessed for a given STag.

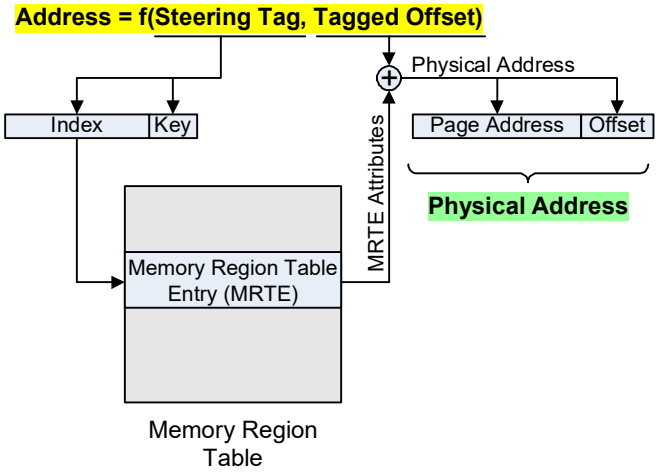

Figure 11-7. Direct Page Translation

The second additional mode of address translation is designed to enable software to make more efficient use of PBL address space when large numbers of large buffers are used for an application at the expense of additional accesses to host memory in order to calculate the ultimate physical address. Figure 11-8 shows a mode where PBLs are accessed twice by breaking the PBL virtual address into three pieces instead of two. The root PBLE is first accessed to find the PBLE associated with the leaf PBL. Once the leaf PBL is identified, the leaf PBL index is used to identify the leaf PBLE address that contains the page address portion of the physical address. In this mode, the leaf PBLs must be either 256 (64 root PBLEs or 32 leaf PBLEs) or 4096 (1024 root PBLEs or 512 leaf PBLEs) bytes in size. The root PBLs can be any size. This mode enables software to slice up the PBL space into fixed size PBLs for large memory regions of up to 2 GB/s instead of having to reserve large contiguous regions of PBL space for a single STag.

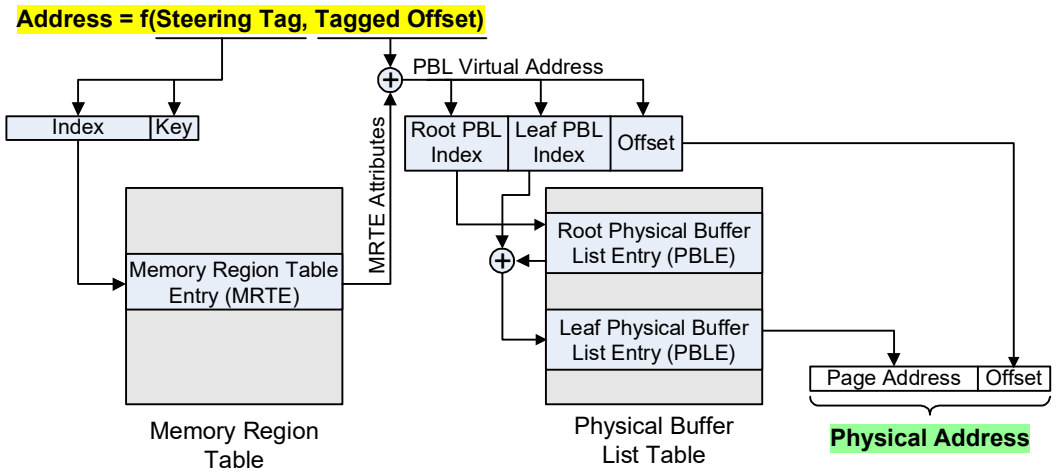

Figure 11-8. Two-Level Page Translation

Each Root PBLE is just a 28-bit object index of the starting PBLE object for the associated leaf PBLE. In other words, each root PBLE points to a another PBLE HMC object that is the start of the leaf PBL. Each leaf PBL is an array of 32 or 512 PBLEs. The size of the root PBL is determined from the region size specified in the MRTE. Each leaf PBLE is a 64-bit pointer to a host memory page which can be a 4 KB or a 2 MB page. For 4 KB pages the lower 12 bits of the host memory page pointer are ignored and for 2 MB pages the lower 21 bits are ignored.

Before we dive into the details of the MRTE and PBL data structures and operations, a brief overview of commonly used terms are provided in the sections that follow.

11.4.1.4.1.1 STag

All local and remote memory accesses require use of an STag. The STag, along with a tagged offset, is used to identify a memory location within a specific memory region or memory window. STags are found in RQ and SQ WQEs and in tagged iWARP messages received from the wire. As shown in Figure 11-9, 32-bit wide STag is further divided into two fields.

Figure 11-9. STag Format

Where:

- **STag Index** — The most significant 24-bits of STag is called the STag Index. Since this field is used as an index into the MRT, it is also known as the memory region table index or MRT index in short. The E810 supports up to 4 MB protection entries. Note that the unused most significant bits of the STag Index can be randomized by software to provided reduced predictability for any MRT attacks.
- **STag Key** — The least significant 8-bits of the STag is called the STag Key. The STag Key field is a user- or driver-provided key that provides an additional level of security for the STag protection check.

11.4.1.4.1.2 Memory Region and Memory Window

Applications must register memory regions prior to accessing the system memory either locally or remotely. Memory regions, and their translation and protection attributes are represented by properly formatted MRT entries. MRT entries of this type are also called Region Entries or RE in short. Memory region registration and de-registration requests are communicated to the E810 (1) by using CQP commands (like: register memory region and de-register memory region) or (2) by work request through a SQ (like: fast register non-shared memory region and invalidate STag).

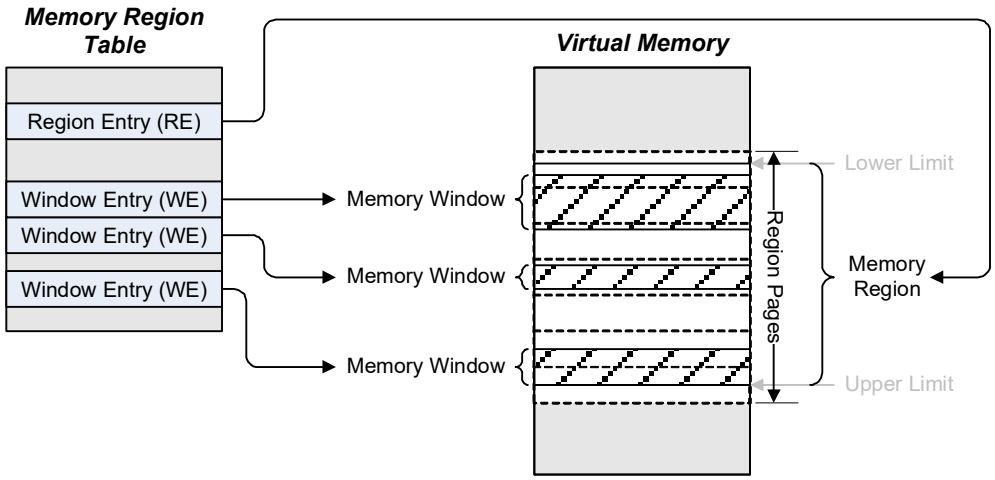

Figure 11-10. Memory Region to Memory Window Relationship

The Verbs specification also defines the memory windows concept. The InfiniBand specification defines Type 1 and Type 2 Windows. Memory windows can be placed anywhere within a valid memory region. Multiple memory windows are allowed within a memory region. Memory windows are allowed to overlap, or be completely included within another memory window. However, memory windows are not allowed to cross memory region boundaries. The E810 supports memory windows through another type of protection entry. These protection entries are also referred as Window Entry (WE). Figure 11-10 shows the relations between memory regions and memory windows.

Memory windows can only be bound to bindable memory regions. A memory window's protection attributes are constrained by the protection attributes of the memory region. The E810 supports byte-level lower and upper address limits for both memory regions and memory windows.

11.4.1.4.1.3 Tagged Offset (TO)

The 64-bit wide Tagged Offset (TO) field specifies the first byte of the buffer being addressed in a memory region or memory window. Memory regions and memory windows have a base attribute as either zero-based TO or Virtual Address (VA)-based TO. For a VA-based TO, the TO of the first memory location associated with the memory region equals the base virtual address value specified when the memory region is registered. For a zero-based TO, the TO of the first memory location associated with the memory region equals zero.

11.4.1.4.1.4 Page Size

Each memory region and memory window has a page size attribute. Memory windows inherit the page size attribute of their associated memory regions. The E810 supports three different page sizes: 4 KB, 2 MB, and 1 GB. All system memory pages that are part of a memory region or memory window must be of the same size.

11.4.1.5 QP

The PE in the E810 supports the verbs QP. QPs are made up of a pair of WQs.

QP WQs are either SQs or RQs. SQs and RQs are associated with their CQs at QP creation time. The E810 supports QPs for PE administrative commands (control QP or CQP), RDMA is supported by iWARP, RoCEv2, and UDA. Each QP type has unique operation types that are described in Section 11.5.3, Section 11.6.6, Section 11.7.1, and Section 11.8.8. Note that CQP does not implement a RQ.

The E810 supports a maximum of 256K QPs that are distributed among that active PCI functions using HMC resource profiles. See Section 9.3.3 for more information on the resource distribution mechanism used with QPs.

The E810 maintains the context of each QP in QP Context data structures in the HMC's function private memory space. The storage elements of QP context reside in system memory. See Section 9.3 for more information on the E810's usage of host memory for QP context.

11.4.1.5.1 Doorbell Pages

To support direct access to E810 hardware for PE functionality, the E810 implements adapter memory that is mappable to a userspace process. The memory is exposed to the system through the PCI BAR registers in a similar manner to the CSRs. Each PCI function optionally has a number of PE pages as shown in Figure 11-11.

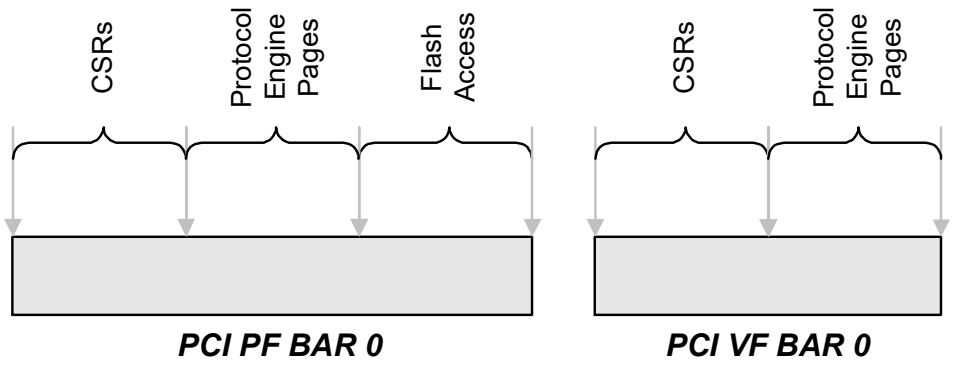

Figure 11-11. PE Page Location in BARs

As shown in Figure 11-12, the first PE page is used for submitting work to PE SQs and also for arming CQs from userspace. 60 KB of space is reserved and then the remaining pages are used to support low latency push mode operation that is described further in Section 11.4.1.5.6.

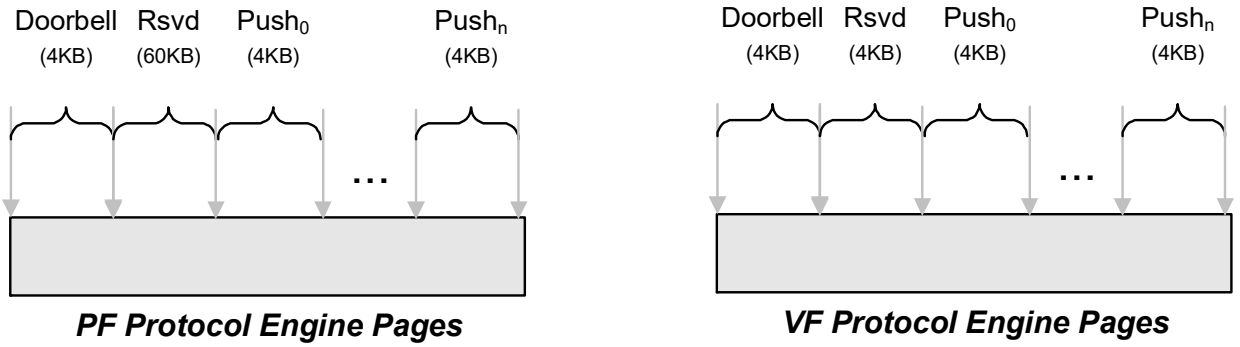

Figure 11-12. PE Pages

The format of the doorbell portion of the PE pages is listed in Table 11-2. The details of each register found in the PE pages are documented in Section 13, "Programming Interface".

Table 11-2. Doorbell Page Register Summary

Offset/Alias Offset	Abbreviation	Name	Block	RW	Section Reference
0x00000000	PFPE_WQEALLOC	PE WQE Allocate Register	PE	RW	13.2.2.28.19
0x00000040	PFPE_CQARM	PE CQ Arm	PE	RW	13.2.2.28.8

11.4.1.5.2 SQ

As shown in Figure 11-13, SQs are organized as circular array of SQ Elements (SQEs). The host memory used for SQs might be physically contiguous or dis-contiguous. Each SQE is 32 bytes in size and can have up to 13 additional fragments for a total of 14. This approach enables Work Requests (WRs) to consume a variable amount of SQ space that enables software to advertise 14 fragments as the maximum supported, but opportunistically pack multiple WRs into a smaller space if the application needed fewer fragments for a given WR.

The E810 takes advantage of variable size WRs by reading 256 bytes at a time from the SQ when processing work. If a WR used all 14 fragments, it would consume the 256 bytes and would be transmitted by itself. If instead the application happened to be using eight consecutive single fragment WRs, all eight WRs would be fetched (assuming software posted the WRs before the E810 managed to read the first WR) with a single read of the SQ, which boosts bus efficiency.

The minimum size of a SQ is four maximum-sized WQEs for proper operations. For example, this means that if a WR can ever use 14 fragments, the SQ must be 1024 bytes. An additional optimization (iWARP only) that the E810 provides is that WRs that are small enough to fit into a single Ethernet packet and fetched as part of the same read of the SQ are sent as a single Ethernet packet for efficiency on the Ethernet fabric.

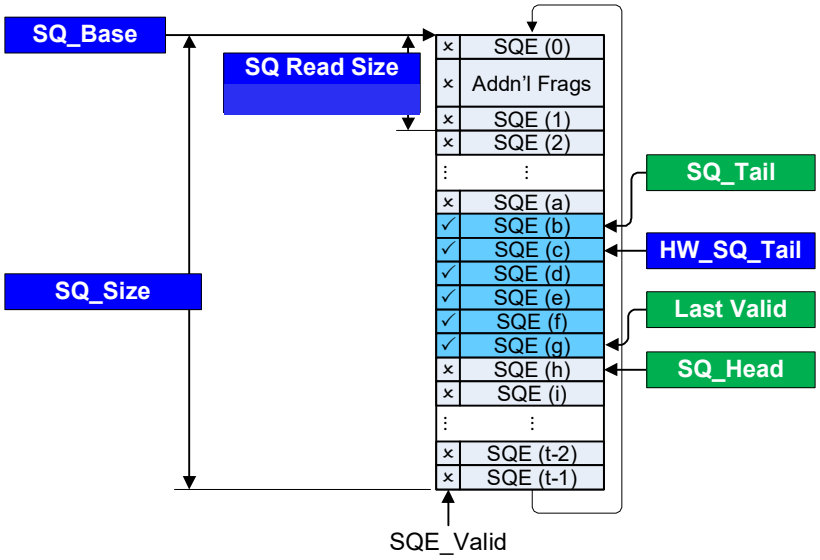

Figure 11-13. PE SQ

Figure 11-13 depicts a typical SQ, where software is tracking *SQ_Head* and *SQ_Tail*, and the E810 tracks *HW_SQ_tail* in QP context. Software must size the SQ large enough to support every SQE with the maximum number of additional fragments. The amount of space required per work request is listed in Table 11-3. Essentially the WR space requirements on the SQ end up rounding up to the next multiple of 32 bytes. SQE 0 is shown using four additional fragments and therefor takes up 96 bytes.

Every SQE must start on an offset that is a multiple of 32 bytes within the SQ and an SQE, and all of related additional fragments must fit into a single 256 byte SQ read block. NOP SQEs can be added if necessary to pad SQEs out when necessary to satisfy this requirement. The 32-byte boundary requirements for SQEs means that there is no difference in SQ size between a WR with four fragments and a WR with five fragments. If SQE 1 required any additional fragments, a single NOP SQE would need to be added in place of SQE 1 and all subsequent SQEs would move down in the SQ so that the SQE 1 and all related additional fragments would fit in the same 256 byte SQ read block.

For the SQ, the maximum size of inline data must also be taken into account when calculating the amount of space required per work request (see Table 11-3).

Table 11-3. QP WR Size Requirements

Number of Fragments Requested at QP Creation	Max Inline Size (SQ Only)	Size Required per Work Request
1	≤ 8 bytes	32 bytes (1 SQE)
2-3	≤ 39 bytes	64 bytes (1 SQE + 2 additional fragments)
4-5 (SQ only)	≤ 70 bytes	96 bytes (1 SQE + 4 additional fragments)
6-7	≤ 101 bytes	128 bytes (1 SQE + 6 additional fragments)
8-9	≤ 132 bytes	160 bytes (1 SQE + 8 additional fragments)
10-11	≤ 163 bytes	192 bytes (1 SQE + 10 additional fragments)
12-13	≤ 194 bytes	224 bytes (1 SQE + 12 additional fragments)
14	≤ 224 bytes	256 bytes (1 SQE + 13 additional fragments)

Figure 11-14 shows a system view of how the E810 processes PE QP SQs. Before describing the flow in Figure 11-14, software must perform a fair amount of initialization. Software starts by populating all QP-related HMC objects necessary for CQs, QPs as well as related memory regions. Next, software allocates buffers for software QP and CQ context, SQ and RQ WRID tracking arrays (software context and WRID tracking arrays do not need to be pinned, QP40, CQ48, and CQ41 in Figure 11-14), QP and CQ doorbell shadow/status areas, Q2 areas, and finally the SQ, RQ, and CQ buffers themselves.

The doorbell shadow/status areas, Q2 and WQs all need to be pinned, and if they are physically dis-contiguous, the page list for each of the pinned buffers must be collected. CQP operations are used to create the CQs (if they do not already exist) and QPs.

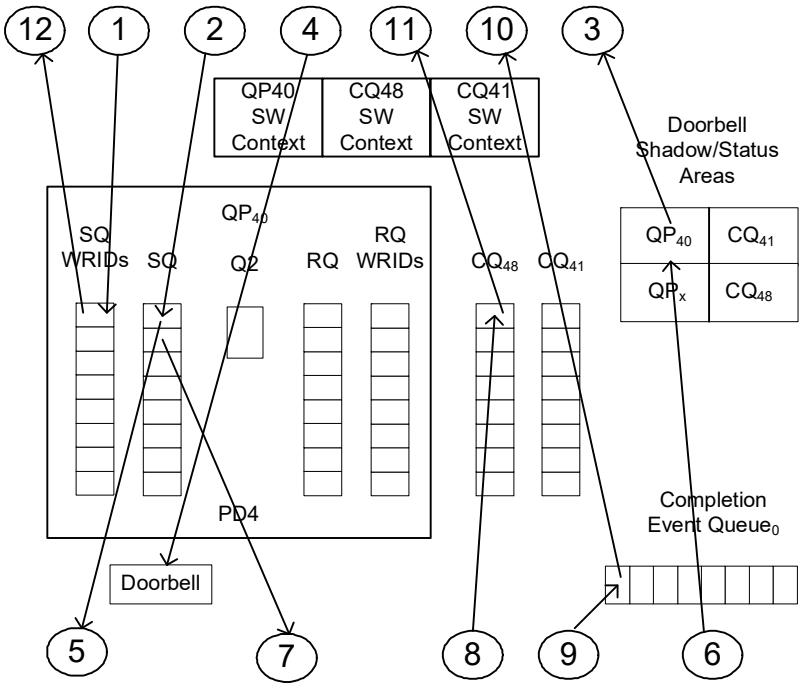

Figure 11-14. PE Operation: SQ

Now that all structures have been created and defined to the E810, the steps shown in Figure 11-14 to process a post-send verbs request are the following:

1. Software stores the WRID supplied by the application on the post-send request to the SQ WRID.
2. Software creates a SQE along with any additional fragments necessary to represent the WR.
   a. If the SQE being created does not consume the rest of the 256-byte SQ read block, software must ensure that the next SQE has the *Valid* bit set to the invalid setting. This is not required if the next SQE starts in a different 256-byte SQ read block.
   b. Step 2a must be done before this step. The *Valid* bit in the SQE must only be set once after all fields are valid, since the E810 can read SQEs at any time. Note that the *Valid* bit is a generational valid bit, which means that for the first (and all subsequent odd) iteration through the SQ, 1b means valid. On all even iterations through the SQ, 0b indicates that the SQE is valid.
3. Software reads *HW_SQ_Tail* from the doorbell status area for the QP.

4. Software determines whether or not to ring the SQ doorbell.
    a. If *HW_SQ_Tail* is in the range of WQEs just posted (taking into account the possibility of wrapping), ring the SQ doorbell.
    b. *SQE_Head* is incremented by the number of SQEs posted since the last doorbell check (WR size in bytes/32 bytes).
5. The E810 reads the 256-byte SQ read block that contains the SQE indicated by QP context value of *HW_SQ_Tail*.
    a. The E810 processes all valid SQEs contained in the 256 byte SQ read block. If no SQEs are valid, proceed to Step 6.
    b. The E810 processes the SQEs, which likely includes fetching data from host memory, sending packets through the Ethernet port, and waiting for TCP acknowledgments.
    c. The E810 can increment the *HW_SQ_Tail* in the doorbell shadow/status area during this processing.
    d. If the last SQE in the 256-byte SQ read block is valid, Step 5 is repeated, which reads the next 256-byte SQ read bock.
6. The E810 writes the doorbell status area for the QP with the current value of *HW_SQ_Tail* or the write can be delayed until later.
7. The E810 reads the 256-byte SQ read block one more time to ensure that software has not posted new work.
    a. If a new valid SQE is found, proceed back to Step 5a.
8. The E810 optionally writes to the CQ associated with the SQ.
9. The E810 optionally writes to the CEQ if the CQ was written and generates an interrupt.
10. Software then fields the interrupt if one was generated and reads the CEQ to determine the CQ that generated the event (an application might be polling the CQ directly in which case Step 9 and Step 10 are skipped). Typically the CEQE contains the most significant 63 bits of the virtual address of CQ context to make CE processing efficient.
11. Software then reads the CQ to determine the QP and WQ that generated the work completion. The SQE index of the WR is reported in the CQE along with a 64-bit pointer that is typically set to the Software QP context address at QP creation time.
12. Software then reads the SQ WRID array for the SQE index from the completion. The resulting WRID is returned to the application as an indication that the original work request completed.

Note: While Step 6 and Step 8 are shown as sequential, the E810 starts both steps simultaneously. Also, Step 1 can be initiated by software at any time as well.

11.4.1.5.2.1 Immediate Data Operations

The E810 supports Immediate Data operation for the SQ.

In iWARP, the intention of this operation was to combine it with a previously-adjacent RDMA Write operation to emulate an RDMA Write with Immediate Data operation. iWARP supports a Write with Immediate Data operation. Send with Immediate Data is not defined for iWARP and is not supported. From a wire perspective, the Immediate data is an untagged operation and consumes an RQ WQE and also a CQE at the peer.

RoCEv2 supports Send with Immediate Data and Write with Immediate Data.

11.4.1.5.2.2 RDMA Read with Multiple SGEs or Local Data Sink Buffer

The InfiniBand definition for RDMA Read has more flexibility than iWARP:

- InfiniBand supports multiple SGEs. iWARP does not.
- InfiniBand does not require remote write access on sink buffers. iWARP does.
- InfiniBand allows privileged applications to use the Reserved L-Key in the SGEs. Because of the remote write access requirement, iWARP does not allow STag 0.

The last item especially puts iWARP at a disadvantage since it requires privileged applications to do fast register and invalidates around RDMA Reads.

The E810 supports RoCEv2, so it has to implement the more general RDMA Read semantics. The E810 provides a way to eliminate these differences for iWARP without changing the wire protocol.

In general, this approach enables multiple data sink SGEs to be used for RDMA Reads by using the *AdditionalFragmentCount* field of the RDMA Read WQE. When the Read Response comes in, the hardware re-read the WQE to determine where to place the data. The hardware validates that the data can be placed against each SGE.

11.4.1.5.2.2.1 iWARP - RDMA Read with Multiple SGEs

Hardware generates an artificial data sink STag. The low 14 bits have the index to the RDMA Read WQE in the SQ. The high bits are randomized and are guaranteed to be non-zero.

When the Read Response comes in, the WQE index in the STag field is used to tell hardware where the WQE is in the SQ. Hardware re-reads the WQE to determine where to place the data. Standard STag validation is done on the RDMA Read WQE SGEs. The exception for the WQE SGEs is that Remote Write access is not required. Since the STag in the Read Response directly references the SQ WQE, there is no additional object required.

The artificial STag is very specific to RDMA Reads and is not used for any other purpose. Nor is it known by software. It is possible that a real STag and an artificial STag could use the same value. Hardware will not have problems since the two values are used in different ways.

Note: The *Infiniband_read_en* flag must be set in the QP context to support InfiniBand style RDMA reads for iWARP. If this flag is not set, iWARP RDMA Reads operate the old way (one SGE, *write_access* required, no support for STag 0).

11.4.1.5.2.2.2 RoCEv2 - RDMA Read

In RoCEv2, hardware allocates a Read Response Entry object before the RDMA Read Request is sent. This object tracks the index of the WQE that needs to be re-read. When a Read Response is received, the SQ WQE index is used to re-read the WQE. When the RDMA Read completes, hardware places the object on the Read Response Entry Free List.

11.4.1.5.3 Memory Keys

When iWARP registers a block of memory, it allocates an STag, which is used for local and remote operations. RoCEv2 defines separate keys for local operations (L_Key) and remote operations (R_Key). The E810 generates one key for registered memory. The key is used for both the L_Key and R_Key values.

This document uses the term STag generically when referring to memory keys.

11.4.1.5.4 Privileged Keys

The use of a privileged key allows QPs to reference physical addresses. They are never placed on the wire, and only privileged QPs are allowed to use them. For this purpose, iWARP defines STag 0, and RoCEv2 defines a Reserved L_Key.

Unlike iWARP's STag 0, RoCEv2 does not architecturally define the value for the Reserved L_Key - it is defined by the device. This implementation uses the value of 0 for the Reserved L_Key.

11.4.1.5.5 Virtual Queues

The E810 supports physically contiguous and physically dis-contiguous WQs for PE QPs. CQs, and CEQs also support both physically contiguous and dis-contiguous buffers. In the case of QPs, the support for physically dis-contiguous WQs is referred to a virtual WQ support. This section describes an example of a SQ.

Figure 11-15 shows a virtually contiguous but physically dis-contiguous SQ. The left side of the figure shows the applications view of the SQ. This particular SQ is composed of four host memory physical pages that are not contiguous. In this scenario, the virtual buffer is pinned and the 1 level page list is retrieved from the operating system. Then an unused page list must be allocated from the HMC PBLE object space with four contiguous PBLEs. This PBL is now populated with the page list retrieved from the operating system. When the QP is created, the *Virtual_WQs* bit is set in CQP Create QP WQE and the *SQ_Base* in QP context is set to the starting PBLE HMC object index instead of a host physical address of the SQ. The RQ for a QP with the *Virtual_WQs* bit set must also use a PBL even if it happens to be physically contiguous. Note that the SQ and RQ in this case must be allocated a host page boundary.

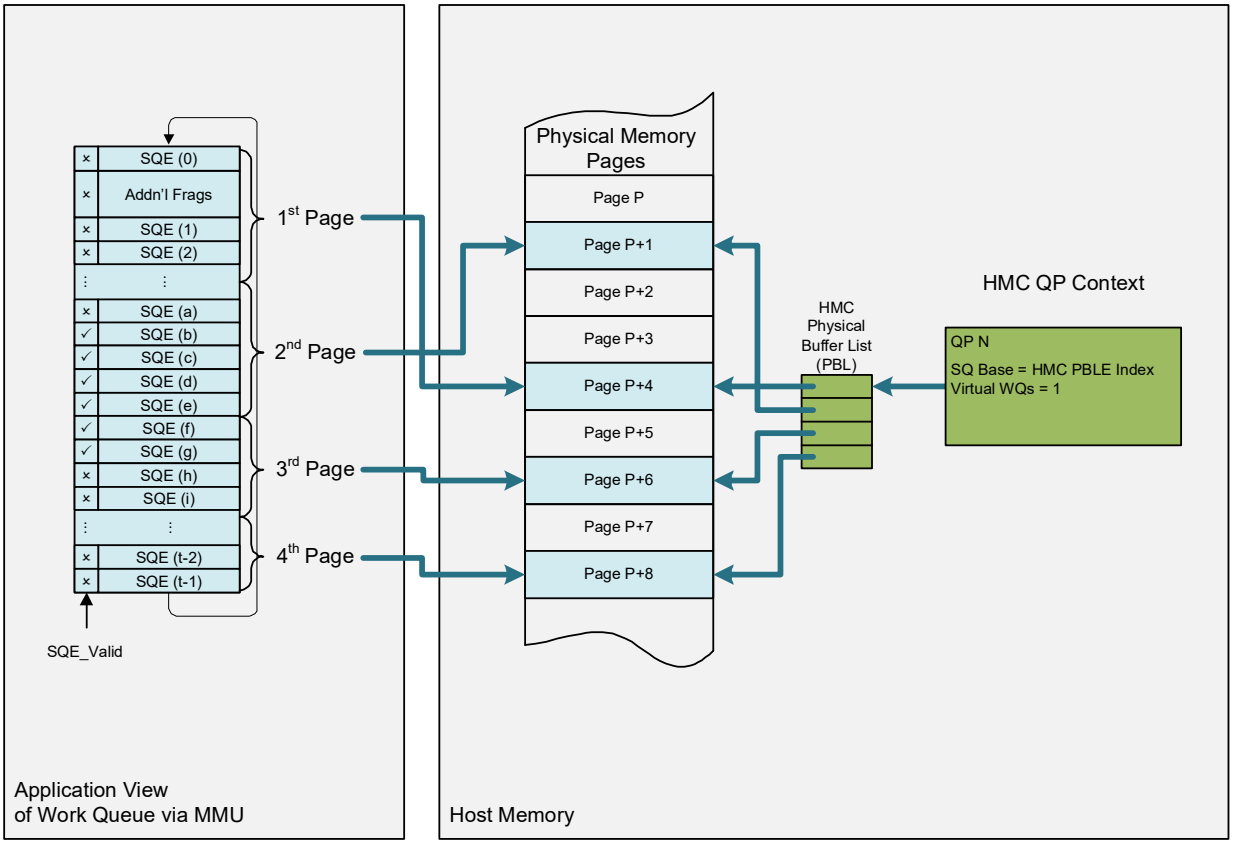

Figure 11-15. PE Operation: Virtual SQ

11.4.1.5.6 SQ Push Mode

Push mode reduces processing latency of the short message posted for transmission on the low-latency QP by eliminating a read of WQE or WQE with inline data from the host memory. This is achieved by software writing WQEs to the adapter memory-mapped address space using processor write-combining buffers. Processor write-combined buffers allow combine writes and make transactions on the bus more efficient. Software is not expected to use this mode to stream high rate of the short messages or use this mode to post a large messages. The size of the message posted using push mode should not exceed a configured scheduling quanta. This feature can be either exposed to the application and have an application responsible for the potential QP bandwidth degradation caused by overuse of this feature, or a verb layer can be instrumented to use information provided by hardware and opportunistically take advantage of push mode messages for the given connection based on true low-latency messaging requirements.

In modern systems, a memory type can be specified within an operating system page structure using an index in the PAT register. This way an individual page of adapter memory can be mapped to the application address space as a write-combined memory. Writes to such page would be combined in the processor write combining buffers. These buffers are flushed on PCI bus in cache lines. In some systems, the same page can be mapped as an un-cached memory page that enables software to use un-cached write (or doorbell ring) to flush push mode WQEs from processor write-combining buffers to the PCIe bus.

Adapter memory-mapped pages used for push mode WQEs are called push pages. The number of push pages exposed to the driver depends on the chip configuration and PCIe function. In most systems, it is not possible to map the same page as both un-cached (non-write-combined) and write-combined. In this case, the GLPE_PSHCFG.*PSHCFG_DB_SPLIT* bit must be set, which forces the doorbell pages to be treated separately from the page used to push the WQEs and data. When GLPE_PSHCFG.*PSHCFG_DB_SPLIT* is set, two push pages are mapped to the application address space where the odd number push page is mapped as un-cached (used as the push doorbell page) and the even numbered push page is mapped as write-combined. This reduces the amount of push pages available to applications by half since a single application requires two separate push pages for proper operation.

Combining writes using dedicated write-combining buffers is a very old feature of the processors. This feature was mainly used for the ancient graphic adapters. Now days all graphics adapters use their own DMA engines to pull the data from the host memory, rather than having it pushed with CPU.

Processors specify a write combining memory region using several mechanisms.

- The MTRR register specifies a memory type per region. Granularity of memory region sizes does not allow the use of MTRR for wide deployment of write-combining for the E810.
- Page Attribute Table (PAT) in conjunction with flags in Page Table Entry (PTE) enables write-combining on a per-page base, which makes it feasible for E810 deployment. Relatively recent distribution of Linux added an interface allowing change page attributes to write-combined page.

Processors have a set of buffers for write-combined accesses. Each buffer has a size of several cache lines. Writes to write-combined memory are intended to be delayed to enable better memory access efficiency and reduced overhead.

Write-combined buffers are evicted or flushed by serialization events, such as SFENCE, LOCK, interrupt, and so on, and read/write to un-cached memory. Partial write-combined buffer eviction can be a result of the serialization event. Eviction of a full write-combined buffer is implementation dependent. Intel assumes that serialization events are evicting/flushing both full and partially filled write-combined buffers. The intention is to use doorbell ring (write to un-cached memory) as a serialization event to evict write-combined buffers.

All types of the PE SQ WQEs can posted using a push mechanism. The maximum size of data that can be pushed together with WQE as an inline data is limited to the 224 bytes, matching the maximum size of data that can be posted using WQE with inline data. Larger messages can be pushed using regular WQE, eliminating a need to read a WQE from the host memory. If an application requested post send, verb layer can decide whether to push the message to adapter based on the message size, configurable threshold and outstanding WQEs previously posted to SQ. In any case, verb layer should always first post WQE to the SQ (without ringing the doorbell) and only then write WQE push mode page, followed by un-cached write to the associated push mode page. Posting WQE to the SQ is required for the proper re-transmission process, and enables hardware to opportunistically discard push mode messages and transmit those using regular SQ processing mechanism.

To avoid security implications, a push mode page cannot be shared by different processes. If it was allowed to be shared, then ProcessA could guess the QP number of ProcessB and other QP attributes, like the push mode page, and make ProcessB send a message pushed by ProcessA as its own. This can lead to a severe security violation. Multiple threads residing in the same process share a process virtual space and belong to the same security domain. The number of push pages for VFs is limited to 15 to reduce the amount of BAR space that the operating system is required to allocate for the E810. To overcome this restriction, a para-virtualized driver is allowed to map PF push pages to the VF for use.

Push mode is an opportunistic latency optimization that is supposed to be used on lightly loaded QPs. If the adapter runs out of resources or software attempts to use push mode WQEs too aggressively, the adapter can discard a push mode WQE, and transmit it later as a regular WQE with inline data posted to SQ.

Software is allowed to post any SQ message using push mechanism. The size of the message should not exceed a configurable quanta value (default of 4 KB). Messages specified as inline operations by application can be pushed together with data. A total of 224 bytes of the message with inline data can be pushed to the E810 to avoid overhead of the SQE and data fetches. Larger messages would avoid a fetch of the SQE element, but still requires a data fetch. Software can post multiple messages with single push operation, as long as all messages are continuously located and do not cross a boundary of the push page SQE element, shown in Figure 11-16 and Figure 11-17.

Push mode does not require any change in WQE format, except for setting a push bit in the SQ WQE. A process is enabled for push mode by allocating a push page shown in Figure 11-16, or a pair of push pages as shown in Figure 11-17 (see Section 11.5.3.8 for the CQP WQE format) from the E810's BAR to a QP and including the push page Index in QP context when the QP is created. Each PCI function has a number of Push mode pages that must be assigned to a queue set handle. See Figure 11-11 and Figure 11-12 for more details on how the E810 exposes push pages to the system. The E810 validates that the push operation is associated with the correct push page and Push SQE index as well as PCI function before acting on the operation.

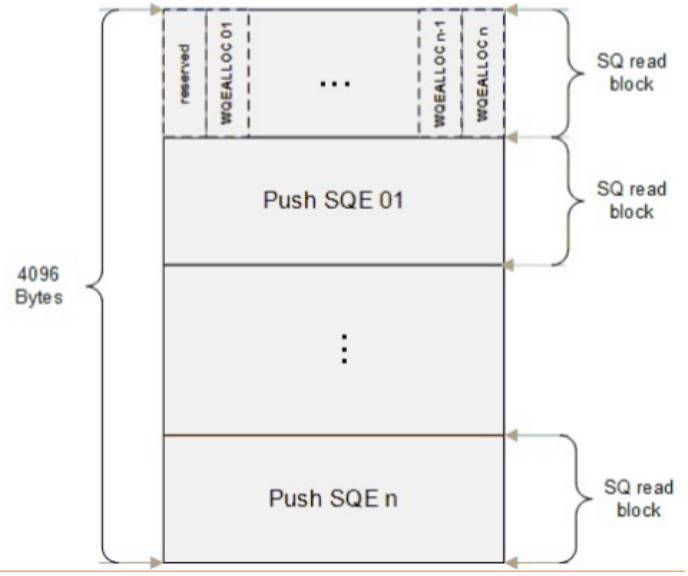

Figure 11-16. Combined Push Page Detail

On a combined push page, the number of WQEs is 15.

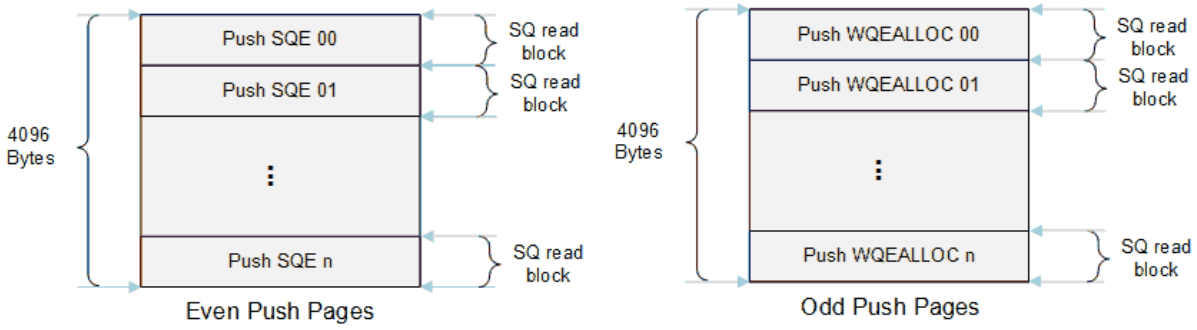

Figure 11-17. Split Push Page Detail

On a split push page, the number of WQEs is 16.

When GLPE_PSHCFG.*PSHCFG_DB_SPLIT* is clear, the push doorbell area is located at first 256-byte region of the push page. Push doorbell area for PFs contains 31 instances of the PFPE_WQEALLOC register described in Section 13.2.2.28.19. PFPE_WQEALLOC instances are continuously located within the push doorbell area starting at offset four bytes into the 256-byte region. Push doorbell area for VFs contains 31 instances of the VFPE_WQEALLOC register described in Section 13.2.2.28.18. VFPE_WQEALLOC instances are continuously located within the Push Doorbell area starting at offset four bytes into the 256-byte region. All QPs associated with a given push page use the same push doorbell area. Each instance of the PFPE_WQEALLOC and VFPE_WQEALLOC corresponds to the respective Push SQE. The Push SQE index matches an index of the respective PFPE_WQEALLOC or VFPE_WQEALLOC registers.

When GLPE_PSHCFG.*PSHCFG_DB_SPLIT* is set, the WQEALLOC instances are located in odd numbered push pages and the PUSH SQEs are located in even numbered push pages. Additionally, the stride of the doorbell array to 256 bytes instead of the packed array of doorbells shown in Figure 11-16. In other words, each odd numbered push page has WQEALLOC instances at offsets 0, 256, 512, ... instead of 0, 4, 8, ... to allow for write-combine avoidance on un-cached writes to the push doorbells.

Figure 11-18 shows the mechanism for pushing a WQE to the E810.

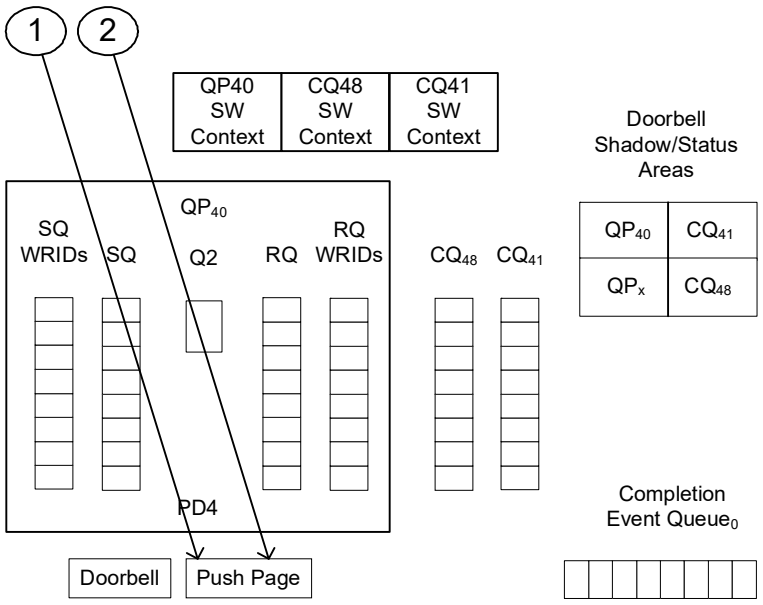

Figure 11-18. PE Operation: SQ Push Mode

Push mode operation builds on the typical SQ operation shown in Figure 11-14. The following two steps replace Step 4 from the procedure defined in Section 11.4.1.5.2.

For the Push operation to be effective, the SQ should be empty before placing WQEs. Software can place multiple Push WQEs (that is, the SQ does not have to be empty as long as they are all Push WQEs). Once a non-Push WQE is placed to the SQ, software should not place any more Push WQEs until the SQ is empty again. In other words, software should not intermix Push and non-Push WQEs. Additionally, if a CQE indicates that a Push WQE has not completed as a Push WQE, software should cease posting Push WQEs until the SQ is empty again.

1. Instead of the usual doorbell page write, a copy of the SQE is written to one of the push page SQEs from Figure 11-16. This page is configured with write combine attributes for this step. If less than 256 bytes WQEs are written to the 256-byte Push WQE and the WQE did not start on a 256-byte boundary within the SQ, the WQE data from the SQ must be written to the matching offset in the Push WQE from the start of the most recent 256-byte boundary in the SQ. For example, if WQE index 9 from the SQ happens to be 32 bytes long and needs to be pushed, 32 bytes need to be written 32 bytes past the start of the Push WQE instead of at offset 0 in the Push WQE. This is because WQE index 9 starts 32 bytes past the previous 256-byte boundary in the SQ. Write to the Push WQE must be eight bytes at a time, on 8-byte boundaries, and all bytes of a Push WQE must be written. There must be no partial cache line writes. If writes are not on natural 8-byte boundaries, the Push WQE is dropped.
2. After writing the SQE to the push page SQE, the push page doorbell is written to indicate that the push is complete. Note that the doorbell written for non-push operations is not written for push operations.

Step 7 from the procedure described in Section 11.4.1.5.2 is typically skipped for push mode operations unless the E810 is low on resources, the traffic class associated with the push page has insufficient bandwidth allocation to complete the operation. Push mode operations are also ignored if the traffic class associated with the push page is flow controlled. In the cases where the E810 ignores the SQE pushed in Step 2 above, the WQE is re-fetched normally and processing continues. The only side effects of the dropped push operation is wasted bandwidth on the PCI bus and wasted CPU cycles. To keep the wasted bandwidth and CPU cycles to a minimum, the next CQE generated after the dropped push operation indicates that the drop occurred and software should stop issuing push operations until it reaches an empty SQ condition.

The maximum number of pending push doorbell resources is 128. Software can prepare the next 128 WQEs, but it should not exceed 128 pending push doorbells. If software exceeds this amount, the hardware directs the push doorbell to the SQ.

11.4.1.5.7 SQ Suspend and Resume

Software is provided with CQP Commands allowing a suspend and resume operation of the SQ. Commands are defined in Section 11.5.3.22 and Section 11.5.3.23, respectively. Those commands are primarily used to migrate QP from one QS to another QS. This migration might be triggered by a system configuration change. For example, a change in number of TCs configured for the particular physical port, which in turn requires reassignment of QPs to the QSs associated with the TCs.

Software is required to reassign all QPs associated with particular QS prior posting an AQ Command that might result in QS removal. Such reassignment of the QP to the new QS should be performed using Suspend and Resume CQP commands (Section 11.5.3.22 and Section 11.5.3.23, respectively). Both Suspend and Resume CQP commands are asynchronous requests, and their completion does not indicate completion of a requested operation. Completion of a resume operation is never reported to software. Completion of a suspend operation is reported using AE_QP_SUSPEND_COMPLETE. Software is allowed to request multiple suspend and resume operations for different QPs accelerating transfer of multiple QPs from one QS to another.

11.4.1.5.8 RQ

As shown in Figure 11-13, RQs are organized as circular array of RQ Elements (RQEs). The host memory used for RQs can be physically contiguous or dis-contiguous. Each RQE is 32 bytes in size and can have up to 13 additional fragments for a total of 14. Unlike SQs, RQs all have fixed size Work Requests (WR) even if the application uses a smaller number of fragments that could be used to represent a WR. The minimum size of a RQ is four maximum sized WQEs for proper operations. For example, this means that if a WR can ever use 14 fragments, then the RQ must be 1024 bytes. This is necessary to allow out-of-order placement of inbound RDMA send operations for iWARP QPs. All RQEs must start on an offset that is a multiple of RQ WQE size and an RQE along with its associated additional fragments must be contained in a single 256-byte RQ read size buffer. This leads to the same RQ buffering requirements per WR as those listed for the SQ in Table 11-3.

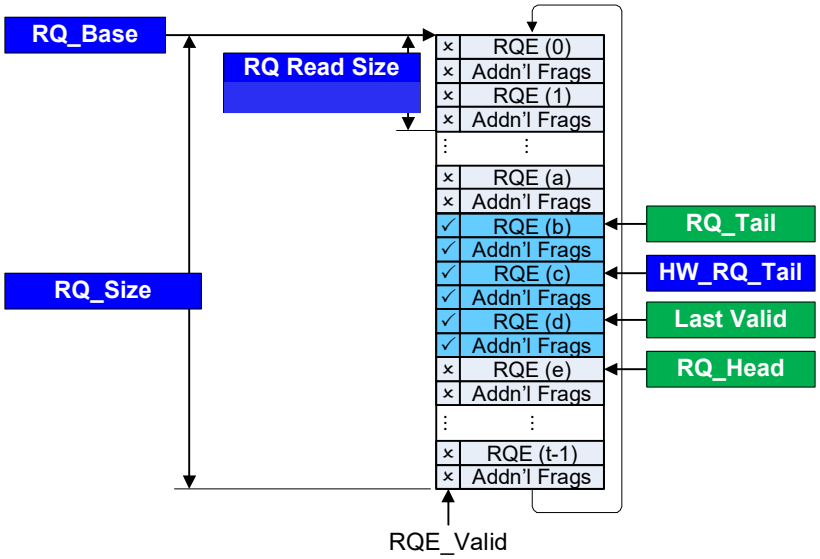

Figure 11-19. PE RQ

Figure 11-19 shows a typical RQ where software is tracking *RQ_Head* and *RQ_Tail*, and the E810 tracks *HW_RQ_Tail* in QP context. Software must size the RQ large enough to support every RQE with the maximum number of additional fragments. All RQEs are shown using two additional fragments and therefore takes 64 bytes. NOP RQEs can be added if necessary to pad RQEs out when necessary to satisfy the RQE alignment requirements. The 32-byte boundary requirements for RQEs means that there is no difference in RQE size between a WR with two fragments and a WR with three fragments.

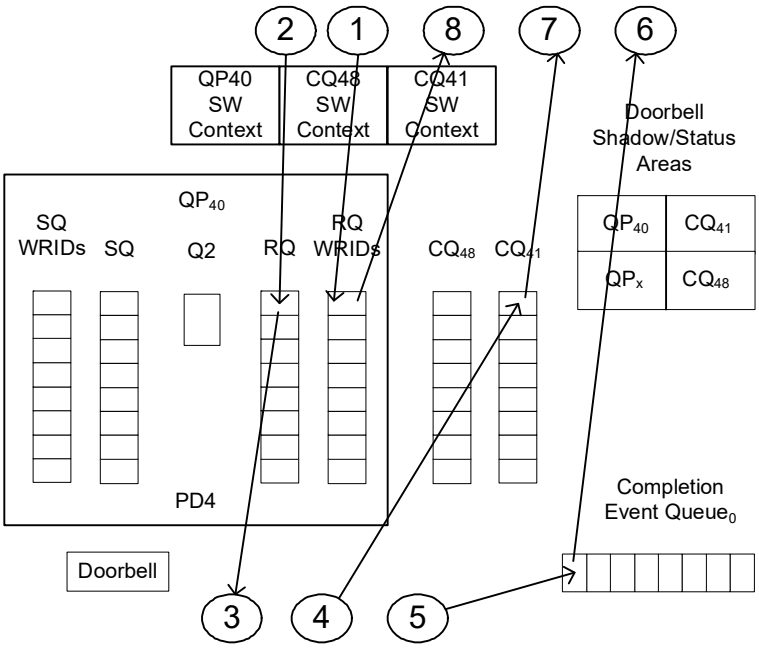

Figure 11-20. PE Operation: RQ

The initialization required to bring a QP to an operation state was generally described in Section 11.4.1.5.2. Once this initialization has been performed, the steps in Figure 11-20 show how software and the E810 interact for RQ operations.

1. Software saves the Work Request ID (WRID) passed in on the post-receive verbs call.
2. Software builds a RQE using the fields that passed in on the post-receive verbs call.
   a. The *Valid* bit in the RQE must only be set once all fields are valid since the E810 might read RQEs at any time. Note that the *Valid* bit is a generational valid bit, which means that the first (and all subsequent odd) iterations through the RQ, 1 means valid, on all even iterations through the RQ, 0 indicates that the RQE is valid.
3. Once an operation targeting a QPs RQ is received, the E810 reads QP context to determine the location of the RQE to be read.
   a. The RQE is read from host memory and the *Valid* bit is checked. If the RQE is invalid, the packet associated with RQE is dropped, or the QP is put into the error state and an AE is generated.
4. The E810 reads the 256-byte RQ read block that contains the RQE indicated by the QP context value of *HW_RQ_Tail*.
   a. The E810 potentially processes all valid RQEs contained in the 256-byte RQ read block if more than one inbound operation targeted this QP's RQ. For this example, it is assumed that a single inbound operation has been received.
   b. The E810 processes RQE 0, which likely includes writing data to host memory and sending TCP acknowledgments.
   c. The E810 increments the *HW_RQ_Tail*.
5. The E810 writes to the CQ associated with the RQ.
6. The E810 optionally writes to the CEQ if the CQ was written and generates an interrupt.

7. Software then fields the interrupt if one was generated and reads the CEQ to determine the CQ that generated the event (an application might be polling the CQ direction in which case Step 6 and Step 7 are skipped). Typically, the CEQE contains the most significant 63 bits of the virtual address of CQ context to make CE processing efficient.
8. Software then reads the CQ to determine the QP and WQ that generated the work completion. The RQE index of the WR is reported in the CQE along with a 64-bit pointer that is typically set to the software QP context address at QP creation time.
9. Software then reads the RQ WRID array for the RQE index from the completion. The resulting WRID is returned to the application as an indication that the original WR has completed.

11.4.2 iWARP State Management

iWARP QP state is controlled by the application to a large extent. The verbs interface enables the application to manage QP transitions and provides rules for what the RNIC Interface (RI) must enforce.

This section is not intended to repeat all information from the verbs specification. It is intended to be an overview of the expected usage model to be used with the E810. In the end, it is a combination of hardware support from the E810 and supporting software that provides a verbs-compliant interface.

Table 11-4 lists the operations performed by the E810 based on the iWARP QP state.

Table 11-4. iWARP QP State Behavior

QP State	QP Activities
Non-existent	• Doorbell rings are dropped silently. • No transmit (because doorbell rings are dropped). • No receive processing (no hash entry).
Idle	• SQ/RQ WQEs can be posted. • No SQ WQEs are processed. • No receive processing (no hash entry).
RTS	• Normal SQ/RQ/CQ/CEQ processing (hash entry added on transition to RTS by firmware).
Closing	• No new SQ work is expected. • Doorbell rings are dropped silently. • No new RQ work is expected. However, if a packet arrives with data it is treated as an error (BAD_CLOSE) and the QP transitions to error state.
Terminate	• No RQ processing (discarding received data). • No new SQ WQEs processed. • SQ WQEs might be retransmitted. • Terminate/FIN might be transmitted.
Error	• No SQ WQEs processed. • No RQ WQEs processed. • Host software eventually requests CQP to remove the hash entry.

QP state transitions and the associated software and hardware/firmware actions driven from software interactions with the application are listed in Table 11-5.

Table 11-5. iWARP QP State Transition

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
Nonexistent -> Idle (CreateQP)	• Initialize the HMC backing pages necessary to support the QP. • Allocate/Initialize all software tracking structures for the PD, CQ, QP. • Assign QP to a PD. • Create CQ. • Allocate SQ and RQ. • Allocate terminate message buffer (Q2). • Allocate the doorbell shadow area. • Perform parameter checks specified by the verbs specification. • Issue CreateQP WQE to CQP.	• Update QP context.
Idle -> Idle	• Perform parameter checks specified by the verbs specification. • Issue Modify QP to CQP, next state = Idle.	• QP state parameters are updated.
Idle -> RTS	• Create a TCP socket and ensure that it is in the established state. • If a streaming mode message is desired, ensure that it has been placed on the SQ immediately following any unacknowledged TCP send data. • Perform parameter checks specified by the verbs specification. • Issue Modify QP to CQP, next state = RTS.	• Set the TCP state to established and RDMA state to RTS. • Insert the QP's hash table entry to receive accelerated data. • Start scheduling work for the QP.
Idle -> Error	• Perform parameter checks specified by the verbs specification. • Issue Modify QP WQE to CQP with the next state set to error, reset connection (if connection not already reset) and remove quad hash (if quad hash entry has not been previously removed) by setting appropriate bits in the bits set. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs. • Handle poll for completion requests for flushed WQEs, the CQ has one CQE for each WQ that had pending WQEs, software must report all pending WQEs as flushed once it gets the single flushed CQE (per WQ with pending WQEs), the number of WQEs flushed can be determined from software's head and tail for the SQ and RQ at the point in time that the poll for completion call is made that returns a flushed CQE.	• Set RDMA state to error. • When the flush WQEs operation is issued and any WQEs are outstanding on the SQ and/or RQ as requested by host software, complete the first pending WQE for each WQ (flushed completion status).

Table 11-5. iWARP QP State Transition [continued]

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
RTS -> Closing	• Perform parameter checks specified by the verbs specification. • Stop processing new PostSQ/RQ requests. • Ensure that no outstanding SQ or outbound RDMA read responses are pending (this is really up to the application). • Start a timer to put a bound on how long a connection is allowed to stay in the closing state. • Submit a Modify QP WQE to CQP the next state = Closing. • If the completion error is a bad close, generate an AE, QP state is already error. • If any RQ WQEs are still pending, issue Flush WQEs operation to CQP.	• If there is pending SQ or Q1 work, generate a completion error (bad close), software needs to translate into an AE. • Else, update RDMA state to closing. • When the flush WQEs operation is issued and any RQ WQEs are outstanding, complete the first pending WQE for each WQ (flushed completion status).
RTS -> RTS	• Perform parameter checks specified by the verbs specification. • Ensure that the number of currently pending outbound RDMA read requests is less than or equal to the new ORD value. • Ensure the only parameter that is changed is ORD size, it is only allowed to shrink or remain the same.	• Update the ORD value.
RTS -> Terminate or Terminate -> Terminate	• Perform parameter checks specified by the verbs specification for the RTS -> Terminate case. • Set terminate action (usually send FIN and terminate). • Start a timer to put a bound on how long the QP is allowed to stay in the terminate state in the case of an abortive tear-down. • If completion error indicates tcp_state = error: — Issue Modify QP WQE to CQP with next state = Error. — Generate LLP connection reset AE. • If terminate sent AE is received, issue an additional Modify QP with next state = Terminate and terminate action set to 3 (do not sent FIN or terminate). • If completion code indicates LLP closed, the TCP state has transitioned to closed or time wait so an LLP close complete AE should be generated by software.	• If the TCP state = Closed, generate completion error indicating *tcp_state* was closed (indicates a reset was received). • Update iWARP state to terminate. • Once all outstanding TCP segments have been acknowledged, send the terminate message and/or FIN. • Generate a terminate sent AE.
RTS -> Error or Closing -> Error or Terminate -> Error	• Perform parameter checks specified by the verbs specification. • See IDLE->Error case for CQP and completion processing. • Block until the RST sent AE has been seen (probably want to start a timer, and upload QP context if it expires to see what has happened). • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs.	• If host software requested the connection to be reset, send a TCP RST segment. • Remove the QP's HTE if the *Remove_Hash_Entry* field is set. • Update iWARP state to error. • Wait for all packets to clear the pipeline. • Clean up QP context (prevent future scheduling). • Generate a RST sent AE. • Set the TCP state to closed.

Table 11-5. iWARP QP State Transition [continued]

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
Error -> Idle	• Software issues destroy QP operation to CQP.	• Destroy the QP.
Error -> Error	• Submit a Modify QP WQE to CQP with next state = Error and the reset_connection bit set. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs.	See RTS-> Error.

QP state transitions and the associated software and hardware/firmware actions driven from wire interactions with remote peer are listed in Table 11-6.

Table 11-6. iWARP QP State Transition Driven from the Wire

Row #	Wire Activity	Initial QP State (TCP, iWARP)	E810 Actions	Software Actions
0	FIN Received	EST, RTS	• Set the TCP state to close wait (note that iWARP state is not changed). • If no work was outstanding on the SQ or Q1: — Issue AE_LLP_FIN_RECEIVED. Else: — Issue AE_RDMAP_ROE_BAD_LLP_CLOSE. • Send ACK to the FIN. • Continue processing SQ WQEs.	• Stop processing new post RQ operations if not already stopped. • Issue appropriate AEs. • If system software does not automatically generate closing, start the closing process based on the received event by issuing Modify QP with the next state set to closing.
1	FIN Received	FW1, Closing	• Send ACK to the FIN. • If the ACK receive with the inbound FIN acks the transmitted FIN: — Set the TCP state to Time Wait. — Issue AE_LLP_CLOSE_COMPLETE. Else: — Set the TCP state to Closing (note that iWARP state is not changed).	• If the AE_LLP_CLOSE_COMPLETE is received: — Cancel the pending disconnect fail safe timer. — Stop processing new post RQ operations if not already stopped. — SQ operation processing should have been stopped on the Modify QP with the next state set to closing. — Issue appropriate AEs. — Issue Flush WQE CQP operation. — The application or system software starts the QP cleanup process.
2	FIN Received	FW2, Closing	• Send ACK to the FIN. • Set the TCP state to time wait (note that iWARP state is not changed). • Issue AE_LLP_CLOSE_COMPLETE.	See Row 1 of Software Actions.
3	FIN Received	EST, Terminate	See Row 0 of E810 Actions.	See Row 1 of Software Actions.
4	FIN Received	FW1, Terminate	See Row 1 of E810 Actions.	See Row 1 of Software Actions.
5	FIN Received	FW2, Terminate	See Row 2 of E810 Actions.	See Row 1 of Software Actions.
7	ACK Received	FW1, Closing or Terminate	• Set the TCP state to FW2.	N/A

Table 11-6. iWARP QP State Transition Driven from the Wire [continued]

Row #	Wire Activity	Initial QP State (TCP, iWARP)	E810 Actions	Software Actions
8	ACK Received	FW2, Closing or Terminate	• Send ACK to the FIN. • Set the TCP state to time wait (note that iWARP state is not changed). • Issue AE_LLP_CLOSE_COMPLETE.	See Row 1 of Software Actions.
9	ACK Received	Closing, Closing or Terminate	• Set the TCP state to time wait (note that iWARP state is not changed). • Issue AE_LLP_CLOSE_COMPLETE.	See Row 1 of Software Actions.

11.4.3 RoCEv2 State Management

RoCEv2 QP state is controlled by the application to a large extent. The verbs interface enables the application to manage QP transitions and provides rules for what the RNIC Interface (RI) must enforce.

This section is not intended to repeat all information from the specification. It is intended to be an overview of the expected usage model to be used with the E810. In the end, it is a combination of hardware support from the E810 and supporting software that provides a verbs-compliant interface.

Table 11-7 lists the operations performed by the E810 based on the RoCEv2 QP state.

Table 11-7. RoCEv2 QP State Behavior

QP State	QP Activities
Non-existent	• Doorbell rings are dropped silently. • No transmit (because doorbell rings are dropped). • No receive processing.
Reset	• Software-only state.
Initialized	• RQ WQEs can be posted. • No SQ WQEs can be posted. • No receive processing.
RTR	• RQ WQEs are processed by hardware. • Process and respond to any inbound operations including read requests. • Software prevents SQ WQEs from being posted. • RQ WQEs can be posted.
RTS	• Normal SQ/CQ/CEQ processing.
SQ Drain	• Hardware finishes SQ WQEs that have been started but does not start new WQEs.
SQ Error (RoCEv2 UD only)	• Software-only state.
Error	• No SQ WQEs processed. • No RQ WQEs processed.

QP state transitions and the associated software and hardware/firmware actions driven from software interactions with the application are listed in Table 11-8.

Table 11-8. RoCEv2 QP State Transition

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
Nonexistent -> Initialized (CreateQP)	• Initialize the HMC backing pages necessary to support the QP. • Allocate/Initialize all software tracking structures for the PD, CQ, QP. • Assign QP to a PD. • Create CQ. • Allocate SQ and RQ. • Allocate the doorbell shadow area. • Perform parameter checks specified by the verbs specification. • Issue CreateQP WQE to CQP.	• Update QP context.
Initialized -> Initialized	• Perform parameter checks specified by the verbs specification. • Issue Modify QP to CQP, next state = Initialized.	• QP state parameters are updated.
Initialized -> RTR	• Issue Modify QP to CQP, next state = RTR, which allows Receives to be processed. • Software maintains the RTR state so it will prevent Sends from being posted.	• Receives can be processed by hardware.
RTR -> RTS	• Modify the software state to RTS (QP is already in RTS state). • Perform parameter checks specified by the verbs specification.	• Start scheduling work for the QP.
AnyState -> Error	• Perform parameter checks specified by the verbs specification. • Issue Modify QP WQE to CQP with the next state set to error, reset connection (if connection not already reset) and remove quad hash (if quad hash entry is present and has not been previously removed) by setting appropriate bits in the bits set. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes. Handle poll for completion requests for flushed WQEs, the CQ has one CQE for each WQ that had pending WQEs, software must report all pending WQEs as flushed once it gets the single flushed CQE (per WQ with pending WQEs), the number of WQEs flushed can be determined from software's head and tail for the SQ and RQ at the point in time that the poll for completion call is made that returns a flushed CQE.	• Set RoCEv2 state to error. • Wait for all packets to clear the pipeline. • Clean up QP context (prevent future scheduling). • When the flush WQEs operation is issued and any WQEs are outstanding on the SQ and/or RQ as requested by host software, complete the first pending WQE for each WQ (flushed completion status).
RTS -> RTS	• Perform parameter checks specified by the verbs specification. • Ensure that the number of currently pending outbound RDMA read requests is less than or equal to the new ORD value. • Ensure the only parameter that is changed is ORD size, it is only allowed to shrink or remain the same. • The ARP index and local MAC Address can also be modified.	• Update the changed value(s).
RTS -> SQD	• Issue Modify QP WQE with the next state set to SQD.	• Hardware completes SQ WQEs that have been started. When these are finished, an AE_QP_SUSPEND_COMPLETE asynchronous event is generated. • Inbound operations continue to be processed.

Table 11-8. RoCEv2 QP State Transition [continued]

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
SQD -> RTS	• Issue Modify QP WQE with the next state set to RTS.	• Resume processing on the SQ.
Error -> Initialized	• Software issues destroy and create QP operations to CQP.	• The hardware does not support this transition, but it can be accomplished by software as described in the Software Actions.
Error -> Error	• Submit a Modify QP WQE to CQP with next state = Error. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes.	• See RTS -> Error.

QP state transitions and the associated software and hardware/firmware actions driven from wire interactions with remote peer are listed in Table 11-9. Software state transitions are not listed.

Table 11-9. RoCEv2 QP State Transition Driven from the Wire

Row #	Wire Activity	Initial QP State	E810 Actions	Software Actions
0	DREQ message Received	Any state except Error		• Stop processing new post RQ operations if not already stopped. • Issue appropriate events. • If system software does not automatically generate closing, start the closing process based on the received event by issuing Modify QP with the next state set to error.
1	DREQ message Received	Error		• When this message is received: — Stop processing new post RQ operations if not already stopped. — SQ operation processing should have been stopped on the Modify QP with the next state set to closing. — Issue appropriate events. — Issue Flush WQE CQP operation. — If DREP has not been sent, send it now. — The application or system software starts the QP cleanup process.

11.4.4 Exception Queues

Each QP designates a UDA queue to receive exceptions. Some exceptions are iWARP partial FPDU support and CRC error packets received during closing errors. The designated UDA queue receives completions, and software is responsible for taking the appropriate action. For most cases, software logs the error and puts the QP in error state. iWARP Partial FPDUs are handled as described in Section 11.4.4.1.

11.4.4.1 iWARP Partial FPDU Support

The E810 supports partial iWARP FPDUs using software assist. High performance iWARP implementations pay attention to the underlying network MTU and form iWARP FPDUs that do not span Ethernet segments. In the case where software iWARP implementations (or other RNICs) form iWARP FPDUs that span Ethernet segments, the E810 reports these Ethernet packets to the UDA queues. Additionally, the PE writes the *first_partial_sequence_number* field in the Q2 area of the associated QP context. See Section 11.6.1 for the definition of the Q2 area.

Once a partial FPDU has been received, all subsequent packets for that QP are also forwarded to the UDA queue until software has been able to process the packets and send them back to the E810. Host software must process the packets, break them into full FPDUs, and send them back to the E810 through a UDA SQ with the *DOLOOPBACK* bit set. The E810 then processes the packets as if they had come from the wire as full FPDUs. Once all the packets have been sent back to the E810, the QP is automatically set back to normal operation and no further packets are sent to the UDA queues until a new partial FPDU is received.

Each time the Q2 area has an updated expected sequence number; the *Sequence_Update_Toggle* field is toggled. Software must keep track of the last value that it has seen in the Q2 area. If the value does not match, software should update its expected sequence number.

Note: Software must perform the MPA CRC check on all packets that are sent back through to the PE using the *DOLOOPBACK* bit in addition to reforming full iWARP FPDUs. The E810 does not support checking the MPA CRC in hardware on this path through the chip.

The high-level software algorithm used to handle partial FPDUs is shown in Figure 11-21.

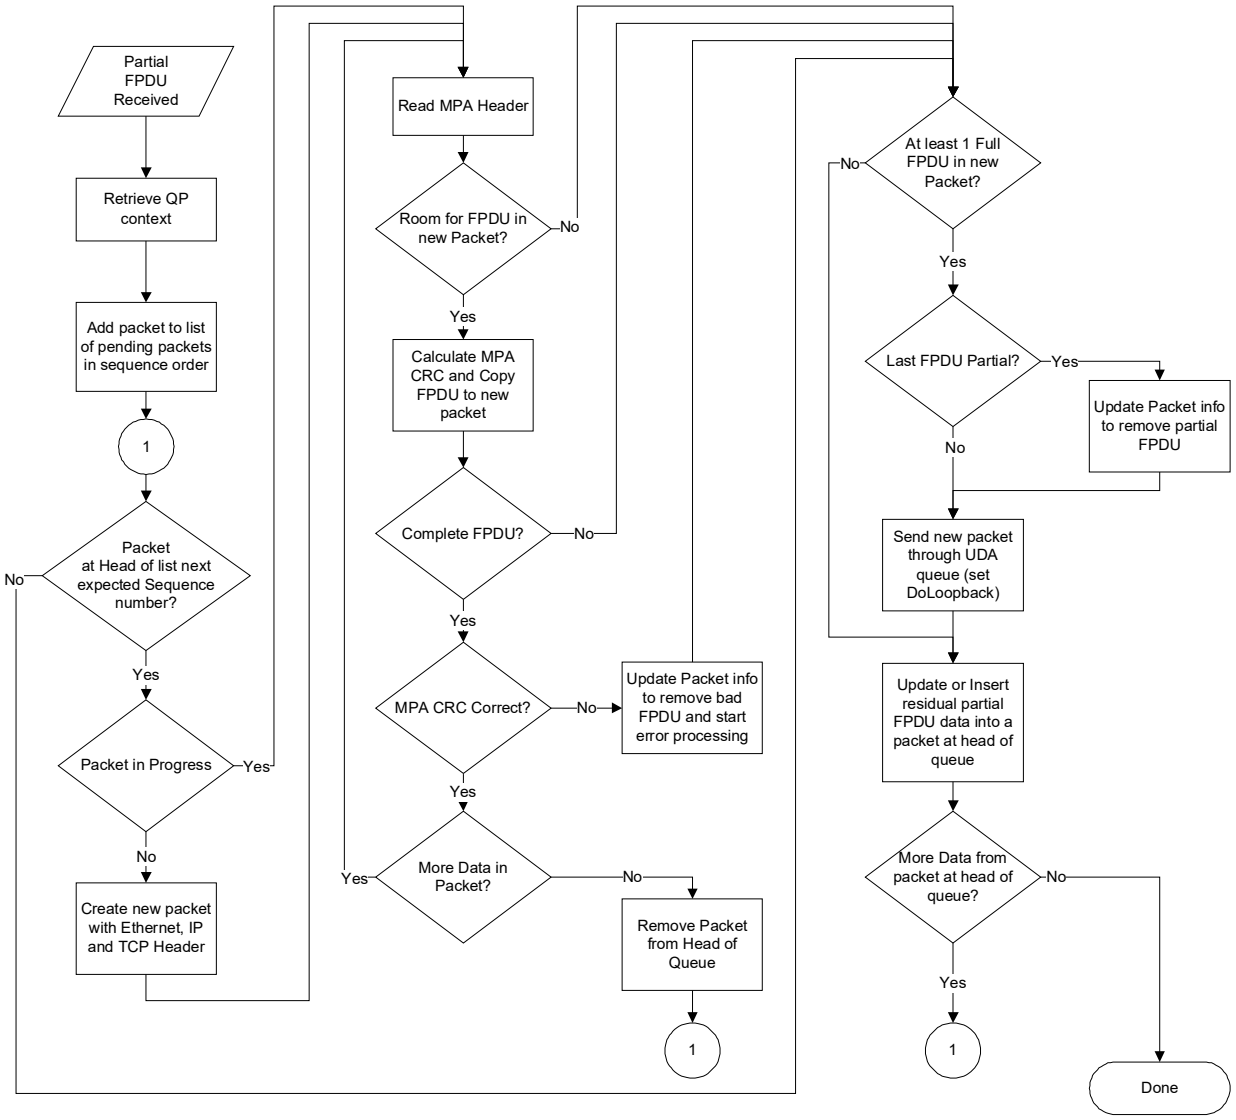

Figure 11-21. Partial FPDU Software Algorithm

11.4.5 Completion Event Queue (CEQ) Entry Format

A CEQ is a circular ring of Completion Event Queue Entries (CEQEs) in host memory. CEQs can be virtually or physically contiguous and are managed using the control QP (see Section 11.5.3.11).

Table 11-10. PE CEQ Entry Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63]	CEQE_Valid	[62:0]	CQ_Context_Value

CEQE_Valid (1 bit)

The *CEQE_Valid* bit for CEQE is a bit that indicates that a CEQE is ready to be processed by software. The polarity of the *Valid* bit changes each time the CEQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid CEQE. Software is responsible to clear (set to 0b) all memory in a CEQ initially at CEQ creation. The first iteration (and subsequent odd numbered iterations) through the CEQ, the E810 sets the *Valid* bit to 1b when it writes a new CEQE. For the second iteration (and all even numbered iterations) through the CEQ, the E810 sets the *Valid* bit to 0b when it writes a new CEQE.

CQ_Context_Value (63 bits)

CQ_Context_Value is the value of *CQ_Context_Value* specified at CQ creation (see Section 11.5.3.3). Typically this value is the low 63 bits of a pointer to a software CQ object to enable software to quickly process new CEs.

11.4.6 Asynchronous Event Queue (AEQ) Entry Format

An AEQ is a circular ring of Asynchronous Event Queue Entries (AEQEs) in host memory. AEQs can be virtually or physically contiguous and are managed using the Control QP (see Section 11.5.3.12).

Table 11-11. PE AEQ Entry Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Completion_Context_Value		
8	[63] [62:61] [60:57] [56:54] [53:50] [49:47]	AEQE_Valid Q2_data_written TCP_State RDMA_State AE_Source RSVD	[46] [45:34] [33] [32:18] [17:0]	QP_CQ_ID_High AE_Code AEQE_Overflow WQ_Desc_Index QP_CQ_ID_Low

Completion_Context_Value (64 bits)

Completion_Context_Value is a software-supplied token that can be used to efficiently locate the software resources necessary to process an AE. The token that is reported can be the *QP_Completion_Context* from the QP that caused the AE, or can be the *CQ_Context_Value* supplied during CQ creation, depending upon the *AE_ID* and *AE_Source* fields of the AE.

WQ_Desc_Index (15 bits)

WQ_Desc_Index value is valid only if the source of the event is a WQ (SQ or RQ) and the *AE_Code* indicates that the *WQ_Desc_Index* field is valid. See Section 11.4.7 for more details on how to determine if *WQ_Desc_Index* is valid.

QP_CQ_ID_Low (18 bits), QP_CQ_ID_High (1 bit)

This field carries either the QP ID that is associated with the AE or the CQ ID that is associated with the AE. The *AE_Source* field (defined later) or the *AE_ID* field are used to determine if the AE is associated with a QP or a CQ.

AE_Code (12 bits)

AE_Code is the AE code the caused the AE. See Section 11.4.7 for more details.

AE_Source (4 bits)

AE_Source defines the source of the AE. The following table lists the values and the related source of the problem.

Value	Description
0000b	Reserved.
00x1b	The AE is associated with the RQ of a QP. *QP_CQ_ID* is the QP ID. *Completion_Context_Value* is set to the value of *QP_Completion_Context* from the associated QP, and *WQ_Desc_Index* is valid.
xx10b	The AE is associated with a CQ. *QP_CQ_ID* is the CQ ID and *Completion_Context_Value* is the *CQ_Context_Value* specified at CQ creation. *WQ_Desc_Index* not valid.
01x1b	*QP_CQ_ID* is the QP ID. *Completion_Context_Value* is set to the value of *QP_Completion_Context* from the associated QP, and *WQ_Desc_Index* is valid. The event is associated with the SQ of a QP.
10x1b	The AE is associated with an inbound RDMA write or inbound RDMA read response operation related to a QP. *QP_CQ_ID* is the QP ID. *Completion_Context_Value* is set to the value of *QP_Completion_Context* from the associated QP, and *WQ_Desc_Index* is not valid.
11x1b	The AE is associated with an outbound RDMA read response operation related to a QP. This value can also be returned is other cases in which the *WQ_Desc_Index* value cannot be retrieved by the E810. *Completion_Context_Value* is set to the value of *QP_Completion_Context* from the associated QP, and *WQ_Desc_Index* is not valid.

Note: Some *AE_ID* values uniquely define the source of the AE. For these events, *AE_Source* should be ignored. See Section 11.4.7 for more details.

RDMA_State (3 bits)

RDMA_State reflects the RDMA state of the connection at the time the AE occurred according to E810 hardware.

Value	Description
000b	Non-existent
001b	Idle
010b	Ready to Send (RTS)
011b	Closing
100b	Reserved
101b	Terminate
110b	Error
111b	Reserved

TCP_State (4 bits)

TCP_State reflects the TCP state of the connection at the time the AE occurred according to E810 hardware. The TCP_State is not valid for RoCEv2 QPs.

Value	Description
0000b	Non-existent
0001b	Closed
0010b	Listen
0011b	Syn_Sent
0100b	Syn_Received
0101b	Established
0110b	Close_Wait
0111b	Fin_Wait_1
1000b	Closing
1001b	Last_Ack
1010b	Fin_Wait_2
1011b	Time_Wait
Note: All other values are reserved.	

AEQE_Valid (1 bit)

The *AEQE_Valid* bit for AEQE indicates that an AEQE is ready to be processed. The polarity of the *Valid* bit changes each time the AEQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid AEQE. Software is responsible to clear (set to 0b) all memory in a AEQ initially at AEQ creation. The first iteration (and subsequent odd numbered iterations) through the AEQ, the E810 sets the *Valid* bit to 1b when it writes a new AEQE. For the second iteration (and all even numbered iterations) through the AEQ, the E810 sets the *Valid* bit to a 0b when it writes an new AEQE.

AEQE_Overflow (1 bit)

The *AEQE_Overflow* bit for AEQE indicates that an AEQE has been completely filled and that there might have been a loss of subsequent AEQEs. No further AEQEs are generated until additional space is allocated to the AEQ using the PFPE_AEQALLOC or VFPE_AEQALLOC register.

Q2_data_written (2 bits)

Q2_data_written provides status regarding error information that is reported for errors detected for iWARP connections when an AE is generated. The Q2 data area is configured as part of QP setup. See Section 11.5.3.2 for more information. This values for this field are:

Value	Description
00b	No data associated with this AE has been written to Q2.
01b	Data written to Q2 starts at the Ethernet header of the offending packet.
10b	Data written to Q2 starts at the MPA header of the offending PDU.
11b	Reserved.

11.4.7 AE Codes

Table 11-12 lists the values that can be returned in the *AE_ID* field of an AEQ entry. The column titled "Source" defines if the source of the AE is pre-determined based on the *AE_Code*, or the *AE_Source* field of the AE field must be used to determine the source. Note that the source of the AE effects the *Completion_Context_Value*, *WQ_Desc_Index*, and *QP_CQ_ID* fields in the AE queue entry defined in Section 11.4.6. The *WQ_Desc_Index* field is not valid for AE codes that have a source designated as QP or CQ.

Table 11-12. PE AE Codes (AE_ID)

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_AMP_UNALLOCATED_STAG	0x102	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window that is in an unallocated state.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_INVALID_STAG	0x103	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window that is in an invalid state.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_BAD_QP	0x104	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory window from a different QP than the QP to which the memory window was bound.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_BAD_PD	0x105	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window from a QP with a different PD than the PD associated memory region or window.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_BAD_STAG_KEY	0x106	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window when the key portion of the STag does not match the key associated with the memory region or window.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_BAD_STAG_INDEX	0x107	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window with an STag index larger than the largest index allowed for the PCI function.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_BOUNDS_VIOLATION	0x108	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access memory outside of the memory area defined by the memory region or memory window.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_RIGHTS_VIOLATION	0x109	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window and a rights violation occurred.	Terminate/ Error	AE_Source	I/R/U

Table 11-12. PE AE Codes (AE_ID) [continued]

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_AMP_TO_WRAP	0x10A	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access a memory region or memory window and the tagged-offset plus the ULPDU length caused the address generated for the memory region or window to wrap.	Terminate/ Error	AE_Source	I/R/U
AE_AMP_FASTREG_VALID_ STAG	0x10C	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to issue a registration operation to a valid memory region.	Terminate/ Error	AE_Source	I/R
AE_AMP_FASTREG_MW_STAG	0x10D	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to issue a registration operation to a memory window.	Terminate/ Error	AE_Source	I/R
AE_AMP_FASTREG_INVALID_ RIGHTS	0x10E	This AE is generated when a memory protection error is detected by the E810. This error indicates that a rights mismatch was detected during a registration operation.	Terminate/ Error	AE_Source	I/R
AE_AMP_FASTREG_INVALID_ LENGTH	0x110	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to issue a registration operation with an invalid length.	Terminate/ Error	AE_Source	I/R
AE_AMP_INVALIDATE_SHARED	0x111	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to invalidate a shared memory region.	Terminate/ Error	AE_Source	I/R
AE_AMP_INVALIDATE_NO_ REMOTE_ACCESS_RIGHTS	0x112	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to remotely invalidate a memory region or memory window that does not have remote access rights specified.	Terminate/ Error	AE_Source	I/R
AE_AMP_INVALIDATE_MR_ WITH_BOUND_WINDOWS	0x113	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to invalidate a memory region that still has one or more memory windows bound to it.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_VALID_ STAG	0x114	This AE is generated when a memory protection error is detected by the E810. This error indicates that the STag used on a bind operation is a memory window that is already valid.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_OF_MR_ STAG	0x115	This AE is generated when a memory protection error is detected by the E810. This error indicates that the STag used on a bind operation is a memory region instead of a memory window.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_TO_ZERO_ BASED_STAG	0x116	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to bind a memory window to a zero-based memory region.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_TO_MW_ STAG	0x117	This AE is generated when a memory protection error is detected by the E810. This error indicates that the STag specified for the memory window to be bound to is a memory window instead of a memory region.	Terminate/ Error	AE_Source	I/R

Table 11-12. PE AE Codes (AE_ID) [continued]

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_AMP_MWBIND_INVALID_ RIGHTS	0x118	This AE is generated when a memory protection error is detected by the E810. This error indicates that a rights violation was detected during a memory window bind operation.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_INVALID_ BOUNDS	0x119	This AE is generated when a memory protection error is detected by the E810. This error indicates that a bounds violation was detected during a memory window bind operation.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_TO_ INVALID_PARENT	0x11A	This AE is generated when a memory protection error is detected by the E810. This error indicates that the memory region that a memory window attempted to bind to was invalid.	Terminate/ Error	AE_Source	I/R
AE_AMP_MWBIND_BIND_ DISABLED	0x11B	This AE is generated when a memory protection error is detected by the E810. This error indicates that the memory region that a memory window bind operation was attempted on a memory region that has bind support disabled.	Terminate/ Error	AE_Source	I/R
AE_PRIV_OPERATION_DENIED	0x11C	This AE is generated when a privileged operation is attempted on a non-privileged QP. This includes: • Bind operations without bind enabled. • Fast register without fast register enabled. • STag zero without privilege is not enabled.	Terminate/ Error	QP	I/R/U
AE_AMP_INVALIDATE_TYPE1_ MW	0x11D	A Local Invalidate or Inbound Invalidate targeted a Type 1 memory window.	Terminate/ Error	QP	I/R
AE_AMP_MWBIND_ZERO_ BASED_TYPE1_MW	0x11E	A memory window bind operation specified zero-based addressing for the memory window to be bound.	Terminate/ Error	QP	I/R
AE_AMP_FASTREG_INVALID_ PBL_HPS_CFG	0x11F	An unsupported PBL/Host Page Size configuration was requested (1G pages cannot have a 2-level PBLE with 4K pages).	Terminate/ Error	QP	I/R
AE_AMP_MWBIND_WRONG_ TYPE	0x120	A memory window bind specified a non-matching window type.	Terminate/ Error	QP	I/R
AE_AMP_FASTREG_PBLE_ MISMATCH	0x121	Invalid VM Fast Register request to change a physical MR to a virtually mapped MR or vice-versa.	Terminate/ Error	QP	I/R
AE_UDA_XMIT_DGRAM_TOO_ LONG	0x132	This AE is generated by the E810 when the total length of the packet exceeds MSS configured for QP.	Terminate/ Error	QP	U
AE_UDA_XMIT_BAD_PD	0x133	This AE is generated when a memory protection error is detected by the E810. This error indicates that an attempt was made to access an Address Handle from a QP with a different PD than the PD associated Address Handle.	Error	QP	U
AE_UDA_L4LEN_INVALID	0x135	The L4LEN field is not valid, or the payload length is less than L4LEN DWords.	Error	QP	U
AE_BAD_CLOSE	0x201	This AE is generated when in iWARP state = closing and an iWARP PDU is received. If the E810 detects SQ or Q1 work during a Modify QP RTS->Closing then a completion error is returned to the Modify QP request instead of an AE.	Error	QP	I

Table 11-12. PE AE Codes (AE_ID) [continued]

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_RDMAP_ROE_BAD_LLP_ CLOSE	0x202	This AE indicates that there was either SQ or Q1 work pending when a FIN was received.	Terminate	QP	I
AE_CQ_OPERATION_ERROR	0x203	The E810 attempted to generate a CQ entry on a full CQ that has overflow detection enabled.	N/A	AE_Source	I/R/U
AE_RDMA_READ_WHILE_ORD_ ZERO	0x205	This AE is generated when an RDMA read request is issued to a QP that has the Outbound RDMA Read Queue Depth (ORD) set to 0b.	Terminate/ Error	QP	I/R
AE_STAG_ZERO_INVALID	0x206	Detected on an inbound RDMA write, RDMA read response, or RDMA read request (either source or sink). Inbound 0 byte RDMA read and RDMA write operations are not indicated as errors since no host data is accessed.	Terminate/ Error	QP	I/R
AE_IB_RREQ_AND_Q1_FULL	0x207	This AE is generated if an inbound RDMA read is received and the target QP's inbound RDMA RQ (Q1) is full.	Terminate/ Error	QP	I/R
AE_IB_INVALID_REQUEST	0x208	The remote side detected an operation that is outside the established use for the transport service (such as an invalid opcode or length too long). ***Note:*** The error is detected on the remote machine, but the AE is on the local machine.	Error	QP	R
AE_WQE_UNEXPECTED_ OPCODE	0x20A	This AE is generated if QP encounters a WQE with an invalid OP code on an SQ.	Transmit Suspended	QP	I/R/U
AE_WQE_INVALID_PARAMETER	0x20B	This AE is generated if QP encounters a WQE with invalid parameters.	Terminate/ Error	AE_Source	I/R/U
AE_WQE_INVALID_FRAG_DATA	0x20C	This occurs when a WQE has more than 14 fragments or more than 224 bytes of inline data. It also occurs when a WQE crosses a 256-byte boundary.	Terminate/ Error		I/R/U
AE_IB_REMOTE_ACCESS_ ERROR	0x20D	This occurs when the receives a NAK for remote access error.	Error	QP	R
AE_IB_REMOTE_OP_ERROR	0x20E	This occurs when the receives a NAK for remote operational error	Error	QP	R
AE_WQE_LSMM_TOO_LONG	0x220	This AE is generated if the last streaming mode message specified on the Modify QP operation from the iWARP IDLE state to RTS state is longer than the MSS.	Terminate/ Error	AE_Source	I
AE_DDP_INVALID_MSN_GAP_ IN_MSN	0x301	The AE is generated when a gap is detected in the MSN used to index the RQ or Q1 when data is in order with respect to TCP sequence space.	Terminate/ Error	AE_Source	I
AE_DDP_UBE_DDP_MESSAGE_ TOO_LONG_FOR_AVAILABLE_ BUFFER	0x303	This AE is generated on inbound iWARP PDUs if the message offset plus the size of the PDU data is larger than the number of bytes in the RQ WQE targeted by the PDU.	Terminate/ Error	AE_Source	I/R
AE_DDP_UBE_INVALID_DDP_ VERSION	0x304	This AE is generated when an inbound iWARP PDU has an incorrect DDP version number.	Terminate	QP	I
AE_DDP_UBE_INVALID_MO	0x305	This AE is generated if the message offset is larger than the number of bytes in the RQ WQE targeted by the PDU on inbound iWARP PDUs.	Terminate/ Error	QP	I

Table 11-12. PE AE Codes (AE_ID) [continued]

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_DDP_UBE_INVALID_MSN_ NO_BUFFER_AVAILABLE	0x306	This AE is generated if an inbound send operation targets an unallocated RQ WQE and the E810 is configured to drop the connection for this condition.	Terminate	AE_Source	I
AE_DDP_UBE_INVALID_QN	0x307	This AE is generated when an inbound untagged iWARP PDU has an incorrect queue number.	Terminate	QP	I
AE_DDP_NO_L_BIT	0x308	Detected when there is no L bit on an inbound RDMA read request.	Terminate	QP	I
AE_RDMAP_ROE_INVALID_ RDMAP_VERSION	0x311	This AE is generated when an inbound iWARP PDU has an incorrect RDMAP version number.	Terminate	QP	I
AE_RDMAP_ROE_UNEXPECTED _OPCODE	0x312	This AE is generated when an inbound iWARP PDU has an incorrect opcode number.	Terminate/ Error	QP	I/R
AE_ROE_INVALID_RDMA_READ _REQUEST	0x313	This AE is generated when an inbound RDMA read iWARP PDU is received, but the QP is not enabled for inbound RDMA read support.	Terminate/ Error	QP	I/R
AE_ROE_INVALID_RDMA_ WRITE_OR_READ_RESP	0x314	This AE is generated when an inbound RDMA read response or RDMA write iWARP PDU is received, but the QP is not enabled for inbound RDMA read responses or RDMA writes.	Terminate/ Error	QP	I/R
AE_RoCE_RSP_LENGTH_ ERROR	0x316	The RoCEv2 responder received a packet with an RETH and the *dma_length* field is inconsistent with the payload length.	Error	QP	R
AE_INVALID_ARP_ENTRY	0x401	This AE is reported when a connection attempts to transmit a packet using an invalid ARP entry. Host software either enables the QP for transmitting after updating the ARP entry, or uploads/destroys the connection because the ARP entry is no longer valid. In the case of updating the ARP entries, statistics report can be off by the number of packets/octets/ messages that were attempted to be transmitted while the ARP entry was invalid.	Transmit Suspended	QP	I/R/U
AE_INVALID_TCP_OPTION_ RCVD	0x402	This AE is generated when the E810 encounters an unsupported TCP option and the E810 is not configured to ignore unsupported TCP options via the *ignore_tcp_uns_options* QP context bit. The packets with invalid TCP options are dropped if this AE is generated.	No Change	QP	I
AE_INVALID_AH_ENTRY	0x406	This AE indicates that the AH was not valid.	Error	QP	R
AE_LLP_CLOSE_COMPLETE	0x501	This AE indicates that the TCP state of an iWARP QP has transitioned to either closed or time wait in a graceful fashion.	No Change	QP	I
AE_LLP_CONNECTION_RESET	0x502	This AE indicates that a TCP packet with the *RST* bit set has been received on a TCP connection that is associated.	Error	QP	I
AE_LLP_FIN_RECEIVED	0x503	This AE indicates that a TCP packet with the *FIN* bit set has been received and the iWARP state is RTS (implies TCP state is established). Host software is responsible for issuing a Modify QP -> Closing to complete the QP transition to the closing the state.	No Change	QP	I

Table 11-12. PE AE Codes (AE_ID) [continued]

Asynchronous Event Code	Value	Description	iWARP/ RoCEv2 State after AE	Source	iWARP / RoCEv2 UDA I/R/U
AE_LLP_RECEIVED_MPA_CRC_ ERROR	0x505	This AE is reported when an MPA or ICRC Error CRC error is detected by software using the AE code capability of the CQP Flush WQEs operation.	Terminate/ Error	QP	I/R
AE_LLP_SEGMENT_TOO_SMALL	0x507	This AE is reported when an iWARP segment is received that is too small to contain a DDP or RDMAP header.	Terminate/ Error	QP	I
AE_LLP_SYN_RECEIVED	0x508	This AE indicates that a TCP packet with the *SYN* bit set is received on a connection that is associated with an iWARP connection.	Error	QP	I
AE_LLP_TERMINATE_RECEIVED	0x509	This AE indicates that a terminate message has been received for an iWARP QP. The received terminate data is placed in the Q2 area associated with the QP in host memory.	Terminate	QP	I
AE_LLP_TOO_MANY_RETRIES	0x50A	This AE is used to report too many retransmission retries.	Transmit Suspended	QP	I/R
AE_LLP_DOUBT_REACHABILITY	0x50C	This AE is used to report that it has reached the doubt reachablity threshold for the given connection. This is used in dead gateway detection or black holes.	No Change	QP	I/R
AE_LLP_CONNECTION_ ESTABLISHED	0x50E	This AE is used to report that a connection has been established. It occurs when the first iWARP message has been received.	RTS	QP	I
AE_RESOURCE_EXHAUSTION	0x520	This AE is used to report that a QP attempted to allocate Q1 or XMIT FIFO resource and no resource was available.	No Change	AE_Source	I/R
AE_RESET_SENT	0x601	This AE is generated when the E810 sends a reset after host software has requested the connection to be reset via a Modify QP operation.	No Change	QP	I
AE_TERMINATE_SENT	0x602	This AE is generated when the E810 sends a terminate message after host software has requested a terminate to be sent on a connection via a Modify QP operation.	No Change	QP	I
AE_RESET_NOT_SENT	0x603	This AE is generated when the E810 did not send a reset after host software has requested the connection to be reset via a Modify QP operation. The reset is not sent due to TCP state already having been transitioned to time wait or closed.	No Change	QP	I
AE_LCE_QP_CATASTROPHIC	0x700	This AE is generated by the E810 when it receives an error on a hardware transaction.	Terminate/ Error	QP	I/R/U
AE_LCE_FUNCTION_ CATASTROPHIC	0x701	This AE is generated by the E810 when it receives an error on a hardware transaction that impacts the entire PCI function. QP_CQ_ID is not reliable for this AE and should be ignored.	Terminate/ Error	N/A	I/R/U
AE_LCE_CQ_CATASTROPHIC	0x702	This AE is generated by the E810 when it receives a local catastrophic error on a hardware transaction that impacts a CQ.	Terminate/ Error	CQ	I/R/U
AE_QP_SUSPEND_COMPLETE	0x900	This AE is generated upon completion of the requested QP Suspend operation.	Transmit Suspended	QP	I/R

11.4.8 Steering Tag (STag) and Processing Hint Support for PE Traffic (TPH)

See Section 3.1.2.6.2 for information on how to enable TLP processing hint support.

Table 11-13 lists how the STag and processing hints are generated and how TPH operation is enabled for different types of DMA traffic associated with the PE.

Table 11-13. STag and Processing Hint Programming

Traffic Access	STag Location	PH Value	Enable
CQ Element Writes	CQ Context *TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	CQ Context *TPH_en*
CQ Doorbell Shadow Area Reads	CQ Context *TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	CQ Context *TPH_en*
CEQ Element Writes	CEQ Context *TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	CEQ Context *TPH_en*
SQ WQ Element Reads	QP Context *SQ_TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	QP Context *SQ_TPH_en*
SQ Work Doorbell Shadow Area Writes	QP Context *SQ_TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	QP Context *SQ_TPH_en*
RQ WQ Element Reads	QP Context *RQ_TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	QP Context *RQ_TPH_en*
Data Payload Writes	QP Context *RQ_TPH_value*	GL_TPH_CTRL.*Data_PH*	QP Context *RCV_TPH_en*
Data Payload Reads	QP Context *SQ_TPH_value*	GL_TPH_CTRL.*Data_PH*[1]	QP Context *XMIT_TPH_en*

1. Default is 10b (target).

The E810 has TPH values for CQ and CEQ in each of the various contexts. When a read is done (such as reading the CQ shadow area), the E810 updates the context with the current TPH hint that is returned in the completion (CQ:*TPH_value*). If the enable bit is set in the particular context, the E810 should provide the TPH information on all subsequent PCI transactions associated with CQ or CEQ transactions. There is no TPH value used on AEQE writes because they are so infrequent that it is unlikely to ever get them on the correct CPU.

QP context has two values for TPH: *SQ_TPH* and *RQ_TPH*. They are independent of each other because the SQ and RQ could be on different processors in PE accelerations. They also have separate enable bits.

11.5 Resource Management

PE resources are managed through a combination of the HMC Function Private Memory (FPM) space (described in Section 9.3) and Control QP operations (described in the following sections).

Figure 11-22 shows the PE-related data structures that are located in host memory and that reside on-die for the E810. Before any QP, or CQ operation is attempted with CQP, the associated HMC pages must be initialized and allocated as specified in Section 9.3.7. Once all FPM Page Descriptor pages and backing pages have been properly allocated, initialized, and allocated to the E810, CQP can be used to create/modify/destroy various objects necessary for PE operations. Note that Figure 11-22 only depicts memory that is visible to the E810. Many other software allocated data structures are allocated to track progress of QPs, CQs, an so on, as shown in Section 11.4.1. All of the host memory shown in Figure 11-22 must be pinned memory. QP and CQ memory including the doorbell shadow areas might be allocated from kernel or userspace virtual memory. However, all other memory shown must be allocated from the kernel to provide the proper level of protection between different processes accessing the E810 concurrently.

Note: Any reset that affects a single PCI function also resets the HMC and require reprogramming of all HMC resources. Global resets also reset the segment descriptor programming that require re-selecting the HMC resource profile if the default profile was not in use.

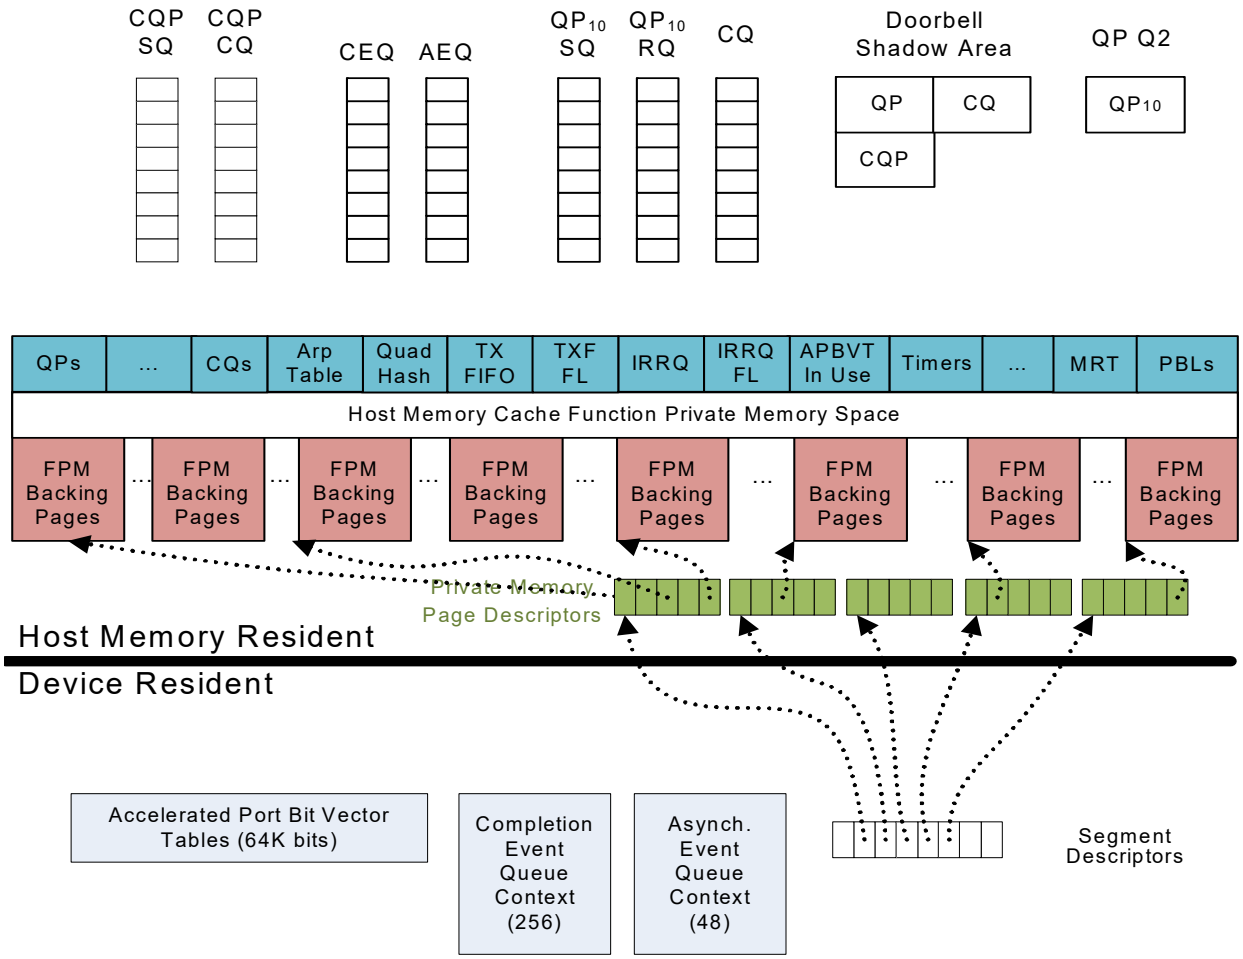

Figure 11-22. E810 and Host Memory Data Structures

FPM page descriptors and backing pages can be allocated on the fly in order to reduce the kernel drivers memory footprint. However, certain objects must be allocated at driver initialization.

Table 11-14. PE Objects Dependencies

PE HMC Object	HMC Object Page Population Algorithm	Object Dependencies	Non-HMC Object Dependences
QP Context	Dynamic	• ARP Table Entries • Quad Hash Entries • Tx FIFO Entries • APBVT In-Use Table • CQ • Physical Buffer List Entries if Virtually Mapped	• VSI • Local MAC Address • L2 Tag Configuration
CQ Context	Dynamic	• Physical Buffer List Entries if Virtually Mapped	
ARP Table Entries	Dynamic	None	
Quad Hash Entries	Static	None	
Tx FIFO Entry Free List	Static	None	
Tx FIFO Entries	Static	• Tx FIFO Entry Free List	
Inbound Read Request Queue Entry Free List	Static	None	
Inbound Read Request Queue Entries	Static	• IRRQ Entry Free List	
Accelerated Port Bit Vector Table In-Use Table	Static	None	
Multicast Groups	Dynamic	None	
Address Handles	Dynamic	None	
Memory Registration Table	Dynamic	None	
Physical Buffer List Entries	Dynamic	None	
Read Response FIFO Entries Free List	Static	None	
Read Response FIFO Entries	Static	• Read Response FIFO Entries Free List	
Header	Static	• Metadata	
Metadata	Static	• Header	
Out of Order Send Completion (OOISC) FIFO	Static	• Out of Order Send Completion (OOISC) FIFO Free List	
Out of Order Send Completion (OOISC) FIFO Free List	Static	None	

All PE objects marked as "Static" in Table 11-14 must be allocated at driver initialization time. Entries marked as "Dynamic" can be allocated and deallocated on an as-needed basis. Deallocation of HMC FPM page descriptor pages and backing pages is described in Section 9.3.8. Objects shown as dependencies must be populated and allocated via CQP (along with the HMC FPM memory for the object itself) prior to issuing a CQP operation to manipulate the PE object. More information regarding the object dependencies is available in the individual CQP operations in following sections.

Note: PF resets clears the PE state including any HMC configuration settings for the PF and all associated VFs. VF resets clear all PE state and HMC configuration settings only for the VF if the VF is enabled for PE accelerations. See Table 4-1 on page 298 for more information on reset sources and the affected internal logic.

Dynamic objects of the same type can share a cache line. However, a dynamic object must not share any cache lines with another object that has a different type.

11.5.1 PE Initialization

Table 11-15 lists the high-level steps required to initialize a PE. Table 11-16 and Table 11-17 list the high-level steps required to bring an RDMA or UDA QP to the operational state for the E810. These lists are not meant to be exhaustive, but more as a guide to show examples of a typical initialization flow. It is assumed that the LAN initialization of the VSI has enabled PE operation and has the LAN queues operational for the PF.

Table 11-15. PE Resource Initialization

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Determine the IP and MAC Addresses for the associated LAN queue pool.	E810 driver.	Each PE interface is associated with a specific LAN interface. The mechanism to find the interface information is operating system specific.	
2	Enable RDMA/UDA for the corresponding VSI.	E810 driver.	Enable the RDMA Packet Profiles for RDMA in this VSI.	
3	Enable Local VSI Loopback.	E810 driver.	PE enables communication between QPs associated with the same VSI. Set *ALLOWLOOPBACK* and *ALLOWLOCALLOOPBACK* bits in VSI_SRCSWIDCTRL register.	This step is not required. The PE uses SWPE to perform loopback.
4	Setup the PE portion of the HMC.	E810 driver.	Wait for PE firmware to be initialized by polling GLPE_CPUSTATUS0 is set to 0x80. First the HMC base and size registers must be programmed for this PF. Subsequently appropriate backing pages must be initialized.	See Section 9.3 for details on initializing the HMC.
5	Acquire one or more MSI-X vectors for the PE.	E810 driver.	MSI-X vectors can be shared between LAN and protocol operation or can be partitioned to enable independent operation.	See the previous section on LAN initialization for more information on MSI-X vector initialization.
6	Initialize the PE control QP.	E810 driver.	Allocate memory for the CQP SQ and CQP context and write to the PECCQPHIGH and PECCQPLOW registers.	See Section 11.5.2.1 for more details.
7	Initialize the PE CQ 0.	E810 driver.	Allocate memory for the CQ and issue a create CQ operation to CQP.	See Section 11.5.3.3 for details on the Create CQ CQP operation.
8	Initialize the PE CEQ 0.	E810 driver.	Allocate memory for the CEQ and issue a create CEQ operation to CQP, The CEQ is associated with a E810 interrupt.	See Section 11.5.3.11 for details on the create CEQ CQP operation.
9	Initialize the PE AEQ.	E810 driver.	Allocate memory for the AEQ and issue a create CEQ operation to CQP.	See Section 11.5.3.12 for details on the create AEQ CQP operation.

Table 11-16 lists steps required to bring RDMA QP to the operational state. PE initialization steps are common for RDMA and UDA traffic and should be done only once.

Table 11-16. RDMA Resource Initialization

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Create a Protection Domain.	E810 driver on behalf of a verbs application.	Reserve a doorbell page from the PE doorbell pages in the E810 BAR.	See Section 11.4.1.5.1 for more information on doorbell pages.
2	Allocate a CQ.	E810 driver on behalf of a verbs application.	Allocate memory for the CQ and issue a create CQ operation to CQP. The CQ is associated with the CEQ from Step 7.	See Section 11.5.3.3 for details on the create CQ CQP operation.
3	Allocate a QP.	E810 driver on behalf of a verbs application.	Allocate memory for the QPs SQ and RQ and issue a Create QP operation to CQP.	See Section 11.5.3.2 for details on the create QP CQP operation.
4	Allocate Memory Regions.	E810 driver on behalf of a verbs application.	Allocate physical buffer list entry ranges for the page list that backs the memory provided by the application and then issue register memory region CQP operation.	See Section 11.5.3.4 for more information on the register memory region operation and also Section 11.4.1.4 for an overview of the E810's memory registration capabilities.
5	Post Work Requests to the QPs RQ.	E810 driver on behalf of a verbs application.	Fill in a RQ work request with the information supplied by the application and submit the work.	See Section 11.6.6.2 for information about the RQ work request format and Section 11.4.1.5.8 for more information on RQ operation.
6	Post Work Requests to the QPs SQ.	E810 driver on behalf of a verbs application.	Fill in a SQ work request with the information supplied by the application and submit the work.	See Section 11.6.6.1 for information about the SQ work request format and Section 11.4.1.5.2 for more information on SQ operation.
7	Process Interrupts and the CEQ (optional).	E810 driver.	Once an interrupt occurs for a CEQ, the CQ can be determined from the CEQ Entry. Events are generated to that application to let the application know that an event for a specific CQ has been received.	See Section 11.4.1.2 for more information on processing CEQ entries.
8	Process the CQ (optional).	E810 driver on behalf of a verbs application.	Once the application has either received a completion event or is constantly polling the CQ, CQ entries are processed by the application.	See Section 11.4.1.3 for more information on processing CQ entries.

Table 11-17 lists steps required to bring UDA QP to the operational state. PE initialization steps are common for RDMA and UDA traffic and should be done only once.

Table 11-17. UDA Resource Initialization

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Create a Protection Domain.	E810 driver on behalf of a verbs application.	Reserve a doorbell page from the PE doorbell pages in the E810 BAR.	See Section 11.4.1.5.1 for more information on doorbell pages.
2	Allocate a CQ.	E810 driver on behalf of a verbs application.	Allocate memory for the CQ and issue a create CQ operation to CQP. The CQ is associated with the CEQ from Step 7.	See Section 11.5.3.3 for details on the create CQ CQP operation.
3	Allocate a QP.	E810 driver on behalf of a verbs application.	Allocate memory for the QPs SQ and RQ and issue a create QP operation to CQP.	See Section 11.5.3.2 for details on the create QP CQP operation.
4	Allocate Memory Regions.	E810 driver on behalf of a verbs application.	Allocate PBL entry ranges for the page list that backs the memory provided by the application and then issue register memory region CQP operation.	See Section 11.5.3.4 for more information on the register memory region operation and also Section 11.4.1.4 for an overview of the E810's memory registration capabilities.
5	Allocate Address Handle (optional).	E810 driver on behalf of a verbs application.	For each destination Node issue a create address handle operation to CQP. Allocated address handle is used to generate Ethernet/IP headers.	See Section 11.5.3.16 for more information on the create address handle operation and also Section 11.5.3.6 for an overview of the E810's address handle capabilities.
6	Bind to Local Port (optional).	E810 driver on behalf of a verbs application.	For each local port allocated for UDP traffic issue a management quad hash entry operation to CQP. This operation will enable forwarding of unicast packet to the QP.	See Section 11.5.3.20 for more information on the manage quad hash operation.
7	Post Work Requests to the QPs RQ.	E810 driver on behalf of a verbs application.	Fill in a RQ work request with the information supplied by the application and submit the work.	See Section 11.6.6.2 for information about the RQ work request format and Section 11.4.1.5.8 for more information on RQ operation.
8	Post Work Requests to the QPs RQ.	E810 driver on behalf of a verbs application.	Fill in a SQ work request with the information supplied by the application and submit the work.	See Section 11.6.6.1 for information about the RQ work request format and Section 11.4.1.5.2 for more information on RQ operation.
9	Process Interrupts and the CEQ (optional).	E810 driver.	Once an interrupt occurs for a CEQ, the CQ can be determined from the CEQ Entry. Events are generated to that application to let the application know that an event for a specific CQ has been received.	See Section 11.4.1.2 for more information on processing CEQ entries.
10	Process the CQ (optional).	E810 driver on behalf of a verbs application.	Once the application has either received a completion event or is constantly polling the CQ, CQ entries are processed by the application.	See Section 11.4.1.3 for more information on processing CQ entries.

11.5.2 Control QP (CQP) Operation

CQP operations are modeled after verbs SQ operations as far as the work submission process. Some differences exist for CQP when compared to a typical PE QP:

- CQP QP context is located on-die instead of in the HMC.
- The doorbell register used for work submission is PFPE_CQPDB instead of PFPE_WQEALLOC.
- PFPE_CQPDB take SQ head as input and there is no QP ID specified since each PE enabled PCI function has a dedicated CQP.
- There is no doorbell shadow area associated with CQP.
- Hardware tail can be read from the PFPE_CQPTAIL, but in general software can just track SQ tail based on completion processing from CQ0.

The operations defined for CQP are listed in Table 11-21. CQ0 is the CQ associated with the CQP for each function. All other CQs are available for accelerated PE use.

11.5.2.1 Creating the CQP

CQP is created by first allocating memory for CQP context shown in Section 11.5.2.3 and initializing context. The HMC resource profile is also able to be selected during the CQP creation process.

Note: HMC resource profile is selected during first CQP creation on a device and is then locked. Subsequent attempts to change the HMC resource profile are ignored until all CQPs created on the device have been destroyed.

The resource profile that has been selected is reported in the PFPE_CCQPSTATUS register after CQP has been successfully created. Additionally, the SQ memory and FPM configuration buffer must also be allocated. This memory must be pinned and the physical address must be determined.

Once software has filled in the CQP context properly, the physical address of CQP context is written to the PFPE_CCQPHIGH and PFPE_CCQPLOW registers to notify the E810 of the create CQP operation. Both registers must be written, and the PFPE_CCQPLOW register must be written last. The E810 then fetches the context and create CQP for the current PCI function.

Once CQP has be successfully created, the *CCQP_DONE* bit in the PFPE_CCQPSTATUS register is set to 1b. If an error was encountered while attempting to create CQP, the CCQP_ERR bit is set instead of the CCQP_DONE bit. The major and minor error codes are available in the PFPE_CQPERRCODES register. The next six operations necessary to get CQP to a functional state are to:

1. Query FPM Values.
2. Commit FPM Values.
3. Initialize the HMC resources for CQ0.
4. Create CQ 0.
5. Create CEQ.
6. Create the AEQ.

The operations must be done in this order or unexpected results might be observed. In addition to the CQ0 HMC backing pages initialized in Step 3, if either the CQ or CEQ need to be virtually mapped, the PBLE HMC object backing pages must also be populated before creating the CQ and/or CEQ.
RDMA-enabled VFs use the VFPE_* versions of the registers previously mentioned. These steps involve issuing standard CQP operations with the following exceptions:

- PFPE_CQPTAIL must be polled until the create CQ operation has been submitted to CQP, and only a single CQP operation must be submitted at a time to CQP while polling CQP Tail. Any errors encountered via CQP is reported via the CQP_ERR bit in the PFPE_CQPTAIL register. The major and minor error codes are available in the PFPE_CQPERRCODES register.
- CQ0 can be polled for the completion of the create CQ operation. No events can be generated since there is no CEQ created at the point when CQ0 is created.

One additional CQP operation must be issued anytime after Step 3 but before any iWARP QPs can be created. The static HMC pages allocated operation must be submitted after all static HMC objects have been allocated and configured for the PCI function. See Table 11-14 for the list of statically configured HMC objects.

11.5.2.2 Destroying the CQP

Once all PE resources have been destroyed and deallocated, the control QP related resources much also be destroyed. The flow is the following:

1. Issue a CQP operation to destroy the AEQ.
2. Issue a CQP operation to destroy the CEQ(s).
3. Poll CQ0 to verify these operations completed.
4. Issue a CQP operation to destroy CQ0 (CQP's CQ).
5. Poll CQP tail for completion of the destroy CQ.
6. Destroy CQP by writing the PFPE_CCQPHIGH and PFPE_CCQPLOW registers with 0b.
7. Poll the PFPE_CCQPSTATUS register until it changes to 0b.
8. Destroy the CQ0 HMC resources to ensure that no further accesses to host memory is performed.

Once CQP is destroyed, CQ0 is destroyed as well.

11.5.2.3 CQP Context

CQP context describes the SQ for the control QP.

Table 11-18. CQP Context Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:40] [39:32] [31:24] [23:12] [11:8]	RSVD num_CEQs_per_VF StructVersion RSVD SQ_Size	[7:5] [4:3] [2] [1] [0]	RSVD protocol_used RoCEv2_RTO_Policy Disable_FPDU_Packing Enable_Fine_Grained_Timers
8	[63:9]	SQ_Base	[8:0]	RSVD
16	[63:38] [37:32] [31:8]	RSVD PEEnabledVfCount RSVD	[7:4] [3] [2:0]	rdpa_assist remote_endpoint_trk_en HMCProfileType
24	[63:0]	QP_Completion_Context		
32	[63:32] [31:16]	RSVD hw_major_version	[15:0]	hw_minor_version
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

StructVersion (8 bits)

Used to specify changes in CQP context format. The only value defined is 0.

Enable_Fine_Grained_Timers (1 bit)

This bit enables fine-grained TCP timer mode for the PCI function associated with the CQP to be created. Fine-grained TCP timer mode changes the PE TCP timers from normal values (2 minutes to ~100 ms) to a more aggressive set of values (~1 s to ~100 μs). Fine-grained TCP timer mode is useful for environments with low packet congestion and/or low packet loss.

SQ_Size (4 bits)

This field encodes the maximum number of work requests for each WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. Since each CQP WQE takes 64 bytes (as if it consumed an additional fragment descriptor), only the following settings are valid for CQP (all other settings are reserved and might cause unexpected results):

Value	Description
0001b	4 WQEs
0010b	8 WQEs
0011b	16 WQEs
0100b	32 WQEs
0101b	64 WQEs
0110b	128 WQEs
0111b	256 WQEs
1000b	512 WQEs
1001b	1024 WQEs

Value	Description
1010b	2048 WQEs
Note: All other values are reserved.	

Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow. WQ overflow results in indeterministic behavior for the affected WQ.

SQ_Base (55 bits)

SQ_base is the most significant bits of the physical address of the SQ for the control QP. The WQ base address must be evenly divisible by 512 for proper behavior.

HMCProfileType (3 bits)

This field specifies the HMC resource profile to be activated.

Value	Description
001b	Default
010b	SR-IOV VF Primary
011b	SR-IOV Even Distribution
Note: All other values are reserved.	

Specifying a reserved HMC resource profile causes the current HMC resource profile to remain active. This field is ignored for VFs.

remote_endpoint_trk_en (1 bit)

This field enables/disables endpoint tracking. This is experimental.

Value	Description
0b	Disabled
1b	Enabled

PEEnabledVfCount (6 bits)

Only valid when *HMCProfileType* is one of the SR-IOV profile types. Specifies the number of PE enabled VFs to be allocated. Values larger than 32 are rounded down to 32. A value of zero forces the default profile to be selected. This field is ignored for VFs.

See Section 9.3.3, "Private Memory Space Profiles" for more information on HMC resource profiles.

QP_Completion_Context (64 bits)

QP_Completion_Context is reported in every CQ Entry related to the CQP.

Disable_FPDU_Packing (1 bit)

Disables transmission of packets with more than one FPDU per packet for iWARP Queue Pairs.

RoCEv2_RTO_Policy (1 bit)

Value	Description
0b	The RoCEv2 retransmission timer stays constant.
1b	The RoCEv2 retransmission timer doubles on every retransmission up to a maximum value.

protocol_used (2 bits)

Selects which protocol is used.

Value	Description
00b	Any
01b	iWARP
10b	RoCEv2
11b	Reserved

num_CEQs_per_VF (8 bits)

This specifies the max CEQs needed for each VF. The purpose of this field is to limit the number of CEQs a VF uses in the even distribution profile to leave enough CEQs for the PF. A value of 0 preserves the behavior of evenly allocating the CEQs across all functions. This field is valid only if SR-IOV is enabled and the balanced profile is in use.

hw_major_version, hw_minor_version (16 bits each)

Version of hardware that the software driver supports.

Major version values are:

Value	Description
0	E810
Note: All other values are reserved.	

rdpa_assist (4 bits)

This specifies the rate of assist: 0x0=none, 0xF=max.

11.5.2.4 CQP Error Codes

CQP can return a number of error and status code the operations that it performs. Table 11-19 lists these error and status codes that can be returned in the CQ entry listed in Table 11-20.

Table 11-19. CQP Error Codes

Major Error Code	Minor Error Code	Completion Reason	Description
0x0000	0xkk00	STag Valid	The STag queried is in the valid state, where kk is the STag key.
0x0000	0x0001	STag Invalid	The STag queried is in the invalid state.
0x0000	0x0002	RQ WQE Flushed	A RQ WQE was flushed as a result of the flush WQEs operation.
0x0000	0x0003	SQ WQE Flushed	A SQ WQE was flushed as a result of the flush WQEs operation.
0x0000	0x0004	SQ and RQ WQEs Flushed	Both a RQ WQE and a SQ WQE were flushed as a result of the flush WQEs operation.
0x0000	0x0005	Suspend Pending	A suspend QP WQE was issued referencing a busy QP. An AE_QP_SUSPEND_COMPLETE AE is generated when the QP has been successfully suspended.
0xF000	0x000x	Object Cache Error	An object cache error has reported to CQP during this operation. Object cache errors reported in x include: 0: Cache Address Translation Error
0xF001	0x000x	Context Cache Error	A context cache error was reported to CQP during this operation. Context cache errors include: 0x1 – PMAT Error during normal operation 0x2 – PMAT Error during reset 0x4 - Context CRC Error
0xFFFF	0x3000	Packet Count Error	A packet count issue has been detected on a QP that is either being destroyed or uploaded. The state of the QP is indeterminate once this completion code has been observed.
0xFFFF	0x3001	Scratchpad Flush Error	CQP has timed out waiting for TEP to flush scratchpads for a QP that is getting destroyed or uploaded. This error has never been observed and is not expected.
0xFFFF	0x3002	Bad Queue Set Handle	The given queue set handle is associated with a work scheduler node that was not properly enabled.
0xFFFF	0x3003	Invalid WS Node Weight	Returned by Manage Work Scheduler Node if an invalid weight is provided for the specified node_type and/or priority_type.
0xFFFF	0x3004	Invalid Traffic Class	Returned by Manage Work Scheduler Node if the given traffic class is invalid for the current system configuration
0xFFFF	0x4000	Memory Window Bound	The destroy QP operation failed because there are still MWs bound to the QP.
0xFFFF	0x6000	Insufficient Resources (General)	There is an insufficient amount of the resources needed to complete this operation.
0xFFFF	0x6001	Insufficient FLM Resources	A create QP was attempted but there were no available transmit of Q1 FIFO entries.
0xFFFF	0x6002	Insufficient Doorbell Resources	Returned by commit FPM (if requested number of QPs or CQs is greater than count allotted in partition registers).
0xFFFF	0x6003	Hash Filter Programming Failed	An ADD or REMOVE of a hash filter entry was attempted but was not successful.
0xFFFF	0x6004	PCIe Unsupported Request	Access of a software-provided host physical address resulted in an Unsupported Request response from PCIe.
0xFFFF	0x8000	ID Too Big	The ID specified on the operation is too large for the on-board memory configuration.

Table 11-19. CQP Error Codes [continued]

Major Error Code	Minor Error Code	Completion Reason	Description
0xFFFF	0x8002	Invalid State	The operation requested is not valid for this resource based upon its current state.
0xFFFF	0x8003	Invalid Next QP State	The next state specified on the Modify QP operation is not valid based on the QP's current state.
0xFFFF	0x8004	Invalid Queue Size	The SQ, RQ, or Q1 is too large or to small.
0xFFFF	0x8005	Invalid QP Type	The operation is not valid for this type of QP.
0xFFFF	0x8006	No WQE Pending	A flush operation was attempted but there was not a WQE pending.
0xFFFF	0x8007	Bad Close	A Modify QP from RTS->Closing was attempted while there was SQ and/or Q1 activity in progress.
0xFFFF	0x8009	LLP Closed	Returned by Modify QP (next RDMA state = Terminate if the TCP state is already closed or time wait).
0xFFFF	0x800A	Reset Not Sent	Returned by Modify QP (if the TCP state is already closed).
0xFFFF	0x800C	SD Index Out of Range	An attempt has been made to update a VF's page descriptor using an SD that does not reference a PBLE object.
0xFFFF	0x800D	PD Index Out of Range	An attempt has been made to update a VF's page descriptor using a SD and PD index that does not reference a PBLE object.
0xFFFF	0x800E	PD Page Boundary Exceeded	An attempt has been made to update a VF's page descriptor but the request has crossed from one PD page to the next PD page.
0xFFFF	0x800F	SD Boundary Exceeded	Returned by commit FPM (if requested number of HMC objects crosses SD boundary for that function).
0xFFFF	0x8010	Invalid Function Type	The operation is not valid for the PCI function type that attempted to issue the operation.
0xFFFF	0x8011	FLM Not Initialized	Returned by create QP if an attempt to create a QP has been attempted before the static resources allocated WQE has been issued.
0xFFFF	0x8012	Invalid ECN Codepoint	An attempt was made to create a QP with an invalid initial ECN codepoint value.
0xFFFF	0x8013	Bad Access	A PF or VF attempted to access resources that it does not own.
0xFFFF	0x8014	Invalid MRTE Index	An attempt was made to access a reserved STag.
0xFFFF	0x8015	Invalid Terminate Message Size	A Terminate was requested with a *Term_length* value that is too small.
0xFFFF	0x8016	Bad Send MSS Value	The value given for SndMSS is invalid.
0xFFFF	0x8017	Shared MR FBO Mismatch	A Shared Memory Region was created with a virtual address that did not match the First Buffer Offset of the parent Memory Region.
0xFFFF	0x8018	Reserved	Reserved.
0xFFFF	0x8019	Invalid Access Rights	An invalid combination of access rights was requested.
0xFFFF	0x8020	Invalid flag on Reg MR	Memory Region bit was no set during a Register MR operation.
0xFFFF	0x8021	Invalid PBL/Host Page	Unsupported PBL/Host Page Size configuration was requested.
0xFFFF	0x8023	Invalid Push Ready List	An attempt has been made to enable Push Mode with a ready list that was not associated with a valid Push Mode Page Table.
0xFFFF	0x8024	Invalid RoCE QPID	An attempt was made to create a RoCE QP (RC or UD) with an ID of 0 or a RoCE RC QP with an ID of 1.
0xFFFF	0x8025	Invalid MW Type Used	An attempt was made to allocate a Type1 Memory Window on a HMC function not configured for the RoCEv2 protocol.
0xFFFF		Window Type Not Allowed	Type 1 Windows are not valid for iWARP.
0xFFFF	0x80EE	Unsupported Opcode	The opcode given is unsupported.

Table 11-19. CQP Error Codes [continued]

Major Error Code	Minor Error Code	Completion Reason	Description
0xFFFF	0x80EF	WQE Not Valid	The WQE fetched due to a CQP doorbell ring is not valid.
0xFFFF	0xFFFF	Error	CQP encountered an error during the processing of this WQE.

11.5.2.5 CQP CQE Format

The CQP CQ entry is listed in Table 11-20. Every work request processed by the control QP returns a completion on CQ 0 (CQ_ID 0). If CQ0 is created with the *Avoid_Memory_Conflicts* bit set, an additional 32 bytes of padding is added to each CQE for a total of 64 bytes per CQE. This doubles the size of the CQ in host memory.

Table 11-20. CQP CQ Entry Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	QP_Completion_Context		
16	[63:32]	RSVD	[31:0]	Operation_Return_Value
24	[63] [62] [61:56] [55]	CQE_Valid SQ Op Error	[54:47] [46:32] [31:16] [15:0]	RSVD WQ_Desc_Index Major_Error_Code Minor_Error_Code

Op (6 bits)

This field reports the opcode from the operation associated with the CQE.

QP_Completion_Context (64 bits)

This field is transferred to the CQE from CQP QP context listed in Table 11-18.

WQ_Desc_Index (15 bits)

WQ are sliced up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. *WQ_Desc_Index* reports the 32-byte quanta index of the WQE associated with the completion.

QP_ID (18 bits)

QP associated with the completed message.

Operation_Return_Value (32 bits)

This field is filled in by CQP with operation dependent return values such as the reachability timestamp or the MAC and IP table Index.

CQE_Valid (1 bit)

The *CQE_Valid* bit for CQE indicates that a CQE is ready to be processed. The polarity of the *Valid* bit changes each time the CQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid CQE.

Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the E810 sets the *Valid* bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the E810 sets the *Valid* bit to a 0b when it writes an new CQE.

Error (1 bit)

The *Error* bit indicates if there was a problem with the operation specified by the WQE associated with the WR that is associated with completion.

Value	Description
0b	No error is being reported with this completion.
1b	An error occurred when processing the WQE associated with this CQE and that the *Error_Code* field is valid.

SQ (1 bit)

The SQ bits is used to determine if the completion is associated with a SQ (SQ) or a RQ (RQ). Always 1b for CQP.

Value	Description
0b	RQ
1b	SQ

Major_Error_Code (16 bits) and Minor_Error_Code (16 bits)

The *Error_Code* fields are valid if the *Error* bit is set or if the operation submitted was query STag. See Table 11-19 for the values that are returned for CQP operations.

11.5.3 CQP SQ Descriptor Format

The following WQE formats are used in conjunction with the Control QP (CQP) to manage internal PE structures that the E810 uses to communicate with host software. Operations that are supported for CQPs are the following:

Table 11-21. CQP Operations

Operation Code	Operation Name	Section Reference
0x00	Create QP	11.5.3.2
0x01	Modify QP	
0x02	Destroy QP	
0x03	Create CQ	11.5.3.3
0x04	Modify CQ	
0x05	Destroy CQ	
0x06-0x08	Reserved	N/A
0x09	Allocate STag	11.5.3.4
0x0A	Register MR	
0x0B	Query STag	11.5.3.5
0x0C	Register Shared MR	11.5.3.4
0x0D	Deallocate STag	
0x0E	Reserved	N/A
0x0F	Manage ARP Cache	11.5.3.6
0x10	Manage VF PBLE Backing Pages	11.5.3.7
0x11	Manage Push Page	11.5.3.8
0x12	RDMA Get Features	11.5.3.29
0x13	Upload Context	11.5.3.9
0x14	Reserved	N/A
0x15	Manage HMC PM Function Table	11.5.3.10
0x16	Create CEQ	11.5.3.11
0x17	Reserved	N/A
0x18	Destroy CEQ	11.5.3.11
0x19	Create AEQ	11.5.3.12
0x1A	Reserved	N/A
0x1B	Destroy AEQ	11.5.3.12
0x1C	Create Address Handle	11.5.3.13
0x1D	Modify Address Handle	
0x1E	Destroy Address Handle	
0x1F	Update PE SDs	11.5.3.14
0x20	Query FPM Values	11.5.3.15
0x21	Commit FPM Values	11.5.3.16
0x22	Flush WQEs	11.5.3.17
0x23	Manage APBV Table Entry	11.5.3.18
0x24	NOP	11.5.3.19
0x25	Manage Quad Hash Table Entry	11.5.3.20
0x26	Create Multicast Group	11.5.3.21
0x27	Modify Multicast Group	
0x28	Destroy Multicast Group	
0x29	Suspend QP	11.5.3.22
0x2A	Resume QP	11.5.3.23
0x2B	Static HMC Pages Allocated	11.5.3.24
0x2C	Manage Work Scheduler Node	11.5.3.27
0x2D	Manage Statistics Instance	11.5.3.25
0x2E	Gather Statistics	11.5.3.26
0x2F	Set UP-UP Mapping	11.5.3.28
0x30-0x3F	Reserved	N/A

11.5.3.1 Common CQP Descriptor Format Fields

The basic CQP WQE is a 64-byte structure that is broken up into 64-bit (8-byte) words. The placement of these fields within the WQE are common among all CQP WQEs and also RDMA WQEs. Table 11-22 lists the basic structure of a CQP WQE including the common fields. The definition of fields marked as "Operation Code Dependent" vary from operation-to-operation and are detailed in subsequent sections.

Table 11-22. CQP Common WQE Fields

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Operation Code Dependent		
8	[63:0]	Operation Code Dependent		
16	[63:0]	Operation Code Dependent		
24	[63] [62:42] [41:38]	WQE_Valid Operation Code Dependent RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP Operation Code Dependent
32	[63:0]	Operation Code Dependent		
40	[63:0]	Operation Code Dependent		
48	[63:0]	Operation Code Dependent		
56	[63:0]	Operation Code Dependent		

OP (6 bits)

CQP operation code for create QP, modify QP, or destroy QP. See Table 11-21 for the specific values.

WQE_Valid (1 bit)

The *WQE_Valid* bit for WQ Entries (WQE) indicates that a WQE is ready to be processed by the E810. The polarity of the *Valid* bit changes each time the WQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead associated with the need to clear a *Valid* bit and also to enable the E810 to read ahead in the WQ to reduce the need for doorbell rings. See Section 11.4.1.5 for more information on submitting work to a QP with the E810.

Software is responsible to clear (set to 0b) all memory in a WQ initially at QP creation. The first iteration (and subsequent odd numbered iterations) through the WQ, software sets the *Valid* bit to 1b when it writes a new WQE. For the second iteration (and all even numbered iterations) through the WQ, software sets the *Valid* bit to a 0b when it writes an new WQE.

11.5.3.2 Create/Modify/Destroy QP Descriptor Format

This WQE format is used by host software to manage QPs. The various *Valid* bits in this format are designed to reduce the load on CQP for determining what has changed. If a *Valid* bit is set for a particular field, CQP updates the value in the E810's context. Otherwise, it does not. The only valid operation for QP type CQP is the destroy operation. See Section 11.5.2.1 for more details on created CQP.

Note: Software is responsible for populating the appropriate HMC objects and have having created objects for the HMC and through CQP that the QP depends on.

Table 11-23. CQP Create/Modify/Destroy QP WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:52] [51:48]	RSVD Term_Length[1]	[47:0]	RSVD
16	[63:0]	QP_Context_Address[1]		
24	[63] [62:60] [59] [58] [57:56] [55] [54] [53:52] [51] [50:48]	WQE_Valid Next_RDMA_State[1] ARP_Table_Index_Valid[1] Reset_Connection[1] Terminate_Actions[1] Remove_Hash_Entry[1] Ignore_MW_Bound[2] RSVD MAC_Valid QP_Type	[47] [46] [45] [44] [43] [42] [41:38] [37:32] [31:18] [17:0]	CQ_Numbers_Valid[1,3] Force_Loopback[3] Virtual_WQs[3] Cached_Variables_Valid[1] TOE_Context_Valid[3] ORD_Valid[1,3] RSVD (AdditionalFragmentCount) OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:7]	Doorbell_Shadow_Address[3]	[6:0]	RSVD
48	[63:0]	RSVD		
56	[63:0]	RSVD		

1. Not used for Destroy QP operations.
2. Only used for Destroy QP operations.
3. Valid for Create and Modify QP operations as long as the iWARP state is not already RTS, error, or terminate.

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

ARP_Table_Index_Valid (1 bit)

Value	Description
0b	CQP must ignore ARP *Cache_Index* field in QP context.
1b	ARP cache index has been updated in the QP context.

TOE_Context_Valid (1 bit)

Value	Description
0b	Ignore the TOE portion of QP context.
1b	The TOE portion of QP context is valid.

This bit is useful if an iWARP QP is created that does not yet have a TOE connection associated with it. Host software can create the SQ/RQ and so on, and then later issue a modify QP to update the TOE context. Updating TOE context is only allowed prior to setting the QP iWARP state to RTS for iWARP QPs and prior to setting the QP TOE state to established for TOE QPs.

ORD_Valid (1 bit)

Value	Description
0b	CQP must ignore the *ORD* field in QP context.
1b	ORD has been updated in QP context.

Virtual_WQs (1 bit)

Value	Description
0b	The SQ and RQ for this QP are physically mapped.
1b	The SQ and RQ for this QP are virtually mapped.

When a QP is using virtual WQs, the RQ and SQ base address in QP context point to the first HMC FPM space PBLE index for the page table for each WQ. Host software is responsible for populating the PBLEs with the page list associated with each WQ before making the QP active (Modify QP with next state of RTS). Both the SQ and the RQ buffers must be aligned to a multiple of 4 KB in host memory when *Virtual_WQs* is set. This field is only valid for QPs in the IDLE state or during the IDLE to RTS transition.

Remove_Hash_Entry (1 bit)

Only valid with Modify QP opcodes.

Value	Description
0b	No effect.
1b	The hash table entry associated with this QP is removed from the hash list.

CQ_Numbers_Valid (1 bit)

Value	Description
0b	*RxCmpQueueNum* and *TxCmpQueueNum* in QP context are ignored.
1b	The values for *RxCmpQueueNum* and *TxCmpQueueNum* in QP context are used to update internal context.

Force_Loopback (1 bit)

This field is used to enable loopback traffic for different IP Addresses with a single VSI.

Value	Description
0b	The traffic is switched normally unless the source and destination IP Addresses and MAC Addresses match.
1b	The traffic for the QP is internally looped back within the VSI associated with the QP.

QP_Type (3 bits)

QP_Type indicates the type of QP for CQP to create. The valid QP types are:

Value	Description
000b	CQP (only valid for DestroyQP)
001b	iWARP
010b	UDA
011b	RoCEv2 RC
100b	RoCEv2 UD
Note: All other values are reserved.	

MAC_Valid (1 bit)

This field is for changing the MAC after RTS. Before RTS, this field is ignored.

Value	Description
0b	CQP must ignore *Src_MAC_Address* field in QP context.
1b	*Src_MAC_Address* has been updated in QP context.

Ignore_MW_Bound (1 bit)

This field is only meaningful for Destroy QP for RDMA QPs.

Value	Description
0b	The destroy fails with a major/minor code of 0xFFFF/0x4000 when memory windows are still bound to the QP.
1b	The QP is destroyed even if memory windows are still bound to the QP.

Terminate_Actions (2 bits)

Only valid for Modify QP for iWARP QPs with *Next_RDMA_State* set to terminate. Values for this field are:

Value	Description
00b	Send both Terminate and FIN
01b	Send Terminate Only
10b	Send FIN Only
11b	Do not send Terminate or FIN

Term_Length (4 bits)

Only valid with modify opcodes when the next RDMA state is set to 5 (terminate) and *Terminate_Actions* is set to 0b or 1b. This field is ignored in all other cases. This field specifies the number of 4-byte DWords to transfer from the Q2 outbound terminate data area when a terminate message is requested. The Q2 area starts with a DWord specifying the *Terminate Control* field as specified in the RDMAP RFC. A maximum of 13 DWords are transmitted (terminate control DWord plus 48 bytes of data for an RDMA read header). Values greater than 13 results in 13 DWords being transmitted.

Cached_Variables_Valid (1 bit)

Only valid with modify opcodes.

Value	Description
0b	No effect.
1b	Only the cached variables associated with this QP are updated on the Modify operation.

See Table 11-67 on page 1490 for the list of variable that are cached. Each cached variable is marked with a table footnote.

Next_RDMA_State (3 bits)

Only valid on Modify QP opcodes for RDMA QPs. The iWARP state definitions are:

Value	Description
000b	NON EXISTENT
001b	IDLE
010b	RTS
011b	CLOSING
100b	Reserved
101b	TERMINATE (iWARP only)
110b	ERROR
111b	Reserved

Reset_Connection (1 bit)

Only valid with Modify QP opcodes. If set (1b), a TCP reset is sent out if the TCP state for the QP has already been ESTABLISHED is not TIME_WAIT or CLOSED. If the QP TCP state is already TIME_WAIT or CLOSED, an AE_RESET_NOT_SENT AE is generated.

QP_ID (18 bits)

QP_ID identifies the QP that is to be acted upon by the E810.

QP_Context_Address (64 bits)

A physically-mapped pointer in host memory that contains QP context. The format of the QP context structures are define in Section 11.6.2, Section 11.5.2.3, and Section 11.6.3. This buffer must be aligned to a multiple of four bytes.

Doorbell_Shadow_Address (57 bits)

A physically-mapped pointer in host memory that hardware writes to when forward progress has been made on SQ work. The format of the doorbell shadow area is listed in Table 11-25. This buffer must be aligned to a multiple of cache-line size bytes.

Modify QP processing performed by CQP for the E810 is not designed to be verbs compliant from the point of view of which iWARP state transitions are allowed. The E810 enables invalid state transitions to enable host hardware to make state transitions to ERROR or TERMINATE autonomously to prevent subsequent work from being processed, but still enable host software the ability to provide verbs compliant behavior to the application.

Additionally, the E810 is not providing support for the transition back to IDLE. It is expected that host software destroys QPs and recreate them when the transition from non-IDLE to IDLE is desired. Table 11-24 describes the transitions allowed by the E810.

Table 11-24. E810 iWARP QP State Transitions

Current iWARP State	Next RDMA State				
	Idle	RTS	Closing	Terminate	Error
Idle	Yes	Yes	No	No	Yes
RTS	No	Yes	Yes	Yes	Yes
Closing	No	No	No	No	Yes
Terminate	No	No	No	Yes	Yes
Error	No (No error reported)	No	No	No	Yes

Table 11-25. QP Doorbell Shadow Area

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:15]	RSVD	[14:0]	HW_SQ_Tail
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63:0]	RSVD		
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

For information on the doorbell ringing algorithm and usage of the QP doorbell shadow area, see Section 11.4.1.5.2.

11.5.3.3 Create/Modify/Destroy CQ Descriptor Format

Host software uses the following structure to manage CQs through the control QP. CQs are comprised of a packed array of CQEs (which are WQ type specific) that are managed as a circular queue. They can be either virtually or physically contiguous memory buffers. Further discussion of CQ operation is found in Section 11.4.1.3.

Table 11-26. CQP Create/Modify/Destroy CQ WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:21]	RSVD	[20:0]	cq_size[1]
8	[63]	RSVD	[62:0]	CQ_Context_Value
16	[63:18]	RSVD	[17:0]	cq_shadow_read_threshold[2]
24	[63] [62] [61] [60] [59:50] [49] [48] [47]	WQE_Valid RSVD Avoid_Memory_Conflicts[2] TPH_en RSVD CEQ_ID_Valid enable_ceqe_mask[2] Virtually_Mapped[1]	[46] [45:44] [43] [42:38] [37:32] [31:22] [21:19] [18:0]	Check_Overflow[2] Leaf_PBL_Size[1] CQ_Resize RSVD OP CEQ_ID RSVD CQ_ID
32	[63:8]	Physical_Buffer_Address[1]	[7:0]	RSVD
40	[63:6]	Doorbell_Shadow_Address	[5:0]	RSVD
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index[1]
56	[63:18] [17:8]	RSVD VSI_Index	[7:0]	TPH_Value

1. Valid on Modify operations with the *CQ_Resize* bit set, or on Create operations.
2. Only valid on Create operations.

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

enable_ceqe_mask (1 bit)

Value	Description
0b	The E810 potentially generates multiple CEQEs per CQ if a request for completion notification is generated by software before a CEQE is consumed by software. This behavior can lead to CEQ overflows.
1b	The E810 only allows one CEQE to be generated per CQ. Subsequent CEQE generation is enabled by writing the CQ ACK register.

CEQ_ID (10 bits)

CEQ_ID specifies the CEQ to associated with the CQ specified by *CQ_ID*. This field is only meaningful when *CEQ_ID_Valid* is set (1b).

CEQ_ID_Valid (1 bit)

Value	Description
0b	The *CEQ_ID* field is ignored.
1b	The E810 updates the CEQ for the CQ.

Changing the *CEQ_ID* for an active CQ is allowed to enable software to redistribute CQ event processing between different processors. Each CEQ for a given function must be assigned to independent MSI-X vectors to take advantage of this capability.

CQ_Resize (1 bit)

Value	Description
0b	Ignore *CQ_Resize*.
1b	CQ resize operation is being requested.

If a resize operation is performed, the *cq_resize_count* CQ context variable (known as *hw_cq_select* in the description of CQ resizing) is incremented by the E810. See the description of CQ resizing in Section 11.4.1.3 for more information on the CQ resizing operation.

Avoid_Memory_Conflicts (1 bit)

Value	Description
0b	Each CQE is 32 bytes in size.
1b	The size of each CQE is padded with 0's to a total of 64 bytes, and the size of the CQ doubles.

TPH_en (1 bit)

Value	Description
0b	TPH is not used for this resource.
1b	TPH is enabled for this resource.

TPH_Value (8 bits)

If *TPH_en* is set (1b), TPH STag is initialized with *TPH_Value*. If *TPH_en* is clear (0b), this field is ignored.

VSI_Index (10 bits)

The VSI index for the CQ. Only defined for Create CQ. It is ignored on Modify CQ and Destroy CQ.

Leaf_PBL_Size (2 bits)

See Section 11.4.1.4.1 for more details on usage of two level PBLs.

Value	Description
00b	Reserved
01b	Variable (one level)
10b	256 bytes (two level)
11b	4 KB (two level)

A leaf page size of 4 KB is not supported for 1 GB pages.

Check_Overflow (1 bit)

Value	Description
0b	It is host software's responsibility to ensure that a CQ cannot overflow.
1b	The E810 checks for CQ overflow conditions.

Virtually_Mapped (1 bit)

Value	Description
0b	*Physical_Buffer_Address* is the physical address of the physically-contiguous CQ ring buffer.
1b	The CQ is virtually-mapped, and *first_pm_pbl_index* is the index of the PBLE HMC object to use for mapping the virtually-contiguous CQ.

The CQ buffer must be aligned to a multiple of 4 KB in host memory when *Virtually_Mapped* is set.

first_pm_pbl_index (28 bits)

Points to the first HMC FPM space PBLE index for the page table for the CQ. Host software is responsible for populating the PBLEs with the page list associated with the CQ before issuing the create CQ operation and the page table is not allowed to be changed.

Physical_Buffer_Address (56 bits)

If *Virtually_Mapped* is set to 0b, this field specifies the physical buffer address associated with the queue in host memory. If *Virtually_Mapped* is set to 1b, this field is ignored by the E810. This address must be aligned to a 256-byte boundary.

cq_size (21 bits)

The number of CQEs allowed on the CQ. Note that the actual number of concurrent CQEs that might be allocated to the CQ is *cq_size* -1. 0 and 1 are invalid sizes for a CQ. Also note that each Immediate Data operation CQE consumes the space of two CQEs.

cq_shadow_read_threshold (18 bits)

Controls when the CQ shadow area is read to update hardware's copy of *CQE_Index*. When the CQ drops below the number for CQEs specified by *cq_shadow_read_threshold*, the CQ shadow area is read to determine which CQEs have been processed by software. The value of 0 indicates that the CQ shadow area is only read when the CQ has no more available entries to use for a new CQE that needs to be generated.

CQ_ID (19 bits)

Identifies the CQ index associated with the current CQP operation.

CQ_Context_Value (63 bits)

This value is returned in the CEQE when an event is generated for the CQ specified by *CQ_ID*. This value is intended to be used by host software to quickly locate host software's CQ context (virtual pointer to CQ context).

Doorbell_Shadow_Address (58 bits)

A physically-mapped pointer in host memory that hardware reads to determine the CQEs that are owned by hardware. The format of the doorbell shadow area is listed in Table 11-27. This buffer must be aligned to a multiple of cache-line size bytes or 64 bytes, whichever is greater.

Table 11-27. CQ Doorbell Shadow Area

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:21]	RSVD	[20:0]	CQE_Index
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63:0]	RSVD		
32	[63:18] [17:16] [15]	RSVD arm_seq_num arm_next_se	[14] [13:0]	arm_next sw_cq_select
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

CQE_Index (21 bits)

Indicates the next CQE that software are polling through verbs. This field is used to update the hardware's version of context to detect CQ overrun conditions.

arm_next (1 bit)

Indicates that software wants a CEQE generated for the next CQ entry posted to the CQ.

arm_next_se (1 bit)

Indicates that software wants a CEQE generated for the next CQ entry posted to the CQ that is associated with a solicited event operation.

arm_seq_num (2 bits)

Arm Sequence Number (*arm_seq_num*) is a valued incremented by software each time an arm request is issued. It is expected that no more than two arm requests are issued per CE received. If more than three arm requests are issued without waiting for a CE, arm request might be lost.

sw_cq_select (14 bits)

This field is used for CQ resize operations. See Section 11.4.1.3 for more details on the usage of this field.

11.5.3.4 Allocate/Register/Registershared/Deallocate STag Descriptor Format

This WQE format is used by host software to manage memory regions and windows. See Section 11.4.1.4.1 for more details on memory registration concepts with the E810.

Table 11-28. CQP Allocate/Register/Registershared/Deallocate STag WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Virtual_Address or First_Buffer_Offset		
8	[63:46]	PD_ID	[45:0]	STag_Length
16	[63:54] [53:32]	RSVD Parent_STag_Index	[31:8] [7:0]	Driver_Key_STag_Index Consumer_Key
24	[63] [62:61] [60] [59] [58] [57:54] [53] [52:48]	WQE_Valid RSVD use_hmc_fcn_index VA_Based_TO MW1_bind_dont_vldt_key RSVD (for PM flags) Remote_Access_Enabled Access_Rights	[47:46] [45:44] [43] [42] [41:38] [37:32] [31:0]	Host_Page_Size Leaf_PBL_Size Memory_Region Memory_Window_Type RSVD OP RSVD
32	[63:0]	Physical_Buffer_Address		
40	[63:6]	RSVD	[5:0]	hmc_fcn_index
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bits)

See Section 11.5.3.1.

Virtual_Address or First_Buffer_Offset (64 bits)

Indicates the base VA for this region/window for VA-based entries and indicates the first buffer offset for zero-based entries. For VA-based entries, the least significant bits (12 bits for entries based on 4 KB pages, 21 bits for entries based on 2 MB pages) of the VA indicate the offset in bytes from the beginning of the first page where the entry begins.

Physical_Buffer_Address (64 bits)

If *Leaf_PBL_Size* is set to zero (00b), this field specifies the physical buffer address associated with the virtual address. If *Leaf_PBL_Size* is not set to zero, this field is ignored by the E810. This address must be aligned to the page size specified in *Host_Page_Size*. Any offset into the page is ignored by the E810.

PD_ID (18 bits)

Indicates the protection domain ID associated with the memory region or window.

STag_Length (46 bits)

Length of the memory region or memory windows specified by the STag index specified by *Driver_Key_Stag_Index*. A value of 0b indicates that the length is not checked. This is typically used for systems that want to address all of RAM with a single STag. The maximum size that can be registered with a single STag with 4 KB pages and 1-level PBLs is 1 TB (2^{28} 4 KB pages). The maximum size that can be registered with a single STag with 2 MB pages and 1-level PBLs is 32 TB (2^{24} 2 MB pages). The maximum size that can be registered with a single STag with 1 GB pages and 1-level PBLs is 32 TB (2^{15} 1 GB pages).

Parent_STag_Index (22 bits)

Index of the STag associated with the memory window (*Memory_Region* = 0) or linked memory region (*OP* = Register Shared MR).

Driver_Key_STag_Index (24 bits)

Index and *Driver Key* fields of the STag associated with the memory window (*Memory_Region* = 0b) or linked memory region (*OP* = register shared MR). The E810 supports a variable size STag index. This means that the number of bits used for *Driver Key* and for *STag_Index* are dependent on the maximum number of STag supported for a given PCI function. For example, if a PCI function read the FPMPEMRSZ field (See Section 13.2.2.20.130) and found that the maximum number of MRTEs was 64 KB, the lower 16 bits of this field would be the STag Index and the upper eight bits would be a driver key that the driver can randomize to make guessing the MRTE layout more difficult to guess. STag index 4M-1 (4,194,303) is reserved for hardware use. The completion returns an error if this reserved STag index is specified.

The width of the *STag_Index* field is based on two things: the Memory Region count supplied in the Commit FPM Buffer and the bit width mask size defined in the MRTE Index Mask (PFPE_MRTEIDXMASK) register. If the Memory Region count requires fewer bits that the minimum mask size, the STag Index size is adjusted up to the minimum. The driver must not randomize bits in the range of the STag index mask bits.

Consumer_Key (8 bits)

Consumer key is the least significant 8-bit portion of the STag. This field is supplied by the user application or the driver.

use_hmc_fcn_index (1 bit)

Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0b) for VF CQP instances.

Value	Description
0b	The HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation.
1b	*hmc_fcn_index* can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command.

hmc_fcn_index (6 bits)

Only valid when issued to a PF CQP instance and *use_hmc_fcn_index* is set to 1b. Ignored otherwise.

VA_Based_TO (1 bit)

VA_Based_TO specifies if the STag is zero-based or Virtual Address (VA)-based. Zero-based STags carry only the first buffer offset in the VA or First Buffer Offset field. VA-based STags carry the full base VA including first buffer offset in the VA or *First_Buffer_Offset* field. The STag is VA-based if *VA_Based_TO* is set (1b). Otherwise, the STag is zero-based.

Remote_Access_Enabled (1 bit)

If set, the entry is enabled for remote access. See the remote access flag in verbs for more details.

Access_Rights (5 bits)

Indicates the rights assigned to this STag. The values for this field are:

Value	Description
00001b	Enable local read
00010b	Enable local write
00100b	Enable remote read
01000b	Enable remote write
10000b	Enable window bind
Note: All other values are reserved.	

Host_Page_Size (2 bits)

Host_Page_Size specifies the page size of the backing pages for the STag. The values for this field are:

Value	Description
00b	4 KB pages
01b	2 MB pages
10b	1 GB pages
11b	Reserved

Leaf_PBL_Size (2 bits)

The E810 supports physically-contiguous STags and two forms of virtually-contiguous STags. Physically-contiguous STag do not require any PBLs and store physical address of the first page of the STag directly with the STag (No leaf PBL). Virtually-contiguous STags that can be represented with a single HMC virtually-contiguous address range require a single level PBL of Variable size. Virtually-contiguous STags that are large (or in cases where the HMC address space for PBLs becomes fragmented) might require two level PBLs. In this case, the E810 needs to know the length of the leaf PBLs to properly manage access to the PBLs. The valid settings for *Leaf_PBL_Size* are the following:

Value	Description
00b	No leaf PBL
01b	Variable (one level)
10b	256 bytes (two level)
11b	4 KB (two level)

Memory_Region (1 bit)

Value	Description
0b	The entry describes a memory window.
1b	The entry describes a memory region.

Memory_Window_Type (1 bit)

Valid only if *Memory_Region* is clear (0b) indicating a memory window.

Value	Description
0b	The entry describes a Type 2B memory window.
1b	The entry describes a Type 1 memory window (sometimes called a wide window).

Note: Type 1 Windows are not valid for iWARP.

MW1_bind_dont_vldt_key (1 bit)

Specifies whether the consumer key is validated on a bind of a Type 1 memory window. This bit is valid only if this is an Allocate of a Type 1 Memory Window.

Value	Description
0b	The consumer key is validated before being updated.
1b	The consumer key is not validated before being updated.

first_pm_pbl_index (28 bits)

Designates the HMC base address for the PBLs for this STag.

Table 11-29 shows the WQE fields that are valid for the STag management WQEs. Fields that are marked as not valid are ignored by the E810.

Table 11-29. WQE Fields Valid for Allocate/Register/Registershared/Deallocate STAG

WQE Field	Allocate	Register	Register Shared	Deallocate	Comments
Memory_Region	Valid	Valid	Not Valid	Valid	
VA_Based_TO	Not Valid	Valid	Valid	Not Valid	
Leaf_PBL_Size	Valid if *MR*=1	Valid	Not Valid	Not Valid	
Access_Rights	Not Valid	Valid	Valid	Not Valid	
Remote_Access_Enabled	Valid	Valid	Valid	Not Valid	
PD_ID	Valid	Valid	Valid	Valid	
Driver_Key_STAG_Index	Valid	Valid	Valid	Valid	
Parent_STAG_Index	Not Valid	Not Valid	Valid	Not Valid	
Consumer_Key	Not Valid	Valid	Valid	Not Valid	Host software is expected to validate the consumer key on a deallocate and on register shared.
*Base_VA*_or_*First_Buffer_Offset*	Not Valid	Valid	Valid if *VA_Based_TO*=1	Not Valid	
Physical_Buffer_Address	Not Valid	Valid	Not Valid	Not Valid	
first_pm_pbl_index	Valid	Valid	Not Valid	Not Valid	
STag_Length	Valid if *MR*=1	Valid	Not Valid	Not Valid	
Host_Page_Size	Valid	Valid	Not Valid	Not Valid	
use_hmc_fcn_index	Valid	Valid	Valid	Valid	This field is ignored (assumed to be 0b) for VFs.

Table 11-29. WQE Fields Valid for Allocate/Register/Registershared/Deallocate STAG

WQE Field	Allocate	Register	Register Shared	Deallocate	Comments
hmc_fcn_index	Valid	Valid	Valid	Valid	Only used when *use_hmc_fcn_index* is 1b.
Memory_Window_Type	Valid	Not Valid	Not Valid	Not Valid	

11.5.3.5 Query STag Descriptor Format

WQE returns the STag value and current state of an STag (valid or invalid) and the consumer key in the completion for the WQE. See Table 11-19 for information on CQP completion codes that indicate the STag state. The full STag value is returned in the *Operation_Return_Value*. Note that the error bit in the CQE should be ignored for query STag operations.

Table 11-30. CQP Query STag WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:30] [29:8]	RSVD STag_Index	[7:0]	RSVD
24	[63] [62:61] [60] [59:42]	WQE_Valid RSVD use_hmc_fcn_index[1] RSVD	[41:38] [37:32] [31:0]	RSVD (AdditionalFragmentCount) OP RSVD
32	[63:0]	RSVD		
40	[63:6]	RSVD	[5:0]	hmc_fcn_index[1]
48	[63:0]	RSVD		
56	[63:0]	RSVD		

1. This field is only valid for PF operations and is treated as 0b for VFs.

OP (6 bits) and WQE_Valid (1 bits)

See Section 11.5.3.1.

STag_Index (22 bits)

STag_Index specifies the index of the STag to be queried.

use_hmc_fcn_index (1 bit)

Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0b) for VF CQP instances.

Value	Description
0b	The HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation.
1b	*hmc_fcn_index* can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command.

hmc_fcn_index (6 bits)

Only valid when issued to a PF CQP instance and *use_hmc_fcn_index* is set to 1b. Ignored otherwise.

11.5.3.6 Manage ARP Table Descriptor Format

This WQE format is used to manage the E810's ARP table. An ARP table entry must be created before a QP can be transitioned to RTS or established since the QP context references an ARP table entry.

Table 11-31. Manage ARP Table WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:32]	RSVD	[31:0]	Reachability_Max
16	[63:48]	RSVD	[47:0]	MAC_Address
24	[63] [62:45] [44] [43] [42}	WQE_Valid RSVD Query Permanent Entry_Valid	[41:38] [37:32] [31:16] [15:0]	RSVD (AdditionalFragmentCount) OP RSVD ARP_Entry_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

ARP_Entry_Index (16 bits)

ARP_Entry_Index specifies the index of the ARP table entry to be manipulated.

Permanent (1 bit)

Value	Description
0b	The entry is created in the reachable state and is aged.
1b	The ARP entry is marked as permanent and is not aged.

Query (1 bit)

Value	Description
0b	The ARP entry is written according to the specified parameters.
1b	The ARP entry is not written. Instead, the entry is read and the reachability timestamp from the ARP entry is returned in the *Operation_Return_Value* field of the CQE.

Entry_Valid (1 bit)

Value	Description
0b	The ARP entry is set to the invalid state.
1b	The ARP entry is set to the valid state.

Note: The lower 32 bits of the AE generated when an ARP entry is stale contain the timestamp value from the ARP table entry.

Reachability_Max (32 bits)

The maximum number of microseconds that should be allowed to expire before generating a doubt neighbor reachability AEQE. Doubt neighbor reachability AEs indicate that there has been TCP/IP transmits outstanding for *Reachability_Max* without receiving any inbound traffic from the associated neighbor. To receive subsequent doubt neighbor reachability AEs, a manage ARP table WQE must be re-submitted to CQP with query clear (0b) and all original information supplied when the ARP entry was last updated.

MAC_Address (48 bits)

MAC Address to be placed in the ARP cache table.

11.5.3.7 Manage VF PBLE Backing Pages Descriptor Format

The Manage VF PBLE Backing Pages Descriptor is used to populate and depopulate VF related HMC page descriptor content. A VF that allocates the PBLE HMC object backing pages can request CQP to copy the page list associated with the backing pages to the PF driver allocated page descriptor pages. A VF might also request CQP to invalidate VF related page descriptor entries. This operation reduces the number of VF to PF messages required to populate the VF related HMC PBLE object backing pages.

Table 11-32. CQP Manage VF PBLE Backing Pages WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:44] RSVD [43:32] SD_Index [31:25] RSVD		[24:16] First_PD_Index [15:10] RSVD [9:0] PD_Entry_Count	
24	[63] WQE_Valid [62] Invalidate_PD_Entries [61:42] RSVD		[41:38] RSVD (AdditionalFragmentCount) [37:32] OP [31:0] RSVD	
32	[63:3]	PD_Pagelist_Physical_Buffer_Address	[2:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Invalidate_PD_Entries (1 bit)

Value	Description
0b	VF PD entries are copied from VF address space to the PF allocated PDs.
1b	The PF allocated PDs are invalidated.

PD_Entry_Count (10 bits)

This field indicates the number of PD entries to be populated or invalidated. Valid values for this field are 1 through 512. Other values generate completion errors for the CQP operation. *PD_Entry_Count* + *First_PD_Index* must not exceed 512 or a completion error is generated.

First_PD_Index (9 bits)

This field indicates the starting index of the PD page. *SD_Index* identifies the PD page, and *First_PD_Index* provides the offset into the PD page that is the destination of the CQP operation. If the PD entries associated with the *SD_Index* and *First_PD_Index* are not related to a PBLE object, a completion error is generated by CQP for this operation.

SD_Index (12 bits)

This field indicates the SD index that identifies the PD page. The SD entries are in no way modified. If the SD is not related to a PBLE object, then CQP returns a completion error.

PD_Pagelist_Physical_Buffer_Address (61 bits)

If *Invalidate_PD_Entries* is clear, this field indicates the 8-byte aligned physical address of the packing page list to be copied to the PD page. This address is a guest physical address. Host software is responsible to properly set the fields of the PD page list entries previous to issuing the request to CQP.

11.5.3.8 Manage Push Page Descriptor Format

The Manage Push Page Descriptor is used to assign a push page from BAR0 to a VSI and TC. For an allocate operation, the push page index assigned by CQP is returned in the *Operation_Return_Value* of the CQE associated with the WQE. For VFs, the push page index is function relative. When GLPE_PSHCFG.*PSHCFG_DB_SPLIT* is set, two pages (one for doorbells and one for push WQEs) are represented by push page index instead of one.

Table 11-33. CQP Manage Push Page WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:10]	RSVD	[9:0]	QS_Handle
24	[63] [62] [61:60] [59:42]	WQE_Valid Free_Page Push_Page_Type RSVD	[41:38] [37:32] [31:10] [9:0]	RSVD (AdditionalFragmentCount) OP RSVD Push_Page_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Free_Page (1 bit)

Value	Description
0b	A push page is allocated for the VSI and TC specified by *QS_Handle*.
1b	The push page specified by *Push_Page_Index* is freed.

Push_Page_Index (10 bits)

Only valid when *Free_Page* is set (1b). Identifies the push page to be freed. For VFs, the push page index is function relative.

QS_Handle (10 bits)

Identifies the QS handle associated with the push page. See Section 8.3.3.4 for more information on scheduler configuration.

Push_Page_Type (2 bits)

Value	Description
00b	Push page.
01b	Userspace DB alias page (experimental).
Note: All other values are reserved.	

The userspace DB alias page is a way to re-map the doorbell page intended for containers.

11.5.3.9 Upload Context Descriptor Format

Upload Context is used by host software to freeze a QPs state and upload the context to the host.

Table 11-34. CQP Upload Context WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	QP_Context_Address		
24	[63] [62] [61:51] [50:48] [47:42]	WQE_Valid Freeze_QP RSVD QP_Type RSVD	[41:38] [37:32] [31:18] [17:0]	RSVD (AdditionalFragmentCount) OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

QP_ID (18 bits)

Identifies the QP number be uploaded to host memory.

QP_Type (3 bits)

Value	Description
001b	iWARP
010b	UDA

Value	Description
011b	RoCEv2 RC
100b	RoCEv2 UD
Note: All other values are reserved.	

Freeze_QP (1 bit)

Value	Description
0b	The QP continues processing normally after the snapshot of the context has been returned.
1b	The QP is frozen before the context is retrieved.

QP_Context_Address (64 bits)

A physically-mapped pointer in host memory that contains uploaded context structure format listed in Table 11-35. This buffer must be aligned to a multiple of four bytes.

Table 11-35. Uploaded Context Structure Format (iWARP/UDA)

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:56] [55:48] [47:8]	RSVD kalive_timer_probes RSVD	[7:4] [3:0]	RDMA_state TCP_state
8	[63:32]	timestamp_page	[31:0]	timestamp_recent
16	[63:32]	snd_wnd	[31:0]	snd_nxt
24	[63:32]	rcv_wnd	[31:0]	rcv_nxt
32	[63:32]	snd_una	[31:0]	snd_max
40	[63:32]	rtt_var	[31:0]	srtt
48	[63:32]	cwnd	[31:0]	ss_thresh
56	[63:32]	snd_wl2	[31:0]	snd_wl1
64	[63:54] [53:48]	RSVD rexmit_count	[47:32] [31:0]	RSVD max_snd_window
72	[63:47] [46:32] [31] [30:27]	RSVD hw_sq_tail q1_wa RSVD	[26:24] [23:16] [15:0]	dupacks probe_cnt RSVD
80	[63:14]	RSVD	[13:0]	hw_rq_tail
88	[63:0]	RSVD		
96	[63:0]	RSVD		
104	[63:0]	RSVD		
112	[63:0]	RSVD		
120	[63:0]	RSVD		

hw_sq_tail

This is the 32-byte WQE quanta index of the first unacknowledged WQE for the SQ. There is not a CQE generated for this WQE.

hw_rq_tail

This is the 32-byte WQE quanta index of the first incomplete WQE for the RQ. There is not a CQE generated for this WQE.

q1_wa

This value is set (1b) if Q1 (or inbound RDMA read queue) work is pending when the context was uploaded. The value is clear (0b) if no Q1 work was pending when the context was uploaded.

kalive_timer_probes

The number of retransmits that have been sent (RFC 1122).

Note: Note: Refer to Section 11.6.2 for more on context variable definitions.

Table 11-36. Uploaded Context Structure Format (RoCEv2)

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:21] [20:16] [15:8]	RSVD ack_credits RSVD	[7:6] [5:3] [2:0]	dctcp_state RoceStateRx RoceStateTx

112	[63:0]	RSVD		
120	[63:0]	RSVD		

11.5.3.10 Manage HMC PM Function Table

The Manage HMC PM Function Table is used to allocate and free HMC private memory functions for VFs associated with a PF. This WQE is only supported for PF CQPs. For allocate operations (*Free_PM_FCN*=0b), the HMC function index is reported in the *Operation_Return_Value* field of the CQE associated with this WQE if the operation is successful.

Table 11-37. CQP Manage HMC PM Function Table WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61:38]	WQE_Valid Free_PM_FCN RSVD	[37:32] [31:8] [7:0]	OP RSVD VF_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Free_PM_FCN (1 bit)

Value	Description
0b	The E810 attempts to allocate a PM function for the VF specified in *VF_Index*.
1b	The E810 frees the PM function specified in *VF_index*.

VF_Index (8 bits)

VF_Index indicates the PCI VF index to be used for the allocation or free request.

11.5.3.11 Create/Destroy CEQ Descriptor Format

Host software uses the following structure to manage CEQs through the control QP. CEQs are comprised of a packed array of CEQ entries (see Section 11.4.5) that are managed as a circular queue. They can be either virtually- or physically-contiguous memory buffers. When MSI-X is enabled, each CEQ might be assigned to independent MSI-X vectors to enable distribution of completion event processing across multiple CPUs. Application's process and MSI-X vector assignment capabilities and mechanisms are specific to each operating system.

Table 11-38. CQP Create/Destroy CEQ WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:18]	RSVD	[17:0]	ceq_size
24	[63] [62:61] [60] [59:48] [47] [46]	WQE_Valid RSVD TPH_en RSVD Virtually_Mapped itr_no_expire	[45:44] [43:42] [41:38] [37:32] [31:10] [9:0]	Leaf_PBL_Size RSVD RSVD (AdditionalFragmentCount) OP RSVD CEQ_ID
32	[63:8]	Physical_Buffer_Address	[7:0]	RSVD
40	[63:0]	RSVD		
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:18] [17:8]	RSVD VSI_Index	[7:0]	TPH_Value

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

CEQ_ID (10 bits)

CEQ_ID specifies the CEQ to manipulated.

TPH_en (1 bit)

Value	Description
0b	THP is not used for this resource.
1b	TPH is enabled for this resource.

TPH_Value (8 bits)

If *TPH_en* is set (1b), TPH STag is initialized with *TPH_Value*. If *TPH_en* is clear (0b), this field is ignored.

VSI_Index (10 bits)

The VSI index for the CEQ. Only defined for Create CEQ. It is ignored on Destroy CEQ.

first_pm_pbl_index (28 bits)

Points to the first HMC FPM space PBLE index for the page table. Host software is responsible for populating the PBLEs with the page list associated with the object before using the object.

Leaf_PBL_Size (2 bits)

See Section 11.4.1.4.1 for more details on usage of two level PBLs.

Value	Description
00b	Reserved
01b	Variable (one level)
10b	256 bytes (two level)
11b	4 KB (two level)

Virtually_Mapped (1 bit)

Value	Description
0b	*Physical_Buffer_Address* is the physical address of the physically-contiguous CEQ ring buffer.
1b	The CEQ is virtually-mapped, and *first_pm_pbl_index* is the index of the PBLE HMC object of the PBL to use for mapping the virtually-contiguous CEQ.

The CEQ buffer must be aligned to a multiple of 4 KB in host memory when virtually mapped is set.

itr_no_expire (1 bit)

Value	Description
0b	There is a short delay before a CEQE is written and the interrupt is issued (if enabled).
1b	The CEQE is written and the interrupt (if enabled) occurs immediately.

Physical_Buffer_Address (56 bits)

If *Virtually_Mapped* is set to 0b, this field specifies the physical buffer address associated with the queue in host memory. If *Virtually_Mapped* is set to 1b, this field is ignored by the E810. This address must be aligned to a 256-byte boundary.

ceq_size (18 bits)

The number of CEQEs allowed on the CEQ. Note that the actual number of concurrent CEQEs that can be allocated to the CEQ is *ceq_size* -1. 0 and 1 are invalid sizes for a CEQ.

11.5.3.12 Create/Destroy AEQ Descriptor Format

Host software uses the following structure to manage AEQs through the control QP. AEQs are comprised of a packed array of AEQ entries (see Section 11.4.6) that are managed as a circular queue. They can be either virtually- or physically-contiguous memory buffers.

Table 11-39. CQP Create/Destroy AEQ WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:19]	RSVD	[18:0]	AEQE_Count
24	[63] [62:48] [47] [46] [45:44]	WQE_Valid RSVD Virtually_Mapped RSVD Leaf_PBL_Size	[43:42] [41:38] [37:32] [31:0]	RSVD RSVD (AdditionalFragmentCount) OP RSVD
32	[63:8]	Physical_Buffer_Address	[7:0]	RSVD
40	[63:0]	RSVD		
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

first_pm_pbl_index (28 bits)

Points to the first HMC FPM space PBLE index for the page table. Host software is responsible for populating the PBLEs with the page list associated with the object before using the object.

Leaf_PBL_Size (2 bits)

See Section 11.4.1.4.1 for more details on usage of two level PBLs.

Value	Description
00b	Reserved
01b	Variable (one level)
10b	256 bytes (two level)
11b	4 KB (two level)

Virtually_Mapped (1 bit)

Value	Description
0b	*Physical_Buffer_Address* is the physical address of the physically-contiguous AEQ ring buffer.
1b	The AEQ is virtually-mapped, and *first_pm_pbl_index* is the index of the PBLE HMC object of the PBL to use for mapping the virtually-contiguous AEQ.

The AEQ buffer must be aligned to a multiple of 4 KB in host memory when virtually mapped is set.

Physical_Buffer_Address (56 bits)

If *Virtually_Mapped* is set to 0b, this field specifies the physical buffer address associated with the queue in host memory. If *Virtually_Mapped* is set to 1b, this field is ignored by the E810. This address must be aligned to a 256-byte boundary.

AEQE_Count (19 bits)

The number of AEQEs allowed on the AEQ. Note that the actual number of concurrent AEQEs that can be allocated to the AEQ is *AEQE_Count* -1. 0 and 1 are invalid sizes for an AEQ.

11.5.3.13 Create/Modify/Destroy Address Handle Descriptor Format

Host software uses following structure to create, modify or destroy address handle. Address Handle is used by UDA and RoCEv2 UD traffic to allow protected Ethernet and IP Headers generation by hardware, while ULP headers (such as UDP) and datagram payload is provided directly by the application or the software library running in the application address space. Address Handle in conjunction with UDA Queue context carries all information necessary for the header generation.

Internal switching capabilities within the same VSI are controlled using the *DoLoopback* bit in Address Handle. Physical Function driver might need to Modify Address Handle to set or clear this bit at runtime using the Modify Address Handle CQP command, depending on the changes in configuration. For example, UDA and OS consumers subscribed or unsubscribed from the multicast group.

Table 11-40. CQP Create/Modify/Destroy Address Handle WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:56] [55:48] [47:40] [39:32]	Src_MAC_Address[5] Src_MAC_Address[4] Src_MAC_Address[3] Src_MAC_Address[2]	[31:24] [23:16] [15:0]	Src_MAC_Address[1] Src_MAC_Address[0] RSVD
8	[63:48] [47:40] [39:32]	PD_Index RSVD Traffic_Class_or_TOS	[31:16] [15:0]	RSVD VLAN_Tag
16	[63:48] [47:40] [39:32]	ARP_Index RSVD Hop_Limit_or_TTL	[31:22] [21:20] [19:0]	RSVD pd_indexd_high Flow_Label
24	[63] [62] [61] [60] [59]	WQE_Valid DoLoopback RSVD Insert_VLAN_Tag IPv4_Valid	[58:42] [41:38] [37:32] [31:17] [16:0]	RSVD RSVD (AdditionalFragmentCount) OP RSVD AH_ID
32	[63:32]	Dest_IP_Address_2	[31:0]	Dest_IP_Address_3
40	[63:32]	Dest_IP_Address_0	[31:0]	Dest_IP_Address_1
48	[63:32]	Src_IP_Address_2	[31:0]	Src_IP_Address_3
56	[63:32]	Src_IP_Address_0	[31:0]	Src_IP_Address_1

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

IPv4_Valid (1 bit)

Value	Description
0b	*Dest_IP_Address* is an IPv6 IP Address.
1b	*Dest_IP_Address* is an IPv4 IP Address.

DoLoopback (1 bit)

Value	Description
0b	Multicast and unicast packets generated using this Address Handle should not be internally switched within same VSI. Internal switching rules between VSIs are based on the switch configuration.
1b	All unicast UDA packets generated using this Address Handle should be internally switched within VSI. All multicast UDA packets should be both sent to the external port, and internally switched within same VSI.

AH_ID (17 bits)

Index of Address Handle as allocated by software. This index together with HMC configuration for the PCI function identifies location of the hardware Address Handle structure in the host memory.

Traffic_Class_or_TOS (8 bits)

This field specifies the IPv4 Type of Service bits (RFC 2474). If these bits represent the IPv4 TOS bits, only the lower 4-bits are valid. These bits are set by software when the address handle is created and transmitted in the IP header of all sent datagrams for this address handle.

Hop_Limit_or_TTL (8 bits)

This field specifies the IPv4 Time-To-Live (TTL) parameter in the IP header (RFC 791). It is initialized by the software.

Dest_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b). The most significant byte of this field (Bits 31:24) is the first byte on the wire for this field.

Dest_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address_2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 IP Address (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The least significant byte of this field (Bits 7:0) is the last byte on the wire for this field.

Src_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b). The most significant byte of this field (Bits 31:24) is the first byte on the wire for this field.

Src_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b).

Src_IP_Address_2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Address. Reserved when *IPv4_Valid* is set (1b).

Src_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 IP Address (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The least significant byte of this field (Bits 7:0) is the last byte on the wire for this field.

Src_MAC_Address[5-0] (8 bits each)

Specifies the MAC Address associated with the source IP Address. Index 0 is the LSB and byte 5 is the MSB.

ARP_Index (16 bits)

Index into the ARP cache to specify the Ethernet MAC Address to use for this connection. Initialized by software during connection establishment. Allows access to the entry ARP table. There are no reserved index values. This field is valid for unicast destination MAC Addresses only. Multicast MAC Address is calculated by hardware based on the destination IP Address.

Flow_Label (20 bits)

Flow Label field of IPv6 header.

PD_Index (16 bits) and pd_index_high (2 bits)

Protection Domain for this address handle. This specifies which one of the 256K protection domains this address handle belongs too. There are no reserved index values.

Insert_VLAN_Tag (1 bit)

This bit is set to enable VLAN processing on a connection. The tag configured in the *VLAN_Tag* field is used for all processing. If this bit is clear (0b), there is no VLAN insertion or removal performed by the Protocol Engine. Additional VLAN and priority setting can be configured through the VSI associated with the QP. The most significant portion of the VLAN tag carries the user-specified priority.

VLAN_Tag (16 bits)

Specifies one of the 4096 VLAN tags for this connection, Three bits of priority and one bit canonical format. All bits are valid. The VLAN is in the lower 12 bits of the VLAN Tag field. The upper three bits are priority.

11.5.3.14 Update PE SDs Descriptor Format

This WQE is used to program HMC segment descriptors (SDs) associated with PE-enabled PCI functions. CQP ensures that PFs only access HMC functions that belong to the PF at the time of issues the CQP request. PFs can access its own SDs or SDs of RDMA-enabled VFs that belong to the PF. Accesses to other HMC functions are denied and generate a completion error. This operation is restricted to PF CQP operations.

Table 11-41. CQP Update PE SDs WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:32]	RSVD	[31:0]	SDCMD0
8	[63:32]	SDDATAHIGH0	[31:0]	SDDATALOW0
16	[63:7] [6]	SD_Buffer_Address RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:42] [41:38] [37:32]	WQE_Valid RSVD RSVD (AdditionalFragmentCount) OP	[31:8] [7] [6:4] [3:0]	RSVD SKIP_SD_ENTRY_0 RSVD SD_ENTRY_COUNT

40	[63:32]	SDDATAHIGH1	[31:0]	SDDATALOW1
48	[63] [62:32]	SD_ENTRY_VALID2 RSVD	[31:0]	SDCMD2
56	[63:32]	SDDATAHIGH2	[31:0]	SDDATALOW2

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

HMC_FCN_ID (6 bits)

This field specifies the HMC function ID for the FPM settings to be queried. For PFs, the *HMC_FCN_ID* is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation.

SD_CMD*n* (32 bits)

Table 11-42. SD_CMD Format

Byte Offset	[Bit Range]	Field Name	Description
0	[32:12]	RSVD	Reserved.
	[11:0]	PMSDIDX	Index of the HMC Segment Descriptor.

SD_DATA_LOW*n* (32 bits)

Table 11-43. SD_DATA_LOW Format

Byte Offset	[Bit Range]	Field Name	Description
0	[32:12]	PMSDDATALOW	Bits 31-12 of the segment descriptor.
	[11:2]	PMSDBPCOUNT	When PMSDTYPE is 0, this field has the number of Page Descriptors in this SD.
	[1]	PMSDTYPE	0b = SD points to a page of 512 Page Descriptors. 1b = SD has the physical address of a physically contiguous region.
	[0]	PMSDVALID	Marks the segment descriptor as valid or invalid.

SD_DATA_HIGH*n* (32 bits)

Table 11-44. SD_DATA_HIGH Format

Byte Offset	[Bit Range]	Field Name	Description
0	[32:0]	PMSDDATAHIGH	Most significant 32 bits of a segment descriptor.

SD_ENTRY_VALID*n* (1 bit)

Indicates the SDCMD and DATA information is used to update additional SD entries.

SKIP_SD_ENTRY_0 (1 bit)

Indicates *SD_CMD0*, *SD_DATA_LOW*/*HIGH0* are to be ignored. This is typically useful only if all the SD updates are specified in the update SD host memory structure instead of this WQE.

SD_Buffer_Address (57 bits)

Most significant address bits of the physical address of the update SD host memory structure (listed in Table 11-45). This structure is used to provide additional SD updates. This host memory is only accessed if *SD_ENTRY_COUNT* is not equal to 0b. The number of entries used from the update SD host memory structure is indicated by *SD_ENTRY_COUNT*.

SD_ENTRY_COUNT (4 bits)

Indicates the number of contiguous (starting with *SDCMD3*) SD updates found in the update SD host memory structure.

Table 11-45. Update SD Host Memory Structure

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:32]	RSVD	[31:0]	SDCMD3
8	[63:32]	SDDATAHIGH3	[31:0]	SDDATALOW3
16	[63:32]	RSVD	[31:0]	SDCMD4
24	[63:32]	SDDATAHIGH4	[31:0]	SDDATALOW4
32	[63:32]	RSVD	[31:0]	SDCMD5
40	[63:32]	SDDATAHIGH5	[31:0]	SDDATALOW5
48	[63:32]	RSVD	[31:0]	SDCMD6
56	[63:32]	SDDATAHIGH6	[31:0]	SDDATALOW6
64	[63:32]	RSVD	[31:0]	SDCMD7

Table 11-45. Update SD Host Memory Structure [continued]

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
72	[63:32]	SDDATAHIGH7	[31:0]	SDDATALOW7
80	[63:32]	RSVD	[31:0]	SDCMD8
88	[63:32]	SDDATAHIGH8	[31:0]	SDDATALOW8
96	[63:32]	RSVD	[31:0]	SDCMD9
104	[63:32]	SDDATAHIGH9	[31:0]	SDDATALOW9
112	[63:32]	RSVD	[31:0]	SDCMD10
120	[63:32]	SDDATAHIGH10	[31:0]	SDDATALOW10

11.5.3.15 Query FPM Values Descriptor Format

This WQE is used to query the FPM configuration for the PE portion of the HMC objects. The query FPM values command is used to trigger firmware to return the FPM base registers based on the previous software settings or default values.

Table 11-46. CQP Query FPM Values WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:42] [41:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:2]	Physical_Buffer_Address	[1:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

HMC_FCN_ID (6 bits)

This field specifies the HMC function ID for the FPM settings to be queried. For PFs, the *HMC_FCN_ID* is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the *HMC_FCN_ID* is determined by firmware.

Physical_Buffer_Address (62 bits)

This field specifies the physical address of the buffer that firmware fills with the object maximum counts and the object size values.

Table 11-47. FPM Query Configuration Structure Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:45] [44:32]	RSVD max_pe_sds	[31:14] [13:0]	RSVD first_pe_sd_index
8	[63:32] [31:19]	GLHMC_PEQPOBJSZ RSVD	[18:0]	max_qps

32	[63:32]	GLHMC_PEHTEOBJSZ	[31:0]	GLHMC_PEHTMAX
40	[63:32]	GLHMC_PEARPOBJSZ	[31:0]	GLHMC_PEARPMAX
48	[63:32]	GLHMC_PEMROBJSZ	[31:0]	GLHMC_PEMRMAX
56	[63:32]	GLHMC_PEXFOBJSZ	[31:0]	GLHMC_PEXFMAX
64	[63:32]	XFBLOCKSIZE	[31:0]	GLHMC_PEXFFLMAX
72	[63:32]	GLHMC_PEQ1OBJSZ	[31:0]	GLHMC_PEQ1MAX
80	[63:32]	Q1BLOCKSIZE	[31:0]	GLHMC_PEQ1FLMAX
88	[63:32]	GLHMC_PETIMEROBJSZ	[31:0]	GLHMC_PETIMERMAX
96	[63:32]	GLHMC_FSIMCOBJSZ	[31:0]	GLHMC_FSIMCMAX
104	[63:32]	GLHMC_FSIAVOBJSZ	[31:0]	GLHMC_FSIAVMAX
112	[63:32]	RSVD	[31:0]	GLHMC_PEPBLMAX
120	[63:48] [47:32] [31:20]	RSVD TIMERBUCKETCNT RSVD	[19:16] [15:10] [9:0]	HTMULTIPLIER RSVD max_ceqs
128	[63:32]	GLHMC_PERRFOBJSZ	[31:0]	GLHMC_PERRFMAX
136	[63:32]	RRFBLOCKSIZE	[31:0]	GLHMC_PERRFFLMAX
144	[63:32]	GLHMC_PEHDROBJSZ	[31:0]	GLHMC_PEHDRMAX
152	[63:32]	GLHMC_PEMDOBJSZ	[31:0]	GLHMC_PEMDMAX
160	[63:32]	GLHMC_PEOOISCOBJSZ	[31:0]	GLHMC_PEOOISCMAX
168	[63:32]	OOISCFBLOCKSIZE	[31:0]	GLHMC_PEOOISCFFLMAX

first_pe_sd_index (14 bits)

This field specifies the function relative starting HMC segment descriptor index for PE resources.

max_pe_sds (13 bits)

This field specifies the maximum number of PE SDs allowed for the HMC function.

max_qps (19 bits)

This field specifies the maximum number of PE QPs allowed for the HMC function.

max_cqs (20 bits)

This field specifies the maximum number of PE CQs allowed for the HMC function.

max_ceqs (10 bits)

This field specifies the maximum number of PE CEQs allowed for the HMC function.

XFBLOCKSIZE (32 bits)

This field specifies the number of transmit FIFO entries per transmit FIFO free list entry. This field is used to determine how much space is consumed for transmit FIFO free list entries. The number of transmit FIFO free list entries is calculated with the following equation:

number of transmit FIFO entries / *XFBLOCKSIZE*

Q1BLOCKSIZE (32 bits)

This field specifies the number of Q1 FIFO entries per Q1 FIFO free list entry. This field is used to determine how much space is consumed for Q1 free list entries. The number of Q1 free list entries is calculated with the following equation:

number of Q1 entries / *Q1BLOCKSIZE*

HTMULTIPLIER (4 bits)

This field specifies the number of hash filter bucket entries per QP. This field is used to determine how much space is consumed for hash filter entries. The number of hash entries is calculated with the following equation:

(round_up_512 (number of QPs + number of Multicast Groups) rounded up to the next power of two) * *HTMULTIPLIER*

TIMERBUCKETCNT (16 bits)

This field specifies the number of timer buckets. This field is used to determine how much space is consumed for timers. The number of timer entries is calculated with the following equation:

(round_up_512 (number of QPs) / 512 + 1) * *TIMERBUCKETCNT*

The remaining fields are register values from the HMC function specified by *HMC_FCN_ID* or the VF index.

RRFBLOCKSIZE (32 bits)

This field specifies the number of Read Response FIFO entries per Read Response FIFO free list entry. This field is used to determine how much space is consumed for Read Response FIFO free list entries. The number of Read Response FIFO free list entries is calculated with the following equation:

number of Read Response FIFO entries / *RRFBLOCKSIZE*

OOISCFBLOCKSIZE (32 bits)

This field specifies the number of Out of Order Send Completion FIFO entries per Out of Order Send Completion FIFO free list entry. This field is used to determine how much space is consumed for Out of Order Send Completion FIFO free list entries. The number of Out of Order Send Completion FIFO free list entries is calculated with the following equation:

number of Out of Order Send Completion FIFO entries / *OOISCFBLOCKSIZE*

11.5.3.16 Commit FPM Values Descriptor Format

This WQE is used to commit the FPM configuration for the PE portion of the HMC objects. The Commit FPM Values command is used to trigger firmware to calculate the FPM base registers based on the software settings.

The Commit FPM Values operation can be applied only once per function. Subsequent uses of this operation for the same function fail with an Invalid State CQP return code. However, the existing values for the function are returned as output in the buffer.

Table 11-48. CQP Commit FPM Values WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:42] [41:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:2]	Physical_Buffer_Address	[1:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

HMC_FCN_ID (6 bits)

This field specifies the HMC function ID for the FPM settings to be programmed. For PFs, the *HMC_FCN_ID* is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the *HMC_FCN_ID* is determined by firmware.

Physical_Buffer_Address (62 bits)

This field specifies the most significant bits of the physical address of the buffer that firmware uses to configure the object maximum counts and the object size values. The buffer described must be aligned to a 4-byte aligned boundary.

Table 11-49. FPM Commit Configuration Structure Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:32] [31:19]	GLHMC_PEQPBASE RSVD	[18:0]	GLHMC_PEQPCNT
8	[63:32] [31:20]	GLHMC_PECQBASE RSVD	[19:0]	GLHMC_PECQCNT
16	[63:0]	RSVD		
24	[63:32]	GLHMC_PEHTEBASE	[31:0]	GLHMC_PEHTCNT[1]
32	[63:32]	GLHMC_PEARPBASE	[31:0]	GLHMC_PEARPCNT
40	[63:32]	GLHMC_APBVTINUSEBASE	[31:0]	RSVD

Table 11-49. FPM Commit Configuration Structure Format [continued]

Byte Offset	[Bit Range]	Field Name		
48	[63:32]	GLHMC_PEMRBASE	[31:0]	GLHMC_PEMRCNT
56	[63:32]	GLHMC_PEXFBASE	[31:0]	GLHMC_PEXFCNT
64	[63:32]	GLHMC_PEXFFLBASE	[31:0]	GLHMC_PEXFFLCNT[1]
72	[63:32]	GLHMC_PEQ1BASE	[31:0]	GLHMC_PEQ1CNT
80	[63:32]	GLHMC_PEQ1FLBASE	[31:0]	GLHMC_PEQ1FLCNT[1]
88	[63:32]	GLHMC_PETIMERBASE	[31:0]	GLHMC_PETIMERCNT[1]
96	[63:32]	GLHMC_FSIMCBASE	[31:0]	GLHMC_FSIMCCNT
104	[63:32]	GLHMC_FSIAVBASE	[31:0]	GLHMC_FSIAVCNT
112	[63:32]	GLHMC_PEPBLBASE	[31:0]	GLHMC_PEPBLCNT
120	[63:0]	RSVD		
128	[63:32]	GLHMC_PERRFBASE	[31:0]	GLHMC_PERRFCNT
136	[63:32]	GLHMC_PERRFFLBASE	[31:0]	GLHMC_PERRFFLCNT[1]
144	[63:32]	GLHMC_PEHDRBASE	[31:0]	GLHMC_PEHDRCNT
152	[63:32]	GLHMC_PEMDBASE	[31:0]	GLHMC_PEMDCNT
160	[63:32]	GLHMC_PEOOISCBASE	[31:0]	GLHMC_PEOOISCCNT
168	[63:32]	GLHMC_PEOOISCFFLBASE	[31:0]	GLHMC_PEOOISCFFLCNT[1]

1. These fields are calculated by CQP and returned on completion. On submission, these fields are ignored.

These fields are register values from the HMC function specified by *HMC_FCN_ID* or the *VF_Index*. On request submission, the GLHMC_{obj}CNT fields must be filled in the software. Upon completion of the request, all fields are filled in with the updated values that were actually committed.

11.5.3.17 Flush WQEs Descriptor Format

This WQE is used to flush pending WQEs to a CQ. The initial usage for the WQE is to support Winsock Direct socket hand-off from one process to another. This WQE is now also used for all WQE flushing. Host software uses this after the quad hash has been deleted for a QP in order to comply with verbs requirements. Note that only a single unprocessed WQE is flushed from the WQ(s) specified by the *FlushRQ*/*FlushSQ* bits. Host software must generate additional completions if more than one outstanding WQE is pending on a WQ that has been flushed.

This WQE can be used to flush pending transmit and receive WQEs for UDA and RDMA QPs. For UDA all filters forwarding to the specified UDA QP must be disabled, prior to flushing WQEs.

Table 11-50. CQP Flush WQEs WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:20] [19:16]	RSVD AE_Source	[15:12] [11:0]	RSVD AE_Code
16	[63:48] [47:32]	SQ_Major_Code SQ_Minor_Code	[31:16] [15:0]	RQ_Major_Code RQ_Minor_Code
24	[63] [62] [61] [60] [59]	WQE_Valid FlushRQ FlushSQ UserFlushCode GenerateAE	[58:42] [41:38] [37:32] [31:18] [17:0]	RSVD RSVD (AdditionalFragmentCount) OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

FlushRQ (1 bit)

Value	Description
0b	Do not flush any pending WQEs from the RQ.
1b	Generate a completion for the first pending RQ with a flushed return code.

FlushSQ (1 bit)

Value	Description
0b	Do not flush any pending WQEs from the SQ.
1b	Generate a completion for the first pending SQ with a flushed return code.

UserFlushCode (1 bit)

UserFlushCode indicates that the WQEs flushed should carry the values specified by SQ/RQ major and minor codes.

Value	Description
0b	Any flushed WQEs carry the flushed completion major and minor codes.
1b	Flushed WQEs for the SQ carry *SQ_Major_Code* and *SQ_Minor_Code*. Flushed WQEs on the RQ carry *RQ_Major_Code* and *RQ_Minor_Code*.

SQ_Major_Code (16 bits)

Valid only when *UserFlushCode*=1b. *SQ_Major_Code* is reported in *Major_Error_Code* field of the CQE for the first flushed WQE for the SQ of the QP specified by *QP_ID*.

SQ_Minor_Code (16 bits)

Valid only when *UserFlushCode*=1b. *SQ_Minor_Code* is reported in *Minor_Error_Code* field of the CQE for the first flushed WQE for the SQ of the QP specified by *QP_ID*.

RQ_Major_Code (16 bits)

Valid only when *UserFlushCode*=1b. *RQ_Major_Code* is reported in *Major_Error_Code* field of the CQE for the first flushed WQE for the RQ of the QP specified by *QP_ID*.

RQ_Minor_Code (16 bits)

Valid only when *UserFlushCode*=1. *RQ_Minor_Code* is reported in *Minor_Error_Code* field of the CQE for the first flushed WQE for the RQ of the QP specified by *QP_ID*.

GenerateAE (1 bit)

GenerateAE indicates that an AE should be generated after the CQEs have been generated for the flushed WQEs.

AE_Code (12 bits)

Valid only when *GenerateAE*=1. See Table 11-12 for the values that should be used for this field.

AE_Source (4 bits)

Valid only when *GenerateAE*=1. See Section 11.4.6 for the values that should be used for this field.

QP_ID (18 bits)

Identifies the QP number targeted for the flush operation. This must be an accelerated QP (UDA or iWARP or RoCEv2).

11.5.3.18 Manage Accelerated Port Bit Vector (APBV)

This WQE sets or clears the bit in the APBV table for the host NIC, IP Address, and TCP or UDP port number specified in the WQE. The APBV table is used to filter TCP segments belonging to accelerated RDMA connections, TCP segments, UDP multicast and unicast datagrams belonging to accelerated UDA QPs. Host software also uses the APBV table to flag inbound TCP packets used for connection setup of accelerated connections.

Table 11-51. CQP Manage Accelerated Port Table WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:16]	RSVD	[15:0]	Local_TCP/UDP_Port
24	[63] [62] [61:42]	WQE_Valid Add_Port RSVD	[41:38] [37:32] [31:0]	RSVD (AdditionalFragmentCount) OP RSVD
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Add_Port (1 bit)

Value	Description
0b	The port is deleted from the table.
1b	The port is added to the table.

Local_TCP/UDP_Port (16 bits)

The local (destination port for inbound packets) TCP/IP or UDP/IP port that is used for accelerated RDMA connections and accelerated UDA UDP unicast and multicast datagrams, and UDA TCP streams. Any inbound TCP packet and UDP datagram who's destination IP Address matches that IP Address table and destination TCP/UDP port matches *Local_TCP/UDP_Port* is filtered through quad hash table. If missed, TCP packet and UDP datagram is passed to the host NIC.

11.5.3.19 NOP Descriptor Format

This WQE can be used to generate a CQE that can be used to trigger subsequent processing in a completion handler or as a synchronization mechanism to indicate when all previously issued CQP requests have completed.

Table 11-52. CQP NOP WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62:42] [41:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

11.5.3.20 Manage Quad Hash Table Descriptor Format

The quad hash table entry can be configured to forward packets to the UDA QP. Multiple entries of the quad hash table can refer to the same QP or multicast group.

The same quad hash table is intended to be shared by RDMA QPs and UDA QPs and multicast groups. The quad hash table must be properly sized to allow a good hit rate. It also must be properly sized with respect to the maximum number of entries that are intended to be allocated. One approach is to limit the total number of resources that can be allowed to use quad hash for the given function. This would enable the best use of the shared table. In any case, since allocation of entries in the quad hash table is controlled by PCI function driver, sizing of the table, and allocation policy should be controlled there.

UDA UDP and TCP traffic should be using quad hash tables associated with respective PCI function (PF or VF).

The quad hash table index is calculated by hardware. All hash functions include destination MAC Address and VLAN (if valid) in addition to the description provided later. Hash function inputs and a kind of hash function depends on a hash table entry type:

- **UDP Unicast** — For the first UDP unicast fragment, or UDP unicast datagram, Hash Function should use as an input a destination IP Address and destination UDP port. Hash Table entry should match both destination IP Address and destination UDP port, and should be of UDP Unicast entry type. Matching entry should carry a destination Queue Pair Number.
- **TCP SYN (ACK Clear)** — For the TCP packets with the SYN bit set, a hash function should be used as an input a destination IP Address and destination TCP port. A hash table entry should match both destination IP Address and destination TCP port, and should be of TCP SYN (ACK clear) entry type. Matching entry should carry a destination QP number.

- **Established TCP** — For the TCP packets with the SYN bit clear or the *SYN* bit set and *ACK* bit set, the hash function should be used as an input source and destination IP Addresses, and source and destination TCP ports. The hash table should match both source and destination IP Addresses, and source and destination TCP ports. Matching entry should carry a destination QP number.
- **RoCEv2 Multicast** — RoCEv2 multicast packets go through the Quad Hash to look up the multicast group number. Hash Table entry should match the destination IP Address, the destination QP has all bits on (1's), and should be of multicast entry type. Matching entry should carry a multicast group number. RoCEv2 unicast packets do not go through the Quad Hash.

Table 11-53. CQP Manage Quad Hash Table WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:48] [47:40] [39:32] [31:24]	RSVD Dest_MAC_Address[5] Dest_MAC_Address[4] Dest_MAC_Address[3]	[23:16] [15:8] [7:0]	Dest_MAC_Address[2] Dest_MAC_Address[1] Dest_MAC_Address[0]
8	[63:50] [49:32]	RSVD QPN/MGN	[31:16] [15:0]	src_port dest_port

32	[63:32]	Src_IP_Address_2	[31:0]	Src_IP_Address_3
40	[63:32]	Src_IP_Address_0	[31:0]	Src_IP_Address_1
48	[63:32]	Dest_IP_Address_2	[31:0]	Dest_IP_Address_3
56	[63:32]	Dest_IP_Address_0	[31:0]	Dest_IP_Address_1

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

QS_Handle (10 bits)

Identifies the queue set handle associated with the hash entry. See Section 8.3.3.4 for more information on scheduler configuration.

Dest_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b). The MSB of this field (Bits 31:24) is the first byte on the wire for this field.

Dest_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address 2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The LSB of this field (Bits 7:0) is the last byte on the wire for this field.

Src_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b). The MSB of this field (Bits 31:24) is the first byte on the wire for this field.

Src_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Src_IP_Address_2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Src_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The LSB of this field (Bits 7:0) is the last byte on the wire for this field.

src_port (16 bits)

Source UDP/TCP port.

dest_port (16 bits)

Destination UDP/TCP port.

QPN/MGN (18 bits)

Index of the QP context or Multicast Group Context associated with the entry. When modifying a quad hash entry for a Multicast Group, the Multicast Group Number is smaller than the QP number. The high bits must be filled with leading zeros.

EntryType (3 bits)

The quad hash table is used as a perfect filter for multiple types of accelerated traffic (Userspace TCP, RoCEv2, Userspace UDP unicast and multicast). Depending on the traffic type different hardware accelerations might apply.

Value	Description
001b	Userspace TCP Established
010b	Userspace TCP SYN (ACK clear)
011b	Userspace UDP Unicast
110b	Userspace UDP Multicast
Note: All other values are reserved	

IPv4_Valid (1 bit)

Value	Description
0b	Indicates that both source and destination IP Addresses are IPv6.
1b	Indicates that both source and destination IP Addresses are IPv4.

ManageEntry (2 bits)

Value	Description
00b	Delete entry from the table.
01b	Add entry to the table.
10b	Modify entry.
11b	Reserved.

Dest_MAC_Address[5-0] (8 bits each)

Specifies the MAC Address associated with the destination IP Address. Index 0 is the LSB and byte 5 is the MSB.

VLAN_ID (12 bits)

Specifies the VLAN ID associated with the hash entry. This field is ignored unless *VLAN_Valid* is set (1b).

VLAN_Valid (1 bit)

Specifies if the hash entry has a VLAN associated with it.

Value	Description
0b	The hash entry is not associated with a VLAN.
1b	The VLAN associated with the hash entry is specified in the *VLAN_ID* field.

11.5.3.21 Create/Modify/Destroy Multicast Group Descriptor Format

This WQE can be used to Create/Modify/Destroy Multicast Group. This WQE can be used only by Physical PCI Function driver. Software owns content of the Multicast Group Context. Every time new QP subscribes or leaves the multicast group, driver should Modify the contents of the Multicast Group Context and issue the Modify Multicast Group descriptor to CQP.

The Create Multicast Group creates an entry in the Quad Hash. The Destroy Multicast Group removes the Quad Hash entry. Modify Multicast Group does not modify the Quad Hash entry.

The Modify Multicast Group requires *HMC_FCN_ID*, *MG_ID* and an updated MG context. The other fields are ignored.

Table 11-54. CQP Create/Modify/Destroy Multicast Group WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:48] [47:40] [39:32] [31:24]	RSVD Dest_MAC_Address[5] Dest_MAC_Address[4] Dest_MAC_Address[3]	[23:16] [15:8] [7:0]	Dest_MAC_Address[2] Dest_MAC_Address[1] Dest_MAC_Address[0]
8	[63:6]	RSVD	[5:0]	HMC_FCN_ID
16	[63:44] [43:32]	RSVD VLAN_ID	[31:16] [9:0]	RSVD QS_Handle
24	[63] [62:61] [60] [59]	WQE_Valid RSVD IPv4_Valid VLAN_Valid	[58:38] [37:32] [31:13] [12:0]	RSVD (AdditionalFragmentCount) OP RSVD MG_ID
32	[63:0]	MGContextAddress		
40	[63:0]	RSVD		
48	[63:32]	Dest_IP_Address_2	[31:0]	Dest_IP_Address_3
56	[63:32]	Dest_IP_Address_0	[31:0]	Dest_IP_Address_1

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

MG_ID (13 bits)

Index of the Multicast Group. Allocated and managed by physical function driver. Each PCI function has a dedicated zero-based Multicast Group IDs space.

MGContextAddress (64 bits)

Physical address of the software Multicast Group context. *MGContextAddress* should be aligned to 64 bytes.

HMC_FCN_ID (6 bits)

This field specifies the HMC function ID for the FPM settings to be queried. For PFs, the *HMC_FCN_ID* is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation.

IPv4_Valid (1 bits)

Value	Description
0b	Indicates that both source and destination IP Addresses are IPv6.
1b	Indicates that both source and destination IP Addresses are IPv4.

Dest_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b). The MSB of this field (Bits 31:24) is the first byte on the wire for this field.

Dest_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address 2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Addresses. Reserved when *IPv4_Valid* is set (1b).

Dest_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The LSB of this field (Bits 7:0) is the last byte on the wire for this field.

Dest_MAC_Address[5-0] (8 bits each)

Specifies the MAC Address associated with the destination IP Address. Index 0 is the LSB and byte 5 is the MSB.

VLAN_ID (12 bits)

Specifies the VLAN ID associated with the hash entry. This field is ignored unless *VLAN_Valid* is set (1b).

VLAN_Valid (1 bit)

Specifies if the hash entry has a VLAN associated with it.

Value	Description
0b	The hash entry is not associated with a VLAN.
1b	The VLAN associated with the hash entry is specified in the *VLAN_ID* field.

QS_Handle (10 bits)

This field specifies Tx-Scheduler QS handle associated with the TC for this QP. See Section 8.3.3.4 for more information on scheduler configuration. For VFs, the *QS_Handle* is checked to ensure that the VF issuing the CQP command is associated with the *QS_Handle*. *QS_Handle* is valid only for Create Multicast Group.

11.5.3.22 Suspend QP Descriptor Format

This WQE can be used to suspend a QP that is to be moved to a different QS than the one to which it is currently assigned. QP suspension is required before changing the QS. This WQE might return suspend pending in which case an AE_QP_SUSPEND_COMPLETE AE is issued when the suspend operation completed.

Table 11-55. CQP Suspend QP WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0] RSVD			
8	[63:0] RSVD			
16	[63:0] RSVD			
24	[63] WQE_Valid [62:42] RSVD [41:38] RSVD (AdditionalFragmentCount)		[37:32] OP [31:18] RSVD [17:0] QP_ID	
32	[63:0] RSVD			
40	[63:0] RSVD			
48	[63:0] RSVD			
56	[63:0] RSVD			

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

QP_ID (18 bits)

Index of the QP to be suspended.

11.5.3.23 Resume QP Descriptor Format

This WQE can be used to resume a QP that had been previous suspended in order to be moved to a different QS than the one to which it was assigned. QP suspension is required before changing the QS.

Table 11-56. CQP Resume QP WQE Format

Byte Offset	[Bit Range]	Field Name		
8	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:10]	RSVD	[9:0]	QS_Handle
24	[63] [62:42] [41:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:18] [17:0]	OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

QP_ID (18 bits)

Index of the QP to be suspended.

QS_Handle (10 bits)

This field specifies Tx-Scheduler QS handle associated with the TC for this QP. See Section 8.3.3.4 for more information on scheduler configuration. For VFs, the *QS_Handle* is checked to ensure that the VF issuing the CQP command is associated with the *QS_Handle*.

11.5.3.24 Static HMC Resources Allocated Descriptor Format

This WQE must be used after the commit FPM values operation is complete and all of the static HMC resources from Table 11-14 have HMC backing pages allocated and configured. CQP then completes initializing the function for PE operation.

Table 11-57. Static HMC Resources Allocated WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:42] [41:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

HMC_FCN_ID (6 bits)

This field specifies the HMC function ID that software has completed the allocation and configuration of the static HMC backing pages. For PFs, the *HMC_FCN_ID* is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the *HMC_FCN_ID* is determined by firmware.

11.5.3.25 Manage Statistics Instance Descriptor Format

Every function (PF or VF) is assigned a statistics instance. By default, all QPs in that function uses the one assigned to its function. However, software is able to allocate a new statistics instance that can be used for one or a set of QPs within the function. For example, all QPs belonging to a VSI.

This WQE is used to allocate or free a statistics instance. This WQE can be used only by the Physical PCI Function driver.

Table 11-58. Manage Statistics Instance WQE Format

Byte Offset	[Bit Range]	Field Name		
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59:42]	WQE_Valid alloc_stats_instance RSVD use_hmc_fcn_index RSVD	[41:38] [37:32] [31:7] [6:0]	RSVD (AdditionalFragmentCount) OP RSVD Statistics_Instance_Index
32	[63:0]	RSVD		
40	[63:6]	RSVD	[5:0]	hmc_fcn_index
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

alloc_stats_instance (1 bit)

Value	Description
0b	The statistics set is deallocated.
1b	A new statistics set is to be allocated. If successful, the number of the statistics set is returned in *Operation_Return_Value*.

use_hmc_fcn_index (1 bit)

Value	Description
0b	The HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation.
1b	*hmc_fcn_index* can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command.

Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0b) for VF CQP operations.

hmc_fcn_index (6 bits)

Only valid when issued to a PF CQP instance and *use_hmc_fcn_index* is set to 1b. Ignored otherwise.

Statistics_Instance_Index (7 bits)

Statistics Set to be deleted. Only valid when *alloc_stats_instance* is set to 0b.

11.5.3.26 Gather Statistics Descriptor Format

This WQE is used to gather the statistics for a function (PF or VF). This WQE can be used only by the Physical PCI Function driver.

Table 11-59. Gather Statistics Instance WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61] [60]	WQE_Valid RSVD Use_Statistics_Instance use_hmc_fcn_index	[59:38] [37:32] [31:7] [6:0]	RSVD (AdditionalFragmentCount) OP RSVD Statistics_Instance_Index
32	[63:0]	Physical_Buffer_Address		
40	[63:6]	RSVD	[5:0]	hmc_fcn_index
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

use_hmc_fcn_index (1 bit)

Value	Description
0b	The HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation.
1b	*hmc_fcn_index* can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command.

Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0) for VF CQP operations.

hmc_fcn_index (6 bits)

Only valid when issued to a PF CQP instance and *use_hmc_fcn_index* is set to 1b. Ignored otherwise.

Physical_Buffer_Address (64 bits)

This field specifies the physical address of the buffer that firmware fills with the statistics.

Use_Statistics_Instance (1 bit)

This field indicates if the default per Private Memory Function statistics are gathered or if one of the additional RDMA statistics instances are gathered for this QP.

Value	Description
0b	The default statistics are used.
1b	The statistics instance indicated by the *Statistics_Instance_Index* field are used.

Statistics_Instance_Index (7 bits)

Statistics Set to be gathered. This field is ignored if *Use_Statistics_Instance* is 0b.

Table 11-60. Statistics Buffer

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name

11.5.3.27 Manage Work Scheduler (WS) Node Descriptor Format

This WQE can be used to Create/Modify/Destroy a WS Node.

Software must create the root node (*Node_ID*=0) for its port. Intermediate or Leaf Nodes can be attached to the root node by specifying that the *Parent_Node_ID*=0 during the add operation.

For an Add operation of a Leaf node, the QSet handle is returned in the *Operation_Return_Value* if the operation is successful.

For a Modify operation, the only fields that can be modified are *Weight* and *enable_node*.

Table 11-61. CQP Create/Modify/Destroy Work Scheduler Node WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61] [60:59] [58:56] [55:52] [51:42]	WQE_Valid enable_node Node_Type Priority_Type Traffic_Class node_op RSVD	[41:38] [37:32] [31:26] [25:16] [15:10] [9:0]	RSVD (AdditionalFragmentCount) OP RSVD Parent_Node_ID RSVD Node_ID
32	[63:58] [57:48] [47] [46:44] [43]	RSVD VSI_Index RSVD failing_port RSVD	[42:40] [39] [38:32] [31:0]	failover_port RSVD Weight RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Node_Type (1 bit)

This field indicates if this is a Leaf Node (1b) or a Parent Node (0b). The following fields must be filled in for a Leaf Node: *Priority_Type*, *Traffic_Class*, *VSI_Index*, *Parent_Node_ID*, and *Weight*.

Priority_Type (2 bits)

This field specifies the priority type used for this node:

Value	Description
00b	Reserved
01b	Weighted Round-Robin
10b	Strict Priority
11b	Weighted Strict Priority

Traffic_Class (3 bits)

The port's traffic class represented by this node.

Parent_Node_ID (10 bits)

This field specifies where in the tree to place the new Node. That is, the new Node becomes the child of the node indicated in the *Parent_Node_ID* field. Node IDs are zero relative within a function. Software does not know what port it is on so a value of (0x0) means "this function's root node".

Node_ID (10 bits)

This is the Node ID that will be used to modify and delete the node. This value is assigned by software and must be unique. Software does not know what port it is on so a value of (0x0) means "this functions root node".

node_op (4 bits)

What operation to perform:

Value	Description
0x0	Add
0x1	Modify
0x2	Delete
0x3	failover_start
0x4	failover_complete
Note: All other values are reserved	

Only one failover can be active at a time.

VSI_Index (10 bits)

The VSI index for the WS node. This field is required for all manage work scheduler node operations.

Weight (7 bits)

Weight given to this node expressed as a percentage relative to it siblings. This value is valid only for Weighted Round-Robin and Weighted Strict Priority (zero is not valid).

enable_node (1 bit)

Value	Description
0b	The Work Scheduler node is disabled. This allows a Work Scheduler node to be created but not yet enabled. The node can be enabled/disabled later with the modify Work Scheduler operation.
1b	The Work Scheduler node is enabled.

This is only for leaf nodes. It is ignored for non-leaf nodes.

failing_port (3 bits)

If *node_op*=failover_start, the work scheduler node is being moved from this port. This field is ignored for any other *node_op* value.

failover_port (3 bits)

If *node_op*=failover_start, the work scheduler node is being moved to this port. This field is ignored for any other *node_op* value.

11.5.3.28 Set UP-UP Mapping

This WQE is used on a PF to set the User Priority (UP) mapping table for a VF. Only valid when issued to a PF CQP instance. Ignored otherwise.

Table 11-62. Set UP-UP Mapping WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:56] [55:48] [47:40] [39:32]	UP_mapping[7] UP_mapping[6] UP_mapping[5] UP_mapping[4]	[31:24] [23:16] [15:8] [7:0]	UP_mapping[3] UP_mapping[2] UP_mapping[1] UP_mapping[0]

48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

hmc_fcn_index (6 bits)

HMC index of the function for this mapping.

UP_mapping[7-0] (8 bits each)

User priorities indexed by the VF UP number.

use_CNP_UP_override (1 bit)

Value	Description
0b	Indicates that CNP packets are sent using the assigned UP.
1b	Indicates that Congestion Notification Packets (CNP) are sent using the UP value in *CNP_UP_override*.

use_VLAN (1 bit)

Value	Description
0b	The priority field is put into the TOS/DSCP field. Bits 0-5 of each byte are used to map the 64 DSCP priorities.
1b	The priority field is put into a VLAN. Bits 0-2 of each byte are used to map the priority.

11.5.3.29 Query RDMA Features

This WQE is used to query the RDMA features and the firmware version. Firmware returns the list of features up to *buffer_len*. Software is responsible for ensuring that the buffer is large enough.

The *feature_cnt* indicates the number of entries that firmware would return assuming the *buffer_len* is large enough. Software should allocate a reasonably-sized buffer. If needed, software can determine if the buffer is too small by looking at the returned *feature_cnt* field, allocate a larger buffer, and re-issue the WQE.

Table 11-63. Query RDMA Features Descriptor Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62:38]	WQE_Valid RSDV	[37:32] [31:0]	OP buffer_len
32	[63:0]	Physical_Buffer_Address		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6 bits) and WQE_Valid (1 bit)

See Section 11.5.3.1.

Physical_Buffer_Address (64 bits)

This field specifies the physical address of the buffer that firmware fills with the RDMA feature information. The buffer must be aligned to an 8-byte boundary.

buffer_len

Length of the buffer provided by software. The minimum length is 8 bytes and must be a multiple of 8 bytes.

Table 11-64. Query RDMA Features Buffer Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0-n	[63:48]	feature_type	[47:0]	feature specific information

feature_type

Enumerated value.

Table 11-65. Query RDMA Feature Types with Specific Information

Feature Type Number	Feature Type Name	Feature Specifics
0	RDMA_FTN_Header (Must always be the first entry in the table.)	[63:48] 0 [47:32] feature_cnt (minimum is 1) [31:16] firmware_major_version [15:0] firmware_minor_version
1	RDMA_FTN_HW_VERSION	[63:48] 1 [47:32] hw_model_used [31:16] hw_major_version [15:0] hw_minor_version
24	RDMA_FTN_ENDPT_TRK	[63:48] 24 [39:1] RSVD [0] 0b = Disabled. 1b = Enabled
26	RDMA_FTN_QSETS_MAX	[63:48] 26 [47:16] RSVD [15:0] qsets_max

hw_model_used (16 bits)

The lower value of the *hw_major_version* of the RNIC hardware and the *hw_major_version* supplied by software at Create CQP time.

hw_major_version, hw_major_version (16 bits each)

See CQP Context description in Section 11.5.2.3.

qsets_max (16 bits)

The maximum number of QSets supported. Each leaf node in the RDMA Work Scheduler refers to a QSet.

11.6 RDMA Functionality

The operations for RDMA via iWARP and RoCEv2 RC are implemented using the context and WQE formats described in the following sections. QP operation, the verbs interface, and system view of the E810 are described in Section 11.4.1. The CQP operations and HMC structures necessary to bring the E810 to a functional state for RDMA are described in Section 11.5.

The maximum number of PE contexts for the device is 256K. These contexts can be allocated in a flexible manner between the functions with a maximum number limit per each function of 256K - 1.

11.6.1 iWARP Q2 Area

iWARP QPs have a memory area that is written under error conditions. The format of this area is listed in Table 11-66. This memory area is reference from the *Q2_Address* variable from the QP context listed in Table 11-67.

Table 11-66. iWARP Q2 Structure Format

Byte Offset	[Bit Range] Field Name
0-55	Outbound_Terminate_Header
56-63	RSVD
64	[63] Sequence_Update_Toggle [62:32] RSVD [31:0] First_Partial_Sequence_Number
72-255	Inbound_Q2_Data

Outbound_Terminate_Header (56 bytes)

This field contains the outbound terminate header used for Modify QP CQP operations when *Terminate_Actions* is set to "Send Terminate Only" or "Send both Terminate and FIN".

First_Partial_Sequence_Number (32 bits)

This field contains the sequence number of the first partial FPDU receive by the E810. This field is defined for partial FPDU support only, and must be ignored during Asynchronous Event (AE) processing. See Section 11.4.3 for more details on partial FPDU support.

Sequence_Update_Toggle (1 bit)

This field toggles each time the *First_Partial_Sequence_Number* is updated by the E810. This field is defined for partial FPDU support only, and must be ignored during Asynchronous Event (AE) processing. See Section 11.4.3 for more details on partial FPDU support.

Inbound_Q2_Data (184 bytes)

This field contains the first 184 bytes of the packet that caused an AE. This could either be an inbound terminate message or the Ethernet packet that had an error.

11.6.2 iWARP QP Context Format

iWARP QP context is used by software to initialize or update the E810 QP context. Create and Modify QP CQP operations (see Section 11.5.3.2) reference this structure.

Table 11-67. iWARP QP Context Structure Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:62] [61:48] [47] [46:42] [41:32] [31] [30] [29] [28] [27:26] [25] [24:22] [21:20] [19]	iwarp_rdmap_ver[3] RSVD Push_Mode_Enable RSVD Push_Page_Index SQ_TPH_en RQ_TPH_en XMIT_TPH_en RCV_TPH_en RSVD DCTCP_enable RSVD pd_index_high err_RQ_index_valid[1]	[18:16] [15] [14] [13:12] [11:10] [9:8] [7] [6] [5] [4] [3] [2] [1:0]	dupack_thresh drop_out_of_order_seg ECN_enable limit RSVD RQ_WQE_Size timestamp RSVD Insert_VLAN_Tag NoNagle[2] IPv4 infiniband_read_en iwarp_ddp_ver[3]

224-248	[63:0]	RSVD		

1. *err_RQ_index_valid* and *err_RQ_index* are only valid on Modify QP to Terminate or Error.
2. This variable is a cached variable. See *Cached_Variables_Valid* in Modify QP operations for more details on cached context variables.
3. Only valid for iWARP QPs.

Push_Page_Index (10 bits)

This field identifies the push page associated with the QP. For VFs, the push page index is function-relative.

Push_Mode_Enable (1 bit)

This field indicates if push mode is enabled for the QP.

ignore_tcp_options (1 bit)

Specifies that the TCP options should be ignored when processing received TCP headers.

ignore_tcp_uns_options (1 bit)

Specifies that the unsupported TCP options should be ignored when processing received TCP headers.

NoNagle (1 bit)

This field indicates if Nagle algorithm is in use on this connection. If this field is set (1b), the Nagle algorithm is disabled on this connection (RFC 896).

PrivilegedEnable (1 bit)

This bit is used to enable privilege mode on STags.

Value	Description
0b	STag 0 is NOT allowed for a local STag, and an AEQE is generated with privilege error indicated.
1b	A local STag of zero (STag 0) is allowed on this connection, and the *TO* field should be treated as a physical address.

STag 0 is never allowed in an inbound RDMA packet.

FastRegisterEnable (1 bit)

This bit is used to enable fast register opcodes on privilege mode QPs.

Value	Description
0b	A fast register is NOT allowed for this connection, and an AEQE is generated with privilege error indicated.
1b	A fast register is allowed on this connection.

BindEnable (1 bit)

This bit is used to enable memory window bind operations on this QP.

Value	Description
0b	Memory window bind operations are NOT allowed on this connection, and an AEQE is generated with privilege error indicated.
1b	Memory window bind operations are allowed on this connection.

TimelyEnable (1 bit)

This bit enables the TIMELY congestion control algorithm.

Receive_Markers (1 bit)

This field specifies if we are to receive MPA markers in the receive stream.

Value	Description
0b	No markers are expected in the receive stream.
1b	Markers are expected every 512 bytes.

Send_Markers (1 bit)

This field specifies if generating MPA markers in the transmit stream.

Value	Description
0b	Markers are not included in the transmit stream.
1b	Markers are expected every 512 bytes.

rdmard_ok (1 bit)

Value	Description
0b	Inbound iWARP RDMA read requests are disabled, and an AEQE is generated.
1b	Inbound iWARP RDMA read requests are enabled.

rdmawr_rdresp_ok (1 bit)

Value	Description
0b	Inbound iWARP RDMA write requests and inbound RDMA read responses are disabled, and an AEQE is generated.
1b	Inbound iWARP RDMA write requests and inbound RDMA read responses are enabled.

timestamp (1 bit)

This field indicates if timestamp option is in use on this connection.

Value	Description
0b	The timestamp option is not present.
1b	The timestamp option is enabled on this connection (RFC 1323).

wscale (1 bit)

This field indicates if window scale option is in use on this connection.

Value	Description
0b	Windows are not scaled.
1b	The window scale option is enabled on this connection in both directions (RFC 1323). The window is scaled by the *snd_wscale* and *rcv_wscale* variables described later.

dupack_thresh (3 bits)

Specifies the number of dupacks received before starting fast retransmit (1-7). A value of 0 is remapped to a default value of 3.

err_RQ_index_valid (1 bit)

Indicates that the *err_RQ_index* is valid. This setting is allowed only for a Modify QP to Terminate or a Modify QP to Error operation.

err_RQ_index (15 bits)

Software uses *err_RQ_index* to override the index in the RQ during a FlushWQEs CQP operation. This is only valid if *err_RQ_index_valid* is on and it is a Modify QP to Terminate or Modify QP to Error operation.

drop_out_of_order_seg (1 bit)

Value	Description
0b	The out-of-order segment is processed.
1b	If a segment is received that is out-of-order, TRX drops the segment and sends an acknowledgment as required by TCP.

DCTCP_enable (1 bit)

Value	Description
0b	Data Center TCP is disabled.
1b	Data Center TCP is enabled and *ECN_enable* is ignored.

TimelyEnable, and *DCTCP_enable* are mutually exclusive. At most, only one can be set.

ECN_enable (1 bit)

Value	Description
0b	ECN functionality per RFC 3168 is disabled.
1b	The *TOS* field of the IPv4 header or *IP TC* field of the IPv6 header contains the ECN code point (bits 6 and 7 - least significant bits) and the code point in the *IP TC* or *TOS* context field must be set to 01b (normal) or code point 10b (optional).

XMIT_TPH_en (1 bit)

Value	Description
0b	THP is not used for data reads associated with this QP.
1b	TPH is enabled for data reads associated with this QP.

SQ_TPH_en (1 bit)

Value	Description
0b	THP is not used for this resource.
1b	TPH is enabled for the SQ of this QP.

SQ_TPH_value (8 bits)

If *SQ_TPH_en* is set (1b), TPH STag associated with SQ operations is initialized with *SQ_TPH_value*. If *SQ_TPH_en* is clear (0b), this field is ignored.

SQ_Size (4 bits)

This field encodes the maximum size for the WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for *SQ_Size*:

Value	Description
0001b	256 bytes
0010b	512 bytes
0011b	1024 bytes
0100b	2048 bytes
0101b	4096 bytes
0110b	8192 bytes
0111b	16384 bytes
1000b	32768 bytes
1001b	65536 bytes

Value	Description
1010b	131072 bytes
1011b	262144 bytes
1100b	524288 bytes
1101b	1048576 bytes
Note: All other values are reserved.	

Software can only allocate N-1 WQEs on the SQ. Each WQE is variable in size and can consume up to 256 bytes of memory. For more information see Section 11.4.1.5.2. The minimum size for an SQ is four WQEs of the maximum size that is used.

RCV_TPH_en (1 bit)

Value	Description
0b	THP is not used for data placement associated with this QP.
1b	TPH is enabled for data placement associated with this QP.

RQ_TPH_en (1 bit)

Value	Description
0b	THP is not used for this resource.
1b	TPH is enabled for the RQ of this QP.

RQ_TPH_value (8 bits)

If *RQ_TPH_en* is set (1b), TPH STag associated with RQ operations is initialized with *RQ_TPH_value*. If *RQ_TPH_en* is clear (0b), this field is ignored.

RQ_Size (4 bits)

This field encodes the maximum size for the WQ. The encoding of the RQ sizes are $4*2^{RQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for *RQ_Size*:

Value	Description
0001b	256 bytes
0010b	512 bytes
0011b	1024 bytes
0100b	2048 bytes
0101b	4096 bytes
0110b	8192 bytes
0111b	16384 bytes
1000b	32768 bytes
1001b	65536 bytes
1010b	131072 bytes
1011b	262144 bytes
1100b	524288 bytes

Value	Description
1101b	1048576 bytes
Note: All other values are reserved.	

The actual number or WQEs that can be posted to the RQ is the size of the WQ divided by the WQE size determined from *RQ_WQE_Size*. Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow. WQ overflow results in indeterministic behavior for the affected WQ. The minimum size for an RQ is eight WQEs.

RQ_WQE_Size (2 bits)

Specifies the number of 32-byte chunks of memory included with each RQ WQE. The maximum number of additional fragments allowed for an RQ WQE is 13 for a total of 14 fragments and a maximum WQE size of 256 bytes. Valid values are:

Value	Description
00b	32 bytes per WQE (no additional fragments)
01b	64 bytes per WQE (1 or 2 additional fragments)
10b	128 bytes per WQE (3 to 6 additional fragments)
11b	256 bytes per WQE (7 to 13 additional fragments)

Insert_VLAN_Tag (1 bit)

This bit is set to enable VLAN processing on a connection. The tag configured in the *VLAN_Tag* field is used for all processing. If this bit is clear (0b), there is no VLAN insertion or removal performed by the PE. Additional VLAN and priority setting can be configured through the VSI associated with the QP. The most significant portion of the VLAN tag carry the user-specified priority.

Value	Description
0b	Received packets destined for the QP with VLAN tags are sent to LAN queues.
1b	Received packets destined for the QP with mis-matched VLAN or no VLAN tag are sent to LAN queues.

IPv4 (1 bit)

This field indicates if the QP is IPv4 or IPv6.

Value	Description
0b	Indicates IPv6.
1b	Indicates IPv4.

infiniband_read_en (1 bit)

Value	Description
0b	Indicates that the RDMA Read operation is iWARP style.
1b	Indicates that the RDMA Read operation can do InfiniBand style reads.

iwarp_ddp_ver (2 bits)

These bits are used to set and check the DV fields of DDP PDUs for this connection.

iwarp_rdmap_ver (2 bits)

These bits are used to set and check the RV fields of RDMAP PDUs for this connection.

RxCmpQueueNum (19 bits)

This field specifies which of the 512K CQs is used for receive completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

TxCmpQueueNum (19 bits)

This field specifies which of the 512K CQs is used for transmit completion notification.The Rx and Tx completions can be mapped to the same CQ or different queues.

SQ_Address (64 bits)

If *Virtual_WQs* bit is clear (0b), this field holds SQ base physical address. It must be aligned to an address divisible by 256 bytes. If *Virtual_WQs* bit is set (1b), this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first *first_pm_pbl_index*).

RQ_Address (64 bits)

If *Virtual_WQs* bit is clear (0b), this field holds RQ base physical address. It must be aligned to an address divisible by 256 bytes. This is the RQ base pointer when this is an iWARP accelerated connection. If *Virtual_WQs* bit is set (1b) and the QP is not associated with a shared RQ, this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first *first_pm_pbl_index*).

Traffic_Class_or_TOS (8 bits)

This field specifies the IPv4 type of service bits (RFC 2474). If these bits represent the IPv4 TOS bits, only the lower 4-bits are valid. These bits are set by software when the connection is created and transmitted in the IP header of all sent datagrams for this connection.

rexmit_thresh (6 bits)

Specifies the number of re-transmissions on this connection that can occur before the AE_LLP_TOO_MANY_RETRIES AE is generated. A value of 0b disables generation of the AE and allows infinite retries.

err_RQ_index_valid (1 bit)

Indicates that the *err_RQ_index* is valid. This setting is allowed only for a Modify QP to Error operation.

err_RQ_index (15 bits)

Software uses *err_RQ_index* to override the index in the RQ during a Flush WQEs CQP operation. This is only valid if *err_RQ_index_valid* is set and it is a Modify QP to Error operation.

avoid_stretch_ack (1 bit)

Value	Description
0b	ACKs can be coalesced if the E810 is busy. In the E810, this works for all cases except when an immediate ACK needs to be generated, in which case the ACK sequence number can advance by more than 2*MSS segments.
1b	An ACK is generated ever 2*MSS sequence numbers from *cur_ack_seq_num* up to current *rcv_nxt* value.

This field is normally clear for iWARP connections.

QS_Handle (10 bits)

This field specifies Tx-Scheduler Queue Set handle associated with the TC for this QP. See Section 8.3.3.4 for more information on scheduler configuration. For VFs, the *QS_Handle* is checked to ensure that the VF issuing the CQP command is associated with the *QS_Handle*.

Exception_UDA_Queue (18 bits)

This field specifies UDA queue that receives partial iWARP FPDUs and TCP/IP packets with the URG bit set. The exception queue MUST use 32-byte RQ WQEs.

limit (2 bits)

This field specifies a limit value for the number of bytes that increase cwnd for each received acknowledgment (as per RFC3465). If an acknowledgment is for less than limit, *cwnd* is advanced by that number of bytes. Generally, this field should be set to 3 (11b) for iWARP connections; other values are for inter-operation with various TCP offload engines:

Value	Description
00b	*cwnd* updated by at most 1*SMSS bytes
01b	*cwnd* updated by at most 2*SMSS bytes.
10b	*cwnd* updated by at most 4*SMSS bytes (experimentation).
11b	*cwnd* updated by the number of bytes Acknowledged (experimentation).

if *limit* = 3 (*cwnd* += *ACK_SEQ* - *snd_una*)

else *cwnd* += min(*ACK_SEQ* - *snd_una*, SMSS<<*limit*)

Hop_Limit_or_TTL (8 bits)

This field specifies the IPv4 Time-To-Live (TTL) parameter in the IP header (RFC 791). It is initialized by software.

Dest_Port_Number (16 bits)

This field specifies the destination TCP port number for the TCP header (RFC 793).

Source_Port_Number (16 bits)

This field specifies the source TCP port number for the TCP header (RFC 793).

Dest_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b). The MSB of this field (Bits 31:24) is the first byte on the wire for this field.

Dest_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b).

Dest_IP_Address_2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b).

Dest_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The LSB of this field (Bits 7:0) is the last byte on the wire for this field. For IPv4 Addresses, the MSB (Bits 31:24) of this field is the first byte of the destination IP Address on the Ethernet wire.

Local_IP_Address_0 (32 bits)

This field specifies bits 127 through 96 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b). The MSB of this field (Bits 31:24) is the first byte on the wire for this field.

Local_IP_Address_1 (32 bits)

This field specifies bits 95 through 64 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b).

Local_IP_Address_2 (32 bits)

This field specifies bits 63 through 32 of the IPv6 IP Addresses. Reserved when *IPv4* is set (1b).

Local_IP_Address_3 (32 bits)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP Address. The LSB of this field (Bits 7:0) is the last byte on the wire for this field. For IPv4 Addresses, the MSB (Bits 31:24) of this field is the first byte of the destination IP Address on the Ethernet wire.

Src_MAC_Address[5-0] (8 bits each)

Specifies the MAC Address associated with the source IP Address. Index 0 is the LSB and byte 5 is the MSB.

snd_mss (14 bits)

Maximum segment size the sender is allowed to transmit. The E810 *snd_mss* is often set to values smaller than the maximum based on the capabilities of the fabric or connection partner. It can change based on the minimum of the *rcv_mss*, Path MTU or Ethernet MTU. This field needs to be set to a value less any TCP options. Rather than setting the value to 1460, if the *timestamp* option is enabled it would be set to 1448. If VLAN is enabled on this QP, subtract 4. The snd_mss value will be rounded down to the nearest multiple of 4.

ARP_Index (16 bits)

Index into the ARP cache to specify the Ethernet MAC Address to use for this connection. Initialized by software during connection establishment. Allows access to 65536 entry ARP table.

VLAN_Tag (16 bits)

Specifies one of the 4096 VLAN tags for this connection; three bits of priority and one bit canonical format. All bits are valid. The VLAN is in the lower 12 bits of the *VLAN_Tag* field. The upper three bits are priority.

TCP_state (4 bits)

Following are the state definitions (RFC 793):

Value	Description
0000b	NON EXISTENT (software state)
0001b	CLOSED
0010b	LISTEN (software state)
0011b	SYN_SENT (software state)
0100b	SYN_RECEIVED (software state)
0101b	ESTABLISHED
0110b	CLOSE_WAIT
0111b	FIN_WAIT_1
1000b	CLOSING (software state)
1001b	LAST_ACK (software state)
1010b	FIN_WAIT_2
1011b	TIME_WAIT (software state)
Note: All other values are reserved.	

Flow Label (20 bits)

This field specifies the IPv6 *Flow Label* field contents (RFC 2460). This field is set by software when a connection is offloaded and can be changed during operation.

pd_index (16 bits) and pd_index_high (2 bits)

Protection domain for this context. This specifies which one of the 256K iWARP protection domains this connection context belongs to. There are no reserved index values.

Snd_wscale (4 bits)

This field specifies the shift count used on the advertised window size received from the other end to obtain the real 32-bit Advertised Window Size (AWS). A value of 0 selects no window scaling. A value of 14 supports a maximum window of 1,073,725,440 bytes [(65536 x 16384) - 1) (RFC 1323]. Software initializes this field from the value supplied during connection establishment (such as SYN segment). Valid values are 0-14, supporting windows up to 1 GB -1. A value of 15 is rolled back to a value of 14.

Rcv_wscale (4 bits)

This field specifies the shift count used every time TCP sends a segment to determine the window size to report. The internal 32-bit window size is right shifted by this field to give the value to place in the TCP header. A value of 0 selects no window scaling. A value of 15 supports a maximum window of 1,073,725,440 bytes ((65536 x 16384) - 1) (RFC 1323). Software initializes this field from the value it supplied during connection establishment (like on the SYN segment) based on the receive buffer size. Valid values are 0-14, supporting a receive window up to 1 GB -1. A value of 15 is rolled back to a value of 14.

timestamp_recent (32 bits)

This field is updated when a segment arrives that includes the expected segment number (RFC 1323). This field is returned in the Echo Reply field of a timestamp.

timestamp_age (32 bits)

This field records the value from *tcp_now* (500 ms timer) the last time *ts_recent* was copied from a receive segment (RFC 1323). This field is required for TCP to perform PAWS.

snd_nxt (32 bits)

The next sequence number that TCP sends in a transmitted packet (RFC 793).

snd_wnd (32 bits)

This field specifies the senders Advertised Window Size (AWS). This field is the 16-bit receive window shifted by *snd_wscale* to come up with the AWS (RFC 793). This is a window our partner advertised that limits our transmit operations.

rcv_nxt (32 bits)

This is the next expected receive sequence number. It is also referred to as the left hand receive pointer (RFC 793).

rcv_wnd (32 bits)

This field specifies the receivers AWS. The AWS is flow control imposed by the receiver. This field is used to generate the 16-bit window size reported in the TCP header, shifted by the receive window scale (*rcv_wscale*). This is the value advertised to the sender (RFC 793).

snd_max (32 bits)

This sequence number points to the maximum send sequence number that has been transmitted. This field sets the upper bound of valid ACK when processing a re-transmission timeout (RFC 793). On connection offload this field is normally set to the same sequence number as *snd_nxt* unless a retransmission was in progress when the connection was offloaded.

snd_una (32 bits)

This sequence number points to the oldest unacknowledged sequence number for this connection (RFC 793).

srtt (32 bits)

This field is the smoothed round-trip time (rtt) << 3 (RFC 793 and RFC 2988) in microseconds. If this field is set to 0b on connection offload then the hardware calculates the value.

rtt_var (32 bits)

Round-trip variation (RTTVAR in RFC 2988) in microseconds. This field MUST never be set to 0b if *srtt* is also set to 0b. Make this a non-zero value if *srtt* is 0b.

ss_thresh (32 bits)

Slow start threshold (RFC 2581).

cwnd (32 bits)

This field is the sender congestion widow. It gets incremented by MSS when an ACK arrives. Software should initialize this field to 1b segment size (in bytes). If a duplicate ACK arrives, this is set to min (*cwnd*, *rcv_wnd*) but at least two segments. On a transport timeout this is set to 1b segment (RFC 2581).

snd_wl1 (32 bits)

Segment sequence number used for last send window update (RFC 793).

snd_wl2 (32 bits)

Segment acknowledgment used for last send window update (RFC 793).

max_snd_window (32 bits)

Indicates the largest send window advertised by the remote peer. Used in step 3 of the sender side SWS algorithm. If at least half of the largest window seen so far is available, send a segment.

Q2_Address (56 bits)

This field points to a buffer in host memory that is used to report a terminate message received on this QP. This pointer is the high 56 bits of the address. The low eight bits are implied as zero (thus the buffer is aligned on a 256-byte boundary). The field can be located at a fixed offset based on some other pointer (receive base pointer); it only points to a one entry queue to handle errors (terminate requests).

last_byte_sent (8 bits)

This is the last byte transmitted on the wire. It is only used during window probes. During modified iWARP only window probes, the E810 transmits the last acknowledged data byte on the wire. This corresponds to the last byte sent because a zero window condition is defined as all bytes acknowledged but no window to continue transmitting. Software should initialize it to the last byte sent before the connect was offloaded the connection to the hardware, so if a streaming mode message had been sent, it is the last byte sent of the last MPA message sent. If after a SYN/ACK handshake then initialize this field to 0b.

rcv_no_mpa_crc (1 bit)

This field specifies if we are to check MPA CRCs in the receive stream.

Value	Description
0b	All inbound FPDUs are checked by the E810.
1b	No MPA CRC checks are performed on FPDUs in the receive stream.

assume_aligned_headers (1 bit)

This field is set by software during connection setup if it knows the other adapter is a E810 that does not generate unaligned headers. This enables the E810 to place all segments that arrive if it passes basic header checks even if the packet was received out of order. Markers are not examined.

iWARP_Mode (1 bit)

This field sets the mode of operation when RQ empty conditions are encountered.

Value	Description
0b	The connection is placed in the terminate state and an AE is generated.
1b	The offending packet is dropped and the peer re-transmits the packet in the hope that the empty condition is resolved by the time the re-transmission occurs.

IRD_Size (3 bits)

This field specifies the number of inbound RDMA resources available for this connection (Q1). Valid settings are:

Value	Description
000b	4 WQEs
001b	16 WQEs
010b	64 WQEs
011b	128 WQEs
100b	256 WQEs
101b	Reserved (defaults to 4 WQEs)
110b	Reserved (defaults to 4 WQEs)
111b	Reserved (defaults to 4 WQEs)

When advertising resources to the other side, only half the queue is available. For example, if *IRD_Size* is set to 64 entries, the ORD size for the connection partner should be set to 32 or less.

ORD_Size (8 bits)

This field specifies the number of outbound RDMA resources available for this connection. Up to 255 outbound RDMA read requests are supported. This field is not encoded because a partner might support a different number of RDMA read requests than on transmit (such as 1, or 10, or 64, and so on).

snd_mrk_offset (9 bits)

This field specifies the offset to the MPA marker in the transmit stream of bytes. Subsequent markers are located every 512 bytes from this location. So modulo math can be used to place the markers in the transmitted byte stream. Software initializes this field upon connection setup.

rcv_mrk_offset (9 bits)

This field specifies the offset to the MPA marker in the receive stream of bytes. Subsequent markers are located every 512 bytes from this location. So modulo math can be used to extract the markers in the receive byte stream. Software initializes this field upon connection setup.

QP_Completion_Context (64 bits)

This field is reported in CQEs and also in AEQEs.

Use_Statistics_Instance (1 bit)

This field indicates if the default per Private Memory Function statistics are used or if one of the additional RDMA statistics instances are used for this QP.

Value	Description
0b	The default statistics are used.
1b	The statistics instance indicated by the *Statistics_Instance_Index* field are used.

Statistics_Instance_Index (7 bits)

This field specifies which of the additional RDMA statistics indexes are used if *Use_Statistics_Instance* is set to 1b. This field is ignored if *Use_Statistics_Instance* is set to 0b.

t_high (12 bits)

The high RTT threshold in microseconds for TIMELY. If the current RTT is higher than this threshold, the congestion window is multiplicatively decreased. If zero, the default value of 500 microseconds is used. This value applies only if *TimelyEnable* is set (1b).

t_low (8 bits)

The low RTT threshold in microseconds for TIMELY. If the current RTT is less than this threshold, the congestion window will be additively increased. If zero, the default value of 50 microseconds is used. This value applies only if *TimelyEnable* is set (1b).

syn_rst_handling (2 bits)

This field indicates how syns and resets are handled.

Value	Description
00b	Hardware uses RFC 5961 syn/rst handling.
01b	Hardware uses RFC 793 syn/rst handling.
10b	Hardware passes syn/rst to firmware which uses RFC 5961 syn/rst handling.
11b	Hardware passes syn/rst to firmware which uses RFC793 syn/rst handling.

remote_endpoint_index (16 bits)

Index in the local table of the remote endpoint. This field is only valid if the *remote_endpoint_trk_en* bit is set (see Section 11.5.2.3). This field is experimental.

RTOmin(7)

Provides a minimum floor for the TCP retransmission timeout value. This field is defined in 10 ms units and has a maximum value of 100, which equates to a 1 s min_rto. Any value greater than 100 and a value of 0 are treated as if a value of 100 was provided.

11.6.3 RoCEv2 QP Context Format

RoCEv2 QP context is used by software to initialize or update the E810 QP context. Create and Modify QP CQP operations (see Section 11.5.3.2) reference this structure for RoCEv2 QPs.

Table 11-68. RoCEv2 QP Context Structure Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:60] [59:48] [47] [46:42] [41:32] [31] [30] [29] [28] [27:26] [25] [24:22]	roce_tver RSVD Push_Mode_Enable RSVD Push_Page_Index SQ_TPH_en RQ_TPH_en XMIT_TPH_en RCV_TPH_en RSVD DCTCP_enable RSVD	[21:20] [19] [18:15] [14] [13:10] [9:8] [7] [6] [5] [4] [3] [2:0]	pd_index_high err_RQ_index_valid[1] RSVD ECN_enable RSVD RQ_WQE_Size RSVD is_QP1 Insert_VLAN_Tag RSVD IPv4 RSVD

- t_low (8 bits)
- remote_endpoint_index (16 bits)
-

roce_tver (4 bits)

The protocol engine uses this value when generating the BTH and compares this value to received BTH headers. The only valid value is 0.

p_key (16 bits)

This field is the Partition Key. It is required for RC and UD QPs.

q_key (32 bits)

This field is the Queue Key. It is used for UD flows. This value is used as the *q_key* if the value in the sending request has the most significant bit set.

ack_credits (5 bits)

This is used to set the initial encoded ACK credit syndrome field in ACKs issued by this node for this connection. The only value defined is 11111b, which disables participation in credit management for this connection on this node.

Dest_QPN (24 bits)

This field is the destination QP number. It is used for RC QPs.

psn_nxt (24 bits)

This field is the send packet sequence number. It is set to the initial psn value for the QP. It should be set to a random value.

epsn (24 bits)

This field is the expected incoming (receive) packet sequence number. It is required for RC connections. The Starting PSN is received in the REQ/REP headers during connection setup.

psn_una (24 bits)

This field is the PSN of the unacknowledged request. On QP create, it should be set to *psn_nxt*.

psn_max (24 bits)

This field is the high watermark of Tx requests. It should be set to the same value as *psn_nxt* at QP create time.

mtu (14 bits)

The maximum payload size. The only supported values are 256, 512, 1024, 2048,and 4096.

is_QP1 (1 bit)

Indicates that the QP is used for RoCEv2 Management Datagram (MAD) processing. This bit is not valid for RC connections. This bit is intended to be used for VMs (not PFs/VFs which have their own QP1).

UDPrivCQEnable (1 bit)

Indicates that the additional values, SMAC and VLAN, are in the UD completion. This bit is not valid for RC connections.

DCQCNEnable (1 bit)

Enables the DCQCN algorithm for RoCEv2. *DCQCNEnable*, *TimelyEnable*, and *DCTCP_enable* are mutually exclusive. At most, only one can be set. When this bit is set (1b), Data Center TCP is enabled and *ECN_enable* is ignored. *TimelyEnable*, and *DCTCP_enable* are mutually exclusive. At most, only one can be set.

rcv_no_icrc (1 bit)

This field specifies if whether to check ICRCs in the receive stream.

Value	Description
0b	All inbound ICRCs are checked.
1b	No ICRC checks are performed in the receive stream.

fw_cc_enable (1 bit)

When *fw_cc_enable* is set (1b), all Congestion Notification Packets (CNPs) are forwarded to firmware. Firmware handles the packet and updates the congestion window. When *fw_cc_enable* is set (1b), *DCQCNEnable* and *TimelyEnable* are ignored.

Src_MAC_Address[5-0] (8 bits each)

Specifies the MAC Address associated with the source IP Address. Index 0 is the LSB and byte 5 is the MSB.

cwnd (24 bits)

Initial congestion window in terms of packets.

lsn (24 bits)

Initial setting for the Limit Sequence Number (LSN). LSN limits the number of messages that can be outstanding at one time. Logically, LSN = MSN + credit count.

rexmit_thresh (6 bits)

Specifies the number of re-transmissions on this connection that can occur before the AE_LLP_TOO_MANY_RETRIES AE is generated. A value of 0b disables generation of the AE and allows infinite retries.

rnr_nak_thresh (3 bits)

Specifies the number of rnr_naks on this connection that can occur before the AE_LLP_TOO_MANY_RETRIES AE is generated. A value of 0 disables generation of the AE and allows infinite retries.

11.6.4 RDMA QP Completion Codes

RDMA QP errors are typically reported via AEs with the E810. After fielding the AEs, software might issue the flush WQES CQP operation (see Section 11.5.3.17) to complete any pending operations. Table 11-69 lists the completion codes reported by the E810 in a CQ entry (Table 11-67). Also note that host software can report any completion code necessary using the flush WQEs operation instead of the codes listed in Table 11-69.

Table 11-69. RDMA QP Error Codes

Major Error Code	Minor Error Code	Completion Reason	Description
0x0001	0x0001	WQE Flushed	The WQE has been flushed due to a ModifyQP state transition.

11.6.5 RDMA CQ Entry Formats

CQ operation for RDMA is described in Section 11.4.1.3. CQs are manipulated through CQP operations. See Section 11.5.3.3 for further details.

When *Avoid_Memory_Conflicts* is not set (0b), the CQE is normally 32 bytes. However, some completions require additional information. In this case, the *Extended_CQE* bit is set (1b) and an additional 32 bytes is added just for that CQE.

When *Avoid_Memory_Conflicts* is set (1b), the CQE is always 64 bytes. If the *Extended_CQE* bit is not set (0b), and the second half of the CQE is all zeros. If the *Extended_CQE* bit is set (1b), the second half of the CQE is described in Table 11-71.

Table 11-70. RDMA CQ Entry Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:32]	TCP_or_Packet_Sequence_Number_or_RTT	[31:0]	Payload_Length
8	[63:0]	QP_Completion_Context		
16	[63:50] [49:32]	RSVD QP_ID	[31:0]	Invalidated_STag_or_L/RKey
24	[63] [62] [61:56] [55] [54] [53] [52]	CQE_Valid SQ OP Error Solicited_Event (RDMA RQ only) STag_or_L/RKey (RDMA RQ only) RSVD	[51] [50] [49:47] [46:32] [31:16] [15:0]	Push_Dropped (RDMA SQ only) Extended_CQE RSVD WQ_Desc_Index Major_Error_Code Minor_Error_Code

Table 11-71. Extended CQ Entry Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
32	[63:56] [55:48] [47:40] [39:32]	Immediate_Data Byte[7] Immediate_Data Byte[6] Immediate_Data Byte[5] Immediate_Data Byte[4]	[31:24] [23:16] [15:8] [7:0]	Immediate_Data Byte[3] Immediate_Data Byte[2] Immediate_Data Byte[1] Immediate_Data Byte[0]
40	[63:0]	RSVD		

Table 11-71. Extended CQ Entry Format [continued]

Byte Offset	[Bit Range]	Field Name		
48	[63:0]	RSVD		
56	[63] [62] [61]	CQE_Valid2 Immediate_Data_valid UD_smac_valid	[60] [59:0]	UD_VLAN_Tag_valid RSVD

OP (6 bits)

This field reports the opcode from the operation associated with the CQE.

Extended_CQE (1 bit)

When the *Extended_CQE* bit is set (1b), the CQE is extended to 64 bytes. The second half of the CQE format is shown in Table 11-71. When the *Extended_CQE* is valid, software must ensure that the *CQE_Valid2* flag has the right polarity. If it is not valid, then the CQE is not complete and software cannot yet process the CQE.

WQ_Desc_Index (15 bits)

WQ is sliced up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. *WQ_Desc_Index* reports the 32-byte quanta index of the WQE associated with the completion.

CQE_Valid (1 bit)

The *CQE_Valid* bit for CQE indicates that a CQE is ready to be processed. The polarity of the *Valid* bit changes each time the CQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid CQE.

Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the E810 sets the Valid bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the E810 sets the valid bit to 0b when it writes an new CQE.

Error (1 bit)

Value	Description
0b	No error.
1b	An error occurred when processing the WQE associated with this CQE and that the *Error_Code* field is valid.

STag_or_L/RKey (1 bit)

Indicates if the *Invalidated_STag_or_L/RKey* field has valid contents.

Value	Description
0b	Ignore *Invalidated_STag_or_L/RKey*.
1b	An STag or L/RKey was invalidated and *Invalidated_STag_or_L/RKey* field is valid.

Solicited_Event (1 bit)

Valid for receive only. Value for SQ completions is undefined.

Value	Description
0b	SE bit not set in received packet.
1b	SE bit set in received packet.

SQ (1 bit)

Value	Description
0b	RQ
1b	SQ

Push_Dropped (1 bit)

Valid only when SQ is set.

Value	Description
0b	Push operations are being processed successfully.
1b	A recent push mode operation has been dropped by the E810. Software should refrain from submitting additional push mode operations until the SQ has encountered an empty condition.

Payload_Length (32 bits)

Total payload length of the completed message. This field is only valid for RQ WQE completions.

TCP_or_Packet_Sequence_Number_or_RTT (32 bits)

For iWARP, this field reports the TCP sequence number associated with the work request specified by the completion. For SQ-related CQEs, RTT is reported instead of the TCP Sequence number if the SQ WQE has the *ReportRTT* bit set.

For a RoCEv2 SQ completions, this field is the Packet Sequence Number or RTT.

QP_Completion_Context (64 bits)

Completion context pointer. This field is transferred to the CQE from QP context.

QP_ID (18 bits)

QP associated with the completed message.

Invalidated_Stag_or_L/RKey (32 bits)

Any STag or L/RKey that was invalidated by the completed message. Only valid if the *STag or L/RKey* bit is also set. If the *STag or L/RKey* bit is clear, *Invalidated_Stag or L/RKey* must be ignored. This is valid only for RC QPs.

Major_Error_Code (16 bits)

Valid if the *Error* is set (1b). See Table 11-69 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 11.5.3.17).

Minor_Error_Code (16 bits)

Valid if *Error* is set (1b). See Table 11-69 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 11.5.3.17).

The following items are in the extended CQE:

CQE_Valid2 (1 bit)

The *CQE_Valid2* bit must match the setting for a valid CQE in the CQ. Normally the value of the *CQE_Valid2* bit will be the same as the *CQE_Valid* bit in this completion. However, there is one case where it is different: if the completion starts in the last entry of the CQ, the second half of the CQE wraps to the start of the CQ so the *CQE_Valid2* bit flips to match the *CQE_Valid* setting for the next pass of the CQ.

Immediate_Data_valid (1 bit)

This bit indicates that immediate data was received.

Immediate_Data (8 bytes)

For iWARP, the *Immediate_Data* field is all eight bytes, which are in bytes 0-7 of the *Immediate_Data* field.

For RoCEv2, the *Immediate_Data* field is four bytes, which are in bytes 0-3 of the *Immediate_Data* field, and bytes 4-7 are ignored.

UD_smac_valid (1 bit)

Must be 0b for RC QPs. See Section 11.7.1.1 for a description of UD CQEs.

UD_VLAN_Tag_valid (1 bit)

Must be 0b for RC QPs. See Section 11.7.1.1 for a description of UD CQEs.

11.6.6 RDMA Descriptor Formats

11.6.6.1 RDMA SQ Descriptors

The following WQE formats are used in conjunction with RDMA QPs. Operations that are supported for RDMA QPs are the listed in Table 11-72.

Table 11-72. RDMA QP Operations

Operation Code	Operation Name	Section Reference
0x00	RDMA Write	11.6.6.1.5
0x01	RDMA Read	11.6.6.1.7
0x02	Reserved	N/A
0x03	Send	11.6.6.1.3
0x04	Send with Invalidate	
0x05	Send with Solicited Event	
0x06	Send with Solicited Event and Invalidate	
0x07	Reserved	N/A
0x08	Memory Window Bind	11.6.6.1.8
0x09	Fast Register Memory Region	11.6.6.1.10
0x0A	Local Invalidate STag	11.6.6.1.9
0x0B	RDMA Read with Local Invalidate	11.6.6.1.7
0x0C	NOP	11.6.6.1.2
0x0D	RDMA Write with Solicited Event	11.6.6.1.5
0x0E-0x2F	Reserved	N/A
0x30	Connection Established	11.6.6.1.11
0x31-0x3F	Reserved	N/A

11.6.6.1.1 Common RDMA SQ Descriptor Format Fields

The basic RDMA WQE is a 32-byte structure that is broken up into 64-bit (8-byte) words. The placement of these fields (when they apply) within WQE are common among all CQP WQEs and also RDMA WQEs.

Table 11-73 lists the basic structure of a QP WQE including the common fields. The definition of fields marked as "Operation Code Dependent" vary from operation-to-operation and are detailed in subsequent sections. Fields marked as "Reserved" must be set to 0b or undesired behavior related to the specific QP associated with the WQE might occur. Additionally, RDMA WQEs can optionally include additional descriptors to enable larger WQEs to be created. The additional descriptor format is listed in Table 11-74 and Table 11-2.

Table 11-73. RDMA Common WQE Fields

Byte Offset	[Bit Range] Field Name			
0	[63:0]	Operation Code Dependent		
8	[63:0]	Operation Code Dependent		
16	[63:0]	Operation Code Dependent		
24	[63]	WQE_Valid	[55:48]	Operation Code Dependent (Inline_Data Length)
	[62]	Signaled_Compeltion	[47]	Operation Code Dependent (Immed_Data_Flag)
	[61]	Local_Fence	[46]	Operation Code Dependent (ReportRTT)
	[60]	Read_Fence	[45:42]	RSVD
	[59]	Operation Code Dependent (wait_for_rcvFPDU)	[41:38]	AdditionalFragmentCount
	[58]	Operation Code Dependent (Streaming_Mode)	[37:32]	OP
	[57]	Operation Code Dependent (Inline_Data_Flag)	[31:0]	Operation Code Dependent
	[56]	Push_WQE		

OP (6 bits)

RDMA operation code. See Table 11-72 for the specific values.

WQE_Valid (1 bit)

The *WQE_Valid* bit for Work Queue Entries (WQE) indicates that a WQE is ready to be processed by the E810. The polarity of the *Valid* bit changes each time the WQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead associated with the need to clear a *Valid* bit and also to enable the E810 to read ahead in the WQ to reduce the need for doorbell rings. See Section 11.4.1.5.2 for more information on submitting work to a QP with the E810.

Software is responsible to clear (set to 0b) all memory in a WQ initially at QP creation. The first iteration (and subsequent odd numbered iterations) through the WQ, software sets the *Valid* bit to 1b when it writes a new WQE. For the second iteration (and all even numbered iterations) through the WQ, software sets the *Valid* bit to 0b when it writes an new WQE.

AdditionalFragmentCount (4 bits)

The maximum number of fragments is 14. In the WQE, the *AdditionalFragmentCount* specifies the number of additional fragment descriptors that are valid for this WQE. When there is no Immediate Data, the first fragment descriptor is in the first quanta, so the max for *AdditionalFragmentCount* is 13. When Immediate Data is present, it consumes the initial fragment, so the max *AdditionalFragmentCount* is 14.

Push_WQE (1 bit)

Indicates that the WQE was pushed to the push page associated with the QP. If this bit is set and the E810 dropped the push operation, the *Push_Dropped* bit is set in the next CQE following this WQE to indicate to software to stop pushing WQEs until an empty SQ condition has been observed. Using this rule prevents additional CPU and PCI bus bandwidth from being consumed when the Ethernet fabric is congested or the E810 is temporarily unable to process push mode operations.

Signaled_Completion (1 bit)

Value	Description
0b	Do not generate a CQE for this message unless there is an error associated with the WQE.
1b	Generate a CQE for this WQE. A CEQE might or might not be generated depending on the state of the CQ.

Local_Fence (1 bit)

This bit set (1b) signifies that the current WQE MUST NOT start until all prior SQ WQEs on the QP completed.

ReportRTT (1 bit)

This bit set (1b) indicates that RTT will be reported in the CQE instead of TCP or Packet Sequence Number. This is the latest SRTT (Smoothed Round Trip Time) according to RFC 6298.

Read_Fence (1 bit)

This bit set (1b) signifies that the current WQE MUST NOT start until any outstanding RDMA read requests on the SQ complete.

11.6.6.1.1.1 Fragment Descriptor Format

Table 11-74. RDMA Fragment Descriptor Format

Byte Offset	[Bit Range] Field Name			
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag

Tagged_Offset (64 bits)

The tagged offset (relative to the STag) associated with the data described by the additional fragment descriptor.

STag (32 bits)

STag associated with the data described by the additional fragment descriptor.

Fragment_Valid (1 bit)

Indicates the fragment is valid. A fragment is valid when this bit matches the *WQE_Valid* bit.

In the additional 32-byte descriptor quantas, when only one fragment is used it is still necessary to set the *Fragment_Valid* bit in both fragments. The second fragment in the 32-byte descriptor quanta will not be used since the *AdditionalFragmentCount* did not include it.

Fragment_Length (31 bits)

Length in bytes of the data described by the additional fragment descriptor.

11.6.6.1.1.2 Inline Data Format

Whether or not the WQE includes Immediate Data, the first eight bytes of Inline Data begin in the first fragment (offset 8 in the WQE). If the Inline Data exceeds eight bytes, the data continues in the next 32-byte descriptor quanta(s).

Table 11-75. Inline Data Format for the First 32-Byte Descriptor Quanta in a WQE

Byte Offset	[Bit Range]	Field Name
0	[63:0]	Immed_Data or RSVD
8	[63:0]	Inline_Data
16	[63:0]	Operation Dependent
24	[63:0]	Opcode, flags, and so on

The format of each additional 32-byte descriptor quanta follows:

Table 11-76. Inline Data Format for the Additional 32-Byte Descriptor Quanta(s) in a WQE

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Inline_Data		
8	[63:0]	Inline_Data		
16	[63:0]	Inline_Data		
24	[63] [62:56]	Inline_Valid RSVD	[55:0]	Inline_Data

The maximum inline data size is 224 bytes.

The *Inline_Valid* flag must be set in every 32-byte descriptor quanta that has inline data. The *Inline_Valid* flag must match the *WQE_Valid* flag.

11.6.6.1.2 SQ WQE Format - NOP

Table 11-77. RDMA SQ NOP WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59:57]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD	[56] [55:42] [41:38] [37:32] [31:0]	Push_WQE RSVD AdditionalFragmentCount OP RSVD

For the following field definitions, see Section 11.6.6.1.1.[1]

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)
- AdditionalFragmentCount (4 bits)[1]

OP (6 bits)

This WQE format is valid for the NOP operation. See Section 11.6.6.1.1 for the associated opcode values.

11.6.6.1.3 SQ WQE Format - Send

Table 11-78. RDMA SQ Send WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59] [58] [57] [56]	WQE_Valid Signaled_Completion Local_Fence Read_Fence wait_for_rcvFPDU Streaming_Mode Inline_Data_Flag Push_WQE	[55:48] [47] [46] [45:42] [41:38] [37:32] [31:0]	RSVD Immed_Data_Flag ReportRTT RSVD AdditionalFragmentCount OP Remote_Invalidate_STag

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)
- ReportRTT (1 bit)
- AdditionalFragmentCount (4 bits)

1. The *AdditionalFragmentCount* can be used instead of placing multiple individual NOPs.

OP (6 bits)

This WQE format is valid for the "Send", "Send with Invalidate", "Send with Solicited Event", and "Send with Solicited Event and Invalidate", as well as the versions of these operations that include inline data. See Section 11.6.6.1.1 for the associated opcode values.

Streaming_Mode (1 bit)

Indicates that this WQE contains data that is to be sent in streaming mode (normal TOE, not iWARP). The only valid OP value with this bit is "Send". The total length of the message must be less than or equal to MSS or an AE (AE_WQE_LSMM_TOO_LONG) is generated and the QP state is transitioned to terminate. This bit does not apply to RoCEv2.

wait_for_rcvFPDU (1 bit)

Only valid if *Streaming_Mode* is set to 1b. When this bit is set, the E810 does not process the WQE following this one until a valid inbound iWARP ULPDU is received. This is useful for the last WQE of the IETF response frame. This bit does not apply to RoCEv2.

Inline_Data_Flag (1 bit)

Set to 0b for no inline data.

Remote_Invalidate_STag (32 bits)

The STag on the remote peer that is to be invalidated by the message. This field is only valid if the operation type indicates an invalidate operations.

Tagged_Offset (64 bits), STag (32 bits), Fragment_Length (31 bits), Fragment_Valid (1 bit)

These fields describe the first fragment of the message to be sent. Additional fragments can be added to the WQE by setting *AdditionalFragmentCount* to a non-zero value.

Immed_Data_Flag (1 bit, RoCEv2 only)

When this bit is set (1b), indicates that immediate data is present. The WQE format is modified as follows:

The fragment at offset 0 will contain only the Immediate Data. The SGEs (if any) start in the first additional fragment.

Note: Immediate Data is not allowed for the invalidate operations ("Send with Invalidate" and "Send with Solicited and Invalidate"). For the invalidate operations, the *Immed_Data_Flag* is reserved and should be set to zero by software.

Table 11-79. Immediate Data Format (First Fragment at Offset 0)

Byte Offset	[Bit Range] Field Name			
0	[63:32] RSVD [31:24] Immediate_Data Byte[3] [23:16] Immediate_Data Byte[2]		[15:8] Immediate_Data Byte[1] [7:0] Immediate_Data Byte[0]	
8	[63:0] RSVD			

Immediate_Data (4 bytes, RoCEv2 only)

Byte 0 is the least significant byte of the data and byte 3 is the most significant. The data is specified in little endian format.

11.6.6.1.4 SQ WQE Format - Send with Inline Data

Table 11-80. RDMA SQ Send with Inline Data WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0]	Immediate_Data or RSVD		
8	[63:0]	Data		
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59:58] [57] [56]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD Inline_Data_Flag Push_WQE	[55:48] [47] [46] [45:38] [37:32] [31:0]	Inline_Data_Length Immed_Data_Flag ReportRTT RSVD OP Remote_Invalidate_STag

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- ReportRTT (1 bit)
- Push_WQE (1 bit)

OP (6 bits)

This WQE format is valid for the "Send", "Send with Invalidate", "Send with Solicited Event", and "Send with Solicited Event and Invalidate", as well as the versions of these operations that include inline data. See Section 11.6.6.1.1 for the associated opcode values.

Inline_Data_Flag (1 bit)

The *Inline_Data_Flag* must be set to 1b. This bit specifies that the data is contained inline with the WQE.

Value	Description
0b	The WQE is using descriptors and the WQE format is listed in Table 11-78.
1b	The WQE has inline data and the WQE format is listed in Table 11-80.

Inline_Data_Length (8 bits)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

Remote_Invalidate_STag (32 bits)

See Section Section 11.6.6.1.3.

Inline_Data

See Section 11.6.6.1.1.2.

Immed_Data_Flag (1 bit, RoCEv2 only)

The *Immed_Data_Flag* set to 1b indicates that immediate data is present.

Note: Immediate Data is not allowed for the invalidate operations ("Send with Invalidate" and "Send with Solicited and Invalidate"). For the invalidate operations, the *Immed_Data_Flag* is reserved and should be set to zero by software.

Immediate_Data (4 bytes)

See Section 11.6.6.1.3.

11.6.6.1.5 SQ WQE Format - RDMA Write

Table 11-81. RDMA SQ RDMA Write WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag
16	[63:0]	Remote_Taged_Offset		
24	[63] [62] [61] [60] [59:58] [57] [56]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD Inline_Data_Flag Push_WQE	[55:48] [47] [46] [45:42] [41:38] [37:32] [31:0]	RSVD Immed_Data_Flag ReportRTT RSVD AdditionalFragmentCount OP Remote_STag

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)
- ReportRTT (1 bit)
- AdditionalFragmentCount (4 bits)

OP (6 bits)

This WQE format is valid for the "Write", "Write with Solicited" opcodes. Write can be used with or without immediate data. Write with Solicited only makes sense if the *Immed_Data_Flag* is on (1b). If the *Immed_Data_Flag* is off (0b), it is the same as a Write. See Section 11.6.6.1.1 for the associated opcode values.

Tagged_Offset (64 bits), STag (32 bits), Fragment_Length (31 bits), Fragment_Valid (1 bit)

These fields describe the first fragment (data source) of the message to be sent. Additional fragments can be added to the WQE by setting *AdditionalFragmentCount* to a non-zero value.

Remote_Tagged_Offset (64 bits), Remote_STag (32 bits)

These fields describe the remote buffer (data sink).

Inline_Data_Flag (1 bit)

Set to 0b for no inline data.

Immed_Data_Flag (1 bit)

The *Immed_Data_Flag* set to 1b indicates that immediate data is present. The WQE format is modified as follows:

The fragment at offset 0 will contain only the Immediate Data. The SGEs (if any) start in the first additional fragment.

Table 11-82. Immediate Data Format (First Fragment at Offset 0)

Byte Offset	[Bit Range] Field Name			
0	[63:56] Immediate_Data Byte[7] [55:48] Immediate_Data Byte[6] [47:40] Immediate_Data Byte[5] [39:32] Immediate_Data Byte[4]		[31:24] Immediate_Data Byte[3] [23:16] Immediate_Data Byte[2] [15:8] Immediate_Data Byte[1] [7:0] Immediate_Data Byte[0]	
8	[63:0] RSVD			

Immediate_Data (8 bytes, iWARP only)

Byte 0 is the least significant byte of the data and byte 7 is the most significant. The data is specified in little endian format.)

Immediate_Data (4 bytes, RoCEv2 only)

Byte 0 is the least significant byte of the data and byte 3 is the most significant. The data is specified in little endian format. Bytes 4-7 are ignored.

11.6.6.1.6 SQ WQE Format - RDMA Write with Inline Data

Table 11-83. RDMA SQ RDMA Write with Inline Data WQE Format

Byte Offset	[Bit Range] Field Name			
0	[63:0] Immed_Data or RSVD			
8	[63:0] Data			
16	[63:0] Remote_Tagged_Offset			
24	[63] WQE_Valid [62] Signaled_Completion [61] Local_Fence [60] Read_Fence [59:58] RSVD [57] Inline_Data_Flag [56] Push_WQE		[55:48] Inline_Data_Length [47] Immed_Data_Flag [46] ReportRTT [45:38] RSVD [37:32] OP [31:0] Remote_STag	

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- ReportRTT (1 bit)
- Push_WQE (1 bit)

OP (6 bits)

See Section 11.6.6.1.1 for the associated opcode value.

Inline_Data_Flag (1 bit)

The *Inline_Data_Flag* must be set to 1b for inline data operations. This bit specifies that the data is contained inline with the WQE.

Value	Description
0b	The WQE is using descriptors and the WQE format is listed in Table 11-81.
1b	The WQE has inline data and the WQE format is listed in Table 11-83.

Inline_Data_Length (8 bits)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

Remote_Tagged_Offset (64 bits), Remote_STag (32 bits)

These fields describe the remote buffer (data sink).

Inline_Data

See Section 11.6.6.1.1.2.

Immed_Data_Flag (1 bit)

The *Immed_Data_Flag* set to 1b indicates that immediate data is present.

Immed_Data (8 bytes or 4 Bytes)

See Section 11.6.6.1.5.

11.6.6.1.7 SQ WQE Format - RDMA Read

RDMA Read now supports multiple SGEs for iWARP as well as RoCEv2. Read with local invalidate is expanded as well. If a Read with local invalidate is issued with multiple SGEs, only the first STag is invalidated.

Table 11-84. RDMA RDMA Read WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag
16	[63:0]	Remote_Tagged_Offset		
24	[63] [62] [61] [60] [59:58] [57] [56]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD RSVD (Inline_Data_Flag, must be 0) Push_WQE	[55:48] [47] [46] [45:42] [41:38] [37:32] [31:0]	RSVD RSVD (Immed_Data_Flag) ReportRTT RSVD AdditionalFragmentCount OP Remote_STag

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)
- ReportRTT (1 bit)

OP (6 bits)

This WQE format is valid for the RDMA read and RDMA read with local invalidate operations. See Section 11.6.6.1.1 for the associated opcode value.

Tagged_Offset (64 bits), STag (32 bits), Fragment_Length (31 bits), Fragment_Valid (1 bit)

These fields describe the local target (data sink) of the RDMA read operation. STag also specifies the local STag to be invalidated for RDMA read with local invalidate operations.

Remote_Tagged_Offset (64 bits), Remote_STag (32 bits)

These fields describe the remote buffer (data source).

If the *infiniband_read_en* bit is set in the iWARP context, this QP supports new semantics for RDMA Read. See Section 11.4.1.5.2.2.1 for a description of the capabilities.

AdditionalFragmentCount (4 bits)

See Section 11.6.6.1.1.

The *AdditionalFragmentCount* field is reserved for iWARP QPs if *infiniband_read_en* is off (0b).

11.6.6.1.8 SQ WQE Format - Memory Window Bind

Table 11-85. SQ Bind Memory Window WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Memory_Window_Base_VA		
8	[63:32]	Parent_Memory_Region_STag	[31:0]	Memory_Window_STag
16	[63:46]	RSVD	[45:0]	Memory_Window_Length
24	[63] [62] [61] [60] [59:57] [56] [55]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD Push_WQE RSVD	[54] [53] [52:48] [47] [46:38] [37:32] [31:0]	Memory_Window_Type VA_Based_TO Access_Rights RSVD (Immed_Data_Flag) RSVD OP RSVD

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)

OP (6 bits)

See Section 11.6.6.1.1 for the associated opcode value.

Memory_Window_Base_VA (64 bits)

This field specifies the starting point of the memory window within the parent memory region's virtual address range for the memory window.

Memory_Window_Length (46 bits)

This field specifies the size of the memory window. Specifying 0b as a length results in an AE code of AE_AMP_MWBIND_INVALID_BOUNDS for Type 2 Windows. Specifying 0b as a length results in an invalidate of a Type 1 Window.

Memory_Window_STag (32 bits)

This field specifies STag of the memory window including the index and additional keys.

If the Window is a Type 1 Window, the key value (STag/R_Key) must change. Software will change the random bits and/or the user key, but the index field must not change. Hardware uses the index to locate the MRTE and will change the key value. Since the index field does not change, the same MRTE continues to be used.

Memory_Window_Type (1 bit)

Value	Description
0b	The entry describes a Type 2B memory window.
1b	The entry describes a type 1 memory window.

Parent_Memory_Region STag (32 bits)

This field specifies STag of the parent memory region to which this memory window is bound including the index and additional keys.

VA_Based_TO (1 bit)

VA_Based_TO specifies if the memory window is zero-based or VA-based.

Value	Description
0b	The memory window is zero-based
1b	The memory window is VA-based

Access_Rights (5 bits)

Indicates the rights assigned to this STag. The valid bits for this field are:

Value	Description
00100b	Enable remote read.
01000b	Enable remote write
Note: All other values are reserved.	

11.6.6.1.9 SQ WQE Format - Local Invalidate

Table 11-86. Local Invalidate WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:32]	RSVD	[31:0]	STag
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59:57] [56]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD Push_WQE	[55:48] [47] [46:38] [37:32] [31:0]	RSVD RSVD (Immed_Data_Flag) RSVD OP RSVD

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)

OP (6 bits)

See Section 11.6.6.1.1 for the associated opcode value.

STag (32 bits)

STag specifies the STag to be invalidated.

11.6.6.1.10 SQ WQE Format - Fast Register

Fast register support for the E810 has two modes of operation that depend on the number of available PBL resources. The prerequisite for issuing a fast register operation is to allocate an invalid memory region with a specific number of page list entries (or PBLEs for the E810). Since the E810 allows host software to directly populate PBLs for memory registration, it is desirable to keep the same approach for fast register operations. The issue with allowing only the mode where host software directly populates the PBLs for fast register is apparent if an application issues fast register, send, local invalidate, fast register operations using the same memory region without waiting for completions for the local invalidate operation. If the E810 only allowed the mode where software directly populated PBLs for fast register operations in these cases, memory corruption would be highly likely to occur. Software mechanisms to resolve the races end up with extremely inefficient fast register operations if they could be made to work at all. To not penalize every application for the previous behaviors, but still provide proper handling of these behaviors, the following algorithm should be used for fast register operations:

1. During the allocate memory region operation, software must reserve the full number of PBL resources necessary to satisfy the allocate memory region request.
2. Software must keep a reference count per allocated memory region to track the number of outstanding fast register operations that are outstanding against the memory region that used the PBL resources allocated during the allocate memory region operation.
3. On fast register operation, if there are enough free PBL resources to satisfy the new request, software should populate a new area of PBLEs and issue the fast register operation without setting the *Copy_Host_PBLs* flag.
4. If there are not enough free PBL resources to satisfy the new request but the reference count of the users of the PBLs allocated during the allocate memory region operation is zero, software can use the PBL resources but must increment the reference count for the memory region.
5. If there are not enough free PBL resources to satisfy the new request but the reference count is one or more, host software must allocate a pinned buffer large enough to hold the page list specified on the fast register operation, populate that buffer with the page list specified by the fast register operation, and set the *Copy_Host_PBLs* bit and increment the reference count.
6. When the memory region associated with the fast register has been invalidated, the reference count for the memory region must be decremented.

This algorithm minimizes that cases where the page list associated with a fast register operation must be copied across the PCI bus while maintaining safe access to the memory region state and page list.

Table 11-87. SQ Fast Register WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Virtual_Address_or_First_Buffer_Offset		
8	[63:12]	PBL_Address	[11:0]	first_pm_pbl_index_high
16	[63:48] [47:46]	first_pm_pbl_index_low RSVD	[45:0]	STag_Length
24	[63] [62] [61] [60] [59:57] [56] [55:54] [53]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD Push_WQE RSVD VA_Based_TO	[52:48] [47:46] [45:44] [43] [42:38] [37:32] [31:8] [7:0]	Access_Rights Host_Page_Size Leaf_PBL_Size Copy_Host_PBLs RSVD OP Driver_Key_STag_Index Consumer_Key

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Local_Fence (1 bit)
- Read_Fence (1 bit)
- Push_WQE (1 bit)

OP (6 bits)

See Section 11.6.6.1.1 for the associated opcode value.

VA_Based_TO (1 bit)

VA_Based_TO specifies if the STag is zero-based or VA-based.

Value	Description
0b	The memory window is zero-based.
1b	The memory window is VA-based.

Zero-based STags carry only the first buffer offset in the *Virtual_Address_or_First_Buffer_Offset* field. VA-based STags carry the full base VA including first buffer offset in the *Virtual_Address_or_First_Buffer_Offset* field.

Virtual_Address_or_First_Buffer_Offset (64 bits)

Indicates the base VA for this region/window for VA-based entries and indicates the first buffer offset for zero-based entries.

STag_Length (46 bits)

Length of the memory region or memory windows specified by the STag index specified by *Driver_Key_Stag_Index*. Specifying 0 as a length results in an AE code of AE_AMP_FASTREG_INVALID_LENGTH. If *Leaf_PBL_Size* is set to 1b and *Host_Page_Size* = 0, AE_AMP_FASTREG_INVALD_LENGTH is also generated if the size exceeds 228 x 4096, or 2^7 host page sizes for VMs.

Access_Rights (5 bits)

Indicates the rights assigned to this STag. The values for this field are:

Value	Description
00001b	Enable local read.
00010b	Enable local write.
00100b	Enable remote read.
01000b	Enable remote write.
10000b	Enable window bind.
Note: All other values are reserved.	

Host_Page_Size (2 bits)

Host_Page_Size specifies the page size of the backing pages for the STag. The values for this field are:

Value	Description
00b	4 KB pages.
01b	2 MB pages.
10b	1 GB pages.
11b	Reserved.

Driver_Key_STag_Index (24 bits)

Index and *Driver Key* fields of the STag associated with the memory region. The E810 supports a variable size STag index. This means that the number of bits used for *Driver Key* and for *STag_Index* are dependent on the maximum number of STags supported for a given PCI function. For example, if a PCI function read the FPMPEMRSZ field (See Section 13.2.2.20.130) and found that the maximum number of MRTEs was 64 KB, the lower 16 bits of this field would be the STag index and the upper 8 bits would be a driver key that the driver can randomize to make guessing the MRTE layout more difficult to guess.

Consumer_Key (8 bits)

Consumer_Key is the least significant 8-bit portion of the STag. This field is supplied by the user application or the driver.

Copy_Host_PBLs (1 bit)

PBLs for an STag are located in host memory for the E810 in the pages allocated for the E810 HMC. In most situations, software copies backing pages for an STag directly to the HMC pages to optimize performance. If software needs the E810 to populate the HMC pages, *Copy_Host_PBLs* must be set to 1b and *PBL_Address* must point to the physical address of the backing pages in host memory.

Note: All PBLEs (root and leaf) must be allocated in chunks of eight.

Leaf_PBL_Size (2 bits)

The E810 supports physically-contiguous STags and two forms of virtually-contiguous STags. Physically-contiguous STags do not require any PBLs and store physical address of the first page of the STag directly with the STag (no leaf PBL). Virtually-contiguous STags that can be represented with a single HMC virtually contiguous address range require a single-level PBL of Variable size. Virtually-contiguous STags that are large (or in cases where the HMC address space for PBLs becomes fragmented) might require two level PBLs. In this case, the E810 needs to know the length of the leaf PBLs to properly manage access to the PBLs. The valid settings for *Leaf_PBL_Size* are the following:

Value	Description
00b	No leaf PBL.
01b	Variable (one level).
10b	256 bytes (two level).
11b	4 KB (two level).

PBL_Address (52 bits)

Only valid if *Copy_Host_PBLs* is set (1b) or if *Leaf_PBL_Size* is set to 0b. If *Copy_Host_PBLs* is set and *Leaf_PBL_Size* is not set to 0b, PBL address is the physical address of the PBLs in host memory if they were not copied to HMC pages by software. If *Leaf_PBL_Size* is 256 or 4 KB, PBL address contains the physical address of a packed array of Root PBLEs. The format of the Root PBLEs is listed in Table 11-88.

If *Leaf_PBL_Size* is variable, *PBL_Address* contains the physical address of the page list in host memory to be copied to *first_pm_pbl_index*. If *Copy_Host_PBLs* is clear and *Leaf_PBL_Size* is set to 0b, the physical address of the physically contiguous memory is contained in this field.

Table 11-88. Format of Root PBLEs in Host Memory for Two-Level PBLs

Byte Offset	[Bit Range] Field Name			
0	[63:0]	Leaf_PBL_Address		
8	[63:28]	RSVD	[27:0]	first_pm_pbl_index

first_pm_pbl_index (28 bits)

This field defines the HMC PBLE object index used for the memory region page list. If *Copy_Host_PBLs* is set (1b), the E810 copies the page list from the host address specified by *PBL_Address* to the HMC object specified by *first_pm_pbl_index*. If *Copy_Host_PBLs* is clear (0b), *first_pm_pbl_index* designates the HMC base address for the PBLs for this STag that software has already initialized with PBL information.

11.6.6.1.11 SQ WQE Format - Connection Established

Table 11-89. SQ Fast Register WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61:38]	WQE_Valid RSVD (Signaled_Completion) RSVD	[37:32] [31:0]	OP RSVD

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)

OP (6 bits)

This WQE tells the device to notify software when the connection is established. An AE (AE_LLP_CONNECTION_ESTABLISHED) informs software that the connection is complete. This WQE is not valid for RoCEv2 or UDA QPs. See Section 11.6.6.1.1 for the associated opcode value.

11.6.6.2 RQ WQE Format

Table 11-90. iWARP RQ WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag
16	[63:0]	RSVD		
24	[63] [62:42] [41:38]	WQE_Valid RSVD AdditionaFragmentCount	[37:32] [31:0]	RSVD (OP) RSVD

WQE_Valid (1 bit) and AdditionalFragmentCount (4 bits)

See Section 11.6.6.1.1.

Tagged_Offset (64 bits), STag (32 bits), Fragment_Length (31 bits), Fragment_Valid (1 bit)

These fields describe the first fragment of the byte stream to be sent. Additional fragments can be added to the WQE by setting AdditionalFragmentCount to a non-zero value.

11.7 UD/UDA Functionality

The operations for RoCEv2 UD and UDA are implemented using the WQE formats described in the following sections. QP operation, the verbs interface, and system view of the E810 are described in Section 11.4.1. The CQP operations and HMC structures necessary to bring the E810 to a functional state for RDMA are described in Section 11.5.

11.7.1 UD/UDA Descriptor Formats

11.7.1.1 UD/UDA CQ Entry Formats

CQ operation for RDMA is described in Section 11.4.1.3. CQs are manipulated through CQP operations. See Section 11.5.3.3 for further details.

For RQ completions, see Section 11.7.1.4 for a description of the received data.

When *Avoid_Memory_Conflicts* is not set (0b), the CQE is normally 32 bytes. However, some completions require additional information. In this case, the *Extended_CQE* bit is set (1b) and an additional 32 bytes is added just for that CQE.

When *Avoid_Memory_Conflicts* is set (1b), the CQE is always 64 bytes. If the *Extended_CQE* bit is not set (0b), the second half of the CQE is all zeros. If the *Extended_CQE* bit is set (1b), the second half of the CQE is described in Table 11-92.

Table 11-91. CQ Entry Format from UD/UDA QP

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:32]	Packet_Sequence_Number_or_RTT	[31:0]	Payload_Length
8	[63:0]	QP_Completion_Context		
16	[63:50] [49:32]	RSVD QP_ID	[31:24] [23:0]	RSVD UD_Src_QPN
24	[63] [62] [61:56] [55] [54] [53] [52]	CQE_Valid SQ OP Error Solicited_Event (RQ Only) IPv4 RSVD	[51] [50] [49:47] [46:32] [31:16] [15:0]	Push_Dropped (SQ Only) Extended_CQE RSVD WQ_Desc_Index Major_Error_Code Minor_Error_Code

Table 11-92. Extended CQ Entry Format from UD QP

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
32	[63:32] [31:24] [23:16]	RSVD Immediate_Data Byte[3] Immediate_Data Byte[2]	[15:8] [7:0]	Immediate_Data Byte[1] Immediate_Data Byte[0]
40	[63:0]	RSVD		
48	[63:48]	UD_VLAN_Tag	[47:0]	UD_smac
56	[63] [62] [61]	CQE_Valid2 Immediate_Data_valid UD_smac_valid	[60] [59:0]	UD_VLAN_Tag_valid RSVD

OP (6 bits)

This field reports the opcode from the operation associated with the CQE.

Extended_CQE (1 bit)

When the *Extended_CQE* bit is set (1b), the CQE is extended to 64 bytes. The second half of the CQE format is shown in Table 11-92. When the Extended_CQE is valid, software must ensure that the *CQE_Valid2* flag has the right polarity. If it is not valid, the CQE is not complete and software cannot yet process the CQE.

WQ_Desc_Index (15 bits)

WQ is sliced up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. *WQ_Desc_Index* reports the 32-byte quanta index of the WQE associated with the completion.

CQE_Valid (1 bit)

The *CQE_Valid* bit for CQE indicates that a CQE is ready to be processed. The polarity of the *Valid* bit changes each time the CQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid CQE. Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the E810 sets the *Valid* bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the E810 sets the *Valid* bit to 0b when it writes an new CQE.

Error (1 bit)

Value	Description
0b	No error.
1b	An error occurred when processing the WQE associated with this CQE and that the *Error_Code* field is valid.

Solicited_Event (1 bit)

Valid for receive only. Value for SQ completions is undefined.

Value	Description
0b	SE bit not set in received packet.
1b	SE bit set in received packet.

IPv4 (1 bit)

This field indicates that the message received was IPv4 or IPv6.

Value	Description
0b	IPv6
1b	IPv4

SQ (1 bit)

Value	Description
0b	RQ
1b	SQ

Push_Dropped (1 bit)

Valid only when SQ is set.

Value	Description
0b	Push operations are being processed successfully.
1b	A recent push mode operation has been dropped by the E810. Software should refrain from submitting additional push mode operations until the SQ has encountered an empty condition.

Payload_Length (32 bits)

Total payload length of the completed message. This field is only valid for RQ WQE completions. The length includes the 40 bytes for the IP header. For UDA QP, the length also includes the L4 header.

Packet_Sequence_Number_or_RTT (32 bits)

For a RoCEv2 SQ completions, this field is the Packet Sequence Number or RTT.

QP_Completion_Context (64 bits)

Completion context pointer. This field is transferred to the CQE from QP context.

QP_ID (18 bits)

QP associated with the completed message.

UD_Src_QPN (24 bits)

QP number of the sender. This is valid only for UD QPs.

Major_Error_Code (16 bits)

Valid if *Error* bit is set (1b). See Table 11-69 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 11.5.3.17).

Minor_Error_Code (16 bits)

Valid if *Error* bit is set (1b). See Table 11-69 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 11.5.3.17).

The following items are in the extended CQE:

CQE_Valid2 (1 bit)

The *CQE_Valid2* bit must match the setting for a valid CQE in the CQ. Normally the value of the *CQE_Valid2* bit will be the same as the *CQE_Valid* bit in this completion. However, there is one case where it is different: if the completion starts in the last entry of the CQ, the second half of the CQE wraps to the start of the CQ, so the *CQE_Valid2* bit flips to match the *CQE_Valid* setting for the next pass of the CQ.

Immediate_Data_valid (1 bit)

This bit indicates that immediate data was received.

For RoCEv2, the *Immediate_Data* field is four bytes, which are in bytes 0-3 the *Immediate_Data* field and bytes 4-7 are ignored.

UD_smac_valid (1 bit)

Indication that the MAC Address of the sender is valid. This is set only if the *UDPrivCQEnable* flag is set in the QP context.

UD_smac (48 bits)

The MAC Address of the sender. This is only set if *UD_smac_valid* is set.

UD_VLAN_Tag_valid (1 bit)

Indication that the *VLAN_Tag* field is valid. This value is set only if the *UDPrivCQEnable* flag is set in the QP context. Port VLAN must not be reported.

UD_VLAN_Tag (16 bits)

VLAN Tag of the sender. This value is set only if *UD_VLAN_Tag_valid* is set.

11.7.1.2 UD/UDA SQ Descriptors

The following WQE formats are used in conjunction with UD QPs. Operations that are supported for UD QPs are the listed in Table 11-93.

The NOP operation is unchanged (see Section 11.6.6.1.2).

Table 11-93. UD/UDA QP Operations

Operation Code	Operation Name	Section Reference
0x00-0x02	Reserved	N/A
0x03	Send	11.7.1.3.3
0x04	Reserved	N/A
0x05	Send with Solicited Event	11.7.1.3.3

Operation Code	Operation Name	Section Reference
0x06-0x0B	Reserved	N/A
0x0C	NOP	11.7.1.3.2
0x0D-0x3F	Reserved	N/A

11.7.1.3 UD/UDA SQ Descriptor Formats

11.7.1.3.1 Common UD/UDA SQ Descriptor Format Fields

The basic RDMA WQE is a 32-byte structure that is broken up into 64-bit (8-byte) words. The placement of these fields with WQE are common among all CQP WQEs, RDMA WQEs and also UD WQEs. Section 11.5.3.1 lists the basic structure of a CQP WQE, including the common fields.

The definition of fields marked as “Operation Code Dependent” vary from operation to operation and are detailed in subsequent sections. Fields marked as “Reserved” must be set to 0b or undesired behavior related to the specific QP associated with the WQE might occur.

Additionally, RDMA WQEs can optionally include additional fragments to enable larger WQEs to be created.

The only UD operation defined for the SQ is Send (immediate data and inline data are allowed).

11.7.1.3.2 UD/UDA SQ WQE Format - NOP

See Section 11.6.6.1.2.

11.7.1.3.3 UD/UDA SQ WQE Format - Send

For UDA queues, the first fragment must contain the TCP or UDP header. The payload can start in the first fragment after the header or it can begin in the second fragment.

Table 11-94. UD/UDA SQ Send WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Tagged_Offset		
8	[63] [62:32]	Fragment_Valid Fragment_Length	[31:0]	STag
16	[63:56] [55:32]	RSVD Dest_QPN	[31:0]	Dest_QKey
24	[63] [62] [61] [60:58] [57] [56] [55:48]	WQE_Valid Signaled_Completion UDP_Header RSVD Inline_Data_Flag Push_WQE RSVD	[47] [46] [45:42] [41:38] [37:32] [31:17] [16:0]	Immed_Data_Flag RSVD L4LEN AdditionalFragmentCount OP RSVD AH_ID

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Push_WQE (1 bit)
- AdditionalFragmentCount (4 bits)

OP (6 bits)

This WQE format is valid for the "Send" and "Send with Solicited Event" as well as the versions of these operations that include immediate data. See Section 11.7.1.2 for the associated opcode values.

Send with solicited and immediate data are not valid for UDA QPs.

Inline_Data_Flag (1 bit)

Set to 0b for no inline data.

Tagged_Offset (64 bits), STag (32 bits), Fragment_Length (31 bits), Fragment_Valid (1 bit)

These fields describe the first fragment of the message to be sent. Additional fragments can be added to the WQE by setting *AdditionalFragmentCount* to a non-zero value.

AH_ID (17 bits)

Index of Address Handle as allocated by software. This index together with HMC configuration for the PCI function identifies location of the hardware Address Handle structure in the host memory.

Dest_QPN (24 bits)

QP Number on the remote machine.

Dest_QKey (32 bits)

If the most significant bit is not set, this is an unprivileged Q_Key. The hardware will send this value for the destination Q_Key.

If the most significant bit is set, this is a privileged Q_Key so hardware will not use this value. Instead, hardware will send the Q_Key that is in the QP context.

Immed_Data_Flag (1 bit)

The *Immed_Data_Flag* set to 1b indicates that immediate data is present. The WQE format is modified as follows:

The fragment at offset 0 will contain only the Immediate Data. The SGEs (if any) start in the first additional fragment.

The Immed_Data_Flag is only valid for UD QPs, It is ignored for UDA queues.

UDP_Header (1 bit)

Value	Description
0b	Indicates that request is sent using TCP.
1b	Indicates that request is sent using UDP.

Software must supply the UDP/TCP header at beginning of the first fragment. The payload can start in the first fragment after the header or it can start in the second fragment.

The *UDP_Header* flag is valid only for UDA QPs. It is ignored for UD QPs.

L4LEN (4bits)

The L4 header length in DWords. It should be set to 8/12 for UDP, respectively, and be equal to or larger than 5 (or 20 bytes) for TCP.

The L4LEN field is valid only for UDA QPs. It is ignored for UD QPs.

Table 11-95. Immediate Data Format (First Fragment at Offset 0)

Byte Offset	[Bit Range] Field Name			
0	[63:32] RSVD [31:24] Immediate_Data Byte[3] [23:16] Immediate_Data Byte[2]		[15:8] Immediate_Data Byte[1] [7:0] Immediate_Data Byte[0]	
8	[63:0] RSVD			

Immediate_Data (4 bytes)

Byte 0 is the least significant byte of the data and byte 3 is the most significant. The data is specified in little endian format.

11.7.1.3.4 UD/UDA SQ WQE Format - Send with Inline Data

For UDA queues, the inline data must start with the TCP or UDP header. The payload starts after the header.

Table 11-96. UD/UDA SQ Send with Inline Data WQE Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:0]	Immediate_Data or RSVD		
8	[63:0]	Data		
16	[63:56] [55:32]	RSVD Dest_QPN	[31:0]	Dest_QKey
24	[63] [62] [61] [60:58] [57] [56] [55:48]	WQE_Valid Signaled_Completion UDP_Header RSVD Inline_Data_Flag Push_WQE Inline_Data_Length	[47] [46] [45:42] [41:38] [37:32] [31:17] [16:0]	Immed_Data_Flag ReportRTT L4LEN RSVD OP RSVD AH_ID

For the following field definitions, see Section 11.6.6.1.1.

- WQE_Valid (1 bit)
- Signaled_Completion (1 bit)
- Push_WQE (1 bit)

For the following field definitions, see Section 11.7.1.3.3.

- Dest_QPN (24 bits)
- Dest_QKey (32 bits)
- UDP_Header (1 bit)
- Immediate_Data (4 Bytes)
- Immed_Data_Flag (1 bit)
- L4LEN (4 bits)
- AH_ID (16 bits)
-

OP (6 bits)

This WQE format is valid for the send and send with solicited event. See Section 11.7.1.2 for the associated opcode values.

Send with solicited and immediate data are not valid for UDA QPs.

Inline_Data_Flag (1 bit)

The *Inline_Data_Flag* must be set to 1b. This bit specifies that the data is contained inline with the WQE.

Value	Description
0b	The WQE is using descriptors and the WQE format is listed in Table 11-78.
1b	The WQE has inline data and the WQE format is listed in Table 11-80.

Inline_Data_Length (8 bits)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

Inline_Data

See Section 11.6.6.1.1.2.

11.7.1.4 UD/UDA RQ Descriptors

The RQ descriptors are not changed. See Section 11.6.6.2 for details.

When a receive completion arrives, the first 40 bytes of the receive buffer contains the IP header of the incoming packet. If the packet was sent using IPv6, the IP header consumes the entire 40 bytes. If the packet was sent using IPv4, the IP header is placed in the second 20 bytes. That is, the IP header consumes bytes 20 through 39 of the receive buffer. The contents of the first 20 bytes is undefined.

For UDA only, in addition to the 40-byte IP header area, the L4 header is included in the receive buffer.

The form of the UD/UDA received buffer is:

- 40-byte area for the IP header (same for UD and UDA).
- UDA QP receive buffers have the L4 header (e.g. TCP or UDP header). This is not present for UD QP receive buffers.
- Payload

11.8 UDA Functionality

Userspace Direct Access (UDA) was intended to provide userspace access queues in a general way, but this feature is not supported in the E810. UDA is available only in the kernel and is limited to iWARP connection setup and error handling. UDA is not available in user space.

The UDA host interface and semantics are very similar to one exposed by RDMA.

- Sending and receiving data.
- Application uses UDA QPs and CQs to send and receive data, see Section 11.5.3.2 and Section 11.5.3.3 for UDA QP and CQ management requests. UDA QPs and CQs resources are shared with RDMA.
- Completion and AE management.
- CE notification mechanism is identical to one used for RDMA, see Section 11.5.3.11 and Section 11.5.3.12 for CEQ and AEQ allocation description. UDA can share event and completion notification structures with RDMA or have its own resources.
- Application buffer memory management.
- An application should register its buffers (see Section 11.5.3.4) to enable direct placement to and from application buffers. Memory registration used for UDA buffers is identical to the memory registration of RDMA, and uses resources from the same pool of memory regions available for PCI function.
- UDA enables send and receive Ethernet frames by posting frame payload and ULP protocol headers to UDA QP using post send and post receive operations described in Section 11.8.8.1 and Section 11.8.8.4. Separate SQ/RQ WQE is used to send and receive single Ethernet frame.

UDA provides a protocol agnostic interface with limited stateless accelerations for the well known protocols. To enable secure userspace networking for non-privileged consumers UDA limits scope of supported protocols to IP-based protocol only, by offloading Ethernet and IP header generation to hardware. Address Handles (see Section 11.5.3.13) are used to provide hardware with information required to generate Ethernet and IP headers.

Hardware provides partial stateless acceleration for the limited scope of protocols, discussed in Section 11.8.1 and Section 11.8.2 later.

UDA acceleration enables a wide scope of applications to take advantage of direct communication with hardware bypassing system overhead. UDA brings a variety of benefits, including deterministic and low latency, low-latency deviation and jitter, high-message processing rate with a very low network communication overhead, lock-free networking, and linear scalability with number of cores in the system without compromising system security.

11.8.1 Transmit UDA Hardware Acceleration

Transmit UDA hardware provides a limited number of partial stateless accelerations.

UDA traffic is not expected to use a dedicated internal switching resources (VSIs). It shares an internal switch virtual port with RDMA traffic. Depending on the assignment of the user priority, UDA traffic might share a QS with RDMA QPs, or use a dedicated QS. Assignment of UDA traffic to the QS is done at QP creation time, and is similar to assignment of RDMA QP.

The E810 generates Ethernet and IP headers based on information provided in address handle for IP-based userspace protocols (see Section 11.5.3.2). Offloading Ethernet and IP headers generation does not bring much performance improvement, but does improve security of UDA for IP-based protocols. In the standard deployment configuration, UDA supports only IP-based protocols, with an option available for the privileged software running in trusted environment allowing to generate all headers by software. Privileged mode can be enabled by setting *Privileged Header Generation Enable* bit in the UDA QP context, see Section 11.8.4.

The E810 supports header generation for non-fragmented datagrams. Hardware is responsible for the *IP Identification* field. Hardware maintains one instance of the *IP Identification* field per UDA QP.

Software is responsible for generating upper protocol headers (UDP/TCP, and so on). Those headers can be provided as a part of the payload WQE fragment or as a separate WQE fragment. In privileged mode, software can provide headers in the same WQE fragment with payload or using one or more dedicated WQE fragments. The E810 also supports an option of inline data, when both upper layer protocol headers and a frame payload are copied directly to the WQE (see Section 11.8.8.2 for more details). Push mode, described in Section 11.4.1.5.6, can be used to transmit UDA WQEs with inline data (see Section 11.8.8.2 for more details).

The E810 offloads checksum generation for non-fragmented UDP and TCP packets.

UDA traffic uses standard internal switching capabilities provided by the E810 to internally switch traffic between different VSIs. Unlike traffic generated by standard operating system stack, UDA QPs also require additional internal switching capabilities within VSI, similar to RDMA. This enables internal switching between userspace processes directly communicating with hardware using UDA QPs. This capability is enabled by setting a *DoLoopback* bit in the Address Handle corresponding to the destination residing on the same VSI. Physical Function device driver is responsible for allocation and management of Address Handles, also responsible for setting and clearing this bit in previously-allocated Address Handles. For the unicast traffic this bit is set to 1b, at Address Handle allocation time, and indicates that all UDA packets generated using this Address Handle are internally switched.

UDA and the host operating system networking stack independently generates the *IP Identification* field. To avoid collision of the IP identification space, the E810 has a configurable option to override *IP Identification* fields generated by the host networking stack and UDA and forces the MSB of the IP identification to different values. The *IP Identification* field override can be enabled per function using IPCONFIG.*USEENTIREIDRANGE* register/bit.

11.8.2 Receive UDA Hardware Filtering and Acceleration

Receive UDA acceleration is focusing on identifying UDA frames and delivering those frames to the associated UDA RQ. This section describes how UDA frames can be identified using various E810 filters, lists E810 filters that can be programmed for UDA traffic identification, and refers to the sections describing programming of each filter in details. UDA E810 filtering descriptions are organized by the traffic types.

11.8.2.1 UDP UDA Filtering and Acceleration

The E810 supports UDA acceleration of the UDP non-fragmented datagrams. Each VSI has a configuration bit that allows to enable UDA UDP acceleration for that VSI. Once enabled, UDP packets forwarded by the E810 internal switching fabric to the VSI are forwarded for the further filtering and processing by PE.

Figure 11-2 on page 1376 shows filtering steps that apply to all traffic types accelerated by Protocol Engine. Following is a description of each one of those steps applied to UDA UDP traffic.

Each VSI allows enabling of UDA UDP acceleration. When enabled, all UDP packets forwarded to such VSI are forwarded for the further processing by PE Filters associated with VSI. If UDA UDP is disabled, all packets forwarded to VSI are processed by LAN. The E810 uses internal switching forwarding tables to forward packets to VSIs.

UDP traffic is processed by UDA filters associated with PCI function that owns VSI (either VF or PF). If PE filters do not accept packet, the packet is forwarded to the LAN logic for further processing.

The Accelerated Port Table (see Section 11.5.3.18) is used by UDA in conjunction with other accelerated traffic types (iWARP) to filter inbound traffic based on the transport protocol destination port. UDA uses this table for UDP and TCP protocol filtering. When UDA QP expects to receive accelerated datagrams on the particular port (result of bind local port operation), UDA software should request to update the Accelerated Port Table (see Section 11.5.3.18). Since the Accelerated Port Table is shared by multiple PCI functions, false positive identification is possible. The Accelerated Port Table applies to filtering non-fragmented UDP datagrams only, or first fragments. Non-first fragments are not forwarded to the Protocol Engine.

If a UDP datagram is allowed by the Accelerated Port Table, it is filtered through perfect Hash Table (see Section 11.5.3.20). When UDA software binds to the local port, it should add a new entry to the Hash table belonging to the respective PCI function. Binding to the local port, software should add an entry to the Hash Table belonging to VF or PF respectively. Actual CQP request to update the Hash Table (see Section 11.5.3.20) should be done by PF driver only. This operation assumes communication between VF and PF UDA drivers.

The Hash Table is used to filter UDP datagrams belonging to the accelerated UDA QPs, and resolve QP for the UDP datagrams. The Hash filter uses different packet header fields to match Quad Hash table entries depending on the protocol type:

- Unfragmented UDP unicast datagrams are matched based on the destination MAC Address, innermost VLAN tag (if present), destination IP Address, and destination UDP port.
- Fragmented UDP packets are not forwarded to the Protocol Engine.

A packet forwarded to UDA QPs are placed to the application buffers provided in RQ WQEs. UDA places the entire Ethernet frame to the buffers provided by the application, except for L2 Tags that can be stripped depending on VSI configuration. See Section 11.8.8.4 for description of RQ WQE format.

A single Ethernet frame consumes one RQ WQE. RQ WQE should have enough buffering for the header and packet payload. The most inner VLAN Tag is provided in completion along with other information describing received packet. See Section 11.8.6.

If the size of the packet header or payload exceeds buffers provided by software, UDA RQ can be configured to:

- Truncate the packet, or the header, and report an error in corresponding Completion Queue Entry (CQE).
- Silently drop the packet, and do not consume the WQE even if packet/header placement is started. Effectively hardware should pretend that packet was never received and unroll the pointers.

If UDA RQ is empty (i.e., software is lagging behind and did not post RQ WQE in time), the inbound packet is dropped, and the GLPES_PFIP4RXDISCARD statistics counter is incremented. E810 RQs can be configured to a large number of WQEs that can be pre-posted by software, in addition to the internal chip buffers that can be flexibly configured to provide additional buffering space. These two factors should minimize chances of intermittent failures by software to pre-post receive descriptors in time.

In addition to filtering inbound accelerated UDP traffic to one or more UDA QPs, the E810 provides several hardware accelerations, described below.

- **Checksum validation for the non-fragmented UDP datagrams** — The E810 calculates and validates IP and UDP checksums for the non-fragmented UDP/IP datagrams. If the checksum does not match, the Ethernet frame is dropped and not delivered to UDA RQ.

11.8.2.2 TCP UDA Filtering and Acceleration

TCP UDA acceleration enables taking advantage of UDA QPs to send and receive unfragmented TCP segments directly from the application address space or from the kernel. iWARP connection management and exception handling is the usage model for this capability.

On the transmit side, TCP UDA acceleration can take advantage of the generic UDA acceleration capabilities described in Section 11.8.1.

This section describes receive filtering capabilities and hardware accelerations that can be used to accelerate TCP segments.

UDA TCP acceleration is enabled as soon as iWARP capabilities are enabled for the E810. Similar to iWARP, PCI function for the inbound TCP segments are identified using destination MAC Address.

UDA TCP acceleration does not support fragmented IP datagrams. All fragments are processed by stateless filters and delivered to the standard host stack.

UDA TCP acceleration uses an accelerated port table to filter out accelerated traffic based on the destination TCP port. Software should allocate a port to be used for UDA TCP accelerated traffic using the CQP operation described in Section 11.5.3.2.

TCP packets that hits an accelerated port table are filtered through the quad hash table.

The quad hash table is a perfect filter that carries an entry for each accelerated TCP connection that is offloaded to the E810's PE. The quad hash table has two kinds of entries used for TCP traffic.

- Quad-touple entries carrying and using as input to hash function a quad of source and destination IP Addresses and source and destination TCP ports.
- Du-touple entries carrying and using as an input to the hash functions a pair of destination IP Address and destination TCP port.

The du-entries are allocated to filter out connection establishment packets that are targeting accelerated connections. Those entries are used to filter out TCP packets with a *SYN* bit set and *ACK* bit clear.

The quad-touple entries are allocated to filter out packets targeting already established accelerated QPs.

The passive side connection establishment flow:

- Listen.
  - — Allocate du-touple entry with local IP Address and local port socket is bound to.
- SYN is received on QP associated with du-touple.
  - — Allocate quad-touple entry with local/remote IP Addresses and local/remote TCP ports.
  - — Send SYN-ACK.
- ACK is received on the QP associated with quad-touple.

The active side connection establishment flow:

- Connect.
  - — Allocate quad-touple entry with local/remote IP Addresses and local/remote TCP ports.

  - — Allocate quad-touple entry with local/remote IP Addresses and local/remote TCP ports.
  - — Send SYN.
- SYN-ACK is received on QP associated with quad-touple.
  - — Send ACK.

UDA TCP uses the quad hash table in the same way this table is used for iWARP traffic. A hit in the table resolves a number of destination QPs. The E810 uses information in QP context to identify iWARP and UDA TCP traffic. If a packet misses the quad hash table, it is forwarded for the further processing to the stateless filters.

TCP UDA software should program the quad hash table with du-touple entry to establish UDA accelerated TCP connection (such as listen or connect socket calls) and to add a quad-touple entry once connection has been established. To avoid race and loss of data, the quad-touple entry can be allocated before the connection establishment handshake completed.

The E810 does not terminate TCP connections for UDA traffic. It forwards identified UDA TCP segments to the corresponding RQ. Multiple TCP tuples can be configured to be delivered to the same RQ. Each WQE in UDA TCP RQ is consumed by single TCP segment.

In addition to forwarding UDA TCP segments, the E810 provides several hardware accelerations.

- **TCP checksum calculation and validation** — The E810 supports calculation and validation of TCP checksum for UDA TCP segments. TCP packets with invalid a checksum is dropped and not delivered to RQ.

11.8.3 UDA Programming Interface

The UDA programming interface is based on the verb semantics described in Section 11.4.1. It uses same basic constructs as RDMA: QP, CQ, CEQ, AEQ and memory regions. Those constructs are described in detail in Section 11.4.1. In addition to those constructs, UDA uses address handles described later in this section.

11.8.3.1 CEQ

CEQ construct enables hardware to provide software with asynchronous completion notifications. Application has a full control over requesting asynchronous completion event for the particular CQ. UDA uses CEQ construct defined for RDMA, described in Section 11.4.1.2.

CEQs are allocated per MSI-X vector per PCI function, and if UDA and RDMA applications are deployed by the same PCI functions or the same application uses both types of traffic, it shares the same CEQ. Each entry in CEQ indicates that a requested CE was received by specified CQ and the application should poll CQ and retrieve completion of transmit or receive operation.

11.8.3.2 AEQ

AEQ construct enables hardware to report AE and error notifications. UDA uses AEQ defined for RDMA, described in Section 11.4.1.1. AEQ is allocated per PCI function and shared by iWARP and UDA if application(s) using both types of traffic are deployed in the same PCI function.

11.8.3.3 CQ

CQ is a construct that enables an application to receive notification about completed transmit and receive operations directly in the application address space. UDA uses CQ construct defined for RDMA, described in Section 11.4.1.3. CQ is associated with RQ and SQ to report completion of transmit and receive operations. The same CQ can be configured to report completion of transmit and receive operations on the same and different QPs. Application is allowed to use same CQ to report completion of UDA and RDMA traffic.

CQ entry indicates what operation has been completed, and depending on the completed operation, it carries additional information. The format of a UDA CQ entry is described in Section 11.8.5. Among other fields, CQ entry carries a 64-bit pointer to the QP completion information. This field can be used to identify a QP that posted completed operation.

Completion of receive operation is always reported in associated CQ. Completion of transmit operation is not necessarily reported and the application can control whether it wants to be notified about a completed transmit operation. Application MUST request completion of transmit operation at least once per SQ size worth of transmit requests.

11.8.3.4 QP

QP is a construct that enables an application to post transmit and receive operations directly from the application address space. QP consists of the pair of queues: SQ and RQ. UDA uses QP construct defined for RDMA, described in Section 11.4.1.5.

Unlike iWARP QP, UDA QP does not have to be associated with any particular connection or connection oriented service and enables mixing of various ULPs such as UDP and TCP on the same QP.

Userspace QP is associated with a particular local IP Address. Non-privileged UDA consumers need to allocate multiple UDA QPs to send UDA packets using different local IP Addresses. Local IP Address in QP context is used for UDA IP header generation only. E810 filters can be configured to receive packets targeting different local IP Addresses on the same QP.

Software should use WQEs described in Section 11.8.6 to post new transmit and receive work to the UDA QP.

UDA QP is associated with a particular TC, and VLAN. If the application needs to use multiple TCs and VLANs, it must create multiple QPs and spread traffic, respectively.

All software errors such as invalid WQE format, invalid STag and memory region boundary violation are considered to be critical errors and result in a transition of QP to the error state and immediately suspend transmit and receive operations of that QP. Respective AE would be reported via AEQ associated with QP (see Section 11.4.7).

11.8.3.5 Send Operation

The process of posting WRs to UDA SQ and flow is similar to one described for RDMA SQs in Section 11.4.1.5.2.

UDA QP enables the application to transmit individual Ethernet frames per posted SQ WQE. Each transmit WQE must refer to a single Ethernet frame. Software is responsible to limit the frame size to the configured MSS. If frame size exceeds MSS, frame would be discarded and error reported in CQE.

Software is allowed to post Ethernet frames shorter than a minimum Ethernet frame length. Hardware pads Ethernet frames to the minimal Ethernet frame length.

Hardware is responsible for Ethernet FCS and IP checksum generation. Software might request hardware to generate TCP/UDP checksum for non-fragmented datagrams.

In default operation mode, Ethernet and IP headers are generated by hardware using information provided in the address handle. Software can provide additional ULP header (e.g. UDP) either as a part of the application buffer referred by SQ WQE fragments or using a private header ring buffer (if enabled for the QP). If the size of the extended header exceeds the size of the private header ring buffer entry, the packet is discarded and the error is reported in CQE.

Privileged consumers are allowed to post Ethernet frames with all headers. To enable privileged SQ operation mode, the *Privileged Header Generation* bit should be set at QP creation (see Section 11.8.4).

Software can selectively request completion of WQEs by setting the *Signaled* bit. Completions with errors are returned regardless of the Signaled bit setting. UDA WQE is completed as soon as hardware finished processing WQE and validated lengths and fragments. Completion of UDA SQ WQE does not indicate that respective Ethernet frames are transmitted or received by the destination.

11.8.3.6 Receive Operation

The structure of RQ is a process of posting WRs to UDA RQ and flow is similar to one described for RDMA RQs in Section 11.4.1.5.8.

UDA QP enables an application to receive an individual Ethernet frame in pre-posted RQ WQEs. Each inbound Ethernet frame consumes one RQ WQE. Software needs to make sure that buffers posted to RQ WQE are large enough. If the size of the Ethernet frame exceeds the size of RQ WQE, the frame is truncated and an error is reported in CQE.

Ethernet frames failing CRC or checksum checks (IP/UDP/TCP) are dropped and not delivered to UDA QPs.

If an Ethernet frame is received while UDA RQ is empty, such frame is dropped and the GLPES_PFIP4RXDISCARD statistics counter is incremented.

RQ completion is delivered with each completed RQ WQE. If a packet carries one or more VLAN tags, the most inner VLAN tag is reported by RQ CQE. Note that VLAN tag is not stripped from the packet header.

11.8.3.7 Memory Registration

Memory region is a construct that enables hardware to access data directly from the application buffers. To enable direct hardware access, an application must register application buffers using the register memory region operation. UDA uses memory regions defined for RDMA described in Section 11.4.1.4.

Memory region construct is not associated with any particular traffic type, and registered memory region can be accessed both by RDMA and UDA traffic. This enables an application to have the same application buffer be directly accessed by iWARP and UDA traffic. For example, UDP data received via one of UDA QPs can be then accessed via RDMA QP without requiring copy operation.

UDA application must register application buffers to be used to send and receive UDA packets.

UDA supports only basic memory registration capabilities and does not support fast memory registration, bind and invalidate operations.

11.8.3.8 Address Handle

Address Handle is a construct that used solely by UD and UDA traffic. Address Handle allows protected generation of Ethernet and IP Headers for the UDA traffic. Application has to allocate Address Handle using CQP command described in Section 11.5.3.13 prior to posting data to transmit. Content of Address Handle is validated by driver. Allocated Address Handle is referred in transmit descriptors, and used by hardware to generate Ethernet and IP Headers.

Address Handle can be allocated by VF or PF driver. Standard anti-spoofing capabilities of the E810 internal switch applies to UDA traffic as well.

11.8.3.9 Push Mode Support

Push mode enables software to reduce processing latency of the short messages by pushing corresponding WQE with inline data to the memory-mapped adapter address space. Pushed WQE with inline data can be immediately processed by the adapter and transmitted to eliminate the need to read WQE and data from the host memory. See Section 11.4.1.5.6 for a detailed description of push mode concept and constructs.

UDA QPs take advantage of push mode defined for RDMA. Software can use push mode WQEs, described in Section 11.4.1.5.6 to reduce processing latency of the short UDA messages. Similar to RDMA, the size of the UDA push mode message is limited to 224 bytes. The UDA push mode message cannot use private ULP header buffers and the entire message with ULP headers must fit the push mode message size restrictions and posted as inline data. The remainder of push mode message software processing flow is identical to one described for RDMA messages in Section 11.4.1.5.6.

11.8.4 UDA QP Context Format

UDA QP context is used by software to initialize or update the E810's QP context. Create and Modify QP CQP operations (see Section 11.5.3.2) reference this structure.

Userspace QP is associated with a particular local IP Address. Non-privileged UDA consumers need to allocate multiple UDA QPs to send UDA packets using different local IP Addresses. The local IP Address in QP context is used for UDA IP header generation only. The E810 filters can be configured to receive packets targeting different local IP Addresses on the same QP.

Table 11-97. UDA QP Context Structure Format

Byte Offset	[Bit Range] Field Name

1. This variable is a cached variable. For more details on cached context variables, see *Cached_Variables_Valid* in Modify QP operations (Section 11.5.3.2).
2. Only Valid for iWARP QPs.

PrivilegedEnable (1 bit)

This bit is used to enable privilege mode on STags.

Value	Description
0b	STag 0 is NOT allowed for a local STag, and an AEQE is generated with a privilege error indicated.
1b	A local STag of zero (STag 0) is allowed on this connection, and the TO field should be treated as a physical address.

XMIT_TPH_en (1 bit)

Value	Description
0b	THP is not used for data reads associated with this QP.
1b	TPH is enabled for data reads associated with this QP.

SQ_TPH_en (1 bit)

Value	Description
0b	THP is not used for this resource.
1b	TPH is enabled for the SQ of this QP.

SQ_TPH_value (8 bits)

If *SQ_TPH_en* is set (1b), TPH STag associated with SQ operations is initialized with *SQ_TPH_value*. If *SQ_TPH_en* is clear (0b), this field is ignored.

SQ_Size (4 bits)

This field encodes the maximum size for the WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for *SQ_Size*:

Value	Description
0001b	256 bytes
0010b	512 bytes
0011b	1024 bytes
0100b	2048 bytes
0101b	4096 bytes
0110b	8192 bytes
0111b	16384 bytes
1000b	32768 bytes
1001b	65536 bytes
1010b	131072 bytes
1011b	262144 bytes
1100b	524288 bytes
1101b	1048576 bytes
Note: All other values are reserved.	

Software can only allocate N-1 WQEs on the SQ, where N is a SQ size previously defined. Each WQE is variable in size and can consume up to 256 bytes of memory. For more information see Section 11.4.1.5.2. The minimum size for an SQ is four WQEs of the maximum size that is used.

RCV_TPH_en (1 bit)

Value	Description
0b	THP is not used for data placement associated with this QP.
1b	TPH is enabled for data placement associated with this QP.

RQ_TPH_en (1 bit)

Value	Description
0b	THP is not used for this resource.
1b	TPH is enabled for the RQ of this QP.

RQ_TPH_value (8 bits)

If *RQ_TPH_en* is set (1b), TPH STag associated with RQ operations is initialized with *RQ_TPH_value*. If *RQ_TPH_en* is clear (0b), this field is ignored.

RQ_Size (4 bits)

This field encodes the maximum size for the WQ. The encoding of the RQ sizes are $4*2^{RQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for *RQ_Size*:

Value	Description
0001b	256 bytes
0010b	512 bytes
0011b	1024 bytes
0100b	2048 bytes
0101b	4096 bytes
0110b	8192 bytes
0111b	16384 bytes
1000b	32768 bytes
1001b	65536 bytes
1010b	131072 bytes
1011b	262144 bytes
1100b	524288 bytes
1101b	1048576 bytes
Note: All other values are reserved.	

The actual number or WQEs that can be posted to the RQ is the size of the WQ divided by the WQE size determined from *RQ_WQE_Size*. Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow, where N is an RQ size previously defined. WQ overflow results in indeterministic behavior for the affected WQ. The minimum size for an RQ is four WQEs.

RQ_WQE_Size (2 bits)

Specifies the number of 32-byte chunks of memory included with each RQ WQE. The maximum number of additional fragments allowed for an RQ WQE is 13 for a total of 14 fragments and a maximum WQE size of 256 bytes. Valid values are:

Value	Description
00b	32 bytes per WQE (no additional fragments)
01b	64 bytes per WQE (1 or 2 additional fragments)
10b	128 bytes per WQE (3 to 6 additional fragments)
11b	256 bytes per WQE (7 to 13 additional fragments)

RxCmpQueueNum (19 bits)

This field specifies which of the 512K CQs is used for receive completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

TxCmpQueueNum (19 bits)

This field specifies which of the 512K CQs is used for transmit completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

SQ_Address (64 bits)

If *Virtual_WQs* bit is clear (0b), this field holds SQ base physical address. It must be aligned to an address divisible by 256 bytes. If *Virtual_WQs* bit is set (1b), this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first *first_pm_pbl_index*).

RQ_Address (64 bits)

If *Virtual_WQs* bit is clear (0b), this field holds RQ base physical address. It must be aligned to an address divisible by 256 bytes. This is the RQ base pointer when this is an RDMA accelerated connection. If *Virtual_WQs* bit is set (1b), this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first *first_pm_pbl_index*).

QS_Handle (10 bits)

This field specifies Tx-Scheduler queue set handle associated with the TC for this QP. See Section 8.3.3.4 for more information on scheduler configuration. For VFs, the *QS_Handle* is checked to ensure that the VF issuing the CQP command is associated with the *QS_Handle*.

pd_index (16 bits) and pd_index_high (2 bits)

Protection domain for this context. This specifies which one of the 32 KB UDA protection domains this connection context belongs too. There are no reserved index values.

QP_Completion_Context (64 bits)

This field is reported in CQEs and also in AEQEs.

Push_Page_Index (10 bits)

This field identifies the push page associated with the QP. For VFs, the push page index is function relative.

Push_Mode_Enable (1 bit)

This field indicates if push mode is enabled for the QP.

snd_mss (14 bits)

This field specifies a maximum MSS size allowed on that QP. MSS includes all headers and payload of the Ethernet frame, both generated by hardware and provided by software. If software posts a SQ WQE that exceeds this value, the frame is dropped, AE_UDA_XMIT_DGRAM_TOO_LONG AE is reported, and QP transitions to the error state.

Use_Statistics_Instance (1 bit)

This field indicates if the default per Private Memory Function statistics are used, or if one of the additional RDMA statistics instances are used for this QP.

Value	Description
0b	The default statistics are used.
1b	The statistics instance indicated by the *Statistics_Instance_Index* field are used.

Statistics_Instance_Index (7 bits)

This field specifies which of the additional RDMA statistics indexes are used if Use_Statistics_Instance is set (1b) This field is ignored if *Use_Statistics_Instance* is cleared (0b).

11.8.5 UDA CQ Entry Formats

The UDA CQE is the same as UD. See Section 11.7.1.1.

The UDA CQE is DEPRECATED.

11.8.6 UDA QP Completion Error Codes

UDA QP completion errors are typically reported via AEs with the E810. After fielding the AEs, software might issue the Flush WQES CQP operation (see Section 11.5.3.17) to complete any pending operations. Table 11-98 lists the completion codes reported by the E810 in a CQ entry (Table 11-91). Received packets that fail checksum validation are dropped by the chip and not delivered to RQ.

Table 11-98. UDA QP Error Codes

Major Error Code	Minor Error Code	Completion Reason	Description
0x0001	0x0001	WQE Flushed	The WQE has been flushed due to a ModifyQP state transition.
0x0002	0x0001	RQ WQE Too Short	The RQ WQE length was shorter than a length of received Ethernet frame. The frame was truncated, and an error reported.
0x0002	0x0003	SQ WQE Too Long	The SQ WQE length exceeded an MSS configured for the QP. SQ WQE length should include the size of the payload, hardware generated Ethernet and IP headers, and extended header provided by software.
0x0002	0x0004	SQ WQE Hdr Too Long	The SQ WQE extended header size exceeded the size of the private header buffer entry.

11.8.7 UDA QP Asynchronous Error Codes

UDA uses asynchronous errors to report unrecoverable critical errors; those errors mostly used to identify invalid use of UDA host interface. UDA uses the asynchronous error notification mechanism described in section Section 11.8.3.2. UDA shares asynchronous error codes with RDMA (see Section 11.4.7.

As a rule, once an unrecoverable critical error is detected on QP. QP transitions to the error state, and suspends all transmit and receive operations. Any incoming packet targeting a QP in an error state is silently discarded. To release buffers posted to a SQ and a RQ, software must use the Flush WQE CQP operation described in Section 11.5.3.17.

11.8.8 UDA Descriptor Formats

11.8.8.1 UDA SQ WQE Format - Send

The UDA SQE is the same as UD. See Section 11.7.1.3.3.

The UDA SQ entry below is DEPRECATED.

11.8.8.2 UDA SQ WQE Format - Send with Inline Data

The UDA send with inline data is the same as UD. See Section 11.7.1.3.4.

The UDA SQ entry is DEPRECATED.

11.8.8.3 UDA SQ WQE Format - NOP

The UDA NOP is the same as UD. See Section 11.7.1.3.2.

The UDA NOP entry is DEPRECATED.

11.8.8.4 UDA RQ WQE Format

The UDA RQE is the same as UD. See Section 11.7.1.4.

The UDA RQ entry is DEPRECATED.

11.9 Protocol Engine Statistics

11.9.1 Summary

Table 11-99 lists the RFCs relevant to the definition of PE statistics.

Table 11-99. Summary of MIBs Supported with E810 Hardware Statistics Counters

RFC	Description
1213	**Title:** Management Information Base for Network Management of TCP/IP-based Internets: MIB-II. **Status:** RFC1213 obsoletes RFC1158. RFC1213 is updated by RFC 2011(IP), 2012(TCP), 2013(UDP), 2863(Interfaces). There are MIB groups in RFC1213 that will be implemented by the E810 SNMP agent (such as the System group), but these do not require E810 hardware accelerations.
2011	**Title:** SNMPv2 MIB for the Internet Protocol using SMIv2. **Description:** Defines objects for managing implementations of IPv4 and ICMP. **Status:** Updates RFC1213, Obsoleted by RFC4293.
2012	**Title:** SNMPv2 MIB for the Transmission Control Protocol using SMIv2. **Description:** Defines objects for managing implementations of TCP. **Status:** Updates RFC1213, Obsoleted by RFC4022.
2013	**Title:** SNMPv2 MIB for the User Datagram Protocol using SMIv2. **Description:** Defines objects for managing implementations of UDP. **Status:** Updates RFC1213, Obsoleted by RFC4113.
4293	**Title:** MIB for the Internet Protocol (IP). **Description:** Defines objects for managing implementations of IPv4 and ICMP. **Status:** Obsoletes RFC2011, PROPOSED STANDARD.
4022	**Title:** MIB for the Transmission Control Protocol (TCP). **Description:** Defines objects for managing implementations of TCP. **Status:** Obsoletes RFC2012, PROPOSED STANDARD.
4113	**Title:** MIB for the User Datagram Protocol (UDP). **Description:** Defines objects for managing implementations of UDP. **Status:** Obsoletes RFC2013, PROPOSED STANDARD.

There are 128 sets of RDMA statistics. Each set can be assigned to an arbitrary/programmable group of one or more Queue Pairs. Any Queue Pair can be assigned to only one stat set. A typical configuration assigns one set to each active PCIe PF and VF, with the extra sets available for assignment as requested by the OS. For example, if 8 PCIe PFs and 32 PCIe VFs are active, then 40 RDMA stat sets are assigned to these functions, with the rest of the sets remaining for allocation as requested by the OS.

Stats colored Magenta are new for the E810.

The naming convention for the PE Statistics register is as follows:

- Physical function instance starts with GLPES_PF prefix following by the register name.

Table 11-100 lists PE registers by their physical function names. Virtual function register name can be recovered by substituting prefix.

Table 11-100. PE Statistics

Name	Size	MIB	Description
GLPES_PFRXVLANERR	24b	private	Ethernet received packets with incorrect VLAN_ID.
GLPES_PFIP4RXOCTS	48b	IP	IPv4 octets received.
GLPES_PFIP4RXPKTS	48b	IP	IPv4 packets received.
GLPES_PFIP4RXDISCARD	32b	IP	IPv4 packets received and discarded.
GLPES_PFIP4RXTRUNC	32b	IP	IPv4 packets received and truncated due to insufficient buffering space in UDA RQ.
GLPES_PFIP4RXMCPKTS	48b	IP	IPv4 multicast packets received.
GLPES_PFIP4RXMCOCTS	48b	IP	IPv4 multicast octets received.
GLPES_PFIP6RXOCTS	48b	IP	IPv6 octets received.
GLPES_PFIP6RXPKTS	48b	IP	IPv6 packets received.
GLPES_PFIP6RXDISCARD	32b	IP	IPv6 packets received and discarded.
GLPES_PFIP6RXTRUNC	32b	IP	IPv6 packets received and truncated due to insufficient buffering space in UDA RQ.
GLPES_PFIP6RXMCPKTS	48b	IP	IPv6 multicast packets received.
GLPES_PFIP6RXMCOCTS	48b	IP	IPv6 multicast octets received.
GLPES_PFIP4TXOCTS	48b	IP	IPv4 octets supplied by the PE to the lower layers for transmission.
GLPES_PFIP4TXPKTS	48b	IP	IPv4 packets supplied by the PE to the lower layers for transmission.
GLPES_PFIP4TXMCPKTS	48b	IP	IPv4 multicast packets transmitted.
GLPES_PFIP4TXMCOCTS	48b	IP	IPv4 multicast octets transmitted.
GLPES_PFIP6TXOCTS	48b	IP	IPv6 octets supplied by the PE to the lower layers for transmission.
GLPES_PFIP6TXPKTS	48b	IP	IPv6 packets supplied by the PE to the lower layers for transmission.
GLPES_PFIP6TXMCPKTS	48b	IP	IPv6 multicast packets transmitted.
GLPES_PFIP6TXMCOCTS	48b	IP	IPv6 multicast octets transmitted.
GLPES_PFIP4TXNOROUTE	24b	IP	IPv4 datagrams discarded due to routing problem (no hit in ARP table).
GLPES_PFIP6TXNOROUTE	24b	IP	IPv6 datagrams discarded due to routing problem (no hit in ARP table).
GLPES_PFTCPRXSEGS	48b	TCP	TCP segments received.
GLPES_PFTCPRXOPTERR	24b	Intel	TCP segments received with unsupported TCP options or TCP option length errors.
GLPES_PFTCPRXPROTOERR	24b	Intel	TCP segments received that are dropped by TRX due to TCP protocol errors.
GLPES_PFTCPTXSEG	48b	TCP	TCP segments transmitted.
GLPES_PFTCPRTXSEG	32b	TCP	Total number of TCP segments retransmitted.
GLPES_PFUDPRXPKTS	48b	UDP	UDP segments received without errors.
GLPES_PFUDPTXPKTS	48b	UDP	UDP segments transmitted without errors.
GLPES_PFRDMARXWRS	48b	Microsoft	RDMAP total RDMA write messages received.
GLPES_PFRDMARXRDS	48b	Microsoft	RDMAP total RDMA read request messages received.
GLPES_PFRDMARXSNDS	48b	Microsoft	RDMAP total RDMA send-type messages received.
GLPES_PFRDMATXWRS	48b	Microsoft	RDMAP total RDMA write messages sent.
GLPES_PFRDMATXRDS	48b	Microsoft	RDMAP total RDMA read request messages sent.

Table 11-100. PE Statistics [continued]

Name	Size	MIB	Description
GLPES_PFRDMATXSNDS	48b	Microsoft	RDMAP total RDMA send-type messages sent.
GLPES_PFRDMAVBND	48b	Microsoft	RDMA verbs total bind operations carried out.
GLPES_PFRDMAVINV	48b	Microsoft	RDMA verbs total invalidate operations carried out.
GLPES_PFRXNPECNMARKEDPKTS	56b		Packets with ECN bits indicating congestion.
GLPES_PFRXRPCNPHANDLED	32b		Counts the number of Congestion Notification Packets that have been handled by the reaction point.
GLPES_PFRXRPCNPIGNORED	24b		Counts the number of Congestion Notification Packets that have been ignored by the reaction point.
GLPES_PFTXNPCNPSENT	24b		Counts the number of Congestion Notification Packets that have been sent by the reaction point.

Note: A simple, conservative estimate for octet counter wrap times at 40 Gb/s:

- 32-bit counter wraps in 0.859 s.
- 36-bit counter wraps in 13.744 s.
- 40-bit counter wraps in 3.665 m.
- 48-bit counter wraps in 15.64 h.
- 56-bit counter wraps in 166.8 d.

There is a set of PE statistics instantiated only once. Table 11-101 lists these statistics, which are all defined by Intel and not part of a MIB.

Table 11-101. PE Intel-Specific Statistics Instantiated Once

Name	Size	Description
GLPES_RDMARXUNALIGN	32b	RDMA stat: TCP segments that probably have unaligned FPDUs.
GLPES_RDMARXMULTFPDUS	56b	RDMA stat: TCP segments that probably have multiple FPDUs.
GLPES_RDMARXOOONOMARK	32b	RDMA stat: FPDUs received out-of-order, with no MPA marker.
GLPES_RDMARXOOODDPLO	56b	RDMA stat: Number of out-of-order placed DDP segments.
GLPES_TCPRXPUREACKS	56b	TCP stat: Number of pure ACKs received.
GLPES_TCPRXONEHOLE	56b	TCP stat: Increments when an accelerated connection opens a first TCP hole.
GLPES_TCPRXTWOHOLE	56b	TCP stat: Increments when an accelerated connection opens a second TCP hole.
GLPES_TCPRXTHREEHOLE	56b	TCP stat: Increments when an accelerated connection opens a third TCP hole.
GLPES_TCPRXFOURHOLE	56b	TCP stat: Increments when an accelerated connection opens a fourth TCP hole.
GLPES_TCPTXRETRANSFAST	56b	TCP stat: Number of TCP re-transmits.
GLPES_TCPTXTOUTSFAST	56b	TCP stat: Number of TCP retransmission timeouts on connections attempting fast re-transmit.
GLPES_TCPTXTOUTS	56b	TCP stat: Number of TCP retransmission timeouts on connections that are not currently attempting fast re-transmit.

11.10 SR-IOV Protocol Engine Functionality

The E810 PE features are supported in virtualized operating systems that support SR-IOV direct assignment and IOMMUs. The E810 also supports para-virtualized drivers in virtualized operating system environments. The goal for the E810 PE programming model for VFs is to preserve as much of the non-virtualized programming model as possible to maximize the existing software investment. HMC resource profiles provide resource distribution/partitioning required to support this independent programming model in the VF. Backing pages for VF HMC pages for most HMC objects and page descriptor pages are allocated from the PF driver to provide improved security and stability. Backing pages for VF HMC PBL objects are allocated in the guest operating systems address space, the doorbell page from the VF BAR is mapped to guest userspace addresses and CQP operations are issued directly from the guest. The differences are in the programming model for VFs and show up in two areas:

- HMC objects — A HMC PCI function needs to be allocated for the VF and a few HMC objects are owned by the PF instead of the VF (specifically multicast groups and PE quad hash objects). Additionally, most HMC objects are allocated and managed by the PF driver. The VF driver uses the VF-to-PF mailbox or operating system-specific back channel mechanism to coordinate this activity.
- Interaction with the LAN portion of the driver.

To enable a VF driver to take advantage of PE functionality, an HMC PCI function must be allocated. There are 32 HMC VF PCI functions available in the E810. Firmware allocates HMC PCI functions on an as-needed basis between the PFs on a given adapter. This allocation takes place when the VF is allocated by the PF driver to a given guest operating system. In the case of multicast group HMC objects, these objects are always owned by PFs and require the VF driver to coordinate access to them by using VF-to-PF communication mechanisms. The difference in interaction with the LAN portion of the driver is operating system specific due to the different approaches that are taken on each vendor.

A sample initialization flow is as follows on top of the usual LAN VF initialization of interrupts, and so on:

1. When the PF driver created the PF CQP instance, it selected one of the SR-IOV HMC resource profiles to enable RDMA for VFs.
2. The PF driver (typically in the hypervisor or privileged host VM) allocates an HMC function on behalf of the VF using the PF CQP instance. See Section 11.5.3.10 for the WQE format.
3. The VF driver in the guest creates a new CQP instance. See Section 11.5.2.1.
4. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a query FPM values operation. See Section 11.5.3.15.
5. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a commit FPM values operation. See Section 11.5.3.16.
6. The PF driver allocates backing pages and page descriptors for all static HMC resources required for the VF and programs the SDs for the HMC function assigned to the VF using Update PE SDs operations. See Section 11.5.3.14. Note that backing pages are not allocated for PBLE HMC objects in the model, but page descriptors are. Also note that direct backing pages are not supported for VF PBLE HMC objects.
7. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a static HMC pages allocated operation. See Section 11.5.3.14.
8. The PF driver (via communication from the VF driver) allocates backing pages and page descriptors for the initial set of HMC resources required by the VF driver. This step involves issuing one or more Update PE SD operations.
9. The VF driver uses its CQP instance to create CQ0, the CEQ, and AEQ for the VF.

10. During runtime, the VF driver signals the PF driver to allocate and initialize more HMC backing pages and/or PDs on its behalf. When PBLEs are needed during memory registration in the VF, the VF driver issues manage VF PBLE backing pages operations. See Section 11.5.3.12.

11.11 NVM RDMA Register Initialization

Table 11-102 describes the RDMA registers that are initialized via NVM settings.

Table 11-102. NVM Initial Values for RDMA Registers

Register	Field	Initial Value
GLPE_PEPM_CTRL	PEPM_PUSH_MARGIN	42
	PEPM_HALT	0
	PEPM_ENABLE	1
GLPE_TSCD_PEPM	MDQ_CREDITS	42
GLPE_PUSH_PEPM	MDQ_CREDITS	42

Table 11-103. Tx-Pipe Monitors Configuration in All Ports Setups

		Control Register	Negotiated Speed (Gb/s)					
			1 to 5 Port Configuration				6, 7, or 8 Port Configuration[1]	
			100	50	25	10[2]	25	10[2]
UPPER PIPE	Per Port Header Buffer Upper Pipe Monitors[3]	PRTDCB_TCUPM_REG_PE_HB_DTHR[0..7].*PORTOFFTH_L*	150	150	150	113	145	75
		PRTDCB_TCUPM_WAIT_PFC_PE_HB_DTHR[0..7].*PORTOFFTH_H*	300	300	300	226	290	150
		PRTDCB_TCUPM_WAIT_PE_HB_DTHR[0..31].*PORTOFFTH*	150	150	150	113	145	75
	Protocol Engine Pipe Monitor[4]	GLPE_PEPM_THRESH_I[0..511].*PEPM_PSQ_THRESH*	22	9	8	4	5	4
		GLPE_PEPM_THRESH_I[0..511].*PEPM_MDQ_THRESH*	492	420	336	124	288	124

1. If there are 6, 7, or 8 ports, the settings for 10 Gb/s and 25 Gb/s are changed to the values in the last two columns.
2. The 10G pipe monitor setup values apply to link speed 5G, 2.5G, 1G and 100M as well.
3. Programmed by EMP.
4. Programmed by CQP in the Protocol Engine.

Chapter 12 System Manageability

Network management is an important requirement in today's networked computer environment. Software-based management applications provide the ability to administer systems while the operating system is functioning in a normal power state (not in a pre-boot state or powered-down state). The Intel® Out of Band Management fills the management void that exists when the operating system is not running or fully functional. This is accomplished by providing mechanisms by which manageability network traffic can be routed to and from a Management Controller (MC).

This section describes the supported management interfaces and hardware configurations for platform system management. It describes the interfaces to an external MC, the partitioning of platform manageability among system components, and the functionality provided by the E810 in each platform configuration.

12.1 Features

Table 12-1 lists the manageability features in the LAN controller.

Table 12-1. System Manageability Features

Description
Sideband Interfaces for connection to an external BMC: • SMBus operating at up to 400 Kb/s, using only MCTP messages. • DMTF-compliant NC-SI Interface 1.1 at 100 Mb/s. • PCIe (using MCTP VDMs).
Sophisticated filters to select received packet flows for delivery or mirroring to the BMC. Each of the following filters is instantiated per-Ethernet port: • 4 MAC filters. • 8 VLAN filters. • 4 EtherType filters. • 4 IPv4 and 4 IPv6 filters. • 16 UDP/TCP port filters. • 1 Flexible Total Cost of Ownership (TCO) filter. • Address Resolution Protocol (ARP) filtering. • Neighbor discovery filtering. • Remote Management Control Protocol (RMCP) filtering. • Internet Control Message Protocol (ICMP) filtering.
Ability to internally switch packets for communication between an OS and BMC.
Supported Protocols: • DSP0222 1.1.0 - NC-SI Including ability to internally switch packets for communication between an OS and BMC. • DSP0261 1.2.0 - NC-SI over MCTP • DSP0236 1.3.0, DSP0238 1.0.1, DSP0237 1.1.0, DSP0239 1.4.0- MCTP over PCIe VDM and over SMBus • DSP0240 1.0.0 - PLDM Base • DSP0248 1.1.0, DSP0249 1.0.0- PLDM Monitoring and Control • DSP0267 1.0.1 - PLDM Firmware Update

12.2 Pass-Through Functionality

Pass-Through (PT) is the term used when referring to the process of sending and receiving Ethernet traffic over the sideband interface. The E810 has the ability to route Ethernet traffic to the host operating system as well as the ability to send Ethernet traffic over the sideband interface to an external MC. See Figure 12-1.

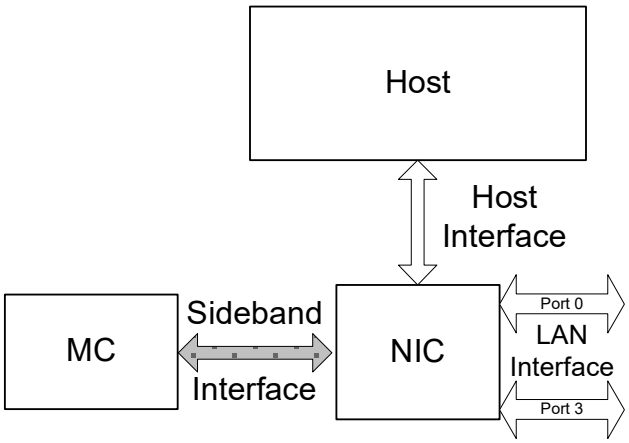

Figure 12-1. Sideband Interface

The sideband interface provides a mechanism by which the E810 can be shared between the host and the MC. By providing this sideband interface, the MC can communicate with the LAN without requiring a dedicated Ethernet controller. The E810 supports three sideband interfaces:

- SMBus (MCTP)
- NC-SI
- PCIe (together with MCTP) - when the system is up.

Notes:

- The usable bandwidth for either direction is up to 400 Kb/s when using SMBus and 100 Mb/s for the NC-SI interface. When working over PCIe, the bandwidth is limited only by the PCIe bandwidth, and the E810 processing capabilities and can sustain any network bandwidth. The E810 should support MCTP over PCIe pass-through traffic at a rate of up to 1 Gb/s. The maximum packet size supported for traffic received from the LAN to the MC is 1518 bytes and an additional STag, or VLAN tags. For traffic from the MC to the LAN, the maximum supported packet size is 1536 bytes including all tags.
- In MCTP mode, the PCIe and SMBus interface can receive MCTP commands in parallel. For example, the MCTP enumeration process can be done both over SMBus and over PCIe. However, only one of the interfaces can receive NC-SI commands or pass-through traffic.

12.2.1 Supported Topologies

The E810 can support up to two connections to management controllers in some topologies. The following connections are available:

- Connection via NC-SI over RBT (RMII) (See Section 12.6).
- Connection via NC-SI over MCTP. This connection can be over SMBus, PCIe or both. This connection can be used either for pass-through or for control only (See Section 12.7).
- Two connections — A connection via NC-SI over RBT for pass-through traffic and a connection via MCTP used only for control traffic (See Section 12.7).

The channel used is for pass-through is defined in the *Redirection Sideband Interface* field, and the channel used for control is defined in the *Control Interface* field, both in the Common Manageability Parameters NVM word (see Section 6.3.57.2) and are common to all the ports in the device.

12.2.2 Pass-Through Packet Routing

When an Ethernet packet reaches the E810, it is examined and compared to a number of configurable filters. These filters are configurable by the MC and include, but are not limited to, filtering on:

- MAC Address
- IP Address
- UDP/IP ports
- VLAN tags
- EtherType

If the incoming packet matches any of the configured filters, it is passed to the MC. Otherwise, it is not passed.

The packet filtering process is described in Section 12.4.

12.3 Components of the Sideband Interface

There are two components to a sideband interface:

- Physical layer
- Logical layer

12.3.1 Physical Layer

This is the electrical connection between the E810 and the MC.

12.3.1.1 SMBus

The SMBus physical layer is defined by the SMBus specification. The interface is made up of two connections: data and clock. Refer to the SMBus specification for details.

The SMBus can run at two speeds: 100 KHz (standard SMBus) or 400 KHz (I^2C fast mode). The speed used while the E810 is the master of the bus is selected by the *SMBus Connection Speed* field in the SMBus Notification Timeout and Flags NVM word. When acting as a slave, the E810 can receive transaction with a clock running at up to 400 KHz.

12.3.1.1.1 PEC Support

SMBus transactions can be protected by using Packet Error Code (PEC). Packet error checking, when applicable, is implemented by appending a PEC byte at the end of each message transfer. The PEC byte is a CRC8 calculation on all the message bytes.

PEC is added in transmit and expected in receive for the following SMBus packets:

- ARP packets
- MCTP over SMBus transactions

For ARA cycles, a PEC is not expected.

Table 12-2 lists the behavior of the E810 in each PEC configured mode for transactions directly handled by hardware after receiving packets with or without PEC.

Table 12-2. SMBus PEC Modes

SMBus transaction (relative to the E810)	E810 PEC Mode	Target PEC Mode[1]	
		PEC Enabled	PEC Disabled
Master Write[2]	Enabled	(A) Target ACKs the PEC byte.	(A) Target NACKs the PEC byte.
	Disabled	(A) Target receives stop before expected PEC byte.	(A) PEC byte is not expected.
Slave Read[3]	Enabled	(A) Target sends the PEC byte. PEC byte is ACKed by the slave.	(A) Target does not send PEC byte and generates stop afterwards.
	Disabled	(R) Target sends the PEC byte. PEC byte is NACKed by the slave	(A) Target does not send PEC byte and generates stop afterwards.

1. (A) - Accept transaction; (R) - Reject transaction.
2. Used in MCTP over SMBus (transmitted transactions).
3. Used in MCTP over SMBus (received transactions).

Note: In both SMBus ARP and MCTP, the specification indicates that PEC must be used. However, if PEC is not used by the master, the transaction is still accepted and processed by the E810.

The PEC behavior is controlled by the *SMBus Transaction PEC* bit in the SMBus Notification Timeout and Flags NVM word. If this bit is set, PEC is added for master SMBus write transactions. A PEC is added to slave read transactions and can be received in slave write transaction. If this bit is cleared, PEC is not added to master write or slave read transactions, a slave write transaction with PEC is dropped. This bit should always be set.

12.3.1.2 NC-SI over RBT

The E810 uses the DMTF standard RBT sideband interface as defined in DMTF DSP0222. This interface consists of seven lines for transmission and reception of Ethernet packets and two optional lines for arbitration among more than one physical network controller.

The RBT physical layer of NC-SI is very similar to the RMII interface, although not an exact duplicate. Refer to the NC-SI specification for details of the differences.

12.3.1.2.1 Electrical Characteristics

The E810 complies with the electrical characteristics defined in the NC-SI 1.0.1 specification.

The E810's NC-SI behavior is configured at power-up in the following manner:

- The *Multi-Drop NC-SI* NVM bit (Section 6.3.57.3) defines the NC-SI topology (point-to-point or multi-drop; the default is point-to-point).

The E810 dynamically drives its NC-SI output signals (NC-SI_DV and NC-SI_RX) as required by the sideband protocol:

- At power-up, the E810 floats the NC-SI outputs.
- If the E810 operates in point-to-point mode, it starts driving the NC-SI outputs some time following power-up.
- If the E810 operates in a multi-drop mode, it drives the NC-SI outputs as configured by the BMC.

12.3.1.3 PCIe Vendor-Defined Messages (VDMs)

The E810 uses VDMs over PCIe defined in the DMTF MCTP specification to convey pass-through traffic or NC-SI control traffic. See Section 3.1 for details of the PCIe interface.

12.3.2 Logical Layer

12.3.2.1 SMBus

12.3.2.1.1 SMBus Transactions

This section gives a brief overview of the SMBus protocol. Table 12-3 shows an example for a format of a typical SMBus transaction.

Table 12-3. Typical SMBus Transaction

1	7	1	1	8	1	8	1	1
S	**Slave Address**	**Wr**	**A**	**Command**	**A**	**PEC**	**A**	**P**
	1100 001	0	0	0000 0010	0	[Data Dependent]	0	

The top row of the table identifies the bit length of the field in a decimal bit count. The middle row (bordered) identifies the name of the fields used in the transaction. The last row appears only with some transactions, and lists the value expected for the corresponding field. This value can be either hexadecimal or binary.

The SMBus controller is a master for some transactions and a slave for others. The differences are identified in this document.

Shorthand field names are listed in Table 12-4 and are fully defined in the SMBus specification.

Table 12-4. Shorthand Field Names

Field Name	Definition
S	SMBus START Symbol
P	SMBus STOP Symbol
PEC	Packet Error Code
A	ACK (Acknowledge)
N	NACK (Not Acknowledge)
Rd	Read Operation (Read Value = 1b)
Wr	Write Operation (Write Value = 0b)

12.3.2.1.2 SMBus Addressing

In MCTP mode, a single SMBus channel is exposed.

SMBus addresses (enabled from the NVM) can be re-assigned using the SMBus ARP protocol.

In addition to the SMBus address values, all parameters of the SMBus (SMBus channel selection, address mode, and address enable) can be set only through NVM configuration. Note that the NVM is read at the E810's power up and resets.

12.3.2.1.3 SMBus ARP Functionality

The E810 supports the SMBus ARP protocol as defined in the SMBus 2.0 specification. The E810 is a persistent slave address device so its SMBus address is valid after power-up and loaded from the NVM. The E810 supports all SMBus ARP commands defined in the SMBus specification both general and directed.

SMBus ARP capability can be disabled through the NVM.

12.3.2.1.3.1 SMBus ARP Flow

SMBus ARP flow is based on the status of two flags:

- **Address Valid (AV)** — This flag is set when the E810 has a valid SMBus address.
- **Address Resolved (AR)** — This flag is set when the E810 SMBus address is resolved (SMBus address was assigned by the SMBus ARP process).

These flags are internal E810 flags and are not exposed to external SMBus devices.

Since the E810 is a Persistent SMBus Address (PSA) device, the AV flag is always set, while the AR flag is cleared after power up until the SMBus ARP process completes. Since AV is always set, the E810 always has a valid SMBus address.

When the SMBus master needs to start an SMBus ARP process, it resets (in terms of ARP functionality) all devices on SMBus by issuing either Prepare to ARP or Reset Device commands. When the E810 accepts one of these commands, it clears its AR flag (if set from previous SMBus ARP process), but not its AV flag (the current SMBus address remains valid until the end of the SMBus ARP process).

Clearing the AR flag means that the E810 responds to SMBus ARP transactions that are issued by the master. The SMBus master issues a Get UDID command (general or directed) to identify the devices on the SMBus. The E810 always responds to the Directed command and to the General command only if its AR flag is not set.

After the Get UDID, the master assigns the E810 SMBus address by issuing an Assign Address command. The E810 checks whether the UDID matches its own UDID and if it matches, it switches its SMBus address to the address assigned by the command (byte 17). After accepting the Assign Address command, the AR flag is set and from this point (as long as the AR flag is set), the E810 does not respond to the Get UDID General command. Note that all other commands are processed even if the AR flag is set. The E810 stores the SMBus address that was assigned in the SMBus ARP process in the NVM, so at the next power up, it returns to its assigned SMBus address.

Figure 12-2 shows the E810 SMBus ARP flow.

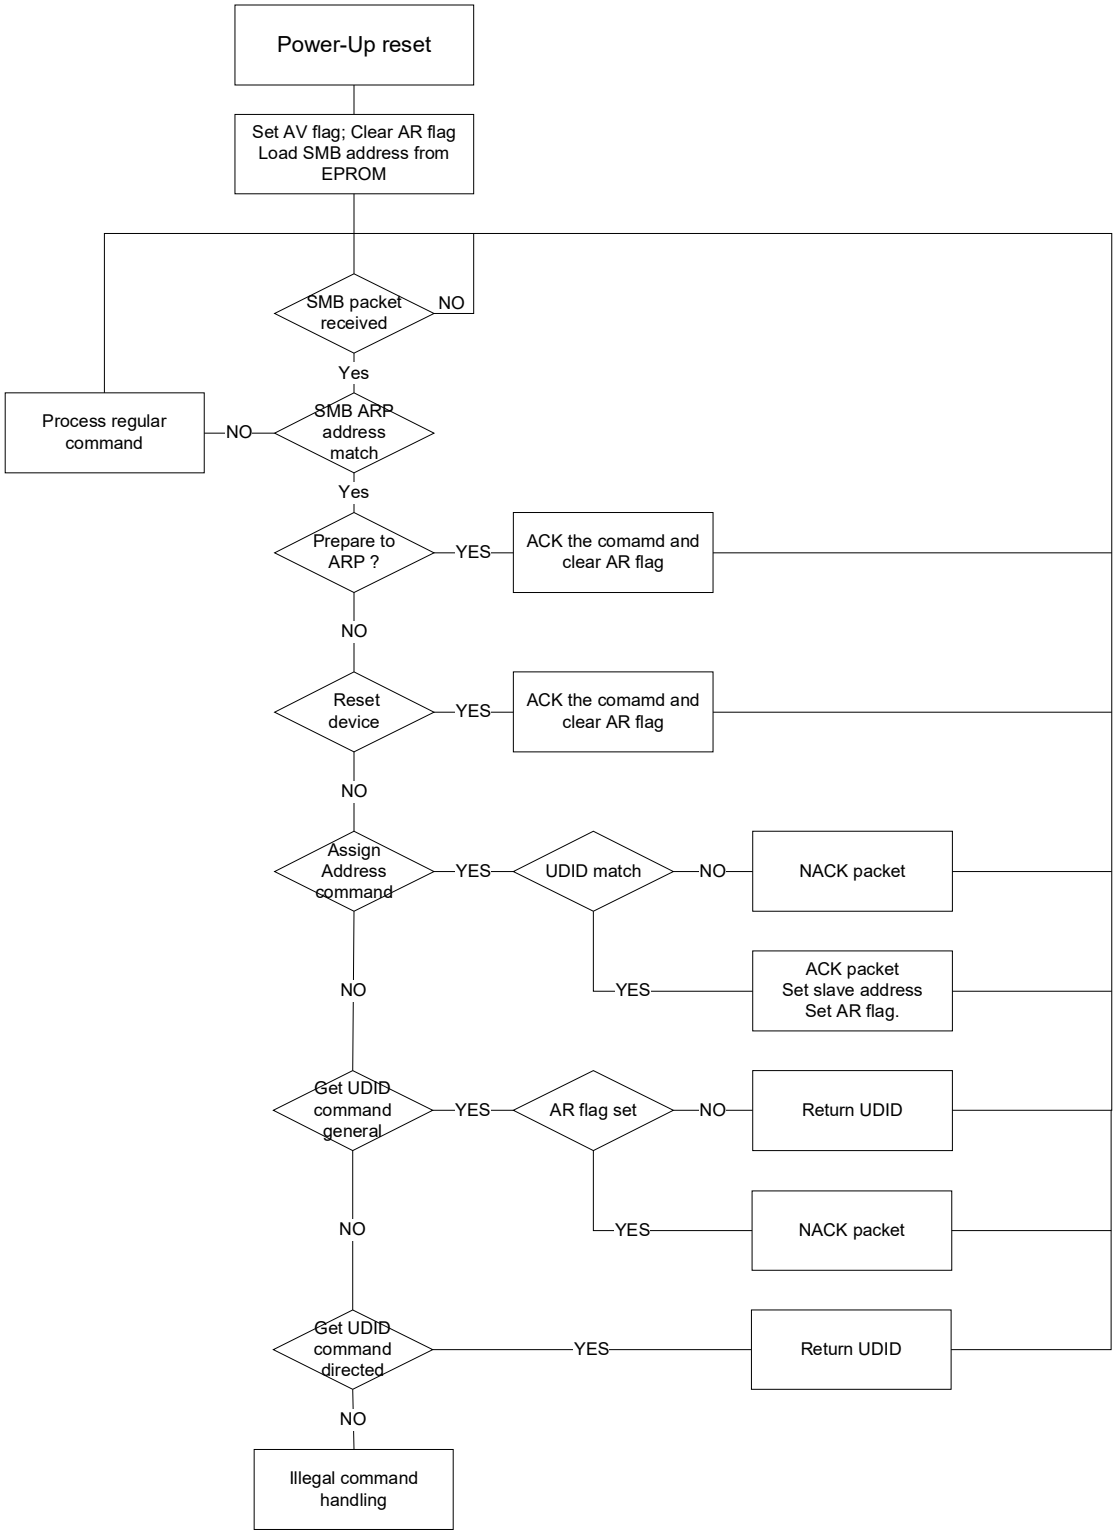

Figure 12-2. SMBus ARP Flow

12.3.2.1.3.2 SMBus ARP UDID Content

The UDID provides a mechanism to isolate each device for the purpose of address assignment. Each device has a unique identifier. The 128-bit number is comprised of the following fields:

Table 12-5. UDID

1 Byte	1 Byte	2 Bytes	2 Bytes	2 Bytes	2 Bytes	2 Bytes	4 Bytes
Device Capabilities	Version/ Revision	Vendor ID	Device ID	Interface	Subsystem Vendor ID	Subsystem Device ID	Vendor Specific ID
See notes that follow	See notes that follow	0x8086	0x1590	0x0004/ 0x0024	0x0000	0x0000	See notes that follow
MSB							LSB

Where:

Vendor ID: The device manufacturer's ID as assigned by the SBS Implementers' Forum or the PCI SIG.

Constant value: 0x8086

Device ID: The device ID as assigned by the device manufacturer (identified by the *Vendor ID* field).

Constant value: 0x1590

Interface: Identifies the protocol layer interfaces supported over the SMBus connection by the device.

Bits 3:0 = 0x4 indicates SMBus Version 2.0
Bit 5 (ASF bit) = 1 in MCTP mode.

Subsystem Fields: These fields are not supported and return zeros.

Device Capabilities: Dynamic and Persistent Address, *PEC Support* bit:

7	6	5	4	3	2	1	0
Address Type		Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)	PEC Supported
0b	1b	0b	0b	0b	0b	0b	0b/1b[1]
MSB							LSB

1. The value is set according to the *SMBus Transaction PEC* bit in the NVM.

Version/Revision: UDID Version 1, Silicon Revision:

7	6	5	4	3	2	1	0
Reserved (0)	Reserved (0)	UDID Version			Silicon Revision ID		
0b	0b	001b			See the following table		
MSB							LSB

Silicon Revision ID:

Silicon Version	Revision ID
A0/A1 in CAM1/CAM2 SKUs.	000b
B0 in CAM1/CAM2 SKUs. A0 in XXVAM2 SKU.	001b
C0	010b

Vendor Specific ID: Four LSB bytes of the device Ethernet MAC Address of the relevant port. The port Ethernet address is taken from the PRTGL_SAL registers of the relevant ports. Note that in the E810 there are up to eight MAC Addresses (one for each port).

1 Byte	1 Byte	1 Byte	1 Byte
MAC Address, Byte 3	MAC Address, Byte 2	MAC Address, Byte 1	MAC Address, Byte 0
MSB			LSB

12.3.2.2 NC-SI

The DMTF defines the protocol layer for the NC-SI interface. NC-SI compliant devices are required to implement a minimum set of commands. The specification also provides a mechanism for vendors to add additional capabilities through the use of OEM commands. Intel OEM NC-SI commands for the E810 are discussed in Section 12.6.4. For information on base NC-SI commands, see the NC-SI specification.

NC-SI traffic can run on top of three different Physical layers:

1. NC-SI physical layer as described in Section 12.3.1.2.
2. MCTP over PCIe VDM. This protocol enables control and pass-through traffic over PCIe of a NIC or a LOM device. The NC-SI over MCTP protocol is slightly different than the standard NC-SI, as it includes additional NC-SI commands. This mode is usually paired with an MCTP over SMBus, where this mode is used in S0 states and the SMBus interface is used in Sx state. The MCTP protocol and the differences from standard NC-SI is described in Section 12.7.
3. MCTP over SMBus. As previously described, this layer is paired with the MCTP over PCIe to support Sx modes.

The E810 exposes one NC-SI package with eight channels, one per port. The E810 implements a type C NC-SI interface (single package, common bus buffers and shared Rx-Queue) as described in Section 5.2 of the NC-SI specification.

12.3.2.2.1 Package ID Setting

The Package ID can be set either from the *Package ID* field in the NC-SI Configuration 1 NVM word (see Section 6.3.58.4) or from an SDP pin. If set from SDP, the package ID is (0b, SDP value, 0b).

The mode used is set by the *Read NCSI Package ID from SDP* field in the NC-SI Configuration 2 NVM word (Section 6.3.58.5). The encoding is as follows:

00b = The Package ID is read from the *Package ID* field in the NC-SI Configuration 1 NVM word (Section 6.3.58.4) // Regular Card

01b = The the Package ID is (Package ID[2], SDP#1 value, SDP#0 value) // OCP, 2 SDPs.

10b = The package ID is (Package ID[2], SDP#1 value, Package ID[0]) // OCP single SDP

11b = Reserved.

Note: When the package ID is set from the SDP pins, the used SDP should be set as an input in the relevant GLGEN_GPIO_CTL register. The SDPs to use are defined in the *PackageID SDP* field in the NC-SI Configuration 2 NVM word (Section 6.3.58.5).

12.3.2.2.2 Channel ID Mapping

The mapping of the channels to physical ports is according to the NC-SI Channel to Port Mapping NVM word (Section 6.3.58.15) if the *Valid* bit is set. If this bit is not set, the following algorithm should be used:

```
Channel_ID = 0
NC-SI_channel[3:0] = -1 // ports not associated with channels yet.
For func = 0 to 7 { // loop on all functions
       Port_ID = PFGEN_PORTNUM[func] // Port associated with function.
       If (PRTGEN_STATUS.PORT_VALID[Port_ID] && NC-SI_channel[Port_ID] == -1 && PHY module is present).
       {
       // Port is valid and port is not already associated with a channel
       NC-SI_channel[Port_ID] = Channel_ID; // assign channel
       PRT2MDEF[Port_ID] = Channel_ID;
       Channel_ID++; // go to next channel
       }
   }
```

This algorithm maps channel numbers that match the order of the PCI function numbers.

If firmware detects a change in the number of ports enabled, it:

- Waits until the *Veto* bit of all ports is cleared.
- Updates the number of exposed channel.
- Moves the package to “Initialization Required” state.

The BMC then re-enumerates the package and discovers the new number of available channels.

12.4 Packet Filtering

Since both the host operating system and an MC use the E810 to send and receive Ethernet traffic, there needs to be a mechanism by which incoming Ethernet packets can be identified as those that should be sent to the MC rather than the host operating system.

A high-level description of the host and MC filtering flow can be found in Section 7.8.2.

There are two different types of filtering available. The first is filtering based upon the MAC Address. With this filtering, the BMC has at least one dedicated MAC Address and incoming Ethernet traffic with the matching MAC Address(es) are passed to the MC. This is the simplest filtering mechanism to use and it enables the MC to receive all types traffic (including, but not limited to, IPMI, NFS, HTTP, and so on).

The other type available uses a highly-configurable mechanism by which packets can be filtered using a wide range of parameters. Using this method, the MC can share a MAC Address (and IP Address, if desired) with the host operating system and receive only specific Ethernet traffic. This method is useful if the MC is only interested in specific traffic, such as IPMI packets.

12.4.1 Manageability Receive Filtering

This section describes the manageability receive packet filtering flow. Packet reception by the E810 can generate one of the following results:

- Discarded
- Sent to host memory
- Sent to the MC
- Sent to both the MC and host memory

The decisions regarding forwarding of packets to the host and to the MC are separate and are configured through two sets of registers. However, the MC might define some types of traffic as exclusive. This traffic is forwarded only to the MC, even if it passes the filtering process of the host. These types of traffic are defined using the PRT_MNG_MNGONLY register.

An example of packets that might be necessary to send exclusively to the MC might be specific TCP/UDP ports of a shared MAC Address or a MAC Address dedicated to the MC. If the MC configures the manageability filters to send these ports to the MC, it should configure the settings to not send them to the host; otherwise, these ports are received and handled by the host operating system.

The MC controls the types of packets that it receives by programming receive manageability filters. The following filters are accessible to the MC:

Table 12-6. Filters Accessible to MC

Filters	Functionality	When Reset
Filters Enable	General configuration of manageability filters.	LAN_PWR_GOOD
Manageability Only	Enables routing of packets exclusively to manageability.	LAN_PWR_GOOD
Manageability Decision Filters [7:0]	Configuration of manageability decision filters.	LAN_PWR_GOOD
MAC Address [3:0]	4 unicast MAC manageability addresses.	LAN_PWR_GOOD
VLAN Filters [7:0]	8 VLAN tag values.	LAN_PWR_GOOD
UDP/TCP Port Filters [15:0]	16 destination port values.	LAN_PWR_GOOD
Flexible 144 bytes TCO Filter	Length and values for one flex TCO filter.	LAN_PWR_GOOD
IPv4 and IPv6 Address Filters [3:0]	IP Address for manageability filtering.	LAN_PWR_GOOD
Special filters modifier	Used to define some special filtering options like 24-bit filtering of IPv6 Addresses and TCP/UDP selection of ASF ports.	LAN_PWR_GOOD

All filtering capabilities are available on the NC-SI interface. Part of the filters are programmed via standard NC-SI commands and part are programmed via the Intel OEM commands described in Section 12.6.4.

All filters are reset only on internal power-on-reset. Register filters that enable filters or functionality are also reset by firmware at internal firmware reset in NC-SI mode. These registers can be loaded from the NVM following a reset in SMBus mode. See Section 6.3.10 through Section 6.3.14 for descriptions of their location in the NVM map.

The high-level structure of manageability filtering is done using two or three steps.

1. The packet is routed by the switch as described in Section 7.8.7. If the switch determines the packet should be routed to the manageability VSIs, the next steps are taken.
2. The packet is parsed and fields in the header are compared to programmed filters.

3. A set of decision filters are applied to the result of the first step.

The following sections describe Step 2 and Step 3 previously listed.

Some general rules apply:

- Fragmented packets are passed to manageability but not parsed beyond the IP header.
- Packets with L2 errors (CRC, alignment, and so on) are not forwarded to the MC.
- Packets longer than 2 KB are filtered out.
- All the filters refers to the outer header of the packet and not to any tunneled header.

The following sections describe the manageability filtering, followed by the final filtering rules.

The filtering rules are created by programming the decision filters as described in Section 12.4.4.

12.4.2 L2 Filters

12.4.2.1 MAC and VLAN Filters

The manageability MAC filters allow a comparison of the destination MAC Address to one of four filters defined in the PRT_MNG_MMAH and PRT_MNG_MMAL registers.

The VLAN filters allow a comparison of the 12-bit VLAN tag to one of eight filters defined in the PRT_MNG_MAVTV registers. The VLAN tag compared is the innermost VLAN in the external L2 header.

12.4.2.2 EtherType Filters

Manageability L2 EtherType filters enable filtering of received packets based on the Layer 2 EtherType field. The L2 type field of incoming packets is compared against the EtherType filters programmed in the manageability EtherType filter (PRT_MNG_METF; up to four filters). The result is incorporated into decision filters.

Each manageability EtherType filter can be configured as pass (positive) or reject (negative) using a polarity bit. For the reverse polarity mode to be effective and block certain type of packets, the EtherType filter should be part of all the enabled decision filters.

An example for using L2 EtherType filters is to determine the destination of 802.1X control packets. The 802.1X protocol is executed at different times in either the management controller or by the host. L2 EtherType filters are used to route these packets to the proper agent.

In addition to the flexible EtherType filters, the E810 supports two fixed EtherType filters used to block NC-SI control traffic (0x88F8) and flow control traffic (0x8808) from reaching the manageability interface. The NC-SI EtherType is used for communication between the MC on the NC-SI link and the E810. Packets coming from the network are not expected to carry this EtherType, and such packets are blocked to prevent attacks on the MC. Flow control packets should be consumed by the MAC, and as such are not expected to be forwarded to the management interface.

Note: EtherType filters should not be configured with IPv4 or IPv6 EtherType values.

12.4.3 L3/L4 Filtering

The manageability filtering stage combines checks done at previous stages with additional L3/L4 checks to make a decision about whether to route a packet to the MC. The following sections describe the manageability filtering done at layers L3/L4 and final filtering rules.

12.4.3.1 ARP Filtering

The E810 supports filtering of ARP request packets (initiated externally) and ARP responses (to requests initiated by the MC).

To limit the reception of ARP packets to the ARP packets dedicated to this station (ARP target IP = MC IP), the ARP request/response filter can be bound to a specific IP Address by setting both the ARP Request/Response and the IP AND bits in an MDEF filter. Note that the IP bit is also set if there is a match on the target IP (the TPA field in the ARP packet) of an ARP request or an ARP response.

Note: If the OR section of the MDEF is cleared and one of the IPv4 Address are set, ARP packets matching the IP Address pass the filter. If these packets should be dropped, an OR EtherType filter with a value of 0x0800 (IPv4) should be added.

See Appendix A.5.3.8 for the format of ARP packets.

12.4.3.2 Neighbor Discovery Filtering and MLD

The E810 supports filtering of the following ICMPv6 packets.

Neighbor discovery packets:

- 0x86 (134d) — Router Advertisement
- 0x87 (135d) — Neighbor Solicitation
- 0x88 (136d) — Neighbor Advertisement
- 0x89 (137d) — Redirect

MLD packets:

- 0x82 (130d) — MLD Query
- 0x83 (131d) — MLDv1 Report
- 0x84 (132d) — MLD Done
- 0x8F (143d) — MLDv2 Report

The neighbor discovery packets have dedicated enables for each type in the decision filters. For MLD, a single enable controls the forwarding of all the MLD packets. This means that either all the MLD packets types are selected for reception, or none of them.

See Appendix A.5.3.5 for the format of ICMPv6 packets.

12.4.3.3 RMCP Filtering

The E810 supports filtering by fixed destination port numbers: port 0x26F and port 0x298. These ports are IANA reserved for RMCP.

UDP or TCP protocols can be included in the comparison using the *PORT_26F_UDP*, *PORT_26F_TCP*, *PORT_298_UDP*, and *PORT_298_TCP* fields in the PRT_MNG_MSFM register.

In SMBus mode, there are filters that can be enabled for these ports. When using NC-SI, they are not specifically available. However, the general filtering mechanism can be utilized to filter incoming RMCP traffic.

12.4.3.4 ICMP Filtering

The E810 supports filtering by ICMPv4. This filter matches if the IP *Protocol* field equals to 1b.

See Appendix A.5.3.4 for the format of ICMP packets.

12.4.3.5 Flexible Port Filtering

The E810 implements 16 flex source/destination port filters. The E810 directs packets whose L4 destination or source port matches to the MC. The MC must ensure that only valid entries are enabled in the decision filters.

For each flex port filter, filtering can be enabled for UDP, TCP or both. It can be enabled either on source or destination port.

12.4.3.6 IP Address Filtering

The E810 supports filtering by destination IP Address using IPv4 and IPv6 Address filters. These are dedicated to manageability. The E810 provides four IPv6 Address filters and four IPv4 Address filters.

For each IPv6 filter, the matching PRT_MNG_MSFM.*IPV6_n_MASK* bit defines if all the IP Address should be compared to the PRT_MNG_MIPAF6 register or only the 24 LS bits should be compared to the 24 LS bits of the PRT_MNG_MIPAF6 register.

The IPv4 match also rises for ARP packets for which the target IP matches the IP Address in the PRT_MNG_MIPAF4 register.

12.4.3.7 Checksum Filtering

The E810 might be instructed to direct packets to the MC only if they pass L3/L4 checksum (if they exist) in addition to matching other filters previously described.

To enable the XSUM filtering when using NC-SI, use the Enable Checksum Offloading command. See Section 12.6.4.13.

Note: Checking the checksum of some complex IPv6 packets with routing extensions is not supported by the E810. Therefore, such packets are passed to the BMC even if their checksum is wrong and checksum offload is enabled. The BMC should check the checksum of such packets itself.

12.4.4 Flexible 144-Byte Filter

The E810 provides one flex TCO filter. This filter looks for a pattern match within the first 144 bytes of the packet.

The flex filter programming should ignore the presence of these fields.

If tags unknown to the programming instance (BMC) are expected in the packet (for example, if the device is removing STag before forwarding the packets to the BMC), the filter should be adapted accordingly by skipping/comparing the removed bytes in the filter.

Notes:

- The flex filter comparison should be disabled in the MDEF registers while the flex filter is being updated.
- The flexible filter is not applied to transmit packets and a transmit packet is considered as if it did not pass the filter.

The association of filters to ports is described in Table 12-7 according to the mode of operation, as defined by the GLGEN_MAC_LINK_TOPO register. For example, in a 4 ports mode, the filter to program for port 2 is PRT_MNG_FTFT_*_1_0.

Table 12-7. Number of Ports to Filter Mapping

Port Number/Mode	1/2 Ports Mode	4 Ports Mode	8 Ports Mode
0	PRT_MNG_FTFT_*_0_0 and PRT_MNG_FTFT_*_1_0[1]	PRT_MNG_FTFT_*_0_0	PRT_MNG_FTFT_*_0_0
1	PRT_MNG_FTFT_*_2_0 and PRT_MNG_FTFT_*_3_0[1]	PRT_MNG_FTFT_*_2_0	PRT_MNG_FTFT_*_2_0
2		PRT_MNG_FTFT_*_1_0	PRT_MNG_FTFT_*_1_0
3		PRT_MNG_FTFT_*_3_0	PRT_MNG_FTFT_*_3_0
4			PRT_MNG_FTFT_*_0_1
5			PRT_MNG_FTFT_*_2_1
6			PRT_MNG_FTFT_*_1_1
7			PRT_MNG_FTFT_*_3_1

1. The two registers should have the same value.

12.4.4.1 Flexible Filter Structure

The filter is composed of the following fields:

- **Flexible filter length** — This field indicates the number of bytes in the packet header that should be inspected. The field also indicates the minimal length of packets inspected by the filter. A packet below that length is not inspected. Valid values for this field are: 8*n, where n=1….
- **Data** — This is a set of up to 144 bytes comprised of values that header bytes of packets are tested against.
- **Mask** — This is a set of bit masks - one bit per byte of data in the packet that indicates if it is tested against its corresponding byte in the filter. Part of the bytes in the filter cannot be used for the filtering, so the mask is used to indicate which of the bytes are used for the filter.

12.4.4.2 TCO Filter Programming

Programming each filter is done using the following commands (NC-SI or SMBus) in a sequential manner:

1. **Filter Mask and Length** — This command configures the following fields:
   a. **Mask** — A set of 16 bytes containing the 128 bits of the mask. Bit 0 of the first byte corresponds to the first byte on the wire.
   b. **Length** — A 1-byte field indicating the length.
2. **Filter Data** — The filter data is divided into groups of bytes as follows:

Group	Test Bytes
0x0	0-29
0x1	30-59
0x2	60-89
0x3	90-119
0x4	120-127

   Each group of bytes must be configured using a separate command, where the group number is given as a parameter. The command has the following parameters:
   a. **Group number** — A 1-byte field indicating the current group addressed.
   b. **Data bytes** — Up to 30 bytes of test-bytes for the current group.

12.4.4.2.1 Flexible TCO Filter Configuration in NVM (Global MNG Offset 0x05)

This section describes the NVM module used to store the flex filter initial data in SMBus mode.

This module is a TLV in the PFA with a type of 7.

12.4.4.2.1.1 Section Header (Offset 0x00)

Bits	Name	Default	Description
15:0	Block Length	0xC	Section length in words (including CRC word and length word).

12.4.4.2.1.2 Flexible Filter Control (Offset 0x01)

Bits	Name	Default	Description
15	Last Filter		
14:8	Reserved		Reserved.
7	Apply Filter to LAN 7		
6	Apply Filter to LAN 6		
5	Apply Filter to LAN 5		
4	Apply Filter to LAN 4		
3	Apply Filter to LAN 3		

Bits	Name	Default	Description
2	Apply Filter to LAN 2		
1	Apply Filter to LAN 1		
0	Apply Filter to LAN 0		

12.4.4.2.1.3 Flexible Filter Length (Offset 0x02)

Bits	Name	Default	Description
15:7	Flexible Filter Length (bytes)		
6:0	Reserved		Reserved.

12.4.4.2.1.4 Flexible Filter Enable Mask (Offset 0x03-0x0A)

Bits	Name	Default	Description
15:0	Flexible Filter Enable Mask		

12.4.4.2.1.5 Flexible Filter Data - (Offset 0x0B-0x4A)

Bits	Name	Default	Description
15:0	Flexible Filter Data		

Note: This section loads all of the flexible filters. The control + mask + filter data are repeatable as the number of filters. Section length in offset 0 is for all filters.

12.4.4.2.1.6 Section Footer (Offset Block Length)

Bits	Name	Default	Description
15:8	CRC 8		CRC8 of the previous section.
7:0	Reserved		Reserved.

12.4.5 Configuring Manageability Filters

There are a number of pre-defined filters that are available for the MC to enable, such as ARPs and IPMI ports 0x298 and 0x26F. These are generally enabled by setting the appropriate bit within the PRT_MNG_MANC register using specific commands.

For more advanced filtering needs, the MC has the ability to configure a number of configurable filters. It is a two-step process to use these filters. They must first be configured and then enabled.

12.4.5.1 Manageability Decision Filters

Manageability Decision Filters (MDEF) are a set of eight filters, each with the same structure. The filtering rule for each decision filter is programmed by the MC and defines which of the L2, VLAN, EtherType, and L2/L3 filters participate in decision making. Any packet that passes at least one rule is directed to manageability and possibly to the host.

The inputs to each decision filter are:

- Packet passed a valid management L2 exact address filter.
- Packet is a broadcast packet.
- Packet has a VLAN header and it passed a valid manageability VLAN filter.
- Packet matched one of the valid IPv4 or IPv6 manageability address filters.
- Packet is a multicast packet.
- Packet passed ARP filtering (request or response).
- Packet passed neighbor solicitation filtering.
- Packet passed MLD filtering.
- Packet passed 0x298/0x26F port filter.
- Packet passed a valid flex port filter.
- Packet passed a valid flex TCO filter.
- Packet is an ICMPv4 packet.
- Packet passed or failed an L2 EtherType filter.
- Packet passed or failed Flow Control or NC-SI L2 EtherType Discard filter.

The structure of each decision filter is shown in Figure 12-3. A boxed number indicates that the input is conditioned by a mask bit defined in the MDEF register and MDEF_EXT register for this rule. Decision filter rules are as follows:

- At least one bit must be set in one of the two registers. If all bits are cleared (MDEF/MDEF_EXT = 0x0000), the decision filter is disabled and ignored.
- All enabled AND filters must match for the decision filter to match. An AND filter not enabled in the MDEF/MDEF_EXT registers is ignored. If an AND filter is preceded by a OR filter, at least one of the enabled OR inputs must match for the filter to pass.
- If no OR filter is enabled in the register, the OR filters are ignored in the decision (the filter might still match).
- If one or more OR filters are enabled in the register, at least one of the enabled OR filters must match for the decision filter to match.

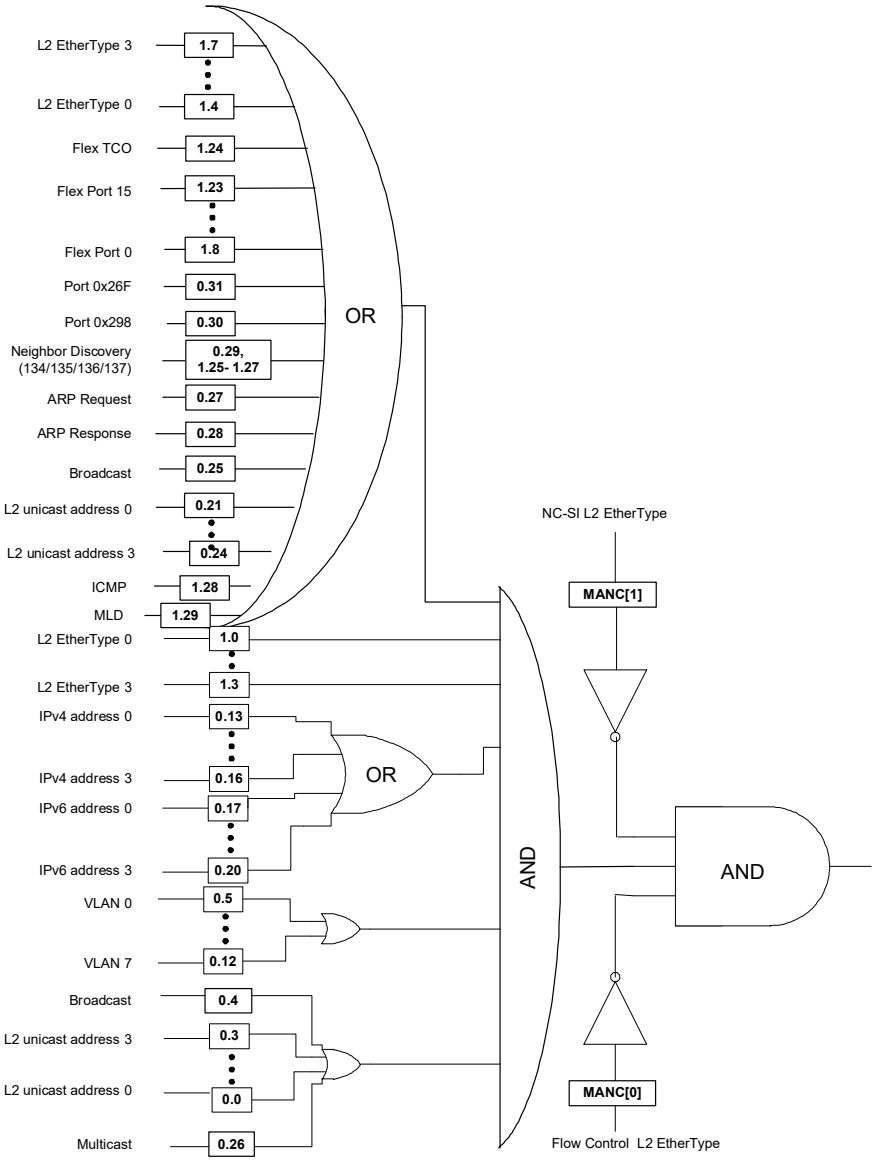

Figure 12-3. Manageability Decision Filters

A decision filter (for any of the eight filters) defines which of the previously described inputs are enabled as part of a filtering rule. The MC programs two 32-bit registers per rule (MDEF[7:0] and MDEF_EXT[7:0]) with the settings as described in Section 13.2.2.29.19 and Section 13.2.2.29.21. A set bit enables its corresponding filter to participate in the filtering decision.

In addition to the controls previously described, the PRT_MNG_MDEF_EXT.*APPLY_TO_HOST_TRAFFIC* and PRT_MNG_MDEF_EXT.*APPLY_TO_NETWORK_TRAFFIC* bits define which traffic is compared to this filter. At least one of these bits must be set for the filter to be valid.

If the PRT_MNG_MDEF_EXT.*APPLY_TO_HOST_TRAFFIC* bit is set, the traffic from the host is a candidate for this filter. If the PRT_MNG_MDEF_EXT.*apply_to_network_traffic* bit is set, the traffic from the network is a candidate for this filter. If both bits are set, this filter is applied to all traffic.

12.4.5.2 Exclusive Traffic

The decisions regarding forwarding of packets to the host for LAN traffic or to the LAN for host traffic are independent from the management decision filters. However, the MC might define some types of traffic as exclusive. The behavior for such traffic is defined by the using the bits corresponding to the decision filter in the PRT_MNG_MNGONLY register (one bit per each of the eight decision rules) and the PRT_MNG_MDEF_EXT.*APPLY_TO_HOST_TRAFFIC* and PRT_MNG_MDEF_EXT.*APPLY_TO_NETWORK_TRAFFIC* bits.

Table 12-8 lists the behavior in each case. If one or more filters match the traffic and at least one of the filters is set as exclusive, the traffic is treated as exclusive.

Table 12-8. Exclusive Traffic Behavior

Traffic Source	Filter Matches		Filter Does Not Match
	PRT_MNG_MNGONLY = 0	PRT_MNG_MNGONLY = 1	
From Network	Traffic is forwarded to manageability. Traffic is forwarded to the host according to host filtering.	Traffic is forwarded only to manageability.	Traffic is forwarded to the host according to host filtering.
From Host	Traffic is forwarded to manageability and to the LAN.	Traffic is forwarded only to manageability.	Traffic is forwarded to the LAN.

Any traffic matching any of the configurable filters (see Section 12.4.5.1) can be used as filters to pass traffic to the host.

Table 12-9. PRT_MNG_MNGONLY Register Description and Usage

Bits	Description	Default
0	Decision Filter 0	Determines if packets that have passed decision filter 0 are sent exclusively to the manageability path.
1	Decision Filter 1	Determines if packets that have passed decision filter 1 are sent exclusively to the manageability path.
2	Decision Filter 2	Determines if packets that have passed decision filter 2 are sent exclusively to the manageability path.
3	Decision Filter 3	Determines if packets that have passed decision filter 3 are sent exclusively to the manageability path.
4	Decision Filter 4	Determines if packets that have passed decision filter 4 are sent exclusively to the manageability path.
5	Unicast and Mixed	NC-SI mode: Determines if unicast and mixed packets are sent exclusively to the manageability path. SMBus mode: Determines if packets that have passed decision filter 5 are sent exclusively to the manageability path.
6	Global Multicast	NC-SI mode: Determines if multicast packets are sent exclusively to the manageability path. SMBus mode: Determines if packets that have passed decision filter 6 are sent exclusively to the manageability path.
7	Broadcast	NC-SI mode: Determines if broadcast packets are sent exclusively to the manageability path. SMBus mode: Determines if ARP packets are sent exclusively to the manageability path.
31:8	Reserved	Reserved.

PRT_MNG_MNGONLY is configurable when using NC-SI using the Set Intel Filters — Manageability Only command (see Section 12.6.4.5.2).

All manageability filters are controlled by the MC only and not by the LAN software device driver.

12.4.5.3 Global Controls

On top of the PRT_MNG_MDEF filters, the PRT_MNG_MANC registers contain some global controls applied to all the packets in order to be a candidate for manageability filtering:

- Receive enable bits:
  - The *RCV_TCO_EN* field controls the reception of manageability traffic. It should be set only if one of the following bits is also set.
  - The *EN_BMC2OS* bit controls the reception of manageability traffic from the host.
  - The *EN_BMC2NET* bit controls the reception of manageability traffic from the network.
- VLAN filtering — To support the NC-SI VLAN modes, the following controls are provided:
  - The *FIXED_NET_TYPE* field controls if only VLAN tagged or VLAN untagged traffic is received. If this bit is cleared, both types are received. If it is set, only the type described by the *NET_TYPE* field is accepted.
  - If set, the *NET_TYPE* field indicates that only VLAN tagged traffic is received, if cleared only packets without VLAN is accepted. This field is validated by the *FIXED_NET_TYPE* field.

  Both fields relate to the inner VLAN.

Table 12-10 lists the relationship between the previously mentioned bits and the forwarding decisions:

Table 12-10. PRT_MNG_MANC Bits Impact

CASE\ PRT_MNG_MANC Bits	RCV_TCO_EN=0b	FIXED_NET_TYPE=1b and NET_TYPE!= What's in the Packet	EN_BMC2OS=0b (Assume EN_BMC2NET=1b)	EN_BMC2NET=0b (Assume EN_BMC2HOST=1b)
Packet sent from host and hits MDEF filters. (host-to-MC traffic)	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is sent to the MC.
Packet sent from host and matches one of the EMP VSI. (host-to-EMP traffic).	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.
Packet received from LAN and hits MDEF filters. (LAN-to-MC traffic)	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is sent to the MC.	Packet is not sent to the MC.
Packet received from LAN and matches on of the EMP VSI. (LAN-to-EMP traffic)	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.
Packet sent from EMP and matches one of the host VSIs. (EMP-to-host traffic)	Packet is sent to the host (and optionally to the LAN).	Packet is sent to the host (and optionally to the LAN).	Packet is sent to the host (and optionally to the LAN).	Packet is sent to the host (and optionally to the LAN).
Packet sent from the EMP and does not match one of the host VSIs. (EMP-to-LAN traffic)	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.
Packet sent from the MC and matches one of the host VSIs. (MC-to-host traffic)	Packet is sent to the host (and optionally to the LAN).	Packet is sent to the host (and optionally to the LAN).	Packet is sent to the LAN.	Packet is sent to the host (and optionally to the LAN).
Packet sent from the MC and does not match one of the host VSIs. (MC-to-LAN traffic)	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is not sent to the LAN (optionally sent to host).

12.4.6 Filtering Programming Interfaces

The E810 provides multiple options to program the forwarding filters, depending on the interface used and the level of flexibility needed. The Table 12-11 lists the different options and points to the description of the relevant commands.

Table 12-11. Filtering Programming Interfaces

Interface	Flexible/Abstract	Description
NC-SI (over RMII or over MCTP)	Abstract (dedicated MAC Address)	The regular NC-SI commands can be used to enable forwarding based on a dedicated MAC Address. The list of supported commands can be found in Section 12.6.2.1. When using these commands, one of the two other modes can be used to add finer grain filtering.
	Abstract (Shared MAC and IP)	The Intel OEM commands described in Section 12.4.6.1 and in Section 12.6.4.14 can be used to define which part of the shared MAC or shared IP traffic should be forwarded. When using these commands, the flexible filtering interface should not be used. This mode is activated using the *Set Shared Mode* command (Section 12.6.4.14.12.1)
	Flexible	This interface described in most of the sub-sections of Section 12.6.4. It uses the packet reduction commands to reduce the forwarding scope of the filters set by the regular NC-SI commands and the packet addition commands to add new packet types to the forwarding rules.

12.4.6.1 Shared MAC and Shared IP Support

The E810 operates in systems where the same MAC and IP are shared between a platform's host operating system and its MC. To support such systems, the E810 supports additional shared MAC filtering options on top of what was supported in previous products. This section describes these options and the NC-SI commands used to program them.

Note: All filtering capabilities are exposed via the regular NC-SI packet reduction and packet addition commands and via the SMBus Set Filtering command. The interface described in this section is a more abstract NC-SI interface.

12.4.6.1.1 Sharing an IP and MAC Address

NC-SI over MCTP is used in desktop and mobile platforms. These platforms are typically used in enterprise environments outside of a data center. IP subnets in these environments are commonly designed such that more than 50% of their available addresses are assigned.

Hence, assigning a second IP Address to an MC would generally necessitate a subnet redesign. Instead, a single IP Address is typically shared between the host operating system and an MC in these platforms.

Because it is possible to bind multiple IP Addresses to a single MAC Address, the E810 needs to know the IP Address shared by an MC to deliver packets to it. An MC uses the Set IP Address command to communicate its IP Address to the E810. The Set IP Address command is defined in Section 12.6.4.14.1.

To notify the E810 that the MC intends to use a shared MAC, the Set Shared Mode command (Section 12.6.4.14.12.1) should be given before programming any filter using the regular NC-SI commands (Set MAC Address or Set VLAN) or the Intel OEM commands (Section 12.6.4.14).

12.4.6.1.1.1 TCP/UDP Ports Owned by an MC

A small subset of the TCP and UDP ports might be dedicated to an MC. The remaining ports are assigned to the host operating system. Hence, port-based filtering and the commands to configure it are required. For example, port-based filtering would be used to route WS-management packets to an MC.

The E810 needs to know the ports owned by an MC to deliver packets to it. An MC uses the Set Port command to communicate its ports to the E810. The Set Port command is defined in Section 12.6.4.14.3. The E810 supports 10 port filters.

The Set Binding command is used to define the combination of MAC, VLAN, IP and ports that should be met to forward packets to the MC (see Section 12.6.4.14.10 for more details).

12.4.6.1.1.2 Sharing Network Infrastructure Packets

In addition to management traffic, an MC needs to monitor network infrastructure traffic along with the host. For each flow, it is possible to define if it should include host traffic only, both host and network, or only network.

12.4.6.1.1.3 ARP Filters Enhancement

ARP request message filtering is controlled by the Enable Broadcast Filter command. However, as currently defined, this command causes either all or no ARP requests to go to an MC. For MCTP over SMBus, attempting to forward all ARP requests within a subnet to an MC can easily overwhelm the available bandwidth. Therefore, an option to have the E810 forward only ARP requests that contain a Target IP Address value that matches the IP Address used by an MC. An amendment to the Enable Broadcast Filter command is defined in the sections that follow to address this requirement.

12.4.7 Possible Configurations

This section describes ways of using management filters. Actual usage might vary.

12.4.7.1 Dedicated MAC Packet Filtering

1. Select one of the eight rules for dedicated MAC filtering.
2. Load the host MAC Address to one of the management MAC Address filters and set the appropriate bit in field 3:0 of the MDEF register.
3. Set other bits to qualify which packets are allowed to pass through. For example:
   - Set Bit 5 in the MDEF register to qualify with the first manageability VLAN.
   - Set relevant Bits 13 to 20 in the MDEF register to qualify with a match to one of the IP Addresses.
   - Set any L3/L4 bits (Bits 27 to 31 in the MDEF register and Bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

12.4.7.2 Broadcast Packet Filtering

1. Select one of the eight rules for broadcast filtering.
2. Set Bit 25 in the MDEF register of the decision rule to enforce broadcast filtering.
3. Set other bits to qualify which broadcast packets are allowed to pass through. For example:
   - Set Bit 5 in the MDEF register to qualify with the first manageability VLAN.
   - Set relevant Bits 13 to 20 in the MDEF register to qualify with a match to one of the IP Addresses.
   - Set any L3/L4 bits (Bits 27 to 31 in the MDEF register and Bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

12.4.7.3 VLAN Packet Filtering

1. Select one of the eight rules for VLAN filtering.
2. Set Bits 5 to 12 in the MDEF register to qualify with the relevant manageability VLANs.
3. Set other bits to qualify which VLAN packets are allowed to pass through. For example:
   - Set any L3/L4 bits (Bits 27 to 31 in the MDEF register and Bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

12.4.7.4 IPv6 Filtering

IPv6 filtering is done using the following IPv6-specific filters:

- **IP Unicast Filtering** — Requires filtering for link local address and a global address. Filtering setup might depend on whether or not the MAC Address is shared with the host or dedicated to manageability:
  - — Dedicated MAC Address (for example, dynamic address allocation with DHCP does not support multiple IP Addresses for one MAC Address). In this case, filtering can be done at L2 using two dedicated unicast MAC filters.
  - — Shared MAC Address (for example, static address allocation sharing addresses with host). In this case, filtering needs to be done at L3, requiring two IPv6 Address filters, one per address.
- **A Neighbor Discovery Filter** — The E810 supports IPv6 neighbor discovery protocol. Since the protocol relies on multicast packets, the E810 supports filtering of these packets. IPv6 multicast addresses are translated into corresponding Ethernet multicast addresses in the form of 33-33-xx-xx-xx-xx, where the last 32 bits of the address are taken from the last 32 bits of the IPv6 multicast address. As a result, two direct MAC filters can be used to filter IPv6 solicited-node multicast packets as well as IPv6 all node multicast packets.

12.4.7.5 Receive Filtering with Shared IP

When using the legacy SMBus interface or the MCTP interface, it is possible to share the host MAC and IP Address with an MC. This functionality is also available when using base NC-SI using Intel OEM commands.

When an MC shares the MAC and IP Address with the host, receive filtering is based on identifying specific flows through port allocation. The following setting might be used when using the legacy SMBus interface:

1. Select one of the eight rules.
2. Set a manageability dedicated MAC filter to the host MAC Address and set the matching bit (0-3) in the MDEF register.
3. If VLAN is used for management, load one or more management VLAN filters and set the matching bit (5-12) in the MDEF register.

ARP filter/neighbor discovery filter is enabled when an MC is responsible for handling the ARP protocol. Set Bit 27 or Bit 28 in the MDEF register for this functionality.

In NC-SI over MCTP, dedicated commands are used to enable shared IP filtering.

12.4.8 Determining Manageability MAC Address

If an MC needs to use a dedicated MAC Address or configure the automatic ARP response mechanism (only available in SMBus mode), it might be beneficial for an MC to be able to determine the MAC Address used by the host.

Both the NC-SI and SMBus interfaces provide an Intel OEM command to read the system MAC Address.

A possible use for this is that the MAC Address programmed at manufacturing time does not increment by one each time, but rather by two. In this way, an MC can read the system MAC Address and add one to it and be guaranteed of a unique MAC Address.

Note: Determining the IP Address being used by the host is beyond the scope of this document.

12.5 OS-to-BMC Traffic

12.5.1 Overview

Traditionally, the communication between a host and a local MC is not handled through the network interface and requires a dedicated interface, such as an IPMI KCS interface. The E810 enables the host and the local MC communication via the regular pass-through interface, and thus enable management of a local console using the same interface used to manage any MC in the network.

When this flow is used, the host sends packets to an MC through the network interface. The E810 examines these packets and then decides if they should be forwarded to an MC. On the inverse path, when an MC sends a packet on the pass-through interface, the E810 checks if it should be forwarded to the network, the host, or both. Figure 12-4 describes the flow for OS-to-BMC traffic for the NC-SI over RBT case. OS2BMC is also available when operating over MCTP.

The OS-to-BMC flow can be enabled using the *OS2BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the NVM.

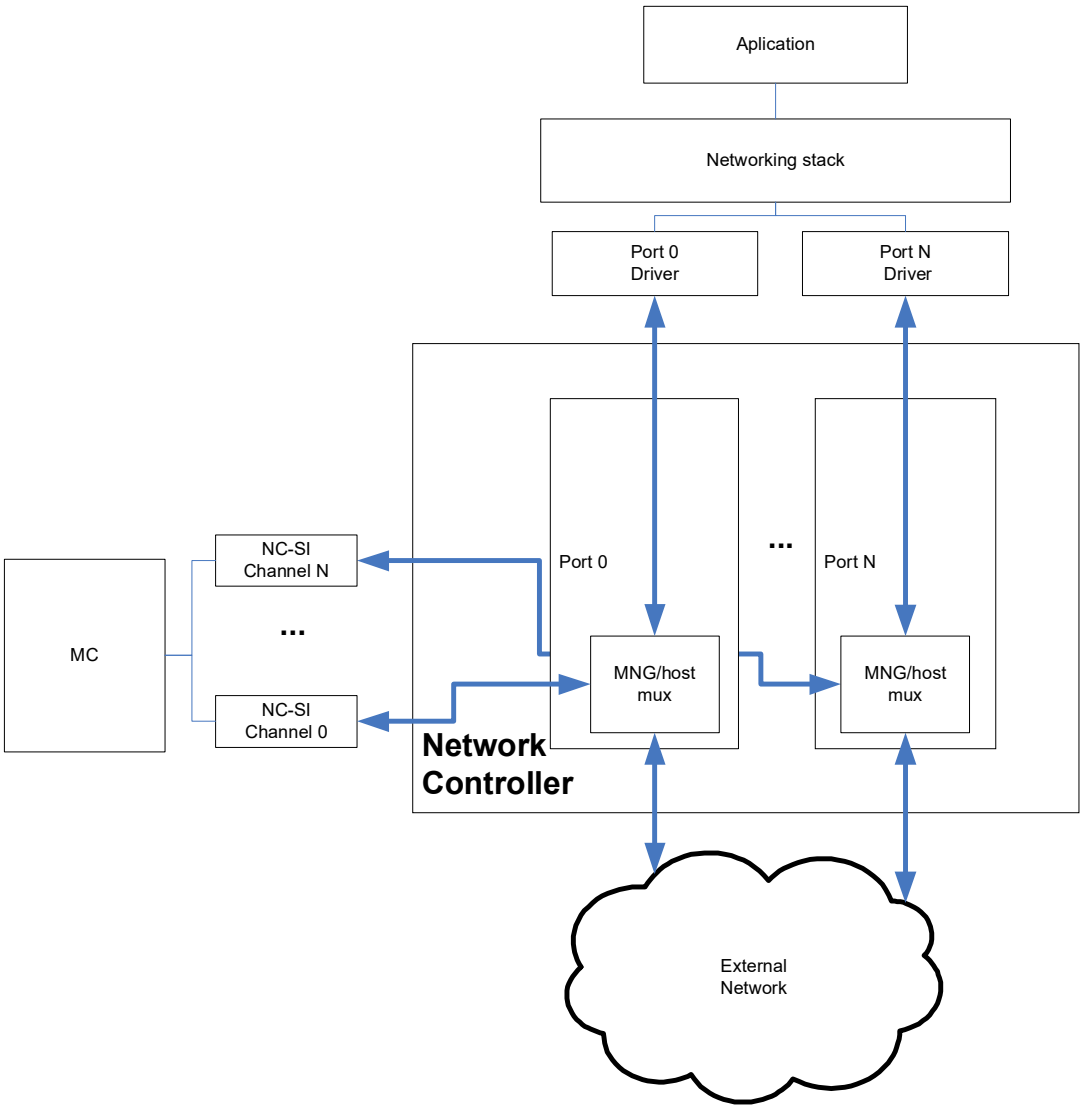

Figure 12-4. OS-to-BMC Flow

The OS-to-BMC flow is enabled only for ports enabled by the NC-SI Enable Channel command or via the *OS2BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the NVM.

OS-to-BMC traffic must comply with NC-SI specifications and is therefore limited to maximum sized frames of 1536 bytes (in both directions).

12.5.2 Filtering

12.5.2.1 OS-to-BMC Filtering

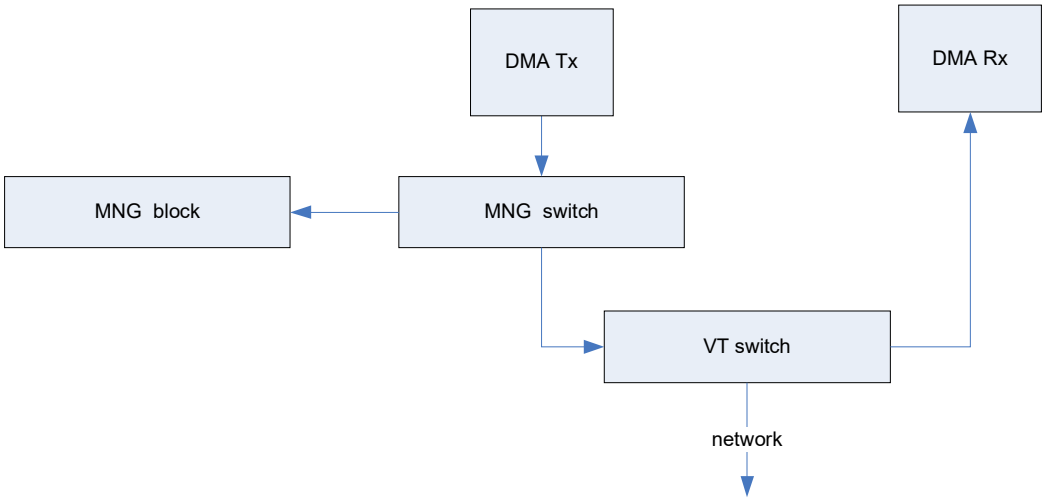

Figure 12-5. OS-to-BMC and VM-to-VM Filtering

12.5.2.2 BMC-to-OS Filtering

The flow used to filter packets from the BMC to the host is similar to the filtering of receive traffic.

Note: Traffic sent from the MC does not cause a PME event, even if it matches one of the wake-up filters set by the port.

12.5.3 Blocking Network-to-BMC Flow

In some systems the MC might have its own private connection to the network and might use a E810 port only for the OS-to-BMC traffic. In this case, the BMC-to-network flow should be blocked while enabling the OS-to-BMC and OS-to-network flows.

This can be done by clearing the PRT_MNG_MANC.*EN_BMC2NET* bit for the relevant port. The MC can control this functionality using the Enable Network-to-BMC flow and Disable Network-to-BMC flow NC-SI OEM commands. This can also be controlled using the *Network to BMC disable* field in the NVM OS2BMC Configuration Structure.

Note: The NC-SI channel should not be enabled for receive or transmit before at least one of the PRT_MNG_MANC.*EN_BMC2NET* or PRT_MNG_MANC.*EN_BMC2OS* fields is set, unless only used for AEN transmissions. In this case, the channel might be enabled for receive, but all receive filters should be cleared.

12.5.4 OS-to-BMC and Flow Control

The traffic between the host and manageability uses the same buffers as any loopback traffic. Thus, it flows through the transmit buffer and then through the receive buffer. If the transmit buffer is flow controlled, then the host-to-MC traffic is also stopped. If the receive buffer is full, the traffic is dropped or the transmit is stopped according to the flow control policy of this traffic class.

Packets received by manageability (either from the host or from the network) might be dropped if the manageability internal buffers are full.

12.5.5 Statistics

Packets sent from the operating system to the MC should be counted by all statistical counters as packets sent by the operating system. If they are sent to both the network and to the MC, they are counted once.

Packets sent from the MC to the host are counted as packets received by the host. If they are sent to the host and to the network, they are counted both as received packets and as packet transmitted to the network.

See Section 9.6.5 for details of the statistics hierarchy.

12.5.6 OS-to-BMC Enablement

The E810 supports the unified network software model for OS-to-BMC traffic, where the OS-to-BMC traffic is shared with the regular traffic. In this model, there is no need for a special configuration of the operating networking stack or the BMC stack, but if the link is down, the OS-to-BMC communication is stopped.

To enable OS-to-BMC, either:

- Enable *OS2BMC* in the port traffic type field in the Traffic Type Parameters NVM word for the relevant port.
- Send an Enable Network-to-BMC command.

Note: When *OS2BMC* is enabled, the operating system must avoid sending packets longer than 1.5 KB to the MC. Such packets are dropped.

12.5.7 SMBus Troubleshooting

This section outlines the most common issues found while working with PT using the SMBus sideband interface.

12.5.7.1 TCO Alert Line Stays Asserted After a Power Cycle

After the E810 resets, all its ports indicate a status change. If the MC only reads status from one port (slave address), the other one continues to assert the TCO alert line.

Ideally, the MC should use the ARA transaction to determine which slave asserted the TCO alert. Many customers only want to use one port for manageability, thus using ARA might not be optimal.

An alternative to using ARA is to configure part of the ports to not report status and to set its SMBus timeout period. In this case, the SMBus timeout period determines how long a port asserts the TCO alert line awaiting a status read from a MC; by default this value is zero (indicates an infinite timeout).

The SMBus configuration section of the NVM has a *SMBus Notification Timeout* (ms) field that can be set to a recommended value of 0xFF (for this issue). Note that this timeout value is for all slave addresses. Along with setting the *SMBus Notification Timeout* to 0xFF, it is recommended that the other ports be configured in the NVM to disable status alerting. This is accomplished by having the *Enable Status Reporting* bit set to 0b for the desired ports in the LAN configuration section of the NVM.

The third solution for this issue is to have the MC hard-code the slave addresses to always read from all ports. As with the previous solution, it is recommend that the other ports have status reporting disabled.

12.5.7.2 When SMBus Commands are Always NACK'd

There are several reasons why all commands sent to the E810 from a MC could be NACK'd. The following are most common:

- **Invalid NVM Image** — The image itself might be invalid or it could be a valid image and is not a PT image. As such, SMBus connectivity is disabled.
- **The MC is not using the correct SMBus address** — Many MC vendors hard-code the SMBus address(es) into their firmware. If the incorrect values are hard-coded, the E810 does not respond.
  - The SMBus address(es) can be dynamically set using the SMBus ARP mechanism.
- **The MC is using the incorrect SMBus interface** — The NVM might be configured to use one physical SMBus port. However, the MC is physically connected to a different one.
- **Bus Interference** — The bus connecting the MC and the E810 might be unstable.

12.5.7.3 SMBus Clock Speed is 16.6666 KHz

This can happen when the SMBus connecting the MC and the E810 is also tied into another device (such as an ICH) that has a maximum clock speed of 16.6666 KHz. The solution is to not connect the SMBus between the E810 and the MC to this device.

12.5.7.4 A Network-Based Host Application is Not Receiving Any Network Packets

Reports have been received about an application not receiving any network packets. The application in question was NFS under Linux. The problem was that the application was using the RMPC/RMCP+ IANA reserved port 0x26F (623) and the system was also configured for a shared MAC and IP Address with the operating system and the MC.

The management control to host configuration, in this situation, was setup not to send RMCP traffic to the operating system (this is typically the correct configuration). This means that no traffic send to port 623 was being routed.

The solution in this case is to configure the problematic application NOT to use the reserved port 0x26F.

12.5.7.5 Unable to Transmit Packets from the MC

If the MC has been transmitting and receiving data without issue for a period of time and then begins to receive NACKs from the E810 when it attempts to write a packet, the problem is most likely due to the fact that the buffers internal to the E810 are full of data that has been received from the network but has yet to be read by the MC.

Being an embedded device, the E810 has limited buffers that are shared for receiving and transmitting data. If a MC does not keep the incoming data read, the E810 can be filled up. This prevents the MC form transmitting more data, resulting in NACKs.

If this situation occurs, the recommended solution is to have the MC issue a Receive Enable command to disable more incoming data, read all the data from the E810, and then use the Receive Enable command to enable incoming data.

12.5.7.6 SMBus Fragment Size

The SMBus specification indicates a maximum SMBus transaction size of 32 bytes. Most of the data passed between the E810 and the MC over the SMBus is RMCP/RMCP+ traffic, which by its very nature (UDP traffic) is significantly larger than 32 bytes in length. Multiple SMBus transactions might therefore be required to move data from the E810 to the MC or to send a data from the MC to the E810.

Recognizing this bottleneck, the E810 handles up to 240 bytes of data in a single transaction. This is a configurable setting in the NVM. The default value in the NVM images is 32, per the SMBus specification. If performance is an issue, increase this size.

During initialization, firmware within the E810 allocates buffers based upon the SMBus fragment size setting within the NVM. E810 firmware has a finite amount of RAM for its use: the larger the SMBus fragment size, the fewer buffers it can allocate. Because this is true, MC implementations must take care to send data over the SMBus efficiently.

For example, E810 firmware has 3 KB of RAM it can use for buffering SMBus fragments. If the SMBus fragment size is 32 bytes, the firmware could allocate 96 buffers of size 32 bytes each. As a result, the MC could then send a large packet of data (such as KVM) that is 800 bytes in size in 25 fragments of size 32 bytes apiece. However, this might not be the most efficient way because the MC must break the 800 bytes of data into 25 fragments and send each one at a time.

If the SMBus fragment size is changed to 240 bytes, E810 firmware can create 12 buffers of 240 bytes each to receive SMBus fragments. The MC can now send that same 800 bytes of KVM data in only four fragments, which is much more efficient.

The problem of changing the SMBus fragment size in the NVM is if the MC does not also reflect this change. If a programmer changes the SMBus fragment size in the E810 to 240 bytes and then wants to send 800 bytes of KVM data, the MC can still only send the data in 32 byte fragments. As a result, firmware runs out of memory. This is because firmware created the 12 buffers of 240 bytes each for fragments; however, the MC is only sending fragments of size 32 bytes. This results in a memory waste of 208 bytes per fragment. Then when the MC attempts to send more than 12 fragments in a single transaction, the E810 NACKs the SMBus transaction due to not enough memory to store the KVM data.

In summary, if a programmer increases the size of the SMBus fragment size in the NVM (recommended for efficiency purposes) take care to ensure that the MC implementation reflects this change and uses that fragment size to its fullest when sending SMBus fragments.

12.5.7.7 Losing Link

Normal behavior for the Ethernet controller when the system powers down or performs a reset is for the link to temporarily go down and then back up again to re-negotiate the link speed. This behavior can have adverse affects on manageability.

For example, if there is an active FTP or Serial over LAN (SoL) session to the MC, this connection can be lost. To avoid this possible situation, the MC can use the Management Control command (detailed in Section 12.6.4.10) to ensure the link stays active at all times. This command is available when using the NC-SI sideband interface as well.

Care should be taken with this command, if the software device driver negotiates the maximum link speed, the link speed remains the same when the system powers down or resets. This can have undesirable power consumption consequences. Currently, when using NC-SI, the MC can re-negotiate the link speed. That functionality is not available when using the SMBus interface.

12.5.7.8 Enable Checksum Filtering

If checksum filtering is enabled, the MC does not need to perform the task of checking this checksum for incoming packets. Only packets that have a valid checksum is passed to the MC. All others are silently discarded.

This is a way to offload some work from the MC.

12.5.7.9 Still Having Problems?

If problems still exist, contact your field representative. Be prepared to provide the following:

- A SMBus trace if possible.
- A dump of the NVM image. This should be taken from the actual E810, rather than the NVM image provided by Intel. Parts of the NVM image are changed after writing (such as the physical NVM size).

12.6 Network Controller Sideband Interface (NC-SI) PT Interface

The NC-SI is a DMTF industry standard protocol for the sideband interface. NC-SI uses a modified version of the industry standard RMII interface for the physical layer (RBT) as well as defining a new logical layer.

The NC-SI specification can be found at:

http://www.dmtf.org/

12.6.1 Overview

12.6.1.1 Terminology

The terminology in this section is taken from the NC-SI specification.

Table 12-12. NC-SI Terminology

Term	Definition
Channel	The control logic and data paths supporting NC-SI pass-through operation on a single network interface (port). A network controller that has multiple network interface ports can support an equivalent number of NC-SI channels.
Channel Arbitration	Refers to operations where more than one of the network controller channels can be enabled to transmit pass-through packets to the BMC at the same time, where arbitration of access to the RXD, CRS_DV, and RX_ER signal lines is accomplished either by software of hardware means.
Control Traffic/Messages/Packets	Command, response, and notification packets transmitted between BMC and the E810 for the purpose of managing NC-SI.
External Network Interface	The interface of the network controller that provides connectivity to the external network infrastructure (port).
Frame vs. Packet	Frame is used in reference to Ethernet, whereas packet is used everywhere else.
Integrated Controller	The term integrated controller refers to a network controller device that supports two or more channels for NC-SI that share a common NC-SI physical interface. For example, a network controller that has two or more physical network ports and a single NC-SI bus connection.
Interface	This refers to the entire physical interface, such as both the transmit and receive interface between the management controller and the network controller.
Internal Host Interface	The interface of the network controller that provides connectivity to the host OS running on the platform.
Logically Enabled/Disabled NC	Refers to the state of the network controller wherein pass-through traffic is able/unable to flow through the sideband interface to and from the management controller, as a result of issuing Enable/Disable Channel command.
Management Controller (MC or BMC)	An intelligent entity comprising of hardware/firmware/software, that resides within a platform and is responsible for some or all management functions associated with the platform (BMC, service processor, and so on).
Multi-Drop	Multi-drop commonly refers to the case where multiple physical communication devices share an electrically common bus, and a single device acts as the master of the bus and communicates with multiple slave or target devices. In NC-SI, a management controller serves the role as the master, and the network controllers are the target devices.
NC Rx	Defined as the direction of ingress traffic on the external network controller interface.
NC Tx	Defined as the direction of egress traffic on the external network controller interface.

Table 12-12. NC-SI Terminology [continued]

Term	Definition
NC-SI Rx	Defined as the direction of ingress traffic on the sideband enhanced NC-SI interface with respect to the network controller.
NC-SI Tx	Defined as the direction of egress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.
Network Controller (NC)	The component within a system that is responsible for providing connectivity to the external Ethernet network world.
Network Controller Sideband Interface	The interface of the network controller that provides connectivity to a management controller. It can be shorten to sideband interface as appropriate in the context.
Package	One or more NC-SI channels in a network controller that share a common set of electrical buffers and common buffer control for the NC-SI bus. Typically, there will be a single, logical NC-SI package for a single physical network controller package (chip or module). However, the specification allows a single physical chip or module to hold multiple NC-SI logical packages.
Pass-Through Traffic/Messages/Packets	Non-control packets passed between the external network and the BMC through the E810.
Point-to-Point	Point-to-point commonly refers to the case where only two physical communication devices are interconnected via a physical communication medium. The devices might be in a master/slave relationship, or could be peers. In NC-SI, point-to-point operation refers to the situation where only a single management controller and single network controller package are used on the bus in a master/slave relationship where the management controller is the master.
Remote Media	The capability to allow remote media devices to appear as if they were attached locally to the host.

12.6.1.2 System Topology

In NC-SI, each physical endpoint (NC package) can have several logical slaves (NC channels). NC-SI defines that one MC and up to four network controller packages can be connected to the same NC-SI link.

Figure 12-6 shows an example topology for a single MC (also know as BMC) and a single NC package. In this example, the NC package has two NC channels.

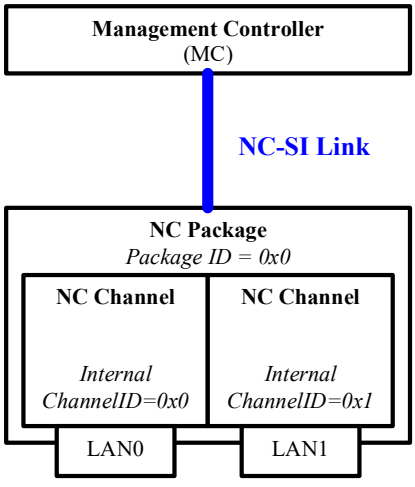

Figure 12-6. Single NC Package, Two NC Channels

Figure 12-7 shows an example topology for a single MC and two NC packages. In this example, one NC package has two NC channels and the other has only one NC channel. Scenarios in which the NC-SI lines are shared by multiple NCs (Figure 12-7) mandate an arbitration mechanism.

The arbitration mechanism is described in Section 12.6.9.1.

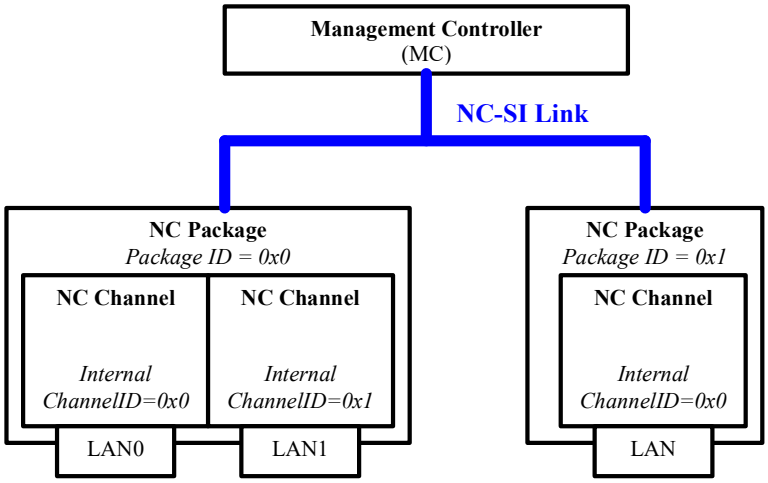

Figure 12-7. Two NC Packages (Left: with Two NC Channels, Right: with One NC Channel)

Note: Channel numbers should match PCI function numbers. If more than one function is defined on a port, the function with the lowest value associated with this port is used. See Section 12.3.2.2.2 for details.

12.6.1.3 Data Transport

Since NC-SI is based upon the RMII transport layer, data is transferred in the form of Ethernet frames.

NC-SI defines two types of transmitted frames:

- Control frames:
  - Configures and controls the interface.
  - Identified by a unique EtherType in their L2 header.
- Pass-through frames:
  - Actual LAN pass-through frames transferred from/to the MC.
  - Identified as not being a control frame.
  - Attributed to a specific NC channel by their source MAC Address (as configured in the NC by the MC).

12.6.1.3.1 Control Frames

NC-SI control frames are identified by a unique NC-SI EtherType (0x88F8).

Control frames are used in a single-threaded operation, meaning commands are generated only by the MC and can only be sent one at a time. Each command from the MC is followed by a single response from the NC (command-response flow), after which the MC is allowed to send a new command.

The only exception to the command-response flow is the Asynchronous Event Notification (AEN). These control frames are sent unsolicited from the NC to the MC.

AEN functionality by the NC must be disabled by default, until activated by the MC using the AEN Enable commands.

To be considered a valid command, a control frame must:

- Comply with the NC-SI header format.
- Be targeted to a valid channel in the package via the Package ID and Channel ID fields. For example, to target a NC channel with package ID of 0x2 and internal channel ID of 0x5, the MC must set the channel ID inside the control frame to 0x45. The channel ID is composed of three bits of package ID and five bits of internal channel ID.
- Contain a correct payload checksum (if used).
- Meet any other condition defined by NC-SI.

There are also commands (such as select package) targeted to the package as a whole. These commands must use an internal channel ID of 0x1F.

For details, refer to the NC-SI specification.

12.6.1.3.2 NC-SI Frames Receive Flow

Figure 12-8 shows the flow for frames received on the NC from the MC.

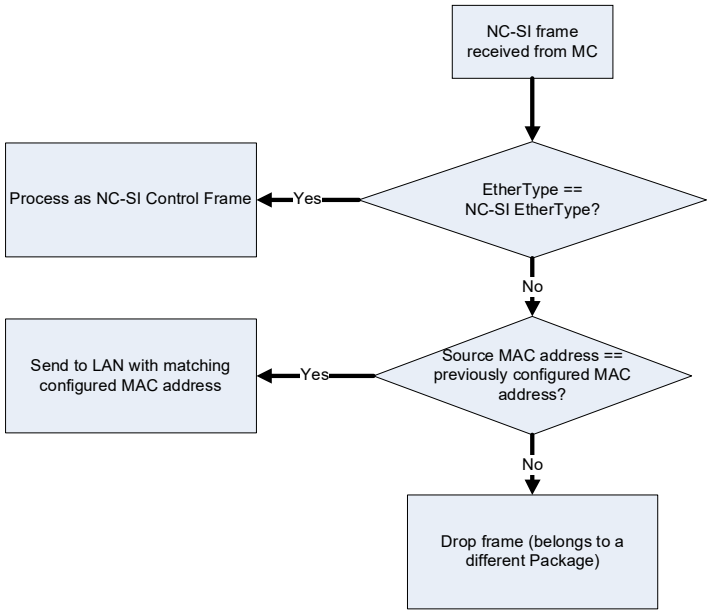

Figure 12-8. NC-SI Frames Receive Flow for the NC

12.6.2 NC-SI Standard Support

12.6.2.1 Supported Features

The E810 supports all the mandatory features of the NC-SI specification. Table 12-13 lists the support for standard NC-SI commands.

The E810 supports NC-SI 1.1.0.

Table 12-13. NC-SI Commands Support

Command	Support over RMII	Supported over MCTP with Pass-Through	Supported over MCTP without Pass-Through
Clear Initial State	Yes	Yes	Yes
Get Version ID	Yes	Yes	Yes
Get Parameters	Yes	Yes	Yes
Get Controller Packet Statistics	Yes (partially)	Yes (partially)	Yes (partially)
Get Link Status	Yes	Yes	Yes
Enable Channel	Yes	Yes	Yes
Disable Channel	Yes	Yes	Yes
Reset Channel	Yes	Yes	Yes
Enable VLAN	Yes[1,2]	Yes[1]	No[3]
Disable VLAN	Yes	Yes	No[3]
Enable Broadcast Filter	Yes	Yes	No[3]
Disable Broadcast Filter	Yes	Yes	No[3]
Set MAC Address	Yes	Yes	No[3]
Get NC-SI Statistics	Yes	Yes	Yes
Set NC-SI Flow Control	Yes	No	No[3]
Set Link Command	Yes	Yes	Yes
Enable Global Multicast Filter	Yes	Yes	No[3]
Disable Global Multicast Filter	Yes	Yes	No[3]
Get Capabilities	Yes	Yes	Yes[4]
Set VLAN Filters	Yes	Yes	No[3]
AEN Enable	Yes	Yes	Yes
Get NC-SI Pass-Through Statistics	Yes (partially)	Yes (partially)	No[3]
Select Package	Yes	Yes	Yes
Deselect Package	Yes	Yes	Yes
Enable Channel Network Tx	Yes	Yes	No
Disable Channel Network Tx	Yes	Yes	No
Get Package Status[5]	Yes	No	No
Get Package UUID[5]	Yes	Yes	Yes
PLDM Request[5]	No	No	No
OEM Command[6]	Yes	Yes	Yes

Table 12-13. NC-SI Commands Support [continued]

Command	Support over RMII	Supported over MCTP with Pass-Through	Supported over MCTP without Pass-Through
Get Supported Media	No	Yes	Yes
Transport Specific AEN Enable	No	Yes	Yes
Get MC MAC Address[7]	Yes	Yes	Yes

1. In cases that one of the LAN devices is assigned for the sole use of the manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation, results in the lowest possible speed chosen. To enable link of higher a speed, the MC should not advertise speeds that are below the desired link speed. When doing it, changing the power state of the LAN device has no effect and the link speed is not re-negotiated.
2. The E810 does not support filtering of User Priority/CFI bits of VLAN.
3. In MCTP without PT mode, only control commands are supported and not PT traffic. Thus many of the regular NC-SI commands are not supported or are supported in a limited manner, only to enable control and status reporting for the device.
4. When PT is disabled, the Get Capabilities command does not expose all the filtering capabilities of the device.
5. Only relevant in NC-SI 1.1.
6. See Section 12.6.3.2 for details.
7. 7.This command is defined in DSP0222 NC-SI 1.2 draft.

Table 12-14 lists optional features supported and the level of support for partially supported commands.

Table 12-14. Optional NC-SI Features Support

Feature	Implement	Details
AENs	Yes	The following AENs are supported: • Link Change AEN • Configuration Required AEN • Driver Status Change AEN • Medium Change AEN (over MCTP) • Initialization error AEN (Intel OEM AEN) The Driver state AEN might be emitted up to one minute after actual driver change if the driver was taken down unexpectedly.
Get Controller Packet Statistics command	Yes (partially)	Supports the following counters[1]: 0-8, 11-16, 21-36[2]. The statistics are not cleared between reads. ***Note:*** The packets counted by counter #35 (1523-9022 byte frames transmitted) are up to 9522 bytes and not 9022 as requested in the specification. If a core reset occurs between reads of statistics, the *Counters Cleared From Last Read* flags are set in the response.
Get NC-SI Statistics	Yes	Supports all the counters[3]. ***Note:*** If a core reset occurs between reads of statistics, the reported statistics might be wrong.
Get NC-SI Pass-Through Statistics	Yes (partially)	Supports the following counters: 1, 6, and 7.
VLAN Modes	Yes (partially)	Supports only modes 1 and 3.
Buffering Capabilities	Yes	8 Kb
MAC Address Filters	Yes	Supports two MAC Addresses per port.
Channel Count	Yes	Supports eight channels.
VLAN Filters	Yes	Supports eight VLAN filters per port. Filtering ignores the *CFI* bit and the 802.1P priority bits.
Broadcast Filters	Yes	Support the following filters: • ARP • DHCP • Net BIOS

Table 12-14. Optional NC-SI Features Support [continued]

Feature	Implement	Details
Multicast Filters	Yes	Supports the following filters: • IPv6 neighbor advertisement • IPv6 router advertisement • DHCPv6 relay and server multicast In NC-SI 1.1 mode, the following filters are also supported: • DHCPv6 multicasts from server to clients listening on well-known UDP ports • IPv6 MLD • IPv6 Neighbor Solicitation
Hardware Arbitration	Yes	Supports NC-SI hardware arbitration.

1. TCTL.*EN* should be set to 1b to activate Tx-related counters, and RCTL.*RXEN*, PRT_MNG_MANC.*RCV_EN* or WUC.*APME* should be set to enable Rx-related counters.
2. As described in the Get Controller Packet Statistics Counter Numbers table in NC-SI specification.
3. The E810 does not increment the NC-SI control packets dropped counter when packets with checksum errors are dropped. In this case, only the NC-SI command checksum errors counter is updated.

12.6.2.1.1 Error Conditions

If the device is not able to respond to a command within the 150 ms limit (three 50 ms retries), it responds with a response code of command unavailable (0x02) and a reason code of package not ready (0x04).

12.6.2.2 AEN Handling

Asynchronous events might occur when the device is not allowed to send them via the AEN Enable command. The following rules define the behavior of the E810 in these cases:

1. While the device is disabled, for each type of AEN only the last event is kept.
2. Outstanding AENs that occurred while a package was deselected are transmitted when a package is selected.
3. On a transition from channel disabled to channel enabled, all outstanding events are erased to prevent stale event notifications.
4. If the AEN becomes outdated before being sent (for example a link down, link up sequence occurring before the AEN is sent), no AEN is sent.

12.6.2.2.1 Driver Status Change AEN Generation

The Host NC Driver Status changes, and the Driver Status Change AEN is emitted in the following conditions:

- **Driver is Active** — When a "Driver Version" AQ command is received from the PF associated with this channel.
- **Driver is Not Active** — When a "Queue Shutdown" AQ command is received from the admit queue of the PF associated with this channel.

12.6.2.3 NC-SI 1.1 New Features

The following features are available when NC-SI version is set to 1.1 in the NC-SI version flag in the NVM NC-SI Configuration 1 word:

- Broadcast and multicast packet reception is enabled by default at initial state after channel is enabled.
- The Get Package UUID command and Get Package Status command are supported. The UUID reported is the same as described in Section 12.7.7.1.3.
- New format for the Set Link and Get Link commands including support for new speeds.

The following filters are added to the Enable Global Multicast Filter command:

  — DHCPv6 multicast packets from server to clients listening on well-known UDP ports.

  — IPv6 MLD.

  — IPv6 Neighbor Solicitation.

- New format for the Capabilities Flags word in Get Capabilities response packet.

12.6.3 External Link Control via NC-SI

12.6.3.1 NC-SI Link State Control

In NC-SI mode, the device might dynamically change the PHY power mode according to the NC-SI channel state, assuming no other functionality requires the PHY to be active (host or wake-up).

The following algorithm is used to define if PHY activity is required:

- At initialization time, the PHY is required to be active only if the *EMP_LINK_ON* bit in Common Firmware Parameters 2 NVM word is set.
- Once a channel is enabled via a Enable Channel NC-SI command, The PHY is powered up.
- If the channel is disabled via a Disable Channel command with the *ALD* bit set, the PHY is disabled.
- If the channel is disabled via a Reset Channel command, the PHY power state is set back to the initial value as define by the *EMP_LINK_ON* bit.

Note: Before transitioning to D3, it is the responsibility of the software device driver to request the PHY to be active for wake-up activities.

12.6.3.2 Set Link Error Codes

The following rules are used to define the error code returned for a Set Link command in case an invalid configuration is requested:

1. Host Driver Check: If a host device driver is present, return a Command Specific Response (0x9) with a Set Link Host OS/Driver Conflict Reason (0x1).
2. Speed Present Check: If no speed is selected, return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).

3. Parameter Validity:
    a. Auto-Negotiation Parameter Validation: If auto-negotiation is requested and none of the selected parameters are valid for the device, return a General Reason Code for a failed command (0x1) with a Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).

        Note: This means, for example, a command requesting 10 GbE on a 1 GbE device succeeds provided that the command requests at least one other supported speed.

        Note: The setting of auto-negotiation *Enabled* field is ignored. For speed and connection types that accept only force mode, force mode is used, and for modes that support only AN, the AN is used to enforce a speed by negotiating only this speed. There are no modes supported by the E810 that supports both AN and force modes.

        The same goes for an unsupported duplex setting (a device with no HD support accepts a command with both FD and HD set), and also for HD being requested with speeds of 1 GbE and higher as long as a speed below 1 GbE is also requested (and is supported in HD). The device simply ignores the unsupported parameters.

    b. Force Mode Parameter Validation:
        - If more than one link speed is being forced, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with a Set Link Speed Conflict Error (0x0905).
        - If more than one duplex setting is being forced, then return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
        - If 1 GbE and above is requested with HD, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Parameter Conflict Reason (0x0903).
4. Media Type Compatibility Check: If current media type is not compatible for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Media Conflict Error (0x0902).
5. Power State Compatibility Check: If current power state does not allow for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Power Mode Conflict Reason (0x0904).
6. If for some reason the hardware cannot perform the flow required for the command, return a General Reason Code for a failed command (0x1) and a Command Specific Response (0x9) with Link Command Failed-Hardware Access Error (0x6).

12.6.3.3 MC External Link Control

The MC can use the NC-SI Set Link command to control the external interface link settings. This command enables the MC to set the auto-negotiation, link speed, duplex, and other parameters.

This command is only available when the host operating system is not present. Indicating the host operating system status can be obtained via the Get Link Status command and/or Host OS Status Change AEN command.

Recommendation:

- Unless explicitly needed, it is not recommended to use this feature. The NC-SI Set Link command does not expose all the possible link settings and/or features. This might cause issues under different scenarios. Even if you decide to use this feature, use it only if the link is down (trust the E810 until proven otherwise).

- It is recommended that the MC first query the link status using the Get Link Status command. The MC should then use this data as a basis and change only the needed parameters when issuing the Set Link command.

For details, refer to the NC-SI specification.

12.6.3.3.1 Set Link while LAN PCIe Functionality is Disabled

In cases where the E810 is used solely for manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation results in the lowest possible speed chosen.

To enable a higher link speed, the MC should not advertise speeds that are below the desired link speed, as the lowest advertised link speed is chosen.

When the E810 is only used for manageability and the link speed advertisement is configured by the MC, changes in the power state of the LAN device is not effected and the link speed is not renegotiated by the LAN device.

12.6.4 NC-SI Mode - Intel-Specific Commands

In addition to regular NC-SI commands, the following Intel vendor-specific commands are supported. The purpose of these commands is to provide a means for the MC to access some of the Intel-specific features present in the E810.

12.6.4.1 Overview

The following features are available via the NC-SI OEM-specific commands:

- Receive filters
- Packet addition decision filters 0x0…0x4
- Packet reduction decision filters 0x5…0x7
- PRT_MNG_MNGONLY register — Controls the forwarding of manageability packets to the host.
- Flex 128 filters
- Flex TCP/UDP port filters 0x0...0x2
- IPv4/IPv6 filters
- Get system MAC Address — This command enables the MC to retrieve the system MAC Address used by the MC. This MAC Address can be used for a shared MAC Address mode.
- Keep PHY link up (Veto bit) enable/disable — This feature enables the MC to block PHY reset, which might cause session loss.
- TCO reset — Enables the MC to reset the E810.
- Checksum offloading — Offloads IP/UDP/TCP checksum checking from the MC.
- OS2BMC control commands
- Firmware version commands
- Shared MAC and shared IP commands

These commands are designed to be compliant with their corresponding SMBus commands (if existing). All of the commands are based on a single DMTF defined NC-SI command, known as OEM Command (Section 12.6.4.1.1).

12.6.4.1.1 OEM Command (0x50)

The OEM command can be used by the MC to request the sideband interface to provide vendor-specific information. The Vendor Enterprise Number (VEN) is the unique MIB/SNMP private enterprise number assigned by IANA per organization. Vendors are free to define their own internal data structures in the vendor data fields.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**

Notes:

- Responses have no command-specific reason code, unless otherwise specified within the command.
- The commands/responses described as follows include only the part up to the data. The padding and checksum are implied.

12.6.4.2 OEM Commands Summary

Table 12-15. OEM-Specific Command Response Reason Codes

Response Code		Reason Code	
Value	**Description**	**Value**	**Description**
0x1	Command Failed	0x5081	Invalid Intel command number.
		0x5082	Invalid Intel command parameter number.
		0x5085	Internal network controller error.
		0x5086	Invalid vendor enterprise code.
		0x508D	Returned when one of the shared IP commands is received with an out of range resource (IP, port, binding) index.
		0x508E	Returned when a request to disable a port or an IP Address used in a active binding is received.
		0x5090	Returned when a binding of a non enabled resource (MAC, VLAN, IP Address, port) is required.
		0x5091	Returned when the Set Port command is received with an unsupported protocol.
		0x5092	Not in shared mode. Returned when shared mode commands are used while not in shared MAC/IP mode.
		0x008E	Returned when a request to disable a VLAN or a MAC Address used in a active binding is received.

Table 12-16 provides a summary of OEM commands.

Note: All the commands are supported over both RMII NC-SI and MCTP.

Table 12-16. OEM Commands Summary

Intel Command	Parameter	Command Name	Supported in MCTP without PT	Section Reference
0x00	0x00	Set IP Filters Control	No	12.6.4.3.1
0x01	0x00	Get IP Filters Control	No	12.6.4.4.1
0x02	0x0F	Set Manageability Only	No	12.6.4.5.2
	0x10	Set Flex Filter Mask and Length		12.6.4.5.3
	0x11	Set Flex Filter Data		12.6.4.5.4
	0x63	Set Flex TCP/UDP Port Filter		12.6.4.5.6
	0x64	Set Flex IPv4 Address Filter		12.6.4.5.7
	0x65	Set Flex IPv6 Address Filter		12.6.4.5.8
	0x67	Set EtherType Filter		12.6.4.5.9
	0x68	Set Packet Addition Extended Decision Filter		12.6.4.5.10
	0x69	Set Special Filter Modifiers		12.6.4.5.11

Table 12-16. OEM Commands Summary [continued]

Intel Command	Parameter	Command Name	Supported in MCTP without PT	Section Reference
0x03	0x0F	Get Manageability Only	No	12.6.4.6.2
	0x10	Get Flex Filter Mask and Length		12.6.4.6.3
	0x11	Get Flex Filter Data		12.6.4.6.4
	0x63	Get Flex TCP/UDP Port Filter		12.6.4.6.6

	0xB	Set Shared Mode		12.6.4.14.12
0x40	0x01	Enable OS2BMC Flow	No	12.6.4.15.1
	0x02	Enable Network-to-BMC Flow		12.6.4.15.2
	0x03	Enable Both Network-to-BMC and Host-to-BMC Flows		12.6.4.15.3
	0x04	Set BMC IP Address		12.6.4.15.4

Table 12-16. OEM Commands Summary [continued]

Intel Command	Parameter	Command Name	Supported in MCTP without PT	Section Reference
0x41	N/A	Get OS2BMC Parameters	No	12.6.4.15.5
0x48	0x1	Get Controller Information	Yes	12.6.4.16.1
0x4B	N/A	Get ASIC Temperature	Yes	12.6.4.17.1

12.6.4.3 Set Intel Filters Control Commands

This command controls different aspects of the Intel filters.

12.6.4.3.1 Set IP Filters Control Command (Intel Command 0x00, Parameter 0x00)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x00	0x00	IP Filters Control (3-2)	
24...25	IP Filters Control (1-0)			

Where *IP Filters Control* has the following format.

Bit #	Name	Default	Description
0	IPv4/IPv6 Mode	1b	0b = IPv6 — There are zero IPv4 filters and four IPv6 filters. 1b = IPv4 — There are four IPv4 filters and four IPv6 filters.
1...31	Reserved		

Note: This command is kept for compatibility with other projects and has no effect in the E810.

12.6.4.3.1.1 Set IP Filters Control Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x00	0x00		

12.6.4.4 Get Intel Filters Control Commands

12.6.4.4.1 Get IP Filters Control Command (Intel Command 0x01, Parameter 0x00)

This command controls different aspects of the Intel filters.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x01	0x00		

12.6.4.4.1.1 Get IP Filters Control Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x01	0x00	IP Filters Control (3-2)	
28...29	IP Filters Control (1-0)			

Note: This command is kept for compatibility with other projects and returns always 0x1 in the E810.

12.6.4.5 Set Intel Filters Formats

12.6.4.5.1 Set Intel Filters Command (Intel Command 0x02)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x02	Parameter Number	Filters Data (optional)	

12.6.4.5.1.1 Set Intel Filters Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	Filter Control Index	Return Data (optional)	

12.6.4.5.2 Set Manageability Only Command (Intel Command 0x02, Parameter 0x0F)

This command sets the PRT_MNG_MNGONLY register. The PRT_MNG_MNGONLY register controls whether pass-through packets destined to the MC are not forwarded to the Host operating system. The PRT_MNG_MNGONLY register is listed in Table 12-9.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x0F	Manageability Only (3-2)	
24...25	Manageability Only (1-0)			

12.6.4.5.2.1 Set Manageability Only Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x0F		

12.6.4.5.3 Set Flex Filter Mask and Length Command (Intel Command 0x02, Parameter 0x10)

The following command sets the Intel flex filters mask and length.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x10	Mask Byte 1	Mask Byte 2
24...27	...	...	...	...
28...31	...	...	...	...
32...35	...	...	...	...
36...37	Mask Byte 15	Mask Byte 16	Reserved	
38	Length			

12.6.4.5.3.1 Set Flex Filter Mask and Length Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x10		

12.6.4.5.4 Set Flex Filter Data Command (Intel Command 0x02, Parameter 0x11)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...	0x02	0x11	Filter Data Group	Filter Data 1
	...	Filter Data N		

The *Filter Data Group* parameter defines which bytes of the Flex filter are set by this command:

Table 12-17. Filter Data Group

Code	Bytes Programmed	Filter Data Length
0x0	Bytes 0–29	1–30
0x1	Bytes 30–59	1–30
0x2	Bytes 60–89	1–30
0x3	Bytes 90–119	1–30
0x4	Bytes 120–127	1–8

Note: Using this command to configure the filters data must be done after the flex filter mask command is issued and the mask is set.

12.6.4.5.4.1 Set Flex Filter Data Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x11		

12.6.4.5.5 Set Packet Addition Decision Filter Command (Intel Command 0x02, Parameter 0x61)

This command is no longer supported. Use the Set Packet Addition Extended Decision Filter Command (Intel Command 0x02, Parameter 0x68 instead (see Section 12.6.4.5.10).

12.6.4.5.6 Set Flex TCP/UDP Port Filter Command (Intel Command 0x02, Parameter 0x63)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x63	Port Filter Index	TCP/UDP Port MSB
24...25	TCP/UDP Port LSB	Port Flags		

Port Filter Index range: 0x0...0xA. When NC-SI 1.1 is supported, the range is 0x0...0x9.

Port Flags are as follows:

Bit 0: Match UDP ports
Bit 1: Match TCP ports
Bit 2: Match destination port (0) or source port (1)
Bit 7:3: Reserved

If flags are not present (payload length = 9), the match is done on TCP and UDP destination ports (legacy behavior).

If the *Port Filter Index* is larger than 10, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.5.6.1 Set Flex TCP/UDP Port Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x63		

12.6.4.5.7 Set Flex IPv4 Address Filter Command (Intel Command 0x02, Parameter 0x64)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x64	IP Filter Index	IPv4 Address (3)
24...26	IPv4 Address (2-0)			

IP Filter Index range: 0x0...0x3.

12.6.4.5.7.1 Set Flex IPv4 Address Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x64		

If the *IP Filter Index* is larger than 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.5.8 Set Flex IPv6 Address Filter Command (Intel Command 0x02, Parameter 0x65)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x65	IP Filter Index	IPv6 Address (MSB, byte 15)
24...27	...	...	...	...
28...31	...	...	...	...
32...35	...	...	...	...
36...38	...	...	IPv6 Address (LSB, byte 0)	

12.6.4.5.8.1 Set Flex IPv6 Address Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x65		

If the *IP Filter Index* is larger the 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.5.9 Set EtherType Filter Command (Intel Command 0x02, Parameter 0x67)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x67	EtherType Filter Index	EtherType Filter MSB
24...26	...	...	EtherType Filter LSB	

Where the *EtherType Filter* has the format as described in Section 13.2.2.29.9.

12.6.4.5.9.1 Set EtherType Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x67		

If the *EtherType Filter Index* is different than 2 or 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.5.10 Set Packet Addition Extended Decision Filter Command (Intel Command 0x02, Parameter 0x68)

See Figure 12-3 on page 1574 for a description of the decision filters structure.

The command must overwrite any previously-stored value. The value set is not checked.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x68	Extended Decision Filter Index	Extended Decision Filter 1 MSB
24...27	...	...	Extended Decision Filter 1 LSB	Extended Decision Filter 0 MSB
28...30	...	...	Extended Decision Filter 0 LSB	

Extended Decision Filter Index range: 0...4

Filter 0: See Table 12-18.

Filter 1: See Table 12-19.

Table 12-18. Extended Decision Filter 0 Values

Bit #	Name	Description
3:0	Unicast (AND)	If set, packets must match unicast filter 0 to 3, respectively.
4	Broadcast (AND)	If set, packets must match the broadcast filter.
12:5	VLAN (AND)	If set, packets must match VLAN filter 0 to 7, respectively.
16:13	IPv4 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
20:17	IPv6 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
24:21	Unicast (OR)	If set, packets can pass if match unicast filter 0 to 3, respectively or a different OR filter.
25	Broadcast (OR)	If set, packets can pass if match the broadcast filter or a different OR filter.
26	Multicast (AND)	If set, packets must match the multicast filter.
27	ARP Request (OR)	If set, packets can pass if match the ARP request filter or a different OR filter.
28	ARP Response (OR)	If set, packets can pass if match the ARP response filter or a different OR filter.
29	Neighbor Discovery - 134 (OR)	If set, packets can pass if match the neighbor discovery filter(type134 - router advertisement) or a different OR filter.
30	Port 0x298 (OR)	If set, packets can pass if match a fixed TCP/UDP port 0x298 filter or a different OR filter.
31	Port 0x26F (OR)	If set, packets can pass if match a fixed TCP/UDP port 0x26F filter or a different OR filter.

Table 12-19. Extended Decision Filter 1 Values

Bit #	Name	Description
3:0	EtherType 0 -3 (AND)	If set, packets must match the EtherType filter 0 to 3, respectively.
7:4	EtherType 0 -3 (OR)	If set, packets must match the EtherType filter 0 to 3, respectively or a different OR filter.
18:8	Flex port 10:0 (OR)	If set, packets can pass if match the TCP/UDP Port filter 10:0.
19	DHCPv6 (OR)	If set, packets can pass if match the DHCPv6 port (0x0223).
20	DHCP Client (OR)	If set, packets can pass if match the DHCP Server port (0x0043).
21	DHCP Server (OR)	If set, packets can pass if match the DHCP Client port (0x0044).
22	NetBIOS Name Service (OR)	If set, packets can pass if match the NetBIOS Name Service port (0x0089).
23	NetBIOS Datagram Service (OR)	If set, packets can pass if match the NetBIOS Datagram Service port (0x008A).
24	Flex TCO (OR)	If set, packets can pass if match the Flex 128 TCO filter.
25	Neighbor Discovery - 135 (OR)	If set, packets must also match the neighbor discovery filter (type135 - Neighbor Solicitation). or a different OR filter.
26	Neighbor Discovery - 136 (OR)	If set, packets must also match the neighbor discovery filter (type136 - Neighbor Advertisement) or a different OR filter.
27	Neighbor Discovery - 137 (OR)	If set, packets must also match the neighbor discovery filter (type137 - Redirect) or a different OR filter.
28	ICMPv4 (OR)	Controls the inclusion of ICMPv4 filtering in the manageability filter decision (OR section).
29	MLD	If set, packets must also match one of the MLD ICMPv6 types or a different OR filter.
31:30	Reserved	Reserved.

12.6.4.5.10.1 Set Packet Addition Extended Decision Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x68		

If the *Extended Decision Filter Index* is larger than 5, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.5.11 Set Special Filter Modifiers Command (Intel Command 0x02, Parameter 0x69)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x69	Special Modifier Register MSB	
24...27	Special Modifier Register LSB		Padding	

Where the special modifier filter has the format as described in Section 13.2.2.29.17. The value set is not checked.

12.6.4.5.11.1 Set Special Filter Modifiers Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x69		

12.6.4.6 Get Intel Filters Formats

12.6.4.6.1 Get Intel Filters Command (Intel Command 0x03)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x03	Parameter Number		

12.6.4.6.1.1 Get Intel Filters Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x03	Parameter Number	Return Data (optional)	

12.6.4.6.2 Get Manageability Only Command (Intel Command 0x03, Parameter 0x0F)

This command retrieves the PRT_MNG_MNGONLY register. The PRT_MNG_MNGONLY register controls whether pass-through packets destined to the MC are also be forwarded to the host operating system.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x03	0x0F		

12.6.4.6.2.1 Get Manageability Only Response

The PRT_MNG_MNGONLY register structure is listed in Table 12-9 on page 1575.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x0F	Manageability to Host (3-2)	
28...29	Manageability to Host (1-0)			

12.6.4.6.3 Get Flex Filter Mask and Length Command (Intel Command 0x03, Parameter 0x10)

The following command retrieves the Intel flex filters mask and length. See Section 12.4.3.6 for details of the values returned by this command.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x03	0x10		

12.6.4.6.3.1 Get Flex Filter Mask and Length Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x10	Mask Byte 1	Mask Byte 2
28...31	...	...	...	...
32...35	...	...	...	...
36...39	...	...	...	...
40...43	...	Mask Byte 16	Reserved	
44	Flexible Filter Length			

12.6.4.6.4 Get Flex Filter Data Command (Intel Command 0x03, Parameter 0x11)

The following command retrieves the Intel flex filters data.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x11	Filter Data Group 0...4	

The *Filter Data Group* parameter defines which bytes of the flex filter are returned by this command.

Table 12-20. Filter Data Group

Code	Bytes Returned
0x0	Bytes 0–29
0x1	Bytes 30–59
0x2	Bytes 60–89
0x3	Bytes 90–119
0x4	Bytes 120–127

12.6.4.6.4.1 Get Flex Filter Data Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...	0x03	0x11	Filter Group Number	Filter Data 1
	...	Filter Data N		

12.6.4.6.5 Get Packet Addition Decision Filter Command (Intel Command 0x03, Parameter 0x61)

This command is no longer supported. Use the Get Packet Addition Extended Decision Filter Command (Intel Command 0x02, Parameter 0x68 instead (see Section 12.6.4.6.10).

12.6.4.6.6 Get Flex TCP/UDP Port Filter Command (Intel Command 0x03, Parameter 0x63)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x63	TCP/UDP Filter Index	

TCP/UDP Filter Index range: 0x0...0x2.

12.6.4.6.6.1 Get Flex TCP/UDP Port Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x63	TCP/UDP Filter Index	TCP/UDP Port (1)
28...29	TCP/UDP Port (0)	Port Flags		

TCP/UDP Filter Index range: 0x0...0x2.

12.6.4.6.7 Get IPv4 Address Filter Command (Intel Command 0x03, Parameter 0x64)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x64	IPv4 Filter Index	

Note: The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: *IPv4 Filter Index* range: 0x0...0x3.

IPv6 Mode: This command should not be used in IPv6 mode.

12.6.4.6.7.1 Get IPv4 Address Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x64	IPv4 Filter Index	IPv4 Address (3)
28...30	IPv4 Address (2-0)			

12.6.4.6.8 Get IPv6 Address Filter Command (Intel Command 0x03, Parameter 0x65)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x65	IPv6 Filter Index	

Note: The filter index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x0...0x2.

IPv6 Mode: Filter index range: 0x0...0x3.

12.6.4.6.8.1 Get IPv6 Address Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x65	IPv6 Filter Index	IPv6 Address (MSB, Byte 16)
28...31	...	...	...	...
32...35	...	...	...	...
36...39	...	...	...	...
40...42	...	...	IPv6 Address (LSB, Byte 0)	

12.6.4.6.9 Get EtherType Filter Command (Intel Command 0x03, Parameter 0x67)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x67	EtherType Filter Index	

Valid indices: 0...3

12.6.4.6.9.1 Get EtherType Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x67	EtherType Filter Index	EtherType Filter MSB
28...30	...	...	EtherType Filter LSB	

If the *EtherType Filter Index* is larger than 3, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.6.10 Get Packet Addition Extended Decision Filter Command (Intel Command 0x03, Parameter 0x68)

This command enables the MC to retrieve the extended decision filter.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x03	0x68	Extended Decision Filter Index	

12.6.4.6.10.1 Get Packet Addition Extended Decision Filter Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x68	Decision Filter Index	Decision Filter 1 MSB
28...31	...	...	Decision Filter 1 LSB	Decision Filter 0 MSB
32...34	...	...	Decision Filter 0 LSB	

Where *Decision Filter 0* and *Decision Filter 1* have the structure as detailed in the respective Set commands.

If the extended *Decision Filter Index* is larger than 4, a command failed Response Code is returned with Invalid Intel Parameter Number reason (0x5082).

12.6.4.6.11 Get Special Filter Modifiers Command (Intel Command 0x03, Parameter 0x69)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x03	0x69	Padding	

Where the special modifier filter has the format as described in Section 13.2.2.29.17.

12.6.4.6.11.1 Get Special Filter Modifiers Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x03	0x69	Special Modifier Register MSB	
28...31	Special Modifier Register LSB		Padding	

12.6.4.7 Set Intel Packet Reduction Filters Formats

The non-extended commands are obsolete. The extended commands (Section 12.6.4.7.2 to Section 12.6.4.7.4) should be used instead.

12.6.4.7.1 Set Intel Packet Reduction Filters Command (Intel Command 0x04)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x04	Packet Reduction Index	Packet Reduction Data	

Note: It is advised that the MC only use the extended packet reduction commands.

The *Packet Reduction Data* field has the following structure:

Table 12-21. Packet Reduction Field Description

Bits	Name	Description
12:0	Reserved	Reserved.
16:13	IPv4 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
20:17	IPv6 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
27:21	Reserved	Reserved.
28	ARP Response (OR)	If set, packets can pass if match the ARP response filter or a different OR filter.
29	Reserved	Reserved.
30	Port 0x298	If set, packets can pass if match a fixed TCP/UDP port 0x298 filter.
31	Port 0x26F	If set, packets can pass if match a fixed TCP/UDP port 0x26F filter.

Table 12-22. Extended Packet Reduction Field Description

Bits	Name	Description
3:0	EtherType 0-3 (AND)	If set, packets must match the EtherType filter 0 to 3, respectively.
7:4	EtherType 0-3 (OR)	If set, packets can pass if match the EtherType filter 0 to 3, respectively.
8:18	Flex port 10:0 (OR)	If set, packets can pass if match the TCP/UDP Port filter 10:0.
23:19	Reserved	Reserved.
24	Flex TCO (OR)	If set, packets can pass if match the Flex 128 TCO filter.
27:25	Reserved	Reserved.
28	ICMPv4	Is set, ICMPv4 packets can pass.
31:29	Reserved	Reserved.

The filtering is divided into two decisions:

- Bit 20:13 in Table 12-21 and Bits 3:2 in Table 12-22 work in an AND manner; it must be true for a packet to pass (if was set).
- Bits 28 in Table 12-21 and Bits 24:10 in Table 12-22 work in an OR manner; at least one of them must be true for a packet to pass (if any were set).

12.6.4.7.1.1 Set Intel Packet Reduction Filters Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x04	Packet Reduction Index		

12.6.4.7.2 Set Extended Unicast Packet Reduction Command (Intel Command 0x04, Parameter 0x10)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x04	0x10	Extended Unicast Reduction Filter MSB	...
24...27	...	Extended Unicast Reduction Filter LSB	Unicast Reduction Filter MSB	...
28...29	...	Unicast Reduction Filter LSB		

The command overwrites any previously-stored value.

Note: See Table 12-21 and Table 12-22 for description of the Unicast Extended Packet Reduction format.

12.6.4.7.2.1 Set Extended Unicast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x04	0x10		

12.6.4.7.3 Set Extended Multicast Packet Reduction Command (Intel Command 0x04, Parameter 0x11)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x04	0x11	Extended Multicast Reduction Filter MSB	...
24...27	...	Extended Multicast Reduction Filter LSB	Multicast Reduction Filter MSB	...
28...29	...	Multicast Reduction Filter LSB		

The command overwrites any previously-stored value.

Note: See Table 12-21 and Table 12-22 for description of the Multicast Extended Packet Reduction format.

12.6.4.7.3.1 Set Extended Multicast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x04	0x11		

12.6.4.7.4 Set Extended Broadcast Packet Reduction Command (Intel Command 0x04, Parameter 0x12)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x04	0x12	Extended Broadcast Reduction Filter MSB	...
24...27	...	Extended Broadcast Reduction Filter LSB	Broadcast Reduction Filter MSB	...
28...29	...	Broadcast Reduction Filter LSB		

The command overwrites any previously-stored value.

Note: See Table 12-21 and Table 12-22 for description of the Broadcast Extended Packet Reduction format.

12.6.4.7.4.1 Set Extended Broadcast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x04	0x12		

12.6.4.8 Get Intel Packet Reduction Filters Formats

The non-extended commands are obsolete. Use the extended commands (Section 12.6.4.8.1 to Section 12.6.4.8.3) instead.

12.6.4.8.1 Get Extended Unicast Packet Reduction Command (Intel Command 0x05, Parameter 0x10)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x05	0x10		

12.6.4.8.1.1 Get Extended Unicast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x05	0x00	Extended Unicast Packet Reduction (3-2)	
28...31	Extended Unicast Packet Reduction (1-0)		Unicast Packet Reduction (3-2)	
32...33	Unicast Packet Reduction (1-0)			

12.6.4.8.2 Get Extended Multicast Packet Reduction Command (Intel Command 0x05, Parameter 0x11)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x05	0x11		

12.6.4.8.2.1 Get Extended Multicast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x05	0x11	Extended Multicast Packet Reduction (3-2)	
28...31	Extended Multicast Packet Reduction (1-0)		Multicast Packet Reduction (3-2)	
32...33	Multicast Packet Reduction (1-0)			

12.6.4.8.3 Get Extended Broadcast Packet Reduction Command (Intel Command 0x05, Parameter 0x12)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x05	0x12		

12.6.4.8.3.1 Get Extended Broadcast Packet Reduction Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x05	0x12	Extended Broadcast Packet Reduction (3-2)	
28...31	Extended Broadcast Packet Reduction (1-0)		Broadcast Packet Reduction (3-2)	
32...33	Broadcast Packet Reduction (1-0)			

12.6.4.9 System MAC Address

12.6.4.9.1 Get System MAC Address Command (Intel Command 0x06)

To support a system configuration that requires the NC to hold the MAC Address for the MC (such as shared MAC Address mode), the following command is provided to enable the MC to query the NC for a valid MAC Address.

The NC must return the system MAC Addresses. The MC should use the returned MAC Address as a shared MAC Address by setting it using the Set MAC Address command as defined in NC-SI 1.0.

When a single function is defined on the port, it returns the LAN MAC Address of this function as read from the PF allocations NVM section or from the Alternate RAM, or as set by the Manage MAC Address Write AQ command. When more than one function is defined on the port, it returns the address of the lowest defined function on this port.

It is also recommended that the MC use packet reduction and the Manageability-to-Host command to set the proper filtering method.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20	0x06			

12.6.4.9.1.1 Get System MAC Address Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x06	MAC Address		
28...30	MAC Address			

12.6.4.10 Set Intel Management Control Formats

12.6.4.10.1 Set Intel Management Control Command (Intel Command 0x20)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...22	0x20	0x00	Intel Management Control 1	

Where *Intel Management Control 1* is as follows:

Bits	Default	Description
0	0b	Enable Critical Session Mode (Keep PHY Link Up and Veto Bit) 0b = Disabled 1b = Enabled When critical session mode is enabled, the following behaviors are disabled: • The PHY is not reset on PE_RST# and PCIe resets (in-band and link drop). Other reset events are not affected — Internal_Power_On_Reset, device disable, Force TCO, and PHY reset by software. In any case, CORER events are not blocked. • The PHY does not change its power state. As a result link speed does not change. • The device does not initiate configuration of the PHY to avoid losing link.
7:1	0x0	Reserved.

Caution: The System Firmware Update Control option in the command should be supported only over MCTP over SMBus.

Notes:

- The Intel Management Control 1 is also reflected in the Get Intel Management Control Response. In this case, the value of "No change" has no meaning, and the current setting should be reflected.
- If the parameter that the BMC sets is not supported by the device, the device returns Response Code 0x1 (Command Failed) with Reason Code 0x5082 (Invalid Intel command parameter number). The setting of the *System Firmware Update Control* field should be kept across EMP reset, so it should be kept in the Alternate RAM.
- The policy set by this command is applicable for any firmware update channel, either from host or via PLDM firmware update.

12.6.4.10.1.1 Set Intel Management Control Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x20	0x00		

12.6.4.11 Get Intel Management Control Formats

12.6.4.11.1 Get Intel Management Control Command (Intel Command 0x21)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x21	0x00		

12.6.4.11.1.1 Get Intel Management Control Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...26	0x21	0x00	Intel Management Control 1	

Where *Intel Management Control 1* is as described in Section 12.6.4.10.1.

12.6.4.12 TCO Reset

Depending on the bit set in the *TCO Mode* field, this command causes the E810 to perform either:

1. **TCO Reset**
   - If *Force TCO Reset* is enabled in the NVM (see Section 6.3.57.2), the TCO Reset command clears the data path (Rx/Tx) of the E810 to enable the MC to transmit/receive packets through the E810.
   - If the MC has detected that the operating system is hung and has blocked the Rx/Tx path, the *Force TCO Reset* clears the data-path (Rx/Tx) of the NC to enable the MC to transmit/receive packets through the NC.

- After successfully performing the command, the NC considers the Force TCO command as an indication that the operating system is hung and clears the internal driver-up indication. If TCO reset is disabled in the NVM, *Force TCO Reset* does not reset the data path and notifies the MC on successful completion.

2. **TCO Isolate**
   - If *TCO Isolate* is enabled in the NVM (see Section 6.3.57.3), the TCO Isolate command disables PCIe write operations to the LAN port.
   - If *TCO Isolate* is disabled in NVM, the E810 does not execute the command, but sends a response to the MC with successful completion.
   - Once TCO isolate is set, the driver is supposed to be disabled, and it is reported as such to the MC.
3. **Firmware Reset**
   - This command causes re-initialization of all the manageability functions and re-loads of manageability-related NVM words (such as firmware patch code).
   - When the MC loads a new management related NVM image (like a firmware patch), the Firmware Reset command loads the management related NVM information without the need to power down the system.
   - This command is issued to the package and affects all channels. After the firmware reset, the Firmware Semaphore register (FWSM) is re-initialized.
   - Applying this command resets the entire device and also has an effect on TCO reset.

Notes: TCO isolate affects only the channel (port) that the command was issued to. Force TCO resets the entire device (all channels in the package).

Following a firmware reset, the MC needs to re-initialize all ports. A firmware reset causes a global reset of the entire device (GLOBR).

Only one of the fields should be set in a given command. Setting more than one field might yield unexpected results.

12.6.4.12.1 Perform Intel TCO Reset Command (Intel Command 0x22)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x22	TCO Mode		

Where *TCO Mode* is:

Field	Bits	Description
DO_TCO_RST	0	**Do TCO Reset** 0b = Do nothing. 1b = Perform TCO reset.
DO_TCO_ISOLATE[1]	1	**Do TCO Isolate** 0b = Enable PCIe write access to LAN port. 1b = Isolate Host PCIe write operation to the port. ***Notes:*** • Should be used for debug only. • The TCO Isolate do not impact MCTP traffic. • When isolate is set, the OS2BMC flow is also disabled.
RESET_MGMT	2	**Reset Manageability** Reload manageability NVM words. 0b = Do nothing. 1b = Issue firmware reset to manageability. Setting this bit generates a one-time firmware reset. Following the reset, management-related data from NVM is loaded. ***Note:*** A reset of the internal firmware causes a reset of the entire device.
Reserved	7:3	Reserved. Set to 0x00.

1. TCO isolate host write operation enabled in NVM.

Note: For compatibility, the TCO Reset command without the *TCO Mode* parameter is accepted (TCO reset is done).

12.6.4.12.1.1 Perform Intel TCO Reset Response

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24	0x22			

12.6.4.13 Checksum Offloading

This command enables the checksum offloading filters in the NC.

When enabled, these filters block any packets that did not pass IP, UDP or TCP checksum from being forwarded to the MC.

12.6.4.13.1 Enable IP/UDP/TCP Checksum Offloading Command (Intel Command 0x23)

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**

12.6.4.14 Shared MAC and Shared IP Support Commands (Intel command 0x25)

To meet the requirements introduced by sharing IP Addresses, modifications and additions to the NC-SI command set are required. These changes include the new commands in this section and the modifications described in Section 12.4.6.

Note: All indexes in this command set start at one to match the NC-SI methodology.

12.6.4.14.1 Set IP Address Command (Intel Command 0x25, Parameter 0x0)

The Set IP Address command is used by the MC to communicate its IP Address to a NC.

If at least one IP Address filter is enabled, only unicast packets that match one of the enabled filters are forwarded through the NC-SI interface. Otherwise, the IP Address is ignored in the unicast filtering process.

This command does not impact the forwarding results. It is used as a preliminary stage to the Set Binding command.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x0	Reserved	
24...27	Management Controller IP Address			
28...31				
32...35				
36...39				
40...43	Reserved		IP Address Number	Set IP Flags
44...47	Checksum			

Where:

- ***Management Controller IP Address*** — An IP Address that is used by the MC.
  - — If the *IP Version* bit of the *Set IP Flags* field is 0b (IPv4), this is a 4-byte unicast IPv4 Address in network byte order. In this case, the address occupies bytes 24-27 of the packet, and bytes 28-39 are ignored.
  - — If the *IP Version* bit of the *Set IP Flags* field is 1b (IPv6), this is a 16-byte unicast IPv6 Address in network byte order. In this case, the address occupies the full field (bytes 24-39 of the packet).
- ***IP Address Number*** — Indicates which IP Address filter is configured by the command. The value can relate to one of three pools of filters according to Table 12-23:

Table 12-23. IP Filter Pools

Set IP Flag.IP Version	Set IP Flag.Mixed Index	Pool to Use	Allowed Values
0	0	IPv4	1 to the number of IPv4 only addresses.
1	0	IPv6	1 to the number of IPv6 only addresses.
X (0/1)	1	Mixed	1 to the number of mixed IP Addresses.

Note: The values shown in the allowed values column refer to the Get Shared IP Capabilities Response (Section 12.6.4.14.6.1).

- ***Set IP Flags*** — The bits in this field are listed in Table 12-24:

Table 12-24. Set IP Flag Field

Bits	Field	Description
0	Enable	0b = Disable the filter. 1b = Enable the filter.
1	IP Version	0b = IPv4 1b = IPv6

Table 12-24. Set IP Flag Field [continued]

Bits	Field	Description
2	Mixed Index	0b = Index relates to the IPv4 or IPv6 only IP filter sets according to the *IP Version* field. 1b = Index relates to the mixed IP filter set.
3	MAC-based IP	This flags define if the IPv6 Address is derived from a MAC Address and thus only the 24 LSB should be used for the comparison. This flag is relevant only if the *IP Version* = IPv6 (1b). 0b = Filter according to the full 128 bits of IPv6 Address. 1b = Filter according to the 24 LS bits of the IPv6 Address.
7:4	Reserved	Reserved.

12.6.4.14.1.1 Set IP Address Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set IP Address command and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x0	Reserved	
28...31	Checksum			

12.6.4.14.2 Get IP Address Command (Intel Command 0x25, Parameter 0x1)

An MC uses the Get IP Address command to determine the IP Address programmed in one of the IP Address filters in a NC.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x1	Reserved	
24...27	Reserved		IP Address Number	IP Filter Pool
28...31	Checksum			

Where:

- ***IP Address Number*** — Defines the index of the IP Address in the pool defined by the IP filter pool. The allowed values are listed in Table 12-23.
- ***IP Filter Pool***:

  0x0 = Mixed IP filters
  0x1 = IPv4 filters
  0x2 = IPv6 filters
  0x3-0xFF = Reserved

12.6.4.14.2.1 Get IP Address Response

The NC, in the absence of a checksum error or identifier mismatch, must always accept the Get IP Address command and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x1	IP Address Number	Get IP Flags
28...31	Management Controller IP Address			
32...35				
36...39				
40...43				
44...47	Checksum			

Where:

- ***Management Controller IP Address*** — An IP Address that is used by the MC.
  - If the *IP Version* bit of the *Get IP Flags* field is 0b (IPv4), this is a 4-byte unicast IPv4 Address in network byte order. In this case, the address occupies bytes 28-31 of the packet, and bytes 32-43 are ignored.
  - If the *IP Version* bit of the Flags field is 1b (IPv6), this is a 16-byte unicast IPv6 Address in network byte order. In this case, the address occupies the full field (bytes 28-43 of the packet).
- ***IP Address Number*** — Indicates which IP Address filter is described in the response. Should be equal to the *IP Address Number* in the command.
- ***Get IP Flags*** — The bits in this field are listed in Table 12-25:

Table 12-25. Get IP Flag Field

Bits	Field	Description
0	Enable	0b = Filter is disabled. 1b = Filter is enabled.
1	IP Version	0b = IPv4 1b = IPv6
2	Mixed Index	0b = Index relates to the IPv4 or IPv6 only IP filter sets according to the *IP Version* field. 1b = Index relates to the mixed IP filter set.
3	MAC-based IP	This flags define if the IPv6 Address is derived from a MAC Address and thus only the 24 LSB should be used for the comparison. This flag is relevant only if the *IP Version* = IPv6 (1b). 0b = Filter according to the full 128 bits of IPv6 Address. 1b = Filter according to the 24 LS bits of the IPv6 Address.
7:4	Reserved	Reserved.

12.6.4.14.3 Set Port Command (Intel Command 0x25, Parameter 0x2)

An MC uses the Set Port command to communicate one of its TCP or UDP ports to a NC.

This command does not impact the forwarding results. It is used as a preliminary stage to the Set Binding command.

If the *Ignore Protocol* flag is cleared, the protocol should also match the *Protocol* field. Otherwise, the *Protocol* field is ignored.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x2	Set Port Flags	Reserved
24...27	Port Index	Protocol	Port	
28...31	Checksum			

Where:

- ***Protocol*** — The value to match in the IPv4 header *Protocol* field or IPv6 header *Next Header* field. These values are defined by IANA. Allowed values are 0x6 (TCP) and 0x11 (UDP).
- ***Port*** — The value to match in the *Destination Port* or *Source Port* field of the TCP or UDP header. The legal port range for both TCP and UDP is 0-65,535. The compared field is defined by the *Port Type* flag.
- ***Port Index*** — Indicates which port filter is configured by the command. Allowed values are 1 to n, where n is the number of port filters supported by the Network Controller.
- ***Set Port Flags*** — The bits in this field are listed in Table 12-26.

Table 12-26. Set Port Flags Field Descriptions

Bits	Field	Description
0	Enable	0b = Disable the filter. 1b = Enable the filter.
1	Ignore Protocol	0b = Filter by port and protocol. 1b = Filter by port only.
2	Port Type	0b = Compare destination port. 1b = Compare source port.
7:3	Reserved	Reserved.

12.6.4.14.3.1 Set Port Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set Port command and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x2	Reserved	
28...31	Checksum			

12.6.4.14.4 Get Port Command (Intel Command 0x25, Parameter 0x3)

An MC uses the Get Port command to determine the TCP or UDP port programmed in one of the port filters in a NC.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x3	Reserved	
24...27	Reserved		Port Index	Reserved
28...31	Checksum			

Table 12-27 lists the fields in the Get Port command.

Table 12-27. Get Port Command Field Descriptions

Field	Field Description	Value Description
Port Index	Indicates which port filter is requested by the command.	1 to n, where n is the number of port filters supported by the NC.

12.6.4.14.4.1 Get Port Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Port command and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x3	Get Port Flags	Reserved
28...31	Port Index	Protocol	Port	
32...35	Checksum			

Where:

- ***Protocol*** — The value compared in the IPv4 header *Protocol* field or IPv6 header *Next Header* field. Possible values are 0x6 (TCP) and 0x11 (UDP).
- ***Port*** — The value compared in the *Destination Port* or *Source Port* field of the TCP or UDP header.
- ***Port Index*** — Indicates which port filter is reported by the response. Should match the *Port Index* in the command.
- ***Get Port Flags*** – The bits in this field are listed in Table 12-28.

Table 12-28. Get Port Flags Field Descriptions

Bits	Field	Description
0	Enable	0b = Filter is disabled. 1b = Filter is enabled.
1	Ignore Protocol	0b = Filter by port and protocol. 1b = Filter by port only.
2	Port Type	0b = Compare destination port. 1b = Compare source port.
7:3	Reserved	Reserved.

12.6.4.14.5 Enable Unicast Infrastructure Filter Command (Intel Command 0x25, Parameter 0x4)

A MC uses the Enable Unicast Infrastructure Filter command to configure a NC to forward copies of network infrastructure packets to it.

Network infrastructure packets contain messages that are necessary for operating the network infrastructure layers (such as DHCP, ARP, and DNS messages). This is required when the MC shares an IP Address with the host. In this case, both the host and the MC need to process the messages. As a result, the NC must forward the packets to both the MC and the host.

This command should be applied only after a MAC Address is added using the Set MAC Address NC-SI command.

All the IP Addresses added through the Set IP command before this command is given are considered as IP Addresses of the MC for the purpose of this command.

If a Set IP command is received after this command was received, the list of IP Address is not updated, and this command should be given again.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11

32...35	Checksum			
36...39	Padding			

Table 12-29 lists the sub fields of the *Unicast Infrastructure Filter Settings* field.

Table 12-29. Unicast Infrastructure Packet Filter Settings Field

Bits	Field	Description
0	ARP Response Packets Received From Wire	**ARP Response Packets Received From Wire** 0b = Forward this packet type to the host only 1b = Forward this packet type to both the host and the MC. For the purposes of this filter, an ARP response packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x0806 (ARP). • The *ARP Opcode* field is set to 0x0002 (response). • The A*RP Target Protocol Address* field contains the IP Address assigned to the MC.

Table 12-29. Unicast Infrastructure Packet Filter Settings Field [continued]

Bits	Field	Description
1	ICMPv4 Request Packets Received From Wire	**ICMPv4 Request Packets Received From Wire** 0b = Forward this packet type to the host only. 1b = Forward this packet type to both the host and the MC. For the purposes of this filter, an ICMP request packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x0800 (IPv4). • The *IP Destination Address* field contains the IPv4 Address assigned to the MC. • The *IP Protocol* field contains 1 (ICMP).
2	ICMPv6 Request Packets Received From Wire	**ICMPv6 Request Packets Received From Wire** 0b = Forward this packet type to the host only. 1b = Forward this packet type to both the host and the MC. For the purposes of this filter, an ICMPv6 request packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6). • The *IP Destination Address* field contains the IPv6 Address assigned to the MC. • The *IP Next Header* field contains 58 (ICMPv6). ***Note:*** This filter is not supported by the E810.
3	DHCP Server Unicast Packets Received From Wire	**DHCP Server Unicast Packets Received From Wire** 0b = Forward this packet type to the host only. 1b = Forward this packet type to both the host and the MC. For the purposes of this filter, a DHCP server unicast packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x0800 (IPv4). • The *IP Destination Address* field contains either 255.255.255.255 (the local broadcast address) or the IPv4 Address assigned to the MC. • The *IP Protocol* field contains 17 (UDP). • The *UDP Destination Port* field contains 68 (bootstrap protocol client).
4	DNS Server Packets Received From Wire	**DNS Server Packets Received From Wire** 0b = Forward this packet type to the host only. 1b = Forward this packet type to both the host and the MC. For the purposes of this filter, a DNS server unicast packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x0800 (IPv4). • The *IP Destination Address* field contains the IPv4 Address assigned to the MC. • The *IP Protocol* field contains 17 (UDP). • The *UDP Source Port* field contains 53 (domain name server).
5	DHCP Client Packets Transmitted By Host	**DHCP Client Packets Transmitted By Host** 0b = Forward this packet type to the wire only. 1b = Forward this packet type to both the wire and the MC. For the purposes of this filter, a DHCP client unicast packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Source Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x0800 (IPv4). • The *IP Protocol* field contains 17 (UDP). • The *UDP Destination Port* field contains 67 (bootstrap protocol server).

Table 12-29. Unicast Infrastructure Packet Filter Settings Field [continued]

Bits	Field	Description
6	DHCPv6 Server Unicast Packets Received From Wire	**DHCPv6 Server Unicast Packets Received From Wire** 0b = Forward this packet type to the host only. 1b = Forward this packet type to both the host and MC. For the purposes of this filter, a DHCPv6 server unicast packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6). • The *IPv6 Destination Address* field contains the IPv6 Address assigned to the MC. • The *IP Protocol* field contains 17 (UDP). • The *UDP Destination Port* field contains 546 (DHCPv6 protocol client).
7	RMCP Primary Port - UDP	**RMCP Primary Port - UDP** 0b = Forward this packet type to the host. 1b = Forward this packet type to the MC only. For the purposes of this filter, a RMCP primary UDP packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). • The *IP Destination Address* field contains the one of the IP Addresses assigned to the MC. • The *IP Protocol* field contains 17 (UDP). • The *UDP Destination Port* field contains 623 [aux bus shunt (primary RMCP port)].
8	RMCP Primary Port - TCP	**RMCP Primary Port - TCP** 0b = Forward this packet type to the host. 1b = Forward this packet type to the MC only. For the purposes of this filter, a RMCP primary TCP packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). • The *IP Destination Address* field contains the one of the IP Addresses assigned to the MC. • The *IP Protocol* field contains 6 (TCP). • The *UDP Destination Port* field contains 623 [aux bus shunt (primary RMCP port)].
9	RMCP Secondary Port - UDP	**RMCP Secondary Port - UDP** 0b = Forward this packet type to the host 1b = Forward this packet type to the MC only. For the purposes of this filter, a RMCP secondary UDP packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). • The *IP Destination Address* field contains the one of the IP Addresses assigned to the MC. • The *IP Protocol* field contains 17 (UDP). • The *UDP Destination Port* field contains 664 [secure aux bus (secondary RMCP port)].
10	RMCP Secondary Port - TCP	**RMCP Secondary Port - TCP** 0b = Forward this packet type to the host. 1b = Forward this packet type to the MC only. For the purposes of this filter, a RMCP secondary TCP packet is defined to be any packet that meets all of the following requirements: • The *Ethernet Destination Address* field contains the MAC Address assigned to the MC. • The *Ethernet Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). • The *IP Destination Address* field contains the one of the IP Addresses assigned to the MC. • The *IP Protocol* field contains 6 (TCP). • The *UDP Destination Port* field contains 664 [secure aux bus (secondary RMCP port)].
31:11	Reserved	Reserved.

12.6.4.14.5.1 Enable Unicast Infrastructure Filter Response

The NC, in the absence of a checksum error or identifier mismatch, must always accept the Enable Unicast Infrastructure Filter command and send a response using the following format.

Note: Currently, no command-specific reason codes are identified for this response.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x4	Reserved	
28...31	Checksum			

12.6.4.14.6 Get Shared IP Capabilities Command (Intel Command 0x25, Parameter 0x5)

An MC uses the Get Shared IP Capabilities command to determine the level of support of shared IP of the device.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x5	Reserved	
24...27	Checksum			

12.6.4.14.6.1 Get Shared IP Capabilities Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Shared IP Capabilities command, and send a response using the following format.

Note: Currently, no command-specific reason codes are identified for this response.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x5	Number of Mixed IP Addresses	Number of IPv4-only Addresses
28...31	Number of IPv6-only Addresses	Number of Ports	Numbers of Bindings	Filtering Capabilities
32...35	Unicast Infrastructure Filter Capabilities			
36...39	Checksum			

Where:

- ***Number of Mixed IP Addresses*** — The number of supported IP filters that can be used for IPv4 or IPv6. The E810 does not support mixed IP Address filters.
- ***Number of IPv4-only Addresses*** — The number of supported IP filters that can be used for IPv4 only. The E810 supports three IPv4 Address filters.
- ***Number of IPv6-only Addresses*** — The number of supported IP filters that can be used for IPv6 only. The E810 supports four IPv6 Address filters.
- ***Number of Ports*** — The number of supported port filters.
- ***Number of Bindings*** — Defines the number of IP Addresses that can be bound with different ports.
- ***Unicast Infrastructure Filter Capabilities*** — Defines the optional unicast infrastructure filter capabilities that the channel supports. The bit definitions for this field correspond directly with the bit definitions for the Unicast Infrastructure Filter Settings field defined for the Unicast Infrastructure Filter command listed in Table 12-29. A bit set to 1b indicates that the channel supports the filter associated with that bit position. Otherwise, the channel does not support that filter. The E810 supports all filters but ICMPv6 filtering, so the returned value is 0x7FB.
- ***Filtering Capabilities —*** The bits in this field are listed in Table 12-30.

Table 12-30. Filtering Capabilities Field Descriptions

Bits	Field	Description
0	IPv4 Support	0b = IPv4 filtering is not supported. 1b = IPv4 filtering is supported.
1	IPv6 Support	0b = IPv6 filtering is not supported. 1b = IPv6 filtering is supported.
2	Protocol Filtering Support	0b = Filtering by protocol is not supported. 1b = Filtering by protocol is supported.
3	Source Port Filtering Support	0b = Port filtering is supported only for destination port. 1b = Port filtering is supported for destination port or source port.
7:4	Reserved	Reserved.

12.6.4.14.7 Shared IP Enable Broadcast Filtering Command (Intel Command 0x25, Parameter 0x6)

The Shared IP Enable Broadcast Filtering command is defined to enable the MC to limit the flow of ARP requests to those that contain a target IP Address value that matches the MC IP Address.

This command should be used instead of the regular NC-SI Enable Broadcast Filtering command.

Note: Receiving a standard NC-SI Enable Broadcast Filtering command enables the matching bits in this command. Receiving a standard NC-SI Disable Broadcast Filter Command clears the settings in this command.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header

28...31	Shared IP Broadcast Packet Filter Settings			
32...35	Checksum			
36...39	Padding			

The content of the *Shared IP Broadcast Packet Filter Settings* field is listed in Table 12-31. Bit 4 has been added to the standard Enable Broadcast Filtering command limit ARP broadcast packets to the MC IP Address.

Table 12-31. Shared IP Broadcast Packet Filter Settings Field

Bits	Field Description	Value Description
3:0	As defined in DSP0222.	As defined in DSP0222 in 8.4.33 Enable Broadcast Filter Command (0x10) - Table 68.
4	Limit ARP Broadcast Packets to Management Controller IP Address.	When Bit 0 is set, it limits the flow of ARP packets to the MC as follows: 0b = Forward all ARP broadcast packets to the MC. 1b = Forward only ARP broadcast packets that are targeted at IP Addresses bound to the MC. All the IPs set by the Set IP command before this command is given are included in forwarding. This field is optional. If unsupported, the behavior for ARP packets is set according to Bit 1 in this structure. The value must be set to 0b if unsupported.
31:5	Reserved	Reserved.

12.6.4.14.7.1 Shared IP Enable Broadcast Filtering Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Shared IP Enable Broadcast Filtering command, and send a response using the following format.

Note: Currently, no command-specific reason codes are identified for this response.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x6	Reserved	
28...31	Checksum			

12.6.4.14.8 Shared IP Enable Global Multicast Filtering Command (Intel Command 0x25, Parameter 0x7)

The Shared IP Enable Global Multicast Filtering command is defined to enable the MC to enable the forwarding of IEEE 802.1X Extensible Authentication Protocol over LAN (EAPOL) frames to the MC IP Address. IEEE 802.1X defines methods for port-based network access control.

This command should be used instead of the regular NC-SI Enable Global Multicast Filtering command.

Note: Receiving a standard NC-SI Enable Global Multicast Filtering command enables the matching bits in this command. Receiving a standard NC-SI Disable Global Multicast Filter command clears the settings in this command.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x7	Reserved	
28...31	Shared IP Multicast Packet Filter Settings			
32...35	Checksum			
36...39	Padding			

The content of the *Shared IP Multicast Packet Filter Settings* field is listed in Table 12-32. Bit 3 has been added to the standard Enable Broadcast Filtering command limit ARP broadcast packets to MC IP Address.

Table 12-32. Shared IP Multicast Packet Filter Settings Field

Bits	Field Description	Value Description
2:0	As defined in DSP0222.	As defined in DSP0222 in 8.4.37 Enable Global Multicast Filter Command (0x12) - Table 74.
3	IEEE 802.1X EAPOL	This field is optional. If unsupported, multicast 802.1X packets are blocked when multicast filtering is enabled, unless they are matched by an address filter configured using the Set MAC Address command. The value must be set to 0b if unsupported. 0b = Filter out this packet type. 1b = Forward this packet type to the MC. For the purposes of this filter, a IEEE 802.1X multicast packet is defined to be any packet that meets all of the following requirements: • The *Destination MAC Address* field is set to the layer 2 multicast address 01:80:c2:00:00:03. • The *EtherType* field is set to 0x888E (802.1X PAE).
31:4	Reserved	Reserved.

12.6.4.14.8.1 Shared IP Enable Global Multicast Filtering Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Shared IP Enable Global Multicast Filtering command, and send a response using the following format.

Note: Currently, no command-specific reason codes are identified for this response.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x7	Reserved	
28...31	Checksum			

12.6.4.14.9 Get Shared IP Parameters Command (Intel Command 0x25, Parameter 0x8)

The Get Shared IP Parameters command can be used by the MC to request that the channel send the MC a copy of part of the currently-stored parameter settings that have been put into effect by the MC related to shared IP filtering.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x8	Reserved	
24...27	Checksum			

12.6.4.14.9.1 Get Shared IP Parameters Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Shared IP Parameters command, and send a response using the following format.

Note: Currently, no command-specific reason codes are identified for this response.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x8	Reserved	
28...31	Number of IP Addresses	IP Address Flags		
32...35	Number of Ports	Port Flags		
36...39	Unicast Infrastructure Filter Settings			
40...43	Broadcast Filtering Settings			
44...47	Multicast Filtering Settings			
48...51	Checksum			

Where:

- ***Number of IP Addresses*** — The number of supported IP filters including all the types of IP Addresses (IPv4 only, IPv6 only and mixed).
- ***IP Address Flags*** — The enable/disable state for each supported IP Address. See Table 12-33.

Table 12-33. IP Address Flags Field

Bits	Field Description	Value Description
0	IP Address 1 Status	0b = Default or unsupported or disabled. 1b = Enabled.
1	IP Address 2 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
2	IP Address 3 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
...		
23	IP Address 24 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.

Note: IP Address flags are organized in the following order: IPv4 Addresses first, followed by IPv6 Addresses, followed by mixed addresses, with the number of each corresponding to those reported through the Get Shared IP Capabilities command.

For example, if the interface reports four IPv4 filters, two IPv6 filters, and two mixed filters, IP Addresses 1 through 4 are those currently configured through the interface's IPv4 filters, IP Addresses 5 and 6 are those configured through the IPv6 filters, and 7 and 8 are those configured through the mixed filters.

The actual settings of each enabled IP Address can be found using the Get IP Address command

- ***Number of Ports*** — The number of supported port filters.
- ***Port Flags*** — The enable/disable state for each supported ports. See Table 12-34.

Table 12-34. Port Flags Field

Bits	Field Description	Value Description
0	Port 1 Status	0b = Default or unsupported or disabled. 1b = Enabled.
1	Port 2 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
2	Port 3 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
...		
23	Port 24 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.

Note: The actual settings of each enabled port can be found using the Get Port command.

- ***Unicast Infrastructure Filter Settings*** — Defines the optional unicast infrastructure filter capabilities settings. The bit definitions for this field correspond directly with the bit definitions for the *Unicast Infrastructure Filter Settings* field defined for the Unicast Infrastructure Filter command in Table 12-29. A bit set to 1b indicates that the filter associated with that bit position is enabled. Otherwise, the filter is not enabled.
- ***Broadcast Filter Settings*** — Defines the optional broadcast filter settings. The bit definitions for this field correspond directly with the bit definitions for the *Broadcast Filter Settings* field defined for the Shared IP Broadcast Filtering command in Table 12-31. A bit set to 1b indicates that the filter associated with that bit position is enabled. Otherwise, the filter is not enabled.
- ***Multicast Filter Settings*** — Defines the optional multicast filter capabilities settings. The bit definitions for this field correspond directly with the bit definitions for the *Multicast Filter Settings* field defined for the Shared IP Global Multicast Filtering command in Table 12-32. A bit set to 1b indicates that the filter associated with that bit position is enabled. Otherwise, the filter is not enabled.

12.6.4.14.10 Set Binding Command (Intel Command 0x25, Parameter 0x9)

The Set Binding command is used by the MC to define which combination of MAC Addresses, VLAN tags, IP Addresses and TCP/UDP ports should be forwarded to the MC.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0x9	Binding Index	Set Binding Flags
24...27	Enabled MAC Addresses			
28...31	Enabled VLAN			
32...35	Enabled IP Addresses			
36...39	Enabled Ports (MSB)			
40...43	Enabled Ports (LSB)			
44...47	Checksum			

Once a Set Binding command is activated, all the previous forwarding rules based on the Set MAC Address or Set VLAN Filter commands are disabled and should be re-enabled using the Set Binding command. Subsequent Set MAC Address or Set VLAN Filter commands are used to enable MAC or VLAN addresses for the Set Binding command, but does not impact the forwarding rules.

Table 12-35 lists the fields in the Set Binding Flags field.

Table 12-35. Set Binding Flags Field Descriptions

Bits	Field Description	Value Description
0	Enable	0b = Disable the binding. 1b = Enable the binding.
1	Exclusive to MC	0b = Traffic matching this filter is sent to the MC and to the host. 1b = Traffic matching this filter is sent to the MC only.
2	Apply to Network[1]	0b = Do not compare traffic received from the network when checking this binding. 1b = Compare traffic received from the network when checking this binding.
3	Apply to Host	0b = Do not compare traffic received from the host when checking this binding. 1b = Compare traffic received from the host when checking this binding.
7:4	Reserved	Reserved.

1. At least one of the apply to network/host flags should be set for enabled bindings. Clearing both of them is equivalent to disabling the filter.

Where:

- ***Binding Index*** — Indicates which binding is configured by the command. The value should be smaller than the number of supported bindings as reported in the Get Shared IP Capabilities response in the *Number of Bindings* field.

- ***Enabled MAC Addresses*** — The MAC Addresses participating in this binding. The numbering of the MAC Addresses is similar to the one used in the *Mac Address Flags* in the Get Parameters response. Namely, MAC Addresses are returned in the following order: unicast filtered addresses first, followed by multicast filtered addresses, followed by mixed filtered addresses, with the number of each corresponding to those reported through the Get Capabilities command. A MAC Address can be added to a binding only if previously enabled through a Set MAC Address NC-SI command
- ***Enabled VLAN*** — The VLAN IDs participating in this binding. The numbering of the VLAN IDs. A VLAN tag can be added to a binding only if previously enabled through a Set VLAN Filter NC-SI command.
- ***Enabled IP Addresses*** — The IP Addresses participating in this binding. The numbering of the IP Addresses is similar to the one used in Section 12.6.4.14.9. An IP Address can be added to a binding only if previously enabled through a Set IP Address Intel OEM command.
- ***Enabled Ports*** — The ports participating in this binding. A port can be added to a binding only if previously enabled through a Set Port Intel OEM command.

12.6.4.14.10.1 Set Binding Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set Binding command and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0x9	Reserved	
28...31	Checksum			

12.6.4.14.11 Get Binding Command (Intel Command 0x25, Parameter 0xA)

The Get Binding command to is used by the MC to determine the current programming of one of the bindings in a NC.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x25	0xA	Binding Number	Reserved
24...27	Checksum			

Where:

- ***Binding Number*** — Indicates which binding is requested by the command. The value should be smaller than the number of supported bindings as reported in the Get Shared IP Capabilities Response in the *Number of Bindings* field.

12.6.4.14.11.1 Get Binding Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Binding command, and send a response using the following format.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7				
8...11				
12...15				
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x25	0xA	Binding Number	Get Binding Flags
28...31	Enabled MAC Addresses			
32...35	Enabled VLAN			
36...39	Enabled IP Addresses			
40...43	Enabled Ports (MSB)			
44...47	Enabled Ports (LSB)			
48...51	Checksum			

The fields in the Get Binding response are equivalent to their counterparts in the Set Binding command.

12.6.4.14.12 Set Shared Mode Command (Intel Command 0x25, Parameter 0xB)

An MC uses the Set Shared Mode command to indicate to the NIC that it intends to operate in shared MAC/ IP mode or in dedicated MAC mode.

If used, this command should be sent before any of the regular or OEM NC-SI commands used to set forwarding filters. When this command is received, all the filters are cleared.

This command is needed only when the Intel OEM commands with command ID 0x25 are used to configure the shared behavior. If other commands are used, users should ensure the correct configuration of the filters.

When shared mode is activated, the Set MAC and Set VLAN NC-SI commands do not impact the receive filtering until a Set Binding or Enable Unicast Infrastructure Filter command is received.

Any other command from this section (Section 12.6.4.14) received before shared mode is set fails with a "Not in Shared Mode" (0x5092) reason.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**
0...3	NC-SI Header			
4...7

20...23	Manufacturer ID (Intel 0x157)			
24...25	0x40	0x03		

12.6.4.15.4 Set BMC IP Address Command (Intel Command 0x40, Parameter 0x04)

This command is used to expose the MC IP Address to the host. This command is supported by the E810, but no action is taken upon reception. The IP Address is not stored, and when a Get OS2BMC Parameters command is received, the *IP Valid* flag is cleared.

The *IP Type* entry indicates whether the IP Address is an IPv4 or an IPv6 Address:

0 = IPv4

1 = IPv6

2 = No IP Address — The command should not include an IP Address.

	Bits

32...35	Padding			
36...39				
40...43				
44...45	Padding			

Where:

- ***Maximum Temperature Value*** — This value is the maximum T-Diode temperature limit in °C at which the E810 can operate at full load for its rated service lifetime. The value should be de-rated to take measurement tolerance into account. The value is reported as a hexadecimal integer number. The value to report for the E810 is: 102 - 0x66 (105 - Thermal sensor accuracy of +/-3).
- ***Current Temperature Value*** — This value is the current real-time temperature of the chip in °C. The value is reported as a hexadecimal integer number.

12.6.4.18 Initialization Error AEN (Intel AEN 0x82)

Note: This AEN was previously called “NVM error AEN”.

The following is the AEN that might be sent by the NC following a detection of an error as part of the firmware initialization (reflected by a non-null error in *GL_MNG_FWSM*). NC is required to store this AEN internally until a connection to the MC is established so the report can be issued in all cases.

This AEN must be enabled using the NC-SI AEN Enable command, using Bit 18 (0x40000) of the AEN enable mask.

	Bits			
Bytes	**31:24**	**23:16**	**15:8**	**7:0**

8...11				
12...15				
20...23	Reserved			0x82
24	Index of firmware module in which the error was found. The encoding is as defined in GL_MNG_FWSM.*EXT_ERR_IND* field.			

12.6.5 Basic NC-SI Workflows

12.6.5.1 Package States

A NC package can be in one of the following two states:

- **Selected** — The package is allowed to use the NC-SI lines, meaning the NC package might send data to the MC.
- **Deselected** — The package is not allowed to use the NC-SI lines, meaning, the NC package cannot send data to the MC.

The MC must select no more than one NC package at any given time. Package selection can be accomplished in one of two methods:

- **Select Package command** — This command explicitly selects the NC package.
- Any other command targeted to a channel in the package also implicitly selects that NC package.

Package de-select can be accomplished only by issuing the Deselect Package command. The MC should always issue the Select Package command as the first command to the package before issuing channel-specific commands. For further details on package selection, refer to the NC-SI specification.

12.6.5.2 Channel States

A NC channel can be in one of the following states:

- **Initial State** — The channel only accepts the Clear Initial State command (the package also accepts the Select Package and Deselect Package commands).
- **Active State** — This is the normal operational mode. All commands are accepted.

For normal operation mode, the MC should always send the Clear Initial State command as the first command to the channel.

12.6.5.3 Discovery

After interface power-up, the MC should perform a discovery process to discover the NCs that are connected to it. This process should include an algorithm similar to the following:

For *package_id* = 0x0 to MAX_PACKAGE_ID:

1. Issue a Select Package command to package ID *package_id*.

   If a response was received:

   a. For *internal_channel_id* = 0x0 to MAX_INTERNAL_CHANNEL_ID.

   b. Issue a Clear Initial State command for *package_id* | *internal_channel_id* (the combination of *package_id* and *internal_channel_id* to create the channel ID).

      If a response was received:

      1. Consider *internal_channel_id* as a valid channel for the *package_id* package.
      2. The MC can now optionally discover channel capabilities and version ID for the channel.

      Else, if a response was not received:

      1. Issue a Clear Initial State command three times.

   c. Issue a Deselect Package command to the package (and continue to the next package).

   Else, if a response was not received:

   a. Issue a Select Packet command three times.

12.6.5.4 Configurations

This section details different configurations that should be performed by the MC.

It is good practice that the MC not consider any configuration valid unless the MC has explicitly configured it after every reset (entry into the initial state). As a result, it is recommended that the MC reconfigure everything at power-up and channel/package resets.

12.6.5.4.1 NC Capabilities Advertisement

NC-SI defines the Get Capabilities command. It is recommended that the MC use this command and verify that the capabilities match its requirements before performing any configurations. For example, the MC should verify that the NC supports a specific AEN before enabling it.

12.6.5.4.2 Receive Filtering

To receive traffic, the BMC must configure the NC with receive filtering rules. These rules are checked on every packet received on the LAN interface (such as from the network). Only if the rules matched, will the packet be forwarded to the BMC.

12.6.5.4.2.1 MAC Address Filtering

NC-SI defines three types of MAC Address filters: unicast, multicast, and broadcast. To be received (not dropped) a packet must match at least one of these filters. The MC should set one MAC Address using the Set MAC Address command and enable broadcast and global multicast filtering.

Unicast/Exact Match (Set MAC Address command)

This filter filters on specific 48-bit MAC Addresses. The MC must configure this filter with a dedicated MAC Address.

The NC might expose three types of unicast/exact match filters (such as MAC filters that match on the entire 48 bits of the MAC Address): unicast, multicast, and mixed. The E810 exposes two mixed filters, which might be used both for unicast and multicast filtering. The MC should use one mixed filter for its MAC Address.

For further details, refer to the Set MAC Address command in the NC-SI specification.

Broadcast (Enable/Disable Broadcast Filter command)

NC-SI defines a broadcast filtering mechanism that has the following states:

- **Enabled** — All broadcast traffic is blocked (not forwarded) to the BMC, except for specific filters (such as ARP request, DHCP, and NetBIOS).
- **Disabled** — All broadcast traffic is forwarded to the BMC, with no exceptions.

For further details, refer to the Enable/Disable Broadcast Filter command in the NC-SI specification.

Global Multicast (Enable/Disable Global Multicast Filter command)

NC-SI defines a multicast filtering mechanism which has the following states:

- **Enabled** — All multicast traffic is blocked (not forwarded) to the BMC.
- **Disabled** — All multicast traffic is forwarded to the BMC, with no exceptions.

The recommended operational mode is Enabled, with specific filters set. Not all multicast filtering modes are necessarily supported. For further details, refer to the Enable/Disable Global Multicast Filter command in the NC-SI specification.

12.6.5.4.3 VLAN

NC-SI defines the following VLAN work modes:

Mode	Command and Name	Description
Disabled	Disable VLAN Command	In this mode, no VLAN frames are received.
Enabled #1	Enable VLAN command with VLAN only	In this mode, only packets that matched a VLAN filter are forwarded to the MC.
Enabled #2	Enable VLAN command with VLAN only + non-VLAN	In this mode, packets from mode 1 + non-VLAN packets are forwarded.
Enabled #3	Enable VLAN command with Any-VLAN + non-VLAN	In this mode, packets are forwarded regardless of their VLAN state.

For further details, refer to the Enable VLAN command in the NC-SI specification.

The E810 only supports modes #1 and #3. Recommendation:

1. Modes:
   - If VLAN is not required, use the disabled mode.
   - If VLAN is required, use the enabled #1 mode.
2. If enabling VLAN, the MC should also set the active VLAN ID filters using the NC-SI Set VLAN Filter command prior to setting the VLAN mode.

12.6.5.5 PT Traffic States

The MC has independent, separate controls for enablement states of the receive (from LAN) and of the transmit (to LAN) PT paths.

12.6.5.6 Channel Enable

This mode controls the state of the receive path:

- **Disabled** — The channel does not pass any traffic from the network to the MC.
- **Enabled** — The channel passes any traffic from the network (that matched the configured filters) to the MC.

This state also affects AENs: AENs is only sent in the enabled state. The default state is disabled.

It is recommended that the MC complete all filtering configuration before enabling the channel.

12.6.5.7 Network Transmit Enable

This mode controls the state of the transmit path:

- **Disabled** — The channel does not pass any traffic from the MC to the network.
- **Enabled** — The channel passes any traffic from the MC (that matched the source MAC Address filters) to the network.

The default state is disabled.

The NC filters PT packets according to their source MAC Address. The NC tries to match that source MAC Address to one of the MAC Addresses configured by the Set MAC Address command. As a result, the MC should enable network transmit only after configuring the MAC Address.

It is recommended that the MC complete all filtering configuration (especially MAC Addresses) before enabling the network transmit.

This feature can be used for fail-over scenarios. See Section 12.6.9.3.

12.6.6 Asynchronous Event Notifications (AENs)

AENs are unsolicited messages sent from the NC to the MC to report status changes (such as link change, operating system state change, and so on).

Recommendations:

- The MC firmware designer should use AENs. To do so, the designer must take into account the possibility that a NC-SI response frame (such as a frame with the NC-SI EtherType), arrives out-of-context (not immediately after a command, but rather after an out-of-context AEN).
- To enable AENs, the MC should first query which AENs are supported, using the Get Capabilities command, then enable desired AEN(s) using the Enable AEN command, and only then enable the channel using the Enable Channel command.

12.6.7 Querying Active Parameters

The MC can use the Get Parameters command to query the current status of the operational parameters.

12.6.8 Resets

In NC-SI there are two types of resets defined:

- Synchronous entry into the initial state.
- Asynchronous entry into the initial state.

Recommendations:

- It is very important that the MC firmware designer keep in mind that following any type of reset, all configurations are considered as lost and thus the MC must reconfigure both the synchronous and asynchronous entries.
- As an asynchronous entry into the initial state might not be reported and/or explicitly noticed, the MC should periodically poll the NC with NC-SI commands (such as Get Version ID, Get Parameters, and so on) to verify that the channel is not in the initial state. Should the NC channel respond to the command with a Clear Initial State Command Expected reason code, the MC should consider the channel (and most probably the entire NC package) as if it underwent a (possibly unexpected) reset event. Thus, the MC should reconfigure the NC. See the NC-SI specification section on Detecting Pass-through Traffic Interruption.
- The Intel-recommended polling interval is 2-3 seconds.

For exact details on the resets, refer to NC-SI specification.

12.6.9 Advanced Workflows

12.6.9.1 Multi-NC Arbitration

As described in Section 12.6.1.2, in a multi-NC environment, there is a need to arbitrate the NC-SI lines. Figure 12-9 shows the system topology of such an environment.

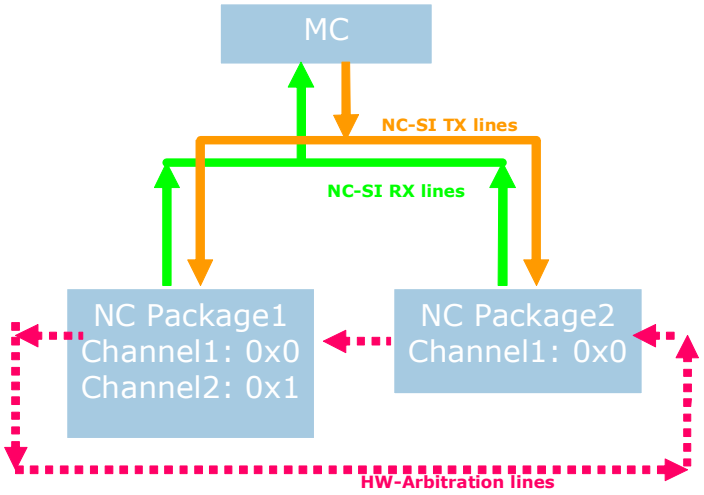

Figure 12-9. Multi-NC Environment

In Figure 12-9, the NC-SI Rx lines are shared between the NCs. To enable sharing of the NC-SI Rx lines, NC-SI has defined an arbitration scheme.

The arbitration scheme mandates that only one NC package can use the NC-SI Rx lines at any given time. The NC package that is allowed to use these lines is defined as selected. All the other NC packages are deselected.

NC-SI has defined two mechanisms for the arbitration scheme:

- **Package selection by the MC** — In this mechanism, the MC is responsible for arbitrating between the packages by issuing NC-SI commands (Select/Deselect Package). The MC is responsible for having only one package selected at any given time.
- **Hardware arbitration** — In this mechanism, two additional pins on each NC package are used to synchronize the NC package. Each NC package has an ARB_IN and ARB_OUT line and these lines are used to transfer tokens. A NC package that has a token is considered selected.

Note: Hardware arbitration is enabled by the *NC-SI HW Arbitration Enable* configuration bit in the NC-SI Configuration 1 NVM word.

For details, refer to the NC-SI specification.

12.6.9.2 Package Selection Sequence Example

Following is an example work flow for a MC and occurs after the discovery, initialization, and configuration.

Assuming the MC needs to share the NC-SI bus between packages, the MC should:

1. Define a time-slot for each device.
2. Discover, initialize, and configure all the NC packages and channels.
3. Issue a Deselect Package command to all the channels.
4. Set *active_package* to 0x0 (or the lowest existing package ID).
5. At the beginning of each time slot the MC should:
   a. Issue a Deselect Package command to the *active_package*. The MC must then wait for a response and then an additional timeout for the package to become deselected (200 μs). See the NC-SI specification Table 10 "parameter NC Deselect to Hi-Z Interval".
   b. Find the next available package (typically *active_package* = *active_package* + 1).
   c. Issue a Select Package command to *active_package*.

12.6.9.3 Multiple Channels (Fail-Over)

To support a fail-over scenario, it is required from the MC to operate two or more channels. These channels might or might not be in the same package.

The key element of a fault-tolerance fail-over scenario is having two (or more) channels identifying to the switch with the same MAC Address, but only one of them being active at any given time (such as switching the MAC Address between channels). To accomplish this, NC-SI provides the following commands:

- Enable Network Tx command — This command enables shutting off the network transmit path of a specific channel. This enables the MC to configure all the participating channels with the same MAC Address but only enable one of them.
- Link Status Change AEN or Get Link Status command.

12.6.9.3.1 Fail-Over Algorithm Example

The following is a sample workflow for a fail-over scenario for the E810 (one package and four channels):

1. The MC initializes and configures all channels after power-up. However, the MC uses the same MAC Address for all of the channels.
2. The MC queries the link status of all the participating channels. The MC should continuously monitor the link status of these channels. This can be accomplished by listening to AENs (if used) and/or periodically polling using the Get Link Status command.
3. The MC then only enables channel 0 for network transmission.
4. The MC then issues a gratuitous ARP (or any other packet with its source MAC Address) to the network. This packet informs the switch that this specific MAC Address is registered to channel 0's specific LAN port.
5. The MC begins normal workflow.

6. Should the MC receive an indication (AEN or polling) that the link status for the active channel (channel 0) has changed, the MC should:
   a. Disable channel 0 for network transmission.
   b. Check if a different channel is available (link is up).

      If found:

      1. Enable network Tx for that specific channel.
      2. Issue a gratuitous ARP (or any other packet with its source MAC Address) to the network. This packet informs the switch that this specific MAC Address is registered to channel 0's specific LAN port.
      3. Resume normal workflow.

      If not found:

      1. Report the error and continue polling until a valid channel is found.

The previous algorithm can be generalized such that the start-up and normal workflow are the same. In addition, the MC might need to use a specific channel (such as channel 0). In this case, the MC should switch the network transmit to that specific channel as soon as that channel becomes valid (link is up).

Recommendations:

- Wait for a link-down-tolerance timeout before a channel is considered invalid. For example, a link re-negotiation might take a few seconds (normally 2 to 3 or might be up to 9). Thus, the link must be re-established after a short time.
- Typically, this timeout is recommended to be three seconds.
- Even when enabling and using AENs, periodically poll the link status, as dropped AENs might not be detected.

12.6.9.4 Statistics

The MC might use the statistics commands as defined in NC-SI. These counters are intended for debug purposes and are not all supported.

The statistics are divided into three commands:

- **Controller Statistics** — These are statistics on the network interface (to the host operating system and the PT traffic). See the NC-SI specification for details.
- **NC-SI Statistics** — These are statistics on the NC-SI control frames (such as commands, responses, AENs, and so on). See the NC-SI specification for details.
- **NC-SI PT Statistics** — These are statistics on the NC-SI PT frames. See the NC-SI specification for details.

12.7 Management Component Transport Protocol (MCTP)

12.7.1 MCTP Overview

MCTP defines a communication model intended to facilitate communication between:

- MCs and other MCs.
- MCs and management devices.

The communication model includes a message format, transport description, message exchange patterns, and configuration and initialization messages.

The basic MCTP specification is described in DMTF's DSP0236 document.

MCTP is designed so that it can potentially be used on many bus types. The protocol is intended to be used for intercommunication between elements of platform management subsystems used in computer systems, and is suitable for use in mobile, desktop, workstation, and server platforms.

Currently, specifications exists for MCTP over PCIe (DMTF's DSP0238) and over SMBus (DMTF's DSP0237). A specification for MCTP over USB is also planned.

MCs such as a Baseboard Management Controller (BMC) can use this protocol for communication between one another, as well as for accessing management devices within the platform.

12.7.1.1 MCTP Usage Model

The E810 supports MCTP protocol over the PCIe and SMBus buses. The E810 can connect through MCTP to a MC or the ME engine in the chipset, as described in Figure 12-10.

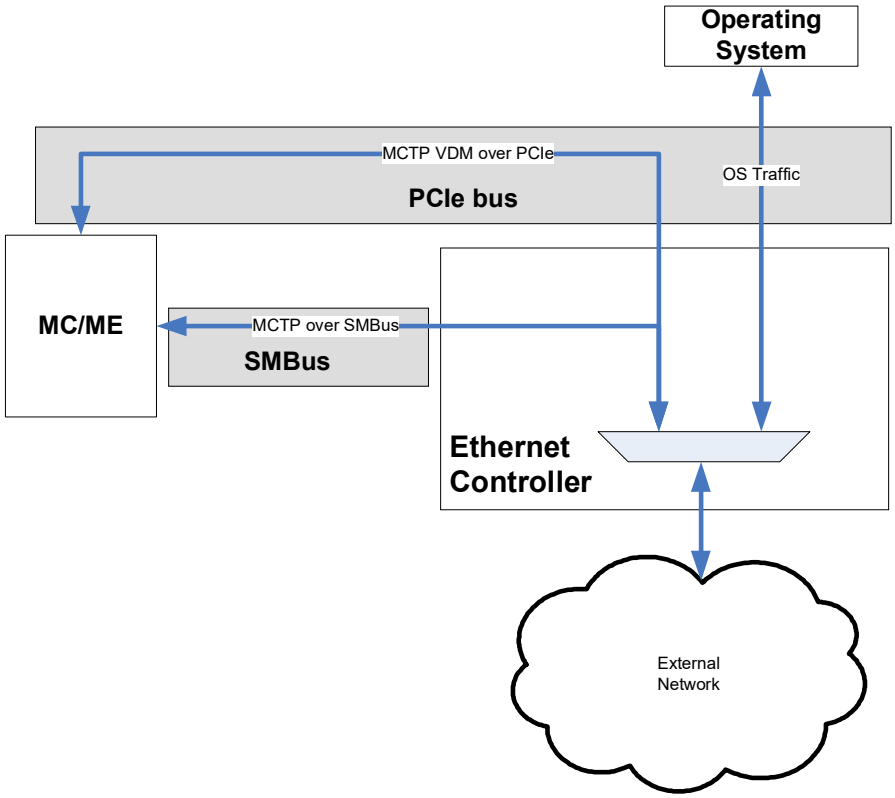

Figure 12-10. E810 MCTP Connections

12.7.1.2 Detecting an MC EID and Physical Address

To enable transactions between the MC and the NIC, the bus physical address (SMBus or PCIe) and the EID of the partner need to be discovered. NICs do not try to discover the MC, and assume the MC initiates the connection. If the NIC is in an NC-SI initial state, the EID and the physical address of the MC are extracted from the Clear Initial State command parameters or any other NC-SI command received later with a channel ID of the E810. Subsequent pass-through traffic is received from or sent to this address only.

If the EID or the physical address of the NIC changes, it indicates the changes to bus owner so that the routing tables can be updated. There is no attempt to directly send an indication to the MC about the change.

See more details in next section.

12.7.1.3 Bus Transition

The following section defines the transition flow between PCIe and SMBus as the bus on which MCTP flows. Figure 12-11 describes the flow to transition between PCIe and SMBus. The following parameters are used to define the flow:

- NIC EID on PCIe
- NIC EID on SMBus

- NIC PCIe Target ID
- Bus Owner EID on PCIe
- Bus Owner EID on SMBus
- Bus Owner PCIe Target ID
- Bus Owner SMBus Address
- MC EID on PCIe
- MC EID on SMBus
- MC PCIe Target ID
- MC SMBus Address
- NIC SMBus Address

All of these variables are initialized to zero at power-on, apart from the SMBus address of the endpoint (NIC), which might be initialized from an NVM value.

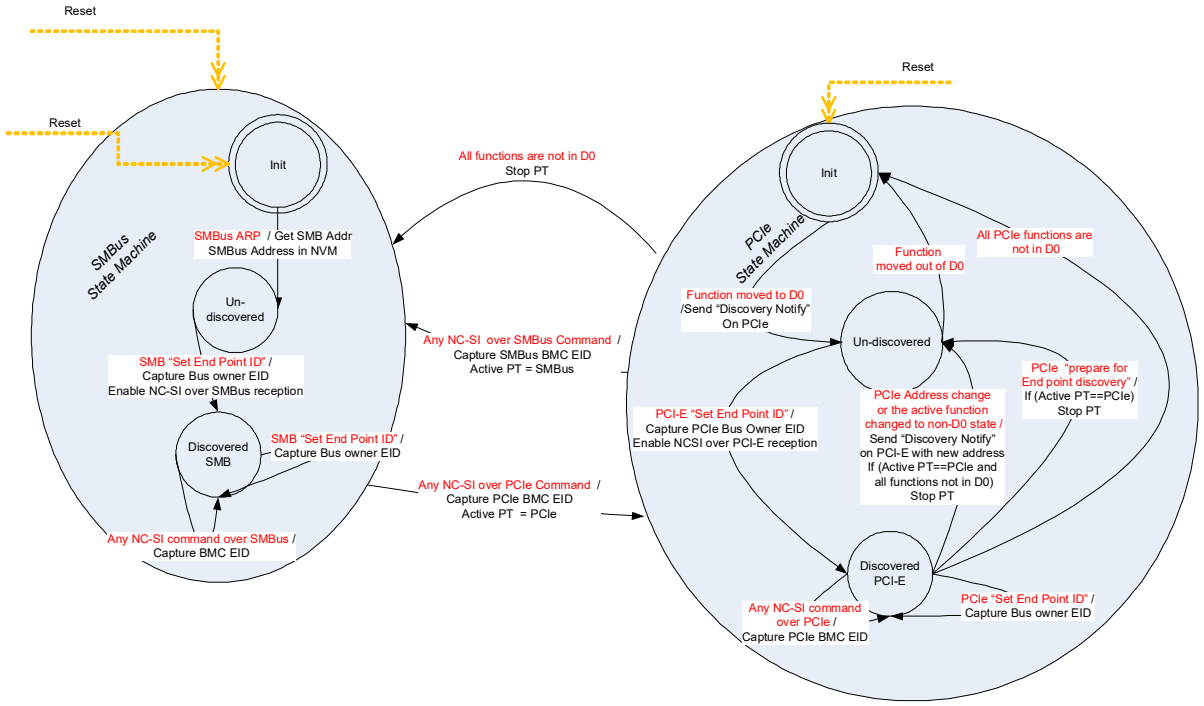

Figure 12-11. MCTP Bus Transition State Machine

12.7.1.3.1 Initial Assignment Flow

1. At power on, the NIC or MC MCTP channel is connected to the SMBus, is not assigned an EID, and is in an undiscovered state.
2. The bus owner might preform an SMBus ARP cycle to assign an SMBus address to the NIC or to the MC. Otherwise, a fixed address might be used. It is assumed that the SMBus address does not change after initialization time.

3. The bus owner performs an EID assignment using a Set Endpoint ID MCTP command. The NIC or the MC captures the SMBus address of the bus owner from the *SMBus Source Slave Address* field, the bus owner EID from the *Source Endpoint ID* field and the NIC/MC EID from the *Destination Endpoint ID* field in the MCTP header as described in Section 10.3 of DSP0236. The NIC/MC is now in a discovered state.
4. The MC might detect the NIC EID using one of the two following modes:
   - Static configuration of the NIC SMBus address in the MC database and Get Routing Table Entries command to find the EID matching the SMBus address.
   - Get all endpoints through a Get Routing Table Entries command and find endpoints supporting NC-SI using the Get Message Type Support command for each endpoint.
5. Once the NIC is found, the MC might send a Clear Initial State command to the NIC to start the NC-SI configuration. The NIC captures the MC SMBus address and MC EID from any NC-SI command received.
6. After the NC-SI channels are enabled, traffic might be sent using the MC and NIC addresses previously discovered.
7. The MC might also send a Get UUID command to get a unique identifier of the NIC that might be used later for re-connection upon topology changes.

12.7.1.3.2 SMBus-to-PCIe Transition

1. If the NIC or the MC detects that the PCIe bus is available by detecting a function that moved to D0 state, it might request a transition using a Discovery Notify MCTP command on the PCIe bus. This command should be sent with a route to root-complex addressing as described in DSP0238, Section 6.8. The source EID should be the EID previously assigned on the SMBus.
2. If the NIC or the MC detects that the PCIe bus is available by detecting a non-zero bus number as reflected in the PF_FUNC_RID.*BUS_NUMBER* field, it might request a transition using a Discovery Notify MCTP command on the PCIe bus. This command should be sent with a route to root-complex addressing as described in DSP0238, Section 6.8. The source EID should be the EID previously assigned on the SMBus.
3. After receiving the Discovery Notify MCTP command on the PCIe bus, the bus owner sends a Set Endpoint ID MCTP command on the PCIe bus and updates the routing table. The bus owner might choose to wait for the Discovery Notify MCTP command of both the MC and the NIC to do the transition. The bus owner should try to keep the EID previously assigned on the SMBus as the EID on PCIe bus.
4. After receiving the Set Endpoint ID MCTP command, the NIC waits for an NC-SI command from the MC indicating it is ready to transition the connection to PCIe. After receiving such a command, the NIC transitions its PT traffic to the PCIe bus using the newly received addresses.
5. The MC on its side, needs to discover the PCIe address of the NIC. This can be done using the Resolve Endpoint ID command if only the physical address changed or using the Resolve Endpoint UUID command also if both EID and physical address changed. It can then send an NC-SI command to the NIC to initiate the transition. The MC should not send any pass-through packets from the moment it sent the first NC-SI command on the PCIe and the moment a response is received for this command.
6. The transition of NC-SI traffic (pass-through or commands/responses) from SMBus to PCIe should be done on a packet boundary and should not interrupt a packet fragmentation or reassembly.

12.7.1.3.3 PCIe Target ID Change

The target ID of one of the endpoints might change due to a new enumeration of the PCIe bus. In this case the following flow should be used:

The target ID of one of the endpoints might change, either due to a new enumeration of the PCIe bus or due to the disabling of one of the functions in the device (move to a non D0 state). In this case, the following flow should be used:

1. The endpoint should send a Discovery Notify MCTP command on the PCIe bus using the new Requester ID.
2. After receiving the Discovery Notify MCTP command with the new Requester ID, the bus owner sends a Set Endpoint ID MCTP command on the PCIe bus and updates the routing table. The bus owner should try to keep the EID previously assigned on the SMBus as the EID on the previous Requester ID.
3. The bus owner sends an Routing Information Update command to all supporting endpoints that might then update the parameters of their counterpart they use.

12.7.1.3.4 PCIe-to-SMBus Transition

1. If the NIC or the MC detects that the PCIe bus is not available by detecting a transition of all functions to a non D0 state, it stops using the PCIe for pass-through traffic or NC-SI traffic.
2. If the NIC or the MC detects that the PCIe bus is not available by detecting a transition to Dr state, it stops using the PCIe for pass-through traffic or NC-SI traffic.
3. Upon detection of the unavailability of the PCIe bus, the MC transitions the NC-SI channel to the MCTP over SMBus as previously described.

Note: The transition of NC-SI traffic (pass-through or commands/responses) from PCIe to SMBus might done at any stage and might interrupt a packet fragmentation or reassembly, as it is assumed that such a transition occurs only when the PCIe bus is not available anymore.

12.7.2 MCTP over PCIe

12.7.2.1 Message Format

The message format used for NC-SI over MCTP over PCIe is as follows:

PCIe TLP Header
MCTP Header
NC-SI Header and Payload

Table 12-38. NC-SI/Ethernet over MCTP over PCIe Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
FMT 011			Type 10r2r1r0[1]					R	TC 000			R	Attr[2]	R	TH[2]	TD[2]	EP[2]	Attr [1:0][2]		AT 00			Length 00_000x_xxxx

																R		Pad Len		MCTP VDM Code - 0000b											
PCI Target ID (For Route by ID messages, otherwise = Reserved)																Vendor ID = 0x1AB4 (DMTF)															
MCTP Reserved				Header Version = 1				Destination Endpoint ID								Source Endpoint ID								SOM	EOM	SEQ#			TO	Tag	
IC	Message Type = 0x02/0x03							NC-SI Command/Pass-Through Data																							
.....																															
NC-SI Command/Pass-Through Data																															

1. r2r1r0 =
   000b: Route to Root Complex
   010b: Route by ID
   011b: Broadcast from Root Complex
2. TD = 0, EP = 0, TH = 0, Attr[2:0] = 0 for sent packets and is ignored for received packets.

12.7.2.2 PCIe Discovery Process

The E810 follows the discovery process described in Section 5.9 of the MCTP PCIe VDM Transport Binding Specification (DSP0238).

After receiving an endpoint discovery message (while in undiscovered stage), the E810 exposes the endpoint on the selected function as previously described.

If the selected function moves to D3 after the endpoint was discovered, or if the bus number of the E810 changes due to a re-enumeration of the bus, the E810 sends a discovery notify message to indicate to the MC that it should do a re-enumeration of the device to discover the new endpoint.

12.7.2.3 MCTP over PCIe Special Features

The E810 supports the following optional features of MCTP when running over PCIe:

- Rate limiting
- ACLs

12.7.2.3.1 MCTP Uplink Rate Limiting

As the PCIe link can carry a traffic bandwidth much higher than what the MC can sustain, to avoid drop of packets, the E810 allows rate limiting of the MCTP pass-through traffic. The E810 supports rate limiting between 1 Mb/s and 1 Gb/s. The following parameters define the behavior of the rate limiter:

- **Max Rate Limit** — Fixed from NVM via the MCTP rate in the MCTP rate limiter config 1 word.
- **Max Burst Size** — Fixed from NVM via the MCTP max credits field in the in the MCTP rate limiter config 2 word). To limit the max burst to one VDM, set this parameter to 5.
- **Decision Point** — Fixed from NVM via the decision point field in the in the MCTP rate limiter config 2 word).

This feature can be controlled dynamically by the DSP0236 Update Rate Limit command.

12.7.2.3.2 Service Provider MCTP Endpoint ACLs

The E810 supports a set of ACLs that allows reception of sensitive commands only from a specific bus number (in the Requester ID). The device and function part of the Requester ID are ignored for this purpose.

If ACLs are enabled (by clearing the *Disable ACLs* NVM bit) the following flow is used decide which packets are accepted.

Commands can be divided to three types:

- ACL programming commands: Such commands can be received only from the address that sent the Prepare For Endpoint Discovery command via broadcast routing.
- Sensitive commands including all the NC-SI commands and PT traffic. These commands can be received only from requesters whose bus number is set in the ACL list. If an MCTP packet is dropped, the SPMEACLD counter is increased. This counter can be read by the MCTP bus owner using the Get ACL Violation Counters command.
- Regular MCTP commands are received from any requester. However, the Set EID command is processed only if received from the address that sent the Prepare For Endpoint Discovery command via broadcast routing.

The E810 supports four ACL entries.

Note: This feature is disabled by default in NVM, as it requires a system infrastructure supporting the feature.

12.7.3 MCTP over SMBus

The message format used for NC-SI over MCTP over SMBus is as follows:

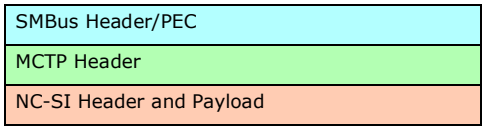

Table 12-39. NC-SI/Ethernet over MCTP over SMBus Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
Destination Slave Address							0	Command Code = MCTP = 0Fh								Byte Count								Source Slave Address							1
MCTP Reserved				Header Version = 1				Destination Endpoint ID								Source Endpoint ID								SOM		EOM		SEQ#		TO	Tag
IC[1]				Message Type = 0x02/0x03				NC-SI Command/Pass-Through Data																							
.....																															
NC-SI Command/Pass-Through Data																															
PEC																															

1. IC = 0 for pass-through sent packets, or as defined by firmware for other packets. Packet received with IC = 1 handling can be defined per message type.

12.7.3.1 SMBus Discovery Process

The E810 follows the discovery process described in Section 6.5 of the MCTP SMBus/I^2C Transport Binding Specification (DSP0237). It indicates support for ASF in the SMBus getUID command (see Section 12.3.2.1.3.2). It responds to any SMBus command using the MCTP command code. This ensures that the bus owner knows the E810 supports MCTP.

Note: MCTP commands over SMBus are received from any master address and are answered to the sender. There is no capturing of the bus owner address from any specific command.

12.7.3.2 MCTP over SMBus Special Features

The E810 supports the following optional features of MCTP when running over SMBus:

- Fairness arbitration

12.7.3.2.1 Fairness Arbitration

When sending MCTP messages over SMBus and when fairness arbitration is enabled (see Section 6.3.58.3), the E810 should adhere to the fairness arbitration as defined in Section 5.13 of DSP0237 when sending MCTP messages.

12.7.4 NC-SI over MCTP

MCTP is a transport layer protocol that does not include the functionality required to control the PT traffic required for an MC connection to the network. This functionality is provided by encapsulating NC-SI traffic as defined in DMTF's DSP0222 document.

The details of NC-SI over MCTP protocol are defined in the DMTF's DSP0261 - *NC-SI Over MCTP Specification*.

An NC-SI over MCTP implementation guide can be found in the DMTF's DSP0219 white paper. The NC-SI over MCTP specification defines two types of MCTP message types: NC-SI (0x2) and Ethernet (0x3). The E810 supports both messages. When used only for control, only the NC-SI (0x2) message type is supported.

In addition to the previous message types supported by the E810, the PCIe-based VDM message type is also supported over PCIe to support ACL commands.

Enabling NC-SI over MCTP for pass through traffic is done by setting the *Redirection Sideband Interface* field in the Common Manageability Parameters NVM word to "MCTP over PCI and SMBus".

Enabling NC-SI over MCTP for control traffic is done by setting the *Control Interface* field in the Common Manageability Parameters NVM word to "MCTP over SMBus/PCI" and by setting the *NC-SI* bit in Common Manageability Parameters 2 NVM word.

The E810 support for NC-SI over MCTP is similar to the support for NC-SI over RBT with the following exceptions:

- A set of new NC-SI OEM commands used to expose the NC-SI over MCTP capabilities.
- The format of the packets is modified to account for the new transport layer as described in the sections that follow.

12.7.4.1 NC-SI to MCTP Mapping

The eight network ports of the E810 (mapped to eight NC-SI channels) are mapped to a single MCTP endpoint on SMBus and to another endpoint over PCIe.

The PCIe endpoint is mapped to a PCIe Requester ID according to the following flow:

1. If the *Bus Master Enable* bit of at least one of the functions is set, the endpoint is mapped to the first available function.
2. If the *Bus Master Enable* bits of all functions are cleared, the MCTP endpoint on PCIe is not exposed, and the MCTP traffic is routed through the SMBus endpoint.

The slave address used for the SMBus endpoint is the slave address of the first port.

Section 12.7.1.2 describes the transition between the two buses.

Both endpoints (SMBus and PCIe) might be active concurrently. However, pass-through traffic can be transferred only through one of them. If the PCIe endpoint is active, it is used for pass-through traffic. Otherwise, the SMBus endpoint is used. The Set EID command can be used to force the transition for the PCIe endpoint to the SMBus endpoint if the bus owner determines the PCIe channel is not functional.

For each channel (SMBus or PCIe), the E810 should expect MCTP commands from two sources: the bus owner and the MC. In addition, it should expect pass-through traffic through one interface only. Thus, it should be able to process up to five interleaved commands/data:

- An MCTP control/OEM command from the PCIe bus owner (single packet message).

- An MCTP control/OEM command from the SMBus bus owner (single packet message).
- An MCTP control/OEM command from the MC over SMBus (single packet message).
- An MCTP control/OEM command from the MC over PCIe (single packet message).
- An NC-SI command or Ethernet packet from the MC over the active channel.

A single source should not interleave packets it sends.

The topology used for MCTP connection is shown in Figure 12-12.

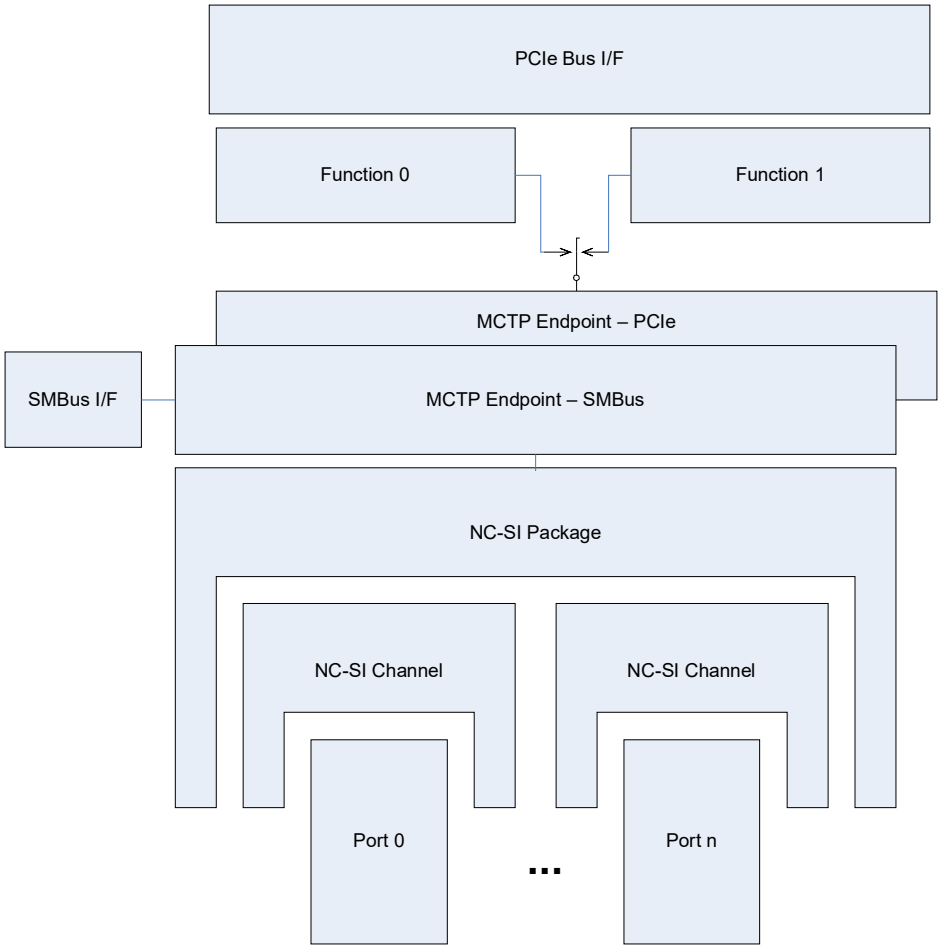

Figure 12-12. MCTP Endpoints Topology

12.7.4.2 NC-SI Packets Format

NC-SI over MCTP defines two different message type for pass-through and for control packets.

Packets with a message type equal to the *Control Packets Message Type* field (default = 0x02) in the NVM are NC-SI control packets (commands, responses, and AENs) and packets with a message type equal to the *Pass-Through Packets Message Type* field (default = 0x03) in the NVM are NC-SI pass-through packets.

12.7.4.2.1 Control Packets

The format used for control packets (commands, responses, and AENs) is as follows:

Table 12-40. NC-SI over MCTP over PCIe/SMBus Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

Checksum																															

1. The channel ID is defined as described in Section 12.3.2.2

Note: The MAC Header and MAC FCS present when working over NC-SI are not part of the packet in MCTP mode.

12.7.4.2.2 Pass-Through Packets

The format used for pass-through packets are as follows. This format is the same for either packets received from the network or packets received from the host.

The CRC is never included in the packet. In receive, the CRC is checked and removed by the E810. In transmit, the CRC is added by the E810.

Table 12-41. Ethernet over MCTP over PCIe/SMBus Message Format

12.7.5 PLDM over MCTP

Enabling PLDM over MCTP for control traffic is done by setting the *Control Interface* field in the Common Manageability Parameters NVM word to "MCTP over SMBus/PCI", and by setting the *PLDM* bit in Common Manageability Parameters 2 NVM word.

12.7.6 OEM Commands

Enabling OEM commands over MCTP for control traffic is done by setting the *Control Interface* field in the Common Manageability Parameters NVM word to "MCTP over SMBus/PCI", and by setting the *OEM Commands* bit in Common Manageability Parameters 2 NVM word.

12.7.7 MCTP Programming

The MCTP programming model is based on:

- A set of MCTP commands used for the discovery process and for the link management. The list of supported commands is described in section Section 12.7.7.1.

- A subset of the NC-SI commands used in the regular NC-SI interface, including all the OEM commands as described in Section 12.6.2 (NC-SI programming I/F). The specific commands supported are listed in Table 12-13 and Table 12-16.

Note: For all MCTP commands (both native MCTP commands and NC-SI over MCTP), the response uses the Msg tag received in the request with *TO* bit cleared.

12.7.7.1 MCTP Commands Support

Table 12-42 lists the MCTP commands supported by the E810.

Table 12-42. MCTP Commands Support

Command Name	Command Code	General Description	E810 Support as Initiator	E810 Support as Responder	Section Reference
Reserved	0x00	Reserved.	---	---	---
Set Endpoint ID	0x01	Assigns an EID to the endpoint at the given physical address.	N/A	Yes	12.7.7.1.1
Get Endpoint ID	0x02	Returns the EID presently assigned to an endpoint. Also returns information about what type the endpoint is and its level of use of static EIDs. See Section 12.7.7.1.2 for details.	No	Yes	12.7.7.1.2
Get Endpoint UUID	0x03	Retrieves a per-device unique UUID associated with the endpoint. See Section 12.7.7.1.3 for details.	No	Yes	12.7.7.1.3
Get MCTP Version Support	0x04	Lists which versions of the MCTP control protocol are supported on an endpoint. See Section 12.7.7.1.4 for details.	No	Yes	12.7.7.1.4
Get Message Type Support	0x05	Lists the message types that an endpoint supports. See Section 12.7.7.1.5 for details.	No	Yes	12.7.7.1.5
Get Vendor Defined Message Support	0x06	Used to discover an MCTP endpoint's vendor specific MCTP extensions and capabilities. See Section 12.7.7.1.6 for details.	No	Yes	12.7.7.1.6
Resolve Endpoint ID	0x07	Used to get the physical address associated with a given EID.	Yes	N/A	---
Allocate Endpoint IDs	0x08	Used by the bus owner to allocate a pool of EIDs to an MCTP bridge.	N/A	N/A	---
Routing Information Update	0x09	Used by the bus owner to extend or update the routing information that is maintained by an MCTP bridge.	N/A	N/A	---
Get Routing Table Entries	0x0A	Used to request an MCTP bridge to return data corresponding to its present routing table entries.	No	N/A	---
Prepare for Endpoint Discovery	0x0B	Used to direct endpoints to clear their discovered flags to enable them to respond to the Endpoint Discovery command.	N/A	Yes[1]	---
Endpoint Discovery	0x0C	Used to discover MCTP-capable devices on a bus, provided that another discovery mechanism is not defined for the particular physical medium.	No	Yes[1]	---
Discovery Notify	0x0D	Used to notify the bus owner that an MCTP device has become available on the bus.	Yes[1]	N/A	---
Get Network ID	0x0E	Used to get the MCTP network ID	No	No	---
Query Hop	0x0F	Used to discover what bridges, if any, are in the path to a given target endpoint and what transmission unit sizes the bridges pass for a given message type when routing to the target endpoint.	No	No	---

Table 12-42. MCTP Commands Support [continued]

Command Name	Command Code	General Description	E810 Support as Initiator	E810 Support as Responder	Section Reference
Query Rate Limit	0x11	Used to discover the data rate limit settings of the given target for incoming messages.	No	Yes	12.7.7.1.7
Request Tx Rate Limit	0x12	Used to request the allowed transmit data rate limit for the given endpoint for outgoing messages.	No	Yes	12.7.7.1.8
Update Rate Limit	0x13	Used to update the receiving side on change to the transmit data rate that was not requested by the receiver.	No	Yes	12.7.7.1.9
Query Supported Interfaces	0x14	Used to discover the existing device MCTP interfaces.	No	Yes	12.7.7.1.10

1. These commands are supported only for MCTP over PCIe.

12.7.7.1.1 Set Endpoint ID (0x01)

The E810 supports the Set EID and Force EID operations defined in the Set Endpoint ID command. When operating over PCIe, the Set Discovered Flag operation is also supported. As endpoints in the E810 can be set only through their own interface, Set EID and Force EID are equivalent. The Reset EID operation is not supported by the E810.

The Set Endpoint ID response of the E810 is described in Table 12-43.

Table 12-43. Set Endpoint ID Response

Byte	Description	Value
1	Completion Code	0x00
2	Completion Status	[7:6] = 00b - Reserved. [5:4] = 00b - EID assignment accepted. [3:2] = 00b - Reserved. [1:0] = 00b - Device does not use an EID pool.
3	EID Setting	If the EID setting was accepted, this value matches the EID passed in the request. Otherwise, this value returns the present EID setting.
4	EID Pool Size	Always return a zero.

12.7.7.1.2 Get Endpoint ID (0x02)

The Get Endpoint ID response of the E810 is listed in Table 12-44.

Table 12-44. Get Endpoint ID Response

Byte	Description	Value
1	Completion Code	
2	Endpoint ID	0x00 = EID not yet assigned.. Otherwise = Returns EID assigned using Set Endpoint ID command
3	Endpoint Type	0x00 (Dynamic EID, Simple Endpoint).
4	Medium Specific	0x00 = PCIe 0x01 = SMBus — Fairness arbitration protocol supported.

12.7.7.1.3 Get Endpoint UUID (0x03)

The UUID returned is calculated according to the following function:

- Time Low = Read from MCTP UUID — Time Low LSB/MSB NVM words of Sideband Configuration Structure.
- Time Mid = Read from MCTP UUID — Time Mid NVM word of Sideband Configuration Structure.
- Time High and Version = Read from MCTP UUID — Time High and Version NVM word of Sideband Configuration Structure.
- Clock Sec and Reserved = Read from MCTP UUID — Clock Seq NVM word of Sideband Configuration Structure.
- Node = MAC Address as taken from the GLPCI_SERL and GLPCI_SERH registers.

12.7.7.1.4 Get MCTP Version Support (0x04)

Table 12-45 lists the returned value according to the requested message type. The list of supported message types is based on the protocols enabled in the NVM and should be the same as the list reported in the Get Message Type Support command in Section 12.7.7.1.5.

Table 12-45. Get MCTP Version Support Returned Value

Byte	Description	Message type						
		0xFF (Base)	0x00 (Control Protocol Message)	0x01 (PLDM	0x02 (NC-SI over MCTP)[1]	0x03 (Ethernet)[2]	0x7E (PCIe-Based VDM Messages)[3]	All Other or Unsupported Messages
1	Completion Code	0x0						0x80
2	Version Number entry count	4	4	1	2	2	2	0
6:3	Version Number entry	0xF1F0FF00 (1.0)	0xF1F0FF00 (1.0)	0xF1F0F000 (1.0.0)	0xF1F0F000 (1.0.0)	0xF1F0F000 (1.0.0)	0xF1F0FF00 (1.0)	0
10:7	Version Number entry 2	0xF1F1F000 (1.1.0)	0xF1F1F000 (1.1.0)		0xF1F1F000 (1.1.0)	0xF1F1F000 (1.1.0)	0xF1F1F000 (1.1.0)	
14:11	Version Number entry 3	0xF1F2F000 (1.2.0)	0xF1F2F000 (1.2.0)		0xF1F2F000 (1.2.0)	0xF1F2F000 (1.2.0)		
19:15		0xF1F3F000 (1.3.0)	0xF1F3F000 (1.3.0)					

1. If NC-SI is supported in the current configuration over this medium.
2. If NC-SI pass-through is supported in the current configuration over this medium.
3. If OEM messages are supported in the current configuration over this medium.

12.7.7.1.5 Get Message Type Support (0x05)

The Get Message Type Support response of the E810 is listed in Table 12-46.

Table 12-46. Get Message Type Support Response

Bytes	Description	Value
1	Completion Code	0x00
2	MCTP Message Type Count	0x01/0x02/0x03 — The E810 supports up to four additional message types, depending on the mode of operation and the bus used.
3:5	List of Message Type Numbers	0x01 (PLDM over MCTP) — If PLDM is supported.
		0x02 (NC-SI over MCTP) — If NC-SI is supported.
		0x03 (Ethernet) — If NC-SI and pass-through are supported.
		0x7E (PCIe based VDM messages) — Over PCIe. Over SMBus also if OEM commands are supported.

12.7.7.1.6 Get Vendor-Defined Message Support (0x06)

The Get Vendor Defined Message Support response of the E810 is listed in Table 12-47 if *Vendor ID Set Selector* equals 0x00.

Table 12-47. Get Vendor-Defined Message Support Response

Byte	Description	Value
1	Completion Code	0x00
2	Vendor ID Set Selector	0xFF = No more capability sets.
3:5	Vendor ID	0x008086 (PCI ID Indicator + Intel Vendor ID)
6:7	Version	0x0100 (Version 1.0)

12.7.7.1.7 Query Rate Limit (0x11)

When receiving a Query Rate Limit command over PCIe, the device should respond with the following parameters:

Table 12-48. Query Rate Limit Response

Offset	Description	Value
2:5	Receive information — Receive buffer size in bytes.	Size of MCTP to manageability buffer in bytes (+ headers).
6:9	Receive Information — Maximum receive data rate limit in packets.	0x1DCD65 — Reflects a rate of 1 Gb/s in 64-bytes packets.
10:13	Transmit Rate limiter capabilities — Maximum supported rate limit.	0x1DCD65 — Reflects a rate of 1 Gb/s in 64-bytes packets.
14:17	Transmit Rate limiter capabilities — Minimum supported rate limit.	0x7A1 — Reflects a rate of 1 Mb/s in 64-bytes packets. ***Note:*** This should cover all products.
18:20	Transmit Rate limiter capabilities — Maximum supported burst size.	Size of manageability to MCTP buffer in 64-bytes packets (+ headers).
21:23	Present Transmit Rate Limit Burst Setting	According to current setting. Initial value based on NVM configuration.
24:27	Present Setting — EID Maximal Transmit data rate limit.	According to current setting. Initial value based on NVM configuration.

Table 12-48. Query Rate Limit Response [continued]

Offset	Description	Value
28.1	Transmit Rate limiting operation capability 0b = Transmit Rate limiting on this EID is applied to requested and non requested messages together. 1b = Transmit Rate limiting on this EID is applied only to non-requested messages	1
28.0	Rate limiting Support on EID	1

Note: When received over SMBus, Bit 28.0 should be set to zero, and Bits 6:9 should also be set to zero. Other fields are don't care.

12.7.7.1.8 Request Tx Rate Limit (0x12)

12.7.7.1.8.1 Request Tx Rate Limit Response

When receiving a Request Tx Rate Limit command from the MC over PCIe, the device should set its rate limit according to the requested values. If received over SMBus, an ERROR_INVALID_DATA is returned.

The setting of the rate limit is done as described in Section 3.5.4.5 "MCTP over PCIe Rate Limiter Configuration" of hardware/firmware interface document.

12.7.7.1.8.2 Request Tx Rate Limit Send

The device currently does not require a rate limit from the MC, assuming the supported bandwidth of 1 Gb/s is large enough to absorb any MC traffic.

12.7.7.1.9 Update Rate Limit (0x13)

The device never sends this command and completes it without error, but ignores it when received.

12.7.7.1.10 Query Supported Interfaces (0x14)

The Query Supported Interfaces command allows the MC or the bus owner to detect the available interfaces.

When receiving a Query Supported Interfaces command over PCIe or SMBus, the device should respond with the following parameters.

Table 12-49. Query Supported Interfaces Response

Offset	Description	Value
2	Supported Interfaces Count	1 or 2 according to the available interfaces.
3	First interface Type	0x01 if SMBus speed is 100 KHz. 0x04 if SMBus speed is 400 KHz. 0x05 if SMBus speed is 1 MHz.
4	First interface EID	The EID assigned to the device over SMBus.
5	Second interface Type	0x0A for PCIe 2.1 device. 0x0B for PCIe 3.0 device. 0x0C for PCIe 4.0 device.
6	Second interface EID	The EID assigned to the device over PCIe.

Note: Bytes 3:4 are returned if SMBus is available. Bytes 5:6 are returned if PCIe is available.

12.8 PLDM Support

The E810 supports PLDM over MCTP protocol. Within PLDM, the following data types are supported:

- 0x0 - PLDM Messaging Control and Discovery
- 0x2 - PLDM Monitoring and Control
- 0x5 - PLDM Firmware Update

This section does not include details of the PLDM specification itself. Rather, this section contains information on the parts of PLDM to implement and the actual data needed to fill the PLDM responses. Following is a list of relevant specifications:

- DSP2040: Platform Level Data Model (PLDM) Base Specification
- DSP0241: Platform Level Data Model (PLDM) over MCTP Binding Specification
- DSP0245: Platform Level Data Model (PLDM) IDs and Codes Specification
- DSP0248: Platform Level Data Model (PLDM) for Platform Monitoring and Control Specification
- DSP0249: Platform Level Data Model (PLDM) State Set Specification
- DSP0267: Platform Level Data Model (PLDM) Firmware update
- oDSP0218: Platform Level Data Model (PLDM) for Redfish Device Enablement

12.8.1 PLDM Base Implementation

PLDM is supported over PCIe or over SMBus. The packet format is described in Table 12-50:

Table 12-50. PLDM over MCTP over PCIe/SMBus Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
SMBus or PCIe Header

SOM								EOM								SEQ#								TO = 1							
Tag								IC = 0								Platform Level Data Model (PLDM) (0x01)								RQ							
D								RSVD								Instance ID								Hdr Ver							
PLDM Type																															
PLDM Command Code																															
PLDM Completion Code[1]																															
PLDM Payload																															
....																															
Command Data																															

1. In response only. This byte is not present in commands.

The description of the PCIe header and MCTP header field is as defined in the specification. The values of the PLDM fields are described in Table 12-51.

Table 12-51. PLDM Fields

Field	Size (Bits)	Description
IC	1	Integrity Check - Always zero. Appears only in first packet of message.
Message Type	7	1 = PLDM Appears only in first packet of message.
RQ, D	2	Request, Datagram D, RQ 00b – For PLDM response messages. 01b – For PLDM request messages. 10b – Reserved. 11b – For Unacknowledged PLDM request messages or asynchronous notifications.
Instance ID	5	Identifier of a command. Should be used in the response also. ***Note:*** The PLDM specification requires the device (terminus) to send commands to generate events, so the device should generate and track instance IDs for the events it sends to the Event Receiver.
Hdr Ver	2	Header Version - Should be 0.
PLDM Type	6	0 for PLDM control messages. 2 for Platform Monitoring and Control messages. 5 for PLDM Firmware Update messages.
PLDM Command Code	8	Command code.
PLDM Completion Code	8	Response code - Appears only in response. Should be according to the Table 4. "Generic PLDM Completion Codes (PLDM_BASE_CODES)" in the DSP0240 PLDM Base Specification or specific codes written in each command.

12.8.1.1 Reset Conditions

The PLDM state is reset when the MCTP layer below it is reset. In the case of PCIe VDM, this is EMPR and PERST reset events.

12.8.1.2 PLDM Control Commands

The following messages (as defined in the DSP0240 PLDM Base Specification) should be supported. For these messages, the PLDM type is zero.

Table 12-52. PLDM Control Commands

Command	Command Code	Description	Section Reference
SetTID	0x01	Sets the TID used in Platform Monitoring and Control messages.	---
GetTID	0x02	Gets the TID currently stored in the device.	---
GetPLDMVersion	0x03	Return supported versions for different PLDM types.	12.8.1.2.1
GetPLDMTypes	0x04	Return supported PLDM types.	12.8.1.2.2
GetPLDMCommands	0x05	Return supported PLDM commands per type.	12.8.1.2.3

12.8.1.2.1 GetPLDMVersion (0x03)

The GetPLDMVersion command returns the supported versions of PLDM types.

The command and response are described in Table 12-53.

The command is supported for PLDM type 0 (PLDM Messaging Control and Discovery) and type 5 (PLDM Firmware Update).

Table 12-53. GetPLDMVersion Command and Response

Byte	Type	Request Data
0:3	uint32	**DataTransferHandle** – ignored by the device

4	enum8	**TransferOperationFlag**
		This field is an operation flag that indicates whether this is the start of the transfer.
		Possible values:
		{
		GetNextPart = 0x00,
		GetFirstPart = 0x01
		}
		Accepted only if *GetFirstPart*.

Byte	**Type**	**Response Data**

0	enum8	**CompletionCode**
		Possible values:
		{
		PLDM_BASE_CODES,
		INVALID_DATA_TRANSFER_HANDLE = 0x80,
		INVALID_TRANSFER_OPERATION_FLAG = 0x81,
		INVALID_PLDM_TYPE_IN_REQUEST_DATA = 0x83
		}

1:4	uint32	**NextDataTransferHandle** = 0x00 Not used as always returning a single message.
5	enum8	**TransferFlag** Return StartAndEnd = 0x05.
4	-	**Portion of PLDMVersionData** For Type = 0 – PLDM Messaging Control and Discovery – return 0xF1F0F000 (1.0.0) For Type = 2 – PLDM for Platform Monitoring and Control – return 0xF1F2F000 (1.2.0) For Type = 5 – PLDM for Firmware update – return 0xF1F0F000 (1.0.0) For Type = 6 – Platform Level Data Model (PLDM) for Redfish Device Enablement – return 0xF1F0F100 (1.0.1)

12.8.1.2.2 GetPLDMType (0x04)

The GetPLDMType command returns the supported PLDM types.

The command and response are described in Table 12-54.

Table 12-54. GetPLDMType Command and Response

Byte	Type	Request Data
-	-	None.
Byte	**Type**	**Response Data**
0	enum8	**CompletionCode** Possible values: {PLDM_BASE_CODES}
1:8	bitfield8[8]	**PLDMType** Each bit represents whether a given PLDM Type is supported: 0b = PLDM Type is not supported. 1b = PLDM Type is supported. For bitfield8[N], where N = 0 to 7: [7] = PLDM Type N*8+7 supported. [..] = … [1] = PLDM Type N*8+1 supported. [0] = PLDM Type N*8+0 supported. Return 0x65 (types 0, 2, 5, and 6). ***Note:*** Type should be reported as supported only if enabled in NVM.

12.8.1.2.3 GetPLDMCommand (0x05)

The GetPLDMCommand command returns the supported command of PLDM per type.

The command and response are described in Table 12-55.

Table 12-55. GetPLDMCommand Command and Response

Byte	Type	Request Data
0	uint8	**PLDMType** This field identifies the PLDM Type for which command support information is being requested. Supported for types 0, 2, and 5. Otherwise, returns an INVALID_PLDM_TYPE_IN_REQUEST_DATA.
1:4	ver32	**Version** This field identifies the version for the specified PLDM Type. Supported values are: For Type = 0: 0xF1F0F000 (1.0.0) For Type = 5: 0xF1F0F000 (1.0.0) Otherwise returns an INVALID_PLDM_VERSION_IN_REQUEST_DATA.
Byte	**Type**	**Response Data**

0	enum8	**CompletionCode**
		Possible values:
		{
		PLDM_BASE_CODES,
		INVALID_PLDM_TYPE_IN_REQUEST_DATA = 0x83,
		INVALID_PLDM_VERSION_IN_REQUEST_DATA = 0x84
		}

1:8	bitfield8[32]	**PLDMCommands** (up to 256 commands supported for the specified PLDM Type) Each bit represents whether a given PLDM command is supported: 0b = PLDM command is not supported. 1b = PLDM command is supported. For bitfield8[N], where N = 0 to 31: [7] = PLDM Command N*8+7 Supported. [..] = … [1] = PLDM Command N*8+1 Supported. [0] = PLDM Command N*8 Supported. For type 0, return 0x3E (commands 1,2,3,4,5) as described in this section. For type 2, return 0x00003_0000_0000_0003_000F_0038 (according to the supported commands in Section 12.8.4 (SetTID & GetTID are not included). For type 5, return 0x0000_0000_0000_0000_3C19_0006 (according to the supported commands in Section 12.8.4. For type 6, return 0x0003_0000_005F_003E (according to the supported commands in Section 12.8.4). ***Note:*** The commands reported must be according to the firmware's actual support for the commands where NC is the responder.

12.8.2 PLDM Monitoring and Control Support

12.8.2.1 PLDM Monitoring and Control Supported Commands

The following messages, as defined in DSP0248, should be supported. For these messages, the PLDM type is two.

Table 12-56. PLDM Monitoring and Control Commands

Command Code	Command	Supported?	Section Reference
0x01	SetTID (see DSP0240)	Yes	---
0x02	GetTID (see DSP0240)	Yes	---
0x03	GetTerminusUID	Yes	12.8.2.1.1
0x04	SetEventReceiver	Yes	12.8.2.1.2
0x05	GetEventReceiver	Yes	12.8.2.1.3
0x0A	PlatformEventMessage	Yes	12.8.2.1.4
0x0B	PollForPlatformEventMessage	Yes	12.8.2.1.5
0x0C	EventMessageSupported	Yes	12.8.2.1.6
0x0D	EventMessageBufferSize	Yes	12.8.2.1.7
0x10	SetNumericSensorEnable	Yes	12.8.2.1.8
0x11	GetSensorReading	Yes	12.8.2.1.9
0x12	GetSensorThresholds	Yes	12.8.2.1.10
0x13	SetSensorThresholds	Yes	12.8.2.1.11
0x14	RestoreSensorThresholds	No	---
0x15	GetSensorHysteresis	Yes	12.8.2.1.12
0x16	SetSensorHysteresis	No	---
0x17	InitNumericSensor	No	---
0x20	SetStateSensorEnables	Yes	12.8.2.1.13
0x21	GetStateSensorReadings	Yes	12.8.2.1.14
0x22	InitStateSensor	No	---
0x30	SetNumericEffecterEnable	No	---
0x31	SetNumericEffecterValue	No	---
0x32	GetNumericEffecterValue	No	---
0x38	SetStateEffecterEnables	No	---
0x39	SetStateEffecterStates	No	---
0x3A	GetStateEffecterStates	No	---
0x40	GetPLDMEventLogInfo	No	---
0x41	EnablePLDMEventLogging	No	---
0x42	ClearPLDMEventLog	No	---
0x43	GetPLDMEventLogTimestamp	No	---
0x44	SetPLDMEventLogTimestamp	No	---

Table 12-56. PLDM Monitoring and Control Commands [continued]

Command Code	Command	Supported?	Section Reference
0x45	ReadPLDMEventLog	No	---
0x46	GetPLDMEventLogPolicyInfo	No	---
0x47	SetPLDMEventLogPolicy	No	---
0x48	FindPLDMEventLogEntry	No	---
0x50	GetPDRRepositoryInfo	Yes	12.8.2.1.15
0x51	GetPDR	Yes	12.8.2.1.16
0x52	FindPDR	No	---
0x53	GetPDRRepositorySignature	Yes	12.8.2.1.17
0x58	RunInitAgent	No	---

12.8.2.1.1 GetTerminusUID (0x3)

The GetTerminusUID command returns a UUID of the device. The command and response are described in Table 12-57.

Table 12-57. GetTerminusUID Command and Response

Type	Request Data
---	None.
Type	**Response Data**
enum8	**completionCode** Value: {PLDM_BASE_CODES}
UUID	**UUID Value**

UUID format is described in Table 12-58.

Table 12-58. UUID Format

Field	UUID Byte	MSB
time low	1	MSB
	2	
	3	
	4	
time mid	5	MSB
	6	
time high and version	7	MSB
	8	
clock seq high and reserved	9	
clock seq low	10	
Node	11	
	12	
	13	
	14	
	15	
	16	

The UUID Value content should be the same as returned as part of the Get Endpoint UUID MCTP command.

12.8.2.1.2 SetEventReceiver (0x4)

The SetEventReceiver command is used to indicate to the device what the address of the Event Receiver is (usually the BMC). The command and response are described in Table 12-59.

Table 12-59. SetEventReceiver Command and Response

Type	Request Data
enum8	**eventMessageGlobalEnable** This value is used to enable or disable event message generation from the terminus. See DSP0248 for details. 0 = Disable 1 = Enable Async — Allows the device to work in event mode (send PlatformEventMessage command). 2 = Enable Polling — Allows the device to work in polling mode (react to PollForPlatformEventMessage commands).
enum8	**transportProtocolType** Only value supported if *eventMessageGlobalEnable* = enable, is 0x00 (MCTP), ignored otherwise. The command is rejected and an INVALID_PROTOCOL_TYPE *completionCode* returned if the *transportProtocolType* is incorrect.
uint8	**eventReceiverAddressInfo** Reflects the EID of the event receiver, and should be used to create events messages. Valid only if *eventMessageGlobalEnable* is set to enable (1b).
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	INVALID_PROTOCOL_TYPE = 0x80
	}

When this command is received and acknowledged, if the *eventReceiverAddressInfo* changed from what is currently registered in the firmware, the device should find the B,D,F (Bus, Device, Function) of the event receiver as follows:

If the source EID in the packet is the same as the *eventReceiverAddressInfo*, use the requester ID in the TLP as the B,D,F of the receiver.

Otherwise, send a Resolve Endpoint ID MCTP command to get the B,D,F of the Event Receiver. If the command fails four times, events are not sent.

12.8.2.1.3 GetEventReceiver (0x5)

The GetEventReceiver command is used to read from the device the address of the Event Receiver it is connected to. The command and response are described in Table 12-60.

Table 12-60. GetEventReceiver Command and Response

Type	Request Data
---	None.
Type	**Response Data**
enum8	**completionCode** Value: {PLDM_BASE_CODES}
enum8	transportProtocolType Return 0x00 (MCTP)
uint8	eventReceiverAddress Returns the last value that was set using the SetEventReceiver command, or zero if no such command was received.

12.8.2.1.4 PlatformEventMessage (0xA)

The PlatformEventMessage command is a command generated by the device to notify the event receiver of new events. The device should implement a timeout and retry mechanism to ensure that the command is acknowledged by the event receiver.

The retry parameters as defined in *Table 5 - Timing Specifications for PLDM Messages* of DSP0240 should be set to PN1=2 (2 retries) and PT2 (Time-out waiting for a response)=2 seconds.

The destination EID and B,D,F of the command are received through the SetEventReceiver command and Resolve Endpoint ID MCTP command.

The following rules define when to send the message for each sensor:

- For Thermal Sensor and Thermal Trip events the message should be generated every time any of the thresholds is crossed in any direction.
- For Link State sensor events, the message should be generated every time the link state changes.
- For Link Speed sensor events, the message should be generated every time there is a link up event.
- For Health state sensor events, the message should be generated every time there is a change in the health state.
- For power consumption, there is no need to generate messages.
- For configuration change events the message should be generated every time the configuration change state changes (e.g., when PDR changed).
- For presence sensors, the message should be generated every time a cable presence status changes.

The command and response are described in Table 12-61:

Table 12-61. PlatformEventMessage Command and Response

Type	Request Data
uint8	**formatVersion** 0x01
uint8	**TID** Terminus ID for the terminus that originated the event message as received from the SetTID command.
enum8	**eventClass** Value (one of the following): 0x00 = sensorEvent — One of the sensors had a status change. 0x02 = redfishTaskExecutedEvent — A long running task spawned by an RDE Operation task has completed execution. 0x03 = redfishMessageEvent — A Redfish event has occurred. 0x04 = pldmPDRRepositoryChgEvent — A change has been made to the repository.
var	**eventData** Event data based on the *eventClass*.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	UNSUPPORTED_EVENT_FORMAT_VERSION = 0x81
	}

enum8	Status - can be ignored.

12.8.2.1.5 PollForPlatformEventMessage (0xB)

This command enables the Event Receiver to poll for events from a PLDM terminus and acknowledge the receipt of the event message. The SetEventReceiver command enables polling of event messages if the PLDM terminus supports this command.

Table 12-62. PollForPlatformEventMessage Command and Response

Type	Request Data
uint8	**formatVersion** Version of the event format (the format and definition of the following bytes): 0x01 for this specification.
enum8	**TransferOperationFlag** The operation flag that indicates whether this is the start of the transfer. Possible values: 0x00 = GetNextPart 0x01 = GetFirstPart 0x02 = AcknowledgementOnly
uint32	**dataTransferHandle** A handle that is used to identify a package data transfer. This handle is ignored by the responder when the *TransferOperationFlag* is set to GetFirstPart. If *TransferOperationFlag* is set to GetNextPart, *dataTransferHandle* should be equal to the *nextDataTransferHandle* reported in the previous transfer response, otherwise return an ERROR_INVALID_DATA completion code.
uint16	**eventIDToAcknowledge** An event previously received that should be acknowledged. The MC uses the null value 0x0000 when requesting the first entry from the terminus' event queue. The MC uses the sentinel 0xFFFF when in the middle of a multi-part event transfer.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	UNSUPPORTED_EVENT_FORMAT_VERSION = 0x81,
	EVENT_ID_NOT_VALID = 0x82
	}

uint8	**TID**
uint16	**eventID** The Event ID for the returned event in this response. The device assigns the Event ID to an event so the requester can send the acknowledgment on the subsequence invocation of this command. A value is 0x0000 is returned if the terminus internal event queue is empty. If *TransferOperationFlag* in the request message was set to AcknowledgementOnly and the event queue is non-empty, the terminus supplies sentinel value 0xFFFF for this field. *eventID* value generated by firmware is increased for each new event (starting from 1).
All of the following fields are returned only if *eventID* is different than 0x0000 or 0xFFFF.	
uint32	**nextDataTransferHandle** A handle that is used to identify the next portion of the transfer.
enum8	**TransferFlag** The transfer flag that indicates what part of the transfer this response represents. Possible values: 0x1 = Start 0x2 = Middle 0x4 = End 0x5 = StartAndEnd

Table 12-62. PollForPlatformEventMessage Command and Response [continued]

uint8	**eventClass** Values: pldmPDRRepositoryChgEvent —A change has been made to the repository. redfishTaskExecuteEvent — A long running task spawned by an RDE Operation has completed execution. redfishMessageEvent — A Redfish event has occurred.
uint32	**eventDataSize** Size in byes of *eventData*.
var	**eventData** Event data based on the *eventClass*.
uint32	**eventDataIntegrityChecksum** 32-bit CRC for the entirety of event data (all parts concatenated together, excluding this checksum). This field is omitted for non-final chunks of multi-part event messages (TransferFlag ≠ End or StartAndEnd) in the transfer. The DataIntegrityChecksum is not split across multiple chunks. If appending the DataIntegrityChecksum would cause this request message to exceed the negotiated maximum transfer chunk size, the DataIntegrityChecksum is sent as the only data in another chunk. For this command, the CRC-32 algorithm with the polynomial $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ (same as the one used by IEEE 802.3) is used for the integrity checksum computation. The CRC computation involves processing a byte at a time with the least significant bit first.

12.8.2.1.6 EventMessageSupported (0xC)

Table 12-63. EventMessageSupported Command and Response

Type	Request Data
uint8	**formatVersion** Version of the event format (the format and definition of the following bytes): 0x01 for this specification version
Type	**Response Data**

enum8	completionCode
	value:
	{
	PLDM_BASE_CODES,
	UNSUPPORTED_EVENT_FORMAT_VERSION = 0x81
	}

enum8	**synchronyConfiguration**
	This value indicates the messaging style most recently configured via the SetEventReceiver command:
	Value:
	{
	NOT_CONFIGURED = 0x00, // SetEventReceiver command not received
	ASYNCHRONOUS_MESSAGING = 0x01, // Asynchronous messaging
	SYNCHRONOUS_MESSAGING = 0x02// Poll-based messaging
	ASYNCHRONOUS_WITH_HEARTBEAT = 0x03 // Asynchronous messaging, heartbeat
	}

bitfield8	**synchronyConfigurationSupported** This value indicates the event messaging styles supported by the terminus. For each bit, a value of 1b indicates that the mode is supported. [7:4] - Reserved for future use [3] - Asynchronous messaging with heartbeat [2] - Synchronous (poll-based) messaging [1] - Asynchronous messaging, no heartbeat [0] - Reserved. Mus be 0b. The returned value is 0x6 (Synchronous and Asynchronous support without heartbeat).

Table 12-63. EventMessageSupported Command and Response [continued]

uint8	**numberEventClassReturned** The count of *eventClass* enumerated bytes returned in this response. Returns 5 - supported events listed below.
uint8	**eventClass [0]** 0x00 = sensorEvent
uint8	**eventClass [1]** 0x02 = redfishTaskExcuteEvent
uint8	**eventClass [2]** 0x03 = redfishMessageEvent
uint8	**eventClass [3]** 0x04 = pldmPDRRepositoryChgEven
uint8	**eventClass [4]** 0x05 = pldmMessagePollEvent

12.8.2.1.7 EventMessageBufferSize (0xD)

Table 12-64. EventMessageBufferSize Command and Response

Type	Request Data
uint16	eventReceiverMaxBufferSize This is the maximum buffer to hold an event message transferred from the terminus to the event receiver. Minimum value allowed is 14 bytes.
Type	**Response Data**
enum8	**completionCode** Value: {PLDM_BASE_CODES}
uint16	**terminusMaxBufferSize** Return 2048 (2K buffers).

The size used to report events should be min (*eventReceiverMaxBufferSize*, *terminusMaxBufferSize*) This command is medium dependent and different values can be received over PCIe and SMBus.

An INVALID_DATA error is reported if *eventReceiverMaxBufferSize* value is smaller than 14 bytes.

12.8.2.1.8 SetNumericSensorEnable (0x10)

The SetNumericSensorEnable command is supported for the Temperature & Link Speed sensors and is used to enable or disable generation of events from these sensors. The command and response are described in Table 12-65.

The default at init time should be to have all sensors enabled.

Table 12-65. SetNumericSensorEnable Command and Response

Type	Request Data
uint16	**sensorID** Only accepted values are the sensor IDs of Thermal sensors and Link Speed sensors. Otherwise, an INVALID_SENSOR_ID error code is returned.
enum8	**sensorOperationalState** The desired state of the sensor value: {enabled, disabled, unavailable} Defines if the sensor is enabled, disabled or unavailable. Default is enabled.

enum8	**sensorEventMessageEnable**
	This value is used to enable or disable event message generation from the sensor.
	Possible values:
	{
	noChange,
	disableEvents,
	enableEvents,
	enableOpEventsOnly,
	enableStateEventsOnly
	}
	The relevant values are:
	0x0 = noChange
	0x1 = disableEvents
	0x2 = enableEvents
	0x3 = enableOpEventsOnly
	For other values, return an EVENT_GENERATION_NOT_SUPPORTED error.

Type	**Response Data**

enum8	**completionCode**
	Value:
	{
	PLDM_BASE_CODES,
	INVALID_SENSOR_ID = 0x80,
	INVALID_SENSOR_OPERATIONAL_STATE = 0x81,
	EVENT_GENERATION_NOT_SUPPORTED = 0x82 // an attempt was made to enable or disable event generation for a sensor that does not support event message generation
	}

12.8.2.1.9 GetSensorReading (0x11)

The GetSensorReading command is supported for the Temperature, Link speed, and power consumption sensors, and is used to read the current value of the sensor.

The default at init time should be to have all sensors enabled.

Note: Firmware updates sensor states and responds immediately when processing a GetSensorReading command. Hence, in case this command is received before next firmware polling and sensor states are updated, PlatformEventMessage is sent for this particular event.

In rare cases in which old events are still in the internal queue when the GetSensorReading command is received (i.e., retransmission due to transmit failure), BMC will get the stalled events.

The command and response are described in Table 12-66.

Table 12-66. GetSensorReading Command and Response

Type	Request Data
uint16	**sensorID** Only accepted values are the IDs of Temperature, Link Speed, and Power Consumption sensors. Otherwise, an INVALID_SENSOR_ID error code is returned.
bool8	**rearmEventState** Ignored. All sensors are auto-rearm.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	INVALID_SENSOR_ID = 0x80,
	EARM_UNAVAILABLE_IN_PRESENT_STATE = 0x81
	}

enum8	**sensorDataSize** The bit width and format of reading and threshold values that the sensor returns UINT8 (0x0) for thermal sensor and uint32 (0x4) for link speed.

Table 12-66. GetSensorReading Command and Response [continued]

enum8	**sensorOperationalState**
	The state of the sensor itself
	Possible values:
	{
	enabled,
	disabled,
	unavailable,
	statusUnknown,
	failed,
	initializing,
	shuttingDown,
	inTest
	}
	Relevant values are:
	enabled — Enabled and operating. The sensor is able to return valid *presentState*, *previousState*, *presentReading*, and *eventState* values. This state can be set through the SetNumericSensorEnable command.
	disabled — The sensor is disabled from returning *presentReading* and event state values. This state is settable through the SetNumericSensorEnable command.
	unavailable — The sensor should be ignored due to the configuration of the platform or monitored entity. For example, the sensor is for monitoring a processor temperature, but the processor is not installed. This state is settable through the SetNumericSensorEnable command.
	failed — The sensor has failed. The sensor implementation has determined that it can not return correct values for one or more of its *presentState* or *eventState* values.

enum8	**sensorEventMessageEnable**
	Possible values:
	{
	noEventGeneration,
	eventsDisabled,
	eventsEnabled,
	opEventsOnlyEnabled,
	stateEventsOnlyEnabled
	}
	as set in the SetNumericSensorEnable command

enum8	**presentState** The most recently assessed state value monitored by the sensor. If the sensorOperationalState is set to enabled the sensor must return a value other than "Unknown" for the *presentState*. If the *sensorOperationalState* is not set to enabled, the sensor returns "Unknown" for the *presentState*. See Section 12.8.3.2 for the reported state per sensor.
enum8	**previousState** The state that the *presentState* was entered from. See Section 12.8.3.2 for the reported state per sensor. If the *sensorOperationalState* is not set to enabled, the sensor returns "Unknown" for the *previousState*.
enum8	**eventState** Same as *presentState* for all sensors but the thermal sensor (assume no hysteresis). For Thermal sensor return the value of the last crossed threshold including thresholds considerations as described in Section 17.9 of DSP0248.
uint8 | uint32	**presentReading** The present value indicated by the sensor See Section 12.8.3.2 for the reported value per sensor.

12.8.2.1.10 GetSensorThresholds (0x12)

The GetSensorThresholds command is supported for the Temperature sensors and is used to read the current values of the sensor thresholds. The command and response are described in Table 12-67.

Table 12-67. GetSensorThresholds Command and Response

Type	Request Data
uint16	**sensorID** Only accepted values are the Temperature Sensor IDs. Otherwise, an INVALID_SENSOR_ID error code is returned.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	NVALID_SENSOR_ID = 0x80
	}

enum8	**sensorDataSize** uint8 (0x0)
uint8	**upperThresholdWarning** According to the value set in the SetSensorThresholds command. Default is according to the Normal Value.Reported Thermal Sensor *WarningHigh* field in NVM if Thermal Sensor Thresholds.*upperWarning* supported is set, zero otherwise.
uint8	**upperThresholdCritical** According to the value set in the SetSensorThresholds command. Default is according to the Warning Value.Reported Thermal Sensor *CriticalHigh* field in NVM if Thermal Sensor Thresholds.*upperCritical* supported is set, zero otherwise.
uint8	**upperThresholdFatal** According to the value set in the SetSensorThresholds command. Default is according to the Critical Value.Reported Thermal Sensor *FatalHigh* field in NVM if Thermal Sensor Thresholds.*upperFatal* supported is set, zero otherwise.
uint8	**lowerThresholdWarning** Value: 0
uint8	**lowerThresholdCritical** Value: 0
uint8	**lowerThresholdFatal** Value: 0

12.8.2.1.11 SetSensorThresholds (0x13)

The SetSensorThresholds command is supported for the Temperature sensors and is used to set the values of the sensor thresholds. The command and response are described in Table 12-68.

Table 12-68. SetSensorThresholds Command and Response

Type	Request Data
uint16	**sensorID** Only accepted values are the Temperature Sensor IDs. Otherwise, an INVALID_SENSOR_ID error code is returned.
enum8	**sensorDataSize** If the value is different than uint8 (0x0), return an ERROR_INVALID_DATA error code is returned
For sensorDataSize = uint8 or sint8	
uint8 | sint8	**upperThresholdWarning**
uint8 | sint8	**upperThresholdCritical**
uint8 | sint8	**upperThresholdFatal**
uint8 | sint8	**lowerThresholdWarning** Ignored.
uint8 | sint8	**lowerThresholdCritical** Ignored.
uint8 | sint8	**lowerThresholdFatal** Ignored.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	INVALID_SENSOR_ID = 0x80
	}

12.8.2.1.12 GetSensorHysteresis (0x15)

The GetSensorHysteresis command is supported for the Temperature sensors and is used to read the values of the sensor hysteresis. For other sensors, an INVALID_SENSOR_ID is returned. The command and response are described in Table 12-69.

Table 12-69. GetSensorHysteresis Command and Response

Type	Request Data
uint16	**sensorID** Accepted values are the Temperature Sensor IDs. Otherwise, an INVALID_SENSOR_ID error code is returned.
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES
	INVALID_SENSOR_ID = 0x80
	}

enum8	**sensorDataSize** The bit width of the hysteresis value that is being returned. Value: 0 (uint8)
uint8 | sint8	**hysteresisValue** Read from *Hysteresis* field in Thermal Sensor Tolerance & Hysteresis NVM word for the relevant sensor.

12.8.2.1.13 SetStateSensorEnables (0x20)

The SetStateSensorEnables command is supported for the link state, health state, presence, configuration change, thermal Trip, and power consumption sensors and is used to enable or disable generation of events from these sensors. The command and response are described in Table 12-70.

Table 12-70. SetStateSensorEnables Command and Response

Type	Request Data
uint16	**sensorID** Accepted values the sensor IDs of the supported sensors described above. Otherwise, an INVALID_SENSOR_ID error code is returned.
uint8	**compositeSensorCount** Number of *OpFields* present. If the value is higher than the number of sensors within the composite sensor, an ERROR_INVALID_DATA error code is returned. If the value is lower than the number of sensors within the composite sensor, return info for the first *compositeSensorCount* sensors The accessed sensors are 0-*compositeSensorCount*-1
compositeSensorCount instances of *OpFields*:	

enum8	**sensorOperationalState**
	The desired state of the sensor. Defines if the sensor is enabled, disabled or unavailable.
	Possible values:
	{
	enabled,
	disabled,
	unavailable
	}
	Default is enabled.

enum8	**EventMessageEnable**
	This value is used to enable or disable event message generation from the sensor.
	Possible values:
	{
	noChange,
	disableEvents,
	enableEvents,
	enableOpEventsOnly,
	enableStateEventsOnly
	}
	The relevant values are:
	0x0 = noChange
	0x1 = disableEvents
	0x2 = enableEvents
	0x4 = enableStateEventsOnly — For health state, thermal trip, configuration, configuration changed, present and link state sensors
	0x0 = noChange — For power sensor.
	For other values, return an EVENT_GENERATION_NOT_SUPPORTED error.
	enableEvents and *enableStateEventsOnly* are treated the same.

Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES
	INVALID_SENSOR_ID = 0x80,
	EVENT_GENERATION_NOT_SUPPORTED = 0x82
	}

12.8.2.1.14 GetStateSensorReadings (0x21)

The GetStateSensorReadings command is supported for all the state sensors (Composite network controller sensor, Composite NIC sensor, Port link sensor, Cable Presence Sensor, Plug Composite Sensor) and is used to read the current state of the sensors. The command and response are described in Table 12-71.

Table 12-71. GetStateSensorReadings Command and Response

Type	Request Data
uint16	**sensorID** Accepted values are all state sensors IDs. Otherwise, an INVALID_SENSOR_ID error code is returned.
bitfield8	**sensorRearm** Ignored. All sensors are auto-rearm.
uint8	Reserved Value = 0x00
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	INVALID_SENSOR_ID = 0x80
	}

uint8	**compositeSensorCount** Return the number of sensors within the composite sensor.
Repeated once per sensor within the composite sensor.	
enum8	**sensorOperationalState** The state of the sensor itself as set using the SetStateSensorEnables command.
enum8	**presentState** This field is used to return a state value from a PLDM State Set that is associated with the sensor. The value reflects the most recently assessed state. See Section 12.8.3.2 for the state events reported.
enum8	**previousState** The state that the *presentState* was entered from. See Section 12.8.3.2 for the reported state per sensor. If the *sensorOperationalState* is not set to enabled, the sensor returns "Unknown" for the previousState.
enum8	**eventState** same as *presentState*.

12.8.2.1.15 GetPDRRepositoryInfo (0x50)

The GetPDRRepositoryInfo is used to provide a generic description of the PDRs in the device. The command and response are described in Table 12-72.

Table 12-72. GetPDRRepositoryInfo Command and Response

Type	Request Data
---	None.
Type	**Response Data**
enum8	**completionCode** Value: {PLDM_BASE_CODES}

enum8	**repositoryState**
	Possible values:
	{
	available, // Record data can be read from the repository.
	updateInProgress, // Record data is unavailable because an update is in progress.
	failed // Record data is unavailable because of a detected failure condition.
	}
	Should be available (0x0) in regular cases.
	If a configuration change was detected (cable plug, link configuration change), might return *updateInProgress* (0x1).

timestamp104	**updateTime** This time stamp identifies when the standard PDR Repository data was originally created, or the time of the most recent update if the data has been updated after it was created. This time does not include changes of PDRs that have a PDR Type of "OEM". Returns the time in internal clock of the firmware of the last PDR update.
timestamp104	**OEMUpdateTime** This time stamp identifies when OEM PDRs in the PDR Repository were originally created, or the time of the most recent update if the data has been updated after it was created. Currently no OEM PDRs are defined, so return 0.
uint32	**recordCount** Total number of PDRs in this repository.
uint32	**repositorySize** Size of the PDR Repository in bytes. This value provides information that can be used for helping estimate buffer size requirements when accessing PDRs. This size covers only the cumulative sizes of the PDR record fields. This size does not include the size for any internal header structures that are used for maintaining the PDRs. This number does not report and may not directly correlate to the amount of internal storage used for PDRs because. For example, an implementation might elect to internally compress or use other encodings of the PDR data. An implementation is allowed to round this number up to the nearest kilobyte (1024 bytes). Return the size of the entire PDR data structure rounded up to 1K.
uint32	**largestRecordSize** Size of the largest record in the PDR Repository in bytes. This value provides information that can be used for helping estimate buffer size requirements when accessing PDRs. An implementation is allowed to round this number of up to the nearest 64-byte increment. Return largest PDR size in bytes rounded up to 128 bytes.

Table 12-72. GetPDRRepositoryInfo Command and Response [continued]

uint8	**dataTransferHandleTimeout** The minimum interval, in seconds, that a *dataTransferHandle* value remains valid after it was delivered in the response of a GetPDR or FindPDR command. Special values: 0x00 = No timeout 0x01 = Default minimum timeout 0xFF = Timeout >254 seconds. Any timeout values that are less than the specified default minimum timeout are illegal. Return 0x01 (default timeout of 30 seconds).

12.8.2.1.16 GetPDR (0x51)

The GetPDRRepositoryInfo is used to access the PDRs in the device. The command and response are described in Table 12-73.

The PDR data structures used to fill the *recordData* in this command are described in Section 12.8.3.3.

Table 12-73. GetPDR Command and Response

Type	Request Data
uint32	**recordHandle** See Section 12.8.3.3 for details of the PDR to return for each handle. A value of 0x0000_0000 returns the NIC association PDR (1100).
uint32	**dataTransferHandle** Reflects the offset in bytes of the data within the PDR. Special value: {use 0x0000_0000 if the *transferOperationFlag* is *GetFirstPart*}

enum8	**transferOperationFlag**
	Indicates whether this request is for the first portion of the PDR.
	Possible values:
	{
	GetNextPart = 0x00,
	GetFirstPart = 0x01
	}

uint16	**requestCount** The maximum number of record bytes requested to be returned in the response to this instance of the GetPDR command. ***Note:*** The responder may return fewer bytes than were requested.
uint16	**recordChangeNumber** If the *transferOperationFlag* field is set to *GetFirstPart*, set this value to 0x0000. If the *transferOperationFlag* field is set to *GetNextPart*, set this to the *recordChangeNumber* value that was returned in the header data from the first part of the PDR
Type	**Response Data**

enum8	**completionCode**
	Possible values:
	{
	PLDM_BASE_CODES,
	INVALID_DATA_TRANSFER_HANDLE = 0x80,
	INVALID_TRANSFER_OPERATION_FLAG = 0x81,
	INVALID_RECORD_HANDLE = 0x82,
	INVALID_RECORD_CHANGE_NUMBER = 0x83,
	TRANSFER_TIMEOUT = 0x84,
	REPOSITORY_UPDATE_IN_PROGRESS = 0x85
	}

Table 12-73. GetPDR Command and Response [continued]

uint32	**nextRecordHandle** The next record handle is based on Table 12-80, where the handles are returned in ascending values. ***Note:*** When RDE is enabled, an additional list of PRDs is added, as described in Section 12.8.3.3.7. Special value: 0x0000_0000 = No more PDRs following this one.
uint32	**nextDataTransferHandle** A handle that identifies the next portion of the PDR data to be transferred, if any portions are remaining. Reflects the offset in bytes of the next data within the PDR Special value: Returns 0x0000_0000 if there is no remaining data.

enum8	**transferFlag**
	Indicates what portion of the PDR is being transferred
	Possible values:
	{
	Start = 0x00,
	Middle = 0x01,
	End = 0x04,
	StartAndEnd = 0x05
	}
	Set according to the requestCount.value.

uint16	**responseCount** The number of *recordData* bytes returned in this response. Special value: Returns 0x0000 if the *requestCount* was 0x0000.
(var)	**recordData** PDR data bytes. This field is absent if *responseCount*=0x0000. The number of PDR data bytes returned in this field must match *responseCount*.
If *transferFlag* = End	
uint8	**ransferCRC** A CRC-8 for the overall PDR. This is provided to help verify data integrity for a PDR when it is transferred using a multi-part transfer. The CRC is calculated over the entire PDR data using the polynomial x8 + x2 + x1 + 1 (This is the same polynomial used in the MCTP over SMBus/I^2C transport binding specification). The CRC is calculated from most-significant bit to least-significant bit on bytes in the order that they are received. This field is only present when *transferFlag*=End.

12.8.2.1.17 GetPDRRepositorySignature (0x53)

The PDR Repository Signature is a value that represents the entire collection of terminus Platform Device Records (PDRs). This is different than the GetPDRRepositoryInfo command because only an opaque 32-bit value is returned. The purpose of the PDR Repository Signature is to provide the management controller the capability to determine if a terminus PDR repository has changed during state transitions such as power cycles.

Table 12-74. GetPDRRepositorySignature Command and Response

Type	Request Data
-	-
Type	**Response Data**
enum8	**completionCode** Value: {PLDM_BASE_CODES}
uint32	**pdrRepositorySignature** This is a 32-bit value and remains persistent unless a change is detected in any record of the PDR repository. This field should be computed once (during device boot) as low 32 bits of SHA256 of PDRs

12.8.2.2 PLDM Monitoring and Control Events

The following events can be generated by the E810:

- **sensorEvent** — See DSP0248 for more details. This event is sent to BMC upon a change in the state of one of the sensors.
- **redfishTaskExecuteEvent** — See DSP0248 for more details. This event is sent to BMC upon long running task completion
- **redfishMessageEvent** — See DSP0248 for more details. This event is sent to BMC in case a redfish message should be sent.
- **pldmPDRRepositoryChgEvent** — This message is sent in case of a change in the PDR structure.

  This event reports PDR change in runtime. This Event is to signal the PLDM Event Receiver that there is a change in the terminus PDR repository. The device returns the PDR Types or the PDR Record Handles for the PDRs to be retrieved from the terminus. This allows a simple method for a terminus to indicate which portion of its "virtual" PDR Repository needs to be refreshed. The PLDM terminus client (or event receiver) will need to comprehend additions, deletions and modifications of the PDRs as it updates the system primary PDR repository. See Table 12-75 and Table 12-76 for the event format.
- **pldmMessagePollEvent** — This event is returned in asynchronous mode only when the reported event cannot fit into a single PLDM message.

Table 12-75 through Table 12-79 describe the various events formats:

Table 12-75. PDR Repository Change Event Data

Type	Request Data

enum8	**eventDataFormat**
	Possible values:
	{
	refreshEntireRepository,
	formatIsPDRTypes,
	formatIsPDRHandles
	}
	This field indicates if the *changedRecords* are of "PDR Types" or "PDR Record Handles". The device signals to the event receiver to re-enumerate the entire device PDR repository by supplying the value *refreshEntireRepository*. To signal that only certain types of PDRs should be refreshed, the device supplies the value *formatIsPDRTypes* and provides one change record below for each type of PDR to be refreshed.

uint8	**numberOfChangeRecords** The number of *changeRecords* (N_R) following this field. If the *eventDataFormat* is *refreshEntireRepository*, this value is zero.
var	**changeRecord [0]** See Table 12-76 for details. This field is not present if the *numberOfChangeRecords* is zero (0).
var	**changeRecord [1]**
...	...
var	**changeRecord [N_R - 1]**

Table 12-76. pldmPDRRepositoryChgEvent changeRecord Format

Type	Request Data

enum8	**eventDataOperation**
	Possible values:
	{
	refreshAllRecords,
	recordsDeleted,
	recordsAdded,
	recordsModified
	}
	For each pldmPDRRepositoryChgEvent record, there can only be a single operation. This simplifies the parsing for both the terminus and the event receiver. The order the event records are provided is "RefreshAll", "Deleted", "Added", "Modified".
	The value *refreshAllRecords* is only supplied when *eventDataFormat* was set to formatIsPDRTypes. In this case, the entries below represent a series of PDR types to be refreshed.

uint8	**numberOfChangeEntries** The number of change entries (N_E) following this field.
uint32	**changeEntry [0]** This value is either a "PDR Type" enumeration or a "PDR Record Handle" as enumerated by the *eventDataFormat* field in the pldmPDRRepositoryChgEvent event message. There can be multiple PDR Types (such as Numeric Sensor, State Sensor, and Entity Association Sensor) to be retrieved due to a "hot plug" event for the terminus. All the changed PDR Types can be returned in a single event message. The client (or event receiver) can use the FindPDR command to gather the PDR record. Alternatively, the terminus can provide a list of PDR Record Handles, which the MC can use as input to the GetPDR command.
uint32	**changeEntry [1]**
...	...
uint32	**changeEntry [N_E - 1]**

Table 12-77. redfishTaskExecutedEvent Class eventData Format

Type	Request Data
uint32	**resourceID** ResourceID associated with the Task that has completed execution as received in RDeOperationInit RDE command.
uint16	**operationID** Operation associated with the Task that has completed execution as received in RDeOperationInit RDE command.

Table 12-78. redfishMessageEvent Class eventData Format

Type	Request Data
uint8	**eventCount** The number of Redfish Events (N) encoded in the *eventData* field below.
uint16	**eventDataLength** Length in bytes of the *eventData* field below, which comprises the encoding of one or more Redfish Events contained within this PLDM event. This value must not exceed the negotiated event message size.
uint32	**resourceID [0]** An opaque handle referencing the particular collection of schema-based Redfish data associated with the first Redfish Event encoded in the *eventData* field below.
enum8	**eventSeverity [0]** The severity of the first Redfish Event in the Redfish EventRecords array encoded in *eventData* below. Values: 0 = OK 1 = Warning 2 = Critical
uint32	**resourceID [N - 1]** An opaque handle referencing the particular collection of schema-based Redfish data associated with the last Redfish Event encoded in the *eventData* field below.
enum8	**eventSeverity [N - 1]** The severity of the last Redfish Event in the Redfish EventRecords array encoded in *eventData* below. Values: 0 = OK 1 = Warning 2 = Critical
bejEncoding	**eventData** BEJ encoded Event payload data. The *bejEncoding* PLDM type is defined in DSP0218.

Table 12-79. pldmMessagePollEvent

Type	Request Data
uint8	**formatVersion** Version of the event format (the format and definition of the following bytes): 0x01 for this specification.
uint16	**eventID** Identifier for the event that requires multi-part transfer.
uint32	**dataTransferHandle** A handle that is used to identify the event data to be received via the PollForPlatformEventMessage command.

12.8.2.3 PDR Dynamic Changes Flow

In the OCP 3.0 PLDM model, PDRs can change dynamically due to changes in the NIC configuration. The following events might cause a change in the PDR structure:

- QSFP/SFP module plug/unplug.
- Transition from breakout to non-breakout cable configuration and vice versa. See Section 12.8.2.3.1 on the events that indicates these events.

Once a topology change impacting the PDR structure is detected, the following logical flow should be applied:

1. Prepare a separate copy of the new PDR structure.
2. For each record that changed, or that was not present in the previous structure, increase the *recordChangeNumber*.
3. Change the state of the Configuration Change sensor in the NIC composite sensor to Configuration Change Detected.
4. If a GetPDR command is in the middle of reading the PDR structure (the last GetPDR response did not have the *transferFlag* set to End or StartAndEnd), wait until the read is done, or 30 seconds from PDR change.
5. In case of timeout, abort the current transfer.
6. Copy the new PDR to the active one.
7. Update the updateTime used in the GetPDRRepositoryInfo answer to reflect the current time (using the free-running timer of the FW).
8. Update the *RecordCount*, *largestRecordSize*, and *repositorySize* according to the new structure.

12.8.2.3.1 PDR Change Events

12.8.2.3.1.1 QSFP/SFP Plug Events

A module plug event creates a “Media Inserted” event within the firmware. There are two parts of the PDR that can be impacted by this event:

- New plug, cables, and associated sensors additions. These are added immediately.
- New channels. Those are added only if there is no media conflict. Otherwise, they are added only after the next reset after the media conflict is resolved. Added channels create new Link association PDRs.

12.8.2.3.1.2 QSFP/SFP Unplug Events

A module unplug event creates a “Media Removed” event within the firmware. In this case, all the PDRs listed in the previous section are removed.

12.8.2.3.1.3 Transition Between Breakout to Non-Breakout Cable Configurations

These transitions are initiated by the user after a media-conflict event notification. In this case, a reboot of the system is required, causing a PERST# event that in turn causes a re-read of the topology and a “Port Mode Change” event. Once a “Port Mode Change” event is received, the Link Association PDR should be updated accordingly

12.8.3 PLDM Monitoring and Control Generic Structures

12.8.3.1 Sensors Numbering

The OCP 3.0 NIC modeling proposal defines a set of IDs for each type of sensor, as in Table 12-80:

Table 12-80. Sensors and Handles Numbering

Item	Max Count	Supported Number	Base Container ID	Max Container ID	Base Handle	Max Handle	Base Sensor ID	Max Sensor ID	Base Instance
NIC	1	1	100		1100				1
Card Composite State Sensor	1	1			1101	1101	5	5	1
Connectors	4	4	200	203	1105	1108			1
NIC Temp Sensors	10	3			1110	1119	20	29	1
Network Controllers	10	1	1000	1009	1120	1129			1
Network Controller State	1	1			1130	1139	50	59	1
Ports of Network Controller	10	8			1200	1219			1
Link Speed of Network Controller	10	8			1800	1899	600	699	1
Link State of Network Controller	10	8			1900	1999	700	799	1
Temp Sensor per Network Controller	10	3			1300	1399	200	299	1
Plugs	4	4	1010	1013	1250	1253			1
Plug Power Sensor	20	4			1140	1159	250	269	1
Plug Temp Sensor	10	4			1500	1699	300	499	1
Plug Composite Sensor	1	4 (1 per plug)			1400	1419	500	519	1
Plug Entity Association	20	8	1040	1059	1160	1179			1
Channel Entity Association	20	8	1060	1079	1180	1199			21

Calculated
Model Constant
User Parameter

Where:

Item	The Name of the References Items
Max Count	Max number of elements of this type allowed by the PLDM model.
Supported Number	The largest number of instances expected by this feature.
Base Container ID / Max Container ID	The first and last ID of the device as referenced in PDRs Base Handle.
Max Handle	The first and last ID of the PDRs describing the instances.
Base Sensor ID / Max Sensor-ID:	The first and last sensor ID of this sensor type
Base Instance	The first instance of this type as listed in the containing PDR.

This maps (after some changes) to the following PDR/Sensor Diagram:

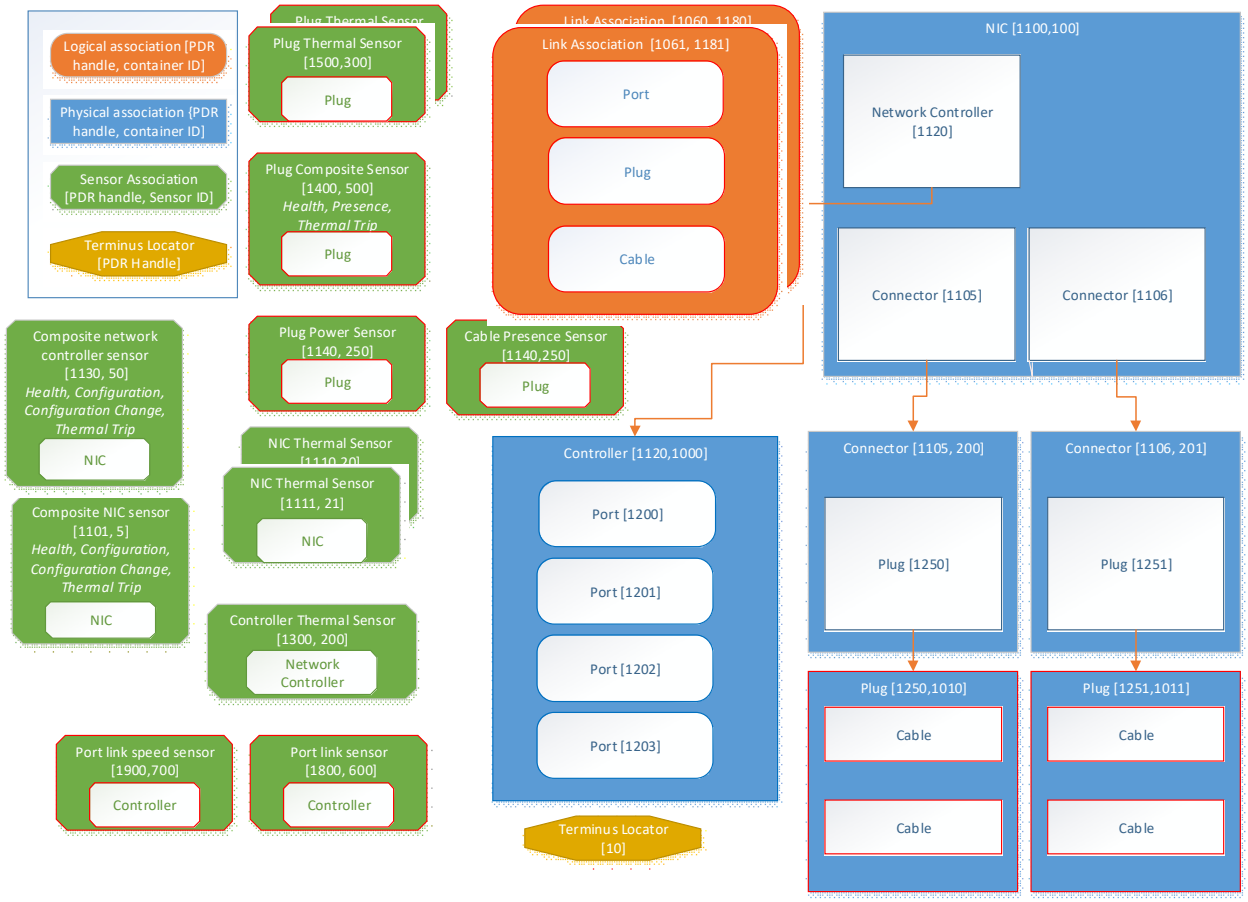

Figure 12-13. PDR/Sensor Diagram

Note: The PDRs with a red border are dynamic and may change due to module plug events or breakout cables insertion events.

12.8.3.2 Sensors

The following sensors are maintained in the device to be reported via the PLDM commands described in Section 12.8.2.1.

- Numeric Sensors:
  - Temperature Sensors
  - NIC/Controller/Plug
  - Link Speed Sensors
  - Plug power consumption Sensors
- Composite State Sensors:
  - NIC: {Health, Configuration, Configuration Change, Thermal Trip}
  - Controller: {Health, Configuration, Configuration Change, Thermal Trip}
  - Plug: {Health, Presence, Thermal Trip}
  - Regular State Sensors: Link state

The numbering of the sensors is according to Section 12.8.3.1.

12.8.3.2.1 Numeric Sensors

12.8.3.2.1.1 Temperature Sensor Data Structure

There are three types of possible thermal sensors:

- Internal (on-die) thermal sensors
- External (on board) thermal sensors
- Plug (SFP/QSFP) thermal sensors

The identification of the type is set according to the following Topology Netlist fields:

- Sensor Location at word 9 (Port Affinity High) of the Node Thermal Configuration Section of the Temperature Sensor node.
- Node Part Number at word 3 (Part Number and Node Options) of the Node Header Section of the Temperature Sensor node.

Sensor Type	Sensor Location	Node Part Number
Internal	0x01	0x36 = Embedded in Internal PHY
External (PHY)	0x02 - 0x07	Embedded in external PHY, e.g. 0x31 = C827 0x32 = X557 0x33 = 88E1543 0x34 = 88E1512 0x35 = 88E1514
Plug SFP (SFF-8472 compliant)	0x10	0x44 = Embedded in SFP plug
Plug QSFP (SFF-8636/8436 compliant)	0x11	0x45 = Embedded in QSFP plug

Notes:

- Firmware uses of Sensor Location to determine Sensor Type. Part Numbers is informative only, as the list may dynamically grow further.
- Temperature Sensors should be implemented only if the *Expose Thermal Sensors* bit in the PLDM control word is set. The number of thermal sensors exposed from each type is derived from the network topology. The current temperature for each sensor can be read through the GET_TEMP DNL script.

Type	Request Data
uint16	**sensorID** = According to Section 12.8.3.1 (300 +n, 20 +n, 200 for plug, NIC, Controllers sensors respectively).
enum8	**sensorEventClass** = numericSensorState (0x2) or sensorOpState (0x0) If the Sensor has a *sensorEventMessageEnable* value of *enableOpEventsOnly*, return a *sensorOpState*. If the Sensor has a *sensorEventMessageEnable* value of *enableEvents*, return a *numericSensorState*. Otherwise, events are not generated.
enum8	**presentState** The *eventState* value from the state change that triggered the event message. If temperature is >= Fatal Threshold, Return *UpperFatal* (0xA) If temperature is >= Critical Threshold return *UpperCritical* (0x9). If temperature is >= Warning Threshold return *UpperWarning* (0x8) Otherwise, return Normal (0x1). Thresholds are set by the SetSensorThresholds command.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Return the state that was reported in previous events. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).
enum8	**sensorDataSize** = 0x0 (uint8) - returned only if *sensorEventClass* = *numericSensorState* (0x2).
uint8	**presentReading** Temperature. The resolution is according to the resolution defined in the Thermal Sensor PDR (Section 12.8.3.3.6.1) - returned only if *sensorEventClass* = *numericSensorState* (0x2).

12.8.3.2.1.2 Link Speed Data Structure

Type	Request Data
uint16	**sensorID** = 599 + Port#
enum8	**sensorEventClass** = numericSensorState (0x2) or sensorOpState (0x0) If the Sensor has a *sensorEventMessageEnable* value of *enableOpEventsOnly*, return a *sensorOpState*. If the Sensor has a *sensorEventMessageEnable* value of *enableEvents*, return a *numericSensorState*. Otherwise, events are not generated.
enum8	**presentState** Return Normal (0x1).
enum8	**previousState** Return Normal (0x1).
enum8	**sensorDataSize** = uint32 (0x4) - returned only if *sensorEventClass* = *numericSensorState* (0x2).
uint8	**presentReading** Link Speed in Megabits per second - returned only if *sensorEventClass* = *numericSensorState* (0x2).

12.8.3.2.1.3 Plug Power Data Structure

Type	Request Data
uint16	**sensorID** = 250 + Plug#
enum8	**sensorEventClass** = numericSensorState (0x2) or sensorOpState (0x0) If the Sensor has a *sensorEventMessageEnable* value of *enableOpEventsOnly*, return a *sensorOpState*. If the Sensor has a *sensorEventMessageEnable* value of *enableEvents*, return a *numericSensorState*. Otherwise, events are not generated.
enum8	**presentState** Return Normal (0x1).
enum8	**previousState** Return Normal (0x1).
enum8	**sensorDataSize** = uint32 (0x4) - returned only if *sensorEventClass* = *numericSensorState* (0x2).
uint8	**presentReading** Plug nominal power as read from addresses below in the module EEPROM through I^2C read. The reported value is translated to 0.1 Watts units. SFPx - SFF-8472 v12.2 - 0xA0 - byte 64 in Table 8-3. QSFPx - SFF-8636 v2.7 - 0xA0 - byte 129 in Table 6-16. Returned only if *sensorEventClass* = *numericSensorState* (0x2). The value is returned from the sff_get_pwr (activity ID = 0x0027) DNL script.

12.8.3.2.2 NIC Composite State Sensors

12.8.3.2.2.1 NIC Health State Data Structure

Type	Request Data
uint16	**sensorID** = 5
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x0 (offset in NIC composite state structure)
enum8	**presentState** ***Note:*** All thermal sensing events here relate to the all the registered sensors. The state reflects the worst state of all sensors. The *eventState* value from the state change that triggered the event message. Return 0x1 (Normal) if all NVM checks are OK and thermal sensor value is below the warning threshold. Return 0x5 - Upper Non-Critical, if the thermal sensor value is above the warning threshold and below the Critical Threshold. Return 0x7 - Upper Critical, if the thermal sensor value is above the critical threshold and below the Fatal Threshold. Return 0x9 - Upper Fatal, if the thermal sensor value is above the fatal threshold Return 0x0 (Unknown) otherwise. ***Note:*** Changes to the Health sensor are coordinated with thermal events. So events will occur according to the thermal Sensor hysteresis rules.

12.8.3.2.2.2 NIC Configuration Data Structure

Type	Request Data
uint16	**sensorID** = 5
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x1 (offset in NIC composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. One of the following: 1 = Valid Configuration 2 = Invalid Configuration TBD - For now Invalid configuration means the firmware failed to find all the needed TLVs in the PFA or other associated errors.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.2.3 NIC Changed Configuration State Data Structure

Type	Request Data
uint16	**sensorID** = 5
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x2 (offset in NIC composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. One of the following: 1 = Normal. Initial State. 2 = Configuration Change Detected. If a change in the PDR structure was detected. Move back to Normal after State is read.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.2.4 NIC Thermal Trip State Data Structure

Type	Request Data
uint16	**sensorID** = 5
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x3 (offset in NIC composite state structure)
enum8	**presentState** ***Note:*** All thermal sensing events here relate to the all the registered sensors. The state reflects the worst state of all sensors. The *eventState* value from the state change that triggered the event message. Return 0x1 (Normalalways). ***Note:*** If auto shutdown will be implemented, will also support Thermal trip state (0x2).

12.8.3.2.3 Controller Composite State Sensors

12.8.3.2.3.1 Controller Health State Data Structure

Type	Request Data
uint16	**sensorID** = 50
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x0 (offset in Controller composite state structure)
enum8	**presentState** ***Note:*** All thermal sensing events here relate to the controller internal TS. The *eventState* value from the state change that triggered the event message. Return 0x1 (Normal) if all NVM checks are OK and thermal sensor value is below the warning threshold. Return 0x5 - Upper Non-Critical, if the thermal sensor value is above the warning threshold and below the Critical Threshold. Return 0x7 - Upper Critical, if the thermal sensor value is above the critical threshold and below the Fatal Threshold. Return 0x9 - Upper Fatal, if the thermal sensor value is above the fatal threshold. Return 0x0 (Unknown) otherwise. ***Note:*** Changes to the Health sensor are coordinated with thermal events. So events will occur according to the Thermal Sensor hysteresis rules.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).
enum8	**previousState** The eventState value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.3.2 Controller Configuration Data Structure

Type	Request Data
uint16	**sensorID** = 50
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x1 (offset in Controller composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. One of the following: 1 = Valid Configuration 2 = Invalid Configuration Invalid configuration means the firmware failed to find all the needed TLVs in the PFA or other associated errors.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.3.3 Controller Configuration Change Data Structure

Type	Request Data
uint16	**sensorID** = 50
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x2 (offset in Controller composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. One of the following: 1 = Normal. Initial State. 2 = Configuration Change Detected. Returned if a change in the one of the channels associations was detected, or an NVM update occurred. Move back to Normal after State is read. An NVM update is detected by a Shadow RAM dump command
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.3.4 Controller Thermal Trip State Data Structure

Type	Request Data
uint16	**sensorID** = 50
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x3 (offset in Controller composite state structure)
enum8	**presentState** ***Note:*** All thermal sensing events here relate to the controller internal TS. The *eventState* value from the state change that triggered the event message. Return 0x1 (Normal).

12.8.3.2.4 Plug Composite State Sensors

12.8.3.2.4.1 Plug Health State Data Structure

Type	Request Data
uint16	**sensorID** = 500
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x0 (offset in Plug composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. Return 0x1 (Normal) if thermal sensor value is below the warning threshold. Return 0x5 - Upper Non-Critical, if the thermal sensor value is above the warning threshold and below the Critical Threshold. Return 0x7 - Upper Critical, if the thermal sensor value is above the critical threshold and below the Fatal Threshold. Return 0x9 Upper Fatal, if the thermal sensor value is above the fatal threshold Return 0x0 (Unknown) otherwise ***Note:*** Changes to the Health sensor are coordinated with thermal events. So events will occur according to the thermal Sensor hysteresis rules. TBD how to fix - For now equivalent to the crossed threshold of the plug thermal sensor.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.4.2 Plug Presence State Data Structure

Type	Request Data
uint16	**sensorID** = 500
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x1 (offset in Plug composite state structure)
enum8	**presentState** The *eventState* value from the state change that triggered the event message. Return 0x1 (Present) if a the plug is connected. Return 0x2 (Not Present) if the plug is not connected TBD if should be plug or cable presence.
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.4.3 Plug Thermal Trip State Data Structure

Type	Request Data
uint16	**sensorID** = 500
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x2 (offset in Plug composite state structure)
enum8	**presentState** ***Note:*** All thermal sensing events here relate to the plug internal TS. The *eventState* value from the state change that triggered the event message. Return 0x1 (Normal).
enum8	**previousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state. Special value: This value must be set to the same value as *presentState* if the *previousState* is unknown (which may be the case for events that are generated on the first status assessment that occurs after a sensor has been initialized).

12.8.3.2.5 Simple Sensors

12.8.3.2.5.1 Port Link Sensor

Type	Request Data
uint16	**sensorID** = 699+ port#
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x0 (not part of a composite)
enum8	**presentState** The eventState value from the state change that triggered the event message. Return 0x1 (Connected) if a link is present. Return 0x2 (Not Connected) if a link is not present.
enum8	**PreviousState** The **eventState** value for the state from which the present state was entered Use the same logic as for the present state, only for the previous state.

12.8.3.2.5.2 Cable Present Sensor (currently not needed)

There is a single sensor per plug even in case of plugout cable.

Type	Request Data
uint16	**sensorID** = 250
enum8	**sensorEventClass** = stateSensorState (0x1)
uint8	**sensorOffset** = 0x0 (not part of a composite)
enum8	**presentState** The *eventState* value from the state change that triggered the event message Return 0x1 (Connected) if a cable is connected. Return 0x2 (Not Connected) if a cable is not present.
enum8	**PreviousState** The *eventState* value for the state from which the present state was entered. Use the same logic as for the present state, only for the previous state.

12.8.3.3 PDRs

The PDRs are numbered according to Section 12.8.3.1, "Sensors Numbering". The link list used to create the Next Handle Record, which should be created based on the exposed PDRs.

12.8.3.3.1 Terminus Locator PDR

Type	PDR Fields
uint32	**recordHandle** = 0x0000_0010
uint8	**PDRHeaderVersion** = 0x01
uint8	**PDRType** = 0x1 (Terminus Locator PDR)
uint16	**recordChangeNumber** = 0x0 (no changes expected in Terminus Locator PDR)
uint16	**dataLength** = 0x9
uint16	**PLDMTerminusHandle** = 0x0001
enum8	**Validity** = 0x1 (valid)
uint8	**TID** = PLDM Terminus ID as received by SetTID command (default is 0).
uint16	**containerID** = 0x0 (system)
enum8	**terminusLocatorType** = 0x1 (MCTP_EID)
enum8	**terminusLocatorValueSize** = 0x1 (one uint8)
terminusLocatorValue for *terminusLocatorType* = MCTP_EID:	
uint8	**EID** = The MCTP EID that is assigned to the device for the relevant medium.

12.8.3.3.2 Physical Association PDRs

The PDRs are exposed in a high-level representation for the association PDRs.

12.8.3.3.2.1 NIC Association PDR

A single NIC association PDR exists. The number of connectors exposed is based on the specific card configuration and is derived from the link topology (OCP 3.0 supports 1 or 2 connectors, but other cards might support more). The example below shows two connectors.

NIC Entity Association PDR		
Container ID	100	
Container Entity		
Entity Type	68	Add-in Card
Entity Instance Number	1	
Container Entity Container ID	0	
Association Type	Physical to Physical containment	
Contained Entity - Network Controller		
Entity Type	144	Network Controller
Entity Instance Number	1	
Container Entity Container ID	100	
Contained Entity - Connector		
Entity Type	185	Connector
Entity Instance Number	1	
Container Entity Container ID	100	
Contained Entity - Connector		
Entity Type	185	Connector
Entity Instance Number	2	
Container Entity Container ID	100	

12.8.3.3.2.2 Controller Association PDR

The controller includes all its ports. There can be up to eight ports for the E810. The actual number is derived from the link topology. The example below assumes two ports.

Network Controller Association PDR		
Container ID	1000	
Container Entity		
Entity Type	144	Network Controller
Entity Instance Number	1	
Container Entity Container ID	100	NIC
Association Type	Physical to Physical containment	
Contained Entity - Connector		
Entity Type	6	Communication Port
Entity Instance Number	1	
Container Entity Container ID	1000	
Contained Entity - Connector		
Entity Type	6	Communication Port
Entity Instance Number	2	
Container Entity Container ID	1000	

12.8.3.3.2.3 Connector Association PDR

A connector association PDR exists per cage of the device, as reflected from the topology file.

This PDR always exists only if a module is plugged. In case of module plug-in or plug-out event, the presence state event changes its state.

Connector #n Entity Association PDR (n = 1... number of cages)		
Container ID	199 + n	
Container Entity		
Entity Type	185	Connector
Entity Instance Number	n	
Container Entity Container ID	100	
Association Type	Physical to Physical containment	
Contained Entity - Plug		
Entity Type	189	Plug
Entity Instance Number	1	
Container Entity Container ID	199 + n	

12.8.3.3.2.4 Plug Association PDR

A plug association PDR exists per cable per cage of the device, as reflected from the topology file. In case of breakout cables, multiple cables may be associated with the same plug.

This PDR exists only if a module is plugged in and a cable is plugged in it. In case of cable plug-in or plug-out event, a PDR change should be triggered through the NIC configuration change event.

Plug #n Entity Association PDR		
Container ID	1009 + n	
Container Entity		
Entity Type	189	Plug
Entity Instance Number	n	
Container Entity Container ID	199 + n	
Association Type	Physical to Physical containment	
Contained Entity - Cable #1		
Entity Type	187	Cable
Entity Instance Number	1	
Container Entity Container ID	1009 + n	
Contained Entity - Cable #2 - Breakout Only		
Entity Type	187	Cable
Entity Instance Number	2	
Container Entity Container ID	1009 + n	
Contained Entity - Cable #3 - Breakout Only		
Entity Type	187	Cable
Entity Instance Number	3	
Container Entity Container ID	1009 + n	
Contained Entity - Cable #4 - Breakout Only		
Entity Type	187	Cable
Entity Instance Number	4	
Container Entity Container ID	1009 + n	

12.8.3.3.3 Logical Association PDRs

The PDRs are exposed in a high-level representation for the association PDRs.

12.8.3.3.3.1 Channel Entity Association PDR

This PDR describes a link. It defines a channel that associates a logical port (MAC) with a pluggable module, and a specific cable in the module.

This PDR exists only if a module is plugged in and a cable is plugged into it, and the MAC is associated with a specific cable. In case of cable plug-in or plug-out event, a PDR change should be triggered through the NIC configuration change event.

Channel #1 Entity Association		
Container ID	1060	
Container Entity		
Entity Type	6	Communication Channel
Entity Instance Number	1	
Container Entity Container ID	1000	Controller
Association Type	Logical to Physical containment	
Contained Entity - Plug		
Entity Type	189	Plug
Entity Instance Number	n	
Container Entity Container ID	1060	
Contained Entity - Cable		
Entity Type	187	Cable
Entity Instance Number	k	Number of the cable within the plug
Container Entity Container ID	1060	

12.8.3.3.4 Composite State Sensor PDRs

12.8.3.3.4.1 NIC Composite State Sensor

NIC Composite State Sensor		
Entity Type	68	Add-in Card
Entity Instance Number	1	
Container Entity Container ID	100	
Terminus Handle	0	
Sensor ID	5	
Composite Sensor Count	4	
Sensor Type	1	Health State
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 7=Upper Critical	
Sensor Type	15	Configuration
Possible States	1=Valid Configuration, 2=Invalid Configuration	
Sensor Type	16	Configuration Change
Possible States	1=Normal, 2=Change in Configuration	
Sensor Type	21	Thermal Trip
Possible States	1=Normal	

12.8.3.3.4.2 Controller Composite State Sensor

Network Controller Composite State Sensor		
Entity Type	68	Add-in Card
Entity Instance Number	1	
Container Entity Container ID	100	
Terminus Handle	0	
Sensor ID	5	
Composite Sensor Count	4	
Sensor Type	1	Health State
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 7=Upper Critical	
Sensor Type	15	Configuration
Possible States	1=Valid Configuration, 2=Invalid Configuration	
Sensor Type	16	Configuration Change
Possible States	1=Normal, 2=Change in Configuration	
Sensor Type	21	Thermal Trip
Possible States	1=Normal	

12.8.3.3.4.3 Plug Composite State Sensor

Plug #n Composite State Sensor		
Entity Type	189	Port
Entity Instance Number	1	
Container Entity Container ID	1009 + n	
Terminus Handle	0	
Sensor ID	499 + n	
Composite Sensor Count	1	
Sensor Type	1	Health State
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 7=Upper Critical	
Sensor Type	13	Presence
Possible States	1=Present, 2=Not_Present	
Sensor Type	21	Thermal Trip
Possible States	1=Normal, 2=Over-Temp Shutdown	

12.8.3.3.5 Simple State Sensors PDRs

12.8.3.3.5.1 Port Link State

Port #n Link State Sensor		
Entity Type	6	Communication Channel
Entity Instance Number	Port Number	The ordering number of the port reported in controller association PDR (Section 12.8.3.3.2.2)
Container Entity Container ID	1000	
Terminus Handle	0	
Sensor ID	699 + n	
Composite Sensor Count	1	
Sensor Type	33	Link State
Possible States	1=Connected, 2=Disconnected	

12.8.3.3.5.2 Cable Presence State

Port #n Cable Presence State Sensor		
Entity Type	189	Plug
Entity Instance Number	1	
Container Entity Container ID	1009 + n	
Terminus Handle	0	
Sensor ID	1139 + n	
Composite Sensor Count	1	
Sensor Type	13	Presence State (Cable)
Possible States	1=Connected, 2=Disconnected	

12.8.3.3.6 Numeric Sensors PDRs

12.8.3.3.6.1 Thermal Sensors

The parameters of the PDR for each sensor can be extracted through the GETNODEATTR DNL script on the Node Thermal Configuration Section.

Type	PDR Fields
uint32	**recordHandle** According to Section 12.8.3.1, "Sensors Numbering" (thermal sensors).
uint8	**PDRHeaderVersion** = 0x01
uint8	**PDRType** = 0x2 (Numeric Sensor PDR)
uint16	**recordChangeNumber** According to Section 12.8.2.3, "PDR Dynamic Changes Flow".
uint16	**dataLength** = 0x43 (67)
uint16	**PLDMTerminusHandle** = 0x0001
uint16	**sensorID** According to Section 12.8.3.1, "Sensors Numbering" (thermal sensors).
uint16	**entityType** For Controller Sensor = 0x90 (Physical | Network Controller (144)) For NIC Sensor = 0x44 (Physical | Add on card (68)) For Plug Sensor = 0xBD (Physical | Plug (189))
uint16	**entityInstanceNumber** Sensor Number (starting from 0)
uint16	**containerID** According to the container of the thermal Sensor in Section 12.8.3.1, "Sensors Numbering".
enum8	**sensorInit** = noInit (0x0) The Initialization Agent does not take any steps to initialize, enable or disable this particular sensor.
bool8	**sensorAuxiliaryNamesPDR** = FALSE Sensor does not have an associated Sensor Auxiliary Names PDR.
enum8	**baseUnit** = 0x2 (Degrees C).
sint8	**unitModifier** = 0x0 (No modifier)
enum8	**rateUnit** = None (0x0)

Type	PDR Fields
uint8	**baseOEMUnitHandle** = 0x0 (N/A)
enum8	**auxUnit** = None (0x0)
sint8	**auxUnitModifier** = 0x0
enum8	**auxrateUnit** = None (0x0)
enum8	**Rel** = 0x0 (N/A)
uint8	**auxOEMUnitHandle** = 0x0 (N/A)
bool8	**isLinear** = TRUE
enum8	**sensorDataSize** = 0x0 (uint8)
real32	**resolution** As read from resolution Low/Resolution High fields in Node Thermal Configuration.
real32	**Offset** As read from Offset Low/Offset High fields in Node Thermal Configuration Section. A constant value that is added in as part of the conversion process of converting a raw sensor reading to Units.
uint16	**Accuracy** As read from accuracy field in Node Thermal Configuration Section.
uint8	**plusTolerance** As read from Tolerance in Node Thermal Configuration Section.
uint8	**minusTolerance** As read from Tolerance in Node Thermal Configuration Section.
uint8	**Hysteresis** As read from Thermal Sensor Hysteresis in Node Thermal Configuration Section.
birfield8	**supportedThresholds** Return 0x7 (*upperThresholdFatal*, *upperThresholdCritical*, *upperThresholdWarning*)
birfield8	**thresholdAndHysteresisVolatility** Return 0x3 (PLDM subsystem power up, Initialization Agent controller restart/update). TBD if others also.
real32	**stateTransitionInterval** Return the internal firmware sensors polling interval (in real32). Current value is 1 second (0x3F800000).
real32	**updateInterval** Return the internal firmware sensors polling interval (in real32) - current value is 1 second (0x3F800000).
uint8	**maxReadable** As read from *maxReadable* in Node Thermal Configuration Section.
uint8	**minReadable** As read from *minReadable* in Node Thermal Configuration Section.
enum8	**rangeFieldFormat** = 0x2 (uint16)
birfield8	**rangeFieldSupport** Return 0x2A (normalMax, criticalHigh, fatalHigh supported).
uint16	**nominalValue** = Return 0x0
uint16	**normalMax** As read from *normalMax* field in Node Thermal Configuration Section. Value is in degrees C, should be adapted according to the resolution field.
uint16	**normalMin** = Return 0x0
uint16	**warningHigh** As read from *warningHigh* field in Node Thermal Configuration Section.
uint16	**warningLow** = Return 0x0

Type	PDR Fields
uint16	**criticalHigh** As read from *criticalHigh* field in Node Thermal Configuration Section. Value is in degrees C, should be adapted according to the resolution field.
uint16	**criticalLow** = Return 0x0
uint16	**fatalHigh** As read from *fatalHigh* field in Node Thermal Configuration Section.
uint16	**fatalLow** = Return 0x0

12.8.3.3.6.2 Plug Power Sensors

Type	PDR Fields
uint32	**recordHandle** = 1139 + plug number (1..n)
uint8	**PDRHeaderVersion** = 0x01
uint8	**PDRType** = 0x2 (Numeric Sensor PDR)
uint16	**recordChangeNumber** According to Section 12.8.2.3, "PDR Dynamic Changes Flow".
uint16	**dataLength** = 0x47 (71)
uint16	**PLDMTerminusHandle** = 0x0001
uint16	**sensorID** = 249 + plug number (1..n)
uint16	**entityType** = 0xBD (Physical | Plug (189))
uint16	**entityInstanceNumber** = 1
uint16	**containerID** = 1009 + port# (1..n)
enum8	**sensorInit** = noInit (0x0) The Initialization Agent does not take any steps to initialize, enable or disable this particular sensor.
bool8	**sensorAuxiliaryNamesPDR** = FALSE Sensor does not have an associated Sensor Auxiliary Names PDR
enum8	**baseUnit** = 0x7 (Watts) The reported value is a the max power for the class.
sint8	**unitModifier** = -1 Tenth of watts.
enum8	**rateUnit** = 0x0 (None)
uint8	**baseOEMUnitHandle** = 0x0 (N/A)
enum8	**auxUnit** = None (0x0)
sint8	**auxUnitModifier** = 0x0
enum8	**auxrateUnit** = None (0x0)
enum8	**Rel** = 0x0 (N/A)

uint32	AdditionalResourceID [PortCount - 2]	300 + PFs[PFCount - 1]
uint16	AdditionalResourceSubURILengthBytes[PortCount - 2]	Length in bytes of SubURI
strUTF-8	AdditionalResourceSubURI[PortCount - 2]	"PCIeFunctions/"n""
ver32	MajorSchemaVersion	0xF1F2F100
uint16	MajorSchemaDictionaryLengthBytes	Actual length of dictionary stored in NVM.

Type	Description	Value
uint32	MajorSchemaDictionarySignature	32-bit CRC of the schema dictionary.
uint8	MajorSchemaNameLength	46
strUTF-8	MajorSchemaName	"PCIeFunction.PCIeFunction\0"
uint16	OEMCount	0

12.8.3.3.9 Non-ACD PDRs

There are several schemas that are beyond the ACD profile definition. Figure 12-15 defines those PDRs. The supported fields are based on the OCP Baseline Hardware Management profile v1_0_0.

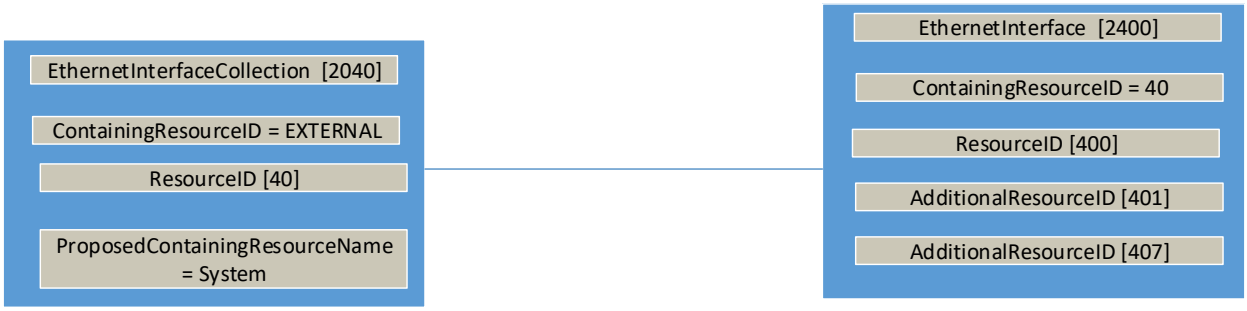

Figure 12-15. Non-ACD PDRs

12.8.3.3.9.1 EthernetInterfaceCollection

Type	Description	Value
uint32	recordHandle	4040
uint32	ResourceID	40
bitfield8	ResourceFlags	5 (is_device_root | is_collection)
uint32	ContainingResourceID	0 (External)
uint16	ProposedContainingResourceLengthBytes	6
strUTF-8	ProposedContainingResourceName	"System\0"
uint16	SubURILengthBytes	Length in bytes of SubURI
strUTF-8	SubURI	Null
uint16	AdditionalResourceIDCount	0
ver32	MajorSchemaVersion	0xFFFFFFFF
uint16	MajorSchemaDictionaryLengthBytes	Actual length of dictionary stored in NVM.
uint32	MajorSchemaDictionarySignature	32-bit CRC of the schema dictionary.
uint8	MajorSchemaNameLength	28
strUTF-8	MajorSchemaName	"EthernetInterfaceCollection. EthernetInterfaceCollection"
uint16	OEMCount	0

12.8.3.3.9.2 EthernetInterface

Type	Description	Value
uint32	recordHandle	4400
uint32	ResourceID	400 +Ports[0]
bitfield8	ResourceFlags	2 (is_contained_in_collection)
uint32	ContainingResourceID	40
uint16	ProposedContainingResourceLengthBytes	1
strUTF-8	ProposedContainingResourceName	"\0"
uint16	SubURILengthBytes	Length in bytes of SubURI
strUTF-8	SubURI	"0"
uint16	AdditionalResourceIDCount	2*PortCount-1
uint32	AdditionalResourceID [0]	2400 + Ports[1]
uint16	AdditionalResourceSubURILengthBytes[0]	Length in bytes of SubURI
strUTF-8	AdditionalResourceSubURI[0]	"1"
uint32	...	...
uint32	AdditionalResourceID [PortCount - 2]	400 + Ports[PortCount - 1]
uint16	AdditionalResourceSubURILengthBytes[PortCount - 2]	Length in bytes of SubURI
strUTF-8	AdditionalResourceSubURI[PortCount - 2]	"n"
uint32	AdditionalResourceID [PortCount - 1]	410 + Ports[0]
uint16	AdditionalResourceSubURILengthBytes[PortCount - 1]	Length in bytes of SubURI
strUTF-8	AdditionalResourceSubURI[PortCount - 1]	"0/Settings"
uint32	...	...
uint32	AdditionalResourceID [2*PortCount - 2]	410 + Ports[PortCount-1]
uint16	AdditionalResourceSubURILengthBytes[PortCount - 2]	Length in bytes of SubURI
strUTF-8	AdditionalResourceSubURI[PortCount - 2]	""n"/Settings"
ver32	MajorSchemaVersion	0xF1F4F100
uint16	MajorSchemaDictionaryLengthBytes	Actual length of dictionary stored in NVM.
uint32	MajorSchemaDictionarySignature	32-bit CRC of the schema dictionary.
unit8	MajorSchemaNameLength	18
strUTF-8	MajorSchemaName	"EthernetInterface.EthernetInterface"
uint16	OEMCount	0

12.8.3.3.10 RDE Action PDRs

The only action currently supported is the ResetSettingsToDefault action PDR related to NetworkAdapter resource.

See DSP0248 for the PDR definition.

12.8.3.3.10.1 ResetSettingsToDefault

Type	Description	Value
uint8	ActionPDRIndex	0
uint16	RelatedResourceCount	1
uint32	RelatedResourceID [0]	2001
uint8	ActionCount	1
uint8	ActionNameLengthBytes [0]	23
utf8string	ActionName [0]	"ResetSettingsToDefault\0"
uint8	ActionPathLengthBytes [0]	ActionPath length in bytes.
utf8string	ActionPath [0]	Null-terminated string detailing the path to the root of the Action within the resource's major dictionary.

12.8.4 PLDM Firmware Update Commands

The firmware should support the following PLDM commands and responses according to DSP0267.

Table 12-82. PLDM for Firmware Update Command Codes

Command	Command Code	Command Requestor (Initiator)	Supported	Section Reference
QueryDeviceIdentifiers	0x01	BMC	Yes	12.8.4.2.1
GetFirmwareParameters	0x02	BMC	Yes	12.8.4.2.2
RequestUpdate	0x10	BMC	Yes	12.8.4.2.3
GetPackageData	0x11	Firmware	Yes	12.8.4.1.1
GetDeviceMetaData	0x12	BMC	No	---
PassComponentTable	0x13	BMC	Yes	12.8.4.2.4
UpdateComponent	0x14	BMC	Yes	12.8.4.2.5
RequestFirmwareData	0x15	Firmware	Yes	12.8.4.1.2
TransferComplete	0x16	Firmware	Yes	12.8.4.1.3
VerifyComplete	0x17	Firmware	Yes	12.8.4.1.4
ApplyComplete	0x18	Firmware	Yes	12.8.4.1.5
GetMetaData	0x19	Firmware	No	---
ActivateFirmware	0x1A	BMC	Yes	12.8.4.2.6
GetStatus	0x1B	BMC	Yes	12.8.4.2.7
CancelUpdateComponent	0x1C	BMC	Yes	12.8.4.2.8
CancelUpdate	0x1D	BMC	Yes	12.8.4.2.9

12.8.4.1 Firmware-to-BMC Commands

This section describes the commands that are sent by firmware to BMC. Please refer to DSP0267 for full descriptions of each command and its fields.

Upon error code or timeout, in response firmware should act as follows:

- Implement "6.3.2 Requirements for Requesters" as specified in DSP0240.
  - Number of request retries PN1.
  - Request-to-response time PT1.
  - Time out waiting for a response PT2.
- In addition, firmware should implement the state transition in case of error or timeout, as explained in "8.2 State machine" in DSP0267.
- In the case of an error that does not allow firmware to continue the update and firmware actions are not described in "8.2 State machine" in DSP0267, firmware does one of the following:
  - Cancel Update (return to IDLE) in case of an error in the following states:
    - IDLE
    - LEARN
    - ACTIVATE
  - Cancel Component Update (return to READY XFER):
    - READY XFER
    - DOWNLOAD
    - VERIFY
    - APPLY

12.8.4.1.1 GetPackageData (Command Code 0x11)

The package data includes the following fields:

- Byte [0].Bit 0 = PFA Preserve (default mode). Should be set to zero.
- Byte [0].Bit 1 = Reserved (was O-ROM version to be set in VPD).
- Byte [0].Bits [7:2] = Reserved
- TLV as follows:
  - Type – 2 bytes:
    - CURRENT_GFID – 0x1
  - Length – 2 bytes = 36 words
  - Value:
    - 17:0 = Current GFID
    - 35:18 = Original GFID

GFID length and value: Same as in Section 6.3.6.2 and Section 6.3.56.

It is assumed that GFID is unique per OEM thus should not change during the update.

Current GFID is the GFID of the currently running image planned to update. Original GFID is the basic image from which this map is derived.

- A set of TLVs as needed as follows:
  - Type – 2 bytes:
    - TLV + Offset update - 0x10 // used to update TLVs
  - Length – 2 bytes:
    - According to size of value (in words)
  - Value
    - uint16: TLV number
    - uint16: offset in words (offset 0 is the beginning of the TLV data)
    - uint16: Data length in words
    - Variable: Data
- A set of TLVs as needed as follows:
  - Type – 2 bytes:
    - VPD Key update - 0x11 // Used to update VPD entries
    - Length - 2 bytes (According to size of value (in words))
  - Value:
    - uint16: VPD key (ascii - e.g. V2 = 0x5632 (ascii('V'), ascii('2')))
    - uint16: Data length (in bytes) // should match current VPD entry size - error otherwise

      Note: If Data Length is odd, add a pad byte at end of data to make the TLV word aligned.
    - Variable: Data

Note: The TLVs can be in any order.

12.8.4.1.2 RequestFirmwareData (Command Code 0x15)

For the FD to retrieve a section of a component image, the FD sends *RequestFirmwareData* request message to the UA, specifying its offset and length. The UA sends a response message that includes the component image portion specified by the offset and length from the request message. See DSP0267, Chapter 11.6.

Implementation note: Firmware should minimize the number of NVM Update commands by doing 4 KB updates.

12.8.4.1.3 TransferComplete (Command Code 0x16)

The FD sends *TransferComplete* command to the UA once the FD has transferred all the data for the component image or determines the transfer has failed. See DSP0267, Chapter 11.7.

12.8.4.1.4 VerifyComplete (Command Code 0x17)

Firmware performs a validation check against the component image that was received. See DSP0267, Chapter 11.8.

Firmware performs the same verification check as performed today during the NVM/S-RAM/O-ROM update using the NVM Update admin commands. See Section 3.4.5.

Firmware should also verify that the parameters received before the download match the downloaded components.

12.8.4.1.5 ApplyComplete (Command Code 0x18)

As firmware has already completed the component image transfer into the storage location, it should only return the Activation method:

- [5] AC power cycle = POR
- [4] DC power cycle = PCIe Reset
- [3] System reboot = In-band Reset
- [2] Medium-specific reset = EMPR
- [1] Self-Contained reset = EMPR is performed by firmware upon *ActivateFirmware*
- [0] Automatic = EMPR is performed by firmware as the Apply completes, or as download completes if the FD performs an auto-apply

Command Parameter	Description
ComponentActivationMethodsModification	"DC power cycle" or "Self-Contained reset" based on the decision described in Section 12.8.5.6.

12.8.4.2 BMC-to-Firmware Commands

This section describes the firmware responses for commands that arrived from the BMC.

Refer to DSP0267 for full description of each command and its fields.

12.8.4.2.1 QueryDeviceIdentifiers (Command Code 0x01)

This command is used by the UA to obtain the firmware identifiers for the FD. The FD must provide a response message to this command in all states, including IDLE. See DSP0267, Chapter 10.1.

Response Parameter	Description
DescriptorCount	Should be set to 4.
Descriptors	Refer to Section 12.8.5.2.1 for FD *InitialDescriptorType*, *InitialDescriptorLength*, *InitialDescriptorData*.

12.8.4.2.2 GetFirmwareParameters (Command Code 0x02)

The UA sends *GetFirmwareParameters* command to acquire the component details, such as classification types and corresponding versions of the FD. The FD must provide a response message to this command in all states, including IDLE. See DSP0267, Chapter 10.2.

Response Parameter	Description
CapabilitiesDuringUpdate	Set the following bits: Bit 4 = 0 – No host OS environment restriction for update mode. Bit 3 = 1 – Firmware Device can support a partial update, whereby a package that contains a component image set that is a subset of all components currently residing on the FD, can be transferred. Bit 2 = 1 – Device host functionality will be reduced, perhaps becoming inaccessible, during Firmware Update. Bit 1 = 0 – Device can have component updated again without exiting update mode and restarting transfer via RequestUpdate command. Bit 0 = 0 – Device will revert to previous component image upon a failure, timeout, or cancellation of the transfer.
ComponentCount	Set to 3 (NVM, OROM, Netlist).
ActiveComponentImageSetVersionStringType	Refer to *ComponentImageSetVersionStringType* in Section 12.8.5.2.1.
PendingComponentImageSetVersionStringType	Same as for active set, but for pending component.
ActiveComponentImageSetVersionString	Refer to *ComponentImageSetVersionString* in Section 12.8.5.2.1.
PendingComponentImageSetVersionString	Same format as for active set.
ComponentClassification	Refer to *ComponentClassification* in Section 12.8.5.2.1.
ComponentIdentifier	Refer to *ComponentIdentifier* in Section 12.8.5.2.1.
ComponentClassificationIndex	Not used. Set to 0.
ActiveComponentComparisonStamp	Refer to *ComponentComparisonStamp* in Section 12.8.5.2.1.
ActiveComponentVersionStringType	Refer to *ComponentVersionStringType* in Section 12.8.5.2.1.
ActiveComponentReleaseDate	Refer to *ComponentReleaseDate* in Section 12.8.5.2.1.
PendingComponentComparisonStamp	Same format as for active component.
PendingComponentVersionStringType	Same as for active component.
PendingComponentReleaseDate	Same format as for active component.
ComponentActivationMethods	"DC power cycle" or "Self-Contained reset".
CapabilitiesDuringUpdate	Bit 0 = 0 – Firmware Device executes an operation during the APPLY state, which includes migrating the new component image to its final non-volatile storage destination.
ActiveComponentVersionString	Refer to *ComponentVersionString* in Section 12.8.5.2.1.
PendingComponentVersionString	Same as for active component.

12.8.4.2.3 RequestUpdate (Command Code 0x10)

This is the first PLDM command to initiate a firmware update for an FD. The FD must enter update mode if that command response indicates success. See DSP0267, Chapter 11.1.

Firmware should verify the parameters that have been received and return errors in cases when it does not match.

Firmware takes OWNERSHIP over NVM. In any case of return to IDLE state due to:

- Timeout
- Reset
- Error

After already being in update mode, firmware should release the OWNERSHIP of the NVM.

Command Parameter	Description
NumberOfComponents	Up to "3". Should be ≤ *ComponentCount* in *GetFirmwareParameters*.
PackageDataLength	Should be > 0. See Section 12.8.4.1.1.

Response Parameter	Description
FirmwareDeviceMetaDataLength	Set to 0, as *GetMetaData* is not supported.

12.8.4.2.4 PassComponentTable (Command Code 0x13)

The *PassComponentTable* command is used to pass component information to the FD after the FD enters update mode. The *PassComponentTable* command contains the component information table for a specific component including *ComponentClassificationIndex*, *ComponentClassification*, and version details.

If the firmware update package contains more than one component, multiple *PassComponentTable* commands are required to be sent by the UA (one for each component). The UA must pass the component table for all applicable components listed in the firmware package header in ascending order of index. See DSP0267, Chapter 11.4.

Firmware verifies the parameters that have been received and returns an error in case they do not match.

Command Parameter	Description
ComponentClassification	Refer to *ComponentClassification* at in Section 12.8.5.2.1.
ComponentIdentifier	Refer to *ComponentIdentifier* in Section 12.8.5.2.1.
ComponentComparisonStamp	Refer to *ComponentComparisonStamp* in Section 12.8.5.2.1.
ComponentVersionStringType	Refer to *ComponentVersionStringType* in Section 12.8.5.2.1.
ComponentVersionString	Refer to *ComponentVersionString* in Section 12.8.5.2.1.

12.8.4.2.5 UpdateComponent (Command Code 0x14)

The UA sends the *UpdateComponent* command to request updating a specific firmware component. See DSP0267, Chapter 11.5

Command Parameter	Description
UpdateOptionFlags	Bit 0 = Request Force Update of component – Can be used to inform the FD device to perform a transfer even if the component has a lower or equal component comparison stamp, or version string, than what is currently installed. The UA sets this bit for any component that has the force update bit set in the *ComponentOptions* field of the package header. Additionally, the UA could set the bit as instructed by commands used to provide the update package to the UA (these commands are out of scope for this specification).

If Bit 0 is set, firmware should allow downgrade only up to security version.

12.8.4.2.6 ActivateFirmware (Command Code 0x1A)

After all firmware components in the FD have been transferred and applied, the UA sends this command to inform the FD to prepare all successfully-applied components to become active at the next activation.

The UA can also request activation of all components that have an activation method of "Self-Contained". See DSP0267, Chapter 11.11.

Command Parameter	Description
SelfContainedActivationRequest	Self contained activate is not supported.

Response Parameter	Description
EstimatedTimeForSelfContainedActivation	Should be set to 0 if no self-contained components.

12.8.4.2.7 GetStatus (Command Code 0x1B)

The UA sends this command to acquire the status of the FD. See DSP0267, Chapter 11.12.

Response Parameter	Description
ProgressPercent	IDLE – 0% LEARN COMPONENTS – 0% READY XFER – 0% DOWNLOAD – 100% * num_downloaded / total_num_of_comp VERIFY – 100% * num_verified / total_num_of_comp APPLY – 100% * num_applied / total_num_of_comp ACTIVATE – 0%

12.8.4.2.8 CancelUpdateComponent (Command Code 0x1C)

During the firmware component transfer process, the UA can send this command to the FD. The FD, upon receiving this command, must stop sending *RequestFirmwareData* commands to the UA, and cancel the current component update procedure. The FD controller must transition to the READY XFER state of update mode and be ready to accept another *UpdateComponent* command. The UA can attempt to resend the same component image to the UA. See DSP0267, Chapter 11.13.

See DSP0267, Chapter 8.2, "State Machine".

Even though it is not required by DSP0267, it is expected that firmware get back to normal activity using the currently active component.

12.8.4.2.9 CancelUpdate (Command Code 0x1D)

This command signals to the FD that it should exit from update mode even if activation is required to begin operating at the new firmware level. The UA should always attempt to complete the transfer of all components and use this command only if it determines that there is no other method to continue with the transfer process. See DSP0267, Chapter 11.14.

See DSP0267, Chapter 8.2, "State Machine".

Even though it is not required by DSP0267, it is expected that firmware get back to normal activity using the currently active components.

Response Parameter	Description
NonFunctioningComponentIndication	Always False meaning that all components will be functional.
NonFunctioningComponentBitmap	All zeros.

12.8.5 PLDM Firmware Update Flow

This section describes the implementation of DSP0267 - PLDM firmware update protocol.

12.8.5.1 Update Components

The firmware update over PLDM can be done to the following NVM components:

- NVM
- OROM
- Netlist

12.8.5.2 Firmware Update Package

This section describes the fields of the Firmware Update Package that are relevant for this implementation.

Note: Support of packages of several devices is done through device ID and already filtered by the BMC, so the FD receives components that are relevant to its device only.

12.8.5.2.1 Package Versions

This section describes the components versions format and identifiers as to be set inside the Firmware Update package. Only the fields that are relevant to this implementation are covered here.

For firmware usage of the fields below, see Section 12.8.4, "PLDM Firmware Update Commands".

The following parameters are to be defined on a package level. See the details in Table 12-83 through Table 12-85.

- Component
  - Version
  - Classification
  - Identifier
  - Comparison Stamp
  - Release Date
- Component Set
  - Version
- Firmware Device
  - Type
  - Identifier

General Versions:

- NVM component version string is an 18-character ASCII-encoded buffer as CCCCCCCC.SSSSSSSS<nul>, where CCCCCCCC and SSSSSSSS are the 32-bit ComponentComparisonStamp and security revision (Iad_srev), respectively, rendered in hex with leading zeros as needed, and terminated by a null byte.
- O-ROM component version string is an 18-character ASCII-encoded buffer as CCCCCCCC.SSSSSSSS<nul>, where CCCCCCCC and SSSSSSSS are the 32-bit ComponentComparisonStamp and security revision (Iad_srev), respectively, rendered in hex with leading zeros as needed, and terminated by a null byte. uEFI OROM version in PCIR structure, as reported by Get Controller Information command (Section 12.6.4.16.1).
- Netlist component version string is:

  Concatenate (BaseReleaseVersion.Major,".",BaseReleaseVersion.Minor,".", BaseReleaseVersion.Type,".",CustomerNetlistVersion.IANA,".",CustomerNetlistVersion)/

  The versions are represented as eight ASCII characters, each with leadings zeros added as needed. The CustomerNetlistVersion is two bytes (four characters) only. The length of this version is fixed to 42 (including null padding).

  The comparison algorithm for topology netlist is:

  CN = Current Netlist

  NN = New Netlist

  CV = CustomerNetlistVersion

  BRV = BaseReleaseVersion

  If (CN.BaseReleaseVersion.Type <> NN.BaseReleaseVersion.Type), then Error (not matching Netlist).

If (CN.OEM IANA <> NN.OEM IANA) then Error (not matching OEM).

Else according to the following table:

BRV."major.minor"	CV	Result	Notes
CN = NN	CN = NN	Same version	Everything is equal so it is the same version.
CN < NN	Don't care	Upgrade	If the BRV is higher, allow upgrade regardless of CV setting.
CN = NN	CN < NN	Upgrade	If the BRV is equal, allow upgrade when CV setting is higher in the New Netlist.
CN > NN	Don't care	Downgrade	If the BRV is lower, allow downgrade regardless of CV setting.
CN = NN	CN > NN	Downgrade	If the BRV is equal, allow downgrade when CV setting is lower in the New Netlist.

- The ComponentSetVersionString for OEM Gen images is encoded as a 32-character string of the form N:nnnnnnnnO:oooooooT:ttttttttt<nul>, where nnnnnnnn, oooooooo, and tttttttt are the 32-bit NVM, OROM, and netlist Component Comparison Stamps, respectively, rendered in hex with leading zeros as needed, and terminated by a null byte.

Table 12-83. Firmware Device

Type	Name	Format/Value	Mandatory
uint16	**InitialDescriptorType** Indicates the type of the Initial descriptor. The initial descriptor for a device must be defined by one of the following (PCI Vendor ID, IANA Enterprise ID, UUID, PnP Vendor ID, or ACPI Vendor ID). If the FD uses Vendor Defined values as part of its implementation of this specification (for example to provide a vendor defined error code or component classification), the initial descriptor must be set to either PCI Vendor ID or IANA Enterprise ID.	PCI Vendor ID = 0x0000 Length = 2 Bytes	Yes
Variable	**InitialDescriptorData** Payload containing the identifier value for the initial descriptor.	0x8086	Yes
uint16	AdditionalDescriptorType0	PCI Device ID	Yes
Variable	AdditionalDescriptorData0	See Section 14.2.5.2. ***Note:*** All the descriptors field are taken from the config space of PF0.	Yes
uint16	AdditionalDescriptorType1	PCI Subsystem Vendor ID	Yes
Variable	AdditionalDescriptorData1	See Section 14.2.5.10.	Yes
uint16	AdditionalDescriptorType2	PCI Subsystem ID	Yes
Variable	AdditionalDescriptorData2	See Section 14.2.5.11.	Yes
uint16	AdditionalDescriptorType3	PCI Revision ID	No
Variable	AdditionalDescriptorData3	See Section 14.2.5.5.	No

Table 12-84. Component Set

Type	Name	Format/Value	Mandatory
enum8	**ComponentImageSetVersionStringType** ASCII, UTF-8/16/16LE/16BE, Unknown	ASCII – 1	Yes
Variable	**ComponentImageSetVersionString** Up to 255 bytes	See above for OEM Gen ComponentSetVersionString. When written, the *ComponentImageSetVersionString* is stored in PFV TLV #0x127	Yes

Table 12-85. Component

Type	Name	Format/Value	Mandatory
enum8	**ComponentVersionStringType** ASCII, UTF-8/16/16LE/16BE, Unknown	ASCII – 1 NVM Length = 18 O-ROM Length = 18 Netlist length = 42	Yes
Variable	**ComponentVersionString** Up to 255 bytes	See above.	Yes
uint16	**ComponentClassification** 0x000A - Firmware, 0x000B - BIOS/FCode, 0x0006- Firmware/BIOS, 0x8000-0xFFFF – Vendor defined	0x000A - Firmware	Yes
uint16	**ComponentIdentifier** FD vendor selected unique value to distinguish between component images.	NVM lad_module_id = 0x6 O-ROM lad_module_id = 0x5 Topology Net List Module ID = 0x8	Yes
uint8	**ComponentClassificationIndex** Used to distinguish identical components that have the same classification and identifier which can use the same component image but the images are stored in different locations in the FD.	Not used.	No
uint32	**ComponentComparisonStamp** When *ComponentOptions* bit 1 is set, this field must contain a FD vendor selected value to use as a comparison value in determining if a firmware component is down-level or up-level. For the same component identifier, the greater of two component comparison stamps is considered up-level compared to the other when performing an unsigned integer comparison. FD vendors should choose the value for the comparison stamp in a manner that permits interim component versions, such as patch releases. For example, a value for this field can follow the format of *MajorMinorRevisionPatch* where each subfield has a range of 0x00 to 0xFF.	MajorMinor Major = 16 bit Minor = 16 bit NVM bank comparison stamp = 31:25: DevStarterVersion Major (0-99) 24:18: DevStarterVersion Minor (0-99) 17:0: EETrackID OROM bank comparison stamp = CIVD if Combo - Combo Image Version Low/ High in CIVD Section. In case of no OROM, the version reported is all zeros. Net list comparison stamp = BaseReleaseVersion.Major/Minor (32 bit value copied from Netlist identifier block).	No
ASCII[8]	**ComponentReleaseDate** Optional. Firmware returns this information upon *GetFirmwareParameters* command. ***Note:*** It is not part of Component Image information that is passed by BMC to FD. If supported, it is assumed to be part of the component image.	Not used.	No

12.8.5.3 Firmware Flow for Section Update

Table 12-86 includes the commands and the firmware action for each command for any bank update.

Note: The PFA section is preserved and not changed by PLDM update.

Table 12-86. Action Upon Reception of Commands - NVM Section

BMC Command	Firmware Device Command	Firmware Device Action	Remarks	Section Reference
RequestUpdate		Take ownership on NVM. Respond success or other error code. ***Note:*** The Firmware holds ownership of the NVM for 15 minutes. After that, the update process is aborted and NVM ownership is released.	First PLDM command to initiate a firmware update for an FD. Same as Section 9.5.13.6. From the standard: "The FD must then enter an update mode that no longer permits another update request until the UA finishes or cancels the firmware update."	12.8.4.2.3
	GetPackageData			12.8.4.1.1
PassComponentTable		Respond success or other error code. Perform the following checking: Check GFID as described in Section 3.4.5.6.1. Check security revision as described in Section 3.4.9.2. If one of the checks fails, return error code 0x07. *ComponentComparisonStamp* >= *ActiveComponentComparisonStamp* as reported by *GetFirmwareParameters*. If not, return error code 0x1- 0x2 accordingly.	Pass component information. Contains the component information table for a specific component including *ComponentClassificationIndex*, *ComponentClassification*, and version details. Number of commands is the number of components to update. Firmware should allow downgrade only up to security version.	12.8.4.2.4
UpdateComponent		Issue erase command to NVM. (Address in the NVM of the 1st bank pointer of the relevant bank). Respond success or other error code.	Request updating a specific firmware component. See Section 3.4.10.2.	12.8.4.2.5
	RequestFirmwareData	Store internally the received data until 4 KB received, then issue an update NVM command. Respond success or other error code.	See Section 3.4.10.3.	12.8.4.1.2
	TransferComplete	Verify the image authentication. The following is according to Section 3.4.5.6 (OROM)/ Section 3.4.5.6 (NVM), Step 6- Step 8. No authentication check is done on Netlist.		12.8.4.1.3

Table 12-86. Action Upon Reception of Commands - NVM Section [continued]

BMC Command	Firmware Device Command	Firmware Device Action	Remarks	Section Reference
	VerifyComplete	Validation checks same as done by NVM Update admin command. Verify that *ComponentVersionString*, *ComponentComparisonStamp*, *ComponentSetVersionString* as defined in (Section 12.8.4.1.1) as passed before the download matches the downloaded NVM/ OROM bank, see in Section 12.8.5.2.1.		12.8.4.1.4
	ApplyComplete			12.8.4.1.5
ActivateFirmware		Update PFA with the following fields according to the TLVs ion *PackageData*. Respond success or other error code.	See Section 3.4.5.2.1 – Results in validate the new bank and invalidate the old bank. See Section 9.5.13.7.	12.8.4.2.6

12.8.5.4 PLDM Events and Commands

PLDM events are to be answered by firmware during NVM update.

PLDM events have higher priority over PLDM update NVM commands.

PLDM commands are supported regardless of PLDM FWU enable bit in NVM.

PLDM Bit	PLDM FWU Bit	PLDM Commands	PLDM FWU Commands	Legal
Enabled	Enabled	Supported	Supported	Yes
Enabled	Disabled	Supported	Not supported	Yes
Disabled	Disabled	Drop	Drop	Yes
Disabled	Enabled	Drop	Drop	No

12.8.5.5 Reset During Update

The firmware should return to IDLE mode only in POR and EMPR. This is the case now anyway, so no additional handling is required.

In all other reset cases (CORER, GLOBR), the firmware update continue the update.

12.8.5.6 Activation Methods

The activation and reset after update is done by BMC.

The firmware *ApplyComplete* command includes the type of reset required.

Option ROM update requires PERST to take effect.

12.8.6 RDE Support

RDE is a protocol defined to allow exposure of devices directly to the Redfish infrastructure.

System-level architecture for RDE is presented in Figure 12-16. The Administrator issues Redfish commands over HTTP/HTTPS. The Management Controller (MC), which supports Platform Level Data Model (PLDM) and RDE protocols, converts Redfish commands to the binary form used by the RDE Device. The RDE-capable device responds to MC over PLDM using BEJ format.

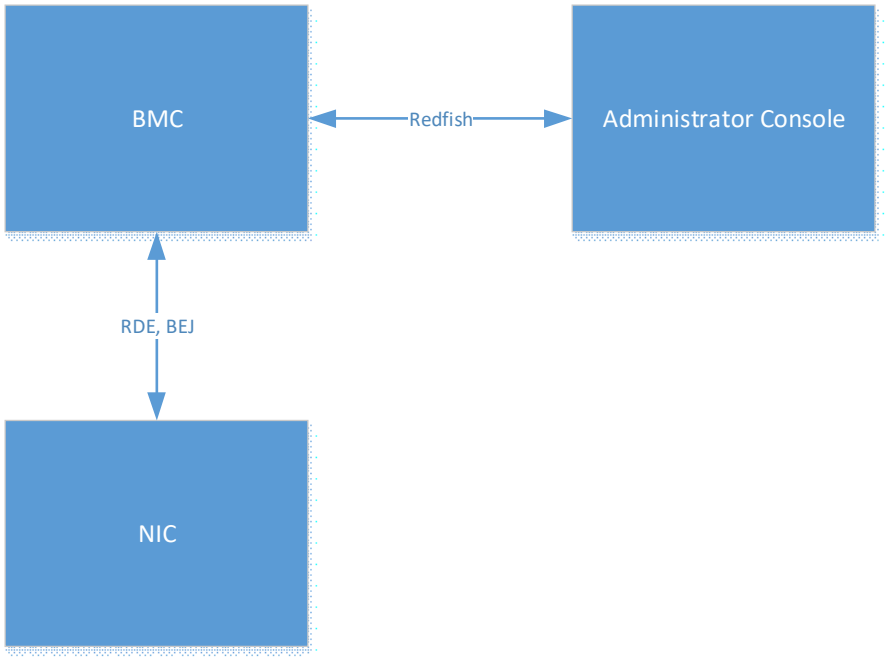

Figure 12-16. RDE Setup

12.8.6.1 Implementation Guidelines

12.8.6.1.1 Presence of Payload in Command/Response

This section defines which actions expect the *contains_request_payload* flag to be set in the RDEOperationInit command, which sets the *HaveResultPayload* flag in the response, and which expects a valid *OperationLocator* field as part of the command.

Field	Read	Update	Replace	Create	Delete	Action	Head
contains_request_payload	MUST NOT	MUST	MUST	CAN	MUST NOT	MUST NOT	MUST NOT
HaveResultPayload	MUST	MUST NOT	MUST NOT	MUST NOT	MUST NOT	MUST NOT	MUST NOT
OperationLocator	CAN	CAN	CAN	CAN	CAN	MUST NOT	CAN

12.8.6.1.2 PUT, PATCH Operation Guidelines

If an operation of type UPDATE or REPLACE is received with a BEJ payload containing a mix of Read-Only and Read-Write properties, the operation silently ignores all Read-Only properties and behaves as if the payload contains Read-Write properties only.

If the payload of a write operation contains Read-Only properties exclusively, the operation ignores the entire payload, performs no write, and returns success.

12.8.6.1.3 String Handling

Any string received with a null character in the middle of the string is treated as an invalid input.

12.8.6.1.4 Resource Permissions

Each resource has associated permissions, which determine the types of operations permitted to be performed on that resource. If an RDE operation is invoked with an Operation Type forbidden by that resource, operation initialization fails with a return code of ERROR_NOT_ALLOWED. See Table 12-90, "Resources Parameters" on page 1772 for a list of allowed operation per resource. Permissions on a Property level are not individually supported, and all errors are silently ignored.

12.8.6.1.5 Resources Exposing @Redfish.Settings Attr.

For the NetworkPort, NetworkDeviceFunction, and EthernetInterface schemas, there are two sets of resources, as follows:

Schema	Regular Resource ID (RO)	Settings Resource ID (RW)
NetworkPort	100-107	110-117
NetworkDeviceFunction	200-207	210-217
EthernetInterface	400-407	410-417

Into each regular instance of the above resources, the following is inserted:

```
"@Redfish.Settings" : {
   "@odata.type": "#Settings.v1_3_0.Settings",
   "SupportedApplyTimes": ["OnReset"],
   "SettingsObject": {
   "@odata.id": 112   // bejResourceLink to Settings Resource NetworkPort 3
   }
}
```

When a write to one of these resources needs to be done, the Settings Resource (110-117, 210-217,410-417) is accessed. The Regular Resource and all its properties are RO. All changes written to by a Settings Resource must delay their application until at reset. After successful RDE Operation completion, the pending setting is stored in non-volatile memory. Any pending changes to the Settings Resources are applied at next PCI reset or EMP reset (internal firmware reset).

12.8.6.2 RDE Commands Summary

All the RDE commands should be implemented according to DSP0218 and follow the limitations/ guidelines as defined in this chapter.

Table 12-87. RDE Commands Summary Table

Command	Command Code	Command Requirement for RDE Device	Section Reference
Discovery and Schema Management Commands			
NegotiateRedfishParameters	0x01	Supported	12.8.6.3.1
NegotiateMediumParameters	0x02	Supported	12.8.6.3.2
GetSchemaDictionary	0x03	Supported	12.8.6.3.3
GetSchemaURI	0x04	Supported	12.8.6.3.4
GetResourceETag	0x05	Supported	12.8.6.3.5
Reserved	0x06 - 0x0F	---	---
RDE Operation and Task Commands			
RDEOperationInit	0x10	Supported	12.8.6.3.6
SupplyCustomRequestParameters	0x11	Supported	12.8.6.3.7
RetrieveCustomResponseParameters	0x12	Not Supported	12.8.6.3.8
RDEOperationComplete	0x13	Supported	12.8.6.3.9
RDEOperationStatus	0x14	Supported	12.8.6.3.10
RDEOperationKill	0x15	Supported	12.8.6.3.11
RDEOperationEnumerate	0x16	Supported	12.8.6.3.12
Reserved	0x17 - 0x2F	---	---
Multi-part Transfer Commands			
MultipartSend	0x30	Supported	12.8.6.3.13
MultipartReceive	0x31	Supported	12.8.6.3.14
Reserved	0x32 - 0x3F	---	---
Reserved			
Reserved	0x40 - 0xFF	---	---

12.8.6.3 Command Details

12.8.6.3.1 NegotiateRedfishParameters (0x01)

Type	Request Data
uint8	**MCConcurrencySupport** Firmware checks that this field is bigger than zero and ignores the value, as the device exposes single concurrent command support. If *MCConcurrencySupport* is equal to zero, return a completion code of ERROR_INVALID_DATA.
bitfield16	**MCFeatureSupport** Firmware ignores this field.
Type	**Response Data**
enum8	**CompletionCode** Value: {PLDM_BASE_CODES}
uint8	**DeviceConcurrencySupport** Return 1.
bitfield8	**DeviceCapabilitiesFlags** Capabilities for this RDE device. [7:2] = Reserved [1] = expand_support — 0b = No support [0] = atomic_resource_read — 0b = No support
bitfield16	**DeviceFeatureSupport** Operations and functionality supported by this RDE device. For each, 1b indicates supported and 0b indicates not supported. [15:8] = Reserved [7] = events_supported — 1b = yes [6] = action_supported — 1b = yes [5] = replace_supported — 1b = yes [4] = update_supported — 1b = yes [3] = delete_supported — 0b = no [2] = create_supported — 0b = no [1] = read_supported — 1b = yes [0] = head_supported — 1b = yes
uint32	**DeviceConfigurationSignature** A signature calculated across all RDE PDRs and dictionaries that the RDE device supports. Use OCS HCU engine with ALGORITHM_MODE = SHA256. Take lower 32 bit. Each PDR and dictionary is padded to 512 bits before added to the calculation.
varstring	**DeviceProviderName** An informal name for the RDE device. If a VPD Identifier String (tag 0x82) exists, use it as *DeviceProviderName*. Otherwise, use “Name” property at NetworkInterface.

12.8.6.3.2 NegotiateMediumParameters (0x02)

Type	Request Data
uint32	**MCMaximumTransferChunkSizeBytes** An indication of the maximum amount of data the MC can support for a single message transfer. A value of less than 64 bytes is considered as an error with ERROR_INVALID_DATA completion code, as it does not support minimal MCTP packet size of 64 bytes.
Type	**Response Data**
enum8	**CompletionCode** Value: {PLDM_BASE_CODES}
uint32	**DeviceMaximumTransferChunkSizeBytes** Report 2048 bytes.

After reception of this command, the device uses a maximal transfer chunk of Min(DeviceMaximumTransferChunkSizeBytes, MCMaximumTransferChunkSizeBytes) for MultipartSend/Receive commands.

The default value before reception of this command is 64 bytes (one message per MCTP packet).

If received on multiple media, use the minimum of all media for MultipartReceive response and accept MultipartSend with the maximum of all media values.

12.8.6.3.3 GetSchemaDictionary (0x03)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of any resource in the Redfish Resource PDR from which to retrieve the dictionary. See Table 12-88 for supported Resource IDs. If resource is not supported, return a completion code of ERROR_NO_SUCH_RESOURCE.
schemaClass	**RequestedSchemaClass** The class of schema being requested. See Table 12-88 for supported schema per Resource IDs. If the a schema of the type requested is not supported, return a completion code of ERROR_UNSUPPORTED unless the supplied Resource ID does not correspond to a collection, but the *RequestedSchemaClass* is COLLECTION_MEMBER_TYPE, in which case, return an ERROR_INVALID_DATA completion code.
Type	**Response Data**

enum8	**CompletionCode**
	Value:
	{
	PLDM_BASE_CODES,
	ERROR_UNSUPPORTED,
	ERROR_NO_SUCH_RESOURCE
	}

uint8	**DictionaryFormat** Return 0x00.
uint32	**TransferHandle** In conjunction with a non-failed *CompletionCode*, the RDE device returns a valid transfer handle as described in Table 12-88.

Table 12-88. Handle per Resource

Schema (*.json)	Dictionary Class Supported	Resource ID
Event.v1_3_1	EVENT	0xFFFF FFFF or any of the other Resource IDs below.
redfish-payload-annotations.v1_0_0	ANNOTATION	
redfish-error.v1_0_0	ERROR	
NetworkAdapter.v1_2_0	MAJOR	1
PCIeDevice.v1_3_0	MAJOR	3
NetworkInterface.v1_1_1	MAJOR	5
NetworkPortCollection	MAJOR	10
	COLLECTION_MEMBER_TYPE	10
PCIeFunctionCollection	MAJOR	30
NetworkDeviceFunctionCollection	MAJOR	20
NetworkDeviceFunction.v1_3_0	COLLECTION_MEMBER_TYPE	20
NetworkPort.v1_2_1	MAJOR	100-107 110-117
NetworkDeviceFunction.v1_3_0	MAJOR	200-207 210-217
PCIFunction.v1_2_1	MAJOR	300-307
EthernetInterface.v1_5_1	MAJOR	400-407 410-417
EthernetInterfaceCollection	MAJOR	40
	COLLECTION_MEMBER_TYPE	40

12.8.6.3.4 GetSchemaURI (0x04)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of any resource in the Redfish Resource PDR from which to retrieve the URI. See Table 12-89 for supported Resource IDs. If resource is not supported, return a completion code of ERROR_NO_SUCH_RESOURCE.
schemaClass	**RequestedSchemaClass** The class of schema being requested. If the a schema of the type requested is not supported, return a completion code of ERROR_UNSUPPORTED.
uint8	**OEMExtensionNumber** No OEM extensions. Return a completion code of ERROR_INVALID_DATA for any non zero value.
Type	**Response Data**

enum8	**CompletionCode**
	Value:
	{
	PLDM_BASE_CODES,
	ERROR_UNSUPPORTED,
	ERROR_NO_SUCH_RESOURCE
	}

uint8	**StringFragmentCount** Return 1
varstring	**SchemaURI [0]** URI string fragment for the schema. The reassembled string is the canonical URI for the JSON Schema used by the RDE Device.

Table 12-89. URI per Resource

Schema	Class	Resource ID	URI
All schemas	EVENT	0xFFFF FFFF or any of the other Resource IDs below.	https://redfish.dmtf.org/schemas/Event.json
	ANNOTATION		https://redfish.dmtf.org/schemas/redfish-payload- annotations.v1_0_2.json
	ERROR		https://redfish.dmtf.org/schemas/v1/redfish-error.v1_0_0.json
NetworkAdapter	MAJOR	1	https://redfish.dmtf.org/schemas/NetworkAdapter.v1_3_0.json
NetworkInterface	MAJOR	5	https://redfish.dmtf.org/schemas/NetworkInterface.v1_1_3.json
PCIeDevice	MAJOR	3	https://redfish.dmtf.org/schemas/PCIeDevice.v1_4_0.json (not implemented)
NetworkPortCollection	COLLECTION_MEMBER_TYPE	10	https://redfish.dmtf.org/schemas/NetworkPort.json
	MAJOR		https://redfish.dmtf.org/schemas/NetworkPortCollection.json
NetworkDeviceFunctionCollection	COLLECTION_MEMBER_TYPE	20	https://redfish.dmtf.org/schemas/NetworkDeviceFunction.json
	MAJOR		https://redfish.dmtf.org/schemas/NetworkDeviceFunctionCollection.json
PCIeFunctionCollection	COLLECTION_MEMBER_TYPE	30	https://redfish.dmtf.org/schemas/PCIeFunction.json
	MAJOR		https://redfish.dmtf.org/schemas/PCIeFunctionCollection.json
NetworkPort	MAJOR	100-107 110-117	https://redfish.dmtf.org/schemas/NetworkPort.v1_2_3.json
NetworkDeviceFunction	MAJOR	200-207 210-217	https://redfish.dmtf.org/schemas/NetworkDeviceFunction.v1_3_3.json
PCIFunction	MAJOR	300-307	https://redfish.dmtf.org/schemas/PCIeFunction.v1_2_3.json
EthernetInterface	MAJOR	400-407 410-417	https://redfish.dmtf.org/schemas/EthernetInterface.v1_5_1.json
EthernetInterfaceCollection	COLLECTION_MEMBER_TYPE	40	https://redfish.dmtf.org/schemas/EthernetInterface.json
	MAJOR		https://redfish.dmtf.org/schemas/EthernetInterfaceCollection.json

12.8.6.3.5 GetResourceETag (0x05)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the instance from which to get an ETag digest, or 0xFFFF FFFF to get a global digest of all resource-based data within the RDE device. For non-existent *ResourceID*, ERROR_NO_SUCH_RESOURCE *CompletionCode* is returned
Type	**Response Data**
enum8	**CompletionCode** Value: {PLDM_BASE_CODES, ERROR_NO_SUCH_RESOURCE }
varstring	**ETag** The ETag string data; the string text format is UTF-8. ETag is calculated as lower 32 bits of SHA256 computed from content using OCS-HCU engine with ALGORITHM_MODE = SHA256. This field is omitted if the *CompletionCode* is not SUCCESS. Firmware should calculate the data that would have been returned for the READ operation of the *ResourceID* and calculate the ETag for it. It should be the same *ETAG* value as returned as part of a read completion of *ResourceID*. Use the same algorithm as for signature at GetSchemaDictionary. ETag is calculated only on the data that is immediately contained within the resource.

12.8.6.3.6 RDEOperationInit (0x10)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. The supported *ResourceIDs* are listed in Table 12-90.
rdeOpID	**OperationID** Identification number for this Operation. Must be matched by all commands relating to this Operation.
enum8	**OperationType** The type of Redfish Operation being performed. The supported operation types per ResourceID are listed in Table 12-90.
bitfield8	**OperationFlags** [7:3] = Reserved [2] = contains_custom_request_parameters — If 1b, the RDE Device should expect to receive a SupplyCustomRequestParameters command request before it may trigger the Operation [1] = contains_request_payload — If 0b, the Operation does not require data to be sent. This bit is expected to be set only if OperationType is OPERATION_UPDATE or OPERATION_REPLACE. [0] = locator_valid — If 0b, the Locator in the *OperationLocator* field is ignore
uint32	**SendDataTransferHandle** Handle to be used with the first MultipartSend command transferring BEJ formatted data for the operation. If no data is to be sent for this operation, or if the request payload fits entirely within this request message, it is0x00000000 (see the *RequestPayloadLength* and *RequestPayload* fields below).
uint8	**OperationLocatorLength** Length in bytes of the *OperationLocator* for this Operation. This field is zero if the *locator_valid* bit in the *OperationFlags* field above is set to 0b.

uint32	**RequestPayloadLength** Length in bytes of the request payload in this message. This value is zero under either of the following conditions: • There is no request payload as indicated by *contains_request_payload* bit of the *OperationFlags* parameter above. • The entire payload cannot fit within this message, subject to the maximum transfer chunk size as determined at registration time via the NegotiateMediumParameters command.
bejLocator	**OperationLocator** BEJ Locator indicating where the new Operation is to take place within the resource specified in *ResourceID*. Supported for Read, Update, and Action operations. This field is omitted if the *OperationLocatorLength* field above is set to zero.
null or bejEncoding	**RequestPayload** The request payload. The format of this parameter is null (consisting of zero bytes) if the *RequestPayloadLength* above is zero. It is bejEncoding otherwise.
Type	**Response Data**
enum8	**CompletionCode** Return ERROR NOT READY if Firmware is in the middle of an operation preventing the access. For example: • Configuration change • Reset • Firmware update Return ERROR_NOT_ALLOWED if operation not allowed for the requested resource (e.g. Update a RO resource). Return ERROR_NO_SUCH_RESOURCE if resource ID is not advertised by the device. Return ERROR_CANNOT_CREATE_OPERATION if attempt to create a task while another task is in-flight. Return ERROR_OPERATION_EXISTS if attempt to re-create the same action with same {ResourceID, OperationID}. Return ERROR_INVALID_DATA if OperationID MSB bit is cleared (device owned operation ID).
enum8	**OperationStatus** Return OPERATION_NEEDS_INPUT if *OperationFlags.contains_custom_request_parameters*=1 OR *OperationFlags.contains_request_payload*=1 AND *SendDataTransferHandle* <> 0 Return OPERATION_RUNNING if no input data needed and operation did not complete within T1. Return OPERATION_HAVE_RESULTS if no input data needed and operation completed within T1, and there are parameters to return that do not fit within the response. Return OPERATION_COMPLETED if no input data needed and operation completed within T1, and there are parameters to return that fit within the response or there are no parameters to return. Return OPERATION_FAILED in case of error.
uint8	**CompletionPercentage** Return 255 if operation is not valid. Return zero if the Operation has not yet been triggered or if the Operation has failed. Return 254 otherwise.
uint32	**CompletionTimeSeconds** Return 0xFFFF FFFF - no support
bitfield8	**OperationExecutionFlags** [7:4] = Reserved [3] = CacheAllowed — 1b = yes; 0b = no Set to 0b for Operations other than read, head. Set to 0b unless Operation has finished. See Section 12.8.6.5.2 for list cacheable parameters. A value of 1b is reported if all the read parameters are cacheable. [2] = HaveResultPayload — 1b = yes. 0b= no. Set to 0b if Operation has not finished. Set to 1b for completed Read operations This bit is set only if *OperationType* is OPERATION_GET. [1] = HaveCustomResponseParameters — 1b = yes. 0b = no Set to 0b if Operation has not finished or no custom response parameters available even if operation is finished. Set to 1b for all other cases. Currently not set. [0] = TaskSpawned — 1b = yes. 0b = no. Set to 1 for tasks longer than PT1 - Request-to-response time as specified at DSP0240. Firmware can start the task and start the timer and return the response depending if it succeeded to finish within PT1 or not, if not it will be a long running task.

uint32	**ResultTransferHandle** 0x00000000: No data to transfer from endpoint to MC. 0xFFFFFFFF: Operation not complete. Other: Handle provided by firmware - should not be a direct address in memory.
bitfield8	**PermissionFlags** Indicates the access level granted to the resource targeted by the Operation. Is set to 0x00 by the RDE device and ignored by the MC if the completion code is not ERROR_NOT_ALLOWED. Bits 0 and 5 are always set. Bits 1 and 2 are set if update and replace operation are allowed. Bits 3 and 4 are always cleared If CompletionCode = ERROR_NOT_ALLOWED, this field returns 0x00.
uint32	**ResponsePayloadLength** As described in specification. Currently no *@Message.ExtendedInfo* planned in case of error.
varstring	**ETag** String data for an ETag digest of the target resource; the string text format is UTF-8. The ETag is skipped (an empty string returned in this field) for any of the following actions: Action, Delete, Replace, and Update. The ETag is also skipped (an empty string returned in this field) if execution of the Operation has failed or not yet finished. To create ETag, use OCS HCU engine with ALGORITHM_MODE = SHA256 and take lower 32 bits of the result.
null or bejEncoding	**ResponsePayload** The response payload. The format of this parameter shall be null (consisting of zero bytes) if the *ResponsePayloadLength* above is zero. It is bejEncoding otherwise.

Note: Firmware should save the {*ResourceID*, *OperationID*}, context until *RDEOperationComplete*., as it is used by MC as a handle for all intermediate commands. It should also keep the *SendDataTransferHandle* and compare it to the *DataTransferHandle* received in the MultipartSend command. It should also keep the returned *ResultTransferHandle* and compare it with the value provided in the MultipartReceive.

Note: A payload (either in the command or in the separate data transfer) is expected only for update and replace operations.

Note: When bit [1] in *OperationFlags* field is not set, the *PayloadLength* and *RequestTransferHandle* fields must be set to zero. Otherwise, ERROR_CANNOT_CREATE_OPERATION error response is returned.

Table 12-90. Resources Parameters

Schema	Resource ID	Allowed Operations
NetworkAdapter	1	Read, Head, Update, Replace, Action
NetworkInterface	5	Read, Head, Update, Replace
PCIeDevice	3	Read, Head, Update, Replace (not implemented)
NetworkPortCollection	10	Read, Head
NetworkDeviceFunctionCollection	20	Read, Head
NetworkPort	100-107	Read, Head
NetworkDeviceFunction	200-207	Read, Head
PCIFunction	300-307	Read, Head, Update, Replace
EthernetInterface	400-407	Read, Head
EthernetInterfaceCollection	40	Read, Head
Setting Resources	110-117 210-217 410-417	Read, Head, Update, Replace

12.8.6.3.7 SupplyCustomRequestParameters (0x11)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. The supported *ResourceIDs* are listed in Table 12-90, "Resources Parameters".
rdeOpID	**OperationID** The {*ResourceID*, *OperationID*} should match the value set in the RDEOperationInit command. Otherwise, an ERROR_UNEXPECTED error is returned.
uint16	**LinkExpand** This value is ignored.
uint16	**CollectionSkip** Defines the number of elements to skip in a GET response. Ignored for other actions. Zero means return all.
uint16	**CollectionTop** Defines the maximum number of elements to return in a GET response. Ignored for other actions. 0xFFFF means return all.
uint16	**PaginationOffset** This value is ignored. The device does not do pagination.
enum8	**ETagOperation** If *ETagOperation* = ETAG_IF_MATCH = 1, do the action only if the calculated ETag for the resource == ETag [0]. If *ETagOperation* = ETAG_IF_MATCH and EtagCount <>1, return a ERROR_INVALID_DATA error. If *ETagOperation* = ETAG_IF_NONE_MATCH = 2, do the action only if the calculated ETag for the resource <> all of {ETag [0] … ETag[*ETagCount*-1]. If *ETagOperation* = ETAG_IF_NONE_MATCH and *EtagCount* == 0, return a ERROR_INVALID_DATA error. If *ETagOperation* = ETAG_IGNORE = 0 and *EtagCount* <> 0 return a ERROR_INVALID_DATA error If *ETagOperation* >= 3, return a ERROR_INVALID_DATA error.
uint8	**ETagCount** Number of ETags supplied in this message. Should be zero if *ETagOperation* above is ETAG_IGNORE, and nonzero otherwise.
varstring	**ETag [0]** String data for first ETag, if *ETagCount* > 0. This string is UTF-8 format. ETag is calculated as lower 32 bits of SHA256 computed from content using OCS-HCU engine.
...	Additional ETags
uint8	**HeaderCount** The number of custom headers being supplied in this operation. Currently no support, so must be zero.
varstring	**HeaderName [0]** The name of the header, including the X- prefix
varstring	**HeaderParameter [0]** The parameter or parameters associated with the header. The MC can pre-process these (though any such preprocessing is outside the scope of this specification) or convey them exactly as received.
...	...

Type	Response Data

enum8	**CompletionCode**
	Values:
	{
	PLDM_BASE_CODES,
	ERROR_ OPERATION_ABANDONED,
	ERROR_ OPERATION_FAILED,
	ERROR_UNSUPPORTED,
	ERROR_UNEXPECTED,
	ERROR_UNRECOGNIZED_CUSTOM_HEADER,
	ERROR_ETAG_MATCH,
	ERROR_NO_SUCH_RESOURCE
	}
	When an unknown *ResourceID* is supplied, ERROR_NO_SUCH_RESOURCE is returned.
	If *OperationID* references an unknown operation, or *OperationID* and *ResourceID* do not both match an existing operation, ERROR_UNEXPECTED is returned.
	If unsupported ETag operation value, return ERROR_UNSUPPORTED/
	Response codes ERROR_UNSUPPORTED and ERROR_UNRECOGNIZED_CUSTOM_HEADER are used to indicate that an unsupported request parameter was sent. These responses represent an Operational failure, not a command failure.

enum8	**OperationStatus**
	Values:
	{
	OPERATION_INACTIVE = 0,
	OPERATION_NEEDS_INPUT = 1,
	OPERATION_TRIGGERED= 2,
	OPERATION_RUNNING = 3,
	OPERATION_HAVE_RESULTS = 4,
	OPERATION_COMPLETED = 5,
	OPERATION_FAILED = 6,
	OPERATION_ABANDONED = 7
	}

uint8	**CompletionPercentage** Return 255 if operation is not valid. Return zero if the Operation has not yet been triggered or if the Operation has failed. Return 254 otherwise.
uint32	**CompletionTimeSeconds** Return 0xFFFF FFFF.
bitfield8	**OperationExecutionFlags** See *OperationExecutionFlags* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
uint32	**ResultTransferHandle** See *ResultTransferHandle* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
bitfield8	**PermissionFlags** See *PermissionFlags* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
uint32	**ResponsePayloadLength** See *ResponsePayloadLength* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
varstring	**ETag** See *ETag* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
null or bejEncoding	**ResponsePayload** See *ResponsePayload* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".

12.8.6.3.8 RetrieveCustomResponseParameters (0x12)

This command is currently not supported, as the NIC does not provide any Custom Response parameters.

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. he supported *ResourceIDs* are listed in Table 12-90, "Resources Parameters".
rdeOpID	**OperationID** The {*ResourceID*, *OperationID*} should match the value set in the RDEOperationInit command. Otherwise, an ERROR_UNEXPECTED error is returned.
Type	**Response Data**

enum8	**CompletionCode**
	Values:
	{
	PLDM_BASE_CODES,
	ERROR_OPERATION_ABANDONED,
	ERROR_OPERATION_FAILED,
	ERROR_UNEXPECTED,
	ERROR_NO_SUCH_RESOURCE
	}
	When an unknown *ResourceID* is supplied, ERROR_NO_SUCH_RESOURCE is returned.
	If *OperationID* references an unknown operation, or *OperationID* and *ResourceID* do not both match an existing operation, ERROR_UNEXPECTED is returned.

uint32	**DeferralTimeframe** Return 0xFF (unknown).
uint32	**NewResourceID** Return 0 - no support for Create command.
uint8	**ResponseHeaderCount** Return 0 - no support for custom headers.
varstring	**HeaderName [0]** N/A
varstring	**HeaderParameter [0]** N/A
...	...

12.8.6.3.9 RDEOperationComplete (0x13)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. The supported *ResourceIDs* are listed in Table 12-90, "Resources Parameters".
rdeOpID	**OperationID** The {*ResourceID*, *OperationID*} should match the value set in the RDEOperationInit command. Otherwise, an ERROR_UNEXPECTED error is returned.

Type	Response Data
enum8	**CompletionCode** Values: {PLDM_BASE_CODES, ERROR_UNEXPECTED, ERROR_NO_SUCH_RESOURCE } When an unknown *ResourceID* is supplied, ERROR_NO_SUCH_RESOURCE is returned. If *OperationID* references an unknown operation, or *OperationID* and *ResourceID* do not both match an existing operation, ERROR_UNEXPECTED is returned.

12.8.6.3.10 RDEOperationStatus (0x14)

Returns status of the current task.

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. The supported *ResourceIDs* are listed in Table 12-90, "Resources Parameters".
rdeOpID	**OperationID** The {*ResourceID*, *OperationID*} should match the value set in the RDEOperationInit command. Otherwise, an ERROR_UNEXPECTED error is returned.
Type	**Response Data**

enum8	**CompletionCode**
	Values:
	{
	PLDM_BASE_CODES,
	ERROR_UNSUPPORTED,
	ERROR_NO_SUCH_RESOURCE, E
	RROR_ETAG_MATCH, E
	RROR_UNRECOGNIZED_
	CUSTOM_HEADER
	}
	When an unknown *ResourceID* is supplied ERROR_NO_SUCH_RESOURCE is returned.
	If *OperationID* references an unknown operation, or *OperationID* and *ResourceID* do not both match an existing operation, ERROR_UNEXPECTED is returned.
	The completion code for RDEOperationStatus is one of the following:
	SUCCESS: A valid active RDE Operation was referenced in the *OperationID* request field and it is not in the failed state. The actual current status of the RDE Operation is returned in the *OperationStatus* field - OR - an inactive RDE Operation was referenced in the *OperationID* request field. *OperationStatus* is OPERATION_INACTIVE in this case.
	ERROR_UNSUPPORTED, ERROR_ETAG_MATCH, ERROR_UNRECOGNIZED_CUSTOM_HEADER: A valid active RDE Operation was referenced in the *OperationID* request field, but the Operation failed with the specified status code. *OperationStatus* is OPERATION_FAILED in this case. These responses indicate a failure in the RDE Operation, not a failure in the RDEOperationStatus command.

enum8	**OperationStatus** According to state machine
uint8	**CompletionPercentage** Return 255 if operation is not valid. Return zero if the Operation has not yet been triggered or if the Operation has failed. Return 254 otherwise.
uint32	**CompletionTimeSeconds** Return 0xFFFF FFFF.

bitfield8	**OperationExecutionFlags** See *OperationExecutionFlags* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
uint32	**ResultTransferHandle** See *ResultTransferHandle* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
bitfield8	**PermissionFlags** See *PermissionFlags* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
uint32	**ResponsePayloadLength** See *ResponsePayloadLength* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
varstring	**ETag** See *ETag* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".
null or bejEncoding	**ResponsePayload** See *ResponsePayload* in Section 12.8.6.3.6, "RDEOperationInit (0x10)".

12.8.6.3.11 RDEOperationKill (0x15)

Type	Request Data
uint32	**ResourceID** The *ResourceID* of a resource in the Redfish Resource PDR for the data that is the target of this operation. The supported *ResourceIDs* are listed in Table 12-90, "Resources Parameters".
rdeOpID	**OperationID** The {*ResourceID*, *OperationID*} should match the value set in the RDEOperationInit command. Otherwise, an ERROR_UNEXPECTED is returned.
bitfield8	**KillFlags** Flags for killing the Operation: [7:2] = Reserved for future use [1] = run_to_completion — If 1b, the Operation should be run to completion but no further response should be sent to the MC. The MC does no set the *run_to_completion* bit without also setting the *discard_record* bit. [0] = discard_record — If 1b and the kill command returns success, the RDE device discards internal records associated with this Operation as soon as it is killed; the RDE device should not expect the MC to call RedfishOperationComplete for this Operation. If the Operation has spawned a Task, the RDE device does not create an Event when execution is finished.
Type	**Response Data**
enum8	**CompletionCode** Value: {PLDM_BASE_CODES, ERROR_OPERATION_ABANDONED, ERROR_OPERATION_FAILED, ERROR_OPERATION_UNKILLABLE, ERROR_NO_SUCH_RESOURCE, ERROR_UNEXPECTED } When an unknown *ResourceID* is supplied, ERROR_NO_SUCH_RESOURCE is returned. If *OperationID* references an unknown operation, or *OperationID* and *ResourceID* do not both match an existing operation, ERROR_UNEXPECTED is returned. If *KillFlags.run_to_completion* is set, but *KillFlags.discard_record* is cleared, return ERROR_INVALID_DATA. If both *KillFlags.run_to_completion* and *KillFlags.discard_record* are set, according to current state returns the following response: • If state is NEED_INPUT, return ERROR_UNEXPECTED. • If state is HAVE_RESULTS, return ERROR_OPERATION_UNKILLABLE/ • If state is FAILED, return ERROR_OPERATION_FAILED. • If state is ABANDONED, return ERROR_OPERATION_ ABANDONED. • If state is other, return SUCCESS.

12.8.6.3.12 RDEOperationEnumerate (0x16)

Type	Request Data
N/A	This request contains no parameters.
Type	Response data.
enum8	**CompletionCode** Value: {PLDM_BASE_CODES}
unit16	**OperationCount** 0 if no active operation; 1 otherwise
unit32	**ResourceID [0]** The resource ID of the active action. Shall be omitted if OperationCount is zero
rdeOpID	**OperationID [0]** The Operation ID of the active action. Shall be omitted if OperationCount is zero
enum8	**OperationType [0]** The type of Operation. Shall be omitted if OperationCount is zero Values: {OPERATION_HEAD = 0, OPERATION_READ = 1, OPERATION_UPDATE = 4, OPERATION_REPLACE = 5, OPERATION_ACTION = 6 } This field is omitted if *OperationCount* above is zero.

12.8.6.3.13 MultipartSend (0x30)

Type	Request Data
uint32	**DataTransferHandle** A handle to uniquely identify the chunk of data to be sent. If *TransferFlag* below is START or START_AND_END, this must match the *SendDataTransferHandle* that was supplied by the RDE Device in the response to RDEOperationInit. The *DataTransferHandle* supplied is either the initial handle to begin or restart a transfer, or the *NextDataTransferHandle* as specified in the previous chunk.
rdeOpID	**OperationID** The *OperationID* received in RDEOperationInit.

enum8	**TransferFlag**
	An indication of current progress within the transfer. The value START_AND_END indicates that the entire transfer consists of a single chunk.
	Values:
	{
	START = 0,
	MIDDLE = 1, E
	ND = 2,
	START_AND_END = 3
	}

uint32	**NextDataTransferHandle** The handle for the next chunk of data for this transfer; zero (0x00000000) if no further data. The firmware should keep this value internally until the next MultipartSend.

uint32	**DataLengthBytes** The length in bytes N of data being sent in this chunk. This value and the Data bytes associated with it must not cause this request message to exceed the negotiated maximum transfer chunk size.
uint8	**Data [0]** The first byte of the current chunk of data. The *Data* field is omitted from the request message if the value of *DataLengthBytes* above is zero
...	...
uint8	**Data [N-1]** The last byte of the current chunk of data
uint32	**DataIntegrityChecksum** 32-bit CRC for the entirety of data (all parts concatenated together). Is omitted for non-final chunks (TransferFlag ≠ END or START_AND_END) in the transfer. For this specification, the CRC-32 algorithm with the polynomial: For this command, the CRC-32 algorithm with the polynomial $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ (same as the one used by IEEE 802.3) is used for the integrity checksum computation. The CRC computation involves processing a byte at a time with the least significant bit first.

Type	Response Data
enum8	**CompletionCode** Values: {PLDM_BASE_CODES, ERROR_OPERATION_ABANDONED, ERROR_OPERATION_FAILED, ERROR_UNEXPECTED, ERROR_BAD_CHECKSUM } If *OperationID* is non-zero and references an unknown operation ERROR_UNEXPECTED is returned. If the *DataTransferHandle* does not correspond to a valid chunk, the RDE Device returns *CompletionCode* ERROR_INVALID_DATA.

enum8	**TransferOperation**
	The follow-up action that the RDE device is requesting of the MC:
	• XFER_FIRST_PART: Resend the initial chunk (restarting the transmission, such as if the checksum of data received did not match the DataIntegrityChecksum in the final chunk).
	• XFER_NEXT_PART: Send the next chunk of data.
	• XFER_ABORT: Stop the transmission and do not retry. In this case, the MC proceeds as if the transmission is permanently failed.
	• XFER_COMPLETE: no further follow-up needed, the transmission completed normally
	Values:
	{
	XFER_FIRST_PART = 0,
	XFER_NEXT_PART = 1,
	XFER_ABORT = 2,
	XFER_COMPLETE = 3
	}

12.8.6.3.14 MultipartReceive (0x31)

Type	Request Data
uint32	**DataTransferHandle** If *TransferOperation* below is XFER_FIRST_PART and the *OperationID* below is zero, this must match the *TransferHandle* supplied by the RDE Device in the response to the GetSchemaDictionary command. If *TransferOperation* below is XFER_FIRST_PART and the *OperationID* below is nonzero, this must match the *SendDataTransferHandle* that was supplied by the RDE Device in the response to RDEOperationInit. If *TransferOperation* below is XFER_NEXT_PART, this must match the *NextDataHandle* supplied by the RDE Device with the previous chunk. The *DataTransferHandle* supplied is either the initial handle to begin or restart a transfer or the *NextDataTransferHandle* supplied with the previous chunk.
rdeOpID	**OperationID** The *OperationID* received in RDEOperationInit. A value of zero is used for Dictionary transfer (not part of an operation).

enum8	**TransferOperation**
	The portion of data requested for the transfer:
	• XFER_FIRST_PART: The MC is asking the transfer to begin or to restart from the beginning.
	• XFER_NEXT_PART: The MC is asking for the next portion of the transfer.
	• XFER_ABORT: The MC is requesting that the transfer be discarded. The RDE device may discard any internal data structures it is maintaining for the transfer.
	Values:
	{
	XFER_FIRST_PART = 0,
	XFER_NEXT_PART = 1,
	XFER_ABORT = 2
	}

Type	**Response Data**

enum8	**CompletionCode**
	Values:
	{
	PLDM_BASE_CODES,
	ERROR_OPERATION_ABANDONED,
	ERROR_OPERATION_FAILED,
	ERROR_UNEXPECTED,
	ERROR_BAD_CHECKSUM
	}
	If *OperationID* is non-zero and references an unknown operation, ERROR_UNEXPECTED is returned.
	If the *DataTransferHandle* does not correspond to a valid chunk, the RDE Device returns *CompletionCode* ERROR_INVALID_DATA.
	If the transfer is aborted, the RDE device acknowledges this status by returning SUCCESS.

enum8	**TransferFlag**
	Values:
	{
	START = 0,
	MIDDLE = 1,
	END = 2, S
	TART_AND_END = 3
	}
	This field is omitted for a non-SUCCESS *CompletionCode* or if the transfer has been aborted.

uint32	**NextDataTransferHandle** The handle for the next chunk of data for this transfer; zero (0x00000000) if no further data. Calculated by firmware. This field is omitted for a non-SUCCESS *CompletionCode* or if the transfer has been aborted.

uint32	**DataLengthBytes** The length in bytes N of data being sent in this chunk. This value and the Data bytes associated with it must not cause this response message to exceed the negotiated maximum transfer chunk size. This field is omitted for a non-SUCCESS *CompletionCode* or if the transfer has been aborted.
uint8	**Data [0]** The first byte of current chunk of data. The *Data* field is omitted from the response message if the value of *DataLengthBytes* above is zero This field is omitted for a non-SUCCESS *CompletionCode* or if the transfer has been aborted.
...	...
uint8	**Data [N-1]** The last byte of the current chunk of data. This field is omitted for a non-SUCCESS *CompletionCode* or if the transfer has been aborted.
uint32	**DataIntegrityChecksum** 32-bit CRC for the entire block of data (all parts concatenated together). Is omitted for non-final chunks (TransferFlag ≠ END or START_AND_END) in the transfer or for aborted transfers. The recipient ignores this value except from the final transfer. For this command, the CRC-32 algorithm with the polynomial $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ (same as the one used by IEEE 802.3) is used for the integrity checksum computation. The CRC computation involves processing a byte at a time with the least significant bit first. Calculated by FW.

12.8.6.4 State Machine

This section describes operating behavior of RDE support from RDE device-centric perspective. States that are a part of state-machine do not represent state of the RDE device but rather state for operation.

To present operation life cycle mechanisms, eight operational states for RDE device are introduced, as shown in Table 12-91.

Table 12-91. RDE Device Operational States

State	Definition
INACTIVE	Default Operation state in which the RDE Device starts after initialization. Device is not processing an Operation, as it has not received an RDEOperationInit command from the MC.
NEED_INPUT	After receiving the RDEOperationInit command, the RDE Device moves to this state if it is expecting additional Operation-specific parameters or a payload that was not in-lined in the RDEOperationInit command.
TRIGGERED	Once the RDE Device receives everything it needs to execute an Operation, it begins executing it immediately.
TASK_RUNNING	If the RDE Device cannot complete the Operation within the time frame needed for the response to the command that triggered it, the RDE Device spawns a Task in which to execute the Operation asynchronously.
HAVE_RESULTS	When execution of the Operation produces a response parameters or a response payload that does not fit in the response message for the command that triggered the Operation (or detected its completion, if a Task was spawned or if there was a payload but no custom request parameters), the RDE Device remains in this state until the MC has collected all of these results.
COMPLETED	The RDE Device has completed processing of the Operation and awaits acknowledgment from the MC that it has received any Operation response data. This acknowledgment is done by the MC issuing the RDEOperationComplete command.
ABANDONED	If MC fails to progress the Operation through this state machine, the RDE Device may abort the Operation and mark it as abandoned.
FAILED	The MC has explicitly killed the Operation or an error prevented execution of the Operation.

Transitions between particular RDE operational states are shown in Figure 12-17. State machine with all possible transitions is defined in *DSP0218: Platform Level Data Model (PLDM) for Redfish Device Enablement, Section 9.2.3.2, Table 45*.

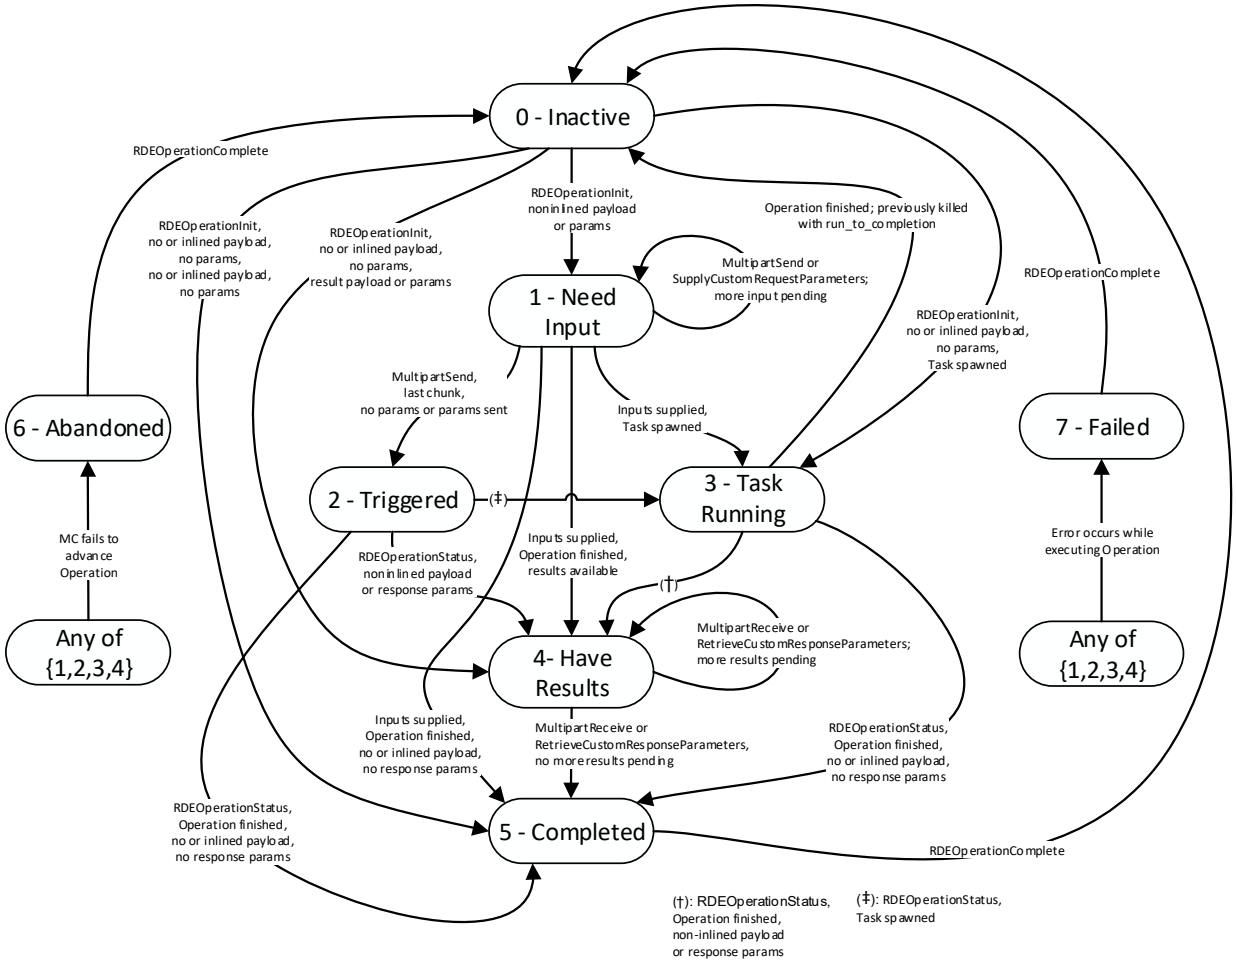

Figure 12-17. Operation Life Cycle State Machine (RDE Device Perspective)

12.8.6.5 Schemas

The following schemas can be found in DSP8010 at https://www.dmtf.org/standards/redfish

This chapter presents the schemas and specifies the relevant properties and where in hardware they refer.

Properties or options that are not mentioned here can be considered as “not supported”.

12.8.6.5.1 Resources Parameters

CacheAllowed - Relevant for RDEOperationInit for the read, head operations. Referring to RFC 7234, a value of "yes" is considered equivalent to Cache-Control response header value "public", and a value of "no" is considered equivalent to Cache-Control response header value "no-store". Typically, static data is allowed to be cached unless, for example, it represents sensitive data such as login credentials; data that changes over time is generally not marked as cacheable. A table in each schema defines if a parameter is writable and/or cacheable.

Note: To make it easier to port to other devices, it is recommended to keep the "E810" string as a variable in firmware.

Schemas that instantiate multiple resources are indexed by last two decimal digits of their *ResourceID*. The value of those two digits is Resource Offset, relevant for ID field.

12.8.6.5.2 Common Fields in All Schemas

The following parameters appear in many schemas and get the following values:

Property	Source	Cacheable	Writable	Notes
@odata.id	Returns bejResourceLink encoded resource ID.	Yes	No	

@odata.type	For simple schemas, a string built as:
	`#Schema_name.vX_Y_Z.Schema_name`
	For example, for NetworkInterface v1.1.1, the @odata_type is:
	`#NetworkInterface.v1_1_1.NetworkInterface`
	For collection schemas, a string built as:
	`#Schema_name.Schema_name`
	For example, for NetworkPortCollection, the @odata_type is:
	`#NetworkPortCollection.NetworkPortCollection`
		Yes	No	

@odata.etag	As reported in GetResourceETag command.	No	No	This field contains common ETag, which is calculated skipping individual ETags.
@odata.context	N/A			Provided through GetSchemaURI
Status.health/ Status.healthRollupDescription	As reflected in health sensor of NIC (Card Composite State Sensor, *sensorID* = 5). Normal = "OK" Upper Non-Critical = "Warning" Upper Critical = "Critical" Upper Fatal = "Critical" If the Card Composite State Sensor (*sensorID* = 5) is uninitialized, Network Controller State sensor (*sensorID* = 50) shall be used instead. If this sensor too is uninitialized, the operation fails.	No/Yes	No/No	Not applicable for collections.
Status.health/ Status.healthRollup	Same as "Status.health/ Status.healthRollupDescription" above.	No	No	Not applicable for collections.

12.8.6.5.3 ACD Schemas

12.8.6.5.3.1 NetworkPort v1.2.3

Note: Function-to-port mapping is linear. Port 0 represents the port that is mapped to function 0.

Note: Resource IDs 100-107 are RO. All changes are done through resource IDs 110-117. After reset (PCIR or EMPR), the contents of 110-117 is applied and copied to 100-107.

Property	Source	Cacheable	Writable	Notes
ActiveLinkTechnology	0 (Ethernet)	Yes	No	
AssociatedNetworkAddresses	NVM, List of LAN and PF MACs	Yes	No	
CurrentLinkSpeedMbps	Use FW API: Link_get_speed Persistent location in NVM: Set the matching PHY types in TLV 0x134.	No	Yes	Integer: {1000, 10000, 25000, 40000, 50000, 100000}
EEEEnabled	Use FW API: PowerDrv_get_EEER Persistent location in NVM: EEE Override Enable field in Link Default Override Mask PFA TLV. Currently hard coded to FALSE. May be set to TRUE if a BASE-T PHY supporting EEE is connected.	No	Yes	Bool: {TRUE, FALSE}
FlowControlConfiguration	Use FW API: Link_get_negotiated_LFC Persistent location in NVM: Set the Link FC options in TLV 0x134.	No	Yes	Enum: {None, TX, RX, TX_RX}
FlowControlStatus	Use FW API: Link_get_negotiated_LFC	No	No	Enum: {None, TX, RX, TX_RX}
LinkStatus	Use FW API: Link is up	No	No	Enum: {Down, Up}
MaxFrameSize		Yes	No	
Name	"E810 Network Port Current Settings" for ResourceID 100-107. "E810 Network Port Pending Settings" for ResourceID 110-117.	Yes	No	
NetDevFuncMaxBWAlloc		Yes	No	
MaxBWAllocPercent	100%	Yes	No	
NetDevFuncMinBWAlloc		Yes	No	
MinBWAllocPercent	100%	Yes	No	
Oem	N/A			
PhysicalPortNumber	Port number (FW)	Yes	No

12.8.6.5.4.2 EthernetInterfaceCollection

Property	Source	Cacheable	Writable	Notes
Name	“EthernetInterfaces”	Yes	No	
Members@odata.count	Size of Members array.	Yes	No	
Members	Resource IDs of all the exposed EthernetInterfaces resources.	Yes	No	400-407, 410-417

12.8.6.5.5 Custom OEM Schema Extensions

Custom OEM extensions to DMTF schemas as well as entirely custom OEM schemas are not described here.

The presence of OEM RDE extensions in an NVM image, if any, are indicated by the non-default value of the IANA field. IANA is maintained in PFA OEM section (for more information, see Section 6.3.58.10).

12.8.6.5.6 Profiles

Each profile defines a specific set of supported schemas. The ACD profile is supported, and all the non-ACD schemas have enable bits inside the NVM.

12.8.6.6 Dictionaries

Dictionaries are stored in signed NVM (not in shadow RAM).

Each of the Major Schema has associated with it an individual Major dictionary. Three additional dictionaries contain definitions of common properties.

Dictionaries must contain definitions for decoding all BEJ tuples that can be generated by this implementation of RDE. All properties that may be encountered during an UPDATE or REPLACE request, but which cannot be ignored, must also have corresponding dictionary definitions. Properties that are ignored on both reads and writes serve no purpose and should be excluded from dictionaries.

12.8.6.6.1 Dictionary Storage in NVM

The Dictionaries are stored at a 4K boundary within the NVM signed area and pointed by the RDE Dictionaries pointer at offset 0x5F in the init module.

The allocated size in NVM map 32K bytes. The format is as follows:

Table 12-92. RDE Dictionaries Format in NVM

Word Offset[1]	Description	Remarks
0x0000	Length	Total section length.
0x0001	Number of dictionaries	13 - For read-only support.
0x0002 + n*5	Resource ID Low	
0x0003 + n*5	Resource ID High	
0x0004 + n*5	Schema Class (Bits[7:0])	Bits[15:8] are reserved
0x0005 + n*5	Schema dictionary offset	If MSB=1, the resolution of the value is 1 page. If MSB=0, the resolution of the value is one WORD.
0x0006 + n*5	Schema URI offset	

1. n = Dictionary index in range from 0 to Number of dictionaries.

Schema dictionary offset points to following structure:

Word Offset	Description	Remarks
0x0000	Section length	Words.
0x0001...	Dictionary	Binary blob.

Dictionaries have a binary format according to DSP0218 standard (Section 7.2.3.2, “Dictionary binary format”).

Schema URI offset points to following structure:

Word Offset	Description	Remarks
0x0000	Section length	In bytes.
0x0001...	URI	String.

Schema URI is stored as a string. The varstring assumes an ASCII encoding. The length is derived from the section length.

12.9 Host Isolate Support

If a MC decides that malicious software prevents its usage of the LAN, it might decide to isolate the NIC from its driver. This is done using the TCO Reset command (Section 12.6.4.12).

If TCO Isolate is enabled in the NVM (Section 6.3.57.3), the TCO Isolate command disables PCIe write operations to the LAN port. As the software device driver needs to access the CSR space to provide descriptors to the NIC, this operation also stops the network traffic including OS2BMC and MC-to-OS traffic as soon as the existing transmit and receive descriptor queues are exhausted.

MCTP over PCIe VDM are still available in this mode.

12.10 OCP NIC 3.0 Support

The OCP 3.0 specification defines a list of manageability features that are needed to be compliant with the specification. The following features are included in the OCP NIC 3.0 support in the E810:

Table 12-93. OCP NIC 3.0 Support

Feature	Notes
NC-SI 1.1	See Section 12.6.
MCTP 1.3	See Section 12.8.
MAC Address Provisioning	Requires NC-SI 1.2. Assumes current draft. May change.
Temperature Reporting - ASIC	See Section 12.7.4.1.
Temperature Reporting - Modules	See Section 12.7.4.1.
SFP/QSFP Modules Power Reporting	See Section 12.7.4.1.
Board Power Reporting	FRU over I^2C. Defined at the board level.
Firmware Inventory and Update	See Section 12.8.4.
Secure Firmware	See Section 3.4.9.
NC-SI Package Addressing	See Section 12.3.2.2.1.
FAN_ON_AUX Pin	See Section 12.10.1.

12.10.1 Support for FAN_ON_AUX Pin

Firmware flow at init is:

1. Check that the FAN_ON_AUX valid bit is set. If it is not, skip its initialization.
2. Check that the FAN_ON_AUX SDP is according SDP hardware range. If it is not, report error in GL_MNG_FWSM.*EXT_ERR_IND* and skip its initialization (report error, but do not enter error flow).
3. Check that the FAN_ON_AUX SDP is configured as Output,. If it is not, report error in GL_MNG_FWSM.*EXT_ERR_IND* and skip its initialization (report error, but do not enter error flow).
4. Configure the FAN_ON_AUX SDP with the FAN_ON_AUX bit value from NVM.

NOTE: ***This page intentionally left blank.***

Chapter 13 Programming Interface

13.1 Introduction

This section details the programmer visible state inside the E810. In some cases, it describes hardware structures invisible to software in order to clarify a concept.

The E810 address space is mapped into four regions with PCI Base Address registers described in Section 14.2.6.1. These regions are listed in Table 13-1.

Table 13-1. Address Space Regions

Addressable Content	Mapping Style	Region Size
Memory BAR (Internal registers, memories and Flash)	Direct memory-mapped	4 MB - 128 MB
I/O BAR (optional Internal registers)	I/O Window mapped	32 bytes[1]
MSI-X BAR (optional)	Direct memory-mapped	64 KB
Expansion ROM BAR (optional)	Direct memory-mapped	64 KB - 8 MB

1. The internal registers can be accessed though I/O space indirectly, as explained in the sections that follow.

Rules for unsupported accesses:

- Accesses to non-implemented or disabled regions within a BAR are dropped for write accesses, or respond with arbitrary data for read accesses. A PCIe error event is not generated and completions return with successful status.
- Section 3.1.2.2 describes supported PCIe access sizes to each of the BARs and its components.

13.1.1 Access Mechanisms

13.1.1.1 Memory-Mapped Access to Internal Registers and Memories

The internal registers and memories might be accessed as direct memory-mapped offsets from the Base Address register (BAR0 or BAR 0/1 see Section 14.2.6.1).

In IOV mode, this area is partially duplicated per VF. All replications contain only the subset of the register set that is available for VF programming.

13.1.1.2 Memory-Mapped Accesses to Flash

The external Flash can be accessed using direct memory-mapped offsets from the memory base address register (BAR0 in 32-bit addressing or BAR0/BAR1 in 64-bit addressing; see Section 14.2.6.1). See Table 13-4 for the location of Flash memory within the memory BAR. Access to Flash memory is restricted to the first 64 KB when GLPCI_LBARCTRL.*FLASH_EXPOSE* is set to 0b.

See Section 3.4 for details on accessing the NVM.

13.1.1.3 Memory-Mapped Access to MSI-X Tables

The MSI-X tables can be accessed as direct memory-mapped offsets from the base address register (BAR3 or BAR3/4; see Section 14.2.6.1). See Section 14.3.3 for the appropriate offset for each specific internal MSI-X register.

In IOV mode, this area is duplicated per VF. It requires a memory space of the maximum between 16 KB and the page size.

13.1.1.4 Memory-Mapped Access to Expansion ROM

The external Flash can also be accessed as a memory-mapped Expansion ROM. Accesses to offsets starting from the Expansion ROM base address (see Section 14.2.6.2) reference the Flash provided that access is enabled from NVM, and if the Expansion ROM base address register contains a valid (non-zero) base memory address.

13.1.1.5 I/O-Mapped Access to Internal Registers

To support pre-boot operation, all internal registers in the regular CSR space can be accessed using I/O operations. I/O accesses are supported only if an I/O base address is allocated and mapped (BAR2; see Section 14.2.6.1), and I/O address decoding is enabled in the PCIe configuration.

When an I/O BAR is mapped, the I/O address range allocated opens a 32-byte window in the system I/O address map. Within this window, two I/O addressable registers are implemented: IOADDR and IODATA. The IOADDR register is used to specify a reference to an internal register, and then the IODATA register is used as a window to the register address specified by IOADDR, as listed in Table 13-2.

Table 13-2. IOADDR and IODATA in I/O Address Space

Offset	Abbreviation	Name	RW	Size
0x00	IOADDR	Internal Register Address. Covers the 8 MB CSR space. 0x00000-0x7FFFFF – Internal Registers. 0x3F0000-0xFFFFFFFF – Undefined.	RW	4 bytes
0x04	IODATA	Data field for reads or writes to the Internal Register location as identified by the current value in IOADDR. All 32 bits of this register can be read from and written to.	RW	4 bytes
0x08-0x1F	Reserved	Reserved.	RO	4 bytes

13.1.1.5.1 IOADDR (I/O Offset 0x00)

The IOADDR register must always be written as a DWord access. Section 3.1.2.3 describes how other access sizes are handled.

Note: For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Because writes must be to a 32-bit quantity, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command). For reads, the IN instruction can have any size target register, but it is recommended that the 32-bit EAX register be used.

At hardware reset (LAN_PWR_GOOD) or PCI reset, this register value resets to 0x00000000. Once written, the value is retained until the next write or reset.

13.1.1.5.2 IODATA (I/O Offset 0x04)

The IODATA register must always be written as a DWord access (assuming the IOADDR register contains a value for the internal register space). Reads to IODATA returns a DWord of data. Section 3.1.2.3 describes how other access sizes are handled.

Notes:

- For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Where 32-bit quantities are required on writes, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command).
- There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses are immediate, except when data is not readily available or acceptable. In this case, the E810 delays the results through normal bus methods (for example, split transaction or transaction retry).
- Because a register read or write takes two I/O cycles to complete, software must provide a guarantee that the two I/O cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

13.1.1.5.3 Undefined I/O Offsets

I/O offsets 0x08 through 0x1F are considered to be reserved offsets with the I/O window. Reads from these addresses return 0xFFFF.

13.1.1.6 Configuration Access to Internal Registers

To support legacy pre-boot 16-bit operating environments without requiring I/O address space, the E810 enables accessing CSRs via the configuration address space by mapping IOADDR and IODATA registers into the configuration address space. If the GLPCI_CAPSUP.*CSR_CONF_EN* bit is set to 1b, access to CSRs via configuration address space is enabled.The register mapping in this case is listed in Table 13-3.

Table 13-3. IOADDR and IODATA in Configuration Address Space

Configuration Address	Abbreviation	Name	RW	Size
0x98	IOADDR	Internal Register Address. Covers the 8 MB CSR space. 0x00000-0x7FFFFF – Internal Registers. 0x3F0000-0xFFFFFFFF – Undefined.	RW	4 bytes
0x9C	IODATA	Data field for reads or writes to the internal register location as identified by the current value in IOADDR. All 32 bits of this register can be read from and written to.	RW	4 bytes

Software writes data to an internal CSR via the configuration space in the following manner:

1. CSR address is written to the IOADDR register, where:
   - Bit 31 (IOADDR.*Configuration IO Access Enable*) of the IOADDR should be set to 1b.
   - Bits 30:0 of IOADDR should hold the actual address of the internal register being written to.
2. Data to be written is written into IODATA.
   - IODATA is used as a window to the register address specified by IOADDR. As a result, the data written to IODATA is written into the CSR pointed to by Bits 30:0 of IOADDR.

3. IOADDR is cleared (all bits [31:0]) to avoid unintentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

Software reads data from an internal CSR via the configuration space in the following manner:

1. CSR address is written to IOADDR, where:
   - Bit 31 (IOADDR.*Configuration IO Access Enable*) of IOADDR should be set to 1b.
   - Bits 30:0 of IOADDR should hold the actual address of the internal register being read.
2. CSR value is read from IODATA.
   - IODATA is used as a window to the register address specified by IOADDR. As a result, the data read from IODATA is the data of the CSR pointed to by Bits 30:0 of IOADDR.
3. IOADDR is cleared (all bits [31:0]) to avoid unintentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

Notes:

- In the event that the GLPCI_CAPSUP.*CSR_CONF_EN* bit is cleared, accesses to IOADDR and IODATA via the configuration address space are ignored and have no effect on the register and the CSRs referenced by IOADDR.
- When functioning in a D3 state, software should not attempt to access CSRs via IOADDR and IODATA.
- To enable CSR access via configuration space, software should set Bit 31 (IOADDR.*Configuration IO Access Enable*) of IOADDR to 1b. Software should clear Bit 31 of IOADDR after completing CSR access to avoid an unintentional clear-by-read operation by another application scanning the configuration address space. Software should also clear Bits 30:0 of IOADDR to remove any trace of previous accesses to the configuration space (see previous flows).
- Bit 31 of IOADDR (IOADDR.*Configuration IO Access Enable*) has no effect when initiating access via I/O address space.

13.1.2 Memory BAR

13.1.2.1 PF BAR Structure

The memory BAR provides access to internal CSRs, to the protocol engine doorbells, to page separated doorbells, and to the external Flash (NVM). This section describes where each of these is located within the BAR space.

The following configuration parameters define the structure of the PF memory BAR 0:

- *FLASH_EXPOSE* bit from the NVM (or the GLPCI_LBARCTRL.*FLASH_EXPOSE* CSR bit).

  0b = Flash memory is not mapped in the memory BAR.

  1b = Flash memory is mapped in the memory BAR. Hardware default; Flash memory is exposed when during initialization the Flash is found to be blank or in error. The Flash area is 16 MB.

- *PE_DB_SIZE* field from the NVM (or the GLPCI_LBARCTRL.*PE_DB_SIZE* CSR field) — Determines the size of the memory space allocated to protocol engine doorbells.

  00b = Memory space is not allocated for PE doorbells.

  01b = A 64 KB area is allocated.

  10b = A (4 MB + 64 KB) area is allocated.

  11b = Reserved.

- GLPCI_LBARCTL.*PAGES_SPACE_EN_PF* enable bit loaded from NVM:

  0b = No region is allocated for SR-IOV mode specific addresses.

  1b = A 96 MB region is allocated.

Table 13-4 lists all supported partitions of the memory BAR as a function of the previously-described parameters. Other combinations of the parameters (not covered in the table) are not supported and considered reserved for future expansion. The following rules apply:

- CSR space is located from the beginning of the BAR until address (8 MB - 64 KB-1).
- PE space (if it exists) is located from address (8 MB - 64 KB) and extends up to address 8 MB, or up to address 16 MB (not including).
- The Flash space (if exposed) is always 16 MB and is in the 16 MB - 32 MB area.
- In scalable I/O mode, the range of 32 MB to 128 MB is used to expose resources in individual 4K pages for user mode access.

The default configuration of the memory BAR (like when the Flash is empty) is defined by hardware default values of the read-only GLPCI_LBARCTRL CSR. GLPCI_LBARCTRL is loaded from the NVM during normal operation (such as when Flash contents are valid).

Table 13-4. Structure of the PF Memory BAR

Flash Exposed	PE_DB Size	SIOV	PE Space		Flash Space		SIOV Space		BAR Size
			Min Addr	Max Addr	Min Addr	Max Addr	Min Addr	Max Addr	
No	00	0 (no SIOV mode)	x	x	x	x	x	x	8 MB
	01		8 MB-64 KB	8 MB					8 MB
	10		8 MB-64 KB	16 MB					16 MB
Yes	00		x	x	16 MB	32 MB			32 MB
	01		8 MB-64 KB	8 MB	16 MB	32 MB			32 MB
	10		8 MB-64 KB	16 MB	16 MB	32 MB			32 MB
No	00	1 (SIOV mode)	x	x	x	x	32 MB	128 MB	128 MB
	01		8 MB-64 KB	8 MB					128 MB
	10		8 MB-64 KB	16 MB					128 MB
Yes	00		x	x	16 MB	32 MB			128 MB
	01		8 MB-64 KB	8 MB	16 MB	32 MB			128 MB
	10		8 MB-64 KB	16 MB	16 MB	32 MB			128 MB

13.1.2.1.1 PF BAR Extension for Scalable I/O Mode

In order to allow allocation of resources to multiple Assignable Interfaces, these resources are mapped to separate 4K pages.

Table 13-5. Resources per area in PF space

Start Address	End Address	Content	Mapping
32 MByte	35 MByte	768 Mailboxes	4K Page/Queue registers
35 MByte	46 MByte	Spare	
46 MByte	47 MByte	Mapping of MSI-X vectors	Contiguous mapping (12K)
47 MByte	48 MByte	256 tail bump registers of Doorbell queues	4K Page/Queue tail bumps
48 MByte	56 MByte	2048 interrupts (0-2047)	4K Page/Interrupt set
56 MByte	64 MByte	2K tail bump registers of Rx-Queues	4K Page/Queue registers
64 MByte	128 MByte	16K tail bump registers of Tx-Queues	4K Page/Queue registers

13.1.2.2 VF BAR Structure

The VF memory BAR provides access to on-die CSRs and (optionally) to Protocol Engine doorbells for VFs.

The GLPCI_LBARCTRL.*VF_PE_DB_SIZE* CSR field determines whether the regions allocated to the Protocol Engine doorbells are provided with a separate region within the BAR:

00b = Memory space is not allocated for PE doorbells.

01b = An 8 KB area is allocated right after the legacy space (0x10000->0x11FFF).

10b = A 64 KB area is allocated (0x10000->0x20000).

11b = Reserved.

Note: Although only 32 VFs supports RDMA, all the VFs requires the same memory space.

Table 13-6 lists all supported partitions of the memory BAR as function of the previously described parameters.

Table 13-6. Structure of the VF Memory BAR

PAGES_SPACE_EN_VF	*VF_PE_DB Size*	BAR Size
0	00b	Max (64 KB, Page Size)
0	01b/10b	Max (128 KB, Page Size)
1	x	Max (256 KB, Page Size)

13.1.3 The MSI-X BAR

The structure of the MSI-X BAR is described in Section 14.3.3 (for a PF) and Section 14.5.3.1 (for a VF).

13.1.4 CSR Organization and Mapping

This section describes how CSRs are mapped into the PF and VF memory BAR. This section does not apply to the following address space:

- The MSI-X BAR (defined per the PCI specifications).
- The memory space allocated to protocol engine doorbells (see Section 13.1.2.1).

13.1.4.1 Mapping by Scope

Registers are associated with a scope. A scope is a set of attributes for a register that define which functions can access the register and how many instances exist for the register. Table 13-7 lists the different scopes.

Table 13-7. Scope Mapping

Scope	PF/VF	Quantity	Exposure	Comments
GL	PF	1	To all PFs.	
GLVF	PF, VF	1	To all PFs and VFs.	Registers are RO.
PRT	PF	8	Each PF has access to the registers of the port it is associated with.	Registers are shared by all PFs on a port.
PRTVF	PF, VF	8	Each PF or VF has access to the registers of the port it is associated with (for a VF, the port is the port the PF is associated with).	Registers are RO. Registers are shared by all PFs and VFs on a port.
PF	PF	8	Each PF has access to its copy only.	
VF[1]	PF, VF	256	Each PF has access to the registers of its VFs only. Each VF has access to its copy only.	
VF16	PF, VF	16	Each PF has access to the registers of its VFs only. Each VF has access to its copy only. Available only for the first 16 VFs.	
VF128	PF, VF	16	Each PF has access to the registers of its VFs only. Each VF has access to its copy only. Available only for the first 128 VFs.	
VP	PF	256	Each PF has access to the registers of its VFs only.	These registers control VF functionality.
VP16	PF	16	Each PF has access to the registers of its VFs only. Available only for the first 16 VFs.	These registers control VF functionality.
VP128	PF	128	Each PF has access to the registers of its VFs only. Available only for the first 128 VFs.	These registers control VF functionality.
QRX	PF, VF	2048	Each PF has access to the registers allocated to it (including its VFs). Each VF has access to the registers allocated to it.	
QTX	PF, VF	16384	Each PF has access to the registers allocated to it (including its VFs). Each VF has access to the registers allocated to it.	
DBLQ	PF, VF	256	Each PF has access to the registers allocated to it (including its VFs). Each VF has access to the registers allocated to it.	
CQ	PF, VF	512	Each PF has access to the registers allocated to it (including its VFs). Each VF has access to the registers allocated to it.	

Table 13-7. Scope Mapping [continued]

Scope	PF/VF	Quantity	Exposure	Comments
VSI	PF	768	All PFs.	Registers are shared by all PFs.
INT	PF	2048	Each PF has access to the registers allocated to it.	
INTVF	PF, VF	512	Each VF has access to the registers allocated to it.[1] Each PF has access to the registers of its VFs only.[1]	

1. PE VF registers are a special case of VF registers. PE resources are provided only to a subset of the VFs (total of 32 VFs). However, all VFs have PE registers mapped in their address space. When a VF accesses a PE register, it is mapped into the internal address space as described here, followed by another translation into one of the 32 physical PE instances. This later translation is not described in this section.

13.1.5 Register Conventions

All registers in the E810 are defined to be 32 bits, and should be accessed as 32-bit DWords. There are some exceptions to this rule:

- Register pairs where two 32-bit registers make up a larger 64-bit logical unit.
- Accesses to Flash memory (via Expansion ROM space, secondary BAR space, or the I/O space) might be byte, word or double word accesses. I/O accesses are limited to DWord accesses (see Section 13.1.1.5).
- Accesses to BAR0 of a VF might be byte, word or DWord accesses. 64-bit (QWord) accesses to this BAR are completed with a Completer Abort (CA) error.
- Access to the MSI-X BAR of the PFs and the VFs might be DWord or QWord accesses.

Reserved bit positions:

Some registers contain certain bits that are marked as reserved. Writes to a reserved field must set the field to its initial value unless specified differently in the field description. Reads from registers containing reserved bits might return indeterminate values in the reserved bit positions unless read values are explicitly stated. When read, these reserved bits should be ignored by software.

Reserved and/or undefined addresses:

Any register address not explicitly declared in this Datasheet are considered to be reserved, and should not be written to. Writing to reserved or undefined register addresses might cause indeterminate behavior. Reads from reserved or undefined configuration register addresses might return indeterminate values unless read values are explicitly stated for specific addresses.

Initial values:

Most registers define the initial hardware values prior to being programmed. In some cases, hardware initial values are undefined and is listed as such via the text undefined, unknown, or X. Such configuration values might need to be set via NVM configuration or via software for proper operation to occur; this need is dependent on the function of the bit. Other registers might cite a hardware default that is overridden by a higher-precedence operation. Operations that might supersede hardware defaults might include a valid NVM load, completion of a hardware operation (such as hardware auto-negotiation), or writing of a different register whose value is then reflected in another bit.

For registers that should be accessed as 32-bit DWords, partial writes (less than a 32-bit DWord) does not take effect (the write is ignored). Partial reads returns all 32 bits of data regardless of the byte enables.

Notes:

- Partial reads to clear-on-read registers (ICR) can have unexpected results since all 32 bits are actually read regardless of the byte enables. Partial reads should not be done.
- All statistics registers are implemented as 32-bit registers. Though some logical statistics registers represent counters in excess of 32 bits in width, registers must be accessed using 32-bit operations (for example, independent access to each 32-bit field). When reading 64-bit statistics registers, the least significant 32-bit register should be read first.

See special notes for VLAN filter table, multicast table arrays, and packet buffer memory that appear in the specific register definitions.

13.1.5.1 Register Abbreviation Naming Conventions

The register abbreviation naming follows (in most cases) the following rules:

- Abbreviation starts with the register's scoping. It could be Port registers (PRT), PF registers (PF) and so on. See Table 13-7 for the complete list of register's scopes.
- Then it follows by the register's main block like DCB (for DCB registers), QF (for queue filters) and so on.
- Then it follows by a few characters that summarize the register's name.

13.1.6 Register Field Attributes

Table 13-8 lists the access type of registers' bit fields. The access rights of the PFs and the VFs to the entire registers are defined per PF and VF registers. In some cases, the PFs and VFs might have Read Only (RO) access rights to registers that can be programmed by the internal logic (either auto-load from the NVM or programmed by the firmware). Registers defined as RO access override any access type defined for its fields.

Table 13-8. Register Field Attributes

Type	Description
RO	**Read Only** A register bit field with this attribute can be read. Writes have no effect on the bit field value. Used also for bits of RO/V type.
RO/V	**Read Only Variant** A register bit field with this attribute can be read. Writes have no effect on the bit field value. The hardware can change the value returned. Software should not expect a static value.
ROCV	**Read Only Clear Value** A register bit field with this attribute can be read. The value returned on the read might be different in each read (typically a counter), and the value is cleared after the read. A write has no effect.
RSV	**Reserved** A register bit field with this attribute can be read and returns an indeterministic value. Writes must set the bit field to its initial value unless specified differently in the field description.
RW	**Read/Write** A register with this attribute can be read and written. Read return the default value, the last value written, or updated status from a previous operation. The field description specifies the field's actual behavior.
RW/V	**Read/Write Variant** Hardware loadable. Software can read from and write to field. Hardware can modify field value. Hardware write have higher priority compare to software write.

Table 13-8. Register Field Attributes [continued]

Type	Description
RCW	**Read Clear/Write** A register bit field with this attribute can be written or read. The value returned on the read might be different than the value written (typically a counter) and the value is cleared after the read.
RW1C	**Read/Write 1 to Clear** A register bit field with this attribute can be read and written. Writing an individual bit within the field to a 1b clears (sets to 0b) the corresponding bit and a write of a 0b has no effect. The value read might return the last value written or the status of a previous operation. The field description specifies the field's actual read behavior.
RW1S	**Read/Write 1 to Set** A register bit field with this attribute can be read and written. Writing an individual bit within the field to a 1b sets (sets to 1b) the corresponding bit and a write of a 0b has no effect. The value read might return the last value written or the status of a previous operation. The field description specifies the field's actual read behavior.
RWC	**Read/Write Clear** A register bit field with this attribute can be written or read. The value returned on the read might be different than the value written (typically a counter), and the value is cleared after a write of any value.
SC	**Self Clear** A register bit field with this attribute can be written or read. he value returned on the read might be different than the value written (typically an action request), as the hardware clears the bit when the action is done/activated.
WO	**Write Only** A register bit field with this attribute can be only written. A read returns a fixed value not reflecting the content of the register. This is used for keys that should be not be visible to other software agents.

13.2 Device Registers - PF

13.2.1 BAR0 Registers Summary

Table 13-9. PF - General Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00074000 + 0x4*VF, VF=0...255	VFGEN_RSTAT[VF]	VF Reset Status	13.2.2.1.1

0x03000008 + 0x1000*n, n=0...2047	PF0INT_ITR_1[n]	PF Interrupt Throttling 1	13.2.2.15.7
0x0300000C + 0x1000*n, n=0...2047	PF0INT_ITR_2[n]	PF Interrupt Throttling 2	13.2.2.15.7

Table 13-40. PF - 4 KB Page Mappings [continued]

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x03800000 + 0x1000*QRX, QRX=0...2047	QRX_TAIL_PAGE[QRX]	Receive Queue Tail Update	13.2.2.26.22
0x04000000 + 0x1000*DBQM, DBQM=0...16383	QTX_COMM_DBELL_PAGE[DBQM]	Transmit Comm Scheduler Queue Doorbell	13.2.2.25.27

13.2.2 Detailed Register Descriptions - PF BAR0

13.2.2.1 PF - General Registers

This category contains registers for general device control and status.

13.2.2.1.1 VF Reset Status - VFGEN_RSTAT[VF] (0x00074000 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFR_STATE	1:0	00b	RW	UNDEFINED	**VFR State** Defines the VFR reset progress as follows: 00b = VFR in progress. 01b = VFR completed. All other values are reserved. This field is used to communicate the reset progress to the VF with no impact on hardware functionality.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.1.2 Firmware Status Register - GL_FWSTS (0x00083048; RO)

This register reports the status of the EMP.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FWS0B	7:0	0x0	RO	N/A	**Firmware Status 0 Byte** This byte is RO through the host interface.
FWROWD	8	0b	RW1C	DYNAMIC	**Firmware Reset on Watchdog Indication** Set when a firmware reset is asserted due to watchdog expiration. Cleared when the host writes a 1b to it. Writing a 0b to this bit does not change its value. ***Note:*** This bit is also set after LAN_PWR_GOOD and is RO through the AUX interface.
FWRI	9	1b	RW1C	DYNAMIC	**Firmware Reset Indication** Set when a firmware reset is asserted. Cleared when the host writes a 1b to it. Writing a 0b to this bit does not change its value. ***Note:*** This bit is also set after LAN_PWR_GOOD and is RO through the AUX interface.
RESERVED	15:10	0x0	RSV	N/A	Reserved.
FWS1B	23:16	0x0	RO	N/A	**Firmware Status 1 Byte** This byte is RO through the host interface.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.1.3 PF State - PFGEN_STATE (0x00088000; RW)

This register defines to software the main characteristics of the PF. It does not have any direct impact on device functionality.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFPEEN	0	0b	RW	UNDEFINED	**PF PE Enable** 0b = Protocol engine services should not be used for this function. 1b = Protocol engine services can be used for this function.
RESERVED	1	0b	RSV	N/A	Reserved.
PFLINKEN	2	0b	RW	UNDEFINED	**PF Link Enable** 0b = The PF driver is disabled. The software device driver must at minimum report it does not have link. 1b = The PF driver is enabled.
PFSCEN	3	0b	RW	UNDEFINED	**PF iSCSI Enable** 0b = iSCSI should not be used for this function. 1b = iSCSI can be used for this function.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.1.4 Global GPIO Control - GLGEN_GPIO_CTL[n] (0x000880C8 + 0x4*n, n=0...6; RW)

These registers control the mode of operation of the following I/O signals:

- Registers 0...3 control SDP_TIMESYNC[0:3], respectively.
- Registers 4 controls the TIME_SYNC (in) signal.
- Registers 5 controls the 1PPS (out) signal.
- Register 6 control the CLK_SYNCE (out) signal.

This register is initialized only at LAN Power Good, preserving the GPIO states across software and PCIe resets.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IN_VALUE	0	0b	RO	N/A	**In Value** Reflect the state of the GPIO (valid for both cases: input and output signal).
IN_TRANSIT	1	0b	RCW	UNDEFINED	**In Transition** This bit is set to one following any transition on the GPIO. Writing "1" to this bit clears it.
OUT_VALUE	2	0b	RW	UNDEFINED	**Out Value** Defines the output level driven on this GPIO. It is meaningful only when the *PIN_DIR* is configured as output.
NO_P_UP	3	1b	RW	UNDEFINED	**No Pull-Up** Defines if GPIO pin has an internal pull-up. 0b = Pull-up 1b = No pull-up
PIN_DIR	4	0b	RW	UNDEFINED	**Pin Direction** Controls whether this GPIOn pin is configured as an input or output. 0b = Input 1b = Output

Field	Bit(s)	Init.	Type	CFG Policy	Description
TRI_CTL	5	0b	RW	UNDEFINED	**Tristate Control** Meaningful only for the single-ended GPIOs when configured as output and driven to high. 0b = The pin is tri-stated. 1b = The pin is driven to high.
RESERVED	7:6	00b	RSV	N/A	Reserved.
PIN_FUNC	11:8	0x0	RW	UNDEFINED	**Pin Function** This field controls the functionality of this GPIOn pin. 0x0 = SDP (software definable input or output). 0x1 = Input Event sampled by EVENT register 0 and AUX_IN 0 of master timer 0. 0x2 = Input Event sampled by EVENT register 1 and AUX_IN 1 of master timer 0. 0x3 = Input Event sampled by EVENT register 2 and AUX_IN 2 of master timer 0. 0x4 = Input Event sampled by EVENT register 0 and AUX_IN 0 of master timer 1. 0x5 = Input Event sampled by EVENT register 1 and AUX_IN 1 of master timer 1. 0x6 = Input Event sampled by EVENT register 2 and AUX_IN 2 of master timer 1. 0x8 = Output signal initiated by TGT register 0 and AUX_OUT 0 of master timer 0. 0x9 = Output signal initiated by TGT register 1 and AUX_OUT 1 of master timer 0. 0xA = Output signal initiated by TGT register 2 and AUX_OUT 2 of master timer 0. 0xB = Output signal initiated by TGT register 3 and AUX_OUT 3 of master timer 0. 0xC = Output signal initiated by TGT register 0 and AUX_OUT 0 of master timer 1. 0xD = Output signal initiated by TGT register 1 and AUX_OUT 1 of master timer 1. 0xE = Output signal initiated by TGT register 2 and AUX_OUT 2 of master timer 1. 0xF = Output signal initiated by TGT register 3 and AUX_OUT 3 of master timer 1.
INT_MODE	13:12	00b	RW	UNDEFINED	**Interrupt Mode** This field selects the interrupt mode for this GPIOn. 00b = No interrupt. 01b = Interrupt on rising edge. 10b = Interrupt on falling edge. 11b = Interrupt on any transition.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.1.5 VF Reset Trigger - VPGEN_VFRTRIG[VF] (0x00090000 + 0x4*VF, VF=0...255; RW)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFSWR	0	0b	RW	UNDEFINED	**VF Software Reset** VF software reset is done by the PF setting the *VFSWR* bit. At reset completion, the PF clears this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.6 VF Reset Status - VPGEN_VFRSTAT[VF] (0x00090800 + 0x4*VF, VF=0...255; RO)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFRD	0	1b	RO	N/A	**VF Reset Done** VF Software Reset Done indication. This flag is cleared when the *VFSWR* bit is set in the VPGEN_VFRTRIG register. It is set back to 1b when the hardware completes its hardware data path cleanup for the VF, or the *VFSWR* bit is cleared in the VPGEN_VFRTRIG register.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.7 PFGEN Control - PFGEN_CTRL (0x00091000; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFSWR	0	0b	RO	UNDEFINED	**PF Software Reset** Set on reset event from IOSF block and when software sets the bit. Cleared only by firmware writing 0 to it (also cleared on core reset).
RESERVED	31:1	0x0	RSV	N/A	Reserved.

Note: PF reset.

13.2.2.1.8 PFR STAT - PFGEN_PFRSTAT (0x00091080; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFRD	0	1b	RO	UNDEFINED	**PF Reset Done** *PFRD* is cleared when GL_XLR_MARKER_TRIG _VMLR sets the relevant PF reset. Set when hardware cleanup is done.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

Note: PF reset.

13.2.2.1.9 PF Driver Unload - PFGEN_DRUN (0x00091180; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DRVUNLD	0	0b	RW	UNDEFINED	**Driver Unload** The PF sets this bit to indicate its driver is unloading.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.10 VM Reset Trigger - VSIGEN_RTRIG[VSI] (0x00091800 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VMSWR	0	0b	RW	UNDEFINED	**VM Software Reset** Initiated by setting the *VMR* bit. At completion of the reset flow, the PF software clears this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.11 VM Reset Status - VSIGEN_RSTAT[VSI] (0x00092800 + 0x4*VSI, VSI=0...767; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VMRD	0	1b	RO	N/A	**VM Reset Done** Cleared when *VMSWR* bit is set in the VSIGEN_VMRTRIG register. Set when hardware cleanup for the VM is completed or when the *VMSWR* bit is cleared in the VSIGEN_VMRTRIG register.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.12 XLR Marker Trigger - GL_XLR_MARKER_TRIG_VMLR (0x00093804; RW)

Field definitions are the same as those defined in Section 13.2.2.10.5.

13.2.2.1.13 Global Marker Count - GLGEN_MARKER_COUNT (0x000939E8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MARKER_COUNT	7:0	0x0	RW	UNDEFINED	**Marker Count** Specifies the value of markers to count for specific client to decide on XLR completion. Valid when *MARKER_COUNT_EN* is set.
RESERVED	30:8	0x0	RSV	N/A	Reserved.
MARKER_COUNT_EN	31	0b	RW	UNDEFINED	**Marker Count Enable** Specifies if the client marker count value is valid and should override the one chosen from the system state configured.

13.2.2.1.14 Global Wait Between Transaction Count - GLGEN_XLR_TRNS_WAIT_COUNT (0x000939EC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
W_BTWN_TRNS_COUNT	4:0	0x8	RW	UNDEFINED	**Wait Between Transaction Count** Number of cycles to wait between two consequent transactions.
RESERVED	7:5	000b	RSV	N/A	Reserved.
W_PEND_TRNS_COUNT	15:8	0x20	RW	UNDEFINED	**Wait Pending Transactions Count** Number of cycles to wait between two pending transactions.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.1.15 Global Wait for HLP After CORER - GLGEN_XLR_MSK2HLP_RDY (0x000939F0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLGEN_XLR_MSK2HLP_RDY	0	1b	RW	UNDEFINED	**XLR Mask 2 HLP Ready** Bit should be set on core reset and can be cleared by software writing into it.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.16 ECC Error Mask Low - GLGEN_ECC_ERR_RST_MASK_L (0x000939F4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CLIENT_NUM	31:0	0xFFFFFFFF	RW	N/A	**Client Number** Defines on which source blocks the reset indication is set. Each bit represents masking to a different client according to the following mapping: MSB: mbx_unc_ecc_err, tclan_unc_ecc_err, pqm_unc_ecc_err, psm_unc_ecc_err, fpmat_unc_ecc_err, stat_mac_ecc_int, stat_tdpu_ecc_int, pe_unc_ecc_err, foc_unc_ecc_err, int_unc_ecc_err, rlan_unc_ecc_err, tdpu_unc_ecc_err, rdpu_unc_ecc_err, tcb_unc_ecc_err, rcb_unc_ecc_err, rcupst_unc_ecc_err, rcuswr_unc_ecc_err, rcurprs_unc_ecc_err, rcutprs_unc_ecc_err, rcukgg_unc_ecc_err, rcukggext_unc_ecc_err, rcuaclext_unc_ecc_err, rcupstext_unc_ecc_err, tpb_unc_ecc_err, mac_unc_ecc_err, rpb_unc_ecc_err, pprs_unc_ecc_err_0, pprs_unc_ecc_err_1, pprs_unc_ecc_err_2, pprs_unc_ecc_err_3, pcie_unc_ecc_err, LSB: mng_unc_ecc_err

13.2.2.1.17 ECC Error Mask High - GLGEN_ECC_ERR_RST_MASK_H (0x000939F8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CLIENT_NUM	6:0	0x7F	RW	N/A	**Client Number** Defines on which source blocks the reset indication is set. Each bit represents masking to a different client according to the following mapping: MSB: stat_rcuacl_ecc_int, stat_rcuswr_ecc_int, stat_rcupst_ecc_int, rcuacl_unc_ecc_err, fds_ecc_int, csr_ecc_int, LSB: tcvmlr_unc_ecc_err
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.18 ECC Error Int Mask Low - GLGEN_ECC_ERR_INT_TOG_MASK_L (0x000939FC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CLIENT_NUM	31:0	0xFFFFFFFF	RW	N/A	**Client Number** Defines on which source blocks the interrupt indication is toggled. Each bit represents masking to a different client according to the following mapping: MSB: mbx_unc_ecc_err, tclan_unc_ecc_err, pqm_unc_ecc_err, psm_unc_ecc_err, fpmat_unc_ecc_err, stat_mac_ecc_int, stat_tdpu_ecc_int, pe_unc_ecc_err, foc_unc_ecc_err, int_unc_ecc_err, rlan_unc_ecc_err, tdpu_unc_ecc_err, rdpu_unc_ecc_err, tcb_unc_ecc_err, rcb_unc_ecc_err, rcupst_unc_ecc_err, rcuswr_unc_ecc_err, rcurprs_unc_ecc_err, rcutprs_unc_ecc_err, rcukgg_unc_ecc_err, rcukggext_unc_ecc_err, rcuaclext_unc_ecc_err, rcupstext_unc_ecc_err, tpb_unc_ecc_err, mac_unc_ecc_err, rpb_unc_ecc_err, pprs_unc_ecc_err_0, pprs_unc_ecc_err_1, pprs_unc_ecc_err_2, pprs_unc_ecc_err_3, pcie_unc_ecc_err, LSB: mng_unc_ecc_err

13.2.2.1.19 ECC Error Int Mask High - GLGEN_ECC_ERR_INT_TOG_MASK_H (0x00093A00; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CLIENT_NUM	6:0	0x7F	RW	N/A	**Client Number** Defines on which source blocks the interrupt indication is toggled. Each bit represents masking to a different client according to the following mapping: MSB: stat_rcuacl_ecc_int, stat_rcuswr_ecc_int, stat_rcupst_ecc_int, rcuacl_unc_ecc_err, fds_ecc_int, csr_ecc_int, LSB: tcvmlr_unc_ecc_err
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.20 PFR STAT - GLGEN_VFLRSTAT[n] (0x00093A04 + 0x4*n, n=0...7; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFLRS	31:0	0x0	RW1C	UNDEFINED	**VFLRS Flags** PFRD is cleaned when GL_XLR_MARKER_TRIG _VMLR set the relevant PF reset. Cleared when hardware cleanup is done.

Note: PF reset.

13.2.2.1.21 TCVMLR XLR Marker Trigger - GL_XLR_MARKER_TRIG_TCVMLR (0x000A2000; RO)

This register is used to initiate XLR marker reset flow. When the register is written, TCVMLR starts drain marker flow.

Field definitions are the same as those defined in Section 13.2.2.10.5.

13.2.2.1.22 Transmit Scheduler Queue Control - GL_TCVMLR_QCTL (0x000A2004; RO)

This register is used to initiate queue halt/marker flow. Flow state can be polled using REQ_STAT and STAT registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QID	13:0	0x0	RW	UNDEFINED	**Queue ID** Queue ID to perform action on: 0-16383
OP	14	0b	RW	UNDEFINED	**Operation** 0b = Halt only. Queue halt request is made to PQM. 1b = Marker only. Only a TC drain marker is sent for the queue.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.1.23 TCVMLR Drain Marker Control - GL_TCVMLR_DRAIN_MARKER (0x000A2008; RO)

This register is used to initiate a TC drain marker to be sent to the pipe.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT	2:0	000b	RW	UNDEFINED	**Port** Port number to send marker to.
TC	7:3	0x0	RW	UNDEFINED	**TC** TC number to send marker to.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.24 TCVMLR Halt Done Down Counter - GL_TCVMLR_QCNTR (0x000A200C; RO)

This register is used to set the number of queue halts that need to complete their flow before hardware initiates interrupt.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CNTR	14:0	0x0	RW	UNDEFINED	**Counter** Number of queue halts that need to complete their flow before hardware initiates interrupt. Value is decremented after each halt done, and interrupt is initiated when value reaches 0. If value is already 0 on halt done, no interrupt is initiated.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.1.25 TCVMLR Queue Port TC Config Control - GL_TCVMLR_QCFG (0x000A2010; RO)

This register is used to configure or request to read port and TC number per queue. They must be configured before hardware can operate correctly.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QID	13:0	0x0	RW	UNDEFINED	**Queue ID**
OP	14	0b	RW	UNDEFINED	**Operation** 0b = Read configuration. Only QID needs to be valid. 1b = Write configuration. All fields must be valid.
PORT	17:15	000b	RW	UNDEFINED	**Port** Port associated with the queue. Valid only on write operation.
TC	22:18	0x0	RW	UNDEFINED	**TC** TC associated with the queue. Valid only on write operation.
RESERVED	31:23	0x0	RSV	N/A	Reserved.

13.2.2.1.26 TCVMLR Queue Port TC Config Status - GL_TCVMLR_QCFG_RD (0x000A2014; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QID	13:0	0x0	RO	N/A	**Queue ID**
PORT	16:14	000b	RO	N/A	**Port** Port associated with the queue.
TC	21:17	0x0	RO	N/A	**TC** TC associated with the queue.
RESERVED	31:22	0x0	RSV	N/A	Reserved.

13.2.2.1.27 TCVMLR Req Flow Status Control - GL_TCVMLR_REQ_STAT (0x000A2018; RO)

This register is used to request or set status of the different disable/reset flows.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ENT_TYPE	2:0	000b	RW	UNDEFINED	**Entity Type** 000b = VF 001b = VM 010b = PF 011b = Queue All other values are reserved.
ENT_ID	16:3	0x0	RW	UNDEFINED	**Entity ID** • VF/VM/PF = Function number • Queue = Queue ID
OP	17	0b	RW	UNDEFINED	**Operation** 0b = Read status. *WRITE_STATUS* does not need to be valid. 1b = Write status.
WRITE_STATUS	20:18	000b	RW	UNDEFINED	**Write Status** Status to be written (as specified in the GL_TCVMLR_STAT register).
RESERVED	31:21	0x0	RSV	N/A	Reserved.

13.2.2.1.28 TCVMLR Req Flow Status Read - GL_TCVMLR_STAT (0x000A201C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ENT_TYPE	2:0	000b	RO	N/A	**Entity Type** 000b = VF 001b = VM 010b = PF 011b = Queue All other values are reserved.
ENT_ID	16:3	0x0	RO	N/A	**Entity ID** • VF/VM/PF = Function number • Queue = Queue ID

Field	Bit(s)	Init.	Type	CFG Policy	Description
STATUS	19:17	000b	RO	N/A	**Status** Status to write for specified reset entity. Reset status: 000b = Normal. No request is pending. 001b = Halt scheduling request pending. Firmware triggered queue halt request and flow is yet served by hardware (relevant only for Q entity). 010b = Drain marker request pending. Firmware triggered drain marker request and flow is yet served by hardware. 011b = Done: • For Q marker flow status is set to done when queues markers exit the pipe (pipe is drained). • For Q halt flow status is set to done when halt request was completed. • For VF/VM/PF flow status is set to done when marker request exits TCVMLR block.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.1.29 TCVMLR Req Flow Error Status - GL_TCVMLR_ERR_STAT (0x000A2024; RO)

Error indication register. Saves data for last error made by firmware (initiating new flow for request already in progress).

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERROR	0	0b	RW	UNDEFINED	**Error** When high, indicates a firmware error was made. Firmware error is when a new reset flow is initiated for a reset in progress.
FW_REQ	1	0b	RW	UNDEFINED	**Firmware Request** Indicates what type of firmware request caused the error. 0b = Firmware tried to initiate queue halt flow. 1b = Firmware tried to initiate marker flow.
STAT	4:2	000b	RW	UNDEFINED	**Status** Reset status at time of firmware request. 000b = Normal. No request is pending. 001b = Halt scheduling request pending. Firmware triggered queue halt request and flow is yet served by hardware (relevant only for Q entity). 010b = Drain marker request pending. Firmware triggered drain marker request and flow is yet served by hardware. 011b = Done. Flow triggered by firmware is done and no request is pending (indicates Q halt done or marker done according to the last flow that was initiated).
ENT_TYPE	7:5	000b	RW	UNDEFINED	**Entity Type** 000b = VF 001b = VM 010b = PF 011b = Queue 100b = TC drain marker All other values are reserved.
ENT_ID	21:8	0x0	RW	UNDEFINED	**Entity ID** • VF/VM/PF = Function number • Queue = Queue ID • TC drain marker = 3b Port number follow by 5b TC number: {PORT, TC}

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:22	0x0	RSV	N/A	Reserved.

13.2.2.1.30 TCVMLR Drain Done Count for TCLAN - GL_TCVMLR_DRAIN_DONE_TCLAN[n] (0x000A20A8 + 0x4*n, n=0...31; RO)

Register per TC that shows amount of drain marker requests that are done on the TCLAN interface. Lowest instance address corresponds to TC 0, highest to TC 31.

Field	Bit(s)	Init.	Type	CFG Policy	Description
COUNT	7:0	0x0	RO	N/A	**Count** Number of drain markers done for a specific TC on TCLAN interface. Can decrement value using GL_TCVMLR_DRAIN_DONE_DEC.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.31 TCVMLR Drain Done Count for TPB - GL_TCVMLR_DRAIN_DONE_TPB[n] (0x000A2128 + 0x4*n, n=0...31; RO)

Register per TC that shows amount of drain marker requests that are done on the TPB interface. Lowest instance address corresponds to TC 0, highest to TC 31.

Field	Bit(s)	Init.	Type	CFG Policy	Description
COUNT	7:0	0x0	RO	N/A	**Count** Number of drain markers done for a specific TC on TPB interface. Can decrement value using GL_TCVMLR_DRAIN_DONE_DEC.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.32 TCVMLR Drain Done Decrement Control - GL_TCVMLR_DRAIN_DONE_DEC (0x000A21A8; RO)

This register is used to decrement the per-TC drain done registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TARGET	0	0b	RW	UNDEFINED	**Target** 0b = TCLAN register. 1b = TPB register.
INDEX	5:1	0x0	RW	UNDEFINED	**Index** TC index to decrement from (0-31). Value needs to be calculated based on port/TC number and MAC topology.
VALUE	13:6	0x0	RW	UNDEFINED	**Value** Value to decrement from counter. Needs to be less than or equal to counter value to work correctly.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.1.33 TCVMLR Drain Done Down Counter - PRT_TCVMLR_DRAIN_CNTR (0x000A21C0; RO)

Status register showing the number of TC drain markers per port that need to complete their flow before hardware initiates interrupt.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CNTR	13:0	0x0	RO	N/A	**Counter** Number of TC drain markers that need to complete their flow time 2 (x2) before hardware initiates interrupt. Value is decremented after each marker done from both TPB and TCLAN interfaces. An Interrupt is initiated when value reaches 0. If value is already 0 on marker done, no interrupt is initiated.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.1.34 TCVMLR Drain Done Down Counter Control - GL_TCVMLR_DRAIN_CNTR_CTL (0x000A21E0; RO)

This register is used to increment or decrement the per-port TC drain done down counters, which generate an interrupt upon reaching zero.

Field	Bit(s)	Init.	Type	CFG Policy	Description
OP	0	0b	RW	UNDEFINED	**Operation** 0b = Decrement value of counter of specified port. 1b = Increment value of counter of specified port.
PORT	3:1	000b	RW	UNDEFINED	**Port** Port number of the counter to increment/decrement.
VALUE	17:4	0x0	RW	UNDEFINED	**Value** Number of TC drain markers that need to complete their flow time 2 (x2) before hardware initiates interrupt. This value is incremented/decremented from counter.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.1.35 Global Status - GLGEN_STAT (0x000B612C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.1.36 General Port Status - PRTGEN_STATUS (0x000B8100; RO)

This register contains general port status information.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_VALID	0	0b	RO	N/A	**Port Valid** Denotes if the respective Ethernet port is enabled. 0b = Port is disabled. 1b = Port is enabled.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_ACTIVE	1	0b	RO	N/A	**Port Active** Denotes if the respective Ethernet port is active. 0b = Port is inactive and its respective PHY is in power down. 1b = Port is active and its respective PHY is powered up. PORT_ACTIVE is 1b when: PORT_VALID = 1b AND If (device is in D0 state) then port should be active: If the software device driver activated the link (ACTIVATE_PORT_LINK = 1b) or link is used for manageability. Else, when device is in Dr state, the port should be active+ If link is used for manageability or WoL.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.1.37 General Port Configuration - PRTGEN_CNF (0x000B8120; RO)

This register contains configuration per Ethernet port loaded from NVM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_DIS	0	1b	RW	UNDEFINED	**Port Disable** Defines if the Ethernet port is enabled from the NVM. 0b = Enabled 1b = Disabled Exception: Port 0 is always enabled and cannot be disabled from the NVM.
ALLOW_PORT_DIS	1	0b	RW	UNDEFINED	**Allow Port Disable** 0b = Asserting DEV_DIS_N has no effect on this port. 1b = Asserting DEV_DIS_N disables this port.
EMP_PORT_DIS	2	0b	RW	UNDEFINED	**EMP Port Disable** Set by the EMP to disable the Ethernet port. The NVM value for this bit should always be 0b (enabled). NVM should use the *PORT_DIS* bit to disable a port.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.1.38 General Port Configuration2 - PRTGEN_CNF2 (0x000B8160; RO)

This register contains configuration per Ethernet port loaded from NVM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ACTIVATE_PORT_LINK	0	0b	RW	UNDEFINED	**Activate Port Link** When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link, using this configuration, is ignored when the interface is used for manageability. To implement this, hardware masks this configuration when the relevant port's PRTPM_GC.*EMP_LINK_ON* is set to 1b.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.1.39 Global Reset Control - GLGEN_RSTCTL (0x000B8180; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GRSTDEL	5:0	0x8	RW	UNDEFINED	**Global Reset Delay** Global/Core and EMP resets delay defined in 100 ms units. Setting *GRSTDEL* to zero bypasses the delay counter.
RESERVED	7:6	00b	RSV	N/A	Reserved.
ECC_RST_ENA	8	0b	RW	UNDEFINED	**ECC Reset Enable** Graceful CORER reset on ECC in any memory other than the EMP memories. 0b = A detected ECC error on these memories generates only an interrupt to the PFs. 1b = A detected ECC error generated a graceful CORER. An ECC_ERR reset event is carried out by firmware. CAR creates an interrupt to firmware with reset type CORER. Firmware triggers reset using the immediate reset triggers.
RESERVED	29:9	0x0	RSV	N/A	Reserved.
ECC_RT_EN	30	0b	RW	UNDEFINED	**ECC Reset Enable** ECC reset flow. Set to 1b to enable legacy flow.
FLR_RT_EN	31	0b	RW	UNDEFINED	**FLR Reset Enable** FLR reset flow. Set to 1b to enable legacy flow.

13.2.2.1.40 Global Clock Status - GLGEN_CLKSTAT (0x000B8184; RO)

This register holds internal clock speeds.

Field	Bit(s)	Init.	Type	CFG Policy	Description
U_CLK_SPEED	2:0	000b	RO	N/A	**Upper Clock Speed** Debug feature. Represents the current speed of the upper clock (core_clk) as follows: 00b = 390.625 MHz. 01b = 195.3125 MHz. 10b = 97.65625 MHz 11b = Reserved
L_CLK_SPEED	5:3	000b	RO	N/A	**Lower Clock Speed** Debug feature. Represents the current speed of the Rx clock for MAC 0. Speeds are represented as follows: Three bits per port (synchronized to the equivalent MAC clock): 000b = 100 Mb/s 001b = 1 GbE 010b = 10 GbE 011b = 40 GbE All other values are reserved.
PSM_CLK_SPEED	8:6	000b	RO	N/A	**PSM Clock Speed** Debug feature. Represents the current speed of the Rx clock for MAC 1. Speeds are represented as follows: Three bits per port (synchronized to the equivalent MAC clock): 000b = 100 Mb/s 001b = 1 GbE 010b = 10 GbE 011b = 40 GbE All other values are reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXCTL_CLK_SPEED	11:9	000b	RO	N/A	**RXCTL Clock Speed** Debug feature. Represents the current speed of the Rx clock for MAC 2. Speeds are represented as follows: Three bits per port (synchronized to the equivalent MAC clock): 000b = 100 Mb/s 001b = 1 GbE 010b = 10 GbE 011b = 40 GbE All other values are reserved.
UANA_CLK_SPEED	14:12	000b	RO	N/A	**UANA Clock Speed** Debug feature. Represents the current speed of the Rx clock for MAC 3. Speeds are represented as follows: Three bits per port (synchronized to the equivalent MAC clock): 000b = 100 Mb/s 001b = 1 GbE 010b = 10 GbE 011b = 40 GbE All other values are reserved.
RESERVED	17:15	000b	RSV	N/A	Reserved.
PE_CLK_SPEED	20:18	000b	RO	N/A	**PE Clock Speed**
RESERVED	31:21	0x0	RSV	N/A	Reserved.

13.2.2.1.41 Global Reset Status - GLGEN_RSTAT (0x000B8188; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEVSTATE	1:0	00b	RO	N/A	**Device State** Device can be at one of the following states: 00b = Device active. 01b = Reset requested. 10b = Reset in progress. 11b = Reserved.
RESET_TYPE	3:2	00b	RO	N/A	**Reset Type** Reflects one of the following resets that are/were in progress: 00b = POR 01b = CORER 10b = GLOBR 11b = EMPR
CORERCNT	5:4	00b	RO	N/A	**Core Reset Count** Counts the number of initiated core resets since POR. The counter wraps around from 11b to 00b. ***Note:*** The counters count only the graceful resets asserted by the GLGEN_RTRIG register. It does not count resets initiated by the GLGEN_IMRTRIG register intended for internal use of the EMP.
GLOBRCNT	7:6	00b	RO	N/A	**Global Reset Count** Counts the number of initiated global resets since POR. The counter wraps around from 11b to 00b. ***Note:*** The counters count only the graceful resets asserted by the GLGEN_RTRIG register. It does not count resets initiated by the GLGEN_IMRTRIG register intended for internal use of the EMP.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EMPRCNT	9:8	00b	RO	N/A	**EMP Reset Count** Counts the number of initiated EMP resets since POR. The counter wraps around from 11b to 00b. ***Note:*** The counters count only the graceful resets asserted by the GLGEN_RTRIG register. It does not count resets initiated by the GLGEN_IMRTRIG register intended for internal use of the EMP.
TIME_TO_RST	15:10	0x0	RO	N/A	**Time to Reset** The reset time is a down counter, loaded from GLGEN_RSTCTL.*GRSTDEL* following a GLOBR or CORER or EMPR. When *TIME_TO_RST* reaches a zero value the actual reset is initiated. This register is valid only in hardware-controlled resets (i.e., FW_RST_CONTROL_EN=0 or resets triggered by firmware AUX).
RTRIG_FLR	16	0b	RO	N/A	**Reset Trigger FLR** Reset request cause is due to FLR reset. Can only be asserted when switch mode is set.
RTRIG_ECC	17	0b	RO	N/A	**Reset Trigger ECC** Reset request cause is due to memories ECC-ERR. Set when GLGEN_RSTCTL_ECC_RST_ENA and memories uncorrectable error event accrued.
RTRIG_FW_AUX	18	0b	RO	N/A	**Reset Trigger Firmware AUX** Reset was triggered from firmware AUX register (for debug). This bit is hot ONLY - from AUX trigger until reset occurs.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.1.42 Global Reset Trigger - GLGEN_RTRIG (0x000B8190; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CORER	0	0b	RW	UNDEFINED	**Core Reset** Setting this bit triggers a graceful core reset flow.
GLOBR	1	0b	RW	UNDEFINED	**Global Reset** Setting this bit triggers a graceful global reset flow.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.1.43 Global Switch Mode Reset Control - GLGEN_ASSERT_HLP (0x000B81E4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CORE_ON_RST	0	0b	RW	UNDEFINED	**Core on Reset** When set, indicates the device to assert HLP core reset on the next assertion of CORER. Asserts (hlpswitch_rst_b)
FULL_ON_RST	1	0b	RW	UNDEFINED	**Full on Reset** When set, indicates the device to assert HLP full reset on the next assertion of CORER. Asserts (hlpswitch_ports_rst_b)
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.1.44 Global Device Timer - GLVFGEN_TIMER (0x000B8214; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GTIME	31:0	0x0	RW	UNDEFINED	**GTIME** A free-running timer fed by a 1 μs clock.

13.2.2.1.45 Global Clock Status - GLGEN_CLKSTAT_SRC (0x000B826C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
U_CLK_SRC	1:0	00b	RO	N/A	**Upper Clock Source** Represents the current source of the respective core clock (core_clk) as follows: 00b = 367 MHz 01b = 416 MHz 10b = 446 MHz 11b = 396 MHz
L_CLK_SRC	3:2	00b	RO	N/A	**Lower Clock Source** Represents the current source of the respective core clock (core_clk) as follows: 00b = 367 MHz 01b = 416 MHz 10b = 446 MHz 11b = 396 MHz
PSM_CLK_SRC	5:4	00b	RO	N/A	**PSM Clock Source** Represents the current source of the respective core clock (core_clk) as follows: 00b = 367 MHz 01b = 416 MHz 10b = 446 MHz 11b = 396 MHz
RXCTL_CLK_SRC	7:6	00b	RO	N/A	**RXCTL Clock Source** Represents the current source of the respective core clock (core_clk) as follows: 00b = 367 MHz 01b = 416 MHz 10b = 446 MHz 11b = 396 MHz
UANA_CLK_SRC	11:8	0x0	RO	N/A	**UANA Clock Source** Represents the current source of the respective core clock (core_clk) as follows: 0x0 = 367 MHz 0x1 = 416 MHz 0x2 = 446 MHz 0x3 = 396 MHz 0x4 = 625 MHz
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.1.46 General Port Configuration3 - PRTGEN_CNF3 (0x000B8280; RO)

This register contains configuration per Ethernet port loaded from NVM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_STAGERING_EN	0	0b	RW	UNDEFINED	**Port Staggering Enable** The purpose of this bit is to allow firmware to stagger the enable of the PHY ports to prevent IR drop. On power-up reset, firmware staggers the enable of the ports that should be active during Sx mode. When moving to s0, it staggers all active ports. When going down to Sx, ports are down by hardware without staggering.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.1.47 LAN Port Number - PFGEN_PORTNUM (0x001D2400; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT NUM	2:0	000b	RW	UNDEFINED	**Port Number** Indicates the LAN port connected to this function.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.1.48 GLGEN_ANA_FLAG_MAP - GLGEN_ANA_FLAG_MAP[n] (0x0020C000 + 0x4*n, n=0...63; RW)

Flags mapping register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLAG_EN	0	0b	RW	UNDEFINED	**Flag Enable** When set, Analyzer flag[N] should be exposed on flag *EXT_FLAG_ID* on the Analyzer outputs.
EXT_FLAG_ID	6:1	0x0	RW	UNDEFINED	**External Flag ID** CSR "i" maps the "i" external flag to *EXT_FLAG_ID* internal flag. Valid when *FLAG_EN* bit is set.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.49 GLGEN_ANA_DEF_PTYPE - GLGEN_ANA_DEF_PTYPE (0x0020C100; RW)

Default PTYPE (when there is no match in PTYPE TCAM and node PTYPE is invalid).

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEF_PTYPE	9:0	0x0	RW	UNDEFINED	**Default PTYPE** Analyzer default PTYPE value.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.1.50 GLGEN_ANA_CFG_CTRL - GLGEN_ANA_CFG_CTRL (0x0020C104; RW)

Table's configuration control register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	17:0	0x0	RW	UNDEFINED	**Line Index** Target memory line.
TABLE_ID	25:18	0x0	RW	UNDEFINED	**Table ID** Target table: 0x00 = TCAM key 0x01 = Xlate table (ALU) 0x02 = PG spill buffer action 0x03 = PG spill buffer key 0x04 = PG mem0 - holds all PG arches that sit at addr%8 0x05 = PG mem1 - holds all PG arches that sit at addr%8 + 1 0x06 = PG mem2 - holds all PG arches that sit at addr%8 + 2 0x07 = PG mem3 - holds all PG arches that sit at addr%8 + 3 0x08 = PG mem4 - holds all PG arches that sit at addr%8 + 4 0x09 = PG mem5 - holds all PG arches that sit at addr%8 + 5 0x0A = PG mem6 - holds all PG arches that sit at addr%8 + 6 0x0B = PG mem7 - holds all PG arches that sit at addr%8 + 7 0x0C = Protocol group memory 0x0D = TCAM action RAM 0x0E = Instruction memory 0x0F = Node cntx ID 0x10 = Marker group memory 0x11 = PTYPE TCAM key 0x12 = PTYPE TCAM action RAM 0x13 = No match PG spill buffer action 0x14 = No match PG spill buffer key 0x15 = No match PG mem0 - holds all PG arches that sit at addr%4 0x16 = No match PG mem1 - holds all PG arches that sit at addr%4 + 1 0x17 = No match PG mem2 - holds all PG arches that sit at addr%4 + 2 0x18 = No match PG mem3 - holds all PG arches that sit at addr%4 + 3 0x19 = Profiles table 0x1A = Profile entity mapping table
RESERVED	28:26	0x0	RW	N/A	Reserved.
OPERATION_ID	31:29	000b	RW	UNDEFINED	**Operation ID** 000b = WR 001b = RD 010b = Lookup for hit index (PG and no match PG) 011b = Lookup for free index (in PG and no match PG) All other values are reserved. To lookup PG, need to select the first memory of PG. To lookup NM PG, need to select the first memory of NM PG.

13.2.2.1.51 GLGEN_ANA_CFG_WRDATA - GLGEN_ANA_CFG_WRDATA (0x0020C108; RW)

Table's configuration write data register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WR_DATA	31:0	0x0	RW	UNDEFINED	**Write Data** 32-bit write data.

13.2.2.1.52 GLGEN_ANA_CFG_RDDATA - GLGEN_ANA_CFG_RDDATA[n] (0x0020C10C + 0x4*n, n=0...15; RO)

Table's configuration read data registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RD_DATA	31:0	0x0	RO	N/A	**Read Data** 32-bit read data.

13.2.2.1.53 GLGEN_ANA_CFG_LU_KEY - GLGEN_ANA_CFG_LU_KEY[n] (0x0020C14C + 0x4*n, n=0...2; RW)

Key to lookup CSR.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LU_KEY	31:0	0x0	RW	UNDEFINED	**Lookup Key** KEY that is looked up when the lookup operations are selected.

13.2.2.1.54 GLGEN_ANA_CFG_HTBL_LU_RESULT - GLGEN_ANA_CFG_HTBL_LU_RESULT (0x0020C158; RO)

Lookup result from hash table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HIT	0	0b	RO	N/A	**Hit** For "look up for hit index" operation, this bit indicates if key is found in PG/NMPG tables. For "lookup for free index" operation, this bit indicates if there is a free entry in PG/NMPG tables.
PG_MEM_IDX	3:1	000b	RO	N/A	**PG Memory Index** For "look up for hit index" operation, this field indicates in which PG/NMPG memory the search key is found. For "lookup for free index" operation, this field indicates in which PG/NMPG memory the free entry is found.
ADDR	12:4	0x0	RO	N/A	**Address** For "look up for hit index" operation, this field indicates the memory address of the search key. For "lookup for free index" operation, this field indicates the memory address of the free entry.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.1.55 GLGEN_ANA_CFG_SPLBUF_LU_RESULT - GLGEN_ANA_CFG_SPLBUF_LU_RESULT (0x0020C15C; RO)

Lookup result for spill buffer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HIT	0	0b	RO	N/A	**Hit** For "look up for hit index" operation, this bit indicates if key is found in PG/NMPG spill buffer. For "lookup for free index" operation, this bit indicates if there is a free entry in PG/NMPG spill buffer.
RESERVED	3:1	000b	RSV	N/A	Reserved.
ADDR	12:4	0x0	RO	N/A	**Address** For "look up for hit index" operation, this field indicates the spill buffer address of the search key. For "lookup for free index" operation, this field indicates the spill buffer address of the free entry.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.1.56 GLGEN_ANA_P2P - GLGEN_ANA_P2P[n] (0x0020C160 + 0x4*n, n=0...15; RW)

Profile-to-profile mapping table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.1.57 GLGEN_ANA_PG0_HASHKEY - GLGEN_ANA_PG0_HASHKEY[n] (0x0020C1A0 + 0x4*n, n=0...3; RW)

Main parse graph unit0 hash key registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the hash key of the first part of the primary parse graph.

13.2.2.1.58 GLGEN_ANA_NMPG0_HASHKEY - GLGEN_ANA_NMPG0_HASHKEY[n] (0x0020C1B0 + 0x4*n, n=0...3; RW)

"No match" parse graph unit0 hash key registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the hash key of the first part of the "no match" parse graph.

13.2.2.1.59 GLGEN_ANA_PG_KEYMASK - GLGEN_ANA_PG_KEYMASK[n] (0x0020C1C0 + 0x4*n, n=0...3; RW)

Main parse graph key mask registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the key mask vector of the primary parse graph. When mask=1, the corresponding bit in the key is cleared. Effective key = key & ~mask.

13.2.2.1.60 GLGEN_ANA_NMPG_KEYMASK - GLGEN_ANA_NMPG_KEYMASK[n] (0x0020C1D0 + 0x4*n, n=0...3; RW)

"No match" parse graph key mask registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the key mask vector of the "no match" parse graph. When mask=1, the corresponding bit in the key is cleared. Effective key = key & ~mask.

13.2.2.1.61 GLGEN_ANA_LAST_PROT_ID - GLGEN_ANA_LAST_PROT_ID[n] (0x0020C1E4 + 0x4*n, n=0...5; RW)

CSR for last override feature.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EN	0	0b	RW	UNDEFINED	**Enable** Enable this protocol to be "last" protocol.
PROT ID	8:1	0x0	RW	UNDEFINED	**Protocol ID**
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.1.62 GLGEN_ANA_PROFIL - GLGEN_ANA_PROFIL_CTRL (0x0020C1FC; RW)

Number of profiles control register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROFILE_SELECT_MDID	4:0	0x0	RW	UNDEFINED	**Profile Select MDID** Used for extracting the "profile select entity" from input interfaces. This field describes the MDID from which the profile select entity is extracted.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROFILE_SELECT_MDSTART	8:5	0x0	RW	UNDEFINED	**Profile Select MDID Start** The *MDstart* and *MDlen* fields define the "profile select entity" location in the MDID as follows: profile select entity = MDID[MDstart + MDlen -1 : MDID_start]
PROFILE_SELECT_MD_LEN	13:9	0x0	RW	UNDEFINED	**Profile Select MDID Length**
NUM_CTRL_DOMAIN	15:14	00b	RW	UNDEFINED	**Number of Control Domains** Defines the control domain key width in the PTYPE marker vector. 00b = 1 control domain (80 markers. No control domain bitmap.) 01b = 2 control domains (78 markers + 2b one-hot control domain bitmap). 10b = 4 control domains (76 markers + 4b one-hot control domain bitmap). 11b = 8 control domains (72 markers + 8b one-hot control domain bitmap).
DEF_PROF_ID	19:16	0x0	RW	UNDEFINED	**Default Profile ID** This profile is considered when the *SEL_DEF_PROF_ID* is set.
SEL_DEF_PROF_ID	20	0b	RW	UNDEFINED	**Select Default Profile ID** Select bit of the default Profile ID.
RESERVED	31:21	0x0	RSV	N/A	Reserved.

13.2.2.1.63 GLGEN_ANA_OUT_OF_PKT - GLGEN_ANA_OUT_OF_PKT (0x0020C200; RW)

"Header of out packet" error control register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
NPC	7:0	0xBF	RW	UNDEFINED	**NPC** Error exception handling PC. Activated when NHO is advanced to a point outside packet after all headers are stored in buffer.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.64 GLGEN_ANA_NO_HIT_PG_NM_PG - GLGEN_ANA_NO_HIT_PG_NM_PG (0x0020C204; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NPC	7:0	0xBF	RW	UNDEFINED	**NPC** Error exception handling PC. Activated when there is no hit either in PG or in no match PG.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.65 GLGEN_ANA_ALU_ACCSS_OUT_OF_PKT - GLGEN_ANA_ALU_ACCSS_OUT_OF_PKT (0x0020C208; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NPC	7:0	0xBF	RW	UNDEFINED	**NPC** Error exception handling PC. Activated when ALU tries to access outside the last byte valid of the 256 bits of data available, or when PG does the same violation to build its key.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.66 GLGEN_ANA_INV_NODE_PTYPE - GLGEN_ANA_INV_NODE_PTYPE (0x0020C210; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INV_NODE_PTYPE	10:0	0x0	RW	UNDEFINED	**Invalid Node PTYPE** Invalid node PTYPE number.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.1.67 GLGEN_ANA_INV_PTYPE_MARKER - GLGEN_ANA_INV_PTYPE_MARKER (0x0020C218; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INV_PTYPE_MARKER	6:0	0x7F	RW	UNDEFINED	**Invalid PTYPE Marker** Invalid PTYPE marker number.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.68 GLGEN_ANA_ABORT_PTYPE - GLGEN_ANA_ABORT_PTYPE (0x0020C21C; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ABORT	9:0	0xFF	RW	UNDEFINED	**Abort** Abort PTYPE number reflected on output interface when malicious packet is detected.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.1.69 GLGEN_ANA_ERR_CTRL - GLGEN_ANA_ERR_CTRL (0x0020C220; RW)

Errors mask register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERR_MASK_EN	31:0	0xFFFFFFBF	RW	UNDEFINED	**Error Mask Enable** Per error type enable bit. When bit is cleared, error detection logic is not activated and error is not reported. Bit 0 = TCAM validity checks (for example: version field in ipv6 != 6). Bit 1 = HO is bigger pocket size. Bit 2 = There is no match in parse graph. Bit 3 = Illegal progress in parse graph (illegal leaf node). Bit 4 = HO is bigger than 504B (max header size). Bit 5 = Analyzer spent too many rounds on packet (number of cycles > fixed configured value). Bit 6 = Analyzer spent too many rounds on packet (number of cycles > packet cycles for performance). Bit 7 = ALU validity checks. Bit 8 = Packet has than 16 packet protocols Bit 9 = *total_ip* field not coherent to *pkt_len* field from interface. Bit 10 = ALU access outside the packet. Bit 11 = No hit in PG and no match PG.

13.2.2.1.70 GLGEN_ANA_TX_FLAG_MAP - GLGEN_ANA_TX_FLAG_MAP[n] (0x0020D000 + 0x4*n, n=0...63; RW)

Flags mapping register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLAG_EN	0	0b	RW	UNDEFINED	**Flag Enable** When set, Analyzer flag[N] should be exposed on flag *EXT_FLAG_ID* on the Analyzer outputs.
EXT_FLAG_ID	6:1	0x0	RW	UNDEFINED	**External Flag ID** CSR "i" maps the "i" external flag to *EXT_FLAG_ID* internal flag. Valid when *FLAG_EN* bit is set.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.71 GLGEN_ANA_TX_DEF_PTYPE - GLGEN_ANA_TX_DEF_PTYPE (0x0020D100; RW)

Default PTYPE (when there is no match in PTYPE TCAM and node PTYPE is invalid).

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEF_PTYPE	9:0	0x0	RW	UNDEFINED	**Default PTYPE** Analyzer default PTYPE value.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.1.72 GLGEN_ANA_TX_CFG_CTRL - GLGEN_ANA_TX_CFG_CTRL (0x0020D104; RW)

Table's configuration control register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	17:0	0c0	RW	UNDEFINED	**Line Index** Target memory line.
TABLE_ID	25:18	0x0	RW	UNDEFINED	**Table ID** Target table: 0x00 = TCAM key 0x01 = Xlate table (ALU) 0x02 = PG spill buffer action 0x03 = PG spill buffer key 0x04 = PG mem0 - Holds all PG arches that sit at addr%8 0x05 = PG mem1 - Holds all PG arches that sit at addr%8 + 1 0x06 = PG mem2 - Holds all PG arches that sit at addr%8 + 2 0x07 = PG mem3 - Holds all PG arches that sit at addr%8 + 3 0x08 = PG mem4 - Holds all PG arches that sit at addr%8 + 4 0x09 = PG mem5 - Holds all PG arches that sit at addr%8 + 5 0x0A = PG mem6 - Holds all PG arches that sit at addr%8 + 6 0x0B = PG mem7 - Holds all PG arches that sit at addr%8 + 7 0x0C = Protocol group memory 0x0D = TCAM action RAM 0x0E = Instruction memory 0x0F = Node cntx ID 0x10 = marker group memory 0x11 = PTYPE TCAM key 0x12 = PTYPE TCAM action RAM 0x13 = no match PG spill buffer action 0x14 = no match PG spill buffer key 0x15 = no match PG mem0- Holds all PG arches that sit at addr%4 0x16 = no match PG mem1 - Holds all PG arches that sit at addr%4 + 1 0x17 = no match PG mem2 - Holds all PG arches that sit at addr%4 + 2 0x18 = no match PG mem3 - Holds all PG arches that sit at addr%4 + 3 0x19 = profiles table 0x1A = profile entity mapping table
RESERVED	28:26	000b	RSV	N/A	Reserved.
OPERATION _ID	31:29	000b	RW	UNDEFINED	**Operation ID** 000b = WR 001b = RD 010b = Lookup for hit index (PG and no match PG) 011b = Lookup for free index (in PG and no match PG) All other values are reserved. To lookup PG, need to select the first memory of PG. To lookup NM PG, need to select the first memory of NM PG.

13.2.2.1.73 GLGEN_ANA_TX_CFG_WRDATA - GLGEN_ANA_TX_CFG_WRDATA (0x0020D108; RW)

Table's configuration write data register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WR_DATA	31:0	0x0	RW	UNDEFINED	**Write Data** 32-bit write data.

13.2.2.1.74 GLGEN_ANA_TX_CFG_RDDATA - GLGEN_ANA_TX_CFG_RDDATA[n] (0x0020D10C + 0x4*n, n=0...15; RO)

Table's configuration read data registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RD_DATA	31:0	0x0	RO	N/A	**Read Data** 32-bit read data.

13.2.2.1.75 GLGEN_ANA_TX_CFG_LU_KEY - GLGEN_ANA_TX_CFG_LU_KEY[n] (0x0020D14C + 0x4*n, n=0...2; RW)

Key to lookup CSR.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LU_KEY	31:0	0x0	RW	UNDEFINED	**Lookup Key** KEY that is looked up when the lookup operations are selected.

13.2.2.1.76 GLGEN_ANA_TX_CFG_HTBL_LU_RESULT - GLGEN_ANA_TX_CFG_HTBL_LU_RESULT (0x0020D158; RO)

Lookup result from hash table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HIT	0	0b	RO	N/A	**Hit** For "look up for hit index" operation, this bit indicates if key is found in PG/NMPG tables. For "lookup for free index" operation, this bit indicates if there is a free entry in PG/NMPG tables.
PG_MEM_IDX	3:1	000b	RO	N/A	**PG Memory Index** For "look up for hit index" operation, this field indicates in which PG/NMPG memory the search key is found. For "lookup for free index" operation, this field indicates in which PG/NMPG memory the free entry is found.
ADDR	12:4	0x0	RO	N/A	**Address** For "look up for hit index" operation, this field indicates the memory address of the search key. For "lookup for free index" operation, this field indicates the memory address of the free entry.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.1.77 GLGEN_ANA_TX_CFG_SPLBUF_LU_RESULT - GLGEN_ANA_TX_CFG_SPLBUF_LU_RESULT (0x0020D15C; RO)

Lookup result for spill buffer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HIT	0	0b	RO	N/A	**Hit** For "look up for hit index" operation, this bit indicates if key is found in PG/NMPG spill buffer. For "lookup for free index" operation, this bit indicates if there is a free entry in PG/NMPG spill buffer.
RESERVED	3:1	000b	RSV	N/A	Reserved.
ADDR	12:4	0x0	RO	N/A	**Address** For "look up for hit index" operation, this field indicates the spill buffer address of the search key. For "lookup for free index" operation, this field indicates the spill buffer address of the free entry.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.1.78 GLGEN_ANA_TX_P2P - GLGEN_ANA_TX_P2P[n] (0x0020D160 + 0x4*n, n=0...15; RW)

Profile-to-profile mapping table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.1.79 GLGEN_ANA_TX_PG0_HASHKEY - GLGEN_ANA_TX_PG0_HASHKEY[n] (0x0020D1A0 + 0x4*n, n=0...3; RW)

Main parse graph unit0 hash key registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the hash key of the first part of the primary parse graph.

13.2.2.1.80 GLGEN_ANA_TX_NMPG0_HASHKEY - GLGEN_ANA_TX_NMPG0_HASHKEY[n] (0x0020D1B0 + 0x4*n, n=0...3; RW)

"No match" parse graph unit0 hash key registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the hash key of the first part of the "no match" parse graph.

13.2.2.1.81 GLGEN_ANA_TX_PG_KEYMASK - GLGEN_ANA_TX_PG_KEYMASK[n] (0x0020D1C0 + 0x4*n, n=0...3; RW)

Main parse graph key mask registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the key mask vector of the primary parse graph. When mask=1, the corresponding bit in the key is cleared. Effective key = key & ~mask.

13.2.2.1.82 GLGEN_ANA_TX_NMPG_KEYMASK - GLGEN_ANA_TX_NMPG_KEYMASK[n] (0x0020D1D0 + 0x4*n, n=0...3; RW)

"No match" parse graph key mask registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_KEY	31:0	0x0	RW	UNDEFINED	**Hash Key** Bits [32*(N+1)-1:32*N] of the key mask vector of the "no match" parse graph. When mask=1, the corresponding bit in the key is cleared. Effective key = key & ~mask.

13.2.2.1.83 GLGEN_ANA_TX_PROFIL_CTRL - GLGEN_ANA_TX_PROFIL_CTRL (0x0020D1FC; RW)

Number of profiles control register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROFILE_SELECT_MDID	4:0	0x0	RW	UNDEFINED	**Profile Select MDID** Used for extracting the "profile select entity" from input interfaces. This field describes the MDID from which the profile select entity is extracted.
PROFILE_SELECT_MDSTART	8:5	0x0	RW	UNDEFINED	**Profile Select MDID Start** The *MDstart* and *MDlen* fields define the "profile select entity" location in the MDID as follows: profile select entity = MDID[MDstart + MDlen -1 : MDID_start]
PROFILE_SELECT_MD_LEN	13:9	0x0	RW	UNDEFINED	**Profile Select MDID Length**
NUM_CTRL_DOMAIN	15:14	00b	RW	UNDEFINED	**Number of Control Domains** Defines the control domain key width in the PTYPE marker vector. 00b = 1 control domain (80 markers. No control domain bitmap.) 01b = 2 control domains (78 markers + 2b one-hot control domain bitmap). 10b = 4 control domains (76 markers + 4b one-hot control domain bitmap). 11b = 8 control domains (72 markers + 8b one-hot control domain bitmap).

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEF_PROF_ID	19:16	0x0	RW	UNDEFINED	**Default Profile ID** This profile is considered when the *SEL_DEF_PROF_ID* is set.
SEL_DEF_PROF_ID	20	0b	RW	UNDEFINED	**Select Default Profile ID** Select bit of the default Profile ID.
RESERVED	31:21	0x0	RSV	N/A	Reserved.

13.2.2.1.84 GLGEN_ANA_TX_NO_HIT_PG_NM_PG - GLGEN_ANA_TX_NO_HIT_PG_NM_PG (0x0020D204; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NPC	7:0	0xBF	RW	UNDEFINED	**NPC** Error exception handling PC. Activated when there is no hit either in PG or in no match PG.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.85 GLGEN_ANA_TX_ALU_ACCSS_OUT_OF_PKT - GLGEN_ANA_TX_ALU_ACCSS_OUT_OF_PKT (0x0020D208; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NPC	7:0	0xBF	RW	UNDEFINED	**NPC** Error exception handling PC. Activated when ALU tries to access outside the last byte valid of the 256b of data available or when PG does the same violation to build its key.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.86 GLGEN_ANA_TX_INV_NODE_PTYPE - GLGEN_ANA_TX_INV_NODE_PTYPE (0x0020D210; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INV_NODE_PTYPE	10:0	0x0	RW	UNDEFINED	**Invalid Node PTYPE** Invalid node PTYPE number.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.1.87 GLGEN_ANA_TX_INV_PROT_ID - GLGEN_ANA_TX_INV_PROT_ID (0x0020D214; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INV_PROT_ID	7:0	0xFF	RW	UNDEFINED	**Invalid Protocol ID** Invalid protocol ID.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.1.88 GLGEN_ANA_TX_INV_PTYPE_MARKER - GLGEN_ANA_TX_INV_PTYPE_MARKER (0x0020D218; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INV_PTYPE_MARKER	6:0	0x7F	RW	UNDEFINED	**Invalid PTYPE Marker** Invalid PTYPE marker number.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.1.89 GLGEN_ANA_TX_ABORT_PTYPE - GLGEN_ANA_TX_ABORT_PTYPE (0x0020D21C; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ABORT	9:0	0xFF	RW	UNDEFINED	**Abort** Abort PTYPE number reflected on output interface when malicious packet is detected.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.1.90 GLGEN_ANA_TX_ERR_CTRL - GLGEN_ANA_TX_ERR_CTRL (0x0020D220; RW)

Errors mask register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERR_MASK_EN	31:0	0xFFFFFFBF	RW	UNDEFINED	**Error Mask Enable** Per error type enable bit. When bit is cleared, error detection logic is not activated and error is not reported. Bit 0 = TCAM validity checks (for example: version field in ipv6 != 6). Bit 1 = HO is bigger pocket size. Bit 2 = There is no match in parse graph. Bit 3 = Illegal progress in parse graph (illegal leaf node). Bit 4 = HO is bigger than 504B (max header size). Bit 5 = Analyzer spent too many rounds on packet (number of cycles > fixed configured value). Bit 6 = Analyzer spent too many rounds on packet (number of cycles > packet cycles for performance). Bit 7 = ALU validity checks. Bit 8 = Packet has than 16 packet protocols Bit 9 = *total_ip* field not coherent to *pkt_len* field from interface. Bit 10 = ALU access outside the packet. Bit 11 = No hit in PG and no match PG.

13.2.2.1.91 GLGEN_ANA_TX_DFD_PACE_OUT - GLGEN_ANA_TX_DFD_PACE_OUT (0x0020D4CC; RW)

DFD pacing.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PUSH	0	0b	SC	UNDEFINED	**Push** Pace the output of the analyzer.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.2 PF - Internal Fuses Registers

13.2.2.2.1 SKU Fuses - GL_UFUSE_SOC (0x000A400C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_MODE	1:0	00b	RO	N/A	**Port Mode** Bit 1:0 in fuse map in Pull Fuse message. 00b = Octal Port 01b = Quad Port 10b = Dual Port 11b = Single Port
BANDWIDTH	3:2	00b	RO	UNDEFINED	**Bandwidth** Bit 3:2 in fuse map in Pull Fuse message. Maximum network speed: 00b = 200 Gb/s 01b = 100 Gb/s 10b = 50 Gb/s 11b = 25 Gb/s
PE_DISABLE	4	0b	RO	UNDEFINED	**PE Disable** Bit 4 in fuse map in Pull Fuse message. Controls the enablement of the PE engine: 0b = PE enabled. 1b = PE disabled.
SWITCH_MODE	5	0b	RO	UNDEFINED	**Switch Mode** Bit 5 in fuse map in Pull Fuse message. Switch mode enable: 0b = Switch mode enabled. 1b = Switch mode disabled.
CSR_PROTECTION_ENABLE	6	0b	RO	UNDEFINED	**CSR Protection Enable** Bit 6 in fuse map in Pull Fuse message. 0b = CSR Protection disabled. 1b = CSR Protection enabled.
RESERVED	8:7	0x0	RSV	N/A	Reserved.
BLOCK_BME_TO_FW	9	0b	RO	UNDEFINED	**Block BME Access to Firmware** Bit 9 in fuse map in Pull Fuse message. 0b = BME is writable by firmware. 1b = BME is not writable by firmware.
SOC_TYPE	10	0b	RO	UNDEFINED	**SoC Type** Bit 10 in fuse map in Pull Fuse message. 0b = ICX-D 1b = SNR
BTS_MODE	11	0b	RO	UNDEFINED	**BTS Mode** Bit 11 in fuse map in Pull Fuse message. 0b = BTS mode. 1b = Non-BTS mode.
RESERVED	31:12	0x0000F	RSV	N/A	Reserved.

13.2.2.3 PF - PCIe Registers

This category contains registers for PCIe configuration and control.

13.2.2.3.1 PFPCIe Subsystem ID - PFPCI_SUBSYSID (0x0009D880; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_SUBSYS_ID	15:0	0x0	RW	UNDEFINED	**PF Subsystem ID** Subsystem ID for this PF.
VF_SUBSYS_ID	31:16	0x0	RW	UNDEFINED	**VF Subsystem ID** Subsystem ID for VFs of this PF.

13.2.2.3.2 PCIe Functions Configuration - PFPCI_FUNC (0x0009D980; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FUNC_DIS	0	1b	RW	UNDEFINED	**Function Disable** Defines if the PCI function is enabled from the NVM. Exception: This bit is RO for PF0. It is always enabled and cannot be disabled from the NVM. 0b = Enabled 1b = Disabled Default: • 0b for PF0. • 1b for other functions.
ALLOW_FUNC_DIS	1	0b	RW	UNDEFINED	**Allow Function Disable** 0b = Asserting PCI_DIS_N has no effect on this PCI function. 1b = Asserting PCI_DIS_N disables this PCI function.
DIS_FUNC_ON_PORT_DIS	2	0b	RW	UNDEFINED	**Disable Function on Port Disable** Defines whether this PF is disabled when the DEV_DIS_N pin is asserted. 0b = Asserting DEV_DIS_N has no effect on this PCI function. 1b = Asserting DEV_DIS_N disables this PCI function.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.3.3 PCIe Function Status 1 - PFPCI_STATUS1 (0x0009DA00; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FUNC_VALID	0	0b	RO	N/A	**Function Valid** 0b = Function is disabled. 1b = Function is enabled. ***Note:*** This bit is valid to firmware even when the function is disabled.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.4 PCIe PM - PFPCI_PM (0x0009DA80; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PME_EN	0	0b	RW	UNDEFINED	**PME Enable** This read/write bit is used by the software device driver to generate a PME event without writing to the Power Management Control/Status Register (PMCSR) in the PCIe configuration space. ***Note:*** The internal PME Enablement is a logic OR function of the following: *PME_EN* flag in the PMCSR, *PME_EN* flag in the PFPCI_PM CSR, and *APME* flag in the PFPM_APM CSR. The bit is reset on STRST (Sticky Reset): bit is reset only on power-on reset (LAN_PWR_GOOD). When *AUX_PWR* = 0b, this bit is also reset when de-asserting PE_RST_N.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.5 PCIe Storage Class - PFPCI_CLASS (0x0009DB00; RO)

Contains per-PF configuration loaded from NVM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
STORAGE_CLASS	0	0b	RW	UNDEFINED	**Storage Class** 0b = The class code of this function is set to 0x020000 (LAN). 1b = The class code of this function is set to 0x010000 (SCSI).
RESERVED	1	0b	RSV	N/A	Reserved.
PF_IS_LAN	2	1b	RW	UNDEFINED	**PF is LAN** 0b = SAN function. 1b = LAN function.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.3.6 PCIe PF Device ID - PFPCI_DEVID (0x0009DE00; RO)

Contains the per-PF Device ID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_DEV_ID	15:0	0x374C	RW	UNDEFINED	**PF Device ID** Contains the device ID for this PF.
VF_DEV_ID	31:16	0x374D	RW	UNDEFINED	**VF Device ID** Contains the device ID for the VFs of this PF.

13.2.2.3.7 Clock Gating Events - GL_CLKGATE_EVENTS (0x0009DE70; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRIMARY_CLKGATE_EVENTS	15:0	0x0	RO	N/A	**Primary Clock Gating Events** P-IOSF Clock gating aliveness indication (increments every clock gating event - wraps around).
SIDEBAND_CLKGATE_EVENTS	31:16	0x0	RO	N/A	**Sideband Clock Gating Events** SB-IOSF Clock gating aliveness indication (increments every clock gating event - wraps around).

13.2.2.3.8 PCI BAR Control - GLPCI_LBARCTRL (0x0009DE74; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PREFBAR	0	1b	RW	UNDEFINED	**Prefetchable BAR** Prefetchable bit indication in the memory BAR and MSI-X BAR (should be set when 64-bit BARs are used). 0b = BARs are marked as non prefetchable. 1b = BARs are marked as prefetchable.
RESERVED	1	0b	RSV	N/A	Reserved.
PAGES_SPACE_EN_PF	2	0b	RW	UNDEFINED	**Pages Space Enable PF** When set, the PF switch mode memory space is accessible through the memory BAR
FLASH_EXPOSE	3	1b	RW	UNDEFINED	**Flash Exposed** When set, the Flash memory is accessible through the memory BAR.
PE_DB_SIZE	5:4	00b	RW	UNDEFINED	**PE Doorbell Size** Determines the size of the memory space allocated to the protocol engine doorbells in the PF BARs: 00b = Memory space is not allocated for PE doorbells. 01b = A 64 KB area is allocated. 10b = A (8 MB + 64 KB) area is allocated. 11b = Reserved.
RESERVED	8:6	111b	RSV	N/A	Reserved.
PAGES_SPACE_EN_VF	9	0b	RW	UNDEFINED	**Pages Space Enable PF** When set, the VF switch mode memory space is accessible through the memory BAR
RESERVED	10	0b	RSV	N/A	Reserved.
EXROM_SIZE	13:11	011b	RW	UNDEFINED	**Expansion ROM Size** This field indicates the size of the Expansion ROM BAR as = 64 KB x (2 ** EXROM_SIZE). 000b = 64 KB size. ... 111b = 8 MB size. Default value is 512 KB.
VF_PE_DB_SIZE	15:14	00b	RW	UNDEFINED	**VF PE Doorbell Size** Determines the size of the memory space allocated to the protocol engine doorbells in the VF BARs: 00b = Memory Space is not allocated for PE doorbells. 01b = An 8 KB area is allocated right after the legacy space (0x10000 ->0x11FFF). 10b = A 64 KB area is allocated (0x10000 ->0x20000). 11b = Reserved.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.9 PCIe Power Data Register - GLPCI_PWRDATA (0x0009DE7C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
D0_POWER	7:0	0x0	RW	UNDEFINED	**D0 Power** The value in this field is reflected in the PCI Power Management Data register of the LAN functions for D0 power consumption and dissipation (*Data_Select* = 0 or 4).

Field	Bit(s)	Init.	Type	CFG Policy	Description
COMM_POWER	15:8	0x0	RW	UNDEFINED	**Common Power** The value in this field is reflected in the PCI Power Management Data register of function 0 when the *Data_Select* field is set to 8 (common function).
D3_POWER	23:16	0x0	RW	UNDEFINED	**D3 Power** The value in this field is reflected in the PCI Power Management Data register of the LAN functions for D3 power consumption and dissipation (*Data_Select* = 3 or 7).
DATA_SCALE	25:24	00b	RW	UNDEFINED	**Data Scale** The value in this field reflects the *Data_Scale* field in the PCI PMCSR register.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.3.10 PCIe Serial Number MAC Address Low - GLPCI_SERL (0x0009DE80; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SER_NUM_L	31:0	0x0	RW	UNDEFINED	**Serial Number Low** The low DWord of the Ethernet MAC Address used to generate the PCIe serial number. The register contents is loaded from NVM. The location in NVM is pointed by the fourth item in the Auto-Generated Pointers Module. It is a per-device manufacturing value that represents the whole device. It can be set identical to the concatenated [PFPM_SAL1|PFPM_SAL0] words of the EMP Settings Module.

13.2.2.3.11 PCIe Serial Number MAC Address High - GLPCI_SERH (0x0009DE84; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SER_NUM_H	15:0	0x0	RW	UNDEFINED	**Serial Number High** The high word of the Ethernet MAC Address used to generate the PCIe serial number. The register contents is loaded from NVM. The location in NVM is pointed by the fifth item in the Auto-Generated Pointers Module. It is a per device manufacturing value which represents the whole device. It can be set identical to the concatenated [PFPM_SAH1|PFPM_SAH0] words of the EMP Settings Module.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.12 PCIe Capabilities Control - GLPCI_CAPCTRL (0x0009DE88; RW)

Determines PCIe capabilities supported by the device and that software is allowed to enable or disable.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VPD_EN	0	0b	RW	UNDEFINED	**VPD Enable** 0b = The PCIe VPD capability is not present and is not exposed. 1b = The PCIe VPD capability is present and exposed.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.13 PCIe Capabilities Support - GLPCI_CAPSUP (0x0009DE8C; RO)

Determines PCIe capabilities supported by the device.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCIE_VER	0	1b	RW	UNDEFINED	**PCIe Version** Determines the PCIe capability version. 0b = Capability version 0x1. 1b = Capability version 0x2.
RESERVED	1	0b	RSV	N/A	Reserved.
LTR_EN	2	0b	RW	UNDEFINED	**LTR Enable** 1b = Indicates support for PCIe Latency Tolerance Reporting (LTR) capability. This bit must be set to 0b (LTR is not supported by this product).
TPH_EN	3	1b	RW	UNDEFINED	**TPH Enable** 1b = Indicates support for the PCIe TPH requester capability.
ARI_EN	4	1b	RW	UNDEFINED	**ARI Enable** 1b = Indicates support for PCIe ARI capability.
IOV_EN	5	1b	RW	UNDEFINED	**IOV Enable** 1b = Indicates support for PCIe SR-IOV capability.
ACS_EN	6	1b	RW	UNDEFINED	**ACS Enable** 1b = Indicates support for PCIe ACS capability.
SEC_EN	7	1b	RW	UNDEFINED	**Secondary Enable** 1b = Indicates support for the secondary PCIe extended capability.
PASID_EN	8	0b	RW	UNDEFINED	**PASID Enable** 1b = Indicates support for PCIe PASID capability.
DLFE_EN	9	0b	RW	UNDEFINED	**Data Link Feature Enable** 1b = Indicates support for PCIe Data Link Feature capability.
GEN4_EXT_EN	10	0b	RW	UNDEFINED	**Gen4 Extended Enable** 1b = Indicates support for PCIe physical layer 13.0 GT/s extended capability.
GEN4_MARG_EN	11	0b	RW	UNDEFINED	**Gen4 Margining Enable** 1b = Indicates support for PCIe lane margining at receiver capability.
RESERVED	15:12	0x0	RSV	N/A	Reserved.
ECRC_GEN_EN	16	1b	RW	UNDEFINED	**ECRC Generation Enable** Loaded into the ECRC. Generation capable bit of the PCIe configuration registers.
ECRC_CHK_EN	17	1b	RW	UNDEFINED	**ECRC Check Enable** Loaded into the ECRC Check capable bit of the PCIe configuration registers.
IDO_EN	18	1b	RW	UNDEFINED	**IDO Enable** Enables ID-based ordering (IDO).
MSI_MASK	19	1b	RW	UNDEFINED	**MSI Mask** MSI per-vector masking setting. This bit is loaded to the masking bit (bit 8) in the message control of the MSI configuration capability structure.
CSR_CONF_EN	20	1b	RW	UNDEFINED	**CSR Configuration Enable** Enables access to CSRs via the PCI configuration space. See the section on Configuration Access to Internal Registers and Memories.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WAKUP_EN	21	0b	RW	UNDEFINED	**Wake-Up Enable** 1b = Wake-up in D3 is exposed in *PME_Support* field in Power Management Capabilities register
RESERVED	29:22	0x0	RSV	N/A	Reserved.
LOAD_SUBSYS_ID	30	0b	RW	UNDEFINED	**Load Subsystem IDs** 1b = Indicates that the device loads its PCIe sub-system ID and sub-system vendor ID from the NVM.
LOAD_DEV_ID	31	0b	RW	UNDEFINED	**Load Device ID** 1b = Indicates that the device loads its PCI device IDs from the NVM.

13.2.2.3.14 PCIe Link Capabilities - GLPCI_LINKCAP (0x0009DE90; RO)

Determines PCIe link capabilities supported by the device.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINK_SPEEDS_VECTOR	5:0	0x0	RW	UNDEFINED	**Supported Link Speeds Vector** Loaded to the Link Capabilities 2 register in the PCIe capability. Bit 0 = 5.0 GT/s Bit 1 = 8.0 GT/s Bits 5:2 = Reserved ***Note:*** 2.5 GT/s is always supported. Must be zero.
RESERVED	8:6	100b	RSV	N/A	Reserved.
MAX_LINK_WIDTH	12:9	0x7	RW	UNDEFINED	**Max Link Width** Loaded to the PCIe Link Capabilities register. 0x1 = Limit max link width to x1. 0x3 = Limit max link width to x4. 0x4 = Limit max link width to x8. 0x7 = Do not limit max link width. Negotiate to the max width supported by the link. All other values are reserved. Must be 0001b
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.3.15 PCIe PM Support - GLPCI_PMSUP (0x0009DE94; RO)

This register contains parameters that define PCIe power management support.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	7:0	0x97	RSV	N/A	Reserved.
L0S_ACC_LAT	10:8	011b	RW	UNDEFINED	**L0s Acceptable Latency** Loaded to the *Endpoint L0s Acceptable Latency* field in the PCIe Device Capabilities register.
L1_ACC_LAT	13:11	110b	RW	UNDEFINED	**L1s Acceptable Latency** Loaded to the *Endpoint L1 Acceptable Latency* field in the PCIe Device Capabilities register.
RESERVED	14	1b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
OBFF_SUP	16:15	00b	RW	UNDEFINED	**OBFF Supported** Loaded to the *OBFF Supported* field in the PCIe Device Capabilities 2 register. Must be set to 0b in the NVM (OBFF is not supported).
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.3.16 PCIe Revision ID - GLPCI_REVID (0x0009DE98; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NVM_REVID	7:0	0x0	RW	UNDEFINED	**NVM Revision ID** Value of the Rev ID loaded from the NVM. The actual value reflected in the config space is the XOR of this field with the GLPCI_DREVID.*DEFAULT_REVID* value.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.3.17 PCIe VF Capabilities Support - GLPCI_VFSUP (0x0009DE9C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VF_PREFETCH	0	1b	RW	UNDEFINED	**VF Prefetchable** 0b = IOV memory BAR and MSI-X BAR are declared as non-prefetchable. 1b = IOV memory BAR and MSI-X BAR are declared as prefetchable.
RESERVED	31:1	0x1	RSV	N/A	Reserved.

13.2.2.3.18 PCIe Global Config - GLPCI_CNF (0x0009DEA0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	1:0	00b	RSV	N/A	Reserved.
WAKE_PIN_EN	2	0b	RW	UNDEFINED	**WAKE Pin Enable** When set to 1b, enables the use of the WAKE pin for a PME event in all power states.
MSIX_ECC_BLOCK_DISABLE	3	0b	RW	UNDEFINED	**MSI-X ECC Block Disable** When set, MSI-X vector tables is not blocked after an ECC error event. This bit can also be used to release the MSI-X table as part of an ECC recovery flow by setting it and then clearing it again.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.3.19 PCIe Vendor ID - GLPCI_VENDORID (0x0009DEC8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VENDORID	15:0	0x8086	RW	UNDEFINED	**Vendor ID** Contains the Vendor ID exposed in offset 0x0 in the config space of all functions. A value of 0xFFFF is ignored.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.20 PCIe Subsystem ID - GLPCI_SUBVENID (0x0009DEE8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SUB_VEN_ID	15:0	0x8086	RW	UNDEFINED	**Subsystem Vendor ID** Loaded to the PCI configuration Subsystem Vendor ID register.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.21 PCIe PF Configuration - PFPCI_CNF (0x0009DF00; RO)

Contains per-PF configuration loaded from NVM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	1:0	00b	RSV	N/A	Reserved.
MSI_EN	2	1b	RW	UNDEFINED	**MSI Enable** Enables the MSI capability structure for this PCI function. 0b = MSI is disabled. 1b = MSI is enabled.
EXROM_DIS	3	0b	RW	UNDEFINED	**Expansion ROM Disable** 0b = The Expansion ROM BAR in the PCI configuration space is enabled. 1b = The Expansion ROM BAR in the PCI configuration space is disabled.
IO_BAR	4	0b	RW	UNDEFINED	**I/O BAR Support** 0b = I/O BAR is not supported. 1b = I/O BAR is supported.
INT_PIN	6:5	00b	RW	UNDEFINED	**Interrupt Pin** Controls the value advertised in the *Interrupt Pin* field of the PCI configuration header for this function. 00b = INTA# 01b = INTB# 10b = INTC# 11b = INTD# The value advertised in the PCI configuration header is the value loaded from NVM + 1.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.3.22 Posted Queue IOSF FIFO Status - PQ_FIFO_STATUS (0x0009DF40; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PQ_FIFO_COUNT	30:0	0x0	RO	N/A	**Posted Queue FIFO Count** Counter of PFB POSTED FIFO. Increases by 1 when the FIFO round is completed.
PQ_FIFO_EMPTY	31	1b	RO	UNDEFINED	**Posted Queue FIFO Empty** PFB POSTED FIFO is empty.

13.2.2.3.23 Push PE IF Status - GLPCI_PUSH_PE_IF_TO_STATUS (0x0009DF44; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLPCI_PUSH_PE_IF_TO_STATUS	0	0b	RW1C	UNDEFINED	**Push PE Interface Timeout Status** Once time-out is reached, the PCIe Push logic silently drains the push buffer in PCIe. Exiting this mechanism is done by CORER or writing 1b.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.24 PCIe VF Flush Done - PFPCI_VF_FLUSH_DONE[VF] (0x0009E000 + 0x4*VF, VF=0...255; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLUSH_DONE	0	0b	RO	N/A	**Flush Done** VF transaction pending bit. Reset by function level reset, and set when the pipe is clean.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.25 PCIe PF Flush Done - PFPCI_PF_FLUSH_DONE (0x0009E400; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLUSH_DONE	0	0b	RO	N/A	**Flush Done** PF transaction pending bit. Reset by function level reset, and set when the pipe is clean.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.26 PCIe VM Flush Done - PFPCI_VM_FLUSH_DONE (0x0009E480; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLUSH_DONE	0	0b	RO	N/A	**Flush Done** VM transaction pending bit. Reset by function level reset, and set when the pipe is clean.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.27 PCIe Configuration Indirect Access Data - PF_PCI_CIAD (0x0009E500; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** Used to access the configuration registers of the VF. It operates together with the PF_PCI_CIAA register as follows: • Reading this register returns the content of the register at offset = *ADDRESS* in the configuration space of VF index = *VF_NUM* (the ADDRESS and VF_NUM parameters are defined by the PF_PCI_CIAA register). • Writing to this register is gated by the *CONFIG_ACCESS_ENABLE* flag in the GL_PCI_DBGCTL register. If enabled, the value written to this register is programmed to the register at offset = *ADDRESS* in the configuration space of VF index = *VF_NUM*.

13.2.2.3.28 PF Configuration Indirect Access Address - PF_PCI_CIAA (0x0009E580; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADDRESS	11:0	0x0	RW	UNDEFINED	**Address** The configuration space address to access.
VF_NUM	19:12	0x0	RW	UNDEFINED	**VF Number** Defines the VF number to access. The VF number is the absolute VF number in the device. ***Note:*** The PF can access any VF (its own VFs as well as other VFs).
RESERVED	31:20	0x0	RSV	N/A	Reserved. Ignore on read. Write 0b.

13.2.2.3.29 PCIe VM Pending Index - PFPCI_VMINDEX (0x0009E600; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VMINDEX	9:0	0x0	RW	UNDEFINED	**VM Index** Software sets the VMINDEX that its transaction pending flag should be reflected in the PFPCI_VMPEND register. The VM index is an absolute index in the range of 0 through 767. It can only be set by software to VMs that the PF owns and only to VMs that are not assigned to a VF.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.3.30 PCIe VM Pending Status - PFPCI_VMPEND (0x0009E800; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PENDING	0	0b	RO	N/A	**PCIe Transaction Pending Status** The reported VM is controlled by the *VMINDEX* field in the PFPCI_VMINDEX register. This flag is set to 1b as long as there is at least one PCIe transaction pending for its completion.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.3.31 Function Requester ID Information Register - PF_FUNC_RID (0x0009E880; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FUNCTION_NUMBER	2:0	000b	RO	N/A	**Function Number** Function number assigned to the function based on BIOS/OS enumeration.
DEVICE_NUMBER	7:3	0x0	RO	N/A	**Device Number** No-ARI mode: Device number assigned to the function based on BIOS/OS enumeration. ARI mode: Upper 5 bits of the 8-bit function number.
BUS_NUMBER	15:8	0x0	RO	N/A	**Bus Number** Bus number assigned to the function based on BIOS/OS enumeration.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.32 Function Active and Power State - PFPCI_FACTPS (0x0009E900; RO)

This register provides different indications about the function status.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FUNC_POWER_STATE	1:0	00b	RO	N/A	**Function Power State** Power state indication of the function. 00b = Dr 01b = D3 10b = D0a 11b = D0u
RESERVED	2	0b	RSV	N/A	Reserved.
FUNC_AUX_EN	3	0b	RO	N/A	**Function Aux Enable** Reflects the Auxiliary Power PM Enable bit from the PCI configuration space.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.3.33 PCIe Statistic Control Register #5...#8 - GLPCI_GSCL_5_8[n] (0x0009E954 + 0x4*n, n=0...3; RW)

These registers control the operation of the leaky bucket counter n.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LBC_THRESHOLD_N	15:0	0x0	RW	UNDEFINED	**Leaky Bucket Counter Threshold n** Threshold for the leaky bucket counter n.
LBC_TIMER_N	31:16	0x0	RW	UNDEFINED	**Leaky Bucket Counter Timer n** Time period between decrementing the value in leaky bucket Counter n. The time period is defined in μs units.

13.2.2.3.34 PCIe Byte Counter High - GLPCI_BYTCTH_P (0x0009E970; RO)

A byte counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_BCT	31:0	0x0	RO	N/A	**PCIe Byte Counter High** Contains the high double-word of a 64-bit counter that counts PCIe payload bytes. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.3.35 PCIe Byte Counter Low - GLPCI_BYTCTL_P (0x0009E994; RO)

A byte counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_BCT	31:0	0x0	RO	N/A	**PCIe Byte Counter Low** Contains the low double-word of a 64-bit counter that counts PCIe payload bytes. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.3.36 PCIe Statistic Control Registers #2 - GLPCI_GSCL_2 (0x0009E998; RW)

This register defines the events counted by the performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GIO_EVENT_NUM_0	7:0	0x0	RW	UNDEFINED	**GIO Event Number 0** Event number that counter 0 counts (GSCN_0).
GIO_EVENT_NUM_1	15:8	0x0	RW	UNDEFINED	**GIO Event Number 1** Event number that counter 1 counts (GSCN_1).
GIO_EVENT_NUM_2	23:16	0x0	RW	UNDEFINED	**GIO Event Number 2** Event number that counter 2 counts (GSCN_2).
GIO_EVENT_NUM_3	31:24	0x0	RW	UNDEFINED	**GIO Event Number 3** Event number that counter 3 counts (GSCN_3).

13.2.2.3.37 PCIe Statistic Counter Registers #0...#3 - GLPCI_GSCN_0_3[n] (0x0009E99C + 0x4*n, n=0...3; RO)

These registers contain the performance counters 0-3.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EVENT_COUNTER	31:0	0x0	RO	N/A	**Event Counter** A 32-bit event counter. See the section on Performance and Statistics Counters. These registers are stuck at their maximum value of 0xFF...F.

13.2.2.3.38 PCIe Default Revision ID - GLPCI_DREVID (0x0009E9AC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEFAULT_REVID	7:0	0x0	RO	N/A	**Default Revision ID** Mirroring of default Rev ID prior to an NVM load.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.3.39 PCIe Packet Counter - GLPCI_PKTCT_P (0x0009E9B0; RO)

A packet counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_PCT	31:0	0x0	RO	N/A	**PCIe Packet Counter** A 32-bit counter that counts PCIe packets. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.3.40 PCIe Statistic Control Register #1 - GLPCI_GSCL_1_P (0x0009E9B4; RW)

This register controls the operation of the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GIO_COUNT_EN_0	0	0b	RW	UNDEFINED	**GIO Counter Enable 0** Enables PCIe statistic counter number 0.
GIO_COUNT_EN_1	1	0b	RW	UNDEFINED	**GIO Counter Enable 1** Enables PCIe statistic counter number 1.
GIO_COUNT_EN_2	2	0b	RW	UNDEFINED	**GIO Counter Enable 2** Enables PCIe statistic counter number 2.
GIO_COUNT_EN_3	3	0b	RW	UNDEFINED	**GIO Counter Enable 3** Enables PCIe statistic counter number 3.
LBC_ENABLE_0	4	0b	RW	UNDEFINED	**Leaky Bucket Counter Enable 0** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 0 operates in leaky bucket mode.
LBC_ENABLE_1	5	0b	RW	UNDEFINED	**Leaky Bucket Counter Enable 1** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 1 operates in leaky bucket mode.
LBC_ENABLE_2	6	0b	RW	UNDEFINED	**Leaky Bucket Counter Enable 2** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 2 operates in leaky bucket mode.
LBC_ENABLE_3	7	0b	RW	UNDEFINED	**Leaky Bucket Counter Enable 3** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 3 operates in leaky bucket mode.
RESERVED	27:8	0x0	RSV	N/A	Reserved.
GIO_64_BIT_EN	28	0b	RW	UNDEFINED	**GIO 64-bit Enable** Enables two 64-bit counters instead of four 32-bit counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GIO_COUNT_RESET	29	0b	RW1S	DYNAMIC	**GIO Counters Reset** Reset indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_STOP	30	0b	RW1S	DYNAMIC	**GIO Counters Stop** Stop indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_START	31	0b	RW1S	DYNAMIC	**GIO Counters Start** Start indication of PCIe statistic counters. Reading this bit returns a 0b.

13.2.2.3.41 PCIe Global Config 2 - GLPCI_CNF2 (0x000BE004; RO)

This register contains global status fields of PCIe configuration.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RO_DIS	0	0b	RW	UNDEFINED	**Relaxed Ordering Disable** 0b = Relaxed ordering is specified per request type. 1b = The device does not request any relaxed ordering transactions.
CACHELINE_SIZE	1	0b	RW	UNDEFINED	**Cache Line Size** Determines the system cache line size. 0b = 64 bytes 1b = 128 bytes This field is loaded from the NVM.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.3.42 PCIe Upper Address - GLPCI_UPADD (0x000BE0D4; RW)

This register is used to block PCIe master accesses above some address. See Section 3.1.5.7, "Blocking on Upper Address".

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	0	0b	RSV	N/A	Reserved.
ADDRESS	31:1	0x0	RW	UNDEFINED	**Address** Bits [31:1] correspond to bits [63:33] in the PCIe address space, respectively.

13.2.2.3.43 PCIe NPQ Config - GLPCI_NPQ_CFG (0x000BFD80; RW)

This register controls some parameters of NPQ.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EXTEND_TO	0	0b	RW	UNDEFINED	**Extend Timeout** Extends timeout in the permitted range. 0b = Max 1b = Min
SMALL_TO	1	0b	RW	UNDEFINED	**Small Timeout** Reduce timeout value for simulation

Field	Bit(s)	Init.	Type	CFG Policy	Description
WEIGHT_AVG	5:2	0x2	RW	UNDEFINED	**Weight Average** Controls the weight of the average filter for average round trip calculation.
NPQ_SPARE	15:6	0x0	RW	UNDEFINED	**NPQ Spare Bits** Spare bits.
NPQ_ERR_STAT	19:16	0x0	RO	N/A	**NPQ Error Status**
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.3.44 PCIe NPQ Watermark of Pipe Monitor - GLPCI_WATMK_CLNT_PIPEMON (0x000BFD90; RO)

This register reports the current value of pipe monitor in NPQ.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA_LINES	15:0	0x4D9	RO	N/A	**Data Lines** Amount of data lines available.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.3.45 PCIe Packet Counter - GLPCI_PKTCT_NP_C (0x000BFD9C; RO)

A packet counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_PCT	31:0	0x0	RO	N/A	**PCIe Packet Counter** A 32-bit counter that counts PCIe packets. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.3.46 PCIe Packet Counter - GLPCI_LATCT_NP_C (0x000BFDA0; RO)

A packet counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_LATENCY_COUNT	31:0	0x0	RO	N/A	**PCIe Latency Counter** When GPLCI_GSCL_0.*cfg_rt_event* = 0, maximal round trip. When GLPCI_GSCL_0.*cfg_rt_event* = 1, minimal round trip. When GLPCI_GSCL_0.*cfg_rt_event* = 2, average round trip.

13.2.2.3.47 PCIe Statistic Control Register #1 - GLPCI_GSCL_1_NP_C (0x000BFDA4; RW)

This register controls the operation of the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	7:0	0x0	RSV	N/A	Reserved.
RT_MODE	8	0b	RW	UNDEFINED	**RT Mode**

Field	Bit(s)	Init.	Type	CFG Policy	Description
RT_EVENT	13:9	0x0	RW	UNDEFINED	**RT Event** 0x0 = Max 0x1 = Min 0x2 = Average
RESERVED	28:14	0x0	RSV	N/A	Reserved.
GIO_COUNT_RESET	29	0b	RW1S	DYNAMIC	**GIO Count Reset** Reset indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_STOP	30	0b	RW1S	DYNAMIC	**GIO Count Stop** Stop indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_START	31	0b	RW1S	DYNAMIC	**GIO Count Start** Start indication of PCIe statistic counters. Reading this bit returns a 0b.

13.2.2.3.48 PCIe Byte Counter High - GLPCI_BYTCTH_NP_C (0x000BFDA8; RO)

A byte counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_BCT	31:0	0x0	RO	N/A	**PCIe Byte Counter High** Contains the high double word of a 64-bit counter that counts PCIe payload bytes. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.3.49 PCIe Byte Counter Low - GLPCI_BYTCTL_NP_C (0x000BFDAC; RO)

A byte counter used by the PCIe performance counters.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_COUNT_BW_BCT	31:0	0x0	RO	N/A	**PCIe Byte Counter Low** Contains the low double word of a 64-bit counter that counts PCIe payload bytes. This register gets stuck at its maximum value of 0xFF...F.

13.2.2.4 PF - MAC Registers

13.2.2.4.1 HSEC CONTROL Receive PFC ENABLE - PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE (0x001E3180; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_PAUSE_ENABLE	8:0	0x0	RW	UNDEFINED	**Rx Pause Enable** Rx priority flow control enable. This field is used to enable priority flow control per priority. When Bit[x] is set to 1b, PFC processing is enabled for priority-x Bit[8] is used to enable 802.3x flow control. ***Note:*** Priority flow control can be enabled only when the receive packet buffer of the port is configured for DCB mode.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.4.2 HSEC CONTROL Transmit PAUSE_ENABLE - PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE (0x001E31A0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_TX_PAUSE_ENABLE	8:0	0x0	RW	UNDEFINED	**Tx Pause Enable** Tx priority flow control enable. This field is used to enable priority flow control per priority. When Bit[x] is set to 1b, PFC packet transmission is enabled for Priority-X. Bit[8] is used to enable 802.3x flow control.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.4.3 HSEC CONTROL Receive ENABLE_GCP - PRTMAC_HSEC_CTL_RX_ENABLE_GCP (0x001E31C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_ENABLE_GCP	0	1b	RW	UNDEFINED	**Rx Enable GCP** When set to 1b and *rx_forward_control* is set to 0, flow control packets are terminated by the HSEC MAC. When set to 0b, both 802.3x and PFC packet processing is disabled and the HSEC MAC forwards all control packets. ***Note:*** To enable 802.3x and PFC functional packet processing, a dedicated enable bit must be configured.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.4.4 HSEC CONTROL Receive PAUSE_DA_UCAST_PART1 - PRTMAC_HSEC_CTL_RX_PAUSE_DA_UCAST_PART1 (0x001E3220; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_PAUSE_DA_UCAST_PART1	31:0	0x0	RW	UNDEFINED	**Rx Pause Destination Address Unicast Part 1** Unicast destination address for pause processing. Valid only if the UC address is enabled for control processing through RX_CHECK_UC_PPP/PCP/GPP/GCP.

13.2.2.4.5 HSEC CONTROL Receive PAUSE_DA_UCAST_PART2 - PRTMAC_HSEC_CTL_RX_PAUSE_DA_UCAST_PART2 (0x001E3240; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_PAUSE_DA_UCAST_PART2	15:0	0x0	RW	UNDEFINED	**Rx Pause Destination Address Unicast Part 2** Unicast destination address for pause processing. Valid only if the UC address is enabled for control processing through RX_CHECK_UC_PPP/PCP/GPP/GCP.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.6 HSEC CONTROL Receive PAUSE_SA_PART1 - PRTMAC_HSEC_CTL_RX_PAUSE_SA_PART1 (0x001E3280; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_PAUSE_SA_PART1	31:0	0x0	RW	UNDEFINED	**Rx Pause Source Address Part 1** Source address for pause processing.

13.2.2.4.7 HSEC CONTROL Receive PAUSE_SA_PART2 - PRTMAC_HSEC_CTL_RX_PAUSE_SA_PART2 (0x001E32A0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_PAUSE_SA_PART2	15:0	0x0	RW	UNDEFINED	**Rx Pause Source Address Part 2** Source address for pause processing.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.8 HSEC CONTROL Receive ENABLE_GPP - PRTMAC_HSEC_CTL_RX_ENABLE_GPP (0x001E34C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_ENABLE_GPP	0	0b	RW	UNDEFINED	**Rx Enable GPP** 1b = Enables 802.3x pause packet processing. ***Note:*** 802.3x pause is also referred to as Global Pause in HSEC registers.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.4.9 HSEC CONTROL Receive ENABLE_PPP - PRTMAC_HSEC_CTL_RX_ENABLE_PPP (0x001E35C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_ENABLE_PPP	0	0b	RW	UNDEFINED	**Rx Enable PPP** 1b = Enables priority pause packet processing.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.4.10 HSEC CONTROL Receive FORWARD_CONTROL - PRTMAC_HSEC_CTL_RX_FORWARD_CONTROL (0x001E36C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_RX_FORWARD_CONTROL	0	0b	RW	UNDEFINED	**Rx Forward Control** 0b = Causes the HSEC MAC to drop control packets. 1b = Indicates that the HSEC MAC forwards control packets to the user.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.4.11 HSEC CONTROL Transmit PAUSE_QUANTA - PRTMAC_HSEC_CTL_TX_PAUSE_QUANTA[n] (0x001E36E0 + 0x20*n, n=0...8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_TX_PAUSE_QUANTA	15:0	0xFFFF	RW	UNDEFINED	**Tx Pause Quanta** These nine buses indicate the quanta to be transmitted for each of the eight priorities in priority-based pause operation and the global pause operation. The value for *stat_tx_pause_quanta*[8] is used for global pause operation. All other values are used for priority pause operation.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.12 HSEC CONTROL Transmit PAUSE_REFRESH_TIMER - PRTMAC_HSEC_CTL_TX_PAUSE_REFRESH_TIMER[n] (0x001E3800 + 0x20*n, n=0...8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_TX_PAUSE_REFRESH_TIMER	15:0	0x0	RW	UNDEFINED	**Tx Pause Refresh Timer** These nine buses set the retransmission time of pause packets for each of the eight priorities in priority-based pause operation and the global pause operation. The value for *stat_tx_pause_refresh_timer*[8] is used for global pause operation. All other values are used for priority pause operation.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.13 HSEC CONTROL Transmit SA_GPP_PART1 - PRTMAC_HSEC_CTL_TX_SA_PART1 (0x001E3960; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_TX_SA_PART1	31:0	0x0	RW	UNDEFINED	**Tx Source Address Part 1** Source address for transmitting pause packets.

13.2.2.4.14 HSEC CONTROL Transmit SA_GPP_PART2 - PRTMAC_HSEC_CTL_TX_SA_PART2 (0x001E3980; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSEC_CTL_TX_SA_PART2	15:0	0x0	RW	UNDEFINED	**Tx Source Address Part 2** Source address for transmitting pause packets.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.15 MAC Rx Silent Drop Count - PRTMAC_RX_PKT_DRP_CNT (0x001E3C20; RW)

This register counts silent drop packets due to CORER, RX_ENABLE, and RPB overflow.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RX_PKT_DRP_CNT	15:0	0x0	RW1C	DYNAMIC	**Rx Packet Drop Count**
RX_MKR_PKT_DRP_CNT	31:16	0x0	RW1C	DYNAMIC	**Rx Marker Packet Drop Count**

13.2.2.4.16 MAC Rx Shift FC Quanta - PRTMAC_HSEC_CTL_RX_QUANTA_SHIFT (0x001E3C40; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRTMAC_HSEC_CTL_RX_QUANTA_SHIFT	15:0	0x0	RW	UNDEFINED	**Rx Quanta Shift** Shift left FC quanta counter values.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.17 MAC Rx Metadata Override Enable - PRTMAC_MD_OVRRIDE_ENABLE[n] (0x001E3C60 + 0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRTMAC_MD_OVRRIDE_ENABLE	31:0	0x0	RW	UNDEFINED	**Metadata Override Enable** Debug feature to force value on metadata Rx.

13.2.2.4.18 MAC Rx Metadata Override Value - PRTMAC_MD_OVRRIDE_VAL[n] (0x001E3D60 +0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRTMAC_MD_OVRRIDE_ENABLE	31:0	0x0	RW	UNDEFINED	**Metadata Override Enable** Debug feature to force value on metadata Rx.

13.2.2.4.19 Link Down Counter - PRTMAC_LINK_DOWN_COUNTER (0x001E47C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINK_DOWN_COUNTER	15:0	0x0	RW1C	DYNAMIC	**Link Down Counter** Increments on link down event. Does not do wrap around.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.20 Link UP Counter Limit - PRTMAC_TX_LNK_UP_CNT (0x001E4840; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TX_LINK_UP_CNT	15:0	0x50	RW	UNDEFINED	**Tx Link Up Counter** Link UP counter limit.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.21 MAC Markers Counter Tx - PRTMAC_TX_CNT_MRKR (0x001E48C0; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TX_CNT_MRKR	15:0	0x0	RW1C	DYNAMIC	**Tx Count Marker**
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.4.22 MAC Markers Counter Rx - PRTMAC_RX_CNT_MRKR (0x001E48E0; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RX_CNT_MRKR	15:0	0x0	RW1C	DYNAMIC	**Rx Count Marker**
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.5 PF - Power Management Registers

Registers related to LTR and EEE.

13.2.2.5.1 PME_TO Indication - GLGEN_PME_TO (0x000B81BC; RO)

This register reflects an incoming PME turn-off message.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PME_TO_FOR_PE	0	0b	RO	N/A	**PME Turn-Off for PE** The bit is set to 1b when a *PME_Turn_off* message is received on the sideband IOSF and cleared upon PE core reset de-assertion.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.5.2 Global Power Mode Control S5 - GL_PWR_MODE_DIVIDE_S5_H_CTRL (0x000B81EC; RO)

000b = No divide; 001b = Divide by 2; 010b = Divide by 4; 011b = Divide by 8; 100b = Divide by 16. All other values are reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DIV_VAL_TBW_50G_H	2:0	000b	RW	UNDEFINED	**Divide Value Total Bandwidth 50G** Core clock divide in S5 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 50G.
DIV_VAL_TBW_25G_H	5:3	001b	RW	UNDEFINED	**Divide Value Total Bandwidth 25G** Core clock divide in S5 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 25G.
DIV_VAL_TBW_10G_H	8:6	010b	RW	UNDEFINED	**Divide Value Total Bandwidth 10G** Core clock divide in S5 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 10G.
DIV_VAL_TBW_4G_H	11:9	011b	RW	UNDEFINED	**Divide Value Total Bandwidth 4G** Core clock divide in S5 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 4G.
DIV_VAL_TBW_A50G_H	15:12	0x0	RW	UNDEFINED	**Divide Value Total Bandwidth Above 50G** Core clock divide in S5 power mode when total bandwidth configuration is up to 100G, and total link speed is above 50G.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.5.3 Global Power Mode Control PE - GL_PWR_MODE_DIVIDE_S0_CTRL_H_PECLK (0x000B81F0; RO)

000b = No divide; 001b = Divide by 2; 010b = Divide by 4; 011b = Divide by 8; 100b = Divide by 16. All other values are reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DIV_VAL_TBW_50G_H	2:0	000b	RW	UNDEFINED	**Divide Value Total Bandwidth 50G** PE core clock divide in S0 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 50G
DIV_VAL_TBW_25G_H	5:3	001b	RW	UNDEFINED	**Divide Value Total Bandwidth 25G** PE core clock divide in S0 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 25G.
DIV_VAL_TBW_10G_H	8:6	010b	RW	UNDEFINED	**Divide Value Total Bandwidth 10G** PE core clock divide in S0 power mode when total bandwidth configuration is up to 100G, and total link speed is up to 10G.

13.2.2.5.28 Energy Efficient Ethernet (EEE) Status - PRTPM_EEE_STAT (0x001E4320; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	28:0	0x0	RSV	N/A	Reserved. Write 0. Ignore on read.
EEE_NEG	29	0b	RO	N/A	**EEE Negotiated** EEE support negotiated on link. 0b = EEE operation not supported on link. 1b = EEE operation supported on link.
RX_LPI_STATUS	30	0b	RO	N/A	**Rx LPI Status** Rx link in LPI state. 0b = Rx in Active state. 1b = Rx in LPI state.
TX_LPI_STATUS	31	0b	RO	N/A	**Tx LPI Status** Tx link in LPI state. 0b = Tx in Active state. 1b = Tx in LPI state.

13.2.2.5.29 Energy Efficient Ethernet (EEE) Register - PRTPM_EEER (0x001E4360; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TW_SYSTEM	15:0	0x0	RW	UNDEFINED	**TW System** Time expressed in microseconds that no data will be transmitted following move from EEE Tx LPI link state to Link Active state. Field holds the Transmit *Tw_sys_tx* value negotiated during EEE LLDP negotiation. ***Notes:*** 1. If value is lower than minimum *Tw_sys_tx* value defined in IEEE802.3az clause 78.5, then interval where no data is transmitted following move out of EEE Tx LPI state defaults to minimum *Tw_sys_tx*. 2. Following link disconnect or auto-negotiation, value of this field returns to default value, until software re-negotiates new *Tw_sys_tx* value via EEE LLDP. 3. Fast Retrain and Local/Remote Fault indication are not considered link disconnect, and do not cause the field to return to the default value. 4. When transmitting flow control frames, device waits the minimum time defined in the IEEE802.3az standard before transmitting the flow control packet. Device does not wait the *TW_SYSTEM* time following exit of LPI before transmitting the flow control frame.
TX_LPI_EN	16	0b	RW	UNDEFINED	**TW LPI Enable** Enable entry into EEE LPI on Tx path. 0b = Disable entry into EEE LPI on Tx path. 1b = Enable entry into EEE LPI on Tx path. ***Notes:*** 1. Even when *TX_LPI_EN* is 1b, device will not enable entry into Tx LPI state for at least PRTPM_EEEC.*TX_LU_LPI_DLY* following the change of *link_status* to OK as defined in IEEE802.3az clause 78.1.2.1. 2. Even if the *TX_LPI_EN* bit is set, device will initiate entry into Tx EEE LPI link state only if EEE support at the link speed was negotiated during auto-negotiation or forced by software to enable EEE on non AN protocols.
RESERVED	31:17	0x0	RSV	N/A	Reserved. Write 0. Ignore on read.

13.2.2.5.30 Energy Efficient Ethernet (EEE) Control - PRTPM_EEEC (0x001E4380; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	15:0	0x0	RSV	N/A	Reserved. Write 0. Ignore on read.
TW_WAKE_MIN	21:16	0xA	RW	UNDEFINED	**TW Wake Minimum** Minimum time (expressed in 1 microseconds) between sending a request to move into EEE Tx LPI and sending a request to move back to Active state. ***Note:*** If conditions to exit LPI during the *TW_WAKE_MIN* interval cease to exist, then device will not move out of Tx LPI after timer has expired.
RESERVED	23:22	00b	RSV	N/A	Reserved.
TX_LU_LPI_DLY	25:24	011b	RW	UNDEFINED	**Tx Link-Up LPI Delay** Delay to enable entry of Tx EEE LPI state following link-up indication. 00b = No delay 01b = 10 ms 10b = 100 ms 11b = 1 second ***Note:*** IEEE802.3az clause 78.1.2.1 defines delay of 1 second following link-up.
TEEE_DLY	31:26	0x3	RW	UNDEFINED	**Tx EEE Delay** Tx EEE LPI entry delay. Field defines delay to EEE entry once conditions to enter EEE LPI are detected. Field resolution is 1 µs. ***Notes:*** 1. If conditions to enter LPI during the *TEEE_DLY* interval cease to exist, device will not enter Tx LPI and continues normal operation. 2. Minimum configuration should be 0x1.

13.2.2.5.31 EEE Rx LPI Count - PRTPM_RLPIC (0x001E43A0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERLPIC	31:0	0x0	RO	N/A	**EEE Rx LPI Counter** Counts EEE Rx LPI entry events. A EEE Rx LPI event occurs when the receiver detects link partner entry into EEE (IEEE802.3az) LPI state. This register only increments if receives are enabled and EEE operation is enabled. Register is cleared on read.

13.2.2.5.32 EEE Tx LPI Count - PRTPM_TLPIC (0x001E43C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ETLPIC	31:0	0x0	RO	N/A	**EEE Tx LPI Counter** Counts EEE Tx LPI entry events. A EEE Tx LPI event occurs when the transmitter enters EEE (IEEE802.3az) LPI state. This register only increments if transmits are enabled and EEE operation is enabled. Register is cleared on read.

13.2.2.5.33 EEE Tx Control - PRTPM_EEETXC (0x001E43E0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TW_PHY	15:0	0x1	RW	UNDEFINED	**TW PHY** *TW_PHY* value is set by firmware and should accommodate for the time defined in IEEE802.3az for the per connected PHY technology *TW_PHY* with the addition of the proper per-PHY technology addition as defined in the GLPM_EEE_SU and GLPM_EEE_SU_EXT registers. Value defined in this field is expressed in 102.4 nanosecond resolution. ***Note:*** The idle time value defined by this field is used when moving out of EEE Tx LPI state to transmit flow control frames even if value specified in EEER.*TW_SYSTEM* field is higher.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.5.34 EEE Tx FW Done - PRTPM_EEEFWD (0x001E4400; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	30:0	0x0	RSV	N/A	Reserved.
EEE_FW_CONFIG_DONE	31	0b	RW	UNDEFINED	**EEE Firmware Configuration Done** Set by firmware to indicate that firmware configuration of the EEE parameters after link establishment is done. Cleared by hardware when link is down.

13.2.2.6 PF - Wake-Up Registers

13.2.2.6.1 Wake-Up Status Register - PFPM_WUS (0x0009DB80; RW1C)

This register is used to record statistics about all wake-up packets received. If a packet matches multiple criteria, then multiple bits could be set. Writing a 1b to any bit clears that bit.

This register is not cleared when PE_RST_N is asserted (excepted for *PME_STATUS* bit). It is only cleared when LAN_PWR_GOOD is de-asserted or when cleared by the software device driver.

Note: If additional packets are received that match one of the wake-up filters, after the original wake-up packet is received, the WUS register is not updated with the new match detection until the register is cleared.

Wakeup statuses are reported in this register also when no wake-up event is generated because a CRC error is detected on the presumed wake-up packet.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LNKC	0	0b	RW1C	DYNAMIC	**Link Change** Link status changed.
MAG	1	0b	RW1C	DYNAMIC	**Magic** Magic packet received.
PME_STATUS	2	0b	RW1C	DYNAMIC	**PME Status** This bit is set when device receives a wake-up event. It is the same as the *PME_Status* bit in the Power Management Control/Status Register (PMCSR). Writing a 1b to this bit also clears the *PME_Status* bit in the PMCSR. Bit is reset only on power-on reset (LAN_PWR_GOOD). When AUX_PWR = 0, bit is reset also on de-assertion of PE_RST_N.
MNG	3	0b	RW1C	DYNAMIC	**MNG** MNG wake-up status.
RESERVED	30:4	0x0	RSV	N/A	Reserved.
FW_RST_WK	31	0b	RW1C	DYNAMIC	**Firmware Reset Wake** Wake due to firmware reset assertion event. When set to 1b, indicates that firmware reset assertion caused system wake so that software driver can re-send proxying information to firmware.

13.2.2.6.2 Wake-Up Filter Control Register - PFPM_WUFC (0x0009DC00; RW)

This register is used to enable each of the pre-defined filters for wake-up support. A value of 1b means the filter is turned on, a value of 0b means the filter is turned off.

The bits reset only on power-on reset (LAN_PWR_GOOD) and on D3/Dr to D0 transitions.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LNKC	0	0b	RW	UNDEFINED	**Link Change** Link status change wake-up enable.
MAG	1	0b	RW	UNDEFINED	**Magic** Magic packet wake-up enable.
RESERVED	2	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MNG	3	0b	RW	UNDEFINED	**MNG** MNG wake-up enable.
RESERVED	30:4	0x0	RSV	N/A	Reserved.
FW_RST_WK	31	0b	RW	UNDEFINED	**Firmware Reset Wake** Enable wake on firmware reset assertion. When set a firmware reset causes system wake so that software driver can re-send Proxying information to firmware.

13.2.2.6.3 Wake-Up Control Register - PFPM_WUC (0x0009DC80; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	4:0	0x0	RSV	N/A	Reserved.
EN_APM_D0	5	0b	RW	UNDEFINED	**Enable APM D0** Enable APM wake also on D0. 0b = Enable wake only when function is in D3/Dr. 1b = Enable wake also in D0. Should be set for normal operation.
RESERVED	31:6	0x0	RSV	N/A	Reserved.

13.2.2.6.4 Wake-Up on MNG Control - GLPM_WUMC (0x0009DEE4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	15:0	0x0	RSV	N/A	Reserved.
MNG_WU_PF	23:16	0x0	RW	UNDEFINED	**MNG Wake-Up PF** *MNG_WU_PF* EMP can set a bit in this field to indicate MNG initiated wake-up event (bit per PF).
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.6.5 APM Control Register - PFPM_APM (0x000B8080; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
APME	0	0b	RW	UNDEFINED	**Advance Power Management Enable** If set to 1b, APM wake-up is enabled. ***Note:*** Bit is reset on Power on reset (LAN_PWR_GOOD) only.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.6.6 MAC Address Low - PRTPM_SAL[n] (0x001E3B20 + 0x20*n, n=0...3; RW)

This register contains the station address lower 32 bits of the 48-bit Ethernet MAC Address. It is loaded by firmware from NVM and can be altered later by PF driver admin command.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFPM_SAL	31:0	0x0	RW	UNDEFINED	**Station Address Low** The lower 32 bits of the 48-bit NVM pre-assigned Ethernet MAC Address. ***Note:*** Field is defined in Big Endian (LS byte of SAL is first on the wire).

13.2.2.6.7 MAC Address High - PRTPM_SAH[n] (0x001E3BA0 + 0x20*n, n=0...3; RW)

This register contains the station address upper 16 bits of the 48-bit Ethernet MAC Address. It is loaded by firmware from NVM and can be altered later by PF driver admin command.

PRTPM_SAH.*AV* determines whether this address is valid and compared against the incoming packet. After reset, firmware loads the relevant MAC Address from NVM, and sets its *Address Valid* field to 1b.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFPM_SAH	15:0	0x0	RW	UNDEFINED	**Station Address High** The upper 16 bits of the 48-bit Ethernet MAC Address. ***Note:*** Field is defined in Big Endian (MS byte of *PRTPM_SAH* is last on the wire).
RESERVED	25:16	0x0	RSV	N/A	Reserved.
PF_NUM	29:26	0x0	RW	UNDEFINED	**PF Number** PF number to be used for reporting the waking PF. Value is written by firmware.
MC_MAG_EN	30	0b	RW	UNDEFINED	**Multicast Magic Packet Enable** Enable promiscuous multicast for Magic Packets. If this bit is set to 1b, every multicast Magic Packet generates a WoL event if enabled in PFPM_WUFC.*MAG*
AV	31	0b	RW	UNDEFINED	**Address Valid** If the NVM is present, the station address is assigned by firmware after loading from the NVM and its *Address Valid* field is set to 1b

13.2.2.7 PF - NVM Registers

13.2.2.7.1 HLP Auto-Load Done Register - GLNVM_AL_DONE_HLP (0x000824C4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HLP_CORER	0	0b	RO	N/A	**HLP Core Reset** Auto-load done indication.
HLP_FULLR	1	0b	RO	N/A	**HLP Full Reset** Auto-load done indication.
RESERVED	31:2	0x0	RSV	N/A	**Reserved.**

13.2.2.7.2 Unit Load Status - GLNVM_ULD (0x000B6008; RO)

This register provides indications on the completion of loading the Shadow RAM and Alternate Module into the device units.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCIER_DONE	0	0b	RO	N/A	**PCIe Reset Done** The PCIe Reset process is done (all related registers are loaded).
PCIER_DONE_1	1	0b	RO	N/A	**PCIe Reset Done 1** The PCIe Reset process is done (all related registers are loaded). Mirror of Bit 0.
RESERVED	2	1b	RSV	N/A	Reserved.
CORER_DONE	3	0b	RO	N/A	**Core Reset Done** The Core Reset process is done (all related registers are loaded).
GLOBR_DONE	4	0b	RO	N/A	**Global Reset Done** The Global Reset process is done (all related registers are loaded).
POR_DONE	5	0b	RO	N/A	**Power On Reset Done** The Power On Reset process is done (all related registers are loaded).
RESERVED	7:6	11b	RSV	N/A	Reserved.
POR_DONE_1	8	0b	RO	N/A	**Power On Reset Done 1** The Power On Reset process is done (all related registers are loaded). Mirror of Bit 5.
PCIER_DONE_2	9	0b	RO	N/A	**PCIe Reset Done 2** The PCIe Reset process is done (all related registers are loaded). Mirror of bit 0.
PE_DONE	10	0b	RO	N/A	**Protocol Engine Done** The Protocol Engine Core Reset process is done (all related registers are loaded).
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.7.3 Protected CSR List - GLNVM_PROTCSR[n] (0x000B6010 + 0x4*n, n=0...59; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADDR_BLOCK	23:0	0xFFFFFF	RW	UNDEFINED	**CSR Blocked Address.** The field contains the address of a "blocked" register included in the CSR Protected List NVM module. Blocked registers cannot be loaded from a CSR format module (Type 1/2/3). The register is loaded from Shadow RAM at POR events only, and only from the CSR Protected List module in NVM. It can be written by EMP. It can be written by host only when in the blank Flash programming mode.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.7.4 Global NVM General Status Register - GLNVM_GENS (0x000B6100; RO)

This register cannot be loaded from NVM via one of the CSR format modules.

Field	Bit(s)	Init.	Type	CFG Policy	Description
NVM_PRES	0	0b	RW	N/A	**NVM Present** Setting this bit to 1b indicates that a Flash part is present and that a correct validity field was found in one of the two basic banks (i.e. validity field value read is 01b).
RESERVED	4:1	0x0	RSV	N/A	Reserved.
SR_SIZE	7:5	110b	RO	N/A	**Shadow RAM Size** This field defines the size of the internal Shadow RAM. The Shadow RAM size is equal to 2^*SR_Size* KB. Initial value is 110b, which corresponds to 2^6 = 64 KB.
BANK1VAL	8	0b	RW	N/A	**Basic Bank 1 Valid** 0b = Indicates that the content of basic banks 0 of the Flash device is valid. 1b = Indicates that the content of basic bank 1 of the Flash device is valid. Meaningful only when *NVM_PRES* bit is read as 1b. It is written by the hardware once at power-up, and then toggled only by EMP.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.7.5 Flash Access Register - GLNVM_FLA (0x000B6108; RO)

This register is writable by the host only when the device is in the blank Flash programming mode. It cannot be loaded from NVM via one of the CSR format modules.

Note: The access type in the PF and VF spaces is determined individually per field. The values are contained in the table that describes the fields in the internal space.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	5:0	0x0	RSV	N/A	Reserved.
LOCKED	6	1b	RW	UNDEFINED	**Locked** Normal NVM programming mode. 0b = The device is in the blank Flash programming mode. 1b = The device is in the normal NVM programming mode. The bit can be cleared by EMP or by software.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.7.6 Auto-Load Timers - GLNVM_ALTIMERS (0x000B6140; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_ALTIMER	11:0	0x010	RW	UNDEFINED	**PCIe Auto-Load Timer** Default is 16 to 15 ms. Resolution is in ms.
GEN_ALTIMER	31:12	0x0012C	RW	UNDEFINED	**General Auto-Load Timer** Default is ~ 300 ms. Resolution is in ms.

13.2.2.7.7 Unit Load Timeout - GLNVM_ULT (0x000B6154; RO)

This register cannot be loaded from NVM via one of the CSR format modules.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CONF_PCIR_AE	0	0b	RW	UNDEFINED	When set, indicates that the PCIe Auto-load Timer has ended before the respective NVM module has been initialized.
CONF_PCIRTL_AE	1	0b	RW	UNDEFINED	When set, indicates that the PCIe Auto-load Timer has ended before the respective NVM module has been initialized.
RESERVED	2	0b	RSV	N/A	Reserved.
CONF_CORE_AE	3	0b	RW	UNDEFINED	When set, indicates that the General Auto-load Timer has ended before the respective NVM module has been initialized.
CONF_GLOBAL_AE	4	0b	RW	UNDEFINED	When set, indicates that the General Auto-load Timer has ended before the respective NVM module has been initialized.
CONF_POR_AE	5	0b	RW	UNDEFINED	When set, indicates that the General Auto-load Timer has ended before the respective NVM module has been initialized.
RESERVED	8:6	000b	RSV	N/A	Reserved.
CONF_PCIALT_AE	9	0b	RW	UNDEFINED	When set, indicates that the PCIe Auto-load Timer has ended before the respective NVM module has been initialized.
CONF_PE_AE	10	0b	RW	UNDEFINED	When set, indicates that the PCIe Auto-load Timer has ended before the respective NVM module has been initialized.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.8 PF - Analyzer Registers (Pre Parser)

Registers used for the pre-parser analyzer configuration.

13.2.2.8.1 L2 Tag Data Low - GL_SWT_L2TAG0[n] (0x000492A8 + 0x4*n, n=0...7; RO)

The data to insert in the fixed part of the L2 tag. Which bytes to take is fixed by the L2TAGTXIB register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** L2TAG Data bytes. Fixed bytes 0-3 of the L2 tag. Unused part of these bytes and the word in which the variable part is inserted should be set to zero.

13.2.2.8.2 L2 Tag Data High - GL_SWT_L2TAG1[n] (0x000492C8 + 0x4*n, n=0...7; RO)

The data to insert in the fixed part of the L2 tag. Which bytes to take is fixed by the L2TAGTXIB register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** L2TAG Data bytes. Fixed bytes 4-7 of the L2 tag. Unused part of these bytes and the word in which the variable part is inserted should be set to zero.

13.2.2.8.3 L2 Tag Tx Insert Bytes - GL_SWT_L2TAGTXIB[n] (0x000492E8 + 0x4*n, n=0...7; RO)

This register describes where to insert the variable part for the tags.

Field	Bit(s)	Init.	Type	CFG Policy	Description
OFFSET	7:0	0x0	RW	UNDEFINED	**Offset** Describes the offset (in bytes) in the header to which the variable data should be inserted.
LENGTH	9:8	00b	RW	UNDEFINED	**Length** Defines the length of the tag to insert. 00b = 8 bits 01b = 16 bits 10b = 24 bits 11b = 32 bits
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.8.4 L2 Tag Rx Extract Bytes - GL_SWT_L2TAGRXEB[n] (0x00052000 + 0x4*n, n=0...7; RW)

Rx byte enable for L2 tag.

Field	Bit(s)	Init.	Type	CFG Policy	Description
OFFSET	7:0	0x0	RW	UNDEFINED	**Offset** Describes the offset in the header from which the variable data should be extracted. Offset is given in bytes and does not include the EtherType.
LENGTH	9:8	00b	RW	UNDEFINED	**Length** Variable part length. 00b = 8 bits 01b = 16 bits 10b = 24 bits 11b = 32 bits
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.8.5 L2 Tag Control - GL_SWT_L2TAGCTRL[n] (0x001D2660 + 0x4*n, n=0...7; RW)

Control register for L2 tags.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LENGTH	6:0	0x0	RW	UNDEFINED	**Length** Describes the number of bytes expected for this tag, not including the EtherType (2/4/6/8 if *LONG* bit is not set, any value otherwise). Length is in bytes (up to 126).
HAS_UP	7	0b	RW	UNDEFINED	**Has UP** Indicates that this tag has a UP field, and this field should be taken into account for UP-to-TC translation if this is the first tag of the packet.
RESERVED	8	0b	RSV	N/A	Reserved.
ISVLAN	9	0b	RW	UNDEFINED	**Is VLAN** If this bit is set, this tag is a VLAN tag. In this case, a tag with VLAN ID = 0 is treated as untagged (priority tagging) and the priority bits can be extracted to the Rx-Descriptor.
INNERUP	10	0b	RW	UNDEFINED	**Inner UP** If this bit is set, the UP remapping is done on this field. Should be set only on one tag. If this bit is set, the *ISVLAN* bit should also be set.
OUTERUP	11	0b	RW	UNDEFINED	**Outer UP** If this bit is set, this is the tag on which the inner-to-outer UP remapping is applied. Should be set only in one tag.
LONG	12	0b	RW	UNDEFINED	**Long** Do not support insert of entire header. In this case, the length can be higher than 8 bytes.
ISMPLS	13	0b	RW	UNDEFINED	**Is MPLS** Identifies the tags that contain a MPLS EtherType. This bit should be set for tags 6 (MPLS unicast) and 7 (MPLS multicast).
ISNSH	14	0b	RW	UNDEFINED	**Is NSH** Identifies the tags that contains a NSH EtherType.
RESERVED	15	0b	RSV	N/A	Reserved.
ETHERTYPE	31:16	0x0	RW	UNDEFINED	**EtherType** The EtherType identifying the L2 tag.

13.2.2.9 PF - FlexiPipe Registers

Registers used to configure the generic parts of the FlexiPipe. Registers specific to the analyzer, switch, ACL or filters are described in their respective sections.

13.2.2.9.1 Force Profile ID - GL_PSTEXT_FORCE_PID[n] (0x0020E000 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
STATIC_PID	15:0	0x1	RW	UNDEFINED	**Static Profile ID** Selected Profile ID if *STATIC_PID_EN* is set.
RESERVED	30:16	0x0	RSV	N/A	Reserved.
STATIC_PID_EN	31	1b	RW	UNDEFINED	**Static Profile ID Enable** Enable static Profile ID selection.

13.2.2.9.2 Profile Level Selector - GL_PSTEXT_PLVL_SEL[n] (0x0020E00C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PLVL_SEL	0	1b	RW	UNDEFINED	**Profile Level Select** 0b = Profile selected by L1 profile (CDID). 1b = Profile selected by L2 profile.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.9.3 L1 Force CDID - GL_PSTEXT_FORCE_L1CDID[n] (0x0020E018 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
STATIC_CDID	3:0	0x0	RW	UNDEFINED	**Static CDID** Static CDID index to be used when static CDID is enabled.
RESERVED	30:4	0x0	RSV	N/A	Reserved.
STATIC_CDID_EN	31	0b	RW	UNDEFINED	**Static CDID Enable** Enable static CDID selection.

13.2.2.9.4 L1 P2P Table Configuration Address - GL_PSTEXT_P2P_L1ADDR[n] (0x0020E024 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	0	0b	RW	UNDEFINED	**Line Index** XLT0 SRAM output to XLT0_CDID translation table entry address.
RESERVED	30:1	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* value on every P2P_L1DATA write/read.

13.2.2.9.5 L1 P2P Table Configuration Data - GL_PSTEXT_P2P_L1DATA[n] (0x0020E030 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** XLT0 SRAM output to XLT0_CDID translation table entry data

13.2.2.9.6 XLT0 Table Configuration Address - GL_PSTEXT_XLT0_L1ADDR[n] (0x0020E03C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	7:0	0x0	RW	UNDEFINED	**Line Index** XLT0 memory address.
RESERVED	30:8	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every XLT0_L1DATA write/read.

13.2.2.9.7 XLT0 Table Configuration Data - GL_PSTEXT_XLT0_L1DATA[n] (0x0020E048 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** XLT0 entry data.

13.2.2.9.8 L1 Bidirectional CTL - GL_PSTEXT_CDMD_L1SEL[n] (0x0020E054 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RX_SEL	4:0	0x0	RW	UNDEFINED	**Rx Select** Selects which MDID is used to select md0 input to XLT0 for Rx traffic.
RESERVED	7:5	000b	RSV	N/A	Reserved.
TX_SEL	12:8	0x0	RW	UNDEFINED	**Tx Select** Selects which MDID is used to select md0 input to XLT0 for Tx traffic.
RESERVED	15:13	000b	RSV	N/A	Reserved.
AUX0_SEL	20:16	0x0	RW	UNDEFINED	**Aux 0 Select** Selects which MDID is used to select md0 input to XLT0 for Rx traffic.
RESERVED	23:21	000b	RSV	N/A	Reserved.
AUX1_SEL	28:24	0x0	RW	UNDEFINED	**Aux 1 Select** Selects which MDID is used to select md0 input to XLT0 for Rx traffic
RESERVED	29	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
BIDIR_ENA	31:30	00b	RW	UNDEFINED	**Bidirectional Enable** 00b = Direction not part of XLT0 input. 01b = LSB bit of direction (GL_PSTEXT_FLGS_L1TBL output) is part of XLT0 input. 10b = Two bits of direction (GL_PSTEXT_FLGS_L1TBL output) are part of XLT0 input. 11b = Reserved.

13.2.2.9.9 L1 Flag Select Table - GL_PSTEXT_FLGS_L1TBL[n] (0x0020E060 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LSB	15:0	0x0	RW	UNDEFINED	**LSB** A 4b->1b (16 entry) table maps the Flags values into a direction indication (LSB).
MSB	31:16	0x0	RW	UNDEFINED	**MSB** A 4b->1b (16 entry) table maps the Flags values into a direction indication (MSB).

13.2.2.9.10 L1 Flag Select Control (0-1) - GL_PSTEXT_FLGS_L1SEL0_1[n] (0x0020E06C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLS0	8:0	0x0	RW	UNDEFINED	**Flag Select 0** Index of first flag used to define the direction from list of flags described in the "MDID Namespace" section.
RESERVED	15:9	0x0	RSV	N/A	Reserved.
FLS1	24:16	0x0	RW	UNDEFINED	**Flag Select 1** Index of second flag used to define the direction from list of flags described in the "MDID Namespace" section
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.9.11 L1 Flag Select Control (2-3) - GL_PSTEXT_FLGS_L1SEL2_3[n] (0x0020E078 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLS2	8:0	0x0	RW	UNDEFINED	**Flag Select 2** Index of third flag used to define the direction from list of flags described in the "MDID Namespace" section.
RESERVED	15:9	0x0	RSV	N/A	Reserved.
FLS3	24:16	0x0	RW	UNDEFINED	**Flag Select 3** Index of fourth flag used to define the direction from list of flags described in the "MDID Namespace" section
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.9.12 L2 Configuration Table Address - GL_PSTEXT_CTLTBL_L2ADDR[n] (0x0020E084 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_OFF	2:0	000b	RW	UNDEFINED	**Line Offset** Data selection for CTLTBL_L2DATA (see Section 13.2.2.9.13). Valid values are 0...4.
RESERVED	7:3	0x0	RSV	N/A	Reserved.
LINE_IDX	10:8	000b	RW	UNDEFINED	**Line Index** CDID selection for MDID digest builder configuration.
RESERVED	30:11	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Auto-increment enable. When this bit is set, the hardware auto-increments the *LINE_OFF* for every write/read of CTLTBL_L2DATA, while incrementing *LINE_IDX* each time *LINE_OFF* reaches 0x4. *LINE_OFF* wraps around on 0x4 value.

13.2.2.9.13 L2 Configuration Table Data - GL_PSTEXT_CTLTBL_L2DATA[n] (0x0020E090 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** CTLTBL data according to CTLTBL_L2ADDR.*LINE_OFF*. For *LINE_OFF* = 0x0 [2:0] = xlt1_adsel [5:3] = xlt2_adsel [14:6] = flg0_sel [23:15] = flg1_sel [31:24] = flg2_sel[7:0] For *LINE_OFF* = 0x1 [0:0] = flg2_sel[5] [9:1] = flg3_sel [10:18] = flg4_sel [27:19] = flg5_sel [31:28] = flg6_sel[3:0] For *LINE_OFF* = 0x2 [4:0] = flg6_sel[8:4] [13:5] = flg7_sel [22:14] = flg8_sel [31:23] = flg9_sel For *LINE_OFF* = 0x3 [8:0] = flg10_sel [17:9] = flg11_sel [26:18] = flg12_sel [31:27] = flg13_sel[4:0] For *LINE_OFF* = 0x4 [3:0] = flg13_sel[5:2] [12:4] = flg14_sel [21:13] = Reserved [26:22] = xlt2_mdsel [31:27] = xlt1_mdsel

13.2.2.9.14 XLT1, XLT2 Partition Mode - GL_PSTEXT_L2PRTMOD[n] (0x0020E09C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
XLT1	1:0	00b	RW	UNDEFINED	**XLT1** Selects the size of the partitions of XLT1: 00b = Single 8K entries partition. 01b = Two 4K entries partitions (selection by xlt1_adsel[0]). 10b = Four 2K entries partitions (selection by xlt1_adsel[1:0]. 11b = Eight 1K entries partitions (selection by xlt1_adsel[2:0].
RESERVED	7:2	0x0	RSV	N/A	Reserved.
XLT2	9:8	00b	RW	UNDEFINED	**XLT2** Selects the size of the partitions of XLT2: 00b = Single 1K entries partition. 01b = Two 512 entries partitions (selection by xlt2_adsel[0]). 10b = Four 256 entries partitions (selection by xlt2_adsel[1:0]. 11b = Eight 128 entries partitions (selection by xlt2_adsel[2:0].
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.9.15 XLT1 Table Configuration Address - GL_PSTEXT_XLT1_L2ADDR[n] (0x0020E0C0 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	10:0	0x0	RW	UNDEFINED	**Line Index** XLT1 memory address.
RESERVED	30:11	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every XLT1_L2DATA write/read.

13.2.2.9.16 XLT1 Table Configuration Data - GL_PSTEXT_XLT1_L2DATA[n] (0x0020E0CC + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** XLT1 memory entry data. Four consequent entries are read/written at once: [7:0] = Offset 0 [15: 8] = Offset 1 [23:16] = Offset 2 [31:24] = Offset 3

13.2.2.9.17 XLT2 Table Configuration Address - GL_PSTEXT_XLT2_L2ADDR[n] (0x0020E0D8 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	8:0	0x0	RW	UNDEFINED	**Line Index** XLT2 memory entry address.
RESERVED	30:9	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every XLT2_L2DATA write/read.

13.2.2.9.18 XLT2 Table Configuration Data - GL_PSTEXT_XLT2_L2DATA[n] (0x0020E0E4 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** XLT2 memory entry data. Two consequent entries are read/written at once: [15:0] = Offset 0 [31:16] = Offset 1

13.2.2.9.19 Profile ID Gen Key Type - GL_PSTEXT_PID_L2GKTYPE[n] (0x0020E0F0 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PID_GKTYPE	1:0	00b	RW	UNDEFINED	**Profile ID Gen Key Type** 00b = CD bitmap not part of key. 01b = 2 bits of CD bitmap are part of key. 10b = 4 bits of CD bitmap are part of key. 11b = 8 bits of CD bitmap are part of key.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.9.20 Profile Key Mask (LSB) - GL_PSTEXT_L2_PMASK0[n] (0x0020E0FC + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BITMASK	31:0	0x0	RW	UNDEFINED	**Bitmask** MDID digest mask (32 LSBs).

13.2.2.9.21 Profile Key Mask (MSB) - GL_PSTEXT_L2_PMASK1[n] (0x0020E108 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BITMASK	15:0	0x0	RW	UNDEFINED	**Bitmask** MDID digest mask (16 MSBs).
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.9.22 TCAM Configuration (Address) - GL_PSTEXT_TCAM_L2ADDR[n] (0x0020E114 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	9:0	0x0	RW	UNDEFINED	**Line Index** TCAM entry index.
RESERVED	30:10	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every TCAM_L2DATAMSB write/read.

13.2.2.9.23 TCAM Configuration LSB (Data) - GL_PSTEXT_TCAM_L2DATALSB[n] (0x0020E120 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATALSB	31:0	0x0	RW	UNDEFINED	**Data LSB** TCAM entry/inverted mask data (LSB).

13.2.2.9.24 TCAM Configuration MSB (Data+Mask) - GL_PSTEXT_TCAM_L2DATAMSB[n] (0x0020E12C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATAMSB	7:0	0x0	RW	UNDEFINED	**Data MSB** TCAM entry/inverted mask data (MSB).
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.9.25 L2 Default Profile - GL_PSTEXT_DFLT_L2PRFL[n] (0x0020E138 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DFLT_PRFL	15:0	0x1	RW	UNDEFINED	**Default Profile** Profile IDX chosen when “no hit” in the TCAM.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.9.26 K2N Table Configuration Address - GL_PSTEXT_K2N_L2ADDR[n] (0x0020E144 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	6:0	0x0	RW	UNDEFINED	**Line Index** TCAM entry to Profile ID mapping entry index (each index serves four TCAM entries).
RESERVED	30:7	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every K2N_L2DATA write/read.

13.2.2.9.27 K2N Table Configuration Data - GL_PSTEXT_K2N_L2DATA[n] (0x0020E150 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA0	7:0	0x0	RW	UNDEFINED	**Data 0** TCAM entry #(4*K2N_L2ADDR.*LINE_IDX*) destination Profile ID.
DATA1	15:8	0x0	RW	UNDEFINED	**Data 1** TCAM entry #(4*K2N_L2ADDR.*LINE_IDX*+1) destination Profile ID.
DATA2	23:16	0x0	RW	UNDEFINED	**Data 2** TCAM entry #(4*K2N_L2ADDR.*LINE_IDX*+2) destination Profile ID.
DATA3	31:24	0x0	RW	UNDEFINED	**Data 3** TCAM entry #(4*K2N_L2ADDR.*LINE_IDX*+3) destination Profile ID.

13.2.2.9.28 K2N Table Configuration Address - GL_PSTEXT_N2N_L2ADDR[n] (0x0020E15C + 0x4*n, n=0...2; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LINE_IDX	5:0	0x0	RW	UNDEFINED	**Line Index** N2N table mapping entry index (each index serves four entries).
RESERVED	30:6	0x0	RSV	N/A	Reserved.
AUTO_INC	31	0b	RW	UNDEFINED	**Auto-Increment** Enable auto-increment. When this bit is set, the hardware automatically increments the *LINE_IDX* on every K2N_L2DATA write/read.

13.2.2.9.29 K2N Table Configuration Data - GL_PSTEXT_N2N_L2DATA[n] (0x0020E168 + 0x4*n, n=0...2; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA0	7:0	0x0	RW	UNDEFINED	**Data 0** K2N entry #(4*N2N_L2ADDR.*LINE_IDX*) destination Profile ID.
DATA1	15:8	0x0	RW	UNDEFINED	**Data 1** K2N entry #(4*N2N_L2ADDR.*LINE_IDX*+1) destination Profile ID.
DATA2	23:16	0x0	RW	UNDEFINED	**Data 2** K2N entry #(4*N2N_L2ADDR.*LINE_IDX*+2) destination Profile ID.
DATA3	31:24	0x0	RW	UNDEFINED	**Data 3** K2N entry #(4*N2N_L2ADDR.*LINE_IDX*+3) destination Profile ID.

13.2.2.9.30 Profile Memory Configuration Data - GL_PSTEXT_PRFLM_DATA_0[n] (0x0020E174 + 0x4*n, n=0...63; RO)

This register array is used by the PE to program QH filter entries.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT	7:0	0x0	RW	UNDEFINED	**Protocol ID** Protocol ID in this FV location.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
OFF	24:16	0x0	RW	UNDEFINED	**Offset** Offset within protocol header.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.9.31 Profile Memory Configuration Data - GL_PSTEXT_PRFLM_DATA_1[n] (0x0020E274 + 0x4*n, n=0...63; RO)

This register array is used by the PE to program QH filter entries.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT	7:0	0x0	RW	UNDEFINED	**Protocol ID** Protocol ID in this FV location.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
OFF	24:16	0x0	RW	UNDEFINED	**Offset** Offset within protocol header.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.9.32 Profile Memory Configuration Data - GL_PSTEXT_PRFLM_DATA_2[n] (0x0020E374 + 0x4*n, n=0...63; RO)

This register array is used by the PE to program QH filter entries.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT	7:0	0x0	RW	UNDEFINED	**Protocol ID** Protocol ID in this FV location.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
OFF	24:16	0x0	RW	UNDEFINED	**Offset** Offset within protocol header.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.9.33 Profile Memory Configuration Control - GL_PSTEXT_PRFLM_CTRL[n] (0x0020E474 + 0x4*n, n=0...2; RO)

This register is used by the PE to program QH filter entries.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRFL_IDX	7:0	0x0	RW	UNDEFINED	**Profile Index** Programmed/read profile index.
RESERVED	29:8	0x0	RSV	N/A	Reserved.
RD_REQ	30	0b	RW	UNDEFINED	**Read Req** Setting the *RD_REQ* flag by the programming entity, the Profile "recipe" is written to GL_PSTEXT_PRFLM_DATA_[n] array, n=0..2. The *RD_REQ* flag is auto-cleared when the programming is received from the Profile "Recipe" Memory.
WR_REQ	31	0b	RW	UNDEFINED	**Write Req** Setting the *WR_REQ* flag by the programming entity, the Profile "recipe" is programmed by data previously written to GL_PSTEXT_PRFLM_DATA_[n] array, n=0..2. The *WR_REQ* flag is auto-cleared when the programming is sent to the Profile "Recipe" Memory.

13.2.2.9.34 PG L2 Flag15 Bitmask (LSB) - GL_PSTEXT_FL15_BMPLSB[n] (0x0020E480 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMPLSB	31:0	0x0	RW	UNDEFINED	**Bitmap LSB** 32 LSBs of bitmask used for "flag 15" calculation.

13.2.2.9.35 PG L2 Flag15 Bitmask (MSB) - GL_PSTEXT_FL15_BMPMSB[n] (0x0020E48C + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMPMSB	31:0	0x0	RW	UNDEFINED	**Bitmap MSB** 32 MSBs of bitmask used for "flag 15" calculation.

13.2.2.9.36 Profile Key Mask (LSB) - GL_PSTEXT_L2_TMASK0[n] (0x0020E498 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BITMASK	31:0	0x0	RW	UNDEFINED	**Bitmask** TCAM input mask (32 LSBs).

13.2.2.9.37 Profile Key Mask (MSB) - GL_PSTEXT_L2_TMASK1[n] (0x0020E4A4 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BITMASK	7:0	0x0	RW	UNDEFINED	**Bitmask** TCAM input mask (8 MSBs).
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.9.38 Force Profile ID - GL_PREEXT_FORCE_PID[n] (0x0020F000 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.1.

13.2.2.9.39 Profile Level Selector - GL_PREEXT_PLVL_SEL[n] (0x0020F00C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.2.

13.2.2.9.40 L1 Force CDID - GL_PREEXT_FORCE_L1CDID[n] (0x0020F018 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.3.

13.2.2.9.41 L1 P2P Table Configuration Address - GL_PREEXT_P2P_L1ADDR[n] (0x0020F024 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.4.

13.2.2.9.42 L1 P2P Table Configuration Data - GL_PREEXT_P2P_L1DATA[n] (0x0020F030 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.5.

13.2.2.9.43 XLT0 Table Configuration Address - GL_PREEXT_XLT0_L1ADDR[n] (0x0020F03C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.6.

13.2.2.9.44 XLT0 Table Configuration Data - GL_PREEXT_XLT0_L1DATA[n] (0x0020F048 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.7.

13.2.2.9.45 L1 Bidirectional CTL - GL_PREEXT_CDMD_L1SEL[n] (0x0020F054 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.8.

13.2.2.9.46 L1 Flag Select Table - GL_PREEXT_FLGS_L1TBL[n] (0x0020F060 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.9.

13.2.2.9.47 L1 Flag Select Control (0-1) - GL_PREEXT_FLGS_L1SEL0_1[n] (0x0020F06C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.10.

13.2.2.9.48 L1 Flag Select Control (2-3) - GL_PREEXT_FLGS_L1SEL2_3[n] (0x0020F078 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.11.

13.2.2.9.49 L2 Configuration Table Address - GL_PREEXT_CTLTBL_L2ADDR[n] (0x0020F084 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.12.

13.2.2.9.50 L2 Configuration Table Data - GL_PREEXT_CTLTBL_L2DATA[n] (0x0020F090 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.13.

13.2.2.9.51 XLT1, XLT2 Partition Mode - GL_PREEXT_L2PRTMOD[n] (0x0020F09C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.14.

13.2.2.9.52 PG L2 CDID Bitmap (LSB) - GL_PREEXT_L2BMP0_3[n] (0x0020F0A8 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMP0	7:0	0x1	RW	UNDEFINED	**Bitmap 0** One-hot encoding for CDID 0.
BMP1	15:8	0x2	RW	UNDEFINED	**Bitmap 1** One-hot encoding for CDID 1.
BMP2	23:16	0x4	RW	UNDEFINED	**Bitmap 2** One-hot encoding for CDID 2.
BMP3	31:24	0x8	RW	UNDEFINED	**Bitmap 3** One-hot encoding for CDID 3.

13.2.2.9.53 PG L2 CDID Bitmap (MSB) - GL_PREEXT_L2BMP4_7[n] (0x0020F0B4 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMP4	7:0	0x10	RW	UNDEFINED	**Bitmap 4** One-hot encoding for CDID 4.
BMP5	15:8	0x20	RW	UNDEFINED	**Bitmap 5** One-hot encoding for CDID 5.
BMP6	23:16	0x40	RW	UNDEFINED	**Bitmap 6** One-hot encoding for CDID 6.
BMP7	31:24	0x80	RW	UNDEFINED	**Bitmap 7** One-hot encoding for CDID 7.

13.2.2.9.54 XLT1 Table Configuration Address - GL_PREEXT_XLT1_L2ADDR[n] (0x0020F0C0 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.15.

13.2.2.9.55 XLT1 Table Configuration Data - GL_PREEXT_XLT1_L2DATA[n] (0x0020F0CC + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.16.

13.2.2.9.56 XLT2 Table Configuration Address - GL_PREEXT_XLT2_L2ADDR[n] (0x0020F0D8 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.17.

13.2.2.9.57 XLT2 Table Configuration Data - GL_PREEXT_XLT2_L2DATA[n] (0x0020F0E4 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.18.

13.2.2.9.58 Profile ID Gen Key Type - GL_PREEXT_PID_L2GKTYPE[n] (0x0020F0F0 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.19.

13.2.2.9.59 Profile Key Mask (LSB) - GL_PREEXT_L2_PMASK0[n] (0x0020F0FC + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.20.

13.2.2.9.60 Profile Key Mask (MSB) - GL_PREEXT_L2_PMASK1[n] (0x0020F108 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.21.

13.2.2.9.61 TCAM Configuration (Address) - GL_PREEXT_TCAM_L2ADDR[n] (0x0020F114 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.22.

13.2.2.9.62 TCAM Configuration LSB (Data) - GL_PREEXT_TCAM_L2DATALSB[n] (0x0020F120 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.23.

13.2.2.9.63 TCAM Configuration MSB (Data+Mask) - GL_PREEXT_TCAM_L2DATAMSB[n] (0x0020F12C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.24.

13.2.2.9.64 L2 Default Profile - GL_PREEXT_DFLT_L2PRFL[n] (0x0020F138 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.25.

13.2.2.9.65 K2N Table Configuration Address - GL_PREEXT_K2N_L2ADDR[n] (0x0020F144 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.26.

13.2.2.9.66 K2N Table Configuration Data - GL_PREEXT_K2N_L2DATA[n] (0x0020F150 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.27.

13.2.2.9.67 K2N Table Configuration Address - GL_PREEXT_N2N_L2ADDR[n] (0x0020F15C + 0x4*n, n=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.9.28.

13.2.2.9.68 K2N Table Configuration Data - GL_PREEXT_N2N_L2DATA[n] (0x0020F168 + 0x4*n, n=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.9.29.

13.2.2.9.69 Profile Key Mask (LSB) - GL_PREEXT_L2_TMASK0[n] (0x0020F498 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.36.

13.2.2.9.70 Profile Key Mask (MSB) - GL_PREEXT_L2_TMASK1[n] (0x0020F4A4 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.37.

13.2.2.9.71 Force Profile ID - GL_ACLEXT_FORCE_PID[n] (0x00210000 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.1.

13.2.2.9.72 Profile Level Selector - GL_ACLEXT_PLVL_SEL[n] (0x0021000C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.2.

13.2.2.9.73 L1 Force CDID - GL_ACLEXT_FORCE_L1CDID[n] (0x00210018 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.3.

13.2.2.9.74 L1 P2P Table Configuration Address - GL_ACLEXT_P2P_L1ADDR[n] (0x00210024 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.4.

13.2.2.9.75 L1 P2P Table Configuration Data - GL_ACLEXT_P2P_L1DATA[n] (0x00210030 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.5.

13.2.2.9.76 XLT0 Table Configuration Address - GL_ACLEXT_XLT0_L1ADDR[n] (0x0021003C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.6.

13.2.2.9.77 XLT0 Table Configuration Data - GL_ACLEXT_XLT0_L1DATA[n] (0x00210048 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.7.

13.2.2.9.78 L1 Bidirectional CTL - GL_ACLEXT_CDMD_L1SEL[n] (0x00210054 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.8.

13.2.2.9.79 L1 Flag Select Table - GL_ACLEXT_FLGS_L1TBL[n] (0x00210060 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.9.

13.2.2.9.80 L1 Flag Select Control (0-1) - GL_ACLEXT_FLGS_L1SEL0_1[n] (0x0021006C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.10.

13.2.2.9.81 L1 Flag Select Control (2-3) - GL_ACLEXT_FLGS_L1SEL2_3[n] (0x00210078 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.11.

13.2.2.9.82 L2 Configuration Table Address - GL_ACLEXT_CTLTBL_L2ADDR[n] (0x00210084 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.12.

13.2.2.9.83 L2 Configuration Table Data - GL_ACLEXT_CTLTBL_L2DATA[n] (0x00210090 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.13.

13.2.2.9.84 XLT1, XLT2 Partition Mode - GL_ACLEXT_L2PRTMOD[n] (0x0021009C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.14.

13.2.2.9.85 PG L2 CDID Bitmap (LSB) - GL_ACLEXT_L2BMP0_3[n] (0x002100A8 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMP0	7:0	0x1	RW	UNDEFINED	**Bitmap 0** One-hot encoding for CDID 0.
BMP1	15:8	0x2	RW	UNDEFINED	**Bitmap 1** One-hot encoding for CDID 1.
BMP2	23:16	0x4	RW	UNDEFINED	**Bitmap 2** One-hot encoding for CDID 2.
BMP3	31:24	0x8	RW	UNDEFINED	**Bitmap 3** One-hot encoding for CDID 3.

13.2.2.9.86 PG L2 CDID Bitmap (MSB) - GL_ACLEXT_L2BMP4_7[n] (0x002100B4 + 0x4*n, n=0...2; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BMP4	7:0	0x10	RW	UNDEFINED	**Bitmap 4** One-hot encoding for CDID 4.
BMP5	15:8	0x20	RW	UNDEFINED	**Bitmap 5** One-hot encoding for CDID 5.
BMP6	23:16	0x40	RW	UNDEFINED	**Bitmap 6** One-hot encoding for CDID 6.
BMP7	31:24	0x80	RW	UNDEFINED	**Bitmap 7** One-hot encoding for CDID 7.

13.2.2.9.87 XLT1 Table Configuration Address - GL_ACLEXT_XLT1_L2ADDR[n] (0x002100C0 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.15.

13.2.2.9.88 XLT1 Table Configuration Data - GL_ACLEXT_XLT1_L2DATA[n] (0x002100CC + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.16.

13.2.2.9.89 XLT2 Table Configuration Address - GL_ACLEXT_XLT2_L2ADDR[n] (0x002100D8 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.17.

13.2.2.9.90 XLT2 Table Configuration Data - GL_ACLEXT_XLT2_L2DATA[n] (0x002100E4 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.18.

13.2.2.9.91 Profile ID Gen Key Type - GL_ACLEXT_PID_L2GKTYPE[n] (0x002100F0 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.19.

13.2.2.9.92 Profile Key Mask (LSB) - GL_ACLEXT_L2_PMASK0[n] (0x002100FC + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.20.

13.2.2.9.93 Profile Key Mask (MSB) - GL_ACLEXT_L2_PMASK1[n] (0x00210108 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.21.

13.2.2.9.94 TCAM Configuration (Address) - GL_ACLEXT_TCAM_L2ADDR[n] (0x00210114 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.22.

13.2.2.9.95 TCAM Configuration LSB (Data) - GL_ACLEXT_TCAM_L2DATALSB[n] (0x00210120 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.23.

13.2.2.9.96 TCAM Configuration MSB (Data) - GL_ACLEXT_TCAM_L2DATAMSB[n] (0x0021012C + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.24.

13.2.2.9.97 L2 Default Profile - GL_ACLEXT_DFLT_L2PRFL[n] (0x00210138 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.25.

13.2.2.9.98 K2N Table Configuration Address - GL_ACLEXT_K2N_L2ADDR[n] (0x00210144 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.26.

13.2.2.9.99 K2N Table Configuration Data - GL_ACLEXT_K2N_L2DATA[n] (0x00210150 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.27.

13.2.2.9.100 K2N Table Configuration Address - GL_ACLEXT_N2N_L2ADDR[n] (0x0021015C + 0x4*n, n=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.9.28.

13.2.2.9.101 K2N Table Configuration Data - GL_ACLEXT_N2N_L2DATA[n] (0x00210168 + 0x4*n, n=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.9.29.

13.2.2.9.102 Profile Key Mask (LSB) - GL_ACLEXT_L2_TMASK0[n] (0x00210498 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.36.

13.2.2.9.103 Profile Key Mask (MSB) - GL_ACLEXT_L2_TMASK1[n] (0x002104A4 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.37.

13.2.2.9.104 L2 Default Profile - GL_ACLEXT_DFLT_L2PRFL_ACL[n] (0x00393800 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.2.9.25.

13.2.2.9.105 Tx Scheduling Correction Control - GLFLXP_TX_SCHED_CORRECT[n,m] (0x00458000 + 0x4*n + 0x100*m, n=0...63, m=0...31; RO)

Controls the reporting of the Tx scheduling corrections from the Rx path, per operator.

The correlation between each field and each CSR within the operator is:

We have 4 corrections per operator, each using 16 tupples (tupple 0 being the highest priority tupple) of protID & recipe.

So:

Correction 0 uses m=0..7, where tupple0/tupple1 use m=0, tupple2/tupple3 use m=1,... tupple14/tupple15 use m=7.

Correction 1 uses m=8..15, where tupple0/tupple1 use m=8, tupple2/tupple3 use m=9,... tupple14/tupple15 use m=15

Correction 2 uses m=16..23, where tupple0/tupple1 use m=16, tupple2/tupple3 use m=17,... tupple14/tupple15 use m=23

Correction 3 uses m=24..31, where tupple0/tupple1 use m=24, tupple2/tupple3 use m=25,... tupple14/tupple15 use m=31

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROTD_ID_2N	7:0	0x0	RW	UNDEFINED	**Protocol ID 2n** ProtID 2n of offset "offset" of operator "operator" to look for in the packet's reported protIDs using prioritization mechanism of "look first for lowest n".
RECIPE_2N	12:8	0x0	RW	UNDEFINED	**Recipe 2n** Recipe 2n of offset "offset" of operator "operator" to be reported in case the matching protID was found ("won" in the priority list) in the packet.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	15:13	000b	RSV	N/A	Reserved.
PROTD_ID_2N_1	23:16	0x0	RW	UNDEFINED	**Protocol ID 2n+1** ProtID 2n+1 of offset "offset" of operator "operator" to look for in the packet's reported protIDs using prioritization mechanism of "look first for lowest n".
RECIPE_2N_1	28:24	0x0	RW	UNDEFINED	**Recipe 2n+1** Recipe 2n+1 of offset "offset" of operator "operator" to be reported in case the matching protID was found ("won" in the priority list) in the packet.
RESERVED	31:29	000b	RSV	N/A	Reserved.

13.2.2.9.106 ProtIDs for Creating RRX CMD Offsets - GLFLXP_RX_CMD_PROTIDS[n,m] (0x0045A000 + 0x4*n + 0x400*m, n=0...255, m=0...5; RO)

Determines the protID for the L3 protocols to match the ones configured in the Analyzer (for later parsing in the Rx-Pipe).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROTID_4N	7:0	0x0	RW	UNDEFINED	**Protocol ID 4n** ProtID #0 for creating offset N to RDPU (out of the 6 RDPU offsets).
PROTID_4N_1	15:8	0x0	RW	UNDEFINED	**Protocol ID 4n+1** ProtID #1 for creating offset N to RDPU (out of the 6 RDPU offsets).
PROTID_4N_2	23:16	0x0	RW	UNDEFINED	**Protocol ID 4n+2** ProtID #2 for creating offset N to RDPU (out of the 6 RDPU offsets).
PROTID_4N_3	31:24	0x0	RW	UNDEFINED	**Protocol ID 4n+3** ProtID #3 for creating offset N to RDPU (out of the 6 RDPU offsets).

13.2.2.9.107 PTYPE_10b to PTYPE_8b Translation - GLFLXP_PTYPE_TRANSLATION[n] (0x0045C000 + 0x4*n, n=0...255; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PTYPE_4N	7:0	0x0	RW	UNDEFINED	**PTYPE 4n** PTYPE_8b for PTYPE_10b N.
PTYPE_4N_1	15:8	0x0	RW	UNDEFINED	**PTYPE 4n+1** PTYPE_8b for PTYPE_10b N+1.
PTYPE_4N_2	23:16	0x0	RW	UNDEFINED	**PTYPE 4n+2** PTYPE_8b for PTYPE_10b N+2.
PTYPE_4N_3	31:24	0x0	RW	UNDEFINED	**PTYPE 4n+3** PTYPE_8b for PTYPE_10b N+3.

13.2.2.9.108 LX Prot & Index for Rx CMD - GLFLXP_RX_CMD_LX_PROT_IDX[n] (0x0045C400 + 0x4*n, n=0...255; RO)

Determines the LX prot and cloud/L4/payload offsets index per 8b PTPYE for RDPU.

Field	Bit(s)	Init.	Type	CFG Policy	Description
INNER_CLOUD_OFFSET_INDEX	2:0	000b	RW	UNDEFINED	**Inner Cloud Offset Index** Index of "L3_header_offset_*" that defines first inner header of the packet (After Outer IP/GRE/ Outer UDP). Value of 000b means there is no cloud tunneling header.
RESERVED	3	0b	RSV	N/A	Reserved.
L4_OFFSET_INDEX	6:4	000b	RW	UNDEFINED	**L4 Offset Index** Index of "L3_header_offset_*" that defines the L4 header in the packet. Value of 000b means there is no L4 header.
RESERVED	7	0b	RSV	N/A	Reserved.
PAYLOAD_OFFSET_INDEX	10:8	000b	RW	UNDEFINED	**Payload Offset Index** Index of "L3_header_offset_*" that defines the payload in the packet. Value of 000b means there is no L4 header.
RESERVED	11	0b	RSV	N/A	Reserved.
L3_PROTOCOL	13:12	00b	RW	UNDEFINED	**L3 Protocol** Indicates the first L3 protocol of the packet: 00b = IP4 01b = IPv6 10b = Non-valid value 11b = Other
L4_PROTOCOL	15:14	00b	RW	UNDEFINED	**L4 Protocol** Indicates the last L4 protocol of the packet. 00b = TCP 01b = UDP 10b = SCTP 11b = Other
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.9.109 RXDID FlexiWord 0 Control - GLFLXP_RXDID_FLX_WRD_0[n] (0x0045C800 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 0 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x38	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default value is aimed to serve the selection of RSS (low word), to match legacy behavior.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.110 RXDID FlexiWord 1 Control - GLFLXP_RXDID_FLX_WRD_1[n] (0x0045C900 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 1 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x39	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default value is aimed to serve the selection of RSS (high word), to match legacy behavior.
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.111 RXDID FlexiWord 2 Control - GLFLXP_RXDID_FLX_WRD_2[n] (0x0045CA00 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 2 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x0	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default = 0 (genericMD_word0.
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.112 RXDID FlexiWord 3 Control - GLFLXP_RXDID_FLX_WRD_3[n] (0x0045CB00 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 3 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x1	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default = 1 (genericMD_word1).
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.113 RXDID FlexiWord 4 Control - GLFLXP_RXDID_FLX_WRD_4[n] (0x0045CC00 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 4 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x5	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default value is aimed to serve the selection of FlowID (low word), to match legacy behavior (called "FDFID" in legacy).
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.114 RXDID FlexiWord 5 Control - GLFLXP_RXDID_FLX_WRD_5[n] (0x0045CD00 + 0x4*n, n=0...63; RO)

Controls the reporting of FlexiWord 5 in the flexible Rx-Descriptors, per RXDID. Default value is meant to be aligned with legacy behavior (RSS/FDID).

Field	Bit(s)	Init.	Type	CFG Policy	Description
PROT_MDID	7:0	0x6	RW	UNDEFINED	**Protocol ID or MDID** This field can hold a protID value or a MDID value (for flexiword[n] of RXDID_IDX "RXDID_idx"). Its decoding is based on the *RXDID_OPCODE* field. ProtID: For reporting its offset or for extracting pkt bytes from its offset. MDID: For reporting the MDID's content. Default value is aimed to serve the selection of FlowID (high word), to match legacy behavior (called "FDFID" in legacy).
EXTRACTION_OFFSET	17:8	0x0	RW	UNDEFINED	**Extraction Offset** Relevant only if *PROT_MDID* field is a ProtID. Used as offset within protID to extract bytes from the packet. Its usage is based on *RXDID_OPCODE* field.
RESERVED	29:18	0x0	RSV	N/A	Reserved.
RXDID_OPCODE	31:30	01b	RW	UNDEFINED	**RXDID Opcode** Opcode to decide what to report in flexword[n] into the Rx-Descriptor: 00b = Fixed Value — Report the value from *PROT_MDID* field itself (for debug purposes). 01b = Metadata Offset — Report the selected MD word from the internal FlexiPipe buses. 10b = Extraction Offset — Report the value of bytes (protID's offset + byte offset) in the packet. 11b = Protocol Offset — Report the offset to the selected protocol.

13.2.2.9.115 RXDID FlexiFlags Control - GLFLXP_RXDID_FLAGS[n,m] (0x0045D000 + 0x4*n + 0x100*m, n=0...63, m=0...4; RO)

Controls the reporting of the FlexiFlags in the flexible Rx-Descriptors.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLEXIFLAG_4N	5:0	0x0	RW	UNDEFINED	**FlexiFlag 4n** Determines the flag index to be reported in flexiflag[4*m] of RXDID_IDX "n" from the 64 available flags in the FlexiPipe.
RESERVED	7:6	00b	RSV	N/A	Reserved.
FLEXIFLAG_4N_1	13:8	0x0	RW	UNDEFINED	**FlexiFlag 4n+1** Same for 4m+1.
RESERVED	15:14	00b	RSV	N/A	Reserved.
FLEXIFLAG_4N_2	21:16	0x0	RW	UNDEFINED	**FlexiFlag 4n+2** Same for 4m+2.
RESERVED	23:22	00b	RSV	N/A	Reserved.
FLEXIFLAG_4N_3	29:24	0x0	RW	UNDEFINED	**FlexiFlag 4n+3** Same for 4m+3.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.9.116 RXDID Flags1 Override Control - GLFLXP_RXDID_FLAGS1_OVERRIDE[n] (0x0045D600 + 0x4*n, n=0...63; RO)

Controls the overriding of the FlexiFlags1 in the flexible Rx-Descriptors with RDPU related information.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLEXIFLAGS1_OVERIDE	3:0	0x0	RW	UNDEFINED	**FlexiFlags 1 Override** If Bit[0] is set, EXT_UDP_0 indication from RDPU replaces the value of flexiflags1[0]. If Bit[1] is set, INT_UDP_0 indication from RDPU replaces the value of flexiflags1[1]. If Bit[2] is set, RECIPE_ERROR indication from RDPU replaces the value of flexiflags1[2]. If Bit[3] is set: OVERSIZE indication from RDPU replaces the value of flexiflags1[3].
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.9.117 Queue Context Flex Extension - QRXFLXP_CNTXT[QRX] (0x00480000 + 0x4*QRX, QRX=0...2047; RW)

Extension to the legacy queue context, supporting RXDID and TimeSync information.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXDID_IDX	5:0	0x0	RW	UNDEFINED	**RXDID Index** Default RXDID_idx for this queue.
RESERVED	7:6	00b	RSV	N/A	Reserved.
RXDID_PRIO	10:8	001b	RW	UNDEFINED	**RXDID Priority** Priority of this RXDID_idx to be compared against previous priority from the pipe. If equal, this one wins.
TS	11	0b	RW	UNDEFINED	**Timestamp** Timestamp reporting per Rx packet enabled for this queue.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.10 PF - Parser Registers

13.2.2.10.1 PRS Balancer Config - GL_PRS_RX_SIZE_CTRL (0x00200004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIN_SIZE	9:0	0x3C	RW	UNDEFINED	**Minimum Size** Minimum frame size (bytes).
RESERVED	14:10	0x0	RSV	N/A	Reserved.
MIN_SIZE_EN	15	0b	RW	UNDEFINED	**Minimum Size Enable** Enable undersize (<49 bytes) frames padding.
MAX_SIZE	25:16	0x1F8	RW	UNDEFINED	**Maximum Size** Maximum frame size (bytes).
RESERVED	30:26	0x0	RSV	N/A	Reserved.
MAX_SIZE_EN	31	1b	RW	UNDEFINED	**Maximum Size Enable** 0b = Read entire packet. 1b = Enable read of header only. Must be set to 1b.

13.2.2.10.2 Rx-Query Pipe-Status Init for Word 0-6 - GL_PRS_RX_PIPE_INIT0[n] (0x0020000C + 0x4*n, n=0...6; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0xFFFF	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.3 Rx-Query Pipe-Status Init for Word 7 - GL_PRS_RX_PIPE_INIT1 (0x00200028; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0x0040	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.4 Rx-Query Pipe-Status Init for Word 8 - GL_PRS_RX_PIPE_INIT2 (0x0020002C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0x2492	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.5 XLR Marker Trigger - GL_XLR_MARKER_TRIG_RCU_PRS (0x002001C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VM_VF_NUM	9:0	0x0	RW	UNDEFINED	**VF/VM Number** The number of the VF/VM to be reset (invalid if *VM_VF_TYPE* = PF).
VM_VF_TYPE	11:10	00b	RW	UNDEFINED	**VF/VM Type** 00b = Reset for VF 01b = Reset for VM. 10b = Reset for PF only. 11b = Reserved.
PF_NUM	14:12	000b	RW	UNDEFINED	**PF Number** PF number of the reset operation (should be valid in VM/VF reset type as well).
RESERVED	15	0b	RSV	N/A	Reserved.
PORT_NUM	18:16	000b	RW	UNDEFINED	**Port Number** The port to which the function belongs.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.10.6 QH Removal Marker Trigger - GL_QH_MARKER_TRIG_RCU_PRS[n] (0x002001C4 + 0x4*n, n=0...3; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QPID	17:0	0x0	RW	UNDEFINED	**Queue Pair ID** RDMA queue pair ID.
PE_TAG	25:18	0x0	RW	UNDEFINED	**PE Tag** Internal PE tag.
PORT_NUM	28:26	000b	RW	UNDEFINED	**Port Number** The port to which the function belongs.
RESERVED	30:29	00b	RSV	N/A	Reserved.
SET_RST	31	0b	SC	UNDEFINED	**SET_RST** 0b = Event is cleared. 1b = Writing operation to this array (0..3) bit triggers marker injection to TCs under *PORT_NUM* port.

13.2.2.10.7 COTF Marker Trigger - GL_COTF_MARKER_TRIG_RCU_PRS[n] (0x002001D4 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SET_RST	0	0b	SC	UNDEFINED	**SET_RST** Writing operation to this array (0..7) triggers marker injection for all TCs. Cleared when marker is sent.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.10.8 XLR Debug Markers Status - GL_XLR_MARKER_STATUS[n] (0x002001F4 + 0x4*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRKR_BUSY	31:0	0x0	RO	N/A	**Marker Busy** Each respective bit represents a pending marker injection, by order of triggering. When 1, indicates marker has not been fully sent yet. 0 means sent. From 2 CSRs - 40 LSb are valid. This CSR should be read before initiating a new XLR marker, to make sure that at least one bit here signals "not-busy".

13.2.2.10.9 QH Debug Markers Status - GL_QH_MARKER_STATUS (0x002001FC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRKR_BUSY	3:0	0x0	RO	N/A	**Marker Busy** Each respective bit represents a pending marker injection, by order of triggering. When 1, indicates marker has not been fully sent yet. 0 means sent. This CSR should be read before initiating a new PE marker, to make sure that the index that will be used is indeed "not-busy".
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.10.10 COTF Debug Markers Status - GL_COTF_MARKER_STATUS (0x00200200; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRKR_BUSY	7:0	0x0	RO	N/A	**Marker Busy** Each respective bit represents a pending marker injection, by order of triggering. When 1, indicates marker has not been fully sent yet. 0 means sent. This CSR should be read before initiating a new COTF marker, to make sure that the index that will be used is indeed "not-busy".
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.10.11 PRS Markers Error Indication (Marker FIFO Full) - GL_PRS_MARKER_ERROR (0x00200204; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
XLR_CFG_ERR	0	0b	RCW	UNDEFINED	**XLR Config Error** Sticky bit. Clears on read.
QH_CFG_ERR	1	0b	RCW	UNDEFINED	**QH Config Error** Sticky bit. Clears on read.
COTF_CFG_ERR	2	0b	RCW	UNDEFINED	**COTF Config Error** Sticky bit. Clears on read.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.10.12 PRS Marker FIFO Read Access - GL_XLR_MARKER_LOG_RCU_PRS[n] (0x00200208 + 0x4*n, n=0...63; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
XLR_TRIG	31:0	0x0	RO	N/A	**XLR Trigger** Each array index relevant to the configured XLR trigger index. Each CSR contains exact write data as logged in CSR write access to *XLR_MARKER_TRIG*.

13.2.2.10.13 Rx ANA CSR Access Control - GL_RPRS_ANA_CSR_CTRL (0x00200708; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SELECT_EN	0	0b	RW	UNDEFINED	**Select Enable** Enable single selected access to ANA0/1. 0b = CSR access to ANA register is broadcasted to both analyzers. Read data is driven only by ANA0. 1b = CSR access is pointed to a single analyzer according to *SELECTED_ANA* bit.
SELECTED_ANA	1	0b	RW	UNDEFINED	**Selected Analyzer** Selected analyzer for CSR access. 0b = CSR access is pointed to Analyzer 0. 1b = CSR access is pointed to Analyzer 1.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.10.14 Pipe Monitor Threshold - GL_TPRS_PM_THR (0x00202000; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PM_THR	13:0	0x2B20	RW	UNDEFINED	**Pipe Monitor Threshold** In byte count resolution.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.10.15 MNG Pipe Monitor Threshold - GL_TPRS_MNG_PM_THR (0x00202004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MNG_PM_THR	13:0	0x1	RW	UNDEFINED	**Management Pipe Monitor Threshold** Pipe monitor threshold for management commands.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.10.16 Pipe Monitor Counters Status - GL_TPRS_PM_CNT[n] (0x00202008 + 0x4*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_PRS_PM_CNT	13:0	0x0	RO	UNDEFINED	**Pipe Monitor Counter** Contains the current PM Counter value.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.10.17 Tx-Query Min/Max Size Control - GL_PRS_TX_SIZE_CTRL (0x00202014; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIN_SIZE	9:0	0x3C	RW	UNDEFINED	**Minimum Size** Minimum frame size (bytes).
RESERVED	14:10	0x0	RSV	N/A	Reserved.
MIN_SIZE_EN	15	1b	RW	UNDEFINED	**Minimum Size Enable** Min size padding enable.
MAX_SIZE	25:16	0x1F8	RW	UNDEFINED	**Maximum Size** Maximum frame size (bytes).
RESERVED	30:26	0x0	RSV	N/A	Reserved.
MAX_SIZE_EN	31	1b	RW	UNDEFINED	**Maximum Size Enable** Max size chopping enable.

13.2.2.10.18 Tx-Query Pipe-Status Init for Word 0-6 - GL_PRS_TX_PIPE_INIT0[n] (0x00202018 + 0x4*n, n=0...6; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0xFFFF	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.19 Tx-Query Pipe-Status Init for Word 7 - GL_PRS_TX_PIPE_INIT1 (0x00202034; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0x1000	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.20 Tx-Query Pipe-Status Init for Word 8 - GL_PRS_TX_PIPE_INIT2 (0x00202038; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPCSR_INIT	15:0	0x2492	RW	UNDEFINED	**GPCSR Initial** Initial value of this word in the pipe_status.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.10.21 Tx ANA CSR Access Control - GL_TPRS_ANA_CSR_CTRL (0x00202100; RO)

Field definitions are the same as those defined in Section 13.2.2.10.13.

13.2.2.10.22 XLR Marker Trigger PE - GL_XLR_MARKER_TRIG_PE (0x005008C0; RO)

Field definitions are the same as those defined in Section 13.2.2.10.5.

13.2.2.11 PF - Switch Registers

Registers used to describe the switch behavior.

13.2.2.11.1 Port - TC Transmit UP Replacement - PRT_TCTUPR[n] (0x00040840 + 0x4*n, n=0...31; RW)

Defines the TC-based Tx UP remapping.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0	2:0	000b	RW	UNDEFINED	**UP 0** Defines the UP to set if UP in packet is zero and packet is sent through TC #n.
RESERVED	3	0b	RSV	N/A	Reserved.
UP1	6:4	001b	RW	UNDEFINED	**UP 1** Defines the UP to set if UP in packet is one and packet is sent through TC #n.
RESERVED	7	0b	RSV	N/A	Reserved.
UP2	10:8	010b	RW	UNDEFINED	**UP 2** Defines the UP to set if UP in packet is two and packet is sent through TC #n.
RESERVED	11	0b	RSV	N/A	Reserved.
UP3	14:12	011b	RW	UNDEFINED	**UP 3** Defines the UP to set if UP in packet is three and packet is sent through TC #n.
RESERVED	15	0b	RSV	N/A	Reserved.
UP4	18:16	100b	RW	UNDEFINED	**UP 4** Defines the UP to set if UP in packet is four and packet is sent through TC #n.
RESERVED	19	0b	RSV	N/A	Reserved.
UP5	22:20	101b	RW	UNDEFINED	**UP 5** Defines the UP to set if UP in packet is five and packet is sent through TC #n.
RESERVED	23	0b	RSV	N/A	Reserved.
UP6	26:24	110b	RW	UNDEFINED	**UP 6** Defines the UP to set if UP in packet is six and packet is sent through TC #n.
RESERVED	27	0b	RSV	N/A	Reserved.
UP7	30:28	111b	RW	UNDEFINED	**UP 7** Defines the UP to set if UP in packet is seven and packet is sent through TC #n.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.11.2 IPsec Function limiting - GL_SWT_FUNCFILT (0x001D2698; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FUNCFILT	0	0b	RW	UNDEFINED	**Function Filter** If set, receiving VSI function should match the function of the packet as indicated by the description engine.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.11.3 Large Action - Single Action Offset - GL_SWT_LAT_SINGLE (0x00204000; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BASE	10:0	0x0	RW	UNDEFINED	**Base** Base of Single Action section in Large Action Table (encoded as base/4).
RESERVED	15:11	0x0	RSV	N/A	Reserved.
SIZE	26:16	0x0	RW	UNDEFINED	**Size** Size of Single Action section in Large Action Table (encoded as size/4).
RESERVED	31:27	0x0	RSV	N/A	Reserved.

13.2.2.11.4 Large Action - Double Action Offset - GL_SWT_LAT_DOUBLE (0x00204004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BASE	10:0	0x0	RW	UNDEFINED	**Base** Base of Double Action section in Large Action Table (encoded as base/4).
RESERVED	15:11	0x0	RSV	N/A	Reserved.
SIZE	26:16	0x0	RW	UNDEFINED	**Size** Size of Double Action section in Large Action Table (encoded as size/4).
RESERVED	31:27	0x0	RSV	N/A	Reserved.

13.2.2.11.5 Large Action - Quad Action Offset - GL_SWT_LAT_QUAD (0x00204008; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BASE	10:0	0x0	RW	UNDEFINED	**Base** Base of Quad Action section in Large Action Table (encoded as base/4).
RESERVED	15:11	0x0	RSV	N/A	Reserved.
SIZE	26:16	0x0	RW	UNDEFINED	**Size** Size of Quad Action section in Large Action Table (encoded as size/4).
RESERVED	31:27	0x0	RSV	N/A	Reserved.

13.2.2.11.6 Replication Table Control - EMP_SWT_REPIND (0x0020401C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
OPCODE	3:0	0x0	RW	UNDEFINED	**Opcode** 0x0 = Done 0x1 = Write (clears on done) 0x2 = Read (clears on done) 0x3 = Write All (clears on done) 0x4 = Read All “And” (clears on done) 0x5 = Read All “Nor” (clears on done) 0x6 = Reserved 0x7 = Read Error (status)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LIST_INDEX_NUMBER	13:4	0x0	RW	UNDEFINED	**List Index Number** Address of the prune table. Allows 0-1023 access range.
RESERVED	15:14	00b	RSV	N/A	Reserved.
VSI_NUM	25:16	0x0	RW	UNDEFINED	**VSI Number** Bit index of VSI bit vector (prune table line). Allowed values are 0-383. Accessing >383 causes "Read Error" status.
RESERVED	30:26	0x0	RSV	N/A	Reserved.
BIT_VALUE	31	0b	RW	UNDEFINED	**Bit Value** Write — Bit write value to VSI index. Read — Upon Opcode=0, bit read value of VSI index. Write All — Bit write value to all VSIs (entire line). Read All "And" — The "And" (&) result of entire line (all ones). Read All "Nor" — The "Nor" result of entire line (all zeros).

13.2.2.11.7 Prune Table Control - EMP_SWT_PRUNIND (0x00204020; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
OPCODE	3:0	0x0	RW	UNDEFINED	**Opcode** 0x0 = Done 0x1 = Write (clears on done) 0x2 = Read (clears on done) 0x3 = Write All (clears on done) 0x4 = Read All "And" (clears on done) 0x5 = Read All "Nor" (clears on done) 0x6 = Reserved 0x7 = Read Error (status)
LIST_INDEX_NUMBER	13:4	0x0	RW	UNDEFINED	**List Index Number** Address of the prune table. Allows 0-1023 access range.
RESERVED	15:14	00b	RSV	N/A	Reserved.
VSI_NUM	25:16	0x0	RW	UNDEFINED	**VSI Number** Bit index of VSI bit vector (prune table line). Allowed values are 0-383. Accessing >383 causes "Read Error" status.
RESERVED	30:26	0x0	RSV	N/A	Reserved.
BIT_VALUE	31	0b	RW	UNDEFINED	**Bit Value** Write — Bit write value to VSI index. Read — Upon Opcode=0, bit read value of VSI index. Write All — Bit write value to all VSIs (entire line). Read All "And" — The "And" (&).

13.2.2.11.8 Unallowed Override Attempt Count - GL_OVERRIDEC (0x002040A4; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
OVERRIDE_ATTEMPTC	15:0	0x0	RWC	UNDEFINED	**Override Attempt Count** Increments on each override attempt from source VSI for which VSI_SRCSWCTRL.*ALLOWDESTOVERRIDE* is not set (override attempt is setting non-zero value in the *SWTCH* field of the descriptor).
LAST_VSI	25:16	0x0	RWC	UNDEFINED	**Last VSI** The value of the last source VSI that attempted override and its VSI_SRCSWCTRL.*ALLOWDESTOVERRIDE* is not set (override attempt is setting non-zero value in the *SWTCH* field of the descriptor).
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.11.9 Switch Metadata Priority - GL_SWT_MD_PRI (0x002040AC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VSI_PRI	2:0	011b	RW	UNDEFINED	**VSI Priority** Priority of VSI action.
RESERVED	3	0b	RSV	N/A	Reserved.
LB_PRI	6:4	011b	RW	UNDEFINED	**Loopback Priority** Priority of Loopback Enable action.
RESERVED	7	0b	RSV	N/A	Reserved.
LAN_EN_PRI	10:8	011b	RW	UNDEFINED	**LAN Enable Priority** Priority of LAN Enable action.
RESERVED	11	0b	RSV	N/A	Reserved.
QH_PRI	14:12	110b	RW	UNDEFINED	**Queue High Priority** Priority of queuing actions with *Q_SET* = 1 in action.
RESERVED	15	0b	RSV	N/A	Reserved.
QL_PRI	18:16	100b	RW	UNDEFINED	**Queue Low Priority** Priority of queuing actions with *Q_SET* = 0 in action.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.11.10 Storm Control - Multicast Current Count - PRT_SWT_MSCCNT (0x00204100; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CCOUNT	24:0	0x0	RO	N/A	**Current Count** IBSC traffic current count. Represents the count of multicast traffic received in the current time interval in units of 64-byte segments.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.11.11 Port - Store Bad Packets VSI - PRT_SBPVSI (0x00204120; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BAD_FRAMES_VSI	9:0	0x0	RW	UNDEFINED	**Bad Frames VSI** Indicates the VSI used to forward error packets if the *SBP* bit is set.
RESERVED	30:10	0x0	RSV	N/A	Reserved.
SBP	31	0b	RW	UNDEFINED	**Store Bad Packets** If set, pass bad frames to the VSI defined in the *BAD_FRAMES_VSI* field.

13.2.2.11.12 Storm Control - Status - PRT_SCSTS (0x00204140; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BSCA	0	0b	RO	N/A	**Broadcast Storm Control Active** Broadcast storm control active.
BSCAP	1	0b	RO	N/A	**Broadcast Storm Control Active Previous** Broadcast storm control active in previous window.
MSCA	2	0b	RO	N/A	**Multicast Storm Control Active** Multicast storm control active.
MSCAP	3	0b	RO	N/A	**Multicast Storm Control Active Previous** Multicast storm control active in previous window.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.11.13 Storm Control - Broadcast Current Count - PRT_SWT_BSCCNT (0x00204160; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CCOUNT	24:0	0x0	RO	N/A	**Current Count** IBSC traffic current count. Represents the count of broadcast traffic received in the current time interval in units of 64-byte segments.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.11.14 Storm Control - Broadcast Threshold - PRT_SWT_BSCTRH (0x00204180; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UTRESH	18:0	0x0	RW	UNDEFINED	**Upper Threshold** Traffic upper threshold size. Represents the upper threshold for broadcast storm control.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.11.15 Storm Control - Multicast Threshold - PRT_SWT_MSCTRH (0x002041C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UTRESH	18:0	0x0	RW	UNDEFINED	**Upper Threshold** Traffic upper threshold size. Represents the upper threshold for multicast storm control.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.11.16 Storm Control - Basic Interval - PRT_SWT_SCBI (0x002041E0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BI	24:0	0x2710	RW	UNDEFINED	**Basic Interval** Basic interval in 100 Mb/s port link rate in 1 μs strobes. The default is equivalent to 1 Mbit of data. ***Notes:*** 1. Initial value defines a basic interval of 10 ms at 100 Mb/s link speed. 2. The interval in higher port link rates is divided by the link speed/100 Mb/s to get the new interval.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.11.17 Storm Control - Control Register - PRT_SWT_SCCRL (0x00204200; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDIPW	0	0b	RW	UNDEFINED	**Multicast Drop if Previous Window** Drop multicast packets (excluding flow control packets) if multicast threshold is exceeded in previous window.
MDICW	1	0b	RW	UNDEFINED	**Multicast Drop if Current Window** Drop multicast packets (excluding flow control packets) if multicast threshold is exceeded in current window.
BDIPW	2	0b	RW	UNDEFINED	**Broadcast Drop if Previous Window** Drop broadcast packets if broadcast threshold is exceeded in previous window.
BDICW	3	0b	RW	UNDEFINED	**Broadcast Drop if Current Window** Drop broadcast packets if broadcast threshold is exceeded in current window.
RESERVED	7:4	0x0	RSV	N/A	Reserved.
INTERVAL	27:8	0xA	RW	UNDEFINED	**Interval** BSC/MSC time interval specification. The interval size for applying Ingress Broadcast or Multicast Storm Control. Interrupt decisions are made at the end of each interval (and most flags are also set at interval end). Setting this field resets the counter.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.11.18 Mirror - LAN Port Ingress Rule - PRT_SWT_MIRIG (0x00204280; RO)

This register defines the rules that request to mirror ingress VSI n.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIRRULE	5:0	0x0	RW	UNDEFINED	**Mirror Rule** Mirror rule index.
RESERVED	6	0b	RSV	N/A	Reserved.
MIRENA	7	0b	RW	UNDEFINED	**Mirror Enable** Mirror enable.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.11.19 Mirror - LAN Port Egress Rule - PRT_SWT_MIREG (0x002042A0; RO)

This register defines the rules that request to mirror egress VSI n.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIRRULE	5:0	0x0	RW	UNDEFINED	**Mirror Rule** Mirror rule index.
RESERVED	6	0b	RSV	N/A	Reserved.
MIRENA	7	0b	RW	UNDEFINED	**Mirror Enable** Mirror enable.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.11.20 Mirror - Target VSI - GL_SWT_MIRTARVSI[n] (0x00204500 + 0x4*n, n=0...63; RO)

This register defines the destination VSI of mirror rules.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFVMNUMBER	9:0	0x0	RW	UNDEFINED	**VF/VM Number** Defines the VF this VSI belongs to, or the VM within the PF associated with this VSI. Must be zero if VSI type is PF or EMP (VSI_VSI2F.*FUNCTIONTYPE* =10b or 11b, respectively). If the VSI is of type VM (VSI_VSI2F.*FUNCTIONTYPE* = 01b), this number should be equal to the VSI number.
FUNCTIONTYPE	11:10	00b	RW	UNDEFINED	**Function Type** Defines the type of VSI: 00b = VF 01b = VM 10b = PF 11b = EMP
PFNUMBER	14:12	000b	RW	UNDEFINED	**PF Number** Defines the PF this VSI belongs to. Should be set to the PF number for all VSI types except EMP (VSI_VSI2PF.*FUNCTIONTYPE* = 00b, 01b, or 10b).
RESERVED	19:15	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TARGETVSI	29:20	0x0	RW	UNDEFINED	**Target VSI** Defines the target VSI of mirror rule #n.
RESERVED	30	0b	RSV	N/A	Reserved.
RULEENABLE	31	0b	RW	UNDEFINED	**Rule Enable** If set, this mirror rule is enabled.

13.2.2.11.21 SWID Stat Block ID - GLSWID_STAT_BLOCK[n] (0x0020A1A4 + 0x4*n, n=0...255; RO)

Defines if one of 32 VEB statistic block is associated with this switch ID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VEBID	4:0	0x0	RW	UNDEFINED	**VEB ID** Defines the stat block ID to which the switch ID is associated.
RESERVED	30:5	0x0	RSV	N/A	Reserved.
VEBID_VALID	31	0b	RW	UNDEFINED	**VEB ID Valid** A switch ID may not be associated with any switch block (GLSWID_STAT_BLOCK.*VEBID_VALID* = 0b)

13.2.2.11.22 Switch Recipes Used - GLSWT_ACT_RESP_0 (0x0020A5A4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLSWT_ACT_RESP	31:0	0x0	RO	UNDEFINED	**Action Recipes** Bitmap of recipes used in actions.

13.2.2.11.23 Switch Recipes Used - GLSWT_ACT_RESP_1 (0x0020A5A8; RO)

Field definitions are the same as those defined in Section 13.2.2.11.22.

13.2.2.11.24 Throughput Counters Config - GL_PLG_AVG_CALC_CFG (0x0020A5AC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CYCLE_LEN	30:0	0x0	RW	UNDEFINED	**Cycle Length**
MODE	31	0b	RW	UNDEFINED	**Mode**

13.2.2.11.25 Throughput Counters Status - GL_PLG_AVG_CALC_ST (0x0020A5B0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
IN_DATA	14:0	0x0	RO	UNDEFINED	**In Data**
RESERVED	15	0b	RSV	N/A	Reserved.
OUT_DATA	30:16	0x0	RO	UNDEFINED	**Out Data**
VALID	31	0b	RO	UNDEFINED	**Valid**

13.2.2.11.26 Hardware Arb Control - GLSWT_ARB_MODE (0x0020A674; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLU_PRI_SHM	0	0b	RW	UNDEFINED	**FLU Priority** rcu_swr FLU-->KGG collectors ARB: 0b = Prioritized according to FIFO level (above occupancy of 4). 1b = RR.
TX_RX_FWD_PRI	1	0b	RW	UNDEFINED	**Tx/Rx Forward Priority** Tx/Rx replica arbitration at MFIFO output: 0b = RR. 1b = SP to Tx.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.11.27 Recipe Data - GL_PRE_CFG_DATA[n] (0x00214074 + 0x4*n, n=0...6; RO)

Indirect configuration of RCU pre-LUTs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_PRE_RCP_DATA	31:0	0x0	RW	UNDEFINED	**Pre RCP Data**

13.2.2.11.28 Recipe Command - GL_PRE_CFG_CMD (0x00214090; RO)

Indirect configuration of RCU pre-LUTs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADDR	12:0	0x0	WO	UNDEFINED	**Address** Index within the table.
RESERVED	15:13	000b	RSV	N/A	Reserved.
TBLIDX	18:16	000b	WO	UNDEFINED	**Table Index** 000b = Recipes 001b = Profile to recipe mapping 010b = Queue context 011b = Large actions 100b = Dependent recipes table All other values are reserved.
RESERVED	28:19	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CMD	29	0b	WO	UNDEFINED	**Command** 0b = Read 1b = Write
RESERVED	30	0b	RSV	N/A	Reserved.
DONE	31	0b	ROCV	N/A	**Done** Done indication. Cleared on read.

13.2.2.11.29 Virtual Port Switch ID - GL_VP_SWITCHID[n] (0x00214094 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SWITCHID	7:0	0x0	RW	UNDEFINED	**Switch ID** Source VSI Switch ID.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.11.30 SWID Field Vector Index - GL_SWT_SWIDFVIDX (0x00214114; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SWIDFVIDX	5:0	0x0	RW	UNDEFINED	**Switch ID Field Vector Index** Destination of Switch ID in the Field Vector.
RESERVED	30:6	0x0	RSV	N/A	Reserved.
PORT_TYPE	31	0b	RW	UNDEFINED	**Port Type** Selects Virtual or Physical port Switch ID. 0b = Physical 1b = Virtual

13.2.2.11.31 FW Config Status - GL_SWT_FW_STS[n] (0x00216000 + 0x4*n, n=0...5; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_SWT_FW_STS	31:0	0x0	RO	UNDEFINED	**Firmware Config Status**

13.2.2.12 PF - VSI Context Registers

These registers create the VSI context. Unless otherwise stated, these registers are accessed by internal firmware. There are 768 VSI contexts shared between all PFs. All VSIs are accessible to all functions, but each function should access only the VSIs allocated to it.

13.2.2.12.1 VSI Tag Insert Register - First Tag - VSI_TIR_0[VSI] (0x00041000 + 0x4*VSI, VSI=0...767; RO)

Controls the port (VSI) based insertion of tags.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_TAG_ID	15:0	0x0	RW	UNDEFINED	**Port Tag ID** Port (VSI) L2 tag to insert. The tag to insert to is defined in the VSI_L2TAGSTXVALID.*TIR0INSERTID* field. The insert enable is VSI_L2TAGSTXVALID.*TIR0_INSERT*.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.12.2 VSI Tag Insert Register - Second Tag - VSI_TIR_1[VSI] (0x00042000 + 0x4*VSI, VSI=0...767; RO)

Controls the port (VSI) based insertion of tags.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_TAG_ID	31:0	0x0	RW	UNDEFINED	**Port Tag ID** Port (VSI) L2 tag to insert. The tag to insert to is defined in the VSI_L2TAGSTXVALID.*TIR1INSERTID* field. The insert enable is VSI_L2TAGSTXVALID.*TIR1_INSERT*.

13.2.2.12.3 VSI Tag Insert Register - Third Tag - VSI_TIR_2[VSI] (0x00043000 + 0x4*VSI, VSI=0...767; RO)

Controls the port (VSI) based insertion of tags.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_TAG_ID	15:0	0x0	RW	UNDEFINED	**Port Tag ID** Port (VSI) L2 tag to insert. The tag to insert to is defined in the VSI_L2TAGSTXVALID.*TIR2INSERTID* field. The insert enable is VSI_L2TAGSVALID.*TIR2_INSERT*.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.12.4 VSI Tag Alternate Insert Register - VSI_TAIR[VSI] (0x00044000 + 0x4*VSI, VSI=0...767; RO)

Contains the alternate port (VSI) based tag for selected queues.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_TAG_ID	15:0	0x0	RW	UNDEFINED	**Port Tag ID** Port VLAN tag to insert if the VSI_L2TAGSTXVALID.*TIR0_INSERT* is set and the *ALT_VLAN* bit in the transmit queue context is set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.12.5 VSI Tag Accept Register - VSI_TAR[VSI] (0x00045000 + 0x4*VSI, VSI=0...767; RO)

Defines which tags can be accepted from the driver. This register impacts only tag insertion from the driver and not tag insertion by the hardware.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ACCEPTTAGGED	9:0	0x0	RW	UNDEFINED	**Accept Tagged** A bitmap describing if a packet with tag N is accepted. ***Note:*** The two first bits are mapped to the pre L2 and MAC headers.
RESERVED	15:10	0x0	RSV	N/A	Reserved.
ACCEPTUNTAGGED	25:16	0x0	RW	UNDEFINED	**Accept Untagged** A bitmap describing if a packet without tag N is accepted (if L2TAGCTRL.*ISVLAN* is set, admits also priority tagged packets (VLAN tag = 0)). ***Note:*** The two first bits are mapped to the pre L2 and MAC headers.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.12.6 VSI L2 Tx Tags Control - VSI_L2TAGSTXVALID[VSI] (0x00046000 + 0x4*VSI, VSI=0...767; RO)

Identifies which of the eight L2 tags are available for this port for Tx traffic.

Note: The IDs for all the valid tags should be different.

Field	Bit(s)	Init.	Type	CFG Policy	Description
L2TAG1INSERTID	2:0	000b	RW	UNDEFINED	**L2 Tag1 Insert ID** Defines the tag ID to which the value in the L2TAG1 descriptor field should be inserted. This field is valid only if *L2TAG1INSERTID_VALID* is set. Otherwise, insertion requests from L2TAG1 are ignored.
L2TAG1INSERTID_VALID	3	0b	RW	UNDEFINED	**L2 Tag1 Inserted ID Valid** If set, the *L2TAG1INSERTID* field contains a valid value.
L2TAG2INSERTID	6:4	000b	RW	UNDEFINED	**L2 Tag2 Insert ID** Defines the tag ID to which the value in the L2TAG2 descriptor field should be inserted. This field is valid only if *L2TAG2INSERTID_VALID* is set. Otherwise, insertion requests from L2TAG2 are ignored.
L2TAG2INSERTID_VALID	7	0b	RW	UNDEFINED	**L2 Tag2 Inserted ID Valid** If set, the *L2TAG2INSERTID* field contains a valid value.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
TIR0INSERTID	18:16	000b	RW	UNDEFINED	**TIR0 Insert ID** Defines the tag ID to which the value in the VSI_TIR[0].*PORT_TAG_ID* field should be inserted. The tags encoding is described in Section 7.12.3.4, "Tag Handling - Programming Interface". The tag is inserted only if the *TIR0_INSERT* bit is set. This tag is the only one that supports alternate tagging using the VSI_TAIR value.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TIR0_INSERT	19	0b	RW	UNDEFINED	**TIR0 Insert** Insert the tag in VSI_TIR_0 to the L2 Tag pointed by the *TIR0INSERID* field.
TIR1INSERTID	22:20	000b	RW	UNDEFINED	**TIR1 Insert ID** Defines the tag ID to which the value in the VSI_TIR[1].*PORT_TAG_ID* field should be inserted. See *TIR0INSERTID* description for this field encoding. The tag is inserted only if the *TIR1_INSERT* bit is set.
TIR1_INSERT	23	0b	RW	UNDEFINED	**TIR1 Insert** Insert the tag in VSI_TIR_1 to the L2 Tag pointed by the *TIR1INSERID* field.
TIR2INSERTID	26:24	000b	RW	UNDEFINED	**TIR2 Insert ID** Defines the tag ID to which the value in the VSI_TIR[2].*PORT_TAG_ID* field should be inserted. See *TIR0INSERTID* description for this field encoding. The tag is inserted only if the *TIR2_INSERT* bit is set.
TIR2_INSERT	27	0b	RW	UNDEFINED	**TIR2 Insert** Insert the tag in VSI_TIR_2 to the L2 Tag pointed by the *TIR2INSERID* field.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.12.7 VSI Transmit UP Replacement - VSI_TUPR[VSI] (0x00047000 + 0x4*VSI, VSI=0...767; RO)

Defines the VSI-based Tx UP remapping.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0	2:0	000b	RW	UNDEFINED	**UP 0** Defines the UP to set if UP in packet is zero.
UP1	5:3	000b	RW	UNDEFINED	**UP 1** Defines the UP to set if UP in packet is one.
UP2	8:6	000b	RW	UNDEFINED	**UP 2** Defines the UP to set if UP in packet is two.
UP3	11:9	000b	RW	UNDEFINED	**UP 3** Defines the UP to set if UP in packet is three.
UP4	14:12	000b	RW	UNDEFINED	**UP 4** Defines the UP to set if UP in packet is four.
UP5	17:15	000b	RW	UNDEFINED	**UP 5** Defines the UP to set if UP in packet is five.
UP6	20:18	000b	RW	UNDEFINED	**UP 6** Defines the UP to set if UP in packet is six.
UP7	23:21	000b	RW	UNDEFINED	**UP 7** Defines the UP to set if UP in packet is seven.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.12.8 VSI Transmit UP Inner to Outer Mapping - VSI_TUPIOM[VSI] (0x00048000 + 0x4*VSI, VSI=0...767; RO)

Defines the VSI-based Tx UP remapping.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0	2:0	000b	RW	UNDEFINED	**UP 0** Defines the UP to set in outer tag if UP in inner tag is zero.
UP1	5:3	000b	RW	UNDEFINED	**UP 1** Defines the UP to set in outer tag if UP in inner tag is one.
UP2	8:6	000b	RW	UNDEFINED	**UP 2** Defines the UP to set in outer tag if UP in inner tag is two.
UP3	11:9	000b	RW	UNDEFINED	**UP 3** Defines the UP to set in outer tag if UP in inner tag is three.
UP4	14:12	000b	RW	UNDEFINED	**UP 4** Defines the UP to set in outer tag if UP in inner tag is four.
UP5	17:15	000b	RW	UNDEFINED	**UP 5** Defines the UP to set in outer tag if UP in inner tag is five.
UP6	20:18	000b	RW	UNDEFINED	**UP 6** Defines the UP to set in outer tag if UP in inner tag is six.
UP7	23:21	000b	RW	UNDEFINED	**UP 7** Defines the UP to set in outer tag if UP in inner tag is seven.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.12.9 VSI Receive UP Replacement - VSI_RUPR[VSI] (0x00050000 + 0x4*VSI, VSI=0...767; RW)

Defines the VSI based Rx UP remapping. The tag on which this translation is done is the tag for which the L2TAGSCTRL.*INNERUP* is set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0	2:0	000b	RW	UNDEFINED	**UP 0** Defines the UP to set if UP in packet is zero.
UP1	5:3	000b	RW	UNDEFINED	**UP 1** Defines the UP to set if UP in packet is one.
UP2	8:6	000b	RW	UNDEFINED	**UP 2** Defines the UP to set if UP in packet is two.
UP3	11:9	000b	RW	UNDEFINED	**UP 3** Defines the UP to set if UP in packet is three.
UP4	14:12	000b	RW	UNDEFINED	**UP 4** Defines the UP to set if UP in packet is four.
UP5	17:15	000b	RW	UNDEFINED	**UP 5** Defines the UP to set if UP in packet is five.
UP6	20:18	000b	RW	UNDEFINED	**UP 6** Defines the UP to set if UP in packet is six.
UP7	23:21	000b	RW	UNDEFINED	**UP 7** Defines the UP to set if UP in packet is seven.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.12.10 VSI Tag Strip Register - VSI_TSR[VSI] (0x00051000 + 0x4*VSI, VSI=0...767; RW)

Defines the behavior of tag extraction from receive packets.

Field	Bit(s)	Init.	Type	CFG Policy	Description
STRIPTAG	9:0	0x0	RW	UNDEFINED	**Strip Tag** A per tag bitmap defining which tags to strip from the packet. The *SHOWTAG* and *SHOWPRIONLY* fields define which part of the tag to extract to descriptor. ***Note:*** The two LS bits of this field relate to the *pre*-L2 and MAC headers and should not be set. Bits 9:2 should be used to configure the striping of the L2 tags.
SHOWTAG	19:10	0x0	RW	UNDEFINED	**Show Tag** A per tag bitmap defining which tags to extract to the descriptor. The *SHOWPRIONLY* field defines which part of the tag to extract to the descriptor. At most, two of these bits should be set. If more than two bits are set, only the two first ones are considered. See For details on the format in the descriptor, see Section 10.4.2.2, "Receive Descriptor - Write-Back Format".
SHOWPRIONLY	29:20	0x0	RW	UNDEFINED	**Strip Priority Only** A per tag bitmap defining which par of the tags to extract to the descriptor. If set, only the priority bits are extracted. Otherwise the entire tag is used. Relevant only if the corresponding bit in SHOWTAG is set. ***Note:*** The two LS bits of this field relate to the pre-L2 and MAC headers and should not be set. Bits 9:2 should be used to configure the exposure of the L2 tags priority bits.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.12.11 PASID Context - VSI_PASID[VSI] (0x0009C000 + 0x4*VSI, VSI=0...767; RW)

PASID context per VSI.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PASID	19:0	0x0	RW	UNDEFINED	**Process Address Space ID** PASID value of PASID TLP prefix.
RESERVED	30:20	0x0	RSV	N/A	Reserved.
EN	31	0b	RW	UNDEFINED	**Enable** Valid for *PASID* field.

13.2.2.12.12 VSI to Function Mapping Multicast - VSI_VSI2F[VSI] (0x001D0000 + 0x4*VSI, VSI=0...767; RW)

This register indicates the function owning the VSI.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFVMNUMBER	9:0	0x0	RW	UNDEFINED	**VF/VM Number** Defines the VF this VSI belongs to, or the VM within the PF associated with this VSI. Must be zero if VSI type is PF or EMP (VSI_VSI2F.*FUNCTIONTYPE* =10b or 11b, respectively). If the VSI is of type VM (VSI_VSI2F.*FUNCTIONTYPE* = 01b), this number should be equal to the VSI number.
FUNCTIONTYPE	11:10	00b	RW	UNDEFINED	**Function Type** Defines the type of VSI: 00b = VF 01b = VM 10b = PF 11b = EMP
PFNUMBER	14:12	000b	RW	UNDEFINED	**PF Number** Defines the PF this VSI belongs to. Should be set to the PF number for all VSI types except EMP (VSI_VSI2PF.*FUNCTIONTYPE* = 00b, 01b, or 10b).
RESERVED	15	0b	RSV	N/A	Reserved.
BUFFERNUMBER	18:16	0x0	RW	UNDEFINED	**Buffer Number** Defines the buffer in the EMP that is used for this VSI. Relevant only if *FUNCTIONTYPE* = EMP (11b).
RESERVED	19	0b	RSV	N/A	Reserved.
VSI_NUMBER	29:20	0x0	RW	UNDEFINED	**VSI Number** Defines the VSI number of this VSI. The default of this field in the VSI#. This field is not used for VSI redirection. ***Note:*** This field is a candidate for removal in future gen products and software/firmware should refrain from referring it.
RESERVED	30	0b	RSV	N/A	Reserved.
VSI_ENABLE	31	0b	RW	UNDEFINED	**VSI Enable** When set, this VSI is enabled and can receive or transmit packets.

13.2.2.12.13 VSI Rx Switch Control - VSI_RXSWCTRL[VSI] (0x00205000 + 0x4*VSI, VSI=0...767; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	7:0	0x0	RSV	N/A	Reserved.
MACVSIPRUNEENABLE	8	0b	RW	UNDEFINED	**MAC VSI Prune Enable** If set, inverse actions are applied to Rx traffic to this VSI (used in default image for MAC source pruning).
PRUNEENABLE	12:9	0x0	RW	UNDEFINED	**Prune Enable** Defines which pruning modes are enabled for Rx traffic. Each bit matches one of the prune index in the recipe (offset 181:180).
SRCPRUNEENABLE	13	0b	RW	UNDEFINED	**Source Prune Enable** Enable source pruning. If set, a packet is not received by this VSI if sent from it.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.12.14 Mirror - Rx Rules VSIs - VSI_SWT_MIREG[VSI] (0x00207000 + 0x4*VSI, VSI=0...767; RO)

This register defines the rules that request to mirror egress VSI n.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIRRULE	5:0	0x0	RW	UNDEFINED	**Mirror Rule** Mirror rule index.
RESERVED	6	0b	RSV	N/A	Reserved.
MIRENA	7	0b	RW	UNDEFINED	**Mirror Enable** Mirror enable.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.12.15 Mirror - Tx Rules VSIs - VSI_SWT_MIRIG[VSI] (0x00208000 + 0x4*VSI, VSI=0...767; RO)

This register defines the rules that request to mirror ingress VSI n.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIRRULE	5:0	0x0	RW	UNDEFINED	**Mirror Rule** Mirror rule index.
RESERVED	6	0b	RSV	N/A	Reserved.
MIRENA	7	0b	RW	UNDEFINED	**Mirror Enable** Mirror enable.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.12.16 VSI Source Switch Control - VSI_SRCSWCTRL[VSI] (0x00209000 + 0x4*VSI, VSI=0...767; RO)

These registers contain the switch ID for each VF. If the VF is identified by an STag, this field should include the STag and the *ISNSTAG* should be cleared. Otherwise, it should include a switch ID and the *ISNSTAG* should be set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ALLOWDESTOVERRIDE	0	0b	RW	UNDEFINED	**Allow Destination Override** Allows destination override by transmit descriptor.
ALLOWLOOPBACK	1	0b	RW	UNDEFINED	**Allow Loopback** Allows forwarding of packets from this VSI to local VSIs.
LANENABLE	2	0b	RW	UNDEFINED	**LAN Enable** If set, packets sent from this VSI can be sent to the external port.
MACAS	3	0b	RW	UNDEFINED	**MAC Anti-Spoofing** Enabling recipes where the inverse_action is set for Tx packets (Enables MAC anti-spoofing in default setting)
PRUNEENABLE	7:4	0x0	RW	UNDEFINED	**Prune Enable** Enables prune actions for Tx traffic. According to the prune_index in recipe (offset 181:180).
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.12.17 Source VSI Switch ID - VSI_SWITCHID[VSI] (0x00215000 + 0x4*VSI, VSI=0...767; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SWITCHID	7:0	0x0	RW	UNDEFINED	**Switch ID** Source VSI Switch ID.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.12.18 VSI Classification Filter - Hash Key - VSIQF_HKEY[n,VSI] (0x00400000 + 0x1000*n + 0x4*VSI, n=0...12, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
KEY_0	7:0	0x0	RW	UNDEFINED	**Key 0** Toeplitz key byte "4*m+3" of VSI "n". Register index is "1024*m + n", where "m" range is 0-12 (total 52 key bytes), and "n" range is 0-767. ***Note:*** Index range 768-1023 of each key-quad register is unused (reserved).
KEY_1	15:8	0x0	RW	UNDEFINED	**Key 1** Toeplitz key byte "4*m+3" of VSI "n". Register index is "1024*m + n", where "m" range is 0-12 (total 52 key bytes), and "n" range is 0-767. ***Note:*** Index range 768-1023 of each key-quad register is unused (reserved).
KEY_2	23:16	0x0	RW	UNDEFINED	**Key 2** Toeplitz key byte "4*m+3" of VSI "n". Register index is "1024*m + n", where "m" range is 0-12 (total 52 key bytes), and "n" range is 0-767. ***Note:*** Index range 768-1023 of each key-quad register is unused (reserved).
KEY_3	31:24	0x0	RW	UNDEFINED	**Key 3** Toeplitz key byte "4*m+3" of VSI "n". Register index is "1024*m + n", where "m" range is 0-12 (total 52 key bytes), and "n" range is 0-767. ***Note:*** Index range 768-1023 of each key-quad register is unused (reserved).

13.2.2.12.19 VSI Classification Filter - Hash Control - VSIQF_HASH_CTL[VSI] (0x0040D000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_LUT_SEL	1:0	00b	RW	UNDEFINED	**Hash LUT Select** Selects the Hash LUT for the VSI: 00b = VSI LUT 01b = Reserved 10b = PF LUT 11b = Global LUT (one of 16 Global LUTs)
GLOB_LUT	5:2	0x0	RW	UNDEFINED	**Global LUT** The Global LUT index for the VSI. This field is relevant only if the *RSS_LUT_SEL* equals to Global LUT. Otherwise it must be set to zero.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HASH_SCHEME	7:6	00b	RW	UNDEFINED	**Hash Scheme** The hash type that can be one of the following: 00b = Toeplitz Hash 01b = Symmetric Toeplitz 10b = Simple XOR 11b = Reserved
TC_OVER_SEL	12:8	0x0	RW	UNDEFINED	**TC Override Select** An index to one of 32 global tables used to override TC regions of queues by some of the packet profiles defined by the GLQF_PROF2TC tables. This field is meaningful only if the *TC_OVER_ENA* flag is set. Otherwise, this field must be set to zero.
RESERVED	14:13	00b	RSV	N/A	Reserved.
TC_OVER_ENA	15	0b	RW	UNDEFINED	**TC Override Enable** Enable packet profile override the TC region of queues according to the *TC_OVER_SEL* parameter.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.12.20 VSI Classification Filter - FD Control 1 - VSIQF_FD_CTL1[VSI] (0x00411000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLT_ENA	0	0b	RW	UNDEFINED	**Filtering Enable** Enable FD filtering for the VSI.
CFG_ENA	1	0b	RW	UNDEFINED	**Configuration Enable** Enable FD programming for the VSI.
EVICT_ENA	2	0b	RW	UNDEFINED	**Evict Enable** Enable auto-evict by FIN/RST for the VSI.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.12.21 VSI Classification Filter - PE Control 1 - VSIQF_PE_CTL1[VSI] (0x00414000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PE_FLTENA	0	0b	RW	UNDEFINED	**PE Filter Enable** Enable PE filter for the VSI.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.12.22 VSI Classification Filter - Hash LUT - VSIQF_HLUT[n,VSI] (0x00420000 + 0x1000*n + 0x4*VSI, n=0...15, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LUT0	3:0	0x0	RW	UNDEFINED	**LUT 0** Hash redirection LUT entry 4 x n, where "n" is the register index.
RESERVED	7:4	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LUT1	11:8	0x0	RW	UNDEFINED	**LUT 1** Hash redirection LUT entry 4 x n+1, where "n" is the register index.
RESERVED	15:12	0x0	RSV	N/A	Reserved.
LUT2	19:16	0x0	RW	UNDEFINED	**LUT 2** Hash redirection LUT entry 4 x n+2, where "n" is the register index.
RESERVED	23:20	0x0	RSV	N/A	Reserved.
LUT3	27:24	0x0	RW	UNDEFINED	**LUT 3** Hash redirection LUT entry 4 x n+3, where "n" is the register index.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.12.23 VSI Classification Filter - Receive TC Queue Regions - VSIQF_TC_REGION[n,VSI] (0x00448000 + 0x1000*n + 0x4*VSI, n=0...3, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TC_BASE0	10:0	0x0	RW	UNDEFINED	**TC Base 0** TC_BASE0 in register "n" defines the TC[2*n] region base (within the VSI space). The hardware does not check if the queue index exceeds the VSI range. So it is the PF software responsibility to ensure that TC_BASE + TC_SIZE does not exceed the VSI space.
TC_SIZE0	14:11	0x0	RW	UNDEFINED	**TC Size 0** TC_SIZE0 in register "n" defines the TC[2*n] region size as follows: Values 0...8 are mapped to the following respective TC sizes: 1, 2, 4, 8, 16, 32, 64, 128, and 256, respectively. Other values (larger than 8) are not defined and should not be used or programmed.
RESERVED	15	0b	RSV	N/A	Reserved.
TC_BASE1	26:16	0x0	RW	UNDEFINED	**TC Base 1** TC_BASE1 in register "n" defines the TC[2*n+1] region base (within the VSI space). The hardware does not check if the queue index exceeds the VSI range. So it is the PF software responsibility to make sure that TC_BASE + TC_SIZE does not exceed the VSI space.
TC_SIZE1	30:27	0x0	RW	UNDEFINED	**TC Size 1** TC_SIZE1 in register "n" defines the TC[2*n+1] region size as follows: Values 0...8 are mapped to the following respective TC sizes: 1, 2, 4, 8, 16, 32, 64, 128, and 256, respectively. Other values (larger than 8) are not defined and should not be used or programmed.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.12.24 VSI Classification Filter - FD Default Action - VSIQF_FD_DFLT[VSI] (0x00457000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEFLT_QINDX	10:0	0x0	RW	UNDEFINED	**Default Queue Index** This field defines the receive queue index within the VSI for packets that miss the FD filter. Permitted values are in the range of the queues of the VSI.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	11	0b	RSV	N/A	Reserved.
DEFLT_TOQUEUE	14:12	000b	RW	UNDEFINED	**Default ToQueue** The ToQueue parameter associates a target queue or a queue group to the FD filter: 000b = The filter assigns a target queue defined by the QINDX. 001b-111b = The filter assigns a region of queues. The region base equals the QINDX and the region size equals 2^(ToQueue).
RESERVED	15	0b	RSV	N/A	Reserved.
COMP_QINDX	26:16	0x0	RW	UNDEFINED	**Completion Queue Index** This field defines the receive queue index of the programming VSI on which the FD filter completion status is reported when the *COMP_QUEUE* flag in the programming descriptor is set to "1".
RESERVED	27	0b	RSV	N/A	Reserved.
DEFLT_QINDX_PRIO	30:28	000b	RW	UNDEFINED	**Default Queue Index Priority** The priority of the default QINDX action.
DEFLT_DROP	31	0b	RW	UNDEFINED	**Default Drop** When set to 1b, packets that miss the FD filters are dropped.

13.2.2.12.25 VSI Classification Filter - FD VSI Space Sizes - VSIQF_FD_SIZE[VSI] (0x00462000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GSIZE	13:0	0x0	RW	UNDEFINED	**FD Guaranteed Size** VSI guaranteed size in the FD table.
RESERVED	15:14	00b	RSV	N/A	Reserved.
FD_BSIZE	29:16	0x0	RW	UNDEFINED	**FD Best Size** VSI best effort size in the FD table.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.12.26 VSI Classification Filter - FD VSI Space Counters - VSIQF_FD_CNT[VSI] (0x00464000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GCNT	13:0	0x0	RW	UNDEFINED	**FD Guaranteed Counter** VSI guaranteed filter counter in the FD table.
RESERVED	15:14	00b	RSV	N/A	Reserved.
FD_BCNT	29:16	0x0	RW	UNDEFINED	**FD Best Counter** VSI best effort filter counter in the FD table.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.13 PF - ACL Registers

13.2.2.13.1 Configuration Access Command - GL_ACL_ACCESS_CMD (0x00391000; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TABLE_ID	7:0	0x0	RW	UNDEFINED	**Table ID** TCAM/Action memory index used for the access (when relevant). Inapplicable indexes will cause the command to fail.
ENTRY_INDEX	19:8	0x0	RW	UNDEFINED	**Entry Index** Entry/Scenario/Profile index. Inapplicable indexes will cause the command to fail.
OPERATION	20	0b	RW	UNDEFINED	**Operation** 0b = Read an entry from the index specified in *ENTRY_INDEX* in the table whose index is specified in *TABLE_ID*. 1b = Write an entry to the index specified in *ENTRY_INDEX* in table whose index is specified in *TABLE_ID*.
RESERVED	23:21	000b	RSV	N/A	Reserved.
OBJ_TYPE	27:24	0x0	RW	UNDEFINED	**Object Type** Accessed object type: 0x0 = TCAM entry. 0x1 = Action memory entry. 0x2 = Scenario configuration. 0x3 = Scenario action memory configuration. 0x4 = Profile dependent configuration (except for range checkers). 0x5 = Range checker configuration (profile dependent). All other values are reserved.
RESERVED	30:28	000b	RSV	N/A	Reserved.
EXECUTE	31	0b	SC	UNDEFINED	**Execute** Execute bit. Setting this self-clearing bit initiates the operation. The hardware clears this bit one cycle after it was set.

13.2.2.13.2 Configuration Access Status - GL_ACL_ACCESS_STATUS (0x00391004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BUSY	0	0b	RO	N/A	**Busy** Busy indication.
DONE	1	0b	RO	N/A	**Done** Done indication.
ERROR	2	0b	RO	N/A	**Error** Error indication.
OPERATION	3	0b	RO	N/A	**Operation** Operation used in last access.
ERROR_CODE	7:4	0x0	RO	N/A	**Error Code** Error code: 0x0 = Table ID out of bounds. 0x1 = Entry index out of bounds. All other values are reserved.
TABLE_ID	15:8	0x0	RO	N/A	**Table ID** Table ID used for last access.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ENTRY_INDEX	27:16	0x0	RO	N/A	**Entry Index** Entry index used for last access.
OBJ_TYPE	31:28	0x0	RO	N/A	**Object Type** Object type used for last access.

13.2.2.13.3 Byte and Word Selection Bases Select per Profile - GL_ACL_PROFILE_BWSB_SEL[n] (0x00391008 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BSB_SRC_OFF	5:0	0x0	RW	UNDEFINED	**Source Byte Offset** Offset (expressed in bytes) for the source byte in the extracted fields vector.
RESERVED	7:6	00b	RSV	N/A	Reserved.
WSB_SRC_OFF	12:8	0x0	RW	UNDEFINED	**Source Word Offset** Offset (expressed in words) for the source word in the extracted fields vector.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.13.4 DWord Selection Base Select per Profile - GL_ACL_PROFILE_DWSB_SEL[n] (0x00391088 + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DWORD_SEL_OFF	3:0	0x0	RW	UNDEFINED	**DWord Selection Offset** Offset (expressed in DWords) for the source DWord in the extracted fields vector
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.13.5 Profile Assignment to Scenario - GL_ACL_PROFILE_PF_CFG[n] (0x003910C8 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SCEN_SEL	5:0	0x0	RW	UNDEFINED	**Scenario Selection** This determines the selected scenario for this PF when this profile is selected.
RESERVED	31:6	0x0	RSV	N/A	Reserved.

13.2.2.13.6 Range Checker Configuration per Profile - GL_ACL_PROFILE_RC_CFG[n] (0x003910E8 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LOW_BOUND	15:0	0x0	RW	UNDEFINED	**Low Boundary** The range checker's output is negative if the related field's value is lower than this value.
HIGH_BOUND	31:16	0x0	RW	UNDEFINED	**High Boundary** The range checker's output is negative if the related field's value is higher than this value.

13.2.2.13.7 Word Selection Base Range Checked Fields Masking per Profile - GL_ACL_PROFILE_RCF_MASK[n] (0x00391108 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MASK	15:0	0x0	RW	UNDEFINED	**Mask** Range checker input mask. When a bit is cleared in this field, the relevant bit is cleared in the range checker's input.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.13.8 Default Action Array - GL_ACL_DEFAULT_ACT[n] (0x00391168 + 0x4*n, n=0...15; RO)

Field definitions are the same as those defined in Section 13.2.2.13.15.

13.2.2.13.9 VSI Dependent ACL Configuration - VSI_ACL_DEF_SEL[VSI] (0x00391800 + 0x4*VSI, VSI=0...767; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RX_PROFILE_MISS_SEL	1:0	00b	RW	UNDEFINED	**Rx Profile Miss Selection** This field selects which action set sets the action when a packet belonging to this VSI is not associated with any profile (i.e., misses the profile table).
RESERVED	3:2	00b	RSV	N/A	Reserved.
RX_TABLES_MISS_SEL	5:4	00b	RW	UNDEFINED	**Rx Tables Miss Selection** This field selects which action set sets the action when a packet belonging to this VSI is not associated with any ACL action (i.e., misses the ACL tables).
RESERVED	7:6	00b	RSV	N/A	Reserved.
TX_PROFILE_MISS_SEL	9:8	00b	RW	UNDEFINED	**Tx Profile Miss Selection** This field selects which action set sets the action when an packet originating from this VSI is not associated with any profile (i.e., misses the profile table).
RESERVED	11:10	00b	RSV	N/A	Reserved.
TX_TABLES_MISS_SEL	13:12	00b	RW	UNDEFINED	**Tx Tables Miss Selection** This field selects which action set sets the action when a packet originating from this VSI is not associated with any ACL action (i.e., misses the ACL tables).

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.13.10 GL_ACL_CHICKEN_REGISTER - GL_ACL_CHICKEN_REGISTER (0x00393810; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCAM_DATA_POL_CH	0	0b	RW	UNDEFINED	**TCAM Data Polarity Chicken**
TCAM_ADDR_POL_CH	1	0b	RW	UNDEFINED	**TCAM Address Polarity Chicken**
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.13.11 TCAM Write Key Low - GL_ACL_TCAM_KEY_L (0x00393814; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_ACL_FFU_TCAM_KEY_L	31:0	0x0	RW	UNDEFINED	**TCAM Key Low** 32 LSB of the entry key to be written to the TCAM.

13.2.2.13.12 TCAM Write Key High - GL_ACL_TCAM_KEY_H (0x00393818; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_ACL_FFU_TCAM_KEY_H	7:0	0x0	RW	UNDEFINED	**TCAM Key High** 8 MSB of the entry key to be written to the TCAM.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.13.13 TCAM Write Key Invert Low - GL_ACL_TCAM_KEY_INV_L (0x0039381C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_ACL_FFU_TCAM_KEY_INV_L	31:0	0x0	RW	UNDEFINED	**TCAM Key Invert Low** 32 LSB of the key invert to be written to the TCAM.

13.2.2.13.14 TCAM Write Key Invert High - GL_ACL_TCAM_KEY_INV_H (0x00393820; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_ACL_FFU_TCAM_KEY_INV_H	7:0	0x0	RW	UNDEFINED	**TCAM Key Invert High** 8 MSB of the key invert to be written to the TCAM.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.13.15 Action Write Data - GL_ACL_ACTMEM_ACT[n] (0x00393824 + 0x4*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALUE	15:0	0x0	RW	UNDEFINED	**Value** Action value.
RESERVED	19:16	0x0	RSV	N/A	Reserved.
MDID	25:20	0x0	RW	UNDEFINED	**MDID** Action metadata ID.
RESERVED	27:26	00b	RSV	N/A	Reserved.
PRIORITY	30:28	000b	RW	UNDEFINED	**Priority** Action priority.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.13.16 Scenario Configuration Write Data Low Part - GL_ACL_SCENARIO_CFG_L[n] (0x0039382C + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SELECT0	6:0	0x0	RW	UNDEFINED	**Select 0** Selects byte 0 of the lookup key: • If *SELECT0* is in the range of 0-31, the value is: KEY16[SELECT0][7:0] • If *SELECT0* is in the range of 32-63, the value is: KEY8[SELECT0 - 32] • If *SELECT0* is in the range of 64-95, the value is 0x0. • If *SELECT0* is in the range of 96-111, the value is: KEY32[SELECT0 - 96][7:0]
RESERVED	7	0b	RSV	N/A	Reserved.
SELECT1	14:8	0x0	RW	UNDEFINED	**Select 1** Selects byte 1 of the lookup key: • If *SELECT1* is in the range of 0-31, the value is: KEY16[SELECT1][15:8] • If *SELECT1* is in the range of 32-63, the value is: KEY8[SELECT1 - 32]. • If *SELECT1* is in the range of 64-95, the value is 0x0. • If *SELECT1* is in the range of 96-111, the value is: KEY32[SELECT1 - 96][15:8]
RESERVED	15	0b	RSV	N/A	Reserved.
SELECT2	22:16	0x0	RW	UNDEFINED	**Select 2** Selects byte 2 of the lookup key: • If *SELECT2* is in the range of 0-31, the value is: KEY16[SELECT2][7:0] • If *SELECT2* is in the range of 32-63, the value is: KEY8[SELECT2 - 32]. • If *SELECT2* is in the range of 64-95, the value is 0x0. • If *SELECT2* is in the range of 96-111, the value is: KEY32[SELECT2 - 96][23:16]
RESERVED	23	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
SELECT3	30:24	0x0	RW	UNDEFINED	**Select 3** Selects byte 3 of the lookup key: • If *SELECT3* is in the range of 0-31, the value is: KEY16[SELECT3][15:8] • If *SELECT3* is in the range of 32-63, the value is: KEY8[SELECT3 - 32]. • If *SELECT3* is in the range of 64-95, the value is 0x0. • If *SELECT3* is in the range of 96-111, the value is: KEY32[SELECT3 - 96][31:24]
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.13.17 Scenario Configuration Write Data High Part - GL_ACL_SCENARIO_CFG_H[n] (0x0039386C + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SELECT4	4:0	0x0	RW	UNDEFINED	**Select 4** Selects byte 4 of the lookup key: Selects KEY8[SelectTop] as the top eight bits of the lookup key. Only KEY8s can be selected for this field.
RESERVED	7:5	000b	RSV	N/A	Reserved.
CHUNKMASK	15:8	0x0	RW	UNDEFINED	**Chunk Mask** Specifies the validity of 64-rule chunks: • ChunkMask[0] enables rules 0..63. • ChunkMask[1] enables rules 64..127. • and so on Used to create smaller per-scenario tables.
RESERVED	23:16	0x0	RSV	N/A	Reserved.
START_COMPARE	24	0b	RW	UNDEFINED	**Start Compare** Starts a compare cascade.
RESERVED	27:25	000b	RSV	N/A	Reserved.
START_SET	28	0b	RW	UNDEFINED	**Start Set** Start a TCAM stacking.
RESERVED	31:29	000b	RSV	N/A	Reserved.

13.2.2.13.18 Scenario Action RAM Configuration Write Data - GL_ACL_SCENARIO_ACT_CFG[n] (0x003938AC + 0x4*n, n=0...19; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ACTMEM_SEL	3:0	0x0	RW	UNDEFINED	**Action Memory Select** Selects which TCAM controls the action memory for this scenario
RESERVED	7:4	0x0	RSV	N/A	Reserved.
ACTMEM_EN	8	0b	RW	UNDEFINED	**Action Memory Enable** Enable/disable control: 0b = The action memory is disable for this scenario. 1b = The action memory is enabled for this scenario.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.14 PF - Rx Filters Registers

13.2.2.14.1 Global Classification Filter - PE Table Clear - GLQF_PETABLE_CLR[n] (0x000AA078 + 0x4*n, n=0...1; RW)

Register '0' is used by the EMP as part of PFR / VFR flows.
Register '1' is used by the PE as part of a function table removal flow.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VM_VF_NUM	9:0	0x0	RW	UNDEFINED	**VM/VF Number** Absolute VF number. Relevant only for *VM_VF_TYPE* = VF (00b). Otherwise, must be set to zero.
VM_VF_TYPE	11:10	00b	RW	UNDEFINED	**VM/VF Type** Defines the impact of the clear action: 00b = VF clear. 10b = PF clear. All other values are reserved.
PF_NUM	14:12	000b	RW	UNDEFINED	**PF Number** PF index.
RESERVED	15	0b	RSV	N/A	Reserved.
PE_BUSY	16	0b	SC	UNDEFINED	**PE Busy** The *BUSY* flag indicates that PE cache clear is in progress. It is set by software and cleared by the device.
PE_CLEAR	17	0b	RW	UNDEFINED	**PE Clear** Setting this flag clears the PE filters entries of the entity (PF/VF) from the PE cache.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.14.2 PF Classification Filter - PE Field Vector Bitmap Enable - GLQF_PE_FVE (0x0020E514; RW)

This register is used by the PE to program QH filter entries.

Field	Bit(s)	Init.	Type	CFG Policy	Description
W_ENA	23:0	0x0	RW	UNDEFINED	**Word Enable** Bit 'i' in this field enables word 'i' in the field vector.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.14.3 Global Classification Filter - Hash Input Set - GLQF_HINSET[n,m] (0x0040E000 + 0x4*n + 0x200*m, n=0...127, m=0...5; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FV_WORD_INDX0	4:0	0x1F	RW	UNDEFINED	**FV Word Index 0** The word index in the FV that is copied to the input set word “m*4” of packet profile “n”, where “n”, “m” are the register's indexes in the array.
RESERVED	6:5	00b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FV_WORD_VAL0	7	1b	RW	UNDEFINED	**FV Word Valid 0** Valid indication for the word defined by *FV_WORD_INDX0*.
FV_WORD_INDX1	12:8	0x1F	RW	UNDEFINED	**FV Word Index 1** The word index in the FV that is copied to the input set word "m*4+1" of packet profile "n", where "n", "m" are the register's indexes in the array.
RESERVED	14:13	00b	RSV	N/A	Reserved.
FV_WORD_VAL1	15	1b	RW	UNDEFINED	**FV Word Valid 1** Valid indication for the word defined by *FV_WORD_INDX1*.
FV_WORD_INDX2	20:16	0x1F	RW	UNDEFINED	**FV Word Index 2** The word index in the FV that is copied to the input set word "m*4+2" of packet profile "n", where "n", "m" are the register's indexes in the array.
RESERVED	22:21	00b	RSV	N/A	Reserved.
FV_WORD_VAL2	23	1b	RW	UNDEFINED	**FV Word Valid 2** Valid indication for the word defined by *FV_WORD_INDX2*.
FV_WORD_INDX3	28:24	0x1F	RW	UNDEFINED	**FV Word Index 3** The word index in the FV that is copied to the input set word "m*4+3" of packet profile "n", where "n", "m" are the register's indexes in the array.
RESERVED	30:29	00b	RSV	N/A	Reserved.
FV_WORD_VAL3	31	1b	RW	UNDEFINED	**FV Word Valid 3** Valid indication for the word defined by *FV_WORD_INDX3*.

13.2.2.14.4 Global Classification Filter - Symmetric Hash - GLQF_HSYMM[n,m] (0x0040F000 + 0x4*n + 0x200*m, n=0...127, m=0...5; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FV_SYMM_INDX0	4:0	0x0	RW	UNDEFINED	**FV Symmetric Index 0** Registers "n" belongs to packet profile "n". There are multiple registers per packet profile indexed by "m". If the *SYMM0_ENA* is set, the input set word index "m*4" equals an XOR function between FV word index = *FV_SYMM_INDX0* (in this register) and FV word index = *FV_INSET_INDX0* (in the GLQF_HINSET register).
RESERVED	6:5	00b	RSV	N/A	Reserved.
SYMM0_ENA	7	0b	RW	UNDEFINED	**Symmetric 0 Enable** Symmetric word indication for the word defined by *FV_SYMM_INDX0*.
FV_SYMM_INDX1	12:8	0x0	RW	UNDEFINED	**FV Symmetric Index 1** Registers "n" belongs to packet profile "n". There are multiple registers per packet profile indexed by "m". If the *SYMM1_ENA* is set, the input set word index "m*4+1" equals an XOR function between FV word index = *FV_SYMM_INDX1* (in this register) and FV word index = *FV_INSET_INDX1* (in the GLQF_HINSET register).
RESERVED	14:13	00b	RSV	N/A	Reserved.
SYMM1_ENA	15	0b	RW	UNDEFINED	**Symmetric 1 Enable** Symmetric word indication for the word defined by *FV_SYMM_INDX1*.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FV_SYMM_INDX2	20:16	0x0	RW	UNDEFINED	**FV Symmetric Index 2** Registers "n" belongs to packet profile "n". There are multiple registers per packet profile indexed by "m". If the *SYMM2_ENA* is set, the input set word index "m*4+2" equals an XOR function between FV word index = *FV_SYMM_INDX2* (in this register) and FV word index = *FV_INSET_INDX2* (in the GLQF_HINSET register).
RESERVED	22:21	00b	RSV	N/A	Reserved.
SYMM2_ENA	23	0b	RW	UNDEFINED	**Symmetric 2 Enable** Symmetric word indication for the word defined by *FV_SYMM_INDX2*.
FV_SYMM_INDX3	28:24	0x0	RW	UNDEFINED	**FV Symmetric Index 3** Registers "n" belongs to packet profile "n". There are multiple registers per packet profile indexed by "m". If the *SYMM3_ENA* is set, the input set word index "m*4+3" equals an XOR function between FV word index = *FV_SYMM_INDX3* (in this register) and FV word index = *FV_INSET_INDX3* (in the GLQF_HINSET register).
RESERVED	30:29	00b	RSV	N/A	Reserved.
SYMM3_ENA	31	0b	RW	UNDEFINED	**Symmetric 3 Enable** Symmetric word indication for the word defined by *FV_SYMM_INDX3*.

13.2.2.14.5 Global Classification Filter - Hash Mask - GLQF_HMASK[n] (0x0040FC00 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSK_INDEX	4:0	0x0	RW	UNDEFINED	**Mask Index** Word index in the Input Set vector to be masked.
RESERVED	15:5	0x0	RSV	N/A	Reserved.
MASK	31:16	0x0	RW	UNDEFINED	**Mask** Mask word. Any bit set to "0" masks out the matched bit of *MSK_INDEX* byte in the field vector.

13.2.2.14.6 Global Classification Filter - Hash Mask Select - GLQF_HMASK_SEL[n] (0x00410000 + 0x4*n, n=0...127; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MASK_SEL	31:0	0x0	RW	UNDEFINED	**Mask Select** The *MASK_SEL* is a bitmap field that enables the GLQF_HMASK registers per packet profile "n", where "n" is the GLQF_HMASK_SEL register index. Bit "x" in this register enables register GLQF_HMASK[x].

13.2.2.14.7 Global Classification Filter - FD Mask Select - GLQF_FDMASK_SEL[n] (0x00410400 + 0x4*n, n=0...127; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MASK_SEL	31:0	0x0	RW	UNDEFINED	**Mask Select** The *MASK_SEL* is a bitmap field that enables the GLQF_FDMASK registers per packet profile "n", where "n" is the GLQF_FDMASK_SEL register index. Bit "x" in this register enables register GLQF_FDMASK[x].

13.2.2.14.8 Global Classification Filter - FD Mask - GLQF_FDMASK[n] (0x00410800 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSK_INDEX	4:0	0x0	RW	UNDEFINED	**Mask Index** Word index in the Input Set vector to be masked.
RESERVED	15:5	0x0	RSV	N/A	Reserved.
MASK	31:16	0x0	RW	UNDEFINED	**Mask** Mask word. Any bit set to "0" masks out the matched bit of *MSK_INDEX* byte in the field vector.

13.2.2.14.9 Global Classification Filter - FD Input Set - GLQF_FDINSET[n,m] (0x00412000 + 0x4*n + 0x200*m, n=0...127, m=0...5; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FV_WORD_INDX0	4:0	0x1F	RW	UNDEFINED	**FV Word Index 0** The word index in the FV that is copied to the input set word "m*4" of packet profile "n", where "n", "m" are the register's indexes in the array.
RESERVED	6:5	00b	RSV	N/A	Reserved.
FV_WORD_VAL0	7	1b	RW	UNDEFINED	**FV Word Valid 0** Valid indication for the word defined by *FV_WORD_INDX0*.

13.2.2.14.16 PF Classification Filter - FD Enable - PFQF_FD_ENA (0x0043A000; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_ENA	0	0b	RW	UNDEFINED	**FD Enable** Enables programming and filtering of the FD filter for the function.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.14.17 PF Classification Filter - PE Enable - PFQF_PE_FILTERING_ENA (0x0043A080; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PE_ENA	0	0b	RW	UNDEFINED	**PE Enable** Enables the filtering and programming of PE filters.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.14.18 Global Classification Filter - Packet Profile to Hash TC Region Mapping - GLQF_PROF2TC[n,m] (0x0044D000 + 0x4*n + 0x200*m, n=0...127, m=0...3; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
OVERRIDE_ENA_0	0	0b	RW	UNDEFINED	**Override Enable 0** Enable for Override TC Region "8*m" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_0	3:1	000b	RW	UNDEFINED	**Region 0** Receive queue region for Override TC Region "8*m" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_0* flag is set.
OVERRIDE_ENA_1	4	0b	RW	UNDEFINED	**Override Enable 1** Enable for Override TC Region "8*m+1" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+1" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_1	7:5	000b	RW	UNDEFINED	**Region 1** Receive queue region for Override TC Region "8*m+1" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+1" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_2	8	0b	RW	UNDEFINED	**Override Enable 2** Enable for Override TC Region "8*m+2" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+2" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_2	11:9	000b	RW	UNDEFINED	**Region 2** Receive queue region for Override TC Region "8*m+2" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+2" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_2* flag is set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
OVERRIDE_ENA_3	12	0b	RW	UNDEFINED	**Override Enable 3** Enable for Override TC Region "8*m+3" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+3" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_3	15:13	000b	RW	UNDEFINED	**Region 3** Receive queue region for Override TC Region "8*m+3" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+3" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_3* flag is set.
OVERRIDE_ENA_4	16	0b	RW	UNDEFINED	**Override Enable 4** Enable for Override TC Region "8*m+4" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+4" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_4	19:17	000b	RW	UNDEFINED	**Region 4** Receive queue region for Override TC Region "8*m+4" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+4" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_4* flag is set.
OVERRIDE_ENA_5	20	0b	RW	UNDEFINED	**Override Enable 5** Enable for Override TC Region "8*m+5" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+5" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_5	23:21	000b	RW	UNDEFINED	**Region 5** Receive queue region for Override TC Region "8*m+5" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+5" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_5* flag is set.
OVERRIDE_ENA_6	24	0b	RW	UNDEFINED	**Override Enable 6** Enable for Override TC Region "8*m+6" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+6" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.
REGION_6	27:25	000b	RW	UNDEFINED	**Region 6** Receive queue region for Override TC Region "8*m+6" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+6" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_6* flag is set.
OVERRIDE_ENA_7	28	0b	RW	UNDEFINED	**Override Enable 7** Enable for Override TC Region "8*m+7" in the Prof2TC table, for packet profile "n", where "n" is the register index and "m" is the word index. The index "8*m+7" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
REGION_7	31:29	000b	RW	UNDEFINED	**Region 7** Receive queue region for Override TC Region "8*m+7" in the Prof2TC table, for packet profile "n", where 'n' is the register index and "m" is the word index. The index "8*m+7" in the table is selected by the *TC_OVER_SEL* field in the VSIQF_HASH_CTL register. This field is meaningful only if the *OVERRIDE_ENA_7* flag is set.

13.2.2.14.19 Global Classification Filter Accelerated Port Bit Vector - GLQF_APBVT[n] (0x00450000 + 0x4*n, n=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
APBVT	31:0	0x0	RW	UNDEFINED	**Accelerated Port Bit Vector** Each bit "i" in the APBVT of register "n" enables port number 32 x "n" + "i".

13.2.2.14.20 Global Classification Filter - FD Profile Evict Enable - GLQF_FDEVICTENA[n] (0x00452000 + 0x4*n, n=0...3; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FDEVICTENA	31:0	0x0	RW	UNDEFINED	**FD Evict Enable** Defines the PCTYPES that are candidates for hardware eviction of Flow Director filters. For register "n", any bit "k" in relation to profile [32*n+k], defines if a packet matching this profile is a candidate for auto-eviction by FIN/RST.

13.2.2.14.21 PF Classification Filter - QH TC Enable - PFQF_PE_TC_CTL (0x00452080; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TC_EN_PF	7:0	0x0	RW	UNDEFINED	**TC Enable PF** Bit "n" in this field enables TC "n" for PE filter for the PF.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
TC_EN_VF	23:16	0x0	RW	UNDEFINED	**TC Enable VF** Bit "n" in this field enables TC "n" for PE filter for the VFs of the PF.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.14.22 Global Classification Filter - PE Control 2 - GLQF_PE_CTL2[n] (0x00455200 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TO_QH	1:0	00b	RW	UNDEFINED	**TO QH** The *TO_QH* field defines the target of the packet profile "n", where "n" is the register index. 00b = Reserved. 01b = Packet is candidate for the QH filter. 10b = Packet is candidate for the PE bypassing the QH filter. 11b = Packet is candidate for the QH filter and forwarded to the PE even if it does not match the filter.
APBVT_ENA	2	0b	RW	UNDEFINED	**APBVT Enable** Packet profile "n" should hit the APBVT to be a candidate for the QH or directly to the PE, where "n" is the register index.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.14.23 Global Classification Filter - Hash LUT Size - GLQF_HLUT_SIZE[n] (0x00455400 + 0x4*n, n=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSIZE	0	0b	RW	UNDEFINED	**Hash Size** Defines the size of the matched Global Hash LUT. 0b = 128 1b = 512
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.14.24 PF Classification Filter - Hash LUT Size - PFQF_HLUT_SIZE (0x00455480; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
HSIZE	1:0	00b	RW	UNDEFINED	**Hash Size** This field defines the size of the PF Hash LUT. 00b = 128 01b = 512 10b = 2K 11b = Reserved
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.14.25 Global PE APBVT LAN Packet Counter - GLQF_PE_APBVT_CNT (0x00455500; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
APBVT_LAN	31:0	0x0	RCW	UNDEFINED	**APBVT LAN** Global counter of packets that matched the APBVT filter that are not directed to the PE just because they miss the QH filter. This counter is expected to provide an indication for the APBVT filter efficiency. ***Note:*** Count is not enabled if the packet is not initiating filter lookup (that is, not enabled by PF/VSI. Profile or packet is RoCE_UC).

13.2.2.14.26 VF Classification Filter - PE Enable - VPQF_PE_FILTERING_ENA[VF] (0x00455800 + 0x4*VF, VF=0...255; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field definitions are the same as those defined in Section 13.2.2.14.17.

13.2.2.14.27 Global Classification Filter - Hash Key - GLQF_HKEY[n] (0x00456000 + 0x4*n, n=0...12; RW)

Field definitions are the same as those defined in Section 13.2.2.12.18.

13.2.2.14.28 Global Classification Filter Control - GLQF_FD_CTL (0x00460000; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FDLONG	3:0	0x1	RW	N/A	**FD Long** FD filter entry found at larger location in the bucket than FDLONGB is reported as such in the receive descriptor. Value of zero, means all collision are reported. In addition, PFQF_FD_CLSN1 statistical counter is incremented for the relevant PF. See PFQF_FD_ST_CTL for details of statistical counter configuration.
HASH_REPORT	4	0b	RW	UNDEFINED	**Hash Report** When this flag is set, the FD Bucket_HASH and Bucket_LEN parameters are reported in the Filter Programming Status Descriptor.
FLT_ADDR_REPORT	5	0b	RW	UNDEFINED	**Filter Address Report** When this flag is set, FD actual FLT_Addr (on-die memory) parameters are reported in the Filter Programming Status Descriptor.
RESERVED	31:6	0x0	RSV	N/A	Reserved.

13.2.2.14.29 Global Classification Filter - FD Space Size - GLQF_FD_SIZE (0x00460010; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GSIZE	14:0	0x0	RW	UNDEFINED	**Guaranteed Size** Global guaranteed number of filters in the FD table.
RESERVED	15	0b	RSV	N/A	Reserved.
FD_BSIZE	30:16	0x0	RW	UNDEFINED	**Best Size** Global best effort number of filters in the FD table,
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.14.30 Global Classification Filter - FD Space Counters - GLQF_FD_CNT (0x00460018; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GCNT	14:0	0x0	RW/V	UNDEFINED	**Guaranteed Count** Global guaranteed filter counter in the FD table.
RESERVED	15	0b	RSV	N/A	Reserved.
FD_BCNT	30:16	0x0	RW/V	UNDEFINED	**Best Count** Global best effort filter counter in the FD table.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.14.31 PF Classification Filter - FD Space Sizes - PFQF_FD_SIZE (0x00460100; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GSIZE	14:0	0x0	RW	UNDEFINED	**Guaranteed Size** PF guaranteed number of filters in the FD table.
RESERVED	15	0b	RSV	N/A	Reserved.
FD_BSIZE	30:16	0x0	RW	UNDEFINED	**Best Size** PF best effort number of filters in the FD table.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.14.32 Global Classification Filter - FD PF Space Counter - PFQF_FD_CNT (0x00460180; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GCNT	14:0	0x0	RW/V	UNDEFINED	**Guaranteed Count** PF guaranteed filter counter in the FD table.
RESERVED	15	0b	RSV	N/A	Reserved.
FD_BCNT	30:16	0x0	RW/V	UNDEFINED	**Best Count** PF best effort filter counter in the FD table.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.14.33 Global Classification Filter - FD PF Space Counter - PFQF_FD_SUBTRACT (0x00460200; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_GCNT	14:0	0x0	WO	UNDEFINED	**Guaranteed Count** Subtract value for PF guaranteed filter counter in the FD table. Value written to this field will subtracted from GLQF_FD_CNT.*FD_GCNT* and PFQF_FD_CNT.*FD_GCNT* (for the same PF number). Reading this register returns 0.
RESERVED	15	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FD_BCNT	30:16	0x0	WO	UNDEFINED	**Best Count** Subtract value for PF best effort filter counter in the FD table. Value written to this field will subtracted from GLQF_FD_CNT.*BFD_CNT* and PFQF_FD_CNT.*FD_BCNT* (for the same PF number). Reading this register will return 0.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.14.34 PF Classification Filter - PE Control - PFQF_PE_CTL1 (0x00470000; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEHSIZE	3:0	0x0	RW	UNDEFINED	**Size** *PEHSIZE* defines the number of "buckets" of the PE Quad Hash filter table for the function defined in power of 2 equals 1K x 2 ** *PEHSIZE*. *PEHSIZE* can have any value between 0 and 10. Other values are reserved. *PEHSIZE* = 0, 1,... 10 is equivalent to 1K, 2K, 4K... 1M buckets.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.14.35 PF Classification Filter - PE Control - PFQF_PE_CTL2 (0x00470040; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEDSIZE	3:0	0x0	RW	UNDEFINED	**Size** *PEDSIZE* defines the number of PE Quad Hash contexts for the function defined in power of 2 equals to 0.5K x 2 ** *PEDSIZE*-1. *PEDSIZE* can have any value between 0 and 9. Other values are reserved. *PEDSIZE* = 0, 1,... 9 is equivalent to 0.5K-1 1K-1 2K-1, 4K-1... 256K-1 contexts.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.14.36 PF Free List Head Array - PFQF_PE_FLHD (0x00470100; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLHD	23:0	0x0	RW	UNDEFINED	**Free List Head** PF Filter Free List Head Pointer is initialized by software, but through operation is managed by hardware. It is a pointer to the Collision FPM, to the first available filter entry in the link list of all unused entries. Upon initialization (i.e. XLR, or function Clear command), software must write this register to zero. This is addition to cleanup of FPM collision area, which should be written to all zeros. After PF configuration is enabled, software must not write to this register. In case of PF initialization, the software is expected to clear and initialize all *FLHD* field of all the VFs of the PF. In case of ungraceful XLR, firmware must perform the register cleanup process.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.14.37 PF Classification Filter PE Filter Counter 0 - PFQF_PECNT_0 (0x00470200; RW)

Total bucket count.

Field	Bit(s)	Init.	Type	CFG Policy	Description
BUCKETCNT	17:0	0x0	RW/V	UNDEFINED	**Bucket Count** Reflects the number of active PE filter buckets of the function. This counter together with the PFQF_PECNT_1 register gives a hint on how uniform the filter's hash function is.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.14.38 PF Classification Filter PE Filter Counter 1 - PFQF_PECNT_1 (0x00470300; RW)

Total filter count.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLTCNT	17:0	0x0	RW/V	DYNAMIC	**Filter Count** Reflects the total number of active PE filters of the function.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.14.39 PF Control Register for the Statistic Counter - PFQF_PE_ST_CTL (0x00470400; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_CNT_EN	0	0b	RW	UNDEFINED	**PE Count Enable** Enable counting PF filters. CLSN0 counts entry hits that are less than or equal to PELONGB. CLSN1 counts entry hits that are higher collision order than PELONGB. ***Note:*** Clearing this bit, does not clear the counter.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFS_CNT_EN	1	0b	RW	UNDEFINED	**VFs Count Enable** Enable counting filters of the PF and all VFs of this PF. CLSN0 counts entry hits that are less than or equal to PELONGB. CLSN1 counts entry hits that are higher collision order than PELONGB. ***Note:*** Clearing this bit, does not clear the counter.
VF_CNT_EN	2	0b	RW	UNDEFINED	**VF Count Enable** Enable counting specific VF of this PF, as specified by *VF_NUM*. CLSN0 counts entry hits that are less than or equal to PELONGB. CLSN1 counts entry hits that are higher collision order than PELONGB. ***Note:*** Clearing this bit, does not clear the counter.
RESERVED	15:3	0x0	RSV	N/A	Reserved.
VF_NUM	23:16	0x0	RW	UNDEFINED	**VF Number** VF number for specific VF counting.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.14.40 PF PE Classification Filter Collision Counter 0 - PFQF_PE_CLSN0 (0x00470480; RCW)

Filter lookup search at low bucket counter.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HITSBCNT	31:0	0x0	RWC	UNDEFINED	**Hots Short Count** Counts processed packets of PF/VFs as defined by *_CNT_EN* in PFQF_PE_ST_CTL register, in which the PE filter is at a position shorter or equal than PELONGB threshold in the GLQF_FD_CTL register.

13.2.2.14.41 PF PE Classification Filter Collision Counter 1 - PFQF_PE_CLSN1 (0x00470500; RCW)

Filter lookup search at high bucket counter.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HITLBCNT	31:0	0x0	RWC	UNDEFINED	**Hits Long Count** Counts processed packets of PF/VFs as defined by *_CNT_EN* in PFQF_PE_ST_CTL register, in which the PE filter is at a position longer than PELONGB threshold in the GLQF_FD_CTL register.

13.2.2.14.42 Global PE Classification Filter Outstanding Request Counter - GLQF_PE_OSR_STS (0x00471040; RCW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QH_SRCH_MAXOSR	9:0	0x0	RCW	UNDEFINED	**QH Search Max Outstanding Search Requests** Reflects actual max number of active outstanding search requests (OSRs)
RESERVED	15:10	0x0	RSV	N/A	Reserved.
QH_CMD_MAXOSR	25:16	0x0	RCW	UNDEFINED	**QH Command Max Outstanding Search Requests** Reflects actual max number of active outstanding Add/Remove requests (OSRs)
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.14.43 QH ADD/REM Commands Status - GLQF_PE_CMD (0x00471080; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADDREM_STS	23:0	0x0	RW/V	UNDEFINED	**Add/Remove Statuses** 12x2-bit vector. Each 2-bit entry corresponds to an incoming command. Codes are: 00b = Free entry 01b = Busy (WIP) 10b = Done Fail 11b = Done Pass The statuses are written cyclically, enabling the monitoring of 12 commands in parallel. Busy indicates for software that the command is in processing and the next command can be inserted. Entries that are Done, are cleared automatically upon read. ***Note:*** Completions (Done) are not in order.
RESERVED	27:24	0x0	RSV	N/A	Reserved.
ADDREM_ID	31:28	0x0	RW/V	UNDEFINED	**Add/Remove Index** Reflects the index of the next free command location in the *ADDREM_STS* vector. The index is for the status entry, which is two bits. Therefore, for offset within the CSR, must to multiply by two.

13.2.2.14.44 Global Classification Filter Control - GLQF_PE_CTL (0x004710C0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PELONG	3:0	0x1	RW	UNDEFINED	**PE Long** PE filter entry found at larger location in the bucket than PELONGB is reported as such in the receive descriptor. Value of one, means all collisions are reported. In addition, PFQF_PE_CLSN1 statistical counter is incremented for the relevant PF. See PFQF_PE_ST_CTL for details of statistical counter configuration.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.14.45 VF Free List Head Array - VPQF_PE_FLHD[VF] (0x00472000 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLHD	23:0	0x0	RW	UNDEFINED	**Free List Head** VF Filter Free List Head Pointer is initialized by software, but through operation is managed by hardware. It is a pointer to the Collision FPM, to the first available filter entry in the link list of all unused entries. Upon initialization (i.e. XLR, or function Clear command), software must write this register to zero. This is addition to cleanup of FPM collision area, which should be written to all zeros. After VF configuration is enabled, software must not write to this register.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.14.46 VF Classification Filter PE Filter Counter 0 - VPQF_PECNT_0[VF] (0x00472800 + 0x4*VF, VF=0...255; RW)

Total bucket count.

Field	Bit(s)	Init.	Type	CFG Policy	Description
BUCKETCNT	17:0	0x0	RW/V	UNDEFINED	**Bucket Count** Reflects the number of active PE filter buckets of the function. This counter together with the VPQF_PECNT_0 register gives a hint on how uniform the filter's hash function is.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.14.47 VF Classification Filter PE Filter Counter 1 - VPQF_PECNT_1[VF] (0x00473000 + 0x4*VF, VF=0...255; RW)

Total filter count.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLTCNT	17:0	0x0	RW/V	UNDEFINED	**Filter Count** Reflects the total number of active PE filters of the function.
RESERVED	31:18	0x0	RSV	N/A	Reserved

13.2.2.14.48 VF Classification Filter - PE Control - VPQF_PE_CTL1[VF] (0x00474000 + 0x4*VF, VF=0...255; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field definitions are the same as those defined in Section 13.2.2.14.34.

13.2.2.14.49 PF Classification Filter - PE Control - VPQF_PE_CTL2[VF] (0x00474800 + 0x4*VF, VF=0...255; RW)

Setting this register, the hardware auto-clears the internal PE Quad Hash context counter and table pointers of the function.

Field definitions are the same as those defined in Section 13.2.2.14.35.

13.2.2.15 PF - Interrupt Registers

13.2.2.15.1 PF General Purpose IO Interrupt Enablement - PFINT_GPIO_ENA (0x00088080; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GPIO0_ENA	0	0b	RW	UNDEFINED	**GPIO 0 Enable** Enable interrupt on GPIO 0.
GPIO1_ENA	1	0b	RW	UNDEFINED	**GPIO 1 Enable** Enable interrupt on GPIO 1.
GPIO2_ENA	2	0b	RW	UNDEFINED	**GPIO 2 Enable** Enable interrupt on GPIO 2.
GPIO3_ENA	3	0b	RW	UNDEFINED	**GPIO 3 Enable** Enable interrupt on GPIO 3.
GPIO4_ENA	4	0b	RW	UNDEFINED	**GPIO 4 Enable** Enable interrupt on GPIO 4.
GPIO5_ENA	5	0b	RW	UNDEFINED	**GPIO 5 Enable** Enable interrupt on GPIO 5.
GPIO6_ENA	6	0b	RW	UNDEFINED	**GPIO 6 Enable** Enable interrupt on GPIO 6.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.15.2 EMP General Purpose IO Interrupt Enablement - EMPINT_GPIO_ENA (0x000880C0; RW)

Field definitions are the same as those defined in Section 13.2.2.15.1.

13.2.2.15.3 VF Vector Allocation - VPINT_ALLOC_PCI[VF] (0x0009D000 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRST	10:0	0x0	RW	UNDEFINED	**First** Index of the first interrupt vector of the VF in the internal physical space.
RESERVED	11	0b	RSV	N/A	Reserved
LAST	22:12	0x0	RW	UNDEFINED	**Last** Index of the last interrupt vector of the VF in the internal physical space.
RESERVED	30:23	0x0	RSV	N/A	Reserved
VALID	31	0b	RW	UNDEFINED	**Valid** Valid indication. When this bit is clear, the contents of this CSR are not valid.

13.2.2.15.4 PF Vector Allocation - PCI - PFINT_ALLOC_PCI (0x0009D800; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRST	10:0	0x0	RW	UNDEFINED	**First** Index of the first interrupt vector of the PF in the internal physical space.
RESERVED	11	0b	RSV	N/A	Reserved
LAST	22:12	0x0	RW	UNDEFINED	**Last** Index of the last interrupt vector of the PF and its VFs in the internal physical space.
RESERVED	30:23	0x0	RSV	N/A	Reserved
VALID	31	0b	RW	UNDEFINED	**Valid** Valid indication. When this bit is clear, the contents of this CSR are not valid.

13.2.2.15.5 Transmit Queue Interrupt Cause Control - QINT_TQCTL[DBQM] (0x00140000 + 0x4*DBQM, DBQM=0...16383; RW)

Field definitions are the same as those defined in Section 13.2.2.15.6.

13.2.2.15.6 Receive Queue Interrupt Cause Control - QINT_RQCTL[QRX] (0x00150000 + 0x4*QRX, QRX=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIX_INDX	10:0	0x0	RW	UNDEFINED	**MSI-X Index** MSI-X vector index within the function space. The software should set the *MSIX_INDX* to values in the range of allocated interrupt vectors to the function.
ITR_INDX	12:11	00b	RW	UNDEFINED	**ITR Index** ITR Index of the interrupt cause. 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR
RESERVED	29:13	0x0	RSV	N/A	Reserved.
CAUSE_ENA	30	0b	RW	UNDEFINED	**Cause Enable** Enable interrupt by this queue. When *CAUSE_ENA* is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.15.7 Global Interrupt Throttling - GLINT_ITR[n,INT] (0x00154000 + 0x2000*n + 0x4*INT, n=0...2, INT=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INTERVAL	11:0	0x0	RW	UNDEFINED	**Interval** ITR "n" interval, where "n" is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 µs units enabling interval range from zero to 8160 µs (0xFF0). Setting the *INTERVAL* to zero enables immediate interrupt. This register can be programmed also by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.15.8 Global Interrupt Rate Limit - GLINT_RATE[INT] (0x0015A000 + 0x4*INT, INT=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INTERVAL	5:0	0x0	RW	UNDEFINED	**Interval** Time interval defined in 4 µs units between consecutive credit incremental. When the interrupt rate limit is enabled by the *INTRL_ENA* flag in this register, the *INTERVAL* must be greater than zero. And for accurate rate limit, the *INTERVAL* must be smaller than 0x3C (up to 236-µs).
INTRL_ENA	6	0b	RW	UNDEFINED	**Interrupt Rate Limit Enable** Enable Interrupt Rate Limit on this interrupt vector.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.15.9 Global PE Completion Event Queue Interrupt Cause Control - GLINT_CEQCTL[INT] (0x0015C000 + 0x4*INT, INT=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIX_INDX	10:0	0x0	RW	UNDEFINED	**MSI-X Index** MSI-X vector index within the function space. The software should set the *MSIX_INDX* to values in the range of allocated interrupt vectors to the function.
ITR_INDX	12:11	0x0	RW	UNDEFINED	**ITR Index** ITR Index of the interrupt cause. 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR
RESERVED	29:13	00b	RSV	N/A	Reserved.
CAUSE_ENA	30	0b	RW	UNDEFINED	**Cause Enable** Enable interrupt by this queue. When *CAUSE_ENA* is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.15.10 Global Interrupt Dynamic Control - GLINT_DYN_CTL[INT] (0x00160000 + 0x4*INT, INT=0...2047; RW)

In case of MSI or Legacy INTA mode of operation Interrupt zero is the only valid interrupt. The space of these registers is according to the number of total interrupt registers for the device. The PF can access only those first "N" interrupts according to the PFINT_ALLOC registers.

Field	Bit(s)	Init.	Type	CFG Policy	Description
INTENA	0	0b	RW	UNDEFINED	**Interrupt Enable** 0b = Interrupt is disabled. 1b = Interrupt is enabled. See auto-clear policy in the Section 9.1.1.1, "Interrupt Enable Procedure". This bit is meaningful only if the *INTENA_MSK* flag in this register is not set. ***Note:*** The *INTENA* and *WB_ON_ITR* flags are mutually exclusive.
CLEARPBA	1	0b	RW1C	UNDEFINED	**Clear PBA** Setting this bit, the matched PBA bit is cleared. This bit is auto-cleared by the hardware.
SWINT_TRIG	2	0b	RW1C	DYNAMIC	**Software Interrupt Trigger** When the bit is set, a software interrupt is triggered. This bit is auto-cleared by the hardware.
ITR_INDX	4:3	00b	RW1C	DYNAMIC	**ITR Index** This field defines the ITR Index to be updated as follows: 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR Update This field is auto-cleared by the hardware.
INTERVAL	16:5	0x0	RW1C	DYNAMIC	**Interval** The interval for the ITR defined by the *ITR_INDX* in this register. This field is auto-cleared by the hardware.
RESERVED	23:17	0x0	RSV	N/A	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	DYNAMIC	**Software ITR Index Enable** This flag enables the programming of the *SW_ITR_INDX* in this register. This flag is auto cleared by the hardware.
SW_ITR_INDX	26:25	00b	RW	UNDEFINED	**Software ITR Index** ITR Index of the software interrupt. 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	N/A	Reserved.
WB_ON_ITR	30	0b	RW	UNDEFINED	**Write Back on ITR** When this bit is set, ITR expiration triggers write back of completed descriptors without an interrupt. ***Note:*** The *INTENA* and *WB_ON_ITR* flags are mutually exclusive.
INTENA_MSK	31	0b	RW1C	DYNAMIC	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by the hardware.

13.2.2.15.11 Global Interrupt Vector 2 Function Allocation - GLINT_VECT2FUNC[INT] (0x00162000 + 0x4*INT, INT=0...2047; RW)

These registers map the interrupts to their functions.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VF_NUM	7:0	0x0	RW	UNDEFINED	**VF Number** An absolute VF index in the range of 0 to 255. It is meaningful only if the *IS_PF* flag in this register is cleared. Otherwise, it should be set to zero.
RESERVED	11:8	0x0	RSV	N/A	Reserved.
PF_NUM	14:12	000b	RW	UNDEFINED	**PF Number** The PF index can be set to 0-7.
RESERVED	15	0b	RSV	N/A	Reserved.
IS_PF	16	0b	RW	UNDEFINED	**Is PF** 0b = The queue belongs to the VF. In this case the *VF_NUM* is valid as well. 1b = The interrupt belongs to the PF.
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.15.12 VF Mailbox Queue Mapping to Interrupt Control - VPINT_MBX_CTL[VSI] (0x0016A000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIX_INDX	10:0	0x0	RW	UNDEFINED	**MSI-X Index** MSI-X vector index within the function space. The software should set the *MSIX_INDX* to values in the range of allocated interrupt vectors to the function.
ITR_INDX	12:11	00b	RW	UNDEFINED	**ITR Index** ITR Index of the interrupt cause. 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR
RESERVED	29:13	0x0	RSV	N/A	Reserved.
CAUSE_ENA	30	0b	RW	UNDEFINED	**Cause Enable** Enable interrupt. When *CAUSE_ENA* is cleared, interrupts are not generated and relevant events are disregarded by the interrupt block. This control is not relevant for OICR causes for which each cause is controlled in *XXINT_PICR_ENA*. For OICR, this bit value is disregarded by the hardware.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.15.13 VF Mailbox Queue Mapping to Interrupt Control - VPINT_MBX_CPM_CTL[VP128] (0x0016B000 + 0x4*VP128, VP128=0...127; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.14 VF HLP Mailbox Queue Mapping to Interrupt Control - VPINT_MBX_HLP_CTL[VP16] (0x0016B200 + 0x4*VP16, VP16=0...15; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.15 VF PSM Mailbox Queue Mapping to Interrupt Control - VPINT_MBX_PSM_CTL[VP16] (0x0016B240 + 0x4*VP16, VP16=0...15; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.16 PF Mailbox Queue Mapping to Interrupt Control - PFINT_MBX_CTL (0x0016B280; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.17 PF0 CPM Mailbox Queue Mapping to Interrupt Control - PF0INT_MBX_CPM_CTL (0x0016B2C0; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.18 PF0 HLP Mailbox Queue Mapping to Interrupt Control - PF0INT_MBX_HLP_CTL (0x0016B2C4; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.19 PF0 PSM Mailbox Queue Mapping to Interrupt Control - PF0INT_MBX_PSM_CTL (0x0016B2C8; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.20 PF0 CPM SB Queue Mapping to Interrupt Control - PF0INT_SB_CPM_CTL (0x0016B2CC; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.21 VF CPM SB Queue Mapping to Interrupt Control - VPINT_SB_CPM_CTL[VP128] (0x0016B400 + 0x4*VP128, VP128=0...127; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.22 PF SB Queue Mapping to Interrupt Control - PFINT_SB_CTL (0x0016B600; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.23 PF0 HLPSB Queue Mapping to Interrupt Control - PF0INT_SB_HLP_CTL (0x0016B640; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.24 VF PE Asynchronous Event Queue Interrupt Cause Control - VPINT_AEQCTL[VF] (0x0016B800 + 0x4*VF, VF=0...255; RW)

Field definitions are the same as those defined in Section 13.2.2.15.33.

13.2.2.15.25 PF Firmware Admin Queue Mapping to Interrupt Control - PFINT_FW_CTL (0x0016C800; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.26 Global Tools Firmware Admin Queue Mapping to Interrupt Control - GLINT_FW_TOOL_CTL (0x0016C840; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.27 PF0 HLP Firmware Admin Queue Mapping to Interrupt Control - PF0INT_FW_HLP_CTL (0x0016C844; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.28 PF0 PSM Firmware Admin Queue Mapping to Interrupt Control - PF0INT_FW_PSM_CTL (0x0016C848; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.29 PF Interrupt Other Cause Enablement - PFINT_OICR_ENA (0x0016C900; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	0	0b	RSV	N/A	Reserved.
INT_ENA	31:1	0x0	RW	UNDEFINED	**Interrupt Enable** Each bit set to '1' in this field enables its matched interrupt cause in the PFINT_OICR register.

13.2.2.15.30 Global Interrupt TimeSync PHY Mask - PFINT_TSYN_MSK (0x0016C980; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PHY_INDX	4:0	0x0	RW	UNDEFINED	**PHY Index** Bit 'i' in this register enables Quad-PHY index 'i' interrupt to the *TSYN_TX* flag in the PFINT_OICR register. This value should be loaded by NVM and correspond to the port-to-PF mapping.
RESERVED	31:5	0x0	RSV	N/A	Reserved

13.2.2.15.31 PF Interrupt Other Cause - PFINT_OICR (0x0016CA00; RCW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	0	1b	RSV	N/A	Reserved.
QUEUE	1	1b	RCW	UNDEFINED	**Queue** Interrupt indication for LAN queues and PE CEQs that are linked to the other cause interrupt vector.
RESERVED	9:2	0x0	RSV	N/A	Reserved.
HH_COMP	10	0b	RCW	UNDEFINED	**HH Complete** Hammock Harbor sequence is completed (matched completion message is received).
TSYN_TX	11	0b	RCW	UNDEFINED	**TimeSync Tx** Tx packet time is sampled.
TSYN_EVNT	12	0b	RCW	UNDEFINED	**TimeSync Event** Event is sampled by the 1588 timer due to a transition in one of the input GPIOs.
TSYN_TGT	13	0b	RCW	UNDEFINED	**TimeSync Target** One of the target time of the 1588 timer is expired.
HLP_RDY	14	0b	RCW	UNDEFINED	**HLP Ready** HLP changed its status from not RDY to RDY or visa versa.
CPM_RDY	15	0b	RCW	UNDEFINED	**CMP Ready** CPM changed its status from not RDY to RDY or visa versa.
ECC_ERR	16	0b	RCW	UNDEFINED	**ECC Error** Unrecoverable ECC Error. This bit is set when an unrecoverable error is detected in one of the device memories.
RESERVED	18:17	00b	RSV	N/A	Reserved.
MAL_DETECT	19	0b	RCW	UNDEFINED	**Malicious Detected** Malicious programming detected.
GRST	20	0b	RCW	UNDEFINED	**Global Resets Requested** CORER, GLOBR, or EMPR.
RESERVED	21	0b	RSV	N/A	Reserved.
GPIO	22	0b	RCW	UNDEFINED	**GPIO** GPIO Event indicates an event on any of the GPIO pins enabled for interrupt by the PFINT_GPIOCTL register. The GPIO state can be fetched on the GLGEN_GPIO_STAT register. The level transition that generates an interrupt is set for GPIO 'n' by the INT_MODE field in the matched GLGEN_GPIO_CTL[n] register.
RESERVED	23	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
STORM_DETECT	24	0b	RCW	UNDEFINED	**Storm Detected** Indicates a change entering the storm control state of the LAN port that is connected to this PF. The storm control state is reflected in the PRT_SWT_SCSTS register.
RESERVED	25	0b	RSV	N/A	Reserved.
HMC_ERR	26	0b	RCW	UNDEFINED	**HMC Errors** PEPMAT or FPMAT. or CMPE. Specific PEMAT errors are reported in the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. Specific FPMAT errors are reported in the PFHMC_ERRORINFO_FPMAT and PFCHMC_ERRORDATA_FPMAT registers. Specific CMPE errors are reported in the PFCM_PE_CRCERRINFO.
PE_PUSH	27	0b	RCW	UNDEFINED	**PE Push** Indication that RDMA engine does not pull data from the push buffer (Indication that pe_pcie_push_rdy watchdog timer expired).
RESERVED	28	0b	RSV	N/A	Reserved.
VFLR	29	0b	RCW	UNDEFINED	**VFLR** VFLR was initiated by one of the VFs of the PF. The PF should read the GLGEN_VFLRSTAT getting an indication for the VF that generated the VFLR.
XLR_HW_DONE	30	0b	RCW	UNDEFINED	**XLR Hardware Done** VF or VM of the PF has set their hardware done indications after VM/VF reset.
SWINT	31	0b	RCW	UNDEFINED	**Software Interrupt indication**

13.2.2.15.32 PF Interrupt Other Cause Control - PFINT_OICR_CTL (0x0016CA80; RW)

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.33 PF PE Asynchronous Event Queue Interrupt Cause Control - PFINT_AEQCTL (0x0016CB00; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIX_INDX	10:0	0x0	RW	UNDEFINED	**MSI-X Index** MSI-X vector index within the function space. The software should set the *MSIX_INDX* to values in the range of allocated interrupt vectors to the function.
ITR_INDX	12:11	00b	RW	UNDEFINED	**ITR Index** ITR Index of the interrupt cause. 00b = ITR0 01b = ITR1 10b = ITR2 11b = No ITR
RESERVED	29:13	0x0	RSV	N/A	Reserved.
CAUSE_ENA	30	0b	RW	UNDEFINED	**Cause Enable** Enable interrupt by this queue. When *CAUSE_ENA* is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.15.34 PF0 Interrupt Other Cause CPM - PF0INT_OICR_CPM (0x0016CC40; RCW)

This register is set by the hardware with the same indication as the PFINT_OICR for the sake of the CPM driver.

Field definitions are the same as those defined in Section 13.2.2.15.31.

13.2.2.15.35 PF0 Interrupt Other Cause PSM - PF0INT_OICR_PSM (0x0016CC44; RCW)

This register is set by the hardware with the same indication as the PFINT_OICR for the sake of the PSM driver.

Field definitions are the same as those defined in Section 13.2.2.15.31.

13.2.2.15.36 PF0 Interrupt Other Cause CPM Control - PF0INT_OICR_CTL_CPM (0x0016CC48; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_CTL mapped in the same 4 KB page as PFINT_OICR3.

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.37 PF0 Interrupt Other Cause HLP Enablement - PF0INT_OICR_ENA_HLP (0x0016CC4C; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_ENA mapped in the same 4 KB page as PFINT_OICR1.

Field definitions are the same as those defined in Section 13.2.2.15.29.

13.2.2.15.38 Global Interrupt TimeSync PHY Indication - GLINT_TSYN_PHY (0x0016CC50; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PHY_INDX	4:0	0x0	RW1C	DYNAMIC	**PHY Index** Bit 'i' in this register is set when Quad-PHY index 'i' initiates the transmit packet timestamp interrupt.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.15.39 Global Interrupt Control - GLINT_CTL (0x0016CC54; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	15:0	0x0	RSV	N/A	Reserved.
ITR_GRAN_200	19:16	0x2	RW	UNDEFINED	**TITR Granularity 200** Defines the granularity of the ITR in 1 µs granularity for the 200 Gb/s Max speed SKU. Min allowed value is 1 µs.
ITR_GRAN_100	23:20	0x2	RW	UNDEFINED	**TITR Granularity 100** Defines the granularity of the ITR in 1 µs granularity for the 100 Gb/s Max speed SKU. Min allowed value is 1 µs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ITR_GRAN_50	27:24	0x2	RW	UNDEFINED	**TITR Granularity 50** Defines the granularity of the ITR in 1 µs granularity for the 50 Gb/s Max speed SKU. Min allowed value is 2 µs.
ITR_GRAN_25	31:28	0x4	RW	UNDEFINED	**TITR Granularity 25** Defines the granularity of the ITR in 1 µs granularity for the 25 Gb/s Max speed SKU. Min allowed value is 4 µs.

13.2.2.15.40 PF0 Interrupt Other Cause PSM Enablement - PF0INT_OICR_ENA_PSM (0x0016CC58; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_ENA mapped in the same 4 KB page as PFINT_OICR2.

Field definitions are the same as those defined in Section 13.2.2.15.29.

13.2.2.15.41 PF0 Interrupt Other Cause HLP Control - PF0INT_OICR_CTL_HLP (0x0016CC5C; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_CTL mapped in the same 4 KB page as PFINT_OICR1.

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.42 PF0 Interrupt Other Cause CPM Enablement - PF0INT_OICR_ENA_CPM (0x0016CC60; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_ENA mapped in the same 4 KB page as PFINT_OICR3.

Field definitions are the same as those defined in Section 13.2.2.15.29.

13.2.2.15.43 PF0 Interrupt Other Cause PSM Control - PF0INT_OICR_CTL_PSM (0x0016CC64; RW)

This register is valid only for PF0. It has the same functionality of PFINT_OICR_CTL mapped in the same 4 KB page as PFINT_OICR2.

Field definitions are the same as those defined in Section 13.2.2.15.12.

13.2.2.15.44 PF0 Interrupt Other Cause HLP - PF0INT_OICR_HLP (0x0016CC68; RCW)

This register is set by the hardware with the same indication as the PFINT_OICR for the sake of the HLP driver.

Field definitions are the same as those defined in Section 13.2.2.15.31.

13.2.2.15.45 Global Interrupt TimeSync Master Select - GLINT_TSYN_PFMSTR[n] (0x0016CCC0 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_MASTER	2:0	000b	RW	UNDEFINED	**PF Master** This field indicates the index of the PF that owns the 1588 master timer 'n', where 'n' is the register index.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.15.46 VF Vector Allocation - VPINT_ALLOC[VF] (0x001D1000 + 0x4*VF, VF=0...255; RW)

This register indicates the interrupt allocation of the VF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRST	10:0	0x0	RW	UNDEFINED	**First** Index of the first interrupt vector of the VF in the internal physical space.
RESERVED	11	0b	RSV	N/A	Reserved.
LAST	22:12	0x0	RW	UNDEFINED	**Last** Index of the last interrupt vector of the VF in the internal physical space.
RESERVED	30:23	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** Valid indication. When this bit is clear, the contents of this CSR are not valid.

13.2.2.15.47 PF Vector Allocation - PFINT_ALLOC (0x001D2600; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRST	10:0	0x0	RW	UNDEFINED	**First** Index of the first interrupt vector of the PF in the internal physical space.
RESERVED	11	0b	RSV	N/A	Reserved.
LAST	22:12	0x0	RW	UNDEFINED	**Last** Index of the last interrupt vector of the PF and its VFs in the internal physical space.
RESERVED	30:23	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** Valid indication. When this bit is clear, the contents of this CSR are not valid.

13.2.2.16 PF - Virtualization PF Registers

13.2.2.16.1 PF Resources Allocation - PF_VT_PFALLOC_HIF (0x0009DD80; RW)

This register indicates the VFs allocated to the each PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTVF	7:0	0x0	RW	UNDEFINED	**First VF** The first VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
LASTVF	15:8	0x0	RW	UNDEFINED	**Last VF** The last VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
RESERVED	30:16	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** The *FIRSTVF* and *LASTVF* fields in this register are valid. If cleared no VFs are allocated to this PF. If cleared, the SR-IOV capability should not be exposed for this PF.

13.2.2.16.2 PF Virtualization Status Register - PF_VIRT_VSTATUS (0x0009E680; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NUM_VFS	7:0	0x0	RO	N/A	**Number of VFs** Reflects the value of the *Num VFs* field in the IOV capability structure.
TOTAL_VFS	15:8	0x0	RO	N/A	**Total VFs** Reflects the value of the *TotalVFs* field in the IOV capability structure.
IOV_ACTIVE	16	0b	RO	N/A	**IOV Active** Reflects the value of the VF Enable (*VFE*) bit in the IOV control/status register
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.16.3 PF Resources Allocation - PF_VT_PFALLOC_PCIE (0x000BE080; RW)

This register indicates the VFs allocated to the each PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTVF	7:0	0x0	RW	UNDEFINED	**First VF** The first VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
LASTVF	15:8	0x0	RW	UNDEFINED	**Last VF** The last VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
RESERVED	30:16	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** The *FIRSTVF* and *LASTVF* fields in this register are valid. If cleared no VFs are allocated to this PF. If cleared, the SR-IOV capability should not be exposed for this PF.

13.2.2.16.4 PF Resources Allocation - PF_VT_PFALLOC (0x001D2480; RW)

This register indicates the VFs allocated to the each PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTVF	7:0	0x0	RW	UNDEFINED	**First VF** The first VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
LASTVF	15:8	0x0	RW	UNDEFINED	**Last VF** The last VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-255.
RESERVED	30:16	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** The *FIRSTVF* and *LASTVF* fields in this register are valid. If cleared no VFs are allocated to this PF. If cleared, the SR-IOV capability should not be exposed for this PF.

13.2.2.17 PF - DCB Registers

13.2.2.17.1 DCB TDPU Control - PRTDCB_TDPUC (0x00040940; RW)

Malicious indication/control register. Drop reasons are not valid on markers/head update packets.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MAX_TXFRAME	15:0	0x2600	RW	UNDEFINED	**Max Tx Frame** Maximum Tx frame size in bytes. Frames longer than the size specified here are discarded and not transmitted (nor looped back). Default and maximum allowed value is 9.5 KB (jumbo frame). Minimum size to be configured here is 60.
MAL_LENGTH	16	0b	RO	N/A	**Malicious Length** Detected malicious length parameters in the Tx-Descriptor
MAL_CMD	17	0b	RO	N/A	**Malicious Commands** Detected malicious combination of commands vs. packet types in the Tx-Descriptor.
TTL_DROP	18	0b	RO	N/A	**TTL Drop** Packet was dropped due to TTL parameter. This indication is invalid on *DUMMY* or UR_DROP.
UR_DROP	19	0b	RO	N/A	**Unsupported Requests Drop** Packet dropped due to unsupported request or dummy completion event of requested packet data.
DUMMY	20	0b	RO	N/A	**Dummy** Packet was dropped because dummy bit was on
BIG_PKT_SIZE	21	0b	RO	N/A	**Big Packet Size** Packet dropped because it exceeds *MAX_TXFRAME* size.
L2_ACCEPT_FAIL	22	0b	RO	N/A	**L2 Acceptance Fail** Packet dropped because of L2 acceptance rules fail. This indication is invalid on *DUMMY* or *UR_DROP*.
DSCP_CHECK_FAIL	23	0b	RO	N/A	**DSCP Check Fail** Packet dropped because of DSCP rule check fail.
RCU_ANTISPOOF	24	0b	RO	N/A	**RCU Anti-Spoof** Packet dropped by RCU.
NIC_DSI	25	0b	RO	N/A	**NIC DSI** Packet dropped because DSI command in NIC mode was identified.
NIC_IPSEC	26	0b	RO	N/A	**NIC IPsec** Packet dropped because IPSEC command in NIC mode was identified.
RESERVED	30:27	0x0	RSV	N/A	Reserved.
CLEAR_DROP	31	0b	SC	UNDEFINED	**Clear Drop** Setting this bit, clears the malicious and drop flags in this register. This bit is auto-cleared.

13.2.2.17.2 DCB Receive UP in TDPU - PRTDCB_RUP_TDPU (0x00040960; RW)

Default UP per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
NOVLANUP	2:0	000b	RW	UNDEFINED	**No VLAN UP** This field assigns a default UP value to untagged incoming packets. The default UP is not inserted in the packet itself, but it controls in which linked list of RPB untagged packets are stored. UP 0 is the default.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.17.3 Tx DCB DSCP to User Priority Control - PRTDCB_TX_DSCP2UP_CTL (0x00040980; RW)

DSCP mode enable/disable per port:

Field	Bit(s)	Init.	Type	CFG Policy	Description
DSCP2UP_ENA	0	0b	RW	UNDEFINED	**DSCP-to-UP Enable** This flag enables the DSCP to User Priority Lookup table. 0b = The DSCP lookup table is disabled and the User Priority is taken from the VLAN tag. 1b = The DSCP to User Priority LUP is enabled.
DSCP_DEFAULT_UP	3:1	000b	RW	UNDEFINED	**DSCP Default UP** Default User Priority for packets without an IP header. This field is meaningful only when the DSCP2UP LUT is enabled by the *DSCP2UP_ENA* flag in this register.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.17.4 Tx DCB DSCP to User Priority LUT for IPv4 Packets - PRTDCB_TX_DSCP2UP_IPV4_LUT[n] (0x000409A0 + 0x20*n, n=0...7; RW)

This register is used to load Tx DSCP2UP tables for IPv4 packets. The table is used for DSCP to UP manipulation, for ports which are DSCP enabled. Result UP from the table is passed in metadata for loopback packets.

Field definitions are the same as those defined in Section 13.2.2.17.5.

13.2.2.17.5 Tx DCB DSCP to User Priority LUT for IPv6 Packets - PRTDCB_TX_DSCP2UP_IPV6_LUT[n] (0x00040AA0 + 0x20*n, n=0...7; RW)

This register is used to load Tx DSCP2UP tables for IPv6 packets. The table is used for DSCP to UP manipulation, for ports which are DSCP enabled. Result UP from the table is passed in metadata for loopback packets.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DSCP2UP_LUT_0	2:0	000b	RW	UNDEFINED	**DSCP-to-UP LUT 0** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n'.
RESERVED	3	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_1	6:4	000b	RW	UNDEFINED	**DSCP-to-UP LUT 1** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+1'.
RESERVED	7	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_2	10:8	000b	RW	UNDEFINED	**DSCP-to-UP LUT 2** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+2'.
RESERVED	11	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_3	14:12	000b	RW	UNDEFINED	**DSCP-to-UP LUT 3** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+3'.
RESERVED	15	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_4	18:16	000b	RW	UNDEFINED	**DSCP-to-UP LUT 4** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+4'.
RESERVED	19	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_5	22:20	000b	RW	UNDEFINED	**DSCP-to-UP LUT 5** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+5'.
RESERVED	23	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_6	26:24	000b	RW	UNDEFINED	**DSCP-to-UP LUT 6** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+6'.
RESERVED	27	0b	RSV	N/A	Reserved.
DSCP2UP_LUT_7	30:28	000b	RW	UNDEFINED	**DSCP-to-UP LUT 7** This entry in register 'n' of the array represents the User Priority output for DSCP input equals to '8*n+7'.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.17.6 Transmit DCSP to TC Enforcement - IPv4 - GL_DCB_TDSCP2TC_BLOCK_IPV4[n] (0x00049018 + 0x4*n, n=0...63; RO)

Defines DSCP-to-TC enforcement for IPv4 packets.

For each DSCP (0..63) this register maps the TCs for which this DSCP is allowed, by having corresponding *TC* bit set or cleared.

For DSCP #n, CSR contains 32 entries. Each entry represents TC per port, according to device mode of operation:

- 1 port x 32 TCs: bit[N] represents TC[N]
- 2 ports x 8 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..1
  T = 0..7
  N = P*8 + T
  bits 16..31 are not valid
- 4 ports x 8 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..4
  T = 0..7
  N = P*8 + T
- 8 ports x 4 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..7
  T = 0..3
  N = P*4 + T

For each entry:

0b = DSCP is allowed for this TC (packet is not blocked)
1b = DSCP is blocked for this TC (packet is blocked if enabled by DSCP2TC_BLOCK_DIS register).

Field	Bit(s)	Init.	Type	CFG Policy	Description
TC_BLOCK_LUT	31:0	0x0	RW	UNDEFINED	**TC Block LUT** Defines if it is allowed to have DSCP #N in packet that is sent through port=x, tc=y and port is DSCP enabled. If number of ports = X, number of TCs = Y, bit Y*port + TC defines if DSCP is allowed for this port/TC. 0b = Allowed. 1b = Block (if enabled by DSCP2TC_BLOCK_DIS register).

13.2.2.17.7 Transmit DCSP to TC Enforcement - IPv6 - GL_DCB_TDSCP2TC_BLOCK_IPV6[n] (0x00049118 + 0x4*n, n=0...63; RO)

Defines DSCP-to-TC enforcement for IPv6 packets.

For each DSCP (0..63) this register maps the TCs for which this DSCP is allowed, by having corresponding *TC* bit set or cleared.

For DSCP #n, CSR contains 32 entries. Each entry represents TC per port, according to device mode of operation:

- 1 port x 32 TCs: bit[N] represents TC[N]
- 2 ports x 8 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..1
  T = 0..7
  N = P*8 + T
  bits 16..31 are not valid
- 4 ports x 8 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..4
  T = 0..7
  N = P*8 + T
- 8 ports x 4 TCs: bit[N] represents port[P] x TC[T], where:

  P = 0..7
  T = 0..3
  N = P*4 + T

For each entry:

0b = DSCP is allowed for this TC (packet is not blocked)
1b = DSCP is blocked for this TC (packet is blocked if enabled by DSCP2TC_BLOCK_DIS register).

Field definitions are the same as those defined in Section 13.2.2.17.6.

13.2.2.17.8 Transmit DCSP to TC Enforcement Enable - GL_DCB_TDSCP2TC_BLOCK_DIS (0x00049218; RO)

If a packet failed in DSCP-to-TC enforcement checks (as configured by TDSCP2TC_BLOCK LUTs), this register determines if the packet is dropped or not.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DSCP2TC_BLOCK_DIS	0	1b	RW	UNDEFINED	**DSCP-to-TC Block Disable** 0b = If DSCP2TC LUT returned status = FAIL, packet is dropped. 1b = Packet is not dropped due to DSCP2TC LUT status=FAIL.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.17.9 Port DCB General Control - PRTDCB_GENC (0x00083000; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	1:0	00b	RSV	N/A	Reserved.
NUMTC	5:2	0x1	RW	UNDEFINED	**Number of TCs** Number of Traffic Classes (TCs) for the port. This field must be set consistently with the settings made in the Tx-Scheduler.
FCOEUP	8:6	0x3	RW	UNDEFINED	Defines the 802.1p UP field used for FCoE traffic over the link.
FCOEUP_VALID	9	1b	RW	UNDEFINED	**FCoE UP Valid** Validity bit for the *FCoEUP* field. 0b = FCoE is not used over this port, and therefore RPB settings must use the same Max Frame Size for all TCs. 1b = The *FCoEUP* field contents is valid.
RESERVED	15:10	0x0	RSV	N/A	Reserved.
PFCLDA	31:16	0x079D	RW	UNDEFINED	**PFC Link Delay Allowance** It is expressed in 16-bytes unit. Default value assumes 9.5 KB jumbo frames over a 10G link with a 10GBASE-T PHY and 100 meter Cat6 cable (no optimization done for lower links speeds). For a 40G link, the number must be 0x1E70.

13.2.2.17.10 Port DCB General Status - PRTDCB_GENS (0x00083020; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DCBX_STATUS	2:0	000b	RW	N/A	**DCBX Status** 000b = NOT_STARTED 001b = IN_PROGRESS 010b = DONE 011b = MULTIPLE_PEERS 111b = DISABLED All other values are reserved.
RESERVED	31:3	0x0	RSV	N/A	Reserved

13.2.2.17.11 Global DCB General Control - GLDCB_GENC (0x00083044; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCIRTT	15:0	0x009C	RW	UNDEFINED	**PCIe Round Trip Time** It is expressed in 16-bytes unit. Default is 2 ms PCIe round trip time assuming 10G links (no optimization done for lower links speeds). For a 40G link, the number must be 0x0270.
RESERVED	31:16	0x0	RSV	N/A	

13.2.2.17.12 DCB Transmit Port DWRR Status - TPB_PRTDCB_TCB_DWRR_CREDITS (0x000991C0; RO)

Field definitions are the same as those defined in Section 13.2.2.17.47.

13.2.2.17.13 DCB Transmit Port DWRR Quanta/Weights - TPB_PRTDCB_TCB_DWRR_QUANTA (0x00099220; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x1	RW	UNDEFINED	**Quanta** Port quanta size in 64-byte granularity. Actual bandwidth share is determined by considering the other ports' quantas.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.14 DCB Transmit Port DWRR Saturation Value - TPB_PRTDCB_TCB_DWRR_SAT (0x00099260; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x1000	RW	UNDEFINED	**Saturation** Port saturation value in bytes. Port DWRR credits cannot be above this value.
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.15 DCB Transmit Regular Bulk DWRR Status - TPB_PRTTCB_BULK_DWRR_REG_CREDITS (0x000992A0; RO)

Field definitions are the same as those defined in Section 13.2.2.17.50.

13.2.2.17.16 DCB Transmit Wait Bulk DWRR Status - TPB_PRTTCB_BULK_DWRR_WB_CREDITS (0x000992C0; RO)

Field definitions are the same as those defined in Section 13.2.2.17.51.

13.2.2.17.17 DCB Transmit Regular Low Latency DWRR Status - TPB_PRTTCB_LL_DWRR_REG_CREDITS (0x00099300; RO)

Field definitions are the same as those defined in Section 13.2.2.17.52.

13.2.2.17.18 DCB Transmit Wait Low Latency DWRR Status - TPB_PRTTCB_LL_DWRR_WB_CREDITS (0x00099320; RO)

Field definitions are the same as those defined in Section 13.2.2.17.53.

13.2.2.17.19 DCB Transmit Regular Bulk DWRR Quanta/Weights - TPB_BULK_DWRR_REG_QUANTA (0x00099340; RW)

Field definitions are the same as those defined in Section 13.2.2.17.54.

13.2.2.17.20 DCB Transmit Wait Bulk DWRR Quanta/Weights - TPB_BULK_DWRR_WB_QUANTA (0x00099344; RW)

Field definitions are the same as those defined in Section 13.2.2.17.55.

13.2.2.17.21 DCB Transmit Regular Low Latency DWRR Quanta/Weights - TPB_LL_DWRR_REG_QUANTA (0x00099348; RW)

Field definitions are the same as those defined in Section 13.2.2.17.56.

13.2.2.17.22 DCB Transmit Wait Low Latency DWRR Quanta/Weights - TPB_LL_DWRR_WB_QUANTA (0x0009934C; RW)

Field definitions are the same as those defined in Section 13.2.2.17.57.

13.2.2.17.23 DCB Transmit Regular Bulk DWRR Saturation Value - TPB_BULK_DWRR_REG_SAT (0x00099350; RW)

Field definitions are the same as those defined in Section 13.2.2.17.58.

13.2.2.17.24 DCB Transmit Wait Bulk DWRR Saturation Value - TPB_BULK_DWRR_WB_SAT (0x00099354; RW)

Field definitions are the same as those defined in Section 13.2.2.17.59.

13.2.2.17.25 DCB Transmit Regular Low Latency DWRR Saturation Value - TPB_LL_DWRR_REG_SAT (0x00099358; RW)

Field definitions are the same as those defined in Section 13.2.2.17.60.

13.2.2.17.26 DCB Transmit Wait Low Latency DWRR Saturation Value - TPB_LL_DWRR_WB_SAT (0x0009935C; RW)

Field definitions are the same as those defined in Section 13.2.2.17.61.

13.2.2.17.27 DCB Transmit Rate Limiter Control per TC - TPB_WB_RL_TC_CFG[n] (0x00099360 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.17.66.

13.2.2.17.28 DCB Transmit Rate Limiter Status per TC - TPB_WB_RL_TC_STAT[n] (0x000993E0 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.17.67.

13.2.2.17.29 TC Rate Limiters Config - GLTPB_WB_RL (0x00099460; RO)

Field definitions are the same as those defined in Section 13.2.2.17.68.

13.2.2.17.30 TPB TC LL Config - GLDCB_TPB_TCLL_CFG (0x00099464; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LLTC	31:0	0x0	RW	UNDEFINED	**Low Latency TC** 1-bit entry per each TC. Each entry controls whether the TC is considered to have low latency needs for the transmit path. 0b = TC is defined to be a Bulk. 1b = TC is defined to be a Low Latency TC for transmit.

13.2.2.17.31 TPB TLPM TC Immediate FC Enable - GLDCB_TPB_IMM_TLPM (0x00099468; RO)

Configures FC immediate mode per TC for TCUPM interface.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IMM_EN	31:0	0xFFFFFFFF	RW	UNDEFINED	**Immediate Enable** Per-TC Tx immediate FC enable. 0b = Conditioned XOFF Forwarding Mode (default). XOFF notifications received from the line or from the internal loopback path are not forwarded upward to the TCUPM, but only once the data pipe monitor for this TC is filled over its threshold. This mode provides better XON recovering time. 1b = Immediate XOFF Forwarding Mode. XOFF notifications received from the line or from the internal loopback path are immediately forwarded internally upward to the TCUPM. This mode is useful to support PFC-enabled TCs of the port like true independent traffic classes when more than two such TCs are configured over the port. This bit should be kept as zero

13.2.2.17.32 TPB TC Immediate FC Enable - GLDCB_TPB_IMM_TPB (0x0009946C; RO)

Configures FC immediate mode per TC for TCB interface.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IMM_EN	31:0	0xFFFFFFFF	RW	UNDEFINED	**Immediate Enable** Per-TC Tx immediate FC enable. 0b = Conditioned XOFF Forwarding Mode (default). XOFF notifications received from the line or from the internal loopback path are not forwarded upward to the TCB, but only once the data pipe monitor for this TC is filled over its threshold. This mode provides better XON recovering time. 1b = Immediate XOFF Forwarding Mode. XOFF notifications received from the line or from the internal loopback path are immediately forwarded internally upward to the TCB.

13.2.2.17.33 Ignore FC per TC List - GLDCB_TFPFCI (0x0009949C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLDCB_TFPFCI	31:0	0x0	RW	UNDEFINED	A bit per TC, that if high FC is ignored for this TC: Packets are dropped and not sent to MAC/RPB (even if FC from MAC/RPB is not set). Indication to pipe monitor is not asserted. MAC/RPB FC is ignored.

13.2.2.17.34 TCB Arbiter Credit Expansion - TPB_PRTTCB_CREDIT_EXP (0x00099644; RW)

Register used to add arbiter credit expansion for packets per port.

Field definitions are the same as those defined in Section 13.2.2.17.62.

13.2.2.17.35 TCB Arbiter Credit Expansion Control - TPB_GLTCB_CREDIT_EXP_CTL (0x00099664; RW)

Used to enable/disable arbiter credit expansion and set minimal packet size for updating credits.

Field definitions are the same as those defined in Section 13.2.2.17.63.

13.2.2.17.36 Global Wait Buffer Strict Priority Enable - TPB_GLDCB_TCB_WB_SP (0x0009966C; RW)

Field definitions are the same as those defined in Section 13.2.2.17.69.

13.2.2.17.37 DCB Transmit Data Pipe Port Monitor Status - PRTDCB_TLPM_REG_DM (0x000A0000; RO)

Regular buffer data monitor status per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Regular buffer port monitor status. Current amount of data in lower pipe not including TPB wait buffer per port, in bytes.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.38 DCB Transmit Data Pipe Port Monitor Threshold - PRTDCB_TLPM_REG_DTHR (0x000A0020; RW)

Regular buffer data monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH_H	11:0	0x1A9	RW	UNDEFINED	**Port OFF Threshold High** Regular buffer port monitor high threshold applied over the Data Pipe. It is expressed in 128-byte units of Layer2 packet lengths (i.e., excluding preamble, IPG, and CRC). When over this threshold, monitor blocks the port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH_L	23:12	0x1A9	RW	UNDEFINED	**Port OFF Threshold Low** Regular buffer port monitor low threshold applied over the Data Pipe. It is expressed in 128Byte units of Layer2 packet lengths (i.e., excluding preamble, IPG, and CRC). When over this threshold, monitor blocks bulk traffic of the port.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.17.39 DCB Transmit Data Pipe Port Waiting Monitor Status - PRTDCB_TLPM_WAIT_PFC_DM (0x000A0040; RO)

Wait + regular buffer data monitor status per port of PFC-enabled TCs only.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer port monitor status. Current amount of data in lower pipe for both regular and wait buffers of TPB per port, in bytes.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.40 DCB Transmit Data Pipe Port Waiting Monitor Threshold - PRTDCB_TLPM_WAIT_PFC_DTHR (0x000A0060; RW)

Wait + regular buffer data monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH	11:0	0x3A0	RW	UNDEFINED	**Port OFF Threshold** High threshold on the total amount of data that is waiting in the TPB waiting lists of the port for all its PFC-enabled TCs, in 128-byte units.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.41 DCB Transmit Data Pipe TC Waiting Monitor Status - TCDCB_TLPM_WAIT_DM[n] (0x000A0080 + 0x4*n, n=0...31; RO)

Wait + regular buffer data monitor status per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer TC monitor status. Current amount of data in lower pipe for both regular and wait buffers of TPB per TC (32), in bytes.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.42 DCB Transmit Data Pipe TC Waiting Monitor Threshold - TCDCB_TLPM_WAIT_DTHR[n] (0x000A0100 + 0x4*n, n=0...31; RW)

Wait + regular buffer data monitor threshold per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCOFFTH	11:0	0x1A9	RW	UNDEFINED	**TC Off Threshold** The total amount of data that can accumulate in the TPB (waiting list included) of the port for the same PFC-enabled TC, in 128B units.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.43 DCB PCIe Tx Data Count - GLDCB_TLPM_PCI_DM (0x000A0180; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Byte count of all the Tx data (for all ports) which is in transit from host PCIe to TDPU block.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.44 DCB PCIe Tx Data Threshold - GLDCB_TLPM_PCI_DTHR (0x000A0184; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_TDATA	11:0	0x96	RW	UNDEFINED	**PCI Data Threshold** Shared threshold expressed in 128-byte units for all Tx data (from all ports) that is in transit between host and TDPU block. When the threshold is reached, no Tx data read request is sent to the host. When we pass under the threshold, data read request(s) for an entire frame can be sent to the host, and so on until we reach the threshold again. The byte count register associated with this threshold is GLDCB_TLPM_PCI_DATA. Default of 19200 bytes provides some good margin when assuming a PCIe round trip time of 1.5 µs.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.45 DCB TC Immediate FC Enable - GLDCB_TLPM_IMM_TCUPM (0x000A018C; RW)

Configures FC immediate mode per TC for TCUPM interface.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IMM_EN	31:0	0xFFFFFFFF	RW	UNDEFINED	**Immediate Enable** Per-TC Tx immediate FC enable. 0b = Conditioned XOFF Forwarding Mode (default). XOFF notifications received from the line or from the internal loopback path are not forwarded upward to the TCUPM, but only once the data pipe monitor for this TC is filled over its threshold. This mode provides better XON recovering time. 1b = Immediate XOFF Forwarding Mode. XOFF notifications received from the line or from the internal loopback path are immediately forwarded internally upward to the TCUPM. This mode is useful to support PFC-enabled TCs of the port like true independent traffic classes when more than two such TCs are configured over the port. This bit should be kept as zero

13.2.2.17.46 DCB TC Immediate FC Mode - GLDCB_TLPM_IMM_TCB (0x000A0190; RW)

Configures FC immediate mode per TC for TCB interface.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IMM_EN	31:0	0xFFFFFFFF	RW	UNDEFINED	**Immediate Enable** Per-TC Tx immediate FC enable. 0b = Conditioned XOFF Forwarding Mode (default). XOFF notifications received from the line or from the internal loopback path are not forwarded upward to the TCB, but only once the data pipe monitor for this TC is filled over its threshold. This mode provides better XON recovering time. 1b = Immediate XOFF Forwarding Mode. XOFF notifications received from the line or from the internal loopback path are immediately forwarded internally upward to the TCB.

13.2.2.17.47 DCB Transmit Port DWRR Status - PRTDCB_TCB_DWRR_CREDITS (0x000AE000; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	17:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port in Tx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value, which is used by Tx-PRR algorithm.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.17.48 DCB Transmit Port DWRR Quanta/Weights - PRTDCB_TCB_DWRR_QUANTA (0x000AE020; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x14	RW	UNDEFINED	**Quanta** Port quanta size in 64-byte granularity. Actual bandwidth share is determined by considering the ratio with other ports' quantas.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.49 DCB Transmit Port DWRR Saturation Value - PRTDCB_TCB_DWRR_SAT (0x000AE040; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x3000	RW	UNDEFINED	**Saturation** Port saturation value in bytes. Port DWRR credits cannot be above this value. Minimal Saturation value depends on Port MTU Size (for all quantas): MTU is [0k-2k]: 3K MTU is [2k-4k]: 6K MTU is [4k-8k]: 12K MTU is [8k-16k] (Jumbo): 24K Final Minimal Saturation = Max(Quanta, MTU Min Saturation).
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.50 DCB Transmit Regular Bulk DWRR Status - PRTTCB_BULK_DWRR_REG_CREDITS (0x000AE060; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	17:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port for bulk regular buffer in Tx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.17.51 DCB Transmit Wait Bulk DWRR Status - PRTTCB_BULK_DWRR_WB_CREDITS (0x000AE080; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	17:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port for bulk wait buffer in Tx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.17.52 DCB Transmit Regular Low Latency DWRR Status - PRTTCB_LL_DWRR_REG_CREDITS (0x000AE0A0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	17:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port for low latency regular buffer in Tx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.17.53 DCB Transmit Wait Low Latency DWRR Status - PRTTCB_LL_DWRR_WB_CREDITS (0x000AE0C0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	17:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port for low latency wait buffer in Tx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.17.54 DCB Transmit Regular Bulk DWRR Quanta/Weights - GLTCB_BULK_DWRR_REG_QUANTA (0x000AE0E0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x1	RW	UNDEFINED	**Quanta** Quanta for bulk buffer DWRR arbitration in 64-byte granularity. This quanta is used for all ports. Actual bandwidth share is determined by considering the ratio with the wait buffer's bulk quanta.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.55 DCB Transmit Wait Bulk DWRR Quanta/Weights - GLTCB_BULK_DWRR_WB_QUANTA (0x000AE0E4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x2	RW	UNDEFINED	**Quanta** Quanta for bulk wait buffer DWRR arbitration in 64-byte granularity. This quanta is used for all ports. Actual bandwidth share is determined by considering the ratio with the regular buffer's bulk quanta.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.56 DCB Transmit Regular Low Latency DWRR Quanta/Weights - GLTCB_LL_DWRR_REG_QUANTA (0x000AE0E8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x1	RW	UNDEFINED	**Quanta** Quanta for low latency regular buffer DWRR arbitration in 64-byte granularity. Actual bandwidth share is determined by considering the ratio with the wait buffer's low latency quanta.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.57 DCB Transmit Wait Low Latency DWRR Quanta/Weights - GLTCB_LL_DWRR_WB_QUANTA (0x000AE0EC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA	10:0	0x2	RW	UNDEFINED	**Quanta** Quanta for low latency wait buffer DWRR arbitration in 64-byte granularity. Actual bandwidth share is determined by considering the ratio with the regular buffer's low latency quanta.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.17.58 DCB Transmit Regular Bulk DWRR Saturation Value - GLTCB_BULK_DWRR_REG_SAT (0x000AE0F0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x2000	RW	UNDEFINED	**Saturation** Bulk regular buffer saturation value in bytes for all ports. Credits cannot be added over this value. Minimal Saturation value depends on Port MTU Size (for all quantas): MTU is [0k-2k]: 3K MTU is [2k-4k]: 6K MTU is [4k-8k]: 12K MTU is [8k-16k] (Jumbo): 24K Final Minimal Saturation = Max(Quanta, MTU Min Saturation).
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.59 DCB Transmit Wait Bulk DWRR Saturation Value - GLTCB_BULK_DWRR_WB_SAT (0x000AE0F4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x2000	RW	UNDEFINED	**Saturation** Bulk wait buffer saturation value in bytes for all ports. Credits cannot be added over this value. Minimal Saturation value depends on Port MTU Size (for all quantas): MTU is [0k-2k]: 3K MTU is [2k-4k]: 6K MTU is [4k-8k]: 12K MTU is [8k-16k] (Jumbo): 24K Final Minimal Saturation = Max(Quanta, MTU Min Saturation).

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.60 DCB Transmit Regular Low Latency DWRR Saturation Value - GLTCB_LL_DWRR_REG_SAT (0x000AE0F8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x2000	RW	UNDEFINED	**Saturation** Low latency regular buffer saturation value in bytes for all ports. Credits cannot be added over this value. Minimal Saturation value depends on Port MTU Size (for all quantas): MTU is [0k-2k]: 3K MTU is [2k-4k]: 6K MTU is [4k-8k]: 12K MTU is [8k-16k] (Jumbo): 24K Final Minimal Saturation = Max(Quanta, MTU Min Saturation).
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.61 DCB Transmit Wait Low Latency DWRR Saturation Value - GLTCB_LL_DWRR_WB_SAT (0x000AE0FC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SATURATION	16:0	0x2000	RW	UNDEFINED	**Saturation** Low latency wait buffer saturation value in bytes for all ports. Credits cannot be added over this value. Minimal Saturation value depends on Port MTU Size (for all quantas): MTU is [0k-2k]: 3K MTU is [2k-4k]: 6K MTU is [4k-8k]: 12K MTU is [8k-16k] (Jumbo): 24K Final Minimal Saturation = Max(Quanta, MTU Min Saturation).
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.62 TCB Arbiter Credit Expansion - PRTTCB_CREDIT_EXP (0x000AE100; RW)

Register used to add arbiter credit expansion for packets per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EXPANSION	7:0	0x18	RW	UNDEFINED	**Expansion** Amount of credits in bytes to be added when updating the arbiter. Can be used to allow arbiter to take into account MAC IPG and so on.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.17.63 TCB Arbiter Credit Expansion Control - GLTCB_CREDIT_EXP_CTL (0x000AE120; RW)

Used to enable/disable arbiter credit expansion and set minimal packet size for updating credits.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EN	0	0b	RW	UNDEFINED	**Enable** Enables credit expansion. 0b = Packet length received is updated to arbiter. 1b = Packet length is expanded according to: new_len = Max(orig_len + expansion, min_pkt)
MIN_PKT	9:1	0x80	RW	UNDEFINED	**Minimal Packet** Used to enforce minimal size for arbiter credit update, expressed in bytes. This value is updated to arbiter for packets smaller than (min_pkt - configured expansion), otherwise the packet size + configured expansion is updated.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.17.64 Global MNG LL Strict Priority Enable - GLDCB_TCB_MNG_SP (0x000AE12C; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MNG_SP	0	1b	RW	UNDEFINED	**MNG Strict Priority** When set, low latency MNG packets get strict priority over low latency wait/regular buffer packets of the same port in TCB arbitration. Otherwise, the wait/regular buffer packets get strict priority over the MNG packets.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.17.65 TC Low Latency Config - GLDCB_TCB_TCLL_CFG (0x000AE134; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LLTC	31:0	0x0	RW	UNDEFINED	**Low Latency TC** Bit per each TC. Each entry controls whether the TC is considered to have low latency needs for the transmit path. 0b = TC is defined to be a Bulk. 1b = TC is defined to be a Low Latency TC for transmit.

13.2.2.17.66 DCB Transmit Rate Limiter Control per TC - TCTCB_WB_RL_TC_CFG[n] (0x000AE138 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TOKENS	11:0	0x381	RW	UNDEFINED	**Tokens** Amount of tokens in bytes added to bucket after each period (period is configured) per TC.
BURST_SIZE	21:12	0x017	RW	UNDEFINED	**Burst Size** Max amount of tokens a bucket can hold in 64-byte resolutions (up to 64KB) per TC.
RESERVED	31:22	0x0	RSV	N/A	Reserved.

13.2.2.17.67 DCB Transmit Rate Limiter Status per TC - TCTCB_WB_RL_TC_STAT[n] (0x000AE1B8 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BUCKET	16:0	0x0	RO	N/A	**Bucket** Current amount of tokens in bytes that are in the bucket per TC.Coded in 2's compliment.
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.68 TC Rate Limiters Config - GLTCB_WB_RL (0x000AE238; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PERIOD	15:0	0x0020	RW	UNDEFINED	**Period** Amount of clock cycles to wait before adding new tokens to bucket. Every PERIOD CC, TCB_WB_RL_TC_CFG.*TOKENS* bytes are added to TCB_WB_RL_TC_STAT.*BUCKET*.
EN	16	0b	RW	UNDEFINED	**Enable** 0b = Disables TCB wait buffer rate limiters. They no longer block WB traffic and receive credit updates. 1b = Enables TCB wait buffer rate limiters.
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.17.69 Global Wait Buffer Strict Priority Enable - GLDCB_TCB_WB_SP (0x000AE310; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WB_SP	0	0b	RW	UNDEFINED	**Wait Buffer Strict Priority** When set, wait buffer packets get strict priority over regular buffer packets of the same port in the same LL/Bulk class, in TCB arbitration. Otherwise, the wait/regular buffer arbitration is done using the weighted round-robin algorithm.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.17.70 DCB Transmit Command Pipe Port Monitor Status - PRTDCB_TCUPM_REG_CM (0x000BC360; RO)

Regular buffer command monitor status per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	14:0	0x0	RW	UNDEFINED	**Monitor** Regular buffer port commands monitor status. Current amount of commands accounted by the Per Port Tx LAN Command Pipe Monitor.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.17.71 DCB Transmit Command Pipe Port Monitor Threshold - PRTDCB_TCUPM_REG_CTHR (0x000BC380; RW)

Regular buffer command monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH_H	14:0	0x43C	RW	UNDEFINED	**Port OFF Threshold High** Regular buffer port OFF commands high threshold. Depth of the per Port Monitor applied over the Tx LAN/RDMA Command Pipes altogether. It is expressed in commands units. Blocks port when monitor is over threshold.
PORTOFFTH_L	29:15	0x43C	RW	UNDEFINED	**Port OFF Threshold Low** regular buffer port OFF commands low threshold. Depth of the per Port Monitor applied over the Tx LAN/RDMA Command Pipes altogether. It is expressed in commands units. Blocks only Legacy TCs of the port when monitor is over threshold.
RESERVED	31:30	0x0	RSV	N/A	Reserved.

13.2.2.17.72 DCB Transmit Data Pipe Port Monitor Status - PRTDCB_TCUPM_REG_DM (0x000BC3A0; RO)

Regular buffer data monitor status per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Regular buffer port data monitor status. Current amount of bytes accounted by the Per Port Tx LAN Data Pipe Monitor.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.73 DCB Transmit Data non-Exceed Pipe Monitor Status - PRTDCB_TCUPM_NO_EXCEED_DM (0x000BC3C0; RO)

Regular buffer non-exceed data monitor status.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Regular buffer non-exceed data monitor status. Total number of bytes in the TCB waiting and regular buffer for all PFC-enabled TCs of the port. Counts scheduled data only (not including exceeded quantas).
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.74 DCB Transmit Data Pipe Port Monitor Threshold - PRTDCB_TCUPM_REG_DTHR (0x000BC3E0; RW)

Regular buffer data monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH_H	11:0	0x98	RW	UNDEFINED	**Port OFF Threshold High** Regular buffer port OFF data high threshold. Depth of the per Port Monitor applied over the Tx LAN/RDMA Command Pipes altogether. It is expressed in 128-byte units. Threshold is checked against the non-Exceed Data Monitor. When GLDCB_TCUPM_GENC.*NON_EXCEED_DIS* is high, threshold applies to the Regular Data Monitor instead. Blocks port when monitor is over threshold.
PORTOFFTH_L	23:12	0x98	RW	UNDEFINED	**Port OFF Threshold Low** Regular buffer port OFF data low threshold. Depth of the per Port Monitor applied over the Tx LAN/RDMA Command Pipes altogether. It is expressed in 128-byte units. Blocks only Legacy TCs of the port when monitor is over threshold.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.17.75 DCB Transmit Data Pipe Port Monitor Status - PRTDCB_TCUPM_REG_PE_HB_DM (0x000BC400; RO)

Regular buffer PE headers monitor status per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	11:0	0x0	RW	UNDEFINED	**Monitor** Regular buffer port PE header buffers monitor status. Current amount of bytes accounted by the per port PE Header Buffers Pipe Monitor, in 32byte units.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.76 DCB Transmit Data Pipe Port Monitor Threshold - PRTDCB_TCUPM_REG_PE_HB_DTHR (0x000BC420; RW)

Regular buffer PE headers monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH_H	11:0	0x98	RW	UNDEFINED	**Port OFF Threshold High** Regular buffer port OFF PE header buffers high threshold. It is expressed in 32-byte units. Blocks port when monitor is over threshold.
PORTOFFTH_L	23:12	0x98	RW	UNDEFINED	**Port OFF Threshold Low** Regular buffer port OFF PE header buffers low threshold. It is expressed in 32-byte units. Blocks only Legacy TCs of the port when monitor is over threshold.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.17.77 DCB Transmit Command Pipe Port Waiting Monitor Status - PRTDCB_TCUPM_WAIT_PFC_CM (0x000BC440; RO)

Wait + regular buffer command monitor status per port of PFC-enabled TCs only.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	14:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer port commands monitor status. Total number of commands in the TCB waiting and regular buffer for all PFC-enabled TCs of the port.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.17.78 DCB Transmit Command Pipe Port Waiting Monitor Threshold - PRTDCB_TCUPM_WAIT_PFC_CTHR (0x000BC460; RW)

Wait + regular buffer command monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH	14:0	0x9F8	RW	UNDEFINED	**Port OFF Threshold** Wait buffer port OFF commands threshold. High threshold on the total amount of commands that is waiting in the TCB waiting lists of the port for all its PFC-enabled TCs. Only PFC-enabled TCs of the port are flow controlled when this threshold is crossed.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.17.79 DCB Transmit Data Pipe Port Waiting Monitor Status - PRTDCB_TCUPM_WAIT_PFC_DM (0x000BC480; RO)

Wait + regular buffer data monitor status per port of PFC-enabled TCs only.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer port data monitor status. Total number of bytes in the TCB waiting and regular buffer for all PFC-enabled TCs of the port.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.80 DCB Transmit Data Pipe Port Waiting Monitor Threshold - PRTDCB_TCUPM_WAIT_PFC_DTHR (0x000BC4A0; RW)

Wait + regular buffer data monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH	11:0	0x274	RW	UNDEFINED	**Port OFF Threshold** Wait buffer port OFF data threshold. High threshold on the total amount of bytes in 128-byte units that is waiting in the TCB waiting lists of the port for all its PFC-enabled TCs. Only PFC-enabled TCs of the port are flow controlled when this threshold is crossed.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.81 DCB Transmit Data Pipe Port Waiting Monitor Status - PRTDCB_TCUPM_WAIT_PFC_PE_HB_DM (0x000BC4C0; RO)

Wait + regular buffer PE headers monitor status per port of PFC enabled TCs only.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	11:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer port PE header buffers monitor status. Expressed in 32-byte units. Total number of PE headers bytes in the TCB waiting and regular buffer for all PFC enabled TCs of the port.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.82 DCB Transmit Data Pipe Port Waiting Monitor Threshold - PRTDCB_TCUPM_WAIT_PFC_PE_HB_DTHR (0x000BC4E0; RW)

Wait + regular buffer PE headers monitor threshold per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORTOFFTH	11:0	0x130	RW	UNDEFINED	**Port OFF Threshold** Wait buffer port OFF PE header buffers threshold. High threshold on the total amount of bytes in 32-byte units that is waiting in the TCB waiting lists of the port for all its PFC-enabled TCs. Only PFC-enabled TCs of the port are flow controlled when this threshold is crossed.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.83 DCB Transmit Command Pipe TC Waiting Monitor Status - TCDCB_TCUPM_WAIT_CM[n] (0x000BC520 + 0x4*n, n=0...31; RO)

Wait + regular buffer command monitor status per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	14:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer TC commands monitor status. Number of commands that are in transit from the host to the TCB (TCB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.17.84 DCB Transmit Command Pipe TC Waiting Monitor Threshold - TCDCB_TCUPM_WAIT_CTHR[n] (0x000BC5A0 + 0x4*n, n=0...31; RW)

Wait + regular buffer command monitor threshold per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCOFFTH	14:0	0x4BC	RW	UNDEFINED	**TC OFF Threshold** Wait buffer TC OFF commands threshold. The total amount of commands that can accumulate in the TCB (waiting list included) of the port for the same PFC-enabled TC.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.17.85 DCB Transmit Data Pipe TC Waiting Monitor Status - TCDCB_TCUPM_WAIT_DM[n] (0x000BC620 + 0x4*n, n=0...31; RO)

Wait + regular buffer data monitor status per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	18:0	0x0	RW	UNDEFINED	**Monitor** Wait Buffer TC data monitor status. Number of bytes that are in transit from the host to the TCB (TCB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.17.86 DCB Transmit Data Pipe TC Waiting Monitor Threshold - TCDCB_TCUPM_WAIT_DTHR[n] (0x000BC6A0 + 0x4*n, n=0...31; RW)

Wait + regular buffer data monitor threshold per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCOFFTH	11:0	0x104	RW	UNDEFINED	**TC OFF Threshold** Wait buffer TC OFF Data Threshold. The total amount of bytes in 128-byte units that can accumulate in the TCB (waiting list included) of the port for the same PFC-enabled TC.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.87 DCB Transmit Data Pipe TC Waiting Monitor Status - TCDCB_TCUPM_WAIT_PE_HB_DM[n] (0x000BC720 + 0x4*n, n=0...31; RO)

Wait + regular buffer PE headers monitor status per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MONITOR	11:0	0x0	RW	UNDEFINED	**Monitor** Wait buffer TC PE header buffers monitor status. Expressed in 32-byte units. Number of bytes that are in transit from the host to the TCB (TCB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.88 DCB Transmit Data Pipe TC Waiting Monitor Threshold - TCDCB_TCUPM_WAIT_PE_HB_DTHR[n] (0x000BC7A0 + 0x4*n, n=0...31; RW)

Wait + regular buffer PE headers monitor threshold per TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCOFFTH	11:0	0x98	RW	UNDEFINED	**TC OFF Threshold** Wait buffer TC OFF PE header buffers threshold. The total amount of bytes in 32-byte units that can accumulate in the TCB (waiting list included) of the port for the same PFC-enabled TC.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.17.89 DCB TC Immediate FC Mode - GLDCB_TCUPM_IMM_EN (0x000BC824; RW)

Configures FC immediate mode for each TC.

Field	Bit(s)	Init.	Type	CFG Policy	Description
IMM_EN	31:0	0xFFFFFFFF	RW	UNDEFINED	**Immediate Enable** Per TC Tx-Pipe immediate FC mode. 0b = Conditioned XOFF Forwarding Mode (default). XOFF notifications received from the TC data pipe monitor are internally forwarded upward to the Tx-Scheduler only once the command pipe monitor for this TC is full. This mode provides better XON recovering time. 1b = Immediate XOFF Forwarding Mode. XOFF notifications received from the TC data pipe monitor are immediately forwarded internally upward to the Tx-Scheduler. This mode is useful to support PFC-enabled TCs of the port like true independent traffic classes when more than two such TCs are configured over the port. This bit should be kept as zero.

13.2.2.17.90 DCB TC Legacy Queues Mapping - GLDCB_TCUPM_LEGACY_TC (0x000BC828; RW)

Configure which TCs send legacy queues.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LEGTC	31:0	0x0	RW	UNDEFINED	**Legacy TC** Per TC configuration to indicate if it is sending legacy queues. Only legacy TCs are halted by the regular buffer data monitor (instead of entire port) when over low threshold. The port is blocked by the non-exceed monitor when over high threshold.

13.2.2.17.91 DCB Transmit Data non-Exceed Monitor Enable - GLDCB_TCUPM_NO_EXCEED_DIS (0x000BC830; RW)

TCUPM non-exceed regular buffer data monitor enable.

Field	Bit(s)	Init.	Type	CFG Policy	Description
NON_EXCEED_DIS	0	1b	RW	UNDEFINED	**Non-Exceed Disable** Disables non-exceed monitor. When disabled, the regular buffer high threshold is applied over the regular (exceed) monitor.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.17.92 DCB Transmit Wait Port Data Monitor Enable - GLDCB_TCUPM_WB_DIS (0x000BC834; RW)

TCUPM wait buffer port/TC data monitor disable.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_DISABLE	0	1b	RW	UNDEFINED	**Port Disable** Disables wait buffer port data monitors.
TC_DISABLE	1	0b	RW	UNDEFINED	**TC Disable** Disables wait buffer TC data monitors.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.17.93 DCB Receive Port Round Robin Control - PRTDCB_RPRRC (0x001220C0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BWSHARE	9:0	0x14	RW	UNDEFINED	**Bandwidth Share** Relative weight of the available bandwidth allocated to the port in Rx. The value of 1 is used for ports operated at 100 Mb/s speed.
RESERVED	30:10	0x0	RSV	N/A	Reserved.
BWSHARE_DIS	31	1b	RW	UNDEFINED	**Bandwidth Share Disable** Disable weighted arbitration. Disabled ports arbitrate in packet-based round-robin manner.

13.2.2.17.94 DCB Receive Port Round Robin Status - PRTDCB_RPRRS (0x001220E0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	31:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by the port in Rx. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value, which is used by Rx-PRR algorithm.

13.2.2.17.95 QRX - GLDCB_RTC2PFC_RCB (0x00122100; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TC2PFC	31:0	0x0	RW	UNDEFINED	**TC-to-Priority Flow Control** Bitmap that controls the use of Priority Flow Control (PFC) per each TC. Bit n set to 1b: TC n uses PFC in Rx and Tx. The TC is referred as a no-drop TC. Bit n clear to 0b: The device does not issue PFC pause frames with bits set to 1b in the *priority_enable_vector* for the UPs attached to that TC. It does not react to bits set to 1b for the UPs attached to that TC in the priority_enable_vector of a received PFC pause frame. The TC is referred as a drop UP. For up to four link topology: Bits 0-7 are for port 0, TC 0 to 7. Bits 8-15 are for port 1, TC 0 to 7. Bits 16-23 are for port 2, TC 0 to 7. Bits 24-31 are for port 3, TC 0 to 7. For more than four link topology: Bits 00-03 are for port 0, TC 0 to 3. Bits 04-07 are for port 1, TC 0 to 3. Bits 08-11 are for port 2, TC 0 to 3. Bits 12-15 are for port 3, TC 0 to 3. Bits 16-19 are for port 4, TC 0 to 3. Bits 20-23 are for port 5, TC 0 to 3. Bits 24-27 are for port 6, TC 0 to 3. Bits 28-31 are for port 7, TC 0 to 3.

13.2.2.17.96 DCB Receive ETS per TC Control - GLDCB_RETSTCC[n] (0x00122140 + 0x4*n, n=0...31; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	30:0	0x0	RSV	N/A	Reserved.
ETSTC	31	0b	RW	UNDEFINED	**ETS TC** Controls the use of ETS as the Transmit Selection Algorithm (TSA) in Rx for TC n, where n is the register index in the array. 0b = TC n uses a Strict Priority or other TSA in Rx. 1b = TC n uses ETS scheme in Rx.

13.2.2.17.97 DCB Receive ETS per TC Status - GLDCB_RETSTCS[n] (0x001221C0 + 0x4*n, n=0...31; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CREDITS	31:0	0x0	RW	UNDEFINED	**Credits** Current amount of credits accumulated by TC n in Rx, where n is the register index in the array. The amount is expressed in byte units and it is formatted as an algebraic 2's complement number. Writing to this field has the effect of loading a new current credit value, which is used by Rx-ETS algorithm.

13.2.2.17.98 DCB Receive ETS Control - PRTDCB_RETSC (0x001222A0; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	0	1b	RSV	N/A	Reserved.
NON_ETS_MODE	1	1b	RW	UNDEFINED	**Non-ETS Mode** Rx non-ETS operating mode. 0b = Strict Priority (SP) mode. 1b = Round Robin (RR) mode.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.17.99 DCB Receive UP to TC Mapping - PRTDCB_RUP2TC (0x001D2640; RW)

Bitmap long by 24 bits, with a 3-bit entry per each UP. Each entry controls the mapping of a UP to a 3-bit TC index in receive. Higher TC index means higher priority of the traffic class.

The same mapping is used for packets received from the wires and for those looped back internally. It defines on the account of which TC a packet is stored in the Rx packet buffer, and which UPs bits are set in the PFC XOFF/XON frames issued to the link partner when the filling state of a TC requires it.

Default mapping maps all UPs to TC0.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0TC	2:0	000b	RW	UNDEFINED	**UP 0 TC** TC index to which UP 0 is mapped.
UP1TC	5:3	000b	RW	UNDEFINED	**UP 1 TC** TC index to which UP 1 is mapped.
UP2TC	8:6	000b	RW	UNDEFINED	**UP 2 TC** TC index to which UP 2 is mapped.
UP3TC	11:9	000b	RW	UNDEFINED	**UP 3 TC** TC index to which UP 3 is mapped.
UP4TC	14:12	000b	RW	UNDEFINED	**UP 4 TC** TC index to which UP 4 is mapped.
UP5TC	17:15	000b	RW	UNDEFINED	**UP 5 TC** TC index to which UP 5 is mapped.
UP6TC	20:18	000b	RW	UNDEFINED	**UP 6 TC** TC index to which UP 6 is mapped.
UP7TC	23:21	000b	RW	UNDEFINED	**UP 7 TC** TC index to which UP 7 is mapped.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.17.100 DCB TC to PFC Mapping - GLDCB_TC2PFC (0x001D2694; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TC2PFC	31:0	0x0	RW	UNDEFINED	**TC-to-Priority Flow Control** Bitmap that controls the use of Priority Flow Control (PFC) per each TC. Bit n set to 1b: TC n uses PFC in Rx and Tx. The TC is referred as a no-drop TC. Bit n clear to 0b: The device does not issue PFC pause frames with bits set to 1b in the *priority_enable_vector* for the UPs attached to that TC. It does not react to bits set to 1b for the UPs attached to that TC in the *priority_enable_vector* of a received PFC pause frame. The TC is referred as a drop UP.

13.2.2.17.101 DCB Transmit UP to TC Mapping - PRTDCB_TUP2TC (0x001D26C0; RW)

Bitmap long by 24 bits, with a 3-bit entry per each UP. Each entry controls the mapping of a UP to a 3-bit TC index in receive. Higher TC index means higher priority of the traffic class.

The same mapping is used for packets received from the wires and for those looped back internally. It defines on the account of which TC a packet is stored in the Rx packet buffer, and which UPs bits are set in the PFC XOFF/XON frames issued to the link partner when the filling state of a TC requires it.

Default mapping maps all UPs to TC0.

Field	Bit(s)	Init.	Type	CFG Policy	Description
UP0TC	2:0	000b	RW	UNDEFINED	**UP 0 TC** TC index to which UP 0 is mapped.
UP1TC	5:3	000b	RW	UNDEFINED	**UP 1 TC** TC index to which UP 1 is mapped.
UP2TC	8:6	000b	RW	UNDEFINED	**UP 2 TC** TC index to which UP 2 is mapped.
UP3TC	11:9	000b	RW	UNDEFINED	**UP 3 TC** TC index to which UP 3 is mapped.
UP4TC	14:12	000b	RW	UNDEFINED	**UP 4 TC** TC index to which UP 4 is mapped.
UP5TC	17:15	000b	RW	UNDEFINED	**UP 5 TC** TC index to which UP 5 is mapped.
UP6TC	20:18	000b	RW	UNDEFINED	**UP 6 TC** TC index to which UP 6 is mapped.
UP7TC	23:21	000b	RW	UNDEFINED	**UP 7 TC** TC index to which UP 7 is mapped.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.17.102 Transmit Flow Control Status - PRTDCB_TFCS (0x001E4560; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TXOFF	0	0b	RO	N/A	**Tx Off** Transmission Paused. Pause state indication of the transmit function when symmetrical link flow control is enabled.
RESERVED	7:1	0x0	RSV	N/A	Reserved.
TXOFF0	8	0b	RO	N/A	**Tx Off 0** TC 0 Transmission Paused. Pause state indication of the TC 0 when priority flow control is enabled.
TXOFF1	9	0b	RO	N/A	**Tx Off 1** TC 1 Transmission Paused. Pause state indication of the TC 1 when priority flow control is enabled.
TXOFF2	10	0b	RO	N/A	**Tx Off 2** TC 2 Transmission Paused. Pause state indication of the TC 2 when priority flow control is enabled.
TXOFF3	11	0b	RO	N/A	**Tx Off 3** TC 3 Transmission Paused. Pause state indication of the TC 3 when priority flow control is enabled.
TXOFF4	12	0b	RO	N/A	**Tx Off 4** TC 4 Transmission Paused. Pause state indication of the TC 4 when priority flow control is enabled.
TXOFF5	13	0b	RO	N/A	**Tx Off 5** TC 5 Transmission Paused. Pause state indication of the TC 5 when priority flow control is enabled.
TXOFF6	14	0b	RO	N/A	**Tx Off 6** TC 6 Transmission Paused. Pause state indication of the TC 6 when priority flow control is enabled.
TXOFF7	15	0b	RO	N/A	**Tx Off 7** TC 7 Transmission Paused. Pause state indication of the TC 7 when priority flow control is enabled.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.17.103 Flow Control Transmit Timer Value n - PRTDCB_FCTTVN[n] (0x001E4580 + 0x20*n, n=0...3; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TTV_2N	15:0	0xFFFF	RW	UNDEFINED	**Transmit Timer Value 2n** Timer value included in XOFF frames as Timer (2n). The same value must be set to User Priorities attached to the same TC, as defined in PRTDCB_RUP2TC register. For legacy 802.3x flow control packets, TTV0 is the only timer that is used.
TTV_2N_P1	31:16	0xFFFF	RW	UNDEFINED	**Transmit Timer Value 2n+1** Timer value included in XOFF frames as Timer (2n+1). The same value must be set to User Priorities attached to the same TC, as defined in PRTDCB_RUP2TC register.

13.2.2.17.104 Flow Control Refresh Threshold Value - PRTDCB_FCRTV (0x001E4600; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FC_REFRESH_TH	15:0	0x7FFF	RW	UNDEFINED	**Flow Control Refresh Threshold** This value is used to calculate the actual refresh period for sending the next pause frame if conditions for a pause state are still valid (buffer fullness above low threshold value). The formula for the refresh period for user priority N is: FCTTV[N/2].*TTV*[Nmod2] - FCRTV.*FC_REFRESH_TH*
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.17.105 Flow Control Configuration - PRTDCB_FCCFG (0x001E4640; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	2:0	000b	RSV	N/A	Reserved.
TFCE	4:3	00b	RW	UNDEFINED	**Transmit Flow Control Enable** These bits indicate that the device transmits Flow Control packets (XON/XOFF frames) based on receive fullness. If auto-negotiation is enabled, this bit should be set by software to the negotiated flow control value. 00b = Transmit flow control disabled. 01b = Link Flow Control enabled. 10b = Priority Flow Control enabled. 11b = Reserved.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.17.106 DCB Transmit PFC Timer Status - PRTDCB_TPFCTS[n] (0x001E4660 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFCTIMER	13:0	0x0	RW	UNDEFINED	**Priority Flow Control Timer** Current value of the PFC Timer of TC n in Tx, where n is the register index in the array. The amount is expressed in milliseconds. The timer saturates to 0x3FFF. Writing to this field has the effect of loading a new current timer value, which can be useful for diagnostic purposes.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.17.107 DCB Receive ETS per TC Control - GLDCB_PRS_RETSTCC[n] (0x002000B0 + 0x4*n, n=0...31; RW)

One register per TC. Register index corresponds to TCID.

Field definitions are the same as those defined in Section 13.2.2.17.96.

13.2.2.17.108 DCB Receive Shared Pipe Monitor Control - GLDCB_PRS_RSPMC (0x00200160; RW)

Field definitions are the same as those defined in Section 13.2.2.31.8.

13.2.2.17.109 DCB Receive Port Round Robin Control - PRTDCB_PRS_RPRRC (0x00200180; RW)

Field definitions are the same as those defined in Section 13.2.2.17.93.

13.2.2.17.110 DCB Receive ETS Control - PRTDCB_PRS_RETSC (0x002001A0; RW)

Field definitions are the same as those defined in Section 13.2.2.17.98.

13.2.2.17.111 DCB Receive ETS per TC Control - GLDCB_SWT_RETSTCC[n] (0x0020A040 + 0x4*n, n=0...31; RW)

One register per TC. Register index corresponds to TCID.

Field definitions are the same as those defined in Section 13.2.2.17.96.

13.2.2.17.112 DCB Receive ETS Control - PRTDCB_SWT_RETSC (0x0020A140; RW)

Field definitions are the same as those defined in Section 13.2.2.17.98.

13.2.2.18 PF - Receive Packet Buffer Registers

13.2.2.18.1 RPB Dedicated Pool High Watermark - GLRPB_DHW[n] (0x000AC000 + 0x4*n, n=0...15; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DHW_TCN	19:0	0x0	RW	UNDEFINED	**Dedicated Pool High Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.2 RPB Dedicated Pool Low Watermark - GLRPB_DLW[n] (0x000AC044 + 0x4*n, n=0...15; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DLW_TCN	19:0	0x0	RW	UNDEFINED	**Dedicated Pool Low Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.3 RPB Dedicated Pool Size - GLRPB_DPS[n] (0x000AC084 + 0x4*n, n=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DPS_TCN	19:0	0x0	RW	UNDEFINED	**Dedicated Pool Size** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
SPS_TCN	19:0	0xE1000	RW	UNDEFINED	**Shared Pool Size** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.5 RPB Shared Pool High Watermark - GLRPB_SHW[n] (0x000AC120 + 0x4*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SHW	19:0	0xC8000	RW	UNDEFINED	**Shared Pool High Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.6 RPB Shared Pool Low Watermark - GLRPB_SLW[n] (0x000AC140 + 0x4*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SLW	19:0	0x0	RW	UNDEFINED	**Shared Pool Low Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.7 TC Pool Config - GLRPB_TC_CFG[n] (0x000AC2A4 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
D_POOL	15:0	0x8	RW	UNDEFINED	**Dedicated Pool** TC dedicated pool index. Allowed values are 0..7.
S_POOL	31:16	0x1	RW	UNDEFINED	**Shared Pool** TC shared pool index. Allowed values are 0..15.

13.2.2.18.8 DSI Traffic Enable - GLRPB_DSI_EN (0x000AC324; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DSI_EN	0	0b	RW	UNDEFINED	**DSI Enable**
DSI_L2_MAC_ERR_DROP_EN	1	1b	RW	UNDEFINED	**DSI L2 MAC Error Drop Enable** Enables the dropping of DSI packets that have l2_mac_error (CRC, oversize, and so on).
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.18.9 RPB TC High Watermark - GLRPB_TCHW[n] (0x000AC330 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCHW	19:0	0x19000	RW	UNDEFINED	**TC High Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.18.10 RPB TC Low Watermark - GLRPB_TCLW[n] (0x000AC3B0 + 0x4*n, n=0...31; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCLW	19:0	0x0	RW	UNDEFINED	**TC Low Watermark** It is expressed in bytes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.19 PF - Transmit Scheduler Registers

Registers related to the Transmit Scheduler.

13.2.2.19.1 TSCD PEPM - GLPE_TSCD_PEPM (0x0051E228; RO)

Credit information for TSCD requests from PEPM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDQ_CREDITS	7:0	0x29	RW	UNDEFINED	**MDQ Credits** The number of MDQ credits TSCD requests from PEPM.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.19.2 Transmit Scheduler FLR - GLPE_TSCD_FLR[n] (0x0051E24C + 0x4*n, n=0...3; RO)

CQP writes these registers to trigger FLR flow through PE.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DRAIN_VCTR_ID	1:0	00b	RW	UNDEFINED	**Drain Vector ID**
PORT	4:2	000b	RW	UNDEFINED	**Port**
PF_NUM	7:5	000b	RW	UNDEFINED	**PF Number**
VM_VF_TYPE	9:8	00b	RW	UNDEFINED	**VM/VF Type**
RESERVED	15:10	0x0	RSV	N/A	Reserved.
VM_VF_NUM	25:16	0x0	RW	UNDEFINED	**VM/VF Number**
RESERVED	30:26	0x0	RSV	N/A	Reserved.
VLD	31	0b	RW	UNDEFINED	**Valid**

13.2.2.19.3 Transmit Scheduler Number of PQS - GLPE_TSCD_NUM_PQS (0x0051E2FC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NUM_PQS	31:0	0x120	RO	N/A	**Number of PQs** The number of PQs that the Transmit Scheduler was built with.

13.2.2.20 PF - Host Memory Cache Registers

Registers for Host Memory Cache.

13.2.2.20.1 FOC Cache Attributes - GLFOC_CACHESIZE (0x000AA074; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x80	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.2 Private Memory Space Segment Descriptor Command - PFHMC_SDCMD_FPMAT (0x00100000; RW)

This register is used to access the Host Memory Cache's segment table. The HMC's segment table is partitioned per Private Memory Function (PMF), and this register is only allowed to access the Segment Table entries allocated to the PMF associated with this register via the SD Partition register, GLHMC_SDPART.

For read operations, PFHMC_SDCMD must be written with *PMSDWR* set to 0b and *PMSDIDX* set to the segment table index to be read. After the write to PFHMC_SDCMD completes, PFHMC_SDDATALOW and PFHMC_SDDATAHIGH can be read to retrieve the segment descriptor contents.

For write operations, PFHMC_SDDATALOW and PFHMC_SDDATAHIGH must be written before writing PFHMC_SDCMD with *PMSDWR* set to 1b and *PMSDIDX* set to the segment table index to be written.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDIDX	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Index** Relative Index of the HMC Segment Descriptor to be read or written. The actual absolute index to be used to access the Segment Table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. On write operations, if (*PMSDIDX* >= *PMSDSIZE*), the write is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD Partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function.
RESERVED	14:12	000b	RSV	N/A	Reserved.
PMSDPARTSEL	15	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Partitioning Select** 0b = (Default) The GLHMC_SDPART register is used for calculating the absolute SD Index to access within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD Index to access within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	30:16	0x0	RSV	N/A	Reserved.
PMSDWR	31	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Write/Read** 0b = Read operations. 1b = Write operations.

13.2.2.20.3 Private Memory Space Segment Descriptor Data Low - PFHMC_SDDATALOW_FPMAT (0x00100100; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDVALID	0	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Valid** Valid bit of an HMC segment descriptor table entry.
PMSDTYPE	1	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Type** 0b = The Segment Descriptor is paged (the SD points to a the physical address of a host memory page that contains an array of Page Descriptors. 1b = The Segment Descriptor directly points the physical address of a physically contiguous 2 MB memory region.
PMSDBPCOUNT	11:2	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Backing Page Count** Backing Page count of an HMC segment descriptor table entry. Every SD entry in a given Function Private memory space must be set to 512, except the last SD. The last SD can have a value from 1 to 512. This field is used to calculate the end of the FPM space associated with a Segment Descriptor without having to read the valid bit for each individual PD entry.
PMSDDATALOW	31:12	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Data Low** Bits 31:12 bits of an HMC segment descriptor table entry.

13.2.2.20.4 Private Memory Space Segment Descriptor Data High - PFHMC_SDDATAHIGH_FPMAT (0x00100200; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDDATAHIGH	31:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Data High** Most significant 32 bits of a segment descriptor.

13.2.2.20.5 Private Memory Space Page Descriptor Invalidate - PFHMC_PDINV_FPMAT (0x00100300; RW)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDIDX	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Index** Relative Index of the HMC Segment Descriptor associated with the HMC Page Descriptor that is to be invalidated. For PFs, the actual index to be used to access the Segment Table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. If (*PMSDIDX* >= *PMSDSIZE*), the invalidate request is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD Partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function. For Protocol Engine enabled VFs, the actual index to be used to invalidate a Segment Table entry is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the GLHMC_VFSDPART register associated with this function. For VFs, if (*PMSDIDX* >= GLHMC_VFSDPART.*PMSDSIZE*), the invalidate request is dropped. The *PMSDPARTSEL* bit is ignored in the GLHMC_VFPDINV registers. For the GLHMC_FWPDINV version of this register, this field is the absolute SD index, and the *PMSDPARTSEL* bit is ignored.
RESERVED	14:12	000b	RSV	N/A	Reserved.
PMSDPARTSEL	15	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Partitioning Select** 0b = (Default) The GLHMC_SDPART register is used for calculating the absolute SD Index to invalidate within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD Index to invalidate within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. This field is ignored in the GLHMC_VFPDINV and GLHMC_FWPDINV versions of this register.
PMPDIDX	24:16	0x0	RW	UNDEFINED	**Private Memory Page Descriptor Index** Index of the Page Descriptor within the Page Descriptor Page indicated by *PMSDIDX*.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.20.6 Host Memory Cache Error Information Register - PFHMC_ERRORINFO_FPMAT (0x00100400; RW)

This register reports the errors detected by the Host Memory Cache. Errors reported through this register also can trigger interrupts through the *HMC_ERR* bit in the PFINT_ICR0 register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMF_INDEX	4:0	0x0	RW	UNDEFINED	**Private Memory Function Index** This field reports the HMC Private Memory Function associated with the error. Writes to this field are ignored.
RESERVED	6:5	00b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMF_ISVF	7	0b	RW	UNDEFINED	**Private Memory Function Is VF** 0b = The Private Memory Function reported in *PMF_INDEX* is associated with a PF. 1b = The Private Memory Function reported in *PMF_INDEX* is associated with a Protocol Engine enabled VF. Writes to this field are ignored.
HMC_ERROR_TYPE	11:8	0x0	RW	UNDEFINED	**HMC Error Type** This field reports the error type detected by the Host Memory Cache. The values are: 0 = Private Memory Function is not valid (the valid bit is clear in the GLHMC_VFPMFMAP register associated with the PMF). 1 = Invalid Private Memory Function index for a Protocol Engine enabled VF in GLHMC_VFPMFMAP. (i.e., The PMF Index programmed in the GLHMC_VFPMFMAP register is < 8 or > 40. This is a firmware error.) 2 = Invalid PF for a Protocol Engine enabled VF in GLHMC_VFPMFTABLE. (i.e., the parent PF index programmed in the GLHMC_VFPMFMAP register did not match the PF index received in the HMC transaction. This is a firmware error.) 3 = Reserved. In predecessor devices it was used to be an indication for Invalid LAN Queue Index or FCoE VF Index. (i.e., The absolute LAN Queue Index or FCoE VF Index received in the HMC transaction was less than the LAN Queue Index Base register or FCoE VF Index Base register associated with the PF Index received in the HMC transaction.) 4 = Index to big error: Indication that Object Index from transaction was larger than the value specified in the object's GLHMC_*CNT register. 5 = Private Memory Address Extends beyond the limits of the Segment Descriptors assigned to the PCIe function. 6 = Segment Descriptor Invalid. 7 = Segment Descriptor Too Small (only applies to Direct Mapped SDs). 8 = Page Descriptor Invalid. 9 = Received Unsupported Request (UR) Completion from PCIe read of object. 10 = Reserved. In predecessor devices this was used to be an indication that the valid bit in PFLAN_QALLOC_PMAT[PF] or PF_VT_PFALLOC_PMAT[PF] register was not set. 11 = An invalid object type was detected. 12 = Reserved. In predecessor devices it was used to be an indication for Object Index for an FCoE DDP Context object was larger than the size specified in the *PFFCDSIZE* or *VFFCDSIZE* field of the corresponding PFQF_CTL_0_PMAT register, or the object index for an FCoE Filter object was larger than the sum of the sizes specified in the *PFFCHSIZE* and *PFFCDSIZE* fields or *VFFCHSIZE* and *VFFCDSIZE* fields of the corresponding PFQF_CTL_0_PMAT register. All other values are reserved. The PFHMC_ERRORDATA register can be read to determine the LAN Queue index or FCoE VF index associated with error type 3. The PFHMC_ERRORDATA register can be read to determine the HMC object index associated with error types 4 and 12. The PFHMC_ERRORDATA register can be read to determine the HMC function relative *SD_Index* and *PD_Index* associated with error types 5 through 9.
RESERVED	15:12	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HMC_OBJECT_TYPE	20:16	0x0	RW	UNDEFINED	**HMC Object Type** Specifies the object type associated with the error. The encodings for the object type are as follows: 0x00 = QP_CNTXT 0x01 = ARP_TBL_ENTRY 0x02 = TXFIFO 0x03 = IRRQ 0x04 = MRTE 0x05 = PBLE 0x06 = CQ_CNTXT 0x07 = SRQ_CNTXT 0x08 = APBVT_INUSE 0x09 = FSI_ADR_VCTR 0x0A = FSI_MCAST_GRP 0x0B = XF_FL 0x0C = Q1_FL 0x0D = TIMER 0x10 = LAN_TXQ_CNTXT 0x11 = LAN_RXQ_CNTXT 0x12 = FCOE_CNTXT 0x13 = FCOE_DDP_HTE 0x16 = QUAD_HTE 0x19 = PD All other values are reserved.
RESERVED	30:21	0x0	RSV	N/A	Reserved.
ERROR_DETECTED	31	0b	RW	UNDEFINED	**Error Detected** This field is set to 1b when a new error has been detected by the HMC. No subsequent errors are recorded until this field is written with a value of 0b. Write of a 0b to this field clears the error and allow a subsequent error to be reported. Writes of 1b to this field are ignored.

13.2.2.20.7 Host Memory Cache Error Data Register - PFHMC_ERRORDATA_FPMAT (0x00100500; RO)

This register reports the HMC function relative *SD_Index* and *PD_Index* or HMC object index related to an error detected by the Host Memory Cache.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HMC_ERROR_DATA	29:0	0x0	RO	N/A	**HMC Error Data** This field reports either the HMC function relative *SD_Index*, *PD_Index*, LAN Queue index, FCoE VF index, or HMC object index associated with the error reported in the PFHMC_ERRORINFO register. FCoE reporting is not valid anymore in this device. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 3: • *HMC_ERROR_DATA*[27:0] reports the LAN Queue index or FCoE VF index associated with the error. • *HMC_ERROR_DATA*[29:28] should be zero. • This option is not valid anymore in this device. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 4 or 12: • *HMC_ERROR_DATA*[27:0] reports the object index associated with the error. • *HMC_ERROR_DATA*[29:28] should be zero. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 5 through 9: • *HMC_ERROR_DATA*[29:9] reports the HMC function relative *SD_Index* and *PD_Index* associated with the error detected by the HMC. • *HMC_ERROR_DATA*[29:18] is set to HMC function relative *SD_Index* for the affected HMC function. • *HMC_ERROR_DATA*[17:9] is set to the *PD_Index*. • HMC_ERROR_DATA[8:0] are reserved for error types 5 through 9. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 0 through 2, or 10 through 1: • *HMC_ERROR_DATA*[29:0] is not valid, and should be zero.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.20.8 Private Memory Segment Table Partitioning Registers - GLHMC_SDPART_FPMAT[n] (0x00100800 + 0x4*n, n=0...7; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDBASE	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Base** Base segment table index for the function n.
RESERVED	15:12	0x0	RSV	N/A	Reserved.
PMSDSIZE	28:16	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Size** Number of valid segment table entries for the function n.
RESERVED	31:29	000b	RSV	N/A	Reserved.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.9 Private Memory Segment Table Partitioning Registers - GLHMC_PFPESDPART_FPMAT[n] (0x00100880 + 0x4*n, n=0...7; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field definitions are the same as those defined in Section 13.2.2.20.41.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.10 Private Memory PE Hash Table Entry Object Size - GLHMC_PEHTEOBJSZ_FPMAT (0x0010202C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHTEOBJSZ	3:0	0x6	RO	N/A	**Protocol Engine Hash Table Entry Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Hash Table Entry objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.11 Private Memory Protocol Engine Hash Entry Max - GLHMC_PEHTMAX_FPMAT (0x00102030; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHTMAX	20:0	0x140000	RO	N/A	**Private Memory PE Hash Table Entry Max** Reports that maximum number of hash table entries supported by the Host Memory Cache.
RESERVED	31:21	0x0	RSV	N/A	Reserved.

Note: This register is different from GLHMC_PEHTMAX because the PE changed to account for multicast groups.

13.2.2.20.12 Private Memory Space Segment Descriptor Data Low - GLHMC_FWSDDATALOW_FPMAT (0x00102074; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.36.

13.2.2.20.13 Private Memory Space Segment Descriptor Data High - GLHMC_FWSDDATAHIGH_FPMAT (0x00102078; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.37.

13.2.2.20.14 Private Memory Space Page Descriptor Invalidate - GLHMC_FWPDINV_FPMAT (0x0010207C; RO)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software.

Field definitions are the same as those defined in Section 13.2.2.20.38.

13.2.2.20.15 FPM PE Hash Table Entry Base - GLHMC_PEHTEBASE_FPMAT[n] (0x00104600 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEHTEBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine Hash Table Entry Base** Reports the Function Private Memory space base address for the Protocol Engine Hash Table Entry objects in 512-byte increments. In other words, the value in this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.16 FPM PE Hash Table Object Count - GLHMC_PEHTCNT_FPMAT[n] (0x00104700 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEHTCNT	28:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine Hash Table Object Count** Used to set the Function Private Memory space size for the Protocol Engine Hash Table objects. The associated base register is updated after the Commit FPM Values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.
RESERVED	31:29	000b	RSV	N/A	Reserved.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.17 Private Memory Space VF Segment Descriptor Data Low - GLHMC_VFSDDATALOW_FPMAT[n] (0x00108100 + 0x4*n, n=0...31; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.36.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.18 Private Memory Space VF Segment Descriptor Data High - GLHMC_VFSDDATAHIGH_FPMAT[n] (0x00108200 + 0x4*n, n=0...31; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.37.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.19 Private Memory Space Page Descriptor Invalidate - GLHMC_VFPDINV_FPMAT[n] (0x00108300 + 0x4*n, n=0...31; RO)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software.

Field definitions are the same as those defined in Section 13.2.2.20.38.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.20 Private Memory Segment Table Partitioning Registers - GLHMC_VFSDPART_FPMAT[n] (0x00108800 + 0x4*n, n=0...31; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field definitions are the same as those defined in Section 13.2.2.20.41.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.21 FPM PE Hash Table Entry Base - GLHMC_VFPEHTEBASE_FPMAT[n] (0x0010C600 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.83.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.22 FPM PE Hash Table Object Count - GLHMC_VFPEHTCNT_FPMAT[n] (0x0010C700 + 0x4*n, n=0...31; RW)

Field definitions are the same as those defined in Section 13.2.2.20.84.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.23 PDOC Cache Attributes - GLPDOC_CACHESIZE_FPMAT (0x00110088; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x40	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.24 Private Memory CQ Doorbell Partition Registers - GLHMC_VFDBCQPART[n] (0x00502E00 + 0x4*n, n=0...31; RO)

These registers are used to partition the shared doorbell array for Protocol Engine Completion Queues PCIe PFs.

Field definitions are the same as those defined in Section 13.2.2.20.26.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.25 Private Memory CEQ Partitioning Registers - GLHMC_VFCEQPART[n] (0x00502F00 + 0x4*n, n=0...31; RO)

This register is used to partition the shared pool of Protocol Engine Completion Event Queues for PCIe PFs.

Field definitions are the same as those defined in Section 13.2.2.20.27.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.26 Private Memory CQ Doorbell Partition Registers - GLHMC_DBCQPART[n] (0x00503180 + 0x4*n, n=0...7; RO)

These registers are used to partition the shared doorbell array for Protocol Engine Completion Queues PCIe PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMDBCQBASE	13:0	0x0	RW	UNDEFINED	**Private Memory Doorbell CQ Base** Base CQ doorbell array index for the Host Memory Cache PCI function n in multiples of 64 CQs.
RESERVED	15:14	00b	RSV	N/A	Reserved.
PMDBCQSIZE	30:16	0x0	RW	UNDEFINED	**Private Memory Doorbell CQ Size** Number of valid doorbell array elements for the Host Memory Cache PCI function n in increments of 64 CQs.
RESERVED	31	0b	RSV	N/A	Reserved.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.27 Private Memory CEQ Partitioning Registers - GLHMC_CEQPART[n] (0x005031C0 + 0x4*n, n=0...7; RO)

This register is used to partition the shared pool of Protocol Engine Completion Event Queues for PCIe PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMCEQBASE	9:0	0x0	RW	UNDEFINED	**Private Memory CEQ Base** Base CEQ index for the function n.
RESERVED	15:10	0x0	RSV	N/A	Reserved.
PMCEQSIZE	25:16	0x0	RW	UNDEFINED	**Private Memory CEQ Size** Number of valid CEQs index for the function n.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.28 Private Memory QP Doorbell Partition Registers - GLHMC_DBQPPART[n] (0x005044C0 + 0x4*n, n=0...7; RO)

These registers are used to partition the shared doorbell array for Protocol Engine Queue Pairs associated with PCIe PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMDBQPBASE	13:0	0x0	RW	UNDEFINED	**Private Memory Doorbell QP Base** Base QP doorbell array index for the Host Memory Cache PCI function n in multiples of 128 QPs.
RESERVED	15:14	00b	RSV	N/A	Reserved.
PMDBQPSIZE	30:16	0x0	RW	UNDEFINED	**Private Memory Doorbell QP Size** Number of valid doorbell array elements for the Host Memory Cache PCI function n in increments of 128 QPs.
RESERVED	31	0b	RSV	N/A	Reserved.

Note: This register must be read only in the PF CSR Space. This register is configured by CQP firmware instead of from NVRAM due to the Protocol Engine clock gating at chip initialization.

13.2.2.20.29 Private Memory VF QP Doorbell Partition Registers - GLHMC_VFDBQPPART[n] (0x00504520 + 0x4*n, n=0...31; RO)

These registers are used to partition the shared doorbell array for Protocol Engine Queue Pairs associated with PCIe PFs.

Field definitions are the same as those defined in Section 13.2.2.20.28.

Note: This register must be read only in the PF CSR Space. This register is configured by CQP firmware instead of from NVRAM due to the Protocol Engine clock gating at chip initialization.

13.2.2.20.30 PEOC0 Cache Attributes - GLPEOC0_CACHESIZE (0x005140A8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x200	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.31 PEOC1 Cache Attributes - GLPEOC1_CACHESIZE (0x005160A8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x200	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.32 PBLOC0 Cache Attributes - GLPBLOC0_CACHESIZE (0x00518074; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x100	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.33 PBLOC1 Cache Attributes - GLPBLOC1_CACHESIZE (0x0051A074; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x100	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.34 MDOC Cache Attributes - GLMDOC_CACHESIZE (0x0051C06C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x80	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x200	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.35 Private Memory Space Segment Descriptor Command - PFHMC_SDCMD (0x00520000; RW)

This register is used to access the Host Memory Cache's segment table. The HMC's segment table is partitioned per Private Memory Function (PMF), and this register is only allowed to access the Segment Table entries allocated to the PMF associated with this register via the SD Partition register, GLHMC_SDPART.

For read operations, PFHMC_SDCMD must be written with *PMSDWR* set to 0b and *PMSDIDX* set to the segment table index to be read. After the write to PFHMC_SDCMD completes, PFHMC_SDDATALOW and PFHMC_SDDATAHIGH can be read to retrieve the segment descriptor contents.

For write operations, PFHMC_SDDATALOW and PFHMC_SDDATAHIGH must be written before writing PFHMC_SDCMD with *PMSDWR* set to 1b and *PMSDIDX* set to the segment table index to be written.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDIDX	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Index** Relative Index of the HMC Segment Descriptor to be read or written. The actual absolute index to be used to access the Segment Table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. On write operations, if (*PMSDIDX* >= *PMSDSIZE*), the write is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD Partition register is selected for the absolute *SD_Index* calculation and for the check that *PMSDIDX* is within the range allowed by this function.
RESERVED	14:12	000b	RSV	N/A	Reserved.
PMSDPARTSEL	15	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Partitioning Select** 0b = (Default) The GLHMC_SDPART register is used for calculating the absolute SD Index to access within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD Index to access within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range.
RESERVED	30:16	0x0	RSV	N/A	Reserved.
PMSDWR	31	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Write/Read** 0b = Read operations. 1b = Write operations.

13.2.2.20.36 Private Memory Space Segment Descriptor Data Low - PFHMC_SDDATALOW (0x00520100; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDVALID	0	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Valid** Valid bit of an HMC segment descriptor table entry.
PMSDTYPE	1	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Type** 0b = The Segment Descriptor is paged (the SD points to a the physical address of a host memory page that contains an array of Page Descriptors. 1b = The Segment Descriptor directly points the physical address of a physically contiguous 2 MB memory region.
PMSDBPCOUNT	11:2	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Backing Page Count** Backing Page count of an HMC segment descriptor table entry. Every SD entry in a given Function Private memory space must be set to 512, except the last SD. The last SD can have a value from 1 to 512. This field is used to calculate the end of the FPM space associated with a Segment Descriptor without having to read the valid bit for each individual PD entry
PMSDDATALOW	31:12	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Data Low** Bits 31:12 bits of an HMC segment descriptor table entry.

13.2.2.20.37 Private Memory Space Segment Descriptor Data High - PFHMC_SDDATAHIGH (0x00520200; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDDATAHIGH	31:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Data High** Most significant 32 bits of a segment descriptor.

13.2.2.20.38 Private Memory Space Page Descriptor Invalidate - PFHMC_PDINV (0x00520300; RW)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDIDX	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Index** Relative Index of the HMC Segment Descriptor associated with the HMC Page Descriptor that is to be invalidated. For PFs, the actual index to be used to access the Segment Table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. If (*PMSDIDX* >= *PMSDSIZE*), the invalidate request is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD Partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function. For Protocol Engine enabled VFs, the actual index to be used to invalidate a Segment Table entry is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the GLHMC_VFSDPART register associated with this function. For VFs, if (*PMSDIDX* >= GLHMC_VFSDPART.*PMSDSIZE*), the invalidate request will be dropped. The *PMSDPARTSEL* bit is ignored in the GLHMC_VFPDINV registers. For the GLHMC_FWPDINV version of this register, this field is the absolute SD index, and the *PMSDPARTSEL* bit is ignored.
RESERVED	14:12	000b	RSV	N/A	Reserved.
PMSDPARTSEL	15	0b	RW	UNDEFINED	**Private Memory Segment Descriptor Partitioning Select** 0b = (Default) The GLHMC_SDPART register is used for calculating the absolute SD Index to invalidate within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD Index to invalidate within the Segment Table, and for checking whether or not *PMSDIDX* is within this function's allocated range. This field is ignored in the GLHMC_VFPDINV and GLHMC_FWPDINV versions of this register.
PMPDIDX	24:16	0x0	RW	UNDEFINED	**Private Memory Page Descriptor Index** Index of the Page Descriptor within the Page Descriptor Page indicated by *PMSDIDX*.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.20.39 Host Memory Cache Error Information Register - PFHMC_ERRORINFO (0x00520400; RW)

This register reports the errors detected by the Host Memory Cache. Errors reported through this register also can trigger interrupts through the *HMC_ERR* bit in the PFINT_ICR0 register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMF_INDEX	4:0	0x0	RW	UNDEFINED	**Private Memory Function Index** This field reports the HMC Private Memory Function associated with the error. Writes to this field are ignored.
RESERVED	6:5	00b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMF_ISVF	7	0b	RW	UNDEFINED	**Private Memory Function Is VF** 0b = The Private Memory Function reported in *PMF_INDEX* is associated with a PF. 1b = The Private Memory Function reported in *PMF_INDEX* is associated with a Protocol Engine enabled VF. Writes to this field are ignored.
HMC_ERROR_TYPE	11:8	0x0	RW	UNDEFINED	**HMC Error Type** This field reports the error type detected by the Host Memory Cache. The values are: 0 = Private Memory Function is not valid (the valid bit is clear in the GLHMC_VFPMFMAP register associated with the PMF) 1 = Invalid Private Memory Function index for a Protocol Engine enabled VF in GLHMC_VFPMFMAP. (i.e., The PMF Index programmed in the GLHMC_VFPMFMAP register is < 8 or > 39. This is a firmware error.) 2 = Invalid PF for a Protocol Engine enabled VF in GLHMC_VFPMFTABLE. (i.e., the parent PF index programmed in the GLHMC_VFPMFMAP register did not match the PF index received in the HMC transaction. This is a firmware error. 3= Reserved. In predecessor devices it was used to be an indication for Invalid LAN Queue Index or FCoE VF Index. (i.e., The absolute LAN Queue Index or FCoE VF Index received in the HMC transaction was less than the LAN Queue Index Base register or FCoE VF Index Base register associated with the PF Index received in the HMC transaction.) 4 = Index to big error: Indication that Object Index from transaction was larger than the value specified in the object's GLHMC_*CNT register. 5 = Private Memory Address Extends beyond the limits of the Segment Descriptors assigned to the PCIe function. 6 = Segment Descriptor Invalid. 7 = Segment Descriptor Too Small (only applies to Direct Mapped SDs). 8 = Page Descriptor Invalid. 9 = Received Unsupported Request (UR) Completion from PCIe read of object. 10 = Reserved. In predecessor devices this was used to be an indication that the valid bit in PFLAN_QALLOC_PMAT[PF] or PF_VT_PFALLOC_PMAT[PF] register was not set. 11 = An invalid object type was detected. 12 = Reserved. In predecessor devices it was used to be an indication for Object Index for an FCoE DDP Context object was larger than the size specified in the *PFFCDSIZE* or *VFFCDSIZE* field of the corresponding PFQF_CTL_0_PMAT register, or the object index for an FCoE Filter object was larger than the sum of the sizes specified in the *PFFCHSIZE* and *PFFCDSIZE* fields or *VFFCHSIZE* and *VFFCDSIZE* fields of the corresponding PFQF_CTL_0_PMAT register. All other values are reserved. The PFHMC_ERRORDATA register can be read to determine the LAN Queue index or FCoE VF index associated with error type 3. The PFHMC_ERRORDATA register can be read to determine the HMC object index associated with error types 4 and 12. The PFHMC_ERRORDATA register can be read to determine the HMC function relative *SD_Index* and *PD_Index* associated with error types 5 through 9.
RESERVED	15:12	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HMC_OBJECT_TYPE	20:16	0x0	RW	UNDEFINED	**HMC Object Type** Specifies the object type associated with the error. The encodings for the object type are as follows: 0x00 = QP_CNTXT 0x01 = ARP_TBL_ENTRY 0x02 = TXFIFO 0x03 = IRRQ 0x04 = MRTE 0x05 = PBLE 0x06 = CQ_CNTXT 0x07 = SRQ_CNTXT 0x08 = APBVT_INUSE 0x09 = FSI_ADR_VCTR 0x0A = FSI_MCAST_GRP 0x0B = XF_FL 0x0C = Q1_FL 0x0D = TIMER 0x10 = LAN_TXQ_CNTXT 0x11 = LAN_RXQ_CNTXT 0x12 = FCOE_CNTXT 0x13 = FCOE_DDP_HTE 0x16 = QUAD_HTE 0x19 = PD All other values are reserved.
RESERVED	30:21	0x0	RSV	N/A	Reserved.
ERROR_DETECTED	31	0b	RW	UNDEFINED	**Error Detected** This field is set to 1b when a new error has been detected by the HMC. No subsequent errors will be recorded until this field is written with a value of 0b. Writes of a 0 to this register clears the error and allow a subsequent error to be reported. Writes of 1 to this field are ignored.

13.2.2.20.40 Host Memory Cache Error Data Register - PFHMC_ERRORDATA (0x00520500; RO)

This register reports the HMC function relative SD_Index and PD_Index or HMC object index related to an error detected by the Host Memory Cache.

Field	Bit(s)	Init.	Type	CFG Policy	Description
HMC_ERROR_DATA	29:0	0x0	RO	N/A	**HMC Error Data** This field reports either the HMC function relative *SD_Index*, *PD_Index*, LAN Queue index, FCoE VF index, or HMC object index associated with the error reported in the PFHMC_ERRORINFO register. FCoE reporting is not valid anymore in this device. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 3: • *HMC_ERROR_DATA*[27:0] reports the LAN Queue index or FCoE VF index associated with the error. • *HMC_ERROR_DATA*[29:28] should be zero. • This option is not valid anymore in this device. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 4 or 12: • *HMC_ERROR_DATA*[27:0] reports the object index associated with the error. • *HMC_ERROR_DATA*[29:28] should be zero. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 5 through 9: • *HMC_ERROR_DATA*[29:9] reports the HMC function relative *SD_Index* and *PD_Index* associated with the error detected by the HMC. • *HMC_ERROR_DATA*[29:18] is set to HMC function relative *SD_Index* for the affected HMC function. • *HMC_ERROR_DATA*[17:9] is set to the *PD_Index*. • HMC_ERROR_DATA[8:0] are reserved for error types 5 through 9. When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 0 through 2, or 10 through 1: • *HMC_ERROR_DATA*[29:0] is not valid, and should be zero.
RESERVED	31:30	0x0	RSV	N/A	Reserved.

13.2.2.20.41 Private Memory Segment Table Partitioning Registers - GLHMC_SDPART[n] (0x00520800 + 0x4*n, n=0...7; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMSDBASE	11:0	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Base** Base segment table index for the function n.
RESERVED	15:12	0x0	RSV	N/A	Reserved.
PMSDSIZE	28:16	0x0	RW	UNDEFINED	**Private Memory Segment Descriptor Size** Number of valid segment table entries for the function n.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.42 Private Memory Segment Table Partitioning Registers - GLHMC_PFPESDPART[n] (0x00520880 + 0x4*n, n=0...7; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field definitions are the same as those defined in Section 13.2.2.20.41.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.43 Private Memory Protocol Engine Header Max - GLHMC_PEHDROBJSZ (0x00522004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHDROBJSZ	3:0	0x6	RO	N/A	**Private Memory Protocol Engine Header Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Header objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.44 FPM PE Header Object Count - GLHMC_PEHDRMAX (0x00522008; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHDRMAX	18:0	0x40000	RO	N/A	**Private Memory Protocol Engine Header Max** Reports the maximum number of Protocol Engine Metadata objects supported by the Host Memory Cache.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.20.45 Private Memory PE Metadata Object Size - GLHMC_PEMDOBJSZ (0x0052200C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEMDOBJSZ	3:0	0x4	RO	N/A	**Private Memory Protocol Engine Metadata Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Metadata objects. 0x4 = 16 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.46 Private Memory Protocol Engine Metadata Max - GLHMC_PEMDMAX (0x00522010; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEMDMAX	23:0	0x800000	RO	N/A	**Private Memory Protocol Engine Metadata Max** Reports the maximum number of Protocol Engine Metadata objects supported by the Host Memory Cache.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.20.47 Private Memory PE Out of Order Send Completion Object Size - GLHMC_PEOOISCOBJSZ (0x00522014; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEOOISCOBJSZ	3:0	0x5	RO	N/A	**Private Memory Protocol Engine Out-of-Order Send Completion Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Out-of-Order Send Completion objects. 0x5 = 32 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.48 Private Memory Protocol Engine Out of Order Send Completion Max - GLHMC_PEOOISCMAX (0x00522018; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEOOISCMAX	18:0	0x40000	RO	N/A	**Private Memory Protocol Engine Out-of-Order Send Completion Max** Reports the maximum number of Protocol Engine Out-of-Order Send Completions supported by the Host Memory Cache.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.20.49 Private Memory PE QP Object Size - GLHMC_PEQPOBJSZ (0x0052201C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEQPOBJSZ	3:0	0x9	RO	N/A	**Private Memory Protocol Engine QP Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Queue Pair objects. 0x9 = 512 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.50 Private Memory PE CQ Object Size - GLHMC_PECQOBJSZ (0x00522020; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPECQOBJSZ	3:0	0x6	RO	N/A	**Private Memory Protocol Engine CQ Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Completion Queue objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.51 Private Memory PE Hash Table Entry Object Size - GLHMC_PEHTEOBJSZ (0x0052202C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHTEOBJSZ	3:0	0x6	RO	N/A	**Private Memory Protocol Engine Hash Table Entry Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Hash Table Entry objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.52 Private Memory Protocol Engine Hash Entry Max - GLHMC_PEHTMAX (0x00522030; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEHTMAX	20:0	0x14A000	RO	N/A	**Private Memory Protocol Engine Hash Table Max** Reports that maximum number of Hash Table entries supported by the Host Memory Cache.
RESERVED	31:21	0x0	RSV	N/A	Reserved.

13.2.2.20.53 Private Memory PE ARP Table Entry Object Size - GLHMC_PEARPOBJSZ (0x00522034; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEARPOBJSZ	2:0	0x4	RO	N/A	**Private Memory Protocol Engine ARP Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache ARP Table Entry objects. 0x4 = 16 bytes
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.20.54 Private Memory Protocol Engine ARP Table Entry Max - GLHMC_PEARPMAX (0x00522038; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEARPMAX	16:0	0x10000	RO	N/A	**Private Memory Protocol Engine ARP Max** Reports that maximum number of ARP Table entries supported by the Host Memory Cache.
RESERVED	31:17	0x0	RSV	N/A	Reserved.

13.2.2.20.55 Private Memory PE Memory Region Table Entry Object Size - GLHMC_PEMROBJSZ (0x0052203C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEMROBJSZ	3:0	0x5	RO	N/A	**Private Memory Protocol Engine Memory Region Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Memory Region Table Entry objects. 0x5 = 32 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.56 Private Memory Protocol Engine Memory Registration Max - GLHMC_PEMRMAX (0x00522040; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEMRMAX	22:0	0x400000	RO	N/A	**Private Memory Protocol Engine Memory Region Max** Reports that maximum number of Memory Registration Table entries supported by the Host Memory Cache.
RESERVED	31:23	0x0	RSV	N/A	Reserved.

13.2.2.20.57 Private Memory PE Xmit FIFO Object Size - GLHMC_PEXFOBJSZ (0x00522044; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEXFOBJSZ	3:0	0x5	RO	N/A	**Private Memory Protocol Engine Transmit FIFO Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Xmit FIFO objects. 0x5 = 32 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.58 Private Memory Protocol Engine Transmit FIFO Entry Max - GLHMC_PEXFMAX (0x00522048; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEXFMAX	27:0	0x8000000	RO	N/A	**Private Memory Protocol Engine Transmit FIFO Max** Reports that maximum number of Transmit FIFO entries supported by the Host Memory Cache.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.20.59 Private Memory Protocol Engine Transmit FIFO Free List Max - GLHMC_PEXFFLMAX (0x0052204C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEXFFLMAX	27:0	0x2000000	RO	N/A	**Private Memory Protocol Engine Transmit FIFO Free List Max** Reports that maximum number of Transmit FIFO Free List entries supported by the Host Memory Cache.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.20.60 Private Memory PE IRRQ Object Size - GLHMC_PEQ1OBJSZ (0x00522050; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEQ1OBJSZ	3:0	0x6	RO	N/A	**Private Memory Protocol Engine Q1 Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Inbound RDMA Read (Q1) objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.61 Private Memory Protocol Engine Q1 Max - GLHMC_PEQ1MAX (0x00522054; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEQ1MAX	27:0	0x8000000	RO	N/A	**Private Memory Protocol Engine Q1 Max** Reports that maximum number of Inbound RDMA Read Queue (Q1) entries supported by the Host Memory Cache.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.20.62 Private Memory Protocol Engine Q1 Free List Max - GLHMC_PEQ1FLMAX (0x00522058; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEQ1FLMAX	25:0	0x2000000	RO	N/A	**Private Memory Protocol Engine Q1 Free List Max** Reports that maximum number of Inbound RDMA Read Queue (Q1) Free List entries supported by the Host Memory Cache.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.20.63 Private Memory FSI Multicast Group Object Size - GLHMC_FSIMCOBJSZ (0x0052205C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMFSIMCOBJSZ	3:0	0x6	RO	N/A	**Private Memory FSI Multicast Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache FSI Multicast Group objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.64 Private Memory FSI Multicast Group Max - GLHMC_FSIMCMAX (0x00522060; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMFSIMCMAX	13:0	0x2000	RO	N/A	**Private Memory FSI Multicast Max** Reports that maximum number of FSI Multicast Group entries supported by the Host Memory Cache.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.20.65 Private Memory FSI Address Vector Object Size - GLHMC_FSIAVOBJSZ (0x00522064; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMFSIAVOBJSZ	3:0	0x6	RO	N/A	**Private Memory FSI Address Vector Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache FSI Address Vector objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.66 Private Memory FSI Address Vector Max - GLHMC_FSIAVMAX (0x00522068; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMFSIAVMAX	17:0	0x20000	RO	N/A	**Private Memory FSI Address Vector Max** Reports that maximum number of FSI Address Vectors supported by the Host Memory Cache.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.20.67 Private Memory Protocol Engine Physical Buffer List Max - GLHMC_PEPBLMAX (0x0052206C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEPBLMAX	28:0	0x10000000	RO	N/A	**Private Memory Protocol Engine Physical Buffer List Max** Reports that maximum number of Physical Buffer List entries supported by the Host Memory Cache.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

13.2.2.20.68 Private Memory Space Segment Descriptor Data Low - GLHMC_FWSDDATALOW (0x00522074; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.36.

13.2.2.20.69 Private Memory Space Segment Descriptor Data High - GLHMC_FWSDDATAHIGH (0x00522078; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.37.

13.2.2.20.70 Private Memory Space Page Descriptor Invalidate - GLHMC_FWPDINV (0x0052207C; RO)

This register is used to invalidate cached HMC Page Descriptors that have been set to the invalid state by software.

Field definitions are the same as those defined in Section 13.2.2.20.38.

13.2.2.20.71 Private Memory PE Timer Object Size - GLHMC_PETIMEROBJSZ (0x00522080; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPETIMEROBJSZ	3:0	0x6	RO	N/A	**Private Memory Protocol Engine Timer Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Protocol Engine Timer objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.72 Private Memory PE Timer Object Max - GLHMC_PETIMERMAX (0x00522084; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPETIMERMAX	28:0	0x10000000	RO	N/A	**Private Memory Protocol Engine Timer Max** Reports that maximum number of PE Timer objects supported by the Host Memory Cache.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

13.2.2.20.73 Private Memory Protocol Engine Read Response Entry Object Size - GLHMC_PERRFOBJSZ (0x00522098; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPERRFOBJSZ	3:0	0x5	RO	N/A	**Private Memory Protocol Engine Read Response FIFO Object Size** Used to calculate the amount of memory that is required to be allocated for Host Memory Cache Read Response FIFO objects. 0x5 = 32 bytes
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.20.74 Private Memory Protocol Engine Read Response FIFO Entry Max - GLHMC_PERRFMAX (0x0052209C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPERRFMAX	27:0	0x8000000	RO	N/A	**Private Memory Protocol Engine Read Response FIFO Max** Reports that maximum number of Read Response FIFO entries supported by the Host Memory Cache.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.20.75 Private Memory Protocol Engine Read Response FIFO Free List Max - GLHMC_PERRFFLMAX (0x005220A0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPERRFFLMAX	25:0	0x2000000	RO	N/A	**Private Memory Protocol Engine Read Response FIFO Free List Max** Reports that maximum number of Read Response FIFO Free List entries supported by the Host Memory Cache.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.20.76 Private Memory Protocol Engine Out of Order Send Completion (OOISC) FIFO Free List Max - GLHMC_PEOOISCFFLMAX (0x005220A4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PMPEOOISCFFLMAX	18:0	0x40000	RO	N/A	**Private Memory Protocol Engine Out-of-Order Send Completion FIFO Free List Max**
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.20.77 Private Memory Protocol Engine Queue Pair Max - GLHMC_DBQPMAX (0x005220EC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLHMC_DBQPMAX	18:0	0x40000	RO	N/A	**Doorbell QP Max** Reports the maximum number of Protocol Engine Queue Pairs supported by the Host Memory Cache and Doorbell array.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.20.78 Private Memory Protocol Engine Completion Queue Max - GLHMC_DBCQMAX (0x005220F0; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLHMC_DBCQMAX	19:0	0x080000	RO	N/A	**Doorbell CQ Max** Reports the maximum number of Protocol Engine Completion Queues supported by the Host Memory Cache and Doorbell array.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.20.79 FPM PE QP Base - GLHMC_PEQPBASE[n] (0x00524000 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEQPBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine QP Base** Reports the Function Private Memory space base address for the Protocol Engine Queue Pair objects in 512-byte increments. In other words, the value is this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.80 FPM PE QP Object Count - GLHMC_PEQPCNT[n] (0x00524100 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEQPCNT	28:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine QP Count** Used to set the Function Private Memory space size for the Protocol Engine Queue Pair objects. The associated base register is updated after Commit FPM Values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.81 FPM PE CQ Base - GLHMC_PECQBASE[n] (0x00524200 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPECQBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine CQ Base** Reports the Function Private Memory space base address for the Protocol Engine Completion Queue objects in 512-byte increments. In other words, the value is this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.82 FPM PE CQ Object Count - GLHMC_PECQCNT[n] (0x00524300 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPECQCNT	28:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine CQ Count** Used to set the Function Private Memory space size for the Protocol Engine Completion Queue objects. The associated base register is updated after the Commit FPM Values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.83 FPM PE Hash Table Entry Base - GLHMC_PEHTEBASE[n] (0x00524600 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEHTEBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine Hash Table Entry Base** Reports the Function Private Memory space base address for the Protocol Engine Hash Table Entry objects in 512-byte increments. In other words, the value is this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.84 FPM PE Hash Table Object Count - GLHMC_PEHTCNT[n] (0x00524700 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEHTCNT	28:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine Hash Table Count** Used to set the Function Private Memory space size for the Protocol Engine Hash Table objects. The associated base register is updated after the Commit FPM Values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.85 FPM PE ARP Table Base - GLHMC_PEARPBASE[n] (0x00524800 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEARPBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine ARP Base** Reports the Function Private Memory space base address for the Protocol Engine ARP Table objects in 512-byte increments. In other words, the value is this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.86 FPM PE ARP Table Object Count - GLHMC_PEARPCNT[n] (0x00524900 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEARPCNT	28:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine ARP Count** Used to set the Function Private Memory space size for the Protocol Engine ARP table objects. The associated base register is updated after the Commit FPM Values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.
RESERVED	31:29	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.87 FPM PE APBVT In-Use Base - GLHMC_APBVTINUSEBASE[n] (0x00524A00 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMAPBINUSEBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory APBVT In-Use Base** Reports the base Function Private Memory Space Address of the Accelerated Port Bit In-Use object in 512-byte increments. There is a single APBVT In-Use object for each PCI function and it is a fixed 8 KB in size. Since there is only a single object and it is a fixed size, there is not a corresponding Object Size or region size register. This register is updated by hardware when the Commit FPM Values CQP operation is performed.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.88 FPM PE MRT Base - GLHMC_PEMRBASE[n] (0x00524C00 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FPMPEMRBASE	23:0	0x0	RW	UNDEFINED	**Function Private Memory Protocol Engine Memory Region Base** Reports the Function Private Memory space base address for the Protocol Engine Memory Region Table objects in 512-byte increments. In other words, the value is this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when the Commit FPM Values CQP operation is performed. Other than for debug purposes, this register should be treated as Read Only.

13.2.2.20.116 Private Memory Space VF Segment Descriptor Data Low - GLHMC_VFSDDATALOW[n] (0x00528100 + 0x4*n, n=0...31; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.36.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion

13.2.2.20.117 Private Memory Space VF Segment Descriptor Data High - GLHMC_VFSDDATAHIGH[n] (0x00528200 + 0x4*n, n=0...31; RO)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the Host Memory Cache's segment table.

Field definitions are the same as those defined in Section 13.2.2.20.37.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion

13.2.2.20.118 Private Memory Space Page Descriptor Invalidate - GLHMC_VFPDINV[n] (0x00528300 + 0x4*n, n=0...31; RO)

This register is used to invalidate cached HMC Page Descriptors that have been set to the invalid state by software.

Field definitions are the same as those defined in Section 13.2.2.20.38.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion

13.2.2.20.119 Private Memory Segment Table Partitioning Registers - GLHMC_VFSDPART[n] (0x00528800 + 0x4*n, n=0...31; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field definitions are the same as those defined in Section 13.2.2.20.41.

Note: This register must be read only in the PF CSR Space.

13.2.2.20.120 FPM PE QP Base - GLHMC_VFPEQPBASE[n] (0x0052C000 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.79.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.121 FPM PE QP Object Count - GLHMC_VFPEQPCNT[n] (0x0052C100 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.80.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.122 FPM PE CQ Base - GLHMC_VFPECQBASE[n] (0x0052C200 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.81.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.123 FPM PE CQ Object Count - GLHMC_VFPECQCNT[n] (0x0052C300 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.82.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.124 FPM PE Hash Table Entry Base - GLHMC_VFPEHTEBASE[n] (0x0052C600 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.83.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.125 FPM PE Hash Table Object Count - GLHMC_VFPEHTCNT[n] (0x0052C700 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.84.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.126 FPM PE ARP Table Base - GLHMC_VFPEARPBASE[n] (0x0052C800 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.85.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.127 FPM PE ARP Table Object Count - GLHMC_VFPEARPCNT[n] (0x0052C900 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.86.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.128 FPM PE APBVT In-Use Base - GLHMC_VFAPBVTINUSEBASE[n] (0x0052CA00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.87.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.129 FPM PE MRT Base - GLHMC_VFPEMRBASE[n] (0x0052CC00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.88.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.130 FPM PE Memory Region Table Object Count - GLHMC_VFPEMRCNT[n] (0x0052CD00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.89.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.131 FPM PE Xmit FIFO Base - GLHMC_VFPEXFBASE[n] (0x0052CE00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.90.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.132 FPM PE Xmit FIFO Object Count - GLHMC_VFPEXFCNT[n] (0x0052CF00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.91.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.133 FPM PE Xmit FIFO Free List Base - GLHMC_VFPEXFFLBASE[n] (0x0052D000 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.92.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.134 FPM PE IRRQ Base - GLHMC_VFPEQ1BASE[n] (0x0052D200 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.93.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.135 FPM PE IRRQ Object Count - GLHMC_VFPEQ1CNT[n] (0x0052D300 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.94.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.136 FPM PE IRRQ Free List Base - GLHMC_VFPEQ1FLBASE[n] (0x0052D400 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.95.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.137 FPM FSI Address Vector Base - GLHMC_VFFSIAVBASE[n] (0x0052D600 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.96.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.138 FPM FSI Address Vector Object Count - GLHMC_VFFSIAVCNT[n] (0x0052D700 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.97.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.139 FPM PE Physical Buffer List Base - GLHMC_VFPEPBLBASE[n] (0x0052D800 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.98.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.140 FPM PE PBL Object Count - GLHMC_VFPEPBLCNT[n] (0x0052D900 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.99.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.141 FPM PE Timer Base - GLHMC_VFPETIMERBASE[n] (0x0052DA00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.100.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.142 FPM PE Timer Object Count - GLHMC_VFPETIMERCNT[n] (0x0052DB00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.101.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.143 FPM FSI Multicast Group Base - GLHMC_VFFSIMCBASE[n] (0x0052E000 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.102.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.144 FPM FSI Multicast Group Object Count - GLHMC_VFFSIMCCNT[n] (0x0052E100 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.103.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.145 FPM PE Header Base - GLHMC_VFPEHDRBASE[n] (0x0052E200 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.104.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.146 FPM PE Header Object Count - GLHMC_VFPEHDRCNT[n] (0x0052E300 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.105.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.147 FPM PE Metadata Base - GLHMC_VFPEMDBASE[n] (0x0052E400 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.106.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.148 FPM PE Metadata Object Count - GLHMC_VFPEMDCNT[n] (0x0052E500 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.107.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.149 FPM PE Out of Order Send Completion Base - GLHMC_VFPEOOISCBASE[n] (0x0052E600 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.108.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.150 FPM PE Out of Order Send Completion Object Count - GLHMC_VFPEOOISCCNT[n] (0x0052E700 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.109.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.151 FPM PE Read Response Base - GLHMC_VFPERRFBASE[n] (0x0052E800 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.110.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.152 FPM PE Read Response Object Count - GLHMC_VFPERRFCNT[n] (0x0052E900 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.111.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.153 FPM PE Read Response FIFO Free List Base - GLHMC_VFPERRFFLBASE[n] (0x0052EA00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.112.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.154 FPM PE Out of Order Send Completion (OOISC) FIFO Free List Base - GLHMC_VFPEOOISCFFLBASE[n] (0x0052EC00 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.20.114.

Note: Eight instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.20.155 PDOC Cache Attributes - GLPDOC_CACHESIZE (0x00530048; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	7:0	0x40	RO	N/A	**Word Size** The cache line size in bytes.
SETS	19:8	0x40	RO	N/A	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.21 PF - Context Manager Registers

13.2.2.21.1 CMPE Cache Attributes - GLCM_PE_CACHESIZE (0x005046B4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
WORD_SIZE	11:0	0x200	RO	N/A	**Word Size** The cache line size in bytes.
SETS	15:12	0x1	RO	N/A	**Sets** The number of cache sets.
WAYS	24:16	0x100	RO	N/A	**Ways** The number of cache ways.
RESERVED	31:25	0x0	RSV	N/A	Reserved.

13.2.2.22 PF - Control Queues Registers

Registers related to the various types of control queues: firmware Admin Queues, sideband queues, and mailbox queues.

13.2.2.22.1 PF Firmware Admin Transmit Queue Base Address Low - PF_FW_ATQBAL (0x00080000; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQBAL_LSB	5:0	0x0	RO	N/A	**Admin Transmit Queue Base Address Low LSB** Tied to zero to achieve alignment.
ATQBAL	31:6	0x0	RW	UNDEFINED	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned (together with ATQBAL_LSB).

13.2.2.22.2 Global Tools Firmware Admin Transmit Queue Base Address Low - GL_FW_TOOL_ATQBAL (0x00080040; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.1.

13.2.2.22.3 PF0 PSM Firmware Admin Transmit Queue Base Address Low - PF0_FW_PSM_ATQBAL (0x00080044; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.1.

13.2.2.22.4 PF0 HLP Firmware Admin Transmit Queue Base Address Low - PF0_FW_HLP_ATQBAL (0x00080048; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.1.

13.2.2.22.5 PF Firmware Admin Receive Queue Base Address Low - PF_FW_ARQBAL (0x00080080; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQBAL_LSB	5:0	0x0	RO	N/A	**Admin Receive Queue Base Address Low LSB** Tied to zero to achieve alignment.
ARQBAL	31:6	0x0	RW	UNDEFINED	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned (together with ARQBAL_LSB).

13.2.2.22.6 Global Tools Firmware Admin Receive Queue Base Address Low - GL_FW_TOOL_ARQBAL (0x000800C0; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.5.

13.2.2.22.7 PF0 PSM Firmware Admin Receive Queue Base Address Low - PF0_FW_PSM_ARQBAL (0x000800C4; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.5.

13.2.2.22.8 PF0 HLP Firmware Admin Receive Queue Base Address Low - PF0_FW_HLP_ARQBAL (0x000800C8; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.5.

13.2.2.22.9 PF Firmware Admin Transmit Queue Base Address High - PF_FW_ATQBAH (0x00080100; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQBAH	31:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Base Address High** Transmit descriptor base address high.

13.2.2.22.10 Global Tools Firmware Admin Transmit Queue Base Address High - GL_FW_TOOL_ATQBAH (0x00080140; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.9.

13.2.2.22.11 PF0 PSM Firmware Admin Transmit Queue Base Address High - PF0_FW_PSM_ATQBAH (0x00080144; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.9.

13.2.2.22.12 PF0 HLP Firmware Admin Transmit Queue Base Address High - PF0_FW_HLP_ATQBAH (0x00080148; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.9.

13.2.2.22.13 PF Firmware Admin Receive Queue Base Address High - PF_FW_ARQBAH (0x00080180; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQBAH	31:0	0x0	RW	UNDEFINED	**Admin Receive Queue Base Address High** Receive descriptor base address high.

13.2.2.22.14 Global Tools Firmware Admin Receive Queue Base Address High - GL_FW_TOOL_ARQBAH (0x000801C0; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.13.

13.2.2.22.15 PF0 PSM Firmware Admin Receive Queue Base Address High - PF0_FW_PSM_ARQBAH (0x000801C4; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.13.

13.2.2.22.16 PF0 HLP Firmware Admin Receive Queue Base Address High - PF0_FW_HLP_ARQBAH (0x000801C8; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.13.

13.2.2.22.17 PF Firmware Admin Transmit Queue Length - PF_FW_ATQLEN (0x00080200; RW)

This register sets the size of the ring. Maximum size is 1024.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQLEN	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	N/A	Reserved.
ATQVFE	28	0b	RW	UNDEFINED	**Admin Transmit Queue VF Error** VF error. This bit is set by firmware on a PF queue when one of its VFs had an Admin Queue error.
ATQOVFL	29	0b	RW	UNDEFINED	**Admin Transmit Queue Overflow** Overflow error. This bit is set by firmware when a message was lost because there was no room on the queue.
ATQCRIT	30	0b	RW	UNDEFINED	**Admin Transmit Queue Critical** Critical error. This bit is set by firmware when a critical error has been detected on this queue.
ATQENABLE	31	0b	RW	UNDEFINED	**Admin Transmit Queue Enable** Enable bit. This bit is set by driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is implemented by a FF and cleared by PFR.

13.2.2.22.18 Global Tools Firmware Admin Transmit Queue Length - GL_FW_TOOL_ATQLEN (0x00080240; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.17.

13.2.2.22.19 PF0 PSM Firmware Admin Transmit Queue Length - PF0_FW_PSM_ATQLEN (0x00080244; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.17.

13.2.2.22.20 PF0 HLP Firmware Admin Transmit Queue Length - PF0_FW_HLP_ATQLEN (0x00080248; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.17.

13.2.2.22.21 PF Firmware Admin Receive Queue Length - PF_FW_ARQLEN (0x00080280; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQLEN	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	N/A	Reserved.
ARQVFE	28	0b	RW	UNDEFINED	**Admin Receive Queue VF Error** VF error. This bit is set by firmware on a PF queue when one of its VFs had an Admin Queue error.
ARQOVFL	29	0b	RW	UNDEFINED	**Admin Receive Queue Overflow** Overflow error. This bit is set by firmware when a message was lost because there was no room on the queue.
ARQCRIT	30	0b	RW	UNDEFINED	**Admin Receive Queue Critical** Critical error. This bit is set by firmware when a critical error has been detected on this queue.
ARQENABLE	31	0b	RW	UNDEFINED	**Admin Receive Queue Enable** Enable bit. This bit is set by driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is implemented by a FF and cleared by PFR.

13.2.2.22.22 Global Tools Firmware Admin Receive Queue Length - GL_FW_TOOL_ARQLEN (0x000802C0; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.21.

13.2.2.22.23 PF0 PSM Firmware Admin Receive Queue Length - PF0_FW_PSM_ARQLEN (0x000802C4; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.21.

13.2.2.22.24 PF0 HLP Firmware Admin Receive Queue Length - PF0_FW_HLP_ARQLEN (0x000802C8; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.21.

13.2.2.22.25 PF Firmware Admin Transmit Head - PF_FW_ATQH (0x00080300; RW)

Admin transmit queue head pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQH	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, the software clears the head pointer. During nominal operation, the firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.26 Global Tools Firmware Admin Transmit Head - GL_FW_TOOL_ATQH (0x00080340; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.25.

13.2.2.22.27 PF0 PSM Firmware Admin Transmit Head - PF0_FW_PSM_ATQH (0x00080344; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.25.

13.2.2.22.28 PF0 HLP Firmware Admin Transmit Head - PF0_FW_HLP_ATQH (0x00080348; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.25.

13.2.2.22.29 PF Firmware Admin Receive Queue Head - PF_FW_ARQH (0x00080380; RW)

Admin receive queue head pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQH	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Head** Receive queue head pointer. At queue initialization, the software clears the head pointer. During nominal operation, the firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.30 Global Tools Firmware Admin Receive Queue Head - GL_FW_TOOL_ARQH (0x000803C0; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.29.

13.2.2.22.31 PF0 PSM Firmware Admin Receive Queue Head - PF0_FW_PSM_ARQH (0x000803C4; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.29.

13.2.2.22.32 PF0 HLP Firmware Admin Receive Queue Head - PF0_FW_HLP_ARQH (0x000803C8; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.29.

13.2.2.22.33 PF Firmware Admin Transmit Tail - PF_FW_ATQT (0x00080400; RW)

Admin transmit queue tail pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQT	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized. And clear to zero at queue initialization.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.34 Global Tools Firmware Admin Transmit Tail - GL_FW_TOOL_ATQT (0x00080440; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.33.

13.2.2.22.35 PF0 PSM Firmware Admin Transmit Tail - PF0_FW_PSM_ATQT (0x00080444; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.33.

13.2.2.22.36 PF0 HLP Firmware Admin Transmit Tail - PF0_FW_HLP_ATQT (0x00080448; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.33.

13.2.2.22.37 PF Firmware Admin Receive Queue Tail - PF_FW_ARQT (0x00080480; RW)

Admin receive queue tail pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQT	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured. And clear to zero at queue initialization.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.38 Global Tools Firmware Admin Receive Queue Tail - GL_FW_TOOL_ARQT (0x000804C0; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.37.

13.2.2.22.39 PF0 PSM Firmware Admin Receive Queue Tail - PF0_FW_PSM_ARQT (0x000804C4; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.37.

13.2.2.22.40 PF0 HLP Firmware Admin Receive Queue Tail - PF0_FW_HLP_ARQT (0x000804C8; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.37.

13.2.2.22.41 Tools Mailbox HOST Interface Buffer Area - GL_HIBA[n] (0x00081000 + 0x4*n, n=0...1023; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_HIBA	31:0	0x0	RW	UNDEFINED	**Host Interface Buffer Area**

13.2.2.22.42 Tools Mailbox HOST Interface Descriptor Area - GL_HIDA[n] (0x00082000 + 0x4*n, n=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_HIDA	31:0	0x0	RW	UNDEFINED	**Host Interface Descriptor Area**

13.2.2.22.43 Tools Mailbox HOST Interface Control Register - GL_HICR (0x00082040; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	0	0b	RSV	N/A	Reserved.
C	1	0b	RW	UNDEFINED	**Command** The tool sets this bit when it has finished putting a command block in the command buffer. This bit should be cleared by the firmware when the command's processing is completed. Setting this bit causes an interrupt to the firmware. This bit can be only set through the CSR (software) interface. and can be cleared through the AUX (firmware) interface. While this bit is set, the memory is RO to software.
SV	2	0b	RW	UNDEFINED	**Status Valid** Indicates that there is a valid status in the first descriptor that the device driver can read. If Flags.BUF is set in the first descriptor, the buffer is valid. 0b = Status not valid. 1b = Status valid.
EV	3	0b	RW	UNDEFINED	**Event Valid** Indicates that there is a valid status in the second descriptor that the device driver can read. If Flags.BUF is set in the second descriptor, the buffer is valid. 0b = Status not valid. 1b = Status valid.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.22.44 Tools Mailbox HOST Interface Enable Register - GL_HICR_EN (0x00082044; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
EN	0	0b	RO	UNDEFINED	**Enable** When set, indicates that the buffer is accessible for the device. ***Note:*** This bit is common to all nodes/functions.
RESERVED	31:1	0x0	RSV	UNDEFINED	Reserved.

13.2.2.22.45 VSI Mailbox Transmit Queue Base Address Low - VSI_MBX_ATQBAL[VSI] (0x00220000 + 0x4*VSI, VSI=0...767; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.46 VSI Mailbox Transmit Queue Base Address High - VSI_MBX_ATQBAH[VSI] (0x00221000 + 0x4*VSI, VSI=0...767; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.47 VSI Mailbox Transmit Queue Length - VSI_MBX_ATQLEN[VSI] (0x00222000 + 0x4*VSI, VSI=0...767; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.48 VSI Mailbox Transmit Head - VSI_MBX_ATQH[VSI] (0x00223000 + 0x4*VSI, VSI=0...767; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.49 VSI Mailbox Transmit Tail - VSI_MBX_ATQT[VSI] (0x00224000 + 0x4*VSI, VSI=0...767; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.50 VSI Mailbox Receive Queue Base Address Low - VSI_MBX_ARQBAL[VSI] (0x00225000 + 0x4*VSI, VSI=0...767; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.51 VSI Mailbox Receive Queue Base Address High - VSI_MBX_ARQBAH[VSI] (0x00226000 + 0x4*VSI, VSI=0...767; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.52 VSI Mailbox Receive Queue Length - VSI_MBX_ARQLEN[VSI] (0x00227000 + 0x4*VSI, VSI=0...767; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.53 VSI Mailbox Receive Head - VSI_MBX_ARQH[VSI] (0x00228000 + 0x4*VSI, VSI=0...767; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.54 VSI Mailbox Receive Tail - VSI_MBX_ARQT[VSI] (0x00229000 + 0x4*VSI, VSI=0...767; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.55 VF Mailbox Transmit Queue Base Address Low - VF_MBX_ATQBAL[VF] (0x0022A000 + 0x4*VF, VF=0...255; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQBAL_LSB	5:0	0x0	RSV	N/A	**Admin Transmit Queue Base Address Low LSB** Tied to zero to achieve alignment.
ATQBAL	31:6	0x0	RW	UNDEFINED	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned (together with ATQBAL_LSB).

13.2.2.22.56 VF Mailbox Transmit Queue Base Address High - VF_MBX_ATQBAH[VF] (0x0022A400 + 0x4*VF, VF=0...255; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQBAH	31:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Base Address High** Transmit descriptor base address high.

13.2.2.22.57 VF Mailbox Transmit Queue Length - VF_MBX_ATQLEN[VF] (0x0022A800 + 0x4*VF, VF=0...255; RW)

This register sets the size of the ring. Maximum size is 1024.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQLEN	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	N/A	Reserved.
ATQVFE	28	0b	RW	UNDEFINED	**Admin Transmit Queue VF Error** VF error. This bit is set by firmware on a PF queue when one of its VFs had an Admin Queue error.
ATQOVFL	29	0b	RW	UNDEFINED	**Admin Transmit Queue Overflow** Overflow error. This bit is set by firmware when a message was lost because there was no room on the queue.
ATQCRIT	30	0b	RW	UNDEFINED	**Admin Transmit Queue Critical** Critical error. This bit is set by firmware when a critical error has been detected on this queue.
ATQENABLE	31	0b	RW	UNDEFINED	**Admin Transmit Queue Enable** Enable bit. This bit is set by driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is implemented by a FF and cleared by PFR.

13.2.2.22.58 VF Mailbox Transmit Head - VF_MBX_ATQH[VF] (0x0022AC00 + 0x4*VF, VF=0...255; RW)

Admin transmit queue head pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQH	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, the software clears the head pointer. During nominal operation, the firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.59 VF Mailbox Transmit Tail - VF_MBX_ATQT[VF] (0x0022B000 + 0x4*VF, VF=0...255; RW)

Admin transmit queue tail pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ATQT	9:0	0x0	RW	UNDEFINED	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized. And clear to zero at queue initialization.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.60 VF Mailbox Receive Queue Base Address Low - VF_MBX_ARQBAL[VF] (0x0022B400 + 0x4*VF, VF=0...255; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQBAL_LSB	5:0	0x0	RO	N/A	**Admin Receive Queue Base Address Low LSB** Tied to zero to achieve alignment.
ARQBAL	31:6	0x0	RW	UNDEFINED	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned (together with ARQBAL_LSB).

13.2.2.22.61 VF Mailbox Receive Queue Base Address High - VF_MBX_ARQBAH[VF] (0x0022B800 + 0x4*VF, VF=0...255; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQBAH	31:0	0x0	RW	UNDEFINED	**Admin Receive Queue Base Address High** Receive descriptor base address high.

13.2.2.22.62 VF Mailbox Receive Queue Length - VF_MBX_ARQLEN[VF] (0x0022BC00 + 0x4*VF, VF=0...255; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQLEN	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	N/A	Reserved.
ARQVFE	28	0b	RW	UNDEFINED	**Admin Receive Queue VF Error** VF error. This bit is set by firmware on a PF queue when one of its VFs had an Admin Queue error.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQOVFL	29	0b	RW	UNDEFINED	**Admin Receive Queue Overflow** Overflow error. This bit is set by firmware when a message was lost because there was no room on the queue.
ARQCRIT	30	0b	RW	UNDEFINED	**Admin Receive Queue Critical** Critical error. This bit is set by firmware when a critical error has been detected on this queue.
ARQENABLE	31	0b	RW	UNDEFINED	**Admin Receive Queue Enable** Enable bit. This bit is set by driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is implemented by a FF and cleared by PFR.

13.2.2.22.63 VF Mailbox Receive Head - VF_MBX_ARQH[VF] (0x0022C000 + 0x4*VF, VF=0...255; RW)

Admin receive queue head pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQH	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Head** Receive queue head pointer. At queue initialization, the software clears the head pointer. During nominal operation, the firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.64 VF Mailbox Receive Tail - VF_MBX_ARQT[VF] (0x0022C400 + 0x4*VF, VF=0...255; RW)

Admin receive queue tail pointer.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ARQT	9:0	0x0	RW	UNDEFINED	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured. And clear to zero at queue initialization.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.22.65 VF CPM Mailbox Transmit Queue Base Address Low - VF_MBX_CPM_ATQBAL[VF128] (0x0022C800 + 0x4*VF128, VF128=0...127; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.66 VF CPM Mailbox Transmit Queue Base Address High - VF_MBX_CPM_ATQBAH[VF128] (0x0022CA00 + 0x4*VF128, VF128=0...127; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.67 VF CPM Mailbox Transmit Queue Length - VF_MBX_CPM_ATQLEN[VF128] (0x0022CC00 + 0x4*VF128, VF128=0...127; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.68 VF CPM Mailbox Transmit Head - VF_MBX_CPM_ATQH[VF128] (0x0022CE00 + 0x4*VF128, VF128=0...127; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.69 VF CPM Mailbox Transmit Tail - VF_MBX_CPM_ATQT[VF128] (0x0022D000 + 0x4*VF128, VF128=0...127; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.70 VF CPM Mailbox Receive Queue Base Address Low - VF_MBX_CPM_ARQBAL[VF128] (0x0022D200 + 0x4*VF128, VF128=0...127; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.71 VF CPM Mailbox Receive Queue Base Address High - VF_MBX_CPM_ARQBAH[VF128] (0x0022D400 + 0x4*VF128, VF128=0...127; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.72 VF CPM Mailbox Receive Queue Length - VF_MBX_CPM_ARQLEN[VF128] (0x0022D600 + 0x4*VF128, VF128=0...127; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.73 VF CPM Mailbox Receive Head - VF_MBX_CPM_ARQH[VF128] (0x0022D800 + 0x4*VF128, VF128=0...127; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.74 VF CPM Mailbox Receive Tail - VF_MBX_CPM_ARQT[VF128] (0x0022DA00 + 0x4*VF128, VF128=0...127; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.75 VF HLP Mailbox Transmit Queue Base Address Low - VF_MBX_HLP_ATQBAL[VF16] (0x0022DC00 + 0x4*VF16, VF16=0...15; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.76 VF HLP Mailbox Transmit Queue Base Address High - VF_MBX_HLP_ATQBAH[VF16] (0x0022DC40 + 0x4*VF16, VF16=0...15; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.77 VF HLP Mailbox Transmit Queue Length - VF_MBX_HLP_ATQLEN[VF16] (0x0022DC80 + 0x4*VF16, VF16=0...15; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.78 VF HLP Mailbox Transmit Head - VF_MBX_HLP_ATQH[VF16] (0x0022DCC0 + 0x4*VF16, VF16=0...15; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.79 VF HLP Mailbox Transmit Tail - VF_MBX_HLP_ATQT[VF16] (0x0022DD00 + 0x4*VF16, VF16=0...15; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.80 VF HLP Mailbox Receive Queue Base Address Low - VF_MBX_HLP_ARQBAL[VF16] (0x0022DD40 + 0x4*VF16, VF16=0...15; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.81 VF HLP Mailbox Receive Queue Base Address High - VF_MBX_HLP_ARQBAH[VF16] (0x0022DD80 + 0x4*VF16, VF16=0...15; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.82 VF HLP Mailbox Receive Queue Length - VF_MBX_HLP_ARQLEN[VF16] (0x0022DDC0 + 0x4*VF16, VF16=0...15; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.83 VF HLP Mailbox Receive Head - VF_MBX_HLP_ARQH[VF16] (0x0022DE00 + 0x4*VF16, VF16=0...15; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.84 VF HLP Mailbox Receive Tail - VF_MBX_HLP_ARQT[VF16] (0x0022DE40 + 0x4*VF16, VF16=0...15; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.85 VF PSM Mailbox Transmit Queue Base Address Low - VF_MBX_PSM_ATQBAL[VF16] (0x0022DE80 + 0x4*VF16, VF16=0...15; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.86 VF PSM Mailbox Transmit Queue Base Address High - VF_MBX_PSM_ATQBAH[VF16] (0x0022DEC0 + 0x4*VF16, VF16=0...15; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.87 VF PSM Mailbox Transmit Queue Length - VF_MBX_PSM_ATQLEN[VF16] (0x0022DF00 + 0x4*VF16, VF16=0...15; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.88 VF PSM Mailbox Transmit Head - VF_MBX_PSM_ATQH[VF16] (0x0022DF40 + 0x4*VF16, VF16=0...15; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.89 VF PSM Mailbox Transmit Tail - VF_MBX_PSM_ATQT[VF16] (0x0022DF80 + 0x4*VF16, VF16=0...15; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.90 VF PSM Mailbox Receive Queue Base Address Low - VF_MBX_PSM_ARQBAL[VF16] (0x0022DFC0 + 0x4*VF16, VF16=0...15; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.91 VF PSM Mailbox Receive Queue Base Address High - VF_MBX_PSM_ARQBAH[VF16] (0x0022E000 + 0x4*VF16, VF16=0...15; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.92 VF PSM Mailbox Receive Queue Length - VF_MBX_PSM_ARQLEN[VF16] (0x0022E040 + 0x4*VF16, VF16=0...15; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.93 VF PSM Mailbox Receive Head - VF_MBX_PSM_ARQH[VF16] (0x0022E080 + 0x4*VF16, VF16=0...15; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.94 VF PSM Mailbox Receive Tail - VF_MBX_PSM_ARQT[VF16] (0x0022E0C0 + 0x4*VF16, VF16=0...15; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.95 PF Mailbox Transmit Queue Base Address Low - PF_MBX_ATQBAL (0x0022E100; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.96 PF Mailbox Transmit Queue Base Address High - PF_MBX_ATQBAH (0x0022E180; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.97 PF Mailbox Transmit Queue Length - PF_MBX_ATQLEN (0x0022E200; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.98 PF Mailbox Transmit Head - PF_MBX_ATQH (0x0022E280; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.99 PF Mailbox Transmit Tail - PF_MBX_ATQT (0x0022E300; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.100 PF Mailbox Receive Queue Base Address Low - PF_MBX_ARQBAL (0x0022E380; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.101 PF Mailbox Receive Queue Base Address High - PF_MBX_ARQBAH (0x0022E400; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.102 PF Mailbox Receive Queue Length - PF_MBX_ARQLEN (0x0022E480; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.103 PF Mailbox Receive Head - PF_MBX_ARQH (0x0022E500; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.104 PF Mailbox Receive Tail - PF_MBX_ARQT (0x0022E580; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.105 PF0 CPM Mailbox Transmit Queue Base Address Low - PF0_MBX_CPM_ATQBAL (0x0022E5C0; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.106 PF0 CPM Mailbox Transmit Queue Base Address High - PF0_MBX_CPM_ATQBAH (0x0022E5C4; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.107 PF0 CPM Mailbox Transmit Queue Length - PF0_MBX_CPM_ATQLEN (0x0022E5C8; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.108 PF0 CPM Mailbox Transmit Head - PF0_MBX_CPM_ATQH (0x0022E5CC; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.109 PF0 CPM Mailbox Transmit Tail - PF0_MBX_CPM_ATQT (0x0022E5D0; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.110 PF0 CPM Mailbox Receive Queue Base Address Low - PF0_MBX_CPM_ARQBAL (0x0022E5D4; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.111 PF0 CPM Mailbox Receive Queue Base Address High - PF0_MBX_CPM_ARQBAH (0x0022E5D8; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.112 PF0 CPM Mailbox Receive Queue Length - PF0_MBX_CPM_ARQLEN (0x0022E5DC; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.113 PF0 CPM Mailbox Receive Head - PF0_MBX_CPM_ARQH (0x0022E5E0; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.114 PF0 CPM Mailbox Receive Tail - PF0_MBX_CPM_ARQT (0x0022E5E4; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.115 PF0 HLP Mailbox Transmit Queue Base Address Low - PF0_MBX_HLP_ATQBAL (0x0022E5E8; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.116 PF0 HLP Mailbox Transmit Queue Base Address High - PF0_MBX_HLP_ATQBAH (0x0022E5EC; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.117 PF0 HLP Mailbox Transmit Queue Length - PF0_MBX_HLP_ATQLEN (0x0022E5F0; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.118 PF0 HLP Mailbox Transmit Head - PF0_MBX_HLP_ATQH (0x0022E5F4; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.119 PF0 HLP Mailbox Transmit Tail - PF0_MBX_HLP_ATQT (0x0022E5F8; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.120 PF0 HLP Mailbox Receive Queue Base Address Low - PF0_MBX_HLP_ARQBAL (0x0022E5FC; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.121 PF0 HLP Mailbox Receive Queue Base Address High - PF0_MBX_HLP_ARQBAH (0x0022E600; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.122 PF0 HLP Mailbox Receive Queue Length - PF0_MBX_HLP_ARQLEN (0x0022E604; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.123 PF0 HLP Mailbox Receive Head - PF0_MBX_HLP_ARQH (0x0022E608; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.124 PF0 HLP Mailbox Receive Tail - PF0_MBX_HLP_ARQT (0x0022E60C; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.125 PF0 PSM Mailbox Transmit Queue Base Address Low - PF0_MBX_PSM_ATQBAL (0x0022E610; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.126 PF0 PSM Mailbox Transmit Queue Base Address High - PF0_MBX_PSM_ATQBAH (0x0022E614; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.127 PF0 PSM Mailbox Transmit Queue Length - PF0_MBX_PSM_ATQLEN (0x0022E618; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.128 PF0 PSM Mailbox Transmit Head - PF0_MBX_PSM_ATQH (0x0022E61C; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.129 PF0 PSM Mailbox Transmit Tail - PF0_MBX_PSM_ATQT (0x0022E620; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.130 PF0 PSM Mailbox Receive Queue Base Address Low - PF0_MBX_PSM_ARQBAL (0x0022E624; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.131 PF0 PSM Mailbox Receive Queue Base Address High - PF0_MBX_PSM_ARQBAH (0x0022E628; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.132 PF0 PSM Mailbox Receive Queue Length - PF0_MBX_PSM_ARQLEN (0x0022E62C; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.133 PF0 PSM Mailbox Receive Head - PF0_MBX_PSM_ARQH (0x0022E630; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.134 PF0 PSM Mailbox Receive Tail - PF0_MBX_PSM_ARQT (0x0022E634; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.135 PF0 CPM Sideband Transmit Queue Base Address Low - PF0_SB_CPM_ATQBAL (0x0022E638; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.136 PF0 CPM Sideband Transmit Queue Base Address High - PF0_SB_CPM_ATQBAH (0x0022E63C; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.137 PF0 CPM Sideband Transmit Queue Length - PF0_SB_CPM_ATQLEN (0x0022E640; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.138 PF0 CPM Sideband Transmit Head - PF0_SB_CPM_ATQH (0x0022E644; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.139 PF0 CPM Sideband Transmit Tail - PF0_SB_CPM_ATQT (0x0022E648; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.140 PF0 CPM Sideband Receive Queue Base Address Low - PF0_SB_CPM_ARQBAL (0x0022E64C; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.141 PF0 CPM Sideband Receive Queue Base Address High - PF0_SB_CPM_ARQBAH (0x0022E650; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.142 PF0 CPM Sideband Receive Queue Length - PF0_SB_CPM_ARQLEN (0x0022E654; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.143 PF0 CPM Sideband Receive Head - PF0_SB_CPM_ARQH (0x0022E658; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.144 PF0 CPM Sideband Receive Tail - PF0_SB_CPM_ARQT (0x0022E65C; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.145 VF CPM Sideband Transmit Queue Base Address Low - VF_SB_CPM_ATQBAL[VF128] (0x0022E800 + 0x4*VF128, VF128=0...127; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.146 VF CPM Sideband Transmit Queue Base Address High - VF_SB_CPM_ATQBAH[VF128] (0x0022EA00 + 0x4*VF128, VF128=0...127; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.147 VF CPM Sideband Transmit Queue Length - VF_SB_CPM_ATQLEN[VF128] (0x0022EC00 + 0x4*VF128, VF128=0...127; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.148 VF CPM Sideband Transmit Head - VF_SB_CPM_ATQH[VF128] (0x0022EE00 + 0x4*VF128, VF128=0...127; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.149 VF CPM Sideband Transmit Tail - VF_SB_CPM_ATQT[VF128] (0x0022F000 + 0x4*VF128, VF128=0...127; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.150 VF CPM Sideband Receive Queue Base Address Low - VF_SB_CPM_ARQBAL[VF128] (0x0022F200 + 0x4*VF128, VF128=0...127; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.151 VF CPM Sideband Receive Queue Base Address High - VF_SB_CPM_ARQBAH[VF128] (0x0022F400 + 0x4*VF128, VF128=0...127; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.152 VF CPM Sideband Receive Queue Length - VF_SB_CPM_ARQLEN[VF128] (0x0022F600 + 0x4*VF128, VF128=0...127; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.153 VF CPM Sideband Receive Head - VF_SB_CPM_ARQH[VF128] (0x0022F800 + 0x4*VF128, VF128=0...127; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.154 VF CPM Sideband Receive Tail - VF_SB_CPM_ARQT[VF128] (0x0022FA00 + 0x4*VF128, VF128=0...127; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.155 PF Sideband Transmit Queue Base Address Low - PF_SB_ATQBAL (0x0022FC00; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.156 PF Sideband Transmit Queue Base Address High - PF_SB_ATQBAH (0x0022FC80; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.157 PF Sideband Transmit Queue Length - PF_SB_ATQLEN (0x0022FD00; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.158 PF Sideband Transmit Head - PF_SB_ATQH (0x0022FD80; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.159 PF Sideband Transmit Tail - PF_SB_ATQT (0x0022FE00; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.160 PF Sideband Receive Queue Base Address Low - PF_SB_ARQBAL (0x0022FE80; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.161 PF Sideband Receive Queue Base Address High - PF_SB_ARQBAH (0x0022FF00; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.162 PF Sideband Receive Queue Length - PF_SB_ARQLEN (0x0022FF80; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.163 PF Sideband Receive Head - PF_SB_ARQH (0x00230000; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.164 PF Sideband Receive Tail - PF_SB_ARQT (0x00230080; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.165 PF0 HLP Sideband Transmit Queue Base Address Low - PF0_SB_HLP_ATQBAL (0x002300C0; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.2.2.22.166 PF0 HLP Sideband Transmit Queue Base Address High - PF0_SB_HLP_ATQBAH (0x002300C4; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.2.2.22.167 PF0 HLP Sideband Transmit Queue Length - PF0_SB_HLP_ATQLEN (0x002300C8; RW)

This register sets the size of the ring. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.2.2.22.168 PF0 HLP Sideband Transmit Head - PF0_SB_HLP_ATQH (0x002300CC; RW)

Admin transmit queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.2.2.22.169 PF0 HLP Sideband Transmit Tail - PF0_SB_HLP_ATQT (0x002300D0; RW)

Admin transmit queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.2.2.22.170 PF0 HLP Sideband Receive Queue Base Address Low - PF0_SB_HLP_ARQBAL (0x002300D4; RW)

This register contains the lower bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.2.2.22.171 PF0 HLP Sideband Receive Queue Base Address High - PF0_SB_HLP_ARQBAH (0x002300D8; RW)

This register contains the higher bits of the 64-bit descriptor base address.

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.2.2.22.172 PF0 HLP Sideband Receive Queue Length - PF0_SB_HLP_ARQLEN (0x002300DC; RW)

This register specifies the receive queue length. Maximum size is 1024.

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.2.2.22.173 PF0 HLP Sideband Receive Head - PF0_SB_HLP_ARQH (0x002300E0; RW)

Admin receive queue head pointer.

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.2.2.22.174 PF0 HLP Sideband Receive Tail - PF0_SB_HLP_ARQT (0x002300E4; RW)

Admin receive queue tail pointer.

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.2.2.22.175 PF SB HLP Remote Device Control Register - PF0_SB_HLP_REM_DEV_CTL (0x002300E8; RW)

Bit mapping of the remote devices allowed to be accessed by HLP PF driver.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEST_EN	15:0	0x0	RW	UNDEFINED	**Destination Enable** Bit mapping of the sideband remote devices allowed to be accessed by the software driver.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.22.176 VF SB CPM Remote Device Control Register - VF_SB_CPM_REM_DEV_CTL (0x002300EC; RW)

Bit mapping of the remote devices allowed to be accessed by CPM VF driver.

Field definitions are the same as those defined in Section 13.2.2.22.175.

13.2.2.22.177 PF SB Remote Device Control Register - PF_SB_REM_DEV_CTL (0x002300F0; RW)

Bit mapping of the remote devices allowed to be accessed by CPK PF driver.

Field definitions are the same as those defined in Section 13.2.2.22.175.

13.2.2.22.178 PF SB CPM Remote Device Control Register - PF0_SB_CPM_REM_DEV_CTL (0x002300F4; RW)

Bit mapping of the remote devices allowed to be accessed by CPM PF driver.

Field definitions are the same as those defined in Section 13.2.2.22.175.

13.2.2.22.179 SB Remote Device Destination Register - SB_REM_DEV_DEST[n] (0x002300F8 + 0x4*n, n=0...7; RW)

This register contains the destination software driver that the SB remote device is mapped to (per remote device source)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEST	3:0	0x0	RW	UNDEFINED	**Destination** Destination software driver of this sideband remote device. 0x0 = CPK driver 0x1 = CPM driver 0x2 = HLP driver All other values are reserved.
RESERVED	30:4	0x0	RSV	N/A	Reserved.
DEST_VALID	31	0b	RW	UNDEFINED	**Destination Valid**

13.2.2.22.180 PF VF Control Register - VP_MBX_PF_VF_CTRL[VSI] (0x00230800 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_EN	0	1b	RW	UNDEFINED	**Queue Enable** A PF can disable a VF's transmit and receive Admin Queues by clearing this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.22.181 PF VF Control Register - VP_MBX_CPM_PF_VF_CTRL[VP128] (0x00231800 + 0x4*VP128, VP128=0...127; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_EN	0	1b	RW	UNDEFINED	**Queue Enable** A PF can disable a VF's transmit and receive Admin Queues by clearing this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.22.182 PF VF Control Register - VP_MBX_HLP_PF_VF_CTRL[VP16] (0x00231A00 + 0x4*VP16, VP16=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_EN	0	1b	RW	UNDEFINED	**Queue Enable** A PF can disable a VF's transmit and receive Admin Queues by clearing this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.22.183 PF VF Control Register - VP_MBX_PSM_PF_VF_CTRL[VP16] (0x00231A40 + 0x4*VP16, VP16=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_EN	0	1b	RW	UNDEFINED	**Queue Enable** A PF can disable a VF's transmit and receive Admin Queues by clearing this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.22.184 PF VF Control Register - VP_SB_CPM_PF_VF_CTRL[VP128] (0x00231C00 + 0x4*VP128, VP128=0...127; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_EN	0	1b	RW	UNDEFINED	**Queue Enable** A PF can disable a VF's transmit and receive Admin Queues by clearing this bit.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.22.185 PF VF Control Register - GL_MBX_PASID (0x00231EC0; RW)

This register contains MBX PASID related configurations.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PASID_MODE	0	0b	RW	UNDEFINED	**PASID Mode** When set, the E810 works in PASID mode, and MBX should handle its queues accordingly.
PASID_MODE_VALID	1	0b	RW	N/A	**PASID Mode Valid** Validates the PASID_MODE bit (for software use only).
RESERVED	31:2	0x0	RSV	UNDEFINED	Reserved.

13.2.2.23 PF - Statistics Registers

Statistics counters. Refer to Section 9.6 for information regarding wide counters, clearing counters, sampling points, and counter consistency rules.

Note: Wide counters (48 bits) are represented as two registers (high and low) containing the 16 most significant bits and 32 least significant bits, respectively. They are implemented as a 64-bit register. Atomicity is only guaranteed when reading both parts in one 64-bit read.

Note: Per-function registers are implemented as an array of 144 registers. Elements 0-127 correspond to VFs 0-127 and elements 128-143 are used for PFs 0-15.

13.2.2.23.1 PORT TC Transmit Byte Count - TPB_PRTTPB_STAT_TC_BYTES_SENT[n] (0x00099094 + 0x4*n, n=0...63; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCCNT	31:0	0x0	RW1C	DYNAMIC	**TC Count** Port per-TC byte count. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.2 PORT Transmit Packet Count - TPB_PRTTPB_STAT_PKT_SENT[n] (0x00099470 + 0x4*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PKTCNT	31:0	0x0	RW1C	DYNAMIC	**Packet Count** Port packet counter.

13.2.2.23.3 Port (Line) Receive Drop Counter - PRTRPB_RDPC (0x000AC260; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CRCERRS	31:0	0x0	RW1C	DYNAMIC	**CRC Errors** Port drop counter. Counts all packets that were dropped due to shortage of storage space.

13.2.2.23.4 Port (LB) Receive Drop Counter - PRTRPB_LDPC (0x000AC280; RWC)

Field definitions are the same as those defined in Section 13.2.2.23.3.

13.2.2.23.5 VSI Received Discard Packet Count - GLV_RDPC[n] (0x00294C04 + 0x4*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDPC	31:0	0x0	RWC	UNDEFINED	**Received Discard Packet Count** Counts (per VSI) packets that were drop due to no descriptors in host queue or other drops in the pipe. Pipe drops includes Flow Director, ACL, and packets directed to invalid receive queues drops. For EMP VSIs, it counts dropped packets due to no EMP buffer space.

13.2.2.23.6 Per VSI Error Drops - GLV_REPC[n] (0x00295804 + 0x4*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NO_DESC_CNT	15:0	0x0	RW	UNDEFINED	**No Descriptors Count** Counts packets dropped from this VSI due to no descriptors available. For VSIs associated with the EMP, counts drops due to EMP buffer full. Stuck at 0xFFFF.
ERROR_CNT	31:16	0x0	RW	UNDEFINED	**Error Count** Counts packet dropped from this VSI due to the following cases: • Packet size is larger than RXMAX of the queue. • Receive descriptor Unsupported Request on the PCI or internal Dummy completion. • Packets directed to disabled receive queues. • Packets dropped due to VM reset, VF reset, or PF reset. Stuck at 0xFFFF

Note: Writing to this register clears both the counters. There is no way to clear a single counter.

13.2.2.23.7 VSI Good Octets Transmit Count Low - GLV_GOTCL[n] (0x00300000 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GOTCL	31:0	0x0	RWC	UNDEFINED	**Good Octet Transmit Count Low** Transmit octet count. Counts the number of bytes transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.8 VSI Good Octets Transmit Count High - GLV_GOTCH[n] (0x00300004 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GOTCH	7:0	0x0	RWC	UNDEFINED	**Good Octet Transmit Count High** Transmit octet count. Counts the number of bytes transmitted by this VSI. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.9 Switch Good Octets Transmit Count Low - GLSW_GOTCL[n] (0x00302000 + 0x8*n, n=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GOTCL	31:0	0x0	RWC	UNDEFINED	**Good Octet Transmit Count Low** Transmit octet count. Counts the number of bytes transmitted. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.10 Switch Good Octets Transmit Count High - GLSW_GOTCH[n] (0x00302004 + 0x8*n, n=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GOTCH	7:0	0x0	RWC	UNDEFINED	**Good Octet Transmit Count High** Transmit octet count. Counts the number of bytes transmitted. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.11 VEB VLAN Transmit Byte Count Low - GL_STAT_SWR_GOTCL[n] (0x00304000 + 0x8*n, n=0...127; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VLBCL	31:0	0x0	RWC	UNDEFINED	**VLAN Byte Count Low** VEB per VLAN byte count low. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.12 VEB VLAN Transmit Byte Count High - GL_STAT_SWR_GOTCH[n] (0x00304004 + 0x8*n, n=0...127; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VLBCH	7:0	0x0	RWC	UNDEFINED	**VLAN Byte Count High** VEB per VLAN byte count High. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.13 VEB UP Transmit Byte Count Low - GLVEBUP_TBCL[n,m] (0x00306000 + 0x8*n + 0x40*m, n=0...7, m=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPBCL	31:0	0x0	RWC	UNDEFINED	**UP Byte Count Low** UP transmit byte count low. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.14 VEB UP Transmit Byte Count High - GLVEBUP_TBCH[n,m] (0x00306004 + 0x8*n + 0x40*m, n=0...7, m=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPBCH	7:0	0x0	RWC	UNDEFINED	**UP Byte Count High** UP transmit byte count High. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.15 VEB UP Transmit Packet Count Low - GLVEBUP_TPCL[n,m] (0x00308000 + 0x8*n + 0x40*m, n=0...7, m=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPPCL	31:0	0x0	RWC	UNDEFINED	**UP Packet Count Low** VEB per UP transmit packets count low. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.16 VEB UP Transmit Packet Count High - GLVEBUP_TPCH[n,m] (0x00308004 + 0x8*n + 0x40*m, n=0...7, m=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPPCH	7:0	0x0	RWC	UNDEFINED	**UP Packet Count High** VEB per UP transmit packets count high. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.17 VSI Unicast Packets Transmit Count Low - GLV_UPTCL[n] (0x0030A000 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPTCL	31:0	0x0	RWC	UNDEFINED	**Unicast Packets Transmit Count Low** Transmit unicast packet count. Counts the number of unicast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.18 VSI Unicast Packets Transmit Count High - GLV_UPTCH[n] (0x0030A004 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GLVUPTCH	7:0	0x0	RWC	UNDEFINED	**Unicast Packets Transmit Count High** Transmit unicast packet count. Counts the number of unicast packets transmitted by this VSI. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.19 VSI Multicast Packets Transmit Count Low - GLV_MPTCL[n] (0x0030C000 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MPTCL	31:0	0x0	RWC	UNDEFINED	**Multicast Packets Transmit Count Low** Transmit multicast packet count. Counts the number of multicast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.20 VSI Multicast Packets Transmit Count High - GLV_MPTCH[n] (0x0030C004 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MPTCH	7:0	0x0	RWC	UNDEFINED	**Multicast Packets Transmit Count High** Transmit multicast packet count. Counts the number of multicast packets transmitted by this VSI. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.21 VSI Broadcast Packets Transmit Count Low - GLV_BPTCL[n] (0x0030E000 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BPTCL	31:0	0x0	RWC	UNDEFINED	**Broadcast Packets Transmit Count Low** Transmit broadcast packet count. Counts the number of broadcast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.22 VSI Broadcast Packets Transmit Count High - GLV_BPTCH[n] (0x0030E004 + 0x8*n, n=0...767; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BPTCH	7:0	0x0	RWC	UNDEFINED	**Broadcast Packets Transmit Count High** Transmit broadcast packet count. Counts the number of broadcast packets transmitted by this VSI. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.23 Switch Unicast Packets Transmit Count Low - GLSW_UPTCL[n] (0x00310000 + 0x8*n, n=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPTCL	31:0	0x0	RWC	UNDEFINED	**Unicast Packets Transmit Count Low** Transmit unicast packet count. Counts the number of unicast packets transmitted. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.24 Switch Unicast Packets Transmit Count High - GLSW_UPTCH[n] (0x00310004 + 0x8*n, n=0...31; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
UPTCH	7:0	0x0	RWC	UNDEFINED	**Unicast Packets Transmit Count High** Transmit unicast packet count. Counts the number of unicast packets transmitted. Higher 8 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MLFC	31:0	0x0	RWC	UNDEFINED	**MAC Local Fault Count** Number of faults in the local MAC.

13.2.2.23.54 Port MAC Local Fault Count - GLPRT_MLFC_H[n] (0x00380044 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MLFC	31:0	0x0	RWC	UNDEFINED	**MAC Local Fault Count** Number of faults in the local MAC.

13.2.2.23.55 Port MAC Remote Fault Count - GLPRT_MRFC[n] (0x00380080 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRFC	31:0	0x0	RWC	UNDEFINED	**MAC Remote Fault Count** Number of faults in the remote MAC.

13.2.2.23.56 Port MAC Remote Fault Count - GLPRT_MRFC_H[n] (0x00380084 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRFC	31:0	0x0	RWC	UNDEFINED	**MAC Remote Fault Count** Number of faults in the remote MAC.

13.2.2.23.57 Port CRC Error Count - GLPRT_CRCERRS[n] (0x00380100 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CRCERRS	31:0	0x0	RWC	UNDEFINED	**CRC Errors** CRC error count. Counts the number of receive packets with CRC errors.

13.2.2.23.58 Port CRC Error Count - GLPRT_CRCERRS_H[n] (0x00380104 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CRCERRS	31:0	0x0	RWC	UNDEFINED	**CRC Errors** CRC error count. Counts the number of receive packets with CRC errors.

13.2.2.23.59 Receive Length Error Count - GLPRT_RLEC[n] (0x00380140 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RLEC	31:0	0x0	RWC	UNDEFINED	**Receive Length Error Count** Number of SNAP packets with receive length errors. A length error occurs if an incoming packet length field in the MAC header does not match the packet length. Does not count length error in tagged packets (like VLAN tagged) or non-SNAP packets

13.2.2.23.60 Receive Length Error Count - GLPRT_RLEC_H[n] (0x00380144 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RLEC	31:0	0x0	RWC	UNDEFINED	**Receive Length Error Count** Number of packets with receive length errors. A length error occurs if an incoming packet length field in the MAC header does not match the packet length.

13.2.2.23.61 Port Illegal Byte Error Count - GLPRT_ILLERRC[n] (0x003801C0 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ILLERRC	31:0	0x0	RWC	UNDEFINED	**Illegal Error Count** Illegal byte error packet count. Counts the number of receive packets with illegal bytes errors (in other words, there is an illegal symbol in the packet).

13.2.2.23.62 Port Illegal Byte Error Count - GLPRT_ILLERRC_H[n] (0x003801C4 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ILLERRC	31:0	0x0	RWC	UNDEFINED	**Illegal Error Count** Illegal byte error packet count. Counts the number of receive packets with illegal bytes errors (in other words, there is an illegal symbol in the packet).

13.2.2.23.63 Receive Undersize Count - GLPRT_RUC[n] (0x00380200 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RUC	31:0	0x0	RWC	UNDEFINED	**Receive Undersize Count** Receive undersize error. Counts the number of received frames that are shorter than minimum size (64 bytes from <Destination Address> through <CRC>, inclusively) and had a valid CRC.

13.2.2.23.64 Receive Undersize Count - GLPRT_RUC_H[n] (0x00380204 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RUC	31:0	0x0	RWC	UNDEFINED	**Receive Undersize Count** Receive undersize error. Counts the number of received frames that are shorter than minimum size (64 bytes from <Destination Address> through <CRC>, inclusively) and had a valid CRC.

13.2.2.23.65 Receive Oversize Count - GLPRT_ROC[n] (0x00380240 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ROC	31:0	0x0	RWC	UNDEFINED	**Receive Oversize Count** Receive oversize error. Counts the number of received frames that are longer than maximum size as defined by the Set MAC Config command (from <Destination Address> through <CRC>, inclusively) and have valid CRC.

13.2.2.23.66 Receive Oversize Count - GLPRT_ROC_H[n] (0x00380244 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ROC	31:0	0x0	RWC	UNDEFINED	**Receive Oversize Count** Receive oversize error. Counts the number of received frames that are longer than maximum size as defined by MAXFRS.*MFS* (from <Destination Address> through <CRC>, inclusively) and have valid CRC.

13.2.2.23.67 Port Link XON Received Count - GLPRT_LXONRXC[n] (0x00380280 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LXONRXCNT	31:0	0x0	RWC	UNDEFINED	**Link XON Received Count** Number of XON packets received.

13.2.2.23.68 Port Link XON Received Count - GLPRT_LXONRXC_H[n] (0x00380284 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LXONRXCNT	31:0	0x0	RWC	UNDEFINED	**Link XON Received Count** Number of XON packets received.

13.2.2.23.69 Port Link XOFF Received Count - GLPRT_LXOFFRXC[n] (0x003802C0 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LXOFFRXCNT	31:0	0x0	RWC	UNDEFINED	**Link XOFF Received Count** Number of XOFF packets received.

13.2.2.23.70 Port Link XOFF Received Count - GLPRT_LXOFFRXC_H[n] (0x003802C4 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LXOFFRXCNT	31:0	0x0	RWC	UNDEFINED	**Link XOFF Received Count** Number of XOFF packets received.

13.2.2.23.71 Priority XON Received Count - GLPRT_PXONRXC[n,m] (0x00380300 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRPXONRXCNT	31:0	0x0	RWC	UNDEFINED	**Priority XON Received Count** Number of XON packets received. Array of eight per port.

13.2.2.23.72 Priority XON Received Count - GLPRT_PXONRXC_H[n,m] (0x00380304 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRPXONRXCNT	31:0	0x0	RWC	UNDEFINED	**Priority XON Received Count** Number of XON packets received. Array of eight per port.

13.2.2.23.73 Priority XOFF Received Count - GLPRT_PXOFFRXC[n,m] (0x00380500 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRPXOFFRXCNT	31:0	0x0	RWC	UNDEFINED	**Priority XOFF Received Count** Number of XOFF packets received. Array of eight per port.

13.2.2.23.74 Priority XOFF Received Count - GLPRT_PXOFFRXC_H[n,m] (0x00380504 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRPXOFFRXCNT	31:0	0x0	RWC	UNDEFINED	**Priority XOFF Received Count** Number of XOFF packets received. Array of eight per port.

13.2.2.23.75 Priority XON to XOFF Count - GLPRT_RXON2OFFCNT[n,m] (0x00380700 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRRXON2OFFCNT	31:0	0x0	RWC	UNDEFINED	**Priority XON to XOFF Count** Number of times transmitter transitioned from XON to XOFF. Array of eight per port.

13.2.2.23.76 Priority XON to XOFF Count - GLPRT_RXON2OFFCNT_H[n,m] (0x00380704 + 0x8*n + 0x40*m, n=0...7, m=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRRXON2OFFCNT	31:0	0x0	RWC	UNDEFINED	**Priority XON to XOFF Count** Number of times transmitter transitioned from XON to XOFF. Array of eight per port.

13.2.2.23.77 Packets Received [64 Bytes] Count Low - GLPRT_PRC64L[n] (0x00380900 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRC64L	31:0	0x0	RWC	UNDEFINED	**Packets Received Count (64 Bytes) Low** Number of good packets received that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.78 Packets Received [64 Bytes] Count High - GLPRT_PRC64H[n] (0x00380904 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRC64H	7:0	0x0	RWC	UNDEFINED	**Packets Received Count (64 Bytes) High** Number of good packets received that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.79 Packets Received [65-127 Bytes] Count Low - GLPRT_PRC127L[n] (0x00380940 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRC127L	31:0	0x0	RWC	UNDEFINED	**Packets Received Count (65-127 Bytes) Low** Number of packets received that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.80 Packets Received [65-127 Bytes] Count High - GLPRT_PRC127H[n] (0x00380944 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRC127H	7:0	0x0	RWC	UNDEFINED	**Packets Received Count (65-127 Bytes) High** Number of packets received that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.23.81 Packets Received [128-255 Bytes] Count Low - GLPRT_PRC255L[n] (0x00380980 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRC255L	31:0	0x0	RWC	UNDEFINED	**Packets Received Count (128-255 Bytes) Low** Number of packets received that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

13.2.2.23.82 Packets Received [128-255 Bytes] Count High - GLPRT_PRC255H[n] (0x00380984 + 0x8*n, n=0...7; RWC)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PRTPRC255H	7:0	0x0	RWC	UNDEFINED	**Packets Received Count (128-255 Bytes) High** Number of packets received that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.24.71 Protocol Engine Statistics RDMA Verbs Bind Operations High - GLPES_PFRDMAVBNDHI[n] (0x00551404 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMAVBNDHI	15:0	0x0	RW1C	DYNAMIC	**RDMA Verbs Binds High** Counts a total number of RDMA Verb Bind operations carried out by the Protocol Engine. This is the high 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.24.72 Protocol Engine Statistics RDMA Verbs Invalidate Operations Low - GLPES_PFRDMAVINVLO[n] (0x00551C00 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMAVINVLO	31:0	0x0	RW1C	DYNAMIC	**RDMA Verbs Invalidates Low** Counts a total number of RDMA Verb Invalidate operations carried out by the Protocol Engine. This is the low 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

13.2.2.24.73 Protocol Engine Statistics RDMA Verbs Invalidate Operations High - GLPES_PFRDMAVINVHI[n] (0x00551C04 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMAVINVHI	15:0	0x0	RW1C	DYNAMIC	**RDMA Verbs Invalidates High** Counts a total number of RDMA Verb Invalidate operations carried out by the Protocol Engine. This is the high 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.24.74 Protocol Engine Statistics TCP Retransmitted Segments - GLPES_PFTCPRTXSEG[n] (0x00552400 + 0x4*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPRTXSEG	31:0	0x0	RW1C	DYNAMIC	**TCP Retransmitted Segments** Counts the number of TCP segments retransmitted by the Protocol Engine.

13.2.2.24.75 Protocol Engine Statistics Congestion Notification Packets Ignored - GLPES_PFRXRPCNPIGNORED[n] (0x00552800 + 0x4*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXRPCNPIGNORED	23:0	0x0	RW1C	DYNAMIC	**Congestion Notification Packets Ignored** Counts the number of Congestion Notification Packets (CNPs) that have been ignored by the reaction point.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.24.76 Protocol Engine Statistics Congestion Notification Packets Handled - GLPES_PFRXRPCNPHANDLED[n] (0x00552C00 + 0x4*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXRPCNPHANDLED	31:0	0x0	RW1C	DYNAMIC	**Congestion Notification Packets Handled** Counts the number of Congestion Notification Packets (CNPs) that have been handled by the reaction point.

13.2.2.24.77 Protocol Engine Statistics with ECN Bits Indicating Congestion Low - GLPES_PFRXNPECNMARKEDPKTSLO[n] (0x00553000 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXNPECNMARKEDPKTSLO	31:0	0x0	RW1C	DYNAMIC	**Congestion Notification Marked Packets Low** Counts the number of packets that have the ECN bits set to indicate congestion. This is a low 32 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

13.2.2.24.78 Protocol Engine Statistics with ECN Bits Indicating Congestion High - GLPES_PFRXNPECNMARKEDPKTSHI[n] (0x00553004 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXNPECNMARKEDPKTSHI	23:0	0x0	RW1C	DYNAMIC	**Congestion Notification Marked Packets High** Counts the number of packets that have the ECN bits set to indicate congestion. This is a high 24 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.24.79 Protocol Engine Congestion Indication Sent Count - GLPES_PFTXNPCNPSENT[n] (0x00553800 + 0x4*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TXNPCNPSENT	23:0	0x0	RW1C	DYNAMIC	**Congestion Notification Packets Sent** Counts the number of Congestion Notification Packets (CNPs) that have been sent by the reaction point.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.24.80 Protocol Engine Statistics RDMA Received Unaligned FPDUs - GLPES_RDMARXUNALIGN (0x0055E000; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMRXAUNALIGN	31:0	0x0	RW1C	DYNAMIC	**RDMA Received Unaligned** Counts the number of TCP segments received by the Protocol Engine that probably carried unaligned FPDUs.

13.2.2.24.81 Protocol Engine Statistics RDMA Received Out of Order No Markers FPDUs - GLPES_RDMARXOOONOMARK (0x0055E004; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMAOOONOMARK	31:0	0x0	RW1C	DYNAMIC	**RDMA Out-of-Order No Markers** Counts RDMA FPDUs received by the Protocol Engine out-of-order and not carrying markers.

13.2.2.24.82 Protocol Engine Statistics RDMA Received Multiple FPDUs Low - GLPES_RDMARXMULTFPDUSLO (0x0055E008; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMARXMULTFPDUSLO	31:0	0x0	RW1C	DYNAMIC	**RDMA Received Multiple FPDUs Low** Counts the number of TCP segments received by the Protocol Engine that probably have multiple FPDUs. This is a low 32 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

13.2.2.24.83 Protocol Engine Statistics RDMA Received Multiple FPDUs High - GLPES_RDMARXMULTFPDUSHI (0x0055E00C; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMARXMULTFPDUSHI	23:0	0x0	RW1C	DYNAMIC	**RDMA Received Multiple FPDUs Low** Counts the number of TCP segments received by the Protocol Engine that probably have multiple FPDUs. This is a high 24 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.24.84 Protocol Engine Statistics RDMA Out of Order Placed DDP Segments Low - GLPES_RDMARXOOODDPLO (0x0055E010; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMARXOOODDPLO	31:0	0x0	RW1C	DYNAMIC	**RDMA Received Out-of-Order DDP Low** Counts the number of the DDP segments received by the Protocol Engine, and out-of-order placed. This is a low 32 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

13.2.2.24.85 Protocol Engine Statistics RDMA Out of Order Placed DDP Segments High - GLPES_RDMARXOOODDPHI (0x0055E014; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMARXOOODDPHI	23:0	0x0	RW1C	DYNAMIC	**RDMA Received Out-of-Order DDP High** Counts the number of the DDP segments received by the Protocol Engine, and out-of-order placed. This is a high 24 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.24.86 Protocol Engine Statistics TCP Received Pure Acks Low - GLPES_TCPRXPUREACKSLO (0x0055E018; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPRXPUREACKLO	31:0	0x0	RW1C	DYNAMIC	**TCP Received Pure Acks Low** Counts the number of TCP Acks received by the Protocol Engine carrying no data. This is a low 32 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

13.2.2.24.87 Protocol Engine Statistics TCP Received Pure Acks High - GLPES_TCPRXPUREACKHI (0x0055E01C; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPRXPUREACKHI	23:0	0x0	RW1C	DYNAMIC	**TCP Received Pure Acks High** Counts the number of TCP Acks received by the Protocol Engine carrying no data. This is a high 24 bits of the 56-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RING_LEN	17:0	0x0	RW	UNDEFINED	**Ring Length** Completion queue length in 16 completions unit (64 bytes).
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.25.6 Tx Completion Queue Context Register 3 - GLTCLAN_CQ_CNTX3[CQ] (0x000F2000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GENERATION	0	0b	RW	UNDEFINED	**Generation** Tx completion queue generation bit exposed on CQ write-back. Value flips each ring wrap-around.
CQ_WR_PTR	22:1	0x0	RW	UNDEFINED	**CQ Write Pointer**
RESERVED	31:23	0x0	RSV	N/A	Reserved.

13.2.2.25.7 Tx Completion Queue Context Register 4 - GLTCLAN_CQ_CNTX4[CQ] (0x000F2800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_NUM	2:0	000b	RW	UNDEFINED	**PF Number** PF number of the CQ.
VMVF_NUM	12:3	0x0	RW	UNDEFINED	**VM/VF Number** VM number or VF number.
VMVF_TYPE	14:13	00b	RW	UNDEFINED	**VM/VF Type** 00b = CQ belongs to a VF. *VMVF_NUM* describes the VM number. 01b = CQ belongs to a VM. *VMVF_NUM* describes the VM number. 10b = CQ is a PF only CQ. *VMVF_NUM* is meaningless. 11b = Reserved.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.25.8 Tx Completion Queue Context Register 5 - GLTCLAN_CQ_CNTX5[CQ] (0x000F3000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TPH_EN	0	0b	RW	UNDEFINED	**TPH Enable** TPH enable for CQ write accesses.
CPU_ID	8:1	0x0	RW	UNDEFINED	**CPU ID** CPUID for CQ write accesses.
FLUSH_ON_ITR_DIS	9	0b	RW	UNDEFINED	**Flush on ITR Discard** 1b = CQ flush when ITR expire is silently dropped.
RESERVED	31:10	0x0	RSV	N/A	Reserved.

13.2.2.25.9 Tx Completion Queue Context Register 6 - GLTCLAN_CQ_CNTX6[CQ] (0x000F3800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.10 Tx Completion Queue Context Register 7 - GLTCLAN_CQ_CNTX7[CQ] (0x000F4000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.11 Tx Completion Queue Context Register 8 - GLTCLAN_CQ_CNTX8[CQ] (0x000F4800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.12 Tx Completion Queue Context Register 9 - GLTCLAN_CQ_CNTX9[CQ] (0x000F5000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.13 Tx Completion Queue Context Register 10 - GLTCLAN_CQ_CNTX10[CQ] (0x000F5800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.14 Tx Completion Queue Context Register 11 - GLTCLAN_CQ_CNTX11[CQ] (0x000F6000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.15 Tx Completion Queue Context Register 12 - GLTCLAN_CQ_CNTX12[CQ] (0x000F6800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.16 Tx Completion Queue Context Register 13 - GLTCLAN_CQ_CNTX13[CQ] (0x000F7000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.17 Tx Completion Queue Context Register 14 - GLTCLAN_CQ_CNTX14[CQ] (0x000F7800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.18 Tx Completion Queue Context Register 15 - GLTCLAN_CQ_CNTX15[CQ] (0x000F8000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.19 Tx Completion Queue Context Register 16 - GLTCLAN_CQ_CNTX16[CQ] (0x000F8800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.20 Tx Completion Queue Context Register 17 - GLTCLAN_CQ_CNTX17[CQ] (0x000F9000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.21 Tx Completion Queue Context Register 18 - GLTCLAN_CQ_CNTX18[CQ] (0x000F9800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.22 Tx Completion Queue Context Register 19 - GLTCLAN_CQ_CNTX19[CQ] (0x000FA000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.23 Tx Completion Queue Context Register 20 - GLTCLAN_CQ_CNTX20[CQ] (0x000FA800 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.24 Tx Completion Queue Context Register 21 - GLTCLAN_CQ_CNTX21[CQ] (0x000FB000 + 0x4*CQ, CQ=0...511; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQ_CACHLINE	31:0	0x0	RW	UNDEFINED	**CQ Cache Line** 32-bit cache line raw data.

13.2.2.25.25 Global Transmit Comm Min/Max Packet - GLCOMM_MIN_MAX_PKT (0x000FC064; RW)

This register is not expected to be accessed by the software.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MAHDL	13:0	0x2600	RW	UNDEFINED	**Maximum Host Data Length** Maximum transmit packet size in Host buffers (defined in byte units).
RESERVED	15:14	00b	RSV	N/A	Reserved.
MIHDL	21:16	0x11	RW	UNDEFINED	**Minimum Host Data Length** Minimum transmit packet size in Host buffers (defined in byte units).
LSO_COMS_MIHDL	31:22	0x0	RW	UNDEFINED	Reserved.

13.2.2.25.26 Transmit Comm Scheduler Tx LAN Cache Control - GLLAN_TCLAN_CACHE_CTL (0x000FC0B8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIN_FETCH_THRESH	5:0	0x8	RW	UNDEFINED	**Minimum Fetch Threshold** Minimum fetch threshold in LAN mode. Descriptor fetch length is rounded up to this value.
RESERVED	6	1b	RSV	N/A	Reserved.
MIN_ALLOC_THRESH	13:7	0x18	RW	UNDEFINED	**Minimum Allocated Threshold** Minimum number of allocated descriptors in the cache for each cache entry. Applicable for both LAN and Comms mode.
RESERVED	21:14	0x0	RSV	N/A	Reserved.
RESERVED	31:22	0x240	RSV	N/A	Reserved.

13.2.2.25.27 Transmit Comm Scheduler Queue Doorbell - QTX_COMM_DBELL[DBQM] (0x002C0000 + 0x4*DBQM, DBQM=0...16383; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QTX_COMM_DBELL	31:0	0x0	RW	UNDEFINED	**QTX Comms Doorbell** See Section 10.5 for complete description of the SSO/LSO/DROP doorbell formats. ***Note:*** This CSR always returns 0x0 when read and not the written value. To get the *TAIL* value of some Tx-Queue, read it from Tx-Queue context.

13.2.2.25.28 Transmit Comm Scheduler Queue Context - QTX_COMM_DBLQ_CNTX[n,DBLQ] (0x002D0000 + 0x400*n + 0x4*DBLQ, n=0...4, DBLQ=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** Comm DBL Queue context data. Bit 'i' in register 'n' is mapped to bit “32*n+i” in the comm DBL queue context described in Section 10.5.5.6.

13.2.2.25.29 Transmit Comm Scheduler Queue Doorbell - QTX_COMM_DBLQ_DBELL[DBLQ] (0x002D1400 + 0x4*DBLQ, DBLQ=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TAIL	12:0	0x0	RW	UNDEFINED	**Tail** Defines the first DBLQ DBL that the software prepares for the hardware (it is the last valid DBLQ DBL plus one). The DBLQ Tail is a relative descriptor index to the beginning of the DBLQ ring. This field is applicable for Comms mode only.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.25.30 Transmit Comm Scheduler Queue Context Data - GLCOMM_QTX_CNTX_DATA[n] (0x002D2D40 + 0x4*n, n=0...9; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DATA	31:0	0x0	RW	UNDEFINED	**Data** Comm Transmit Queue context data. Bit 'i' in register 'n' is mapped to bit “32*n+i” in the comm transmit queue context described in Section 10.5.5.2.1.

13.2.2.25.31 Global Transmit Comm Scheduler Quanta Profile - GLCOMM_QUANTA_PROF[n] (0x002D2D68 + 0x4*n, n=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUANTA_SIZE	13:0	0x0	RW	UNDEFINED	**Quanta Size** Configured Quanta size in bytes. Used by hardware for LSO processing and for legacy Queue. When it configures a legacy Queue Quanta size, the value must be configured in 64-byte granularity (The five LS bits must be set to 0).
RESERVED	15:14	00b	RSV	N/A	Reserved.
MAX_CMD	23:16	0x0	RW	UNDEFINED	**Maximum Commands** Max commands generated in a single Quanta. When a specific quanta exceeds this number, the Tx-Queue is disabled and the PF is notified by CSR GL_MDET_TX_TCLAN.
MAX_DESC	29:24	0x0	RW	UNDEFINED	**Maximum Descriptors** Max descriptors in a single Quanta. When a specific quanta exceeds this number, the Tx-Queue is disabled and the PF is notified by CSR GL_MDET_TX_TCLAN.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.25.32 Global Transmit Comm Scheduler Quanta Profile - GLCOMM_PKT_SHAPER_PROF[n] (0x002D2DA8 + 0x4*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PKTCNT	5:0	0x0	RW	UNDEFINED	**Packet Count** Configured Quanta size in packets. Used in Legacy Host interface Queue.
RESERVED	31:6	0x0	RSV	N/A	Reserved.

13.2.2.25.33 Transmit Comm Scheduler Queue Context Control - GLCOMM_QTX_CNTX_CTL (0x002D2DC8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QUEUE_ID	13:0	0x0	RW	UNDEFINED	**Queue ID** Transmit queue ID accessed by the GLCSCD_TXQ_CNTX registers.
RESERVED	15:14	00b	RSV	N/A	Reserved.
CMD	18:16	000b	RW	UNDEFINED	**Command** Command Opcode as follows: 000b = Read operation. 001b = Write operation, update static and dynamic fields. 011b = Reset Transmit queue context state, updates all static fields. 100b = Update static fields, preserving dynamic fields. All other values are reserved.
CMD_EXEC	19	0b	RW	UNDEFINED	**Command Execute** Setting the *CMD_EXEC* flag kicks off the operation.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.25.34 Transmit Comm Scheduler Queue Context Status - GLCOMM_QTX_CNTX_STAT (0x002D2DCC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CMD_IN_PROG	0	0b	RO	N/A	**Command in Progress** Initiating a command to the GLCSCD_TXQ_CTL register (setting the *CMD_EXEC* flag), the device sets the *CMD_IN_PROG* flag. Then, the *CMD_IN_PROG* flag is cleared when the command is completed.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26 PF - LAN Transmit/Receive Registers

13.2.2.26.1 L2 Tag - Enable - PRT_TDPUL2TAGSEN (0x00040BA0; RW)

L2 tags functionality enable per port.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ENABLE	7:0	0x0	RW	UNDEFINED	**Enable** Defines the L2 tags expected on this port.
NONLAST_TAG	15:8	0x8	RW	UNDEFINED	**Non-Last Tags** For each L2 tag, if tag with same eth_type is expected following this tag, set the corresponding bit in this field to "1". Otherwise, set it to zero. Default is 0x04 to support double VLAN. ***Note:*** This field is implemented only in the TDPU version of this register.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.26.2 Transmit DCSP to TC Enforcement - IPv4 - GL_HLP_PRT_IPG_PREAMBLE_SIZE[n] (0x00049240 + 0x4*n, n=0...20; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
IPG_PREAMBLE_SIZE	7:0	0x14	RW	UNDEFINED	**IPG+Preamble Size** IPG+Preamble size for credit update adjustments to scheduler. Configurable per HLP port.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.26.3 Transmit TDPU Scheduler 4 Adjustment Default Recipe - GL_TDPU_PSM_DEFAULT_RECIPE[n] (0x00049294 + 0x4*n, n=0...3; RO)

TDPU default recipe to scheduler credits four adjustments (default recipe and mode per adjustment).

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADD_IPG	0	0b	RW	UNDEFINED	**Add IPG** 1b = The default recipe includes IPG+Preamble (as configured in HLP_PRT_IPG_PREAMBLE size).
SUB_CRC	1	1b	RW	UNDEFINED	**Subtract CRC** 0b = The default recipe subtracts four MAC CRC bytes.
SUB_ESP_TRAILER	2	1b	RW	UNDEFINED	**Subtract ESP Trailer** 0b = The default recipe subtracts ESP trailer length.
INCLUDE_L2_PAD	3	1b	RW	UNDEFINED	**Include L2 Padding** 0b = The default recipe subtracts the number of L2 padding bytes that were in the packet received by the host. 1b = The default recipe adds L2 padding added by the Transmit data processing unit.

Field	Bit(s)	Init.	Type	CFG Policy	Description

DEFAULT_UPDATE_MODE	4	0b	RW	UNDEFINED	**Default Update Mode**
					Default update mode (upon default recipe).
					0b = For update #N, if no recipe is provided, give same update as for update #N-1. For update #0, use default recipe (also add L2 tags and inner VLAN if were inserted by Tx).
					1b = For update #N, if no recipe is provided, use default recipe as configured in this CSR. (also add L2 tags and inner VLAN if were inserted by Tx).

RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.26.4 Global TSO TCP Mask First - GLLAN_TSOMSK_F (0x00049308; RO)

TSO TCP first-segment Flags mask control.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPMSKF	11:0	0x9	RW	UNDEFINED	**TCP Mask First** TCP Flags mask for the first segment in the TSO. Any bit set to one in the *TCPMSKF* field clears the respective TCP flag in the TSO. Bit zero relates to 'FIN' flag, bit one relates to the 'SYN' flag, and so on.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.26.5 Global TSO TCP Mask Middle - GLLAN_TSOMSK_M (0x0004930C; RO)

TSO TCP middle-segments Flags mask control.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPMSKM	11:0	0x89	RW	UNDEFINED	**TCP Mask Middle** TCP Flags mask for the middle segments in the TSO. See *TCPMSKF* for the impact of each bit in the field.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.26.6 Global TSO TCP Mask Last - GLLAN_TSOMSK_L (0x00049310; RO)

TSO TCP last-segment Flags mask control.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCPMSKL	11:0	0x80	RW	UNDEFINED	**TCP Mask Last** TCP Flags mask for the last segment in the TSO. See *TCPMSKF* for the impact of each bit in the field.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.26.7 VF PF Rx-Queue Mapping Table - VPLAN_RX_QTABLE[n,VF] (0x00060000 + 0x800*n + 0x4*VF, n=0...15, VF=0...255; RW)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QINDEX	11:0	0xFFF	RW	UNDEFINED	**Queue Index** Defines the index of VF queue 'n' in the PF queues space, where 'n' is the register index. Setting the *QINDEX* to 0xFFF means that the queue is not valid for the VF. Relevant only if VPLAN_QBASE.*VFQTABLE_ENA* is set.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.26.8 VF PF DB Queue Mapping Table - VPLAN_DB_QTABLE[n,VF] (0x00070000 + 0x800*n + 0x4*VF, n=0...3, VF=0...255; RW)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QINDEX	8:0	0x1FF	RW	UNDEFINED	**Queue Index** Defines the index of VF queue 'n' in the PF queues space, where 'n' is the register index. Setting the QINDEX to 0x1FF means that the queue is not valid for the VF. Relevant only if VPLAN_QBASE.*VFQTABLE_ENA* is set.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.26.9 VF PF Rx-Queue Range - VPLAN_RX_QBASE[VF] (0x00072000 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFFIRSTQ	10:0	0x0	RW	UNDEFINED	**VF First Queue** Defines the base index of VF 'n' within the range of the PF queues, where 'n' is the VF register index. The *VFFIRSTQ* field is meaningful for this VF only if *VFQTABLE_ENA* is cleared.
RESERVED	15:11	0x0	RSV	N/A	Reserved.
VFNUMQ	23:16	0x0	RW	UNDEFINED	**VF Number of Queues** Defines the number of queues allocated to VF 'n' within the range of the PF queues, where 'n' is the VF register index. The *VFNUMQ* is meaningful for this VF only if *VFQTABLE_ENA* is cleared. The value should be set to the number of queues. A value of 0 means 1 queue and a value of 255 means 256 queues.
RESERVED	30:24	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFQTABLE_ENA	31	1b	RW	UNDEFINED	**VSI Queue Table Enable** Selects between contiguous range of queues for this VSI vs. scattered range: 0b = The VSI is assigned a contiguous range starting at *VSIBASE*. 1b = The VSI is assigned a scattered range defined by the VSILAN_QTABLE. ***Note:*** The default of this bit is 1b to keep backward compatibility with the X710/XXV710/XL710.

13.2.2.26.10 VF LAN RXQ Enablement - VPLAN_RXQ_MAPENA[VF] (0x00073000 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RX_ENA	0	0b	RW	UNDEFINED	**Rx Enable** The VPLAN_RX_QTABLE or VPLAN_RX_QBASE for the VF are enabled only when the *RX_ENA* flag is set.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26.11 VF LAN TXQ Enablement - VPLAN_TXQ_MAPENA[VF] (0x00073800 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TX_ENA	0	0b	RW	UNDEFINED	**Tx Enable** The VPLAN_TX_QTABLE or VPLAN_TX_QBASE for the VF are enabled only when the *TX_ENA* flag is set.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26.12 VF PF Rx-Queue Mapping Table - VPDSI_RX_QTABLE[n,VP16] (0x00074C00 + 0x40*n + 0x4*VP16, n=0...15, VP16=0...15; RW)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PAGE_INDEX0	6:0	0x7F	RW	UNDEFINED	**Page Index 0** Defines the index of a 256-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 32-Queues Page.
RESERVED	7	0b	RSV	N/A	Reserved.
PAGE_INDEX1	14:8	0x7F	RW	UNDEFINED	**Page Index 1** Defines the index of a 32-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	15	0b	RSV	N/A	Reserved.
PAGE_INDEX2	22:16	0x7F	RW	UNDEFINED	**Page Index 2** Defines the index of a 32-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	23	0b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PAGE_INDEX3	30:24	0x7F	RW	UNDEFINED	**Page Index 3** Defines the index of a 32-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.26.13 PF Doorbell Queue Allocation - PFLAN_DB_QALLOC (0x00075680; RW)

These registers define the LAN queue pairs allocation to the PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTQ	7:0	0x0	RW	UNDEFINED	**First Queue** The first Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	15:8	0x0	RSV	N/A	Reserved.
LASTQ	23:16	0x0	RW	UNDEFINED	**Last Queue** The last Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	30:24	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**VALID** Indicates that queues are allocated to this PF. For any active PF, this flag must be set.

13.2.2.26.14 PF Completion Queue Allocation - PFLAN_CP_QALLOC (0x00075700; RW)

These registers define the LAN queue pairs allocation to the PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTQ	8:0	0x0	RW	UNDEFINED	**First Queue** The first Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	15:9	0x0	RSV	N/A	Reserved.
LASTQ	24:16	0x0	RW	UNDEFINED	**Last Queue** The last Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	30:25	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**VALID** Indicates that queues are allocated to this PF. For any active PF, this flag must be set.

13.2.2.26.15 Global Receive Queue Control - QRX_CTRL[QRX] (0x00120000 + 0x4*QRX, QRX=0...2047; RW)

The access type of specific fields in this register are determined individually. It is documented per field in the internal registers space.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QENA_REQ	0	0b	RW	UNDEFINED	**Queue Enable Request** Receive queue enable request. Setting this bit the software should poll the *QENA_STAT* flag (in this register) before using the queue. After clearing this flag the software should poll the *QENA_STAT* flag before releasing the memory structures. Once the software changes the state of the *QENA_REQ* flag, it must poll the *QENA_STAT* flag before it is permitted to revert the state of the *QENA_REQ* once again.
FAST_QDIS	1	0b	RW1C	DYNAMIC	**Fast Queue Disable** See Section 10.4.3.1.2.1 for the usage of this flag. This flag is auto-cleared by the hardware.
QENA_STAT	2	0b	RO	N/A	**Queue Enable Status** Receive queue enable status indication. 0b = Indicated that the queue is inactive. 1b = Indicates that the queue is active.
CDE	3	0b	RW	UNDEFINED	**Conditional Drop Enable** When set, temporarily enables drop of packets of this queue passing through a no droppable TC. The dropping starts with "no drop" TC experiencing TO event for packet of this queue. This can be reversed by software/firmware by resetting the *CDS* bit.
CDS	4	0b	RW1C	DYNAMIC	**Conditional Drop Status** When set, packets of this queue passing through a no droppable TC can be dropped if required. Set event - "no drop" TC experiencing TO event for packet of this queue. Clear event - software writes 1 to this bit.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.26.16 VF PF Tx-Queue Mapping Table - VPLAN_TX_QTABLE[n,VF] (0x001C0000 + 0x800*n + 0x4*VF, n=0...15, VF=0...255; RW)

This register affects the VF but exposed only to the parent PF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QINDEX	14:0	0x7FFF	RW	UNDEFINED	**Queue Index** Defines the index of VF queue 'n' in the PF queues space, where 'n' is the register index. Setting the *QINDEX* to 0x7FFF means that the queue is not valid for the VF. Relevant only if VPLAN_QBASE.*VFQTABLE_ENA* is set.
RESERVED	31:15	0x0	RSV	N/A	Reserved.

13.2.2.26.17 VF PF Tx-Queue Range - VPLAN_TX_QBASE[VF] (0x001D1800 + 0x4*VF, VF=0...255; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VFFIRSTQ	13:0	0x0	RW	UNDEFINED	**VF First Queue** Defines the base index of VF 'n' within the range of the PF queues, where 'n' is the VF register index. The VFFIRSTQ field is meaningful for this VSI only if the *VFQTABLE_ENA* flag is cleared.
RESERVED	15:14	00b	RSV	N/A	Reserved.
VFNUMQ	23:16	0x0	RW	UNDEFINED	**VF Number of Queues** Defines the number of queue allocated to VF 'n' within the range of the PF queues, where 'n' is the VF register index. The VFNUMQ field is meaningful for this VSI only if the *VFQTABLE_ENA* flag is cleared. The value should be set to the number of queues -1 (A value of 0 means 1 queue and a value of 255 means 256 queues).
RESERVED	30:24	0x0	RSV	N/A	Reserved.
VFQTABLE_ENA	31	1b	RW	UNDEFINED	**VF Queue Table Enable** Selects between contiguous range of queues for this VSI vs. scattered range: 0b = The VF is assigned a contiguous range starting at *VFFIRSTQ*. 1b = The VF is assigned a scattered range defined by the VFLAN_QTABLE. ***Note:*** The default of this bit is 1b to keep backward compatibility with the X710/XXV710/XL710.

13.2.2.26.18 VF PF Tx-Queue Mapping Table - VPDSI_TX_QTABLE[n,VP16] (0x001D2000 + 0x40*n + 0x4*VP16, n=0...15, VP16=0...15; RW)

This table maps blocks of queues to DSI VFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PAGE_INDEX0	6:0	0x7F	RW	UNDEFINED	**Page Index 0** Defines the index of a 256-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	7	0b	RSV	N/A	Reserved.
PAGE_INDEX1	14:8	0x7F	RW	UNDEFINED	**Page Index 1** Defines the index of a 256-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	15	0b	RSV	N/A	Reserved.
PAGE_INDEX2	22:16	0x7F	RW	UNDEFINED	**Page Index 2** Defines the index of a 256-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	23	0b	RSV	N/A	Reserved
PAGE_INDEX3	30:24	0x7F	RW	UNDEFINED	**Page Index 3** Defines the index of a 256-Queues Page that is associated with the queue (@VF Address Space). The value 0x7F stands for invalid 256-Queues Page.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.26.19 PF Queue Allocation - PFLAN_RX_QALLOC (0x001D2500; RW)

These registers define the LAN Rx-Queues allocation to the PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTQ	10:0	0x0	RW	UNDEFINED	**First Queue** The first LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-2047.
RESERVED	15:11	0x0	RSV	N/A	Reserved.
LASTQ	26:16	0x0	RW	UNDEFINED	**Last Queue** The last LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-2047.
RESERVED	30:27	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** Indicates that queues are allocated to this PF. For any active PF, this flag must be set.

13.2.2.26.20 PF Queue Allocation - PFLAN_TX_QALLOC (0x001D2580; RW)

These registers define the LAN Tx-Queues allocation to the PFs.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FIRSTQ	13:0	0x0	RW	UNDEFINED	**First Queue** The first Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	15:14	00b	RSV	N/A	Reserved.
LASTQ	29:16	0x0	RW	UNDEFINED	**Last Queue** The last Tx LAN Queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-16383.
RESERVED	30	0b	RSV	N/A	Reserved.
VALID	31	0b	RW	UNDEFINED	**Valid** Indicates that queues are allocated to this PF. For any active PF, this flag must be set.

13.2.2.26.21 Global Receive Queue Context - QRX_CONTEXT[n,QRX] (0x00280000 + 0x2000*n + 0x4*QRX, n=0...7, QRX=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXQ_CONTEXT	31:0	0x0	RW	UNDEFINED	**Receive Queues Context** Composed of eight registers per queue. Bit 'i' (i = 0...31) of register 'n' (n=0...7) defines bit "i + 32*n" in the receive queue context as defined in Section 10.4.3.6 and its subsections. Context structure definition includes several reserved fields. These fields must be set to zeros.

13.2.2.26.22 Receive Queue Tail Update - QRX_TAIL[QRX] (0x00290000 + 0x4*QRX, QRX=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TAIL	12:0	0x0	RW	UNDEFINED	**Tail** Defines the first descriptor that the software hands to the hardware (it is the last valid descriptor plus one). The Tail is a relative descriptor index to the beginning of the receive descriptor ring.
RESERVED	31:13	0x0	RSV	N/A	Reserved.

13.2.2.26.23 Global Receive Queue ITR Expire - QRX_ITR[QRX] (0x00292000 + 0x4*QRX, QRX=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NO_EXPR	0	0b	RW	UNDEFINED	**No Expire** When set, each completed descriptor is written immediately to host memory.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26.24 Global RLAN Control 0 - GLLAN_RCTL_0 (0x002941F8; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PXE_MODE	0	1b	RW1C	DYNAMIC	**PXE Mode** When the *PXE_MODE* flag is set, the device fetches and writes back a single descriptor at a time. During nominal performance operation, (non-PXE mode), this flag must be cleared.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26.25 Global RLAN Control 1 - GLLAN_RCTL_1 (0x002941FC; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	11:0	0x0	RSV	N/A	Reserved.
RXMAX_EXPANSION	15:12	0x0	RW	UNDEFINED	**Rx Maximum Expansion** Maximum number of bytes that can be added to a single receive frame by the hardware offload engines. The field is defined in 32-byte granularity. This field must be set to 0.
RESERVED	16	0b	RSV	UNDEFINED	Reserved.
RXDRDCTL	17	0b	RW	UNDEFINED	**Receive Descriptor Read Control** 0b = Read only those descriptors starting after the latest completed one till the end of the cache line. 1b = Always read whole cache lines.
RXDESCRDROEN	18	0b	RW	UNDEFINED	**Rx-Descriptor Read Relaxed Order Enable** Enables relaxed ordering for Rx-Descriptor reads. 0b = Relaxed ordering is disabled for Rx-Descriptor reads. 1b = Relaxed ordering is enabled for Rx-Descriptor reads.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXDATAWRROEN	19	0b	RW	UNDEFINED	**Rx Data Write Relaxed Order Enable** Enables relaxed ordering for Rx data writes. 0b = Relaxed ordering is disabled for Rx data writes. 1b = Relaxed ordering is enabled for Rx data writes.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.26.26 Global PF LAN Recipe - GLLAN_PF_RECIPE[n] (0x0029420C + 0x4*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RECIPE	1:0	00b	RW	UNDEFINED	**Recipe** Recipe field per PF. Register 'n' is associated with PF 'n'.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.26.27 VF LAN TXQ Enablement - VPLAN_DSI_VF_MODE[VP16] (0x002D2C00 + 0x4*VP16, VP16=0...15; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
LAN_DSI_VF_MODE	0	0b	RW	UNDEFINED	**LAN DSI VF Mode** VF[15:0] Mode: 0b = VF is LAN. 1b = VF is DSI. By default, VF[15:0] are LAN.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.26.28 VSI Receive Queue Mapping Table - VSILAN_QTABLE[n,VSI] (0x00440000 + 0x1000*n + 0x4*VSI, n=0...7, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QINDEX_0	10:0	0x0	RW	UNDEFINED	**Queue Index 0** Defines the index of the VSI queue '2*n' in the PF queues space, where 'n' is the register index. The absolute queue index in the device space equals to *QINDEX* plus PFLAN_QALLOC.*FIRSTQ* of the parent PF. Setting the *QINDEX* to 0x7FF means that the queue is not valid.
RESERVED	15:11	0x0	RSV	N/A	Reserved.
QINDEX_1	26:16	0x0	RW	UNDEFINED	**Queue Index 1** Defines the index of the VSI queue '2*n+1' in the PF queues space, where 'n' is the register index. The absolute queue index in the device space equals to *QINDEX* plus PFLAN_QALLOC.*FIRSTQ* of the parent PF. Setting the *QINDEX* to 0x7FF means that the queue is not valid.
RESERVED	31:27	0x0	RSV	N/A	Reserved.

13.2.2.26.29 VSI Queue Control - VSILAN_QBASE[VSI] (0x0044C000 + 0x4*VSI, VSI=0...767; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VSIBASE	10:0	0x0	RW	UNDEFINED	**VSI Base** Defines the base index of VSI 'n' within the range of the PF queues, where 'n' is the VSI register index. The *VSIBASE* is meaningful for this VSI only if the *VSIQTABLE_ENA* is cleared.
VSIQTABLE_ENA	11	0b	RW	UNDEFINED	**VSI Queue Table Enable** Selects between contiguous range of queues for this VSI vs. scattered range: 0b = The VSI is assigned a contiguous range starting at *VSIBASE*. 1b = The VSI is assigned a scattered range defined by the VSILAN_QTABLE.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.27 PF - TimeSync (IEEE 1588) Registers

13.2.2.27.1 Global TimeSync Enable - GLTSYN_ENA[n] (0x00088808 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYN_ENA	0	0b	RW	UNDEFINED	**TimeSync Enable** 0b = The timer is not incremented. 1b = Enables the 1588 Master 'n', where 'n' is the register index.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.27.2 Global Master TimeSync Command - GLTSYN_CMD (0x00088810; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CMD	7:0	0x0	RW	UNDEFINED	**Command** Command to be executed by the master timer that is defined by *SEL_MASTER*. 0x01 = Init the TIME registers. 0x02 = Init the INCVAL registers. 0x03 = Init both the TIME and INCVAL registers. 0x04 = Adjust the TIME registers by the ADJ registers. 0x0C = Adjust the TIME registers after the TIME cross the INIT_TIME registers. 0x80 = Read the TIME registers of both masters to their INIT_TIME registers. All other values re reserved.
SEL_MASTER	8	0b	RW	UNDEFINED	**Select Master** 0b = Select Master 0. 1b = Select Master 1.
RESERVED	31:9	0x0	RSV	N/A	Reserved.

13.2.2.27.3 Global Master TimeSync Command SYNC Control - GLTSYN_CMD_SYNC (0x00088814; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SYNC	1:0	00b	WO	UNDEFINED	**Sync** Setting the *SYNC* field, the SYNC signals are driven to the 2 x master timers and all the PHYs for one clock, and then the field is auto-cleared by the device. The affected timers are defined by the *SEL_MASTER* in the GLTSYN_CMD register. The *SYNC* field can be one of the following options: 00b = Reserved. 01b = Increment the counter by 1 (the LS bit in the GLTSYN_TIME_L register). 10b = Decrement the counter by 1 (the LS bit in the GLTSYN_TIME_L register). 11b = Execute the programmed CMD when the SYNC signals are driven.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.27.4 Global TimeSync Sync Delay - GLTSYN_SYNC_DLAY (0x00088818; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SYNC_DELAY	4:0	0xF	RW	UNDEFINED	**Sync Delay** Delay in 1588 clocks between assertion of the SYNC in the master register until the CMD is forwarded to the master timers. ***Note:*** This value should match the delay on the top level between the SYNC in the master register and the PHY slaves. For HH, this is the delay from SYNC assertion until the actual sampling of the timestamp.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.27.5 Global HH Sync Delay - GLTSYN_HH_DLAY (0x0008881C; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SYNC_DELAY	3:0	0x0	RW	UNDEFINED	**Sync Delay** Delay in 1588 clocks between assertion of the SYNC in the master register until the CMD is forwarded to the master timers. ***Note:*** This value should match the delay on the top level between the SYNC in the master register and the PHY slaves. For HH, this is the delay from SYNC assertion until the actual sampling of the timestamp.
RESERVED	31:4	0x0	RSV	N/A	Reserved.

13.2.2.27.6 Global TimeSync Semaphore - PFTSYN_SEM (0x00088880; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
BUSY	0	0b	RCW	UNDEFINED	**Busy** This flag is used as a semaphore indication between software entities on the same PF or multiple PFs. Reading the *BUSY* flag by software, the bit is auto-set to '1', indicating to other software entities that the hardware resource is busy. Software clears this flag to '0' when the hardware resource is no longer needed.
RESERVED	3:1	000b	RSV	N/A	Reserved.
PF_OWNER	6:4	000b	RO	N/A	**PF Owner** When the *BUSY* flag is set, this field holds the PF that currently owns the logic.
RESERVED	31:7	0x0	RSV	N/A	Reserved.

13.2.2.27.7 Global TimeSync Status 0 - GLTSYN_STAT[n] (0x000888C0 + 0x4*n, n=0...1; RCW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
EVENT0	0	0b	RCW	UNDEFINED	**Event 0** Set to 1b when the EVENT register zero that belongs to the 1588 master 'n' = GLTSYN_EVNT[n,0] captures the time of an input event, where 'n' is the register index.
EVENT1	1	0b	RCW	UNDEFINED	**Event 1** Set to 1b when the EVENT register one that belongs to the 1588 master 'n' = GLTSYN_EVNT[n,1] captures the time of an input event, where 'n' is the register index.
EVENT2	2	0b	RCW	UNDEFINED	**Event 2** Set to 1b when the EVENT register two that belongs to the 1588 master 'n' = GLTSYN_EVNT[n,2] captures the time of an input event, where 'n' is the register index.
RESERVED	3	0b	RSV	N/A	Reserved.
TGT0	4	0b	RCW	UNDEFINED	**Target Time 0** Set to 1b when the target time zero that belongs to the 1588 master 'n' = GLTSYN_TGT[n,0] expires, where 'n' is the register index.
TGT1	5	0b	RCW	UNDEFINED	**Target Time 1** Set to 1b when the target time one that belongs to the 1588 master 'n' = GLTSYN_TGT[n,1] expires, where 'n' is the register index.
TGT2	6	0b	RCW	UNDEFINED	**Target Time 2** Set to 1b when the target time two that belongs to the 1588 master 'n' = GLTSYN_TGT[n,2] expires., where 'n' is the register index.
TGT3	7	0b	RCW	UNDEFINED	**Target Time 3** Set to 1b when the target time three that belongs to the 1588 master 'n' = GLTSYN_TGT[n,3] expires, where 'n' is the register index.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.27.8 Global TimeSync Time Zero - GLTSYN_TIME_0[n] (0x000888C8 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_0	31:0	0x0	RW	UNDEFINED	**TimeSync Time 0** Bits 0...31 of the 96-bit master timer 'n', where 'n' is the register index. In many applications (depending on the 1588 clock and the INCVAL of the timer), this register holds the sub-nanosecond units of the timer.

13.2.2.27.9 Global TimeSync Time Low - GLTSYN_TIME_L[n] (0x000888D0 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_L	31:0	0x0	RW	UNDEFINED	**TimeSync Time Low** Bits 32...63 of the 96-bit master timer 'n', where 'n' is the register index. In many applications (depending on the 1588 clock and the INCVAL of the timer) this register holds the 32 LS bits of the time in nanosecond units.

13.2.2.27.10 Global TimeSync Time High - GLTSYN_TIME_H[n] (0x000888D8 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_H	31:0	0x0	RW	UNDEFINED	**TimeSync Time High** Upper 32 bits of the master timer 'n', where 'n' is the register index.

13.2.2.27.11 Global TimeSync Shadow Time Zero - GLTSYN_SHTIME_0[n] (0x000888E0 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_0	31:0	0x0	RW	UNDEFINED	**TimeSync Time 0** Used for one of the following programming actions of the master timer 'n', where 'n' is the register index. • Init value for the GLTSYN_TIME_0 register at SYNC. • Used as time limit for master adjust action. • Used to sample the GLTSYN_TIME_0 register at SYNC.

13.2.2.27.12 Global TimeSync Shadow Time Low - GLTSYN_SHTIME_L[n] (0x000888E8 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_L	31:0	0x0	RW	UNDEFINED	**TimeSync Time Low** Used for one of the following programming actions of the master timer 'n', where 'n' is the register index: • Init value for the GLTSYN_TIME_L register at SYNC. • Used as time limit for master adjust action. • Used to sample the GLTSYN_TIME_L register at SYNC.

13.2.2.27.13 Global TimeSync Shadow Time High - GLTSYN_SHTIME_H[n] (0x000888F0 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTIME_H	31:0	0x0	RW	UNDEFINED	**TimeSync Time High** Used for one of the following programming actions of the master timer 'n', where 'n' is the register index: • Init value for the GLTSYN_TIME_H register at SYNC. • Used as time limit for master adjust action. • Used to sample the GLTSYN_TIME_H register at SYNC.

13.2.2.27.14 Global TimeSync HH Time Low - GLTSYN_HHTIME_L[n] (0x000888F8 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.28.

13.2.2.27.15 Global TimeSync HH Time High - GLTSYN_HHTIME_H[n] (0x00088900 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.29.

13.2.2.27.16 Global TimeSync Shadow Adjust Low - GLTSYN_SHADJ_L[n] (0x00088908 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADJUST_L	31:0	0x0	RW	UNDEFINED	**Adjust Low** Low 32 bits of the SHADJ register. It can be used as the lower 32-bit init value of the GLTSYN_INCVAL or the lower 32 bits of the adjust by 'N' command. When used for adjust by 'N' command, negative numbers are presented in 2's complement format.

13.2.2.27.17 Global TimeSync Shadow Adjust High - GLTSYN_SHADJ_H[n] (0x00088910 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ADJUST_H	31:0	0x0	RW	UNDEFINED	**Adjust High** High 32 bits of the SHADJ register. It can be used as the lower 32-bit init value of the GLTSYN_INCVAL or the lower 32 bits of the adjust by 'N' command. When used for adjust by 'N' command, negative numbers are presented in 2's complement format.

13.2.2.27.18 Global TimeSync Increment Value Low - GLTSYN_INCVAL_L[n] (0x00088918 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INCVAL_L	31:0	0x0	RW	UNDEFINED	**Increment Value Low** 32 LS bits of the Increment Value added to the 96-bit 1588 master timer for each 1588 clock of the master timer 'n', where 'n' is the register index.

13.2.2.27.19 Global TimeSync Increment Value High - GLTSYN_INCVAL_H[n] (0x00088920 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
INCVAL_H	7:0	0x0	RW	UNDEFINED	**Increment Value Low** 8 MS bits of the Increment Value added to the 96-bit 1588 master timer for each 1588 clock.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.27.20 Global TimeSync Target Time Low - GLTSYN_TGT_L_0[n] (0x00088928 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTGTT_L	31:0	0x0	RW	UNDEFINED	**TimeSync Target Time Low** 32 LS bits of the target time 'm' of an event out in one of the AUX IO signals of the master timer 'n', where 'n', 'm' are the register indexes.

13.2.2.27.21 Global TimeSync Target Time High - GLTSYN_TGT_H_0[n] (0x00088930 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNTGTT_H	31:0	0x0	RW	UNDEFINED	**TimeSync Target Time High** 32 MS bits of the target time 'm' of an event out in one of the AUX IO signals of the master timer 'n', where 'n', 'm' are the register indexes.

13.2.2.27.22 Global TimeSync Target Time Low - GLTSYN_TGT_L_1[n] (0x00088938 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.20.

13.2.2.27.23 Global TimeSync Target Time High - GLTSYN_TGT_H_1[n] (0x00088940 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.21.

13.2.2.27.24 Global TimeSync Target Time Low - GLTSYN_TGT_L_2[n] (0x00088948 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.20.

13.2.2.27.25 Global TimeSync Target Time High - GLTSYN_TGT_H_2[n] (0x00088950 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.21.

13.2.2.27.26 Global TimeSync Target Time Low - GLTSYN_TGT_L_3[n] (0x00088958 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.20.

13.2.2.27.27 Global TimeSync Target Time High - GLTSYN_TGT_H_3[n] (0x00088960 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.21.

13.2.2.27.28 Global TimeSync Event Time Low - GLTSYN_EVNT_L_0[n] (0x00088968 + 0x4*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNEVNT_L	31:0	0x0	RO	N/A	**TimeSync Event Low** 32 LS bits of the sampled event 'm' time. The sampled event is defined by *EVNTLVL* field in the PRTTSYN_AUX register of the master timer 'n', where 'n', 'm' are the register indexes.

13.2.2.27.29 Global TimeSync Event Time High - GLTSYN_EVNT_H_0[n] (0x00088970 + 0x4*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNEVNT_H	31:0	0x0	RO	N/A	**TimeSync Event Low** 32 MS bit of the sampled event 'm' time of a 1588 event defined by the PRTTSYN_AUX register of the master timer 'n', where 'n', 'm' are the register indexes.

13.2.2.27.30 Global TimeSync Event Time Low - GLTSYN_EVNT_L_1[n] (0x00088978 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.28.

13.2.2.27.31 Global TimeSync Event Time High - GLTSYN_EVNT_H_1[n] (0x00088980 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.29.

13.2.2.27.32 Global TimeSync Event Time Low - GLTSYN_EVNT_L_2[n] (0x00088988 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.28.

13.2.2.27.33 Global TimeSync Event Time High - GLTSYN_EVNT_H_2[n] (0x00088990 + 0x4*n, n=0...1; RO)

Field definitions are the same as those defined in Section 13.2.2.27.29.

13.2.2.27.34 Global TimeSync AUX Output Control - GLTSYN_AUX_OUT_0[n] (0x00088998 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
OUT_ENA	0	0b	RW	UNDEFINED	**Output Enable** Synchronized output enablement for the matched TGT register of master timer 'n'. When set to 1b, the synchronized output signal is enabled according to the other parameters in this register.
OUTMOD	2:1	00b	RW	UNDEFINED	**Output Mode** Output signal mode of operation: 00b = Output Level Mode 01b = Flipped Output Mode 10b = Output Pulse Mode 11b = Output Clock Mode The GPIO signals should be set as 1588 output by the GLGEN_GPIO_CTL[n] registers.
OUTLVL	3	0b	RW	UNDEFINED	**Output Level** Output level driven on the IO signal at the Target Time.
INT_ENA	4	0b	RW	UNDEFINED	**Interrupt Enable** At 1b, interrupt is enabled for this event.
RESERVED	7:5	000b	RSV	N/A	Reserved.
PULSEW	11:8	0x0	RW	UNDEFINED	**Pulse Width** Output pulse width for "Output Pulse Mode" equals to 16 x (PULSEW + 1) 1588 clocks.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.27.35 Global TimeSync AUX Output Control - GLTSYN_AUX_OUT_1[n] (0x000889A0 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.34.

13.2.2.27.36 Global TimeSync AUX Output Control - GLTSYN_AUX_OUT_2[n] (0x000889A8 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.34.

13.2.2.27.37 Global TimeSync AUX Output Control - GLTSYN_AUX_OUT_3[n] (0x000889B0 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.34.

13.2.2.27.38 Global TimeSync Clock Out Duration - GLTSYN_CLKO_0[n] (0x000889B8 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TSYNCLKO	31:0	0x0	RW	UNDEFINED	**TimeSync Clock Out** Clock output duration 'm' defined by the units of the GLTSYN_TIME_L register, controlled by master timer 'n' as described in Section 9.7.6.1, where 'n', 'm' are the register indexes.

13.2.2.27.39 Global TimeSync Clock Out Duration - GLTSYN_CLKO_1[n] (0x000889C0 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.38.

13.2.2.27.40 Global TimeSync Clock Out Duration - GLTSYN_CLKO_2[n] (0x000889C8 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.38.

13.2.2.27.41 Global TimeSync Clock Out Duration - GLTSYN_CLKO_3[n] (0x000889D0 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.38.

13.2.2.27.42 Global TimeSync AUX Input Control - GLTSYN_AUX_IN_0[n] (0x000889D8 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
EVNTLVL	1:0	00b	RW	UNDEFINED	**Event Level** Event level on the I/O signal configured as 1588 input for the matched EVENT register of master timer 'n'. It can be set to one of the following options: 00b = Disable 01b = Rising Edge 10b = Falling Edge 11b = Any Transition The GPIO signals should be set as 1588 input by the GLGEN_GPIO_CTL[n] registers.
RESERVED	3:2	00b	RSV	N/A	Reserved.
INT_ENA	4	0b	RW	UNDEFINED	**Interrupt Enable** At 1b, interrupt is enabled for this event.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.27.43 Global TimeSync AUX Input Control - GLTSYN_AUX_IN_1[n] (0x000889E0 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.42.

13.2.2.27.44 Global TimeSync AUX Input Control - GLTSYN_AUX_IN_2[n] (0x000889E8 + 0x4*n, n=0...1; RW)

Field definitions are the same as those defined in Section 13.2.2.27.42.

13.2.2.27.45 Global Hammock Harbor Timer Control - GLHH_ART_CTL (0x000A41D4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ACTIVE	0	0b	WO	UNDEFINED	**Active** The Firmware sets the *ACTIVE* flag to start the Sync procedure with the ART. It is then cleared by the hardware at sequence completion.
TIME_OUT1	1	0b	RO	N/A	**Timeout 1** The Local Sync message is not received from the ART within time limit.
TIME_OUT2	2	0b	RO	N/A	**Timeout 2** The Sync Comp message is not received from the ART within time limit.
RESERVED	31:3	0x0	RSV	N/A	Reserved.

13.2.2.27.46 Global Hammock Harbor ART Time High - GLHH_ART_TIME_H (0x000A41D8; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ART_TIME_H	31:0	0x0	RO	N/A	**ART Time High** Upper 32 bits of ART time collected in the Local Sync message.

13.2.2.27.47 Global Hammock Harbor ART Time Low - GLHH_ART_TIME_L (0x000A41DC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ART_TIME_L	31:0	0x0	RO	N/A	**ART Time Low** Lower 32 bits of ART time collected in the Local Sync message.

13.2.2.27.48 Global Hammock Harbor Sync-Start DATA - GLHH_ART_DATA (0x000A41E0; RO)

This register defines the HH parameters. It is restricted and should not be modified by the Software or the firmware.

Field	Bit(s)	Init.	Type	CFG Policy	Description
AGENT_TYPE	2:0	001b	RW	UNDEFINED	**Agent Type** 001b for Free-Running type.
SYNC_TYPE	3	1b	RW	UNDEFINED	**Sync Type** 1b for SyncCTR based == Type D HH.
MAX_DELAY	7:4	0x8	RW	UNDEFINED	**Max Allow Delay** 0x8 for Round Range Max.
TIME_BASE	11:8	0x1	RW	UNDEFINED	**Time Base** 0x1 for 1 ns units.
RESERVED	31:12	0x0	RW	UNDEFINED	Reserved. Must be set to zero.

13.2.2.27.49 Global Hammock Harbor Semaphore - PFHH_SEM (0x000A4200; RW)

Field definitions are the same as those defined in Section 13.2.2.27.6.

13.2.2.28 PF - Protocol Engine Registers

Registers related to protocol engine functionality.

13.2.2.28.1 Protocol Engine VF CQP Doorbell - VFPE_CQPDB[VF] (0x00500000 + 0x4*VF, VF=0...255; RW)

This register is used to post work to the Protocol Engine Control QP. Software can determine if CQP has pending work by comparing *WQHEAD* to *WQTAIL* after reading the CQPTAIL register. Software must first populate one or more WQEs in the CQP WQ and then put the index of the WQE following the last populated WQE into *WQHEAD* to submit work to CQP.

Field definitions are the same as those defined in Section 13.2.2.28.3.

13.2.2.28.2 Protocol Engine VF CQP Tail - VFPE_CQPTAIL[VF] (0x00500400 + 0x4*VF, VF=0...255; RO)

This register is used to determine how much work the Protocol Engine Control QP has pending. Software can determine if CQP has pending work by comparing the last value written to *WQHEAD* in the CQPDB register to *WQTAIL* after reading this register. This register is updated after the CQP operation is complete.

Field definitions are the same as those defined in Section 13.2.2.28.4.

13.2.2.28.3 Protocol Engine CQP Doorbell - PFPE_CQPDB (0x00500800; RW)

This register is used to post work to the Protocol Engine Control QP. Software can determine if CQP has pending work by comparing *WQHEAD* to *WQTAIL* after reading the CQPTAIL register. Software must first populate one or more WQEs in the CQP WQ and then put the index of the WQE following the last populated WQE into *WQHEAD* to submit work to CQP.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WQHEAD	10:0	0x0	RW	UNDEFINED	**Work Queue Head** Indicates the WQE index of the next WQE that software will post to CQP.
RESERVED	31:11	0x0	RSV	N/A	Reserved.

13.2.2.28.4 Protocol Engine CQP Tail - PFPE_CQPTAIL (0x00500880; RO)

This register is used to determine how much work the Protocol Engine Control QP has pending. Software can determine if CQP has pending work by comparing the last value written to *WQHEAD* in the CQPDB register to *WQTAIL* after reading this register. This register is updated after the CQP operation is complete.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WQTAIL	10:0	0x0	RW	UNDEFINED	**Work Queue Tail** Indicates the WQE index of the next WQE that CQP will process.
RESERVED	30:11	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQP_OP_ERR	31	0b	RW	UNDEFINED	**CQP Operation Error** Indicates that CQP encountered an error processing an operation. If software has multiple requests outstanding to CQP at the time of the error, *WQTAIL* might not indicate the WQE that caused the error.

13.2.2.28.5 Protocol Engine VF CQ Arm - VFPE_CQARM[VF] (0x00502000 + 0x4*VF, VF=0...255; RW)

This register is used to arm a Protocol Engine Completion Queue for events in conjunction with the Completion Queue Doorbell Shadow Area located in host memory. Arming is also frequently referred to as requesting notification for a Completion Queue. Events can be generated when the next completion is generated or when the next completion related to a solicited operation is generated. On read, this register returns the value of 0.

Field definitions are the same as those defined in Section 13.2.2.28.8.

Note: This register is also located in the Protocol Engine doorbell page section of the BAR.

13.2.2.28.6 Protocol Engine VF CQ Ack - VFPE_CQACK[VF] (0x00502400 + 0x4*VF, VF=0...255; RW)

This register is used to acknowledge a completion event for a Protocol Engine Completion Queue. The interrupt processing logic that handles completion events must write this register to enable new events for a completion queue.

Field definitions are the same as those defined in Section 13.2.2.28.9.

13.2.2.28.7 Protocol Engine VF AEQ Allocate - VFPE_AEQALLOC[VF] (0x00502800 + 0x4*VF, VF=0...255; RW)

This register is used to return Asynchronous Event Queue entries back to the hardware for usage.

Field definitions are the same as those defined in Section 13.2.2.28.10.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.28.8 Protocol Engine CQ Arm - PFPE_CQARM (0x00502C00; RW)

This register is used to arm a Protocol Engine Completion Queue for events in conjunction with the Completion Queue Doorbell Shadow Area located in host memory. Arming is also frequently referred to as requesting notification for a Completion Queue. Events can be generated when the next completion is generated or when the next completion related to a solicited operation is generated. On read, this register returns the value of 0.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECQID	18:0	0x0	RW	UNDEFINED	**Protocol Engine Completion Queue ID** Used to arm a Protocol Engine Completion Queue for generating events.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

Note: This register is also located in the Protocol Engine doorbell page section of the BAR.

13.2.2.28.9 Protocol Engine CQ Ack - PFPE_CQACK (0x00502C80; RW)

This register is used to acknowledge a completion event for a Protocol Engine Completion Queue. The interrupt processing logic that handles completion events must write this register to enable new events for a completion queue.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECQID	18:0	0x0	RW	UNDEFINED	**Protocol Engine Completion Queue ID** Used to enable new events for a Protocol Engine Completion Queue.
RESERVED	31:19	0x0	RSV	N/A	Reserved

13.2.2.28.10 Protocol Engine AEQ Allocate - PFPE_AEQALLOC (0x00502D00; RW)

This register is used to return Asynchronous Event Queue entries back to the hardware for usage.

Field	Bit(s)	Init.	Type	CFG Policy	Description
AECOUNT	31:0	0x0	RW	UNDEFINED	**Asynchronous Event Count** Specifies the number of Asynchronous Event Queue entries that have been processed by software and can now be reused by hardware.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

13.2.2.28.11 Protocol Engine CQE Drop Count - GLPE_VFCQEDROPCNT[n] (0x00503000 + 0x4*n, n=0...31; RW1C)

This register counts the number of CQEs that are dropped due to the *Valid* bit being cleared in the CQ Context for this PF.

Field definitions are the same as those defined in Section 13.2.2.28.14.

Note: There are 16 of these registers, one per PF.

13.2.2.28.12 Protocol Engine CEQE Drop Count - GLPE_VFCEQEDROPCNT[n] (0x00503080 + 0x4*n, n=0...31; RW1C)

This register counts the number of CEQEs that are dropped due to the *Valid* bit being cleared in the CEQ Context for this PF.

Field definitions are the same as those defined in Section 13.2.2.28.15.

Note: There are 16 of these registers, one per PF.

13.2.2.28.13 Protocol Engine AEQE Drop Count - GLPE_VFAEQEDROPCNT[n] (0x00503100 + 0x4*n, n=0...31; RW1C)

This register counts the number of AEQEs that are dropped due to the *Valid* bit being cleared in the AEQ Context for this PF.

Field definitions are the same as those defined in Section 13.2.2.28.16.

Note: There are 16 of these registers, one per PF.

13.2.2.28.14 Protocol Engine CQE Drop Count - GLPE_PFCQEDROPCNT[n] (0x00503200 + 0x4*n, n=0...7; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQEDROPCNT	15:0	0x0	RW1C	DYNAMIC	**CQE Drop Count** Counts the number of CQEs that are dropped due to the *Valid* bit being cleared in the CQ Context for this PF.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

Note: There are 16 of these registers, one per PF.

13.2.2.28.15 Protocol Engine CEQE Drop Count - GLPE_PFCEQEDROPCNT[n] (0x00503220 + 0x4*n, n=0...7; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CEQEDROPCNT	15:0	0x0	RW1C	DYNAMIC	**CEQE Drop Count** Counts the number of CEQEs that are dropped due to the *Valid* bit being cleared in the CEQ Context for this PF.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

Note: There are 16 of these registers, one per PF.

13.2.2.28.16 Protocol Engine AEQE Drop Count - GLPE_PFAEQEDROPCNT[n] (0x00503240 + 0x4*n, n=0...7; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
AEQEDROPCNT	15:0	0x0	RW1C	DYNAMIC	**AEQE Drop Count** Counts the number of AEQEs that are dropped due to the *Valid* bit being cleared in the AEQ Context for this PF.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

Note: There are 16 of these registers, one per PF.

13.2.2.28.17 Protocol Engine CQM Func Invalidate Register - GLPE_CQM_FUNC_INVALIDATE (0x00503300; RO)

This register is used to invalidate all CQs and related structures internal to PE pertaining to a specific function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_NUM	2:0	000b	RW	UNDEFINED	**PF Number** Specifies the PF associated with the invalidate command.
VM_VF_NUM	12:3	0x0	RW	UNDEFINED	**VM/VF Number** Specifies the VM or VF associated with the invalidate command.
VM_VF_TYPE	14:13	00b	RW	UNDEFINED	**VM/VF Type** Specifies the VM_VF TYPE of the function associated with the invalidate command.
PMF_ID	20:15	0x0	RW	UNDEFINED	**PMF ID** The PMF to invalidate. This field is only valid for the doorbell array.
RESERVED	28:21	0x0	RSV	N/A	Reserved.
INVALIDATE_TYPE	30:29	00b	RW	UNDEFINED	**Invalidate Type** Specifies what is being invalidated. 00b = Invalidate CQ Cache. 01b = Invalidate doorbell array. 10b = Invalidate CQ Cache and doorbell array. 11b = Reserved.
ENABLE	31	0b	RW	UNDEFINED	**Enable** This bit is set by software to start the invalidate process, and is cleared by hardware when the invalidate process is complete.

13.2.2.28.18 Protocol Engine VF WQE Allocate Register - VFPE_WQEALLOC[VF] (0x00504000 + 0x4*VF, VF=0...255; RW)

This register is used to post work the Protocol Engine Queue Pairs. On read, this register returns the value of 0.

Field definitions are the same as those defined in Section 13.2.2.28.19.

Note: This register is also located in the Protocol Engine doorbell page section of the BAR.

13.2.2.28.19 Protocol Engine WQE Allocate Register - PFPE_WQEALLOC (0x00504400; RW)

This register is used to post work the Protocol Engine Queue Pairs. On read, this register returns the value of 0.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEQPID	17:0	0x0	RW	UNDEFINED	**Protocol Engine Queue Pair ID** This field should be used to notify hardware that new work is available to be processed.
RESERVED	19:18	00b	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
WQE_DESC_INDEX	31:20	0x0	RW	UNDEFINED	**WQE Descriptor Index** Indicates a high 12 bits of the WQE Index in the Send Queue. This field is used to identify a Push Mode message in the head of the SQ. Push Mode message is processed by hardware only if it is in the head of the Send Queue, and otherwise it is dropped and processed when WQE is re-fetched during regular transmit operation. This field is used for the Push Mode Doorbells only. For the regular Doorbells, this field should be treated as reserved, and ignored by hardware.

Note: This register is also located in the Protocol Engine doorbell page section of the BAR.

13.2.2.28.20 Protocol Engine VF Create CQP Status - VFPE_CCQPSTATUS[VF] (0x00508000 + 0x4*VF, VF=0...255; RO)

This register is used to indicate the progress of creating the control QP for a given PCI function. During host software initialization, these bits are initially 0. Each bit is set when the associated step of the initialization process completes.

Field definitions are the same as those defined in Section 13.2.2.28.27.

13.2.2.28.21 Protocol Engine VF Create CQP Low - VFPE_CCQPLOW[VF] (0x00508400 + 0x4*VF, VF=0...255; RW)

This register stores the lower 32 bits of the 64-bit physical address of the Control QP context for its associated PCI function. Under host software control, each PCI function uses its Create Control QP High/Low registers to create its corresponding Control QP. The 64-bit address must always be updated by writing the GLPE_CCQPLOW field last. Writing a 0 to both GLPE_CCQPHIGH and GLPE_CCQLOW destroys the CQP and clears the GLPE_CCQPSTATUS.*CCQP_DONE* bit.

Field definitions are the same as those defined in Section 13.2.2.28.28.

13.2.2.28.22 Protocol Engine VF Create CQP High - VFPE_CCQPHIGH[VF] (0x00508800 + 0x4*VF, VF=0...255; RW)

This register stores the upper 32 bits of the 64-bit physical address of the Control QP context for its associated PCI function.

Field definitions are the same as those defined in Section 13.2.2.28.29.

13.2.2.28.23 Protocol Engine VF IP Config 0 - VFPE_IPCONFIG0[VF] (0x00508C00 + 0x4*VF, VF=0...255; RW)

This register is used to set or view the *IPID* field that the Protocol Engine writes into the IP header. The Protocol Engine increments this value for each outgoing IP datagram.

Field definitions are the same as those defined in Section 13.2.2.28.30.

13.2.2.28.24 Protocol Engine VF CQP Error Codes - VFPE_CQPERRCODES[VF] (0x00509000 + 0x4*VF, VF=0...255; RO)

This register reports errors encountered by CQP when CQ0 is not available. The contents of this register are only valid when the associated CCQPSTATUS.CCQP_ERR bit or CQPTAIL.CQP_ERR bit is set.

Field definitions are the same as those defined in Section 13.2.2.28.31.

13.2.2.28.25 Protocol Engine VF TCP Now Timer - VFPE_TCPNOWTIMER[VF] (0x00509400 + 0x4*VF, VF=0...255; RO)

This register is a readable register, which contains *TCP_NOW*, a 32-bit counter that provides the TCP time measurement for the all of the timers. It is also used to calculate the TS Value sent in the TCP timestamp option, *TCP_NOW* is added to *TSVAL_TICK_DELTA* to form the TS Value.

Field definitions are the same as those defined in Section 13.2.2.28.32.

13.2.2.28.26 Protocol Engine VF MRTE Index Mask - VFPE_MRTEIDXMASK[VF] (0x00509800 + 0x4*VF, VF=0...255; RO)

This register is used to change the number of significant bits to be used as the Memory Region Table index. The maximum number of bits that may be used is 22, and the minimum number of bits is 14. The number of bits should never be larger than the number of HMC MRTE objects defined for the HMC PM function associated with the PCI function. The remaining bits of the driver portion of the STag are randomized by the driver.

Field definitions are the same as those defined in Section 13.2.2.28.33.

13.2.2.28.27 Protocol Engine Create CQP Status - PFPE_CCQPSTATUS (0x0050A000; RO)

This register is used to indicate the progress of creating the control QP for a given PCI function. During host software initialization, these bits are initially 0. Each bit is set when the associated step of the initialization process completes.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CCQP_DONE	0	0b	RW	UNDEFINED	**Create CQP Done** 0b = Indicates that CQP has not been created. 1b = Indicates that the Create CQP operation triggered by writing to PECCQPHIGH and PECCQPLOW has completed.
RESERVED	3:1	000b	RSV	N/A	Reserved.
HMC_PROFILE	6:4	000b	RW	UNDEFINED	**HMC Profile** Specifies the HMC resource profile that is active. 000b = Reserved 001b = Default 010b = SR-IOV VF Primary 011b = SR-IOV Even Distribution All other values are reserved.
RESERVED	15:7	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMA_EN_VFS	21:16	0x0	RW	UNDEFINED	**RDMA Enabled VFs** Specifies the number of RDMA enabled VFs allocated in the HMC Resource Profile.
RESERVED	30:22	0x0	RSV	N/A	Reserved.
CCQP_ERR	31	0b	RW	UNDEFINED	**Create CQP Error** Indicates that CQP encountered an error processing the last Create CQP request. This bit is reset when CQP is destroyed.

13.2.2.28.28 Protocol Engine Create CQP Low - PFPE_CCQPLOW (0x0050A080; RW)

This register stores the lower 32 bits of the 64-bit physical address of the Control QP context for its associated PCI function. Under host software control, each PCI function uses its Create Control QP High/Low registers to create its corresponding Control QP. The 64-bit address must always be updated by writing the GLPE_CCQPLOW field last. Writing a 0 to both GLPE_CCQPHIGH and GLPE_CCQLOW destroys the CQP and clears the GLPE_CCQPSTATUS.*CCQP_DONE* bit.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECCQPLOW	31:0	0x0	RW	UNDEFINED	**Protocol Engine Create CQP Low** Least significant bits of the Control QP context physical address in host memory.

13.2.2.28.29 Protocol Engine Create CQP High - PFPE_CCQPHIGH (0x0050A100; RW)

This register stores the upper 32 bits of the 64-bit physical address of the Control QP context for its associated PCI function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECCQPHIGH	31:0	0x0	RW	UNDEFINED	**Protocol Engine Create CQP High** Most significant bits of the Control QP context physical address in host memory.

13.2.2.28.30 Protocol Engine IP Config 0 - PFPE_IPCONFIG0 (0x0050A180; RW)

This register is used to set or view the *IPID* field that the Protocol Engine writes into the IP header. The Protocol Engine increments this value for each outgoing IP datagram.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEIPID	15:0	0x0	RW	UNDEFINED	**Protocol Engine IP ID** Specifies the IP Identification field used for IPv4 IP Header Generation. This register is initialized by firmware or driver, and incremented by hardware with each IPv4 datagram transmitted by PE both UDA and iWARP on the given PCI function.

Field	Bit(s)	Init.	Type	CFG Policy	Description
USEENTIREIDRANGE	16	0b	RW	UNDEFINED	**Use Entire ID Range** Specifies that the Protocol Engine should use the entire 16-bit range for the IPID value. When this bit is not set, only the lower 15 bits are used, and the upper bit is set to the value in PEIPID[15].
UDP_SRC_PORT_MASK_EN	17	0b	RW	UNDEFINED	**UDP Source Port Mask Enable** When this bit is set (enabled), for RoCE v2 QPs on the associated function, the *UDP Source Port* field is interpreted as a entropy mask, except if *UDP Source Port* is 0x0 (copied directly to packet in this case). For every "0" bit in the *UDP Source Port* field, the respective UDP packet header bit is randomized based on associated Destination QP ID and Destination IP Address (from Address Handle). For every "1" bit in the *UDP Source Port* field, the respective bit is copied directly as-is to the UDP packet header. This allows for selecting up to any 15 bits of UDP source port for entropy inclusion in the packet. The intent is to enable UDP ECMP capability in the network fabric, where supported in connecting equipment. When this bit is clear (disabled), the *UDP Source Port* field is simply copied as-is per software QP configuration to the UDP packet header.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.28.31 Protocol Engine CQP Error Codes - PFPE_CQPERRCODES (0x0050A200; RO)

This register reports errors encountered by CQP when CQ0 is not available. The contents of this register are only valid when the associated CCQPSTATUS.*CCQP_ERR* bit or CQPTAIL.*CQP_ERR* bit is set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
CQP_MINOR_CODE	15:0	0x0	RW	UNDEFINED	**CQP Minor Code** Minor code that would have been reported in a CQP Completion.
CQP_MAJOR_CODE	31:16	0x0	RW	UNDEFINED	**CQP Major Code** Major code that would have been reported in a CQP Completion.

13.2.2.28.32 Protocol Engine TCP Now Timer - PFPE_TCPNOWTIMER (0x0050A280; RO)

This register is a readable register, which contains *TCP_NOW*, a 32-bit counter that provides the TCP time measurement for the all of the timers. It is also used to calculate the TS Value sent in the TCP timestamp option, *TCP_NOW* is added to *TSVAL_TICK_DELTA* to form the TS Value.

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCP_NOW	31:0	0x0	RO	N/A	**TCP Now** Current value of TCP_NOW.

13.2.2.28.33 Protocol Engine MRTE Index Mask - PFPE_MRTEIDXMASK (0x0050A300; RO)

This register is used to change the number of significant bits to be used as the Memory Region Table index. The maximum number of bits that may be used is 22, and the minimum number of bits is 14. The number of bits should never be larger than the number of HMC MRTE objects defined for the HMC PM function associated with the PCI function. The remaining bits of the driver portion of the STag are randomized by the driver.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRTEIDXMASKBITS	4:0	0x0	RW	UNDEFINED	**MRTE Index Mask Bits** Specifies the number of bits to be used for the MRTE index from the driver portion of the STag. The remaining bits (24 - *MRTEIDEMASKBITS*) are randomized by the driver. The minimum value for this field is 14 and the maximum is 22. Values outside of this range are normalized to 14 or 22 by the hardware.
RESERVED	31:5	0x0	RSV	N/A	Reserved.

13.2.2.28.34 Protocol Engine TCP Now 50us Count - GLPE_VFTCPNOW50USCNT[n] (0x0050B300 + 0x4*n, n=0...31; RO)

Tracks the number of TCPNOW ticks which occur in 50 μs.

Field definitions are the same as those defined in Section 13.2.2.28.39.

13.2.2.28.35 Protocol Engine FLM XMIT Allocate Error - GLPE_VFFLMXMITALLOCERR[n] (0x0050B400 + 0x4*n, n=0...31; RO)

This register holds a count of the XMIT free list allocation errors.

Field definitions are the same as those defined in Section 13.2.2.28.40.

13.2.2.28.36 Protocol Engine FLM Q1 Allocate Error - GLPE_VFFLMQ1ALLOCERR[n] (0x0050B480 + 0x4*n, n=0...31; RO)

This register holds a count of the Q1 free list allocation errors.

Field definitions are the same as those defined in Section 13.2.2.28.41.

13.2.2.28.37 Protocol Engine FLM Read Response Allocate Error - GLPE_VFFLMRRFALLOCERR[n] (0x0050B500 + 0x4*n, n=0...31; RO)

This register holds a count of the Read Response free list allocation errors.

Field definitions are the same as those defined in Section 13.2.2.28.42.

13.2.2.28.38 Protocol Engine FLM Out of Order Send Completion (OOISC) Allocate Error - GLPE_VFFLMOOISCALLOCERR[n] (0x0050B580 + 0x4*n, n=0...31; RO)

This register holds a count of the Read Response free list allocation errors.

Field definitions are the same as those defined in Section 13.2.2.28.43.

13.2.2.28.39 Protocol Engine TCP Now 50us Count - GLPE_PFTCPNOW50USCNT[n] (0x0050B8C0 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
CNT	31:0	0x0	RW	UNDEFINED	**Count** Tracks the number of TCPNOW ticks which occur in 50 μs.

13.2.2.28.40 Protocol Engine FLM XMIT Allocate Error - GLPE_PFFLMXMITALLOCERR[n] (0x0050B900 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERROR_COUNT	15:0	0x0	RO	N/A	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.28.41 Protocol Engine FLM Q1 Allocate Error - GLPE_PFFLMQ1ALLOCERR[n] (0x0050B920 + 0x4*n, n=0...7; RO)

This register holds a count of the Q1 free list allocation errors.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERROR_COUNT	15:0	0x0	RO	N/A	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.28.42 Protocol Engine FLM Read Response Allocate Error - GLPE_PFFLMRRFALLOCERR[n] (0x0050B940 + 0x4*n, n=0...7; RO)

This register holds a count of the Read Response free list allocation errors.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERROR_COUNT	15:0	0x0	RO	N/A	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.28.43 Protocol Engine FLM Out of Order Send Completion (OOISC) Allocate Error - GLPE_PFFLMOOISCALLOCERR[n] (0x0050B960 + 0x4*n, n=0...7; RO)

This register holds a count of the Read Response free list allocation errors.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ERROR_COUNT	15:0	0x0	RO	N/A	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.28.44 Protocol Engine CPU Status 0 - GLPE_CPUSTATUS0 (0x0050BA5C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECPUSTATUS0	31:0	0x0	RW	UNDEFINED	**Protocol Engine CPU Status 0** Provides the Host with the current status of one of the Protocol Engine internal CPUs. Typically, the exclusive writer of this register is CQP, and the exclusive reader is Host software, but other usage models are supported. ***Note:*** Details on the meaning of each status code are not defined in this specification and may change with firmware revision.

13.2.2.28.45 Protocol Engine CPU Status 1 - GLPE_CPUSTATUS1 (0x0050BA60; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECPUSTATUS1	31:0	0x0	RW	UNDEFINED	**Protocol Engine CPU Status 1** Provides the Host with the current status of one of the Protocol Engine internal CPUs. Typically, the exclusive writer of this register is TEP, and the exclusive reader is Host software, but other usage models are supported. ***Note:*** Details on the meaning of each status code are not defined in this specification and may change with firmware revision.

13.2.2.28.46 Protocol Engine CPU Status 2 - GLPE_CPUSTATUS2 (0x0050BA64; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PECPUSTATUS2	31:0	0x0	RW	UNDEFINED	**Protocol Engine CPU Status 2** Provides the Host with the current status of one of the Protocol Engine internal CPUs. Typically, the exclusive writer of this register is OOP, and the exclusive reader is Host software, but other usage models are supported. ***Note:*** Details on the meaning of each status code are not defined in this specification and may change with firmware revision.

13.2.2.28.47 PEPM Control - GLPE_PEPM_CTRL (0x0050C000; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEPM_ENABLE	0	0b	RW	UNDEFINED	**PEPM Enable** 0b = PEPM is disabled, pepm_fc is driven to 1's, and interfaces are blocked/NAK'ed. 1b = PEPM is enabled, pepm_fc behaves normally.
RESERVED	7:1	0x0	RSV	N/A	Reserved.
PEPM_HALT	8	0b	RW	UNDEFINED	**PEPM Halt** 0b = PEPM is not halted, pepm_fc behaves normally. 1b = PEPM is halted, pepm_fc bits driven to '0', and no credits allocated or returned.
RESERVED	15:9	0x0	RSV	N/A	Reserved.
PEPM_PUSH_MARGIN	23:16	0x25	RW	UNDEFINED	**PEPM Push Margin** Used to calculate when to NAK a PUSH request. This value is subtracted from the *PQID* threshold value before comparing to the incoming MDQ credit request.
RESERVED	31:24	0x0	RSV	N/A	Reserved.

13.2.2.28.48 PEPM Dealloc - GLPE_PEPM_DEALLOC (0x0050C004; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDQ_CREDITS	13:0	0x0	RW	UNDEFINED	**MDQ Credits** The number of MDQ credits to deallocate. Must be non-zero if *PSQ_CREDITS*=0.
PSQ_CREDITS	18:14	0x0	RW	UNDEFINED	**PSQ Credits** The number of PSQ credits to deallocate. Must be non-zero if *MDQ_CREDITS*=0.
PQID	27:19	0x0	RW	UNDEFINED	**PQ ID** The PQ ID associated with the credits to deallocate. Must be <= max number of PQs supported for the current configuration.
PORT	30:28	000b	RW	UNDEFINED	**Port** The port associated with the credits to deallocate. Must be <= the max number of ports supported for the current configuration.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DEALLOC_RDY	31	0b	SC	UNDEFINED	**Deallocate Ready** This bit should be set to initiate a request to deallocate the number of MDQ/PSQ credits indicated in this register. This bit is cleared by hardware to indicate that the credits have been deallocated. This register must never be changed when the *DEALLOC_RDY* bit is set, or your results will be indeterminate.

13.2.2.28.49 PEPM PSQ Count - GLPE_PEPM_PSQ_COUNT (0x0050C020; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEPM_PSQ_COUNT	15:0	0x0	RW	UNDEFINED	**PEPM PSQ Count** Indicates the number of allocated PSQ credits per port.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.28.50 PEPM PSQ/MDQ Count - PRT_PEPM_COUNT[n] (0x0050C040 + 0x4*n, n=0...511; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEPM_PSQ_COUNT	4:0	0x0	RW	UNDEFINED	**PEPM PSQ Count** The current count for the number of entries on the PSQ (Packet Scheduling Queue) for the PQ. This value is incremented by allocate requests and decremented by deallocate requests.
RESERVED	15:5	0x0	RSV	N/A	Reserved.
PEPM_MDQ_COUNT	29:16	0x0	RW	UNDEFINED	**PEPM MDQ Count** The current count for the number of entries on the MDQ (Metadata Queue) for the PQ. This value is incremented by allocate requests and decremented by deallocate requests.
RESERVED	31:30	0x0	RSV	N/A	Reserved.

13.2.2.28.51 PEPM PQ Threshold - GLPE_PEPM_THRESH[n] (0x0050C840 + 0x4*n, n=0...511; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PEPM_PSQ_THRESH	4:0	0x0	RW	UNDEFINED	**PEPM PSQ Threshold** The threshold for the PSQ (Packet Scheduling Queue) for the PQ. This value is compared against the *PSQ_COUNT* to determine if the allocation request is successful.
RESERVED	15:5	0x0	RSV	N/A	Reserved.
PEPM_MDQ_THRESH	29:16	0x0	RW	UNDEFINED	**PEPM MDQ Threshold** The threshold for the MDQ (Metadata Queue) for the PQ. This value is compared against the *MDQ_COUNT* to determine if the allocation request is successful.
RESERVED	31:30	0x0	RSV	N/A	Reserved.

13.2.2.28.52 PE Push PEPM - GLPE_PUSH_PEPM (0x0053241C; RO)

Credit values for Push requests from PEPM.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDQ_CREDITS	7:0	0x29	RW	UNDEFINED	**MDQ Credits** The number of credits Push requests from PEPM for a Push WQE doorbell.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.28.53 MDQ Base - GLPE_MDQ_BASE[n] (0x00536000 + 0x4*n, n=0...511; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDOC_INDEX	27:0	0x0	RW	UNDEFINED	**MDOC Index** MDOC base index for this Metadata Queue. The MDQ starts at this index.
RESERVED	31:28	0x0	RSV	N/A	Reserved.

13.2.2.28.54 MDQ Size - GLPE_MDQ_SIZE[n] (0x00536800 + 0x4*n, n=0...511; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDQ_SIZE	13:0	0x0	RW	UNDEFINED	**MDQ Size** Size of MDQ for this PQ. The MDQ wraps at index=base+size.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.28.55 MDQ Pointer - GLPE_MDQ_PTR[n] (0x00537000 + 0x4*n, n=0...511; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDQ_HEAD	13:0	0x0	RW	UNDEFINED	**MDQ Head** Head pointer for Metadata Queue objects in MDOC.
RESERVED	15:14	00b	RSV	N/A	Reserved.
MDQ_TAIL	29:16	0x0	RW	UNDEFINED	**MDQ Tail** Tail pointer for Metadata Queue objects in MDOC.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.29 PF - Manageability Registers

13.2.2.29.1 MNG FW RAM Status Registers - GL_MNG_FW_RAM_STAT (0x0008309C; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FW_RAM_RST_STAT	0	0b	RO	N/A	**Firmware RAM Reset State** Set by firmware and cleared when RAM is initialized: 1. POR reset. 2. EMPR followed ECC reset in EMP memories.
MNG_MEM_ECC_ERR	1	0b	RO	N/A	**MNG Memory EXX Error** ECC error in one of MNG memories. Should be cleaned by firmware.
RESERVED	31:2	0x0	RSV	N/A	Reserved.

13.2.2.29.2 Firmware Reset Count - GL_FWRESETCNT (0x00083100; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
FWRESETCNT	31:0	0x0	RO	N/A	**Firmware Resets Count** Updated by Hardware. Saturates at 0xFFFF,FFFF.

13.2.2.29.3 SHA Extend Value - GL_MNG_SHA_EXTEND[n] (0x00083120 + 0x4*n, n=0...7; RO)

Can be written (by firmware) only once per EMP reset assertion.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_MNG_SHA_EXTEND	31:0	0x0	RO	UNDEFINED	**MNG SHA Extend** SHA value calculated on signed image.

13.2.2.29.4 SHA Extend Value Status - GL_MNG_SHA_EXTEND_STATUS (0x00083148; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
STAGE	2:0	000b	RW	UNDEFINED	**Stage** Firmware load SHA reflected in registers: 000b = No value. 001b = ROM version (in GL_MNG_SHA_EXTEND_ROM). 010b = Mini-loader SHA (in GL_MNG_SHA_EXTEND_ROM). 011b = Mini-loader SHA (no Full FW) (in GL_MNG_SHA_EXTEND_ROM). 100b = Full firmware SHA (in GL_MNG_SHA_EXTEND) and Mini-loader SHA (in GL_MNG_SHA_EXTEND_ROM). All other values are reserved.
RESERVED	29:3	0x0	RSV	UNDEFINED	Reserved.
FW_HALTED	30	0b	RW	UNDEFINED	**Firmware Halted** If set, firmware load process was halted before completion.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DONE	31	0b	RW	UNDEFINED	**Done** If set, indicates this is the final version of GL_MNG_SHA_EXTEND expected.

13.2.2.29.5 SHA ROM Extend Value - GL_MNG_SHA_EXTEND_ROM[n] (0x00083160 + 0x4*n, n=0...7; RO)

Can be written (by firmware) only once per EMP reset assertion.

Field	Bit(s)	Init.	Type	CFG Policy	Description
GL_MNG_SHA_EXTEND_ROM	31:0	0x0	RO	UNDEFINED	**MNG SHA Extend ROM** SHA value calculated on signed image.

13.2.2.29.6 Hardware Arbitration Control - GL_MNG_HWARB_CTRL (0x000B6130; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
NCSI_ARB_EN	0	0b	RW	UNDEFINED	**NC-SI Arbitration Enable** Hardware Arbitration Enable. If this bit is set, it is assumed the NCSI_ARB_IN and NCSI_ARB_OUT are connected to a Hardware arbitration ring. Otherwise, the NCSI_ARB_IN pin is pulled up internally.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.29.7 Firmware Status - GL_MNG_FWSM (0x000B6134; RO)

This register reflects the firmware load status. All the bits in the registers are RW bits and the firmware implements the functionality. Bits 15:0 are reset by EMP reset.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FW_MODES	1:0	00b	RW	UNDEFINED	**Firmware Modes** Indicate in which mode the firmware operates: 00b = Normal Mode 01b = Debug mode 10b = Recovery Mode 11b = Debug + Recovery mode.
RESERVED	9:2	0x0	RW	N/A	Reserved.
EEP_RELOAD_IND	10	0b	RW	UNDEFINED	**EEP Reload Indication** NVM reloaded indication. Set to 1b after firmware reloads the NVM configuration after a Core reset. Cleared by firmware once the first AQ command is received from one of the drivers.
RESERVED	15:11	0x0	RW	N/A	Reserved.
PCIR_AL_FAILURE	16	0b	RW	UNDEFINED	**PCIR Auto-Load Failure** A PCI Reset is requested
POR_AL_FAILURE	17	0b	RW	UNDEFINED	**POR Auto-Load Failure** A Power-on Reset is requested.
RESERVED	18	0b	RW	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EXT_ERR_IND	24:19	0x0	RW	UNDEFINED	**External Error Indication** Firmware writes here the reason that the firmware operation has stopped. Possible values are: 0x00 = No error 0x01 = Parser module failed 0x02 = Switch module failed. 0x03 = Scheduler module failed. 0x04 = DCB module failed 0x05 = Link module failed 0x06 = LLDP module failed 0x07 = Manage module failed. 0x08 = ACL module failed 0x09 = Flow director/RSS module failed 0x3E = Mini-loader failed (If set, devices is in blank flash programming.) 0x3F = ROM process failure (if set, devices is in blank flash programming.) All other values are reserved. ***Note:*** Following error detection and GL_MNG_FWSM.*EXT_IND_ERR* update, the PFINT_ICR0.*ADMINQ* bit is set and an interrupt is sent to the Host. However, when values of 0x0 is placed in this field, the PFINT_ICR0.*ADMINQ* bit is not set and an interrupt is not generated.
RESERVED	31:25	0x0	RW	N/A	Reserved.

13.2.2.29.8 General FW Debug Registers - GENERAL_MNG_FW_DBG_CSR[n] (0x000B6180 + 0x4*n, n=0...9; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
GENERAL_FW_DBG	31:0	0x0	RW	UNDEFINED	**General Firmware Debug** All-purpose general firmware debug.

13.2.2.29.9 Management Ethernet Type Filters - PRT_MNG_METF[n] (0x00214120 + 0x20*n, n=0...3; RO)

The METF registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets (see Section 12.4).

Reset - The METF registers are cleared on LAN_PWR_GOOD only. The initial values for this register might be loaded from the EEPROM after power-up reset.

Field	Bit(s)	Init.	Type	CFG Policy	Description
ETYPE	15:0	0x0	RW	UNDEFINED	**EtherType** EtherType value to be compared against the L2 EtherType field in the Rx packet. ***Note:*** Appears in Little Endian order (high byte first on the wire).
RESERVED	29:16	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
POLARITY	30	0b	RW	UNDEFINED	**Polarity** 0b = Positive filter - Filter enters the decision filters if a match occurred. 1b = Negative filter - Filter enters the decision filters if a match did not occur.
RESERVED	31	0b	RSV	N/A	Reserved.

13.2.2.29.10 Manageability IPv4 Address Filter - PRT_MNG_MIPAF4[n] (0x002141A0 + 0x20*n, n=0...3; RO)

The Manageability IPv6 Address Filter register stores IPv4 Addresses for manageability filtering.

Note: These registers should be written in network order.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIPAF	31:0	0x0	RW	UNDEFINED	**Manageability IP Address Filters** For each n, m, m=0...3, n=0...3, MIPAF[m,n] register holds DWord `n' of IPv6 filter `m' (4 x IPv6 filters).

13.2.2.29.11 Manageability MAC Address High - PRT_MNG_MMAH[n] (0x00214220 + 0x20*n, n=0...3; RO)

These registers contain the upper bits of the 48-bit Ethernet address. The complete address is {MMAH,MMAL}. The MMAH registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets (see Section 12.4).

The initial values for this register can be loaded from the EEPROM after power-up reset or firmware reset.

Note: The MMAH.*MMAH* field should be written in network order.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MMAH	15:0	0x0	RW	UNDEFINED	**Manageability MAC Address High** The upper 16 bits of the 48-bit Ethernet address. ***Note:*** Appears in Big Endian order (MS byte of MMAH is last on the wire).
RESERVED	31:16	0x0	RSV	N/A	Reserved. Reads as 0. Ignored on write.

13.2.2.29.12 Manageability MAC Address Low - PRT_MNG_MMAL[n] (0x002142A0 + 0x20*n, n=0...3; RO)

These registers contain the lower bits of the 48-bit Ethernet address. The MMAL registers are written by the internal firmware and are not accessible to the host for writing. The registers are used to filter manageability packets (see Section 12.4).

Reset - The MMAL registers are cleared on LAN_PWR_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset.

Note: The MMAH.*MMAL* field should be written in network order.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MMAL	31:0	0x0	RW	UNDEFINED	**Manageability MAC Address Low** The lower 32 bits of the 48-bit Ethernet address. ***Note:*** Appears in Big Endian order (LS byte of MMAL is first on the wire).

13.2.2.29.13 Management Flex UDP/TCP Ports - PRT_MNG_MFUTP[n] (0x00214320 + 0x20*n, n=0...15; RO)

Each 32-bit register (n=0...15) refers to one UDP/TCP port filter.

The MFUTP registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets (see Section 12.4).

Reset - The MFUTP registers are cleared on LAN_PWR_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset.

Note: The *MFUTP_N* fields should be written in network order.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MFUTP_N	15:0	0x0	RW	UNDEFINED	**Management Flex UDP/TCP Ports n** n-th Management Flex UDP/TCP port.
UDP	16	0b	RW	UNDEFINED	**UDP** Match if port is UDP
TCP	17	0b	RW	UNDEFINED	**TCP** Match if port is TCP
SOURCE_DESTINATION	18	0b	RW	UNDEFINED	**Source/Destination** 0b = Compare Destination port. 1b = Compare Source port.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.2.29.14 Manageability IPv6 Address Filter - PRT_MNG_MIPAF6[n] (0x00214520 + 0x20*n, n=0...15; RO)

The Manageability IPv6 Address Filter register stores IPv6 Addresses for manageability filtering.

Note: These registers should be written in network order.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIPAF	31:0	0x0	RW	UNDEFINED	**Manageability IP Address Filters** For each n, m, m=0...3, n=0...3, MIPAF[m,n] register holds DWord `n' of IPv6 filter `m' (4 x IPv6 filters).

13.2.2.29.15 Management Control Register - PRT_MNG_MANC (0x00214720; RO)

The MANC register can be written by the BMC and is not accessible to the host for writing.

Field	Bit(s)	Init.	Type	CFG Policy	Description
FLOW_CONTROL_DISCARD	0	0b	RW	UNDEFINED	**Flow Control Discard** 0b = Apply filtering rules to packets with Flow Control EtherType. 1b = Discard packets with Flow Control EtherType. ***Note:*** Flow Control EtherType is 0x8808.
NCSI_DISCARD	1	0b	RW	UNDEFINED	**NC-SI Discard** 0b = Apply filtering rules to packets with NC-SI EtherType. 1b = Discard packets with NC-SI EtherType. ***Note:*** NC-SI EtherType is 0x88F8.
RESERVED	16:2	0x0	RSV	N/A	Reserved.
RCV_TCO_EN	17	0b	RW	UNDEFINED	**Receive TCO Packets Enabled** When this bit is set, it enables the receive flow to the manageability block. This bit should be set only if at least one of MANC.*EN_BMC2OS* or MANC.*EN_BMC2NET* bits are set
RESERVED	24:18	0x0	RSV	N/A	Reserved.
FIXED_NET_TYPE	25	0b	RW	UNDEFINED	**Fixed Next Type** 0b = Both tagged and un-tagged packets can be forwarded to manageability engine. 1b = Only packets matching the net type defined by the *NET_TYPE* field pass to manageability.
NET_TYPE	26	0b	RW	UNDEFINED	**Net Type** 0b = Pass only un-tagged packets. 1b = Pass only VLAN tagged packets. Valid only if *FIXED_NET_TYPE* is set.
RESERVED	27	0b	RSV	N/A	Reserved.
EN_BMC2OS	28	0b	RW	UNDEFINED	**Enable BMC-to-OS and OS-to-BMC Traffic** 0b = The BMC cannot communicate with the OS. 1b = The BMC can communicate with the OS. When cleared, the BMC traffic is not forwarded to the OS, even if the Host address filtering indicates that it should. When cleared, the OS traffic is not forwarded to the BMC, even if the manageability decision filters indicates it should. This bit does not impact the BMC to Network traffic. ***Note:*** • Initial value loaded according to value of Port n traffic types field in NVM. • Bit reflects internal management Aux register bit.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EN_BMC2NET	29	0b	RW	UNDEFINED	**Enable BMC-to-network and network-to-BMC Traffic** 0b = The BMC can not communicate with the network. 1b = The BMC can communicate with the network When cleared, the BMC traffic is not forwarded to the network and the network traffic is not forwarded to the BMC, even if the decision filters indicates it should. This bit does not impact the host-to-BMC traffic. ***Notes:*** • Initial value loaded according to value of Port n traffic types field in NVM. • Bit reflects internal management Aux register bit. • This bit can change while the host is sending or receiving traffic.
RESERVED	31:30	00b	RSV	N/A	Reserved.

13.2.2.29.16 Management Only Traffic Register - PRT_MNG_MNGONLY (0x00214740; RO)

The MNGONLY register allows exclusive filtering of certain type of traffic to the BMC. Exclusive filtering enables the BMC to define certain packets that are forwarded to the BMC but not to the host. The packets are not forwarded to the host even if they pass the host L2 filtering process.

Each manageability decision filter (MDEF and MDEF_EXT) has a corresponding bit in the MNGONLY register. When a manageability decision filter (MDEF and MDEF_EXT) forwards a packet to manageability, it might also block the packet from being forwarded to the host if the corresponding *MNGONLY* bit is set.

Field	Bit(s)	Init.	Type	CFG Policy	Description
EXCLUSIVE_TO_MANAGEABILITY	7:0	0x0	RW	UNDEFINED	**Exclusive to Manageability** When set, indicates that packets forwarded by the manageability filters to manageability are not sent to the host. Bits 0...7 correspond to decision rules defined in registers MDEF[0...7] and MDEF_EXT[0...7].
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.29.17 Manageability Special Filters Modifiers - PRT_MNG_MSFM (0x00214760; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PORT_26F_UDP	0	1b	RW	UNDEFINED	**Port 26F UDP** Port 0x26F match if protocol is UDP.
PORT_26F_TCP	1	1b	RW	UNDEFINED	**Port 26F TCP** Port 0x26F match if protocol is TCP.
PORT_298_UDP	2	1b	RW	UNDEFINED	**Port 298 UDP** Port 0x298 match if protocol is UDP.
PORT_298_TCP	3	1b	RW	UNDEFINED	**Port 298 TCP** Port 0x298 match if protocol is TCP.
IPV6_0_MASK	4	0b	RW	UNDEFINED	**IPv6 0 Mask** Compare only 24 LSB bits of IPv6 Address 0 (MIPAF[0]).

Field	Bit(s)	Init.	Type	CFG Policy	Description
IPV6_1_MASK	5	0b	RW	UNDEFINED	**IPv6 1 Mask** Compare only 24 LSB bits of IPv6 Address 1 (MIPAF[1]).
IPV6_2_MASK	6	0b	RW	UNDEFINED	**IPv6 2 Mask** Compare only 24 LSB bits of IPv6 Address 2 (MIPAF[2]).
IPV6_3_MASK	7	0b	RW	UNDEFINED	**IPv6 3 Mask** Compare only 24 LSB bits of IPv6 Address 3 (MIPAF[3]).
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.29.18 Management VLAN TAG Value - PRT_MNG_MAVTV[n] (0x00214780 + 0x20*n, n=0...7; RO)

The MAVTV registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets (see Section 12.4).

Field	Bit(s)	Init.	Type	CFG Policy	Description
VID	11:0	0x0	RW	UNDEFINED	**VLAN ID** Contains the VLAN ID that should be compared with the incoming packet inner VLAN ID if the corresponding bit in MDEF is set.
RESERVED	31:12	0x0	RSV	N/A	Reserved.

13.2.2.29.19 Manageability Decision Filters1 - PRT_MNG_MDEF[n] (0x00214880 + 0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MAC_EXACT_AND	3:0	0x0	RW	UNDEFINED	**MAC Exact AND** Controls the inclusion of Exact MAC Address 0 to 3 in the manageability filter decision (AND section). Bit 0 corresponds to exact MAC Address 0 (MMAL0 and MMAH0), and so on.
BROADCAST_AND	4	0b	RW	UNDEFINED	**Broadcast AND** Controls the inclusion of broadcast address filtering in the manageability filter decision (AND section).
VLAN_AND	12:5	0x0	RW	UNDEFINED	**VLAN AND** Controls the inclusion of VLAN tag 0 to 7, respectively, in the manageability filter decision (AND section). Bit 5 corresponds to VLAN tag 0, and so on.
IPV4_ADDRESS_AND	16:13	0x0	RW	UNDEFINED	**IPv4 Address AND** Controls the inclusion of IPv4 Address 0 to 3, respectively, in the manageability filter decision (AND section). Bit 13 corresponds to IPv4 Address 0, and so on. ***Note:*** These bits are set also for an ARP request packet if the Target IP match the IP Address configured in the MIPAF register.
IPV6_ADDRESS_AND	20:17	0x0	RW	UNDEFINED	**IPv6 Address AND** Controls the inclusion of IPv6 Address 0 to 3, respectively, in the manageability filter decision (AND section). Bit 17 corresponds to IPv6 Address 0, and so on.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MAC_EXACT_OR	24:21	0x0	RW	UNDEFINED	**MAC Exact OR** Controls the inclusion of exact MAC Address 0 to 3 in the manageability filter decision (OR section). Bit 21 corresponds to exact MAC Address 0 (MMAL0 and MMAH0), and so on.
BROADCAST_OR	25	0b	RW	UNDEFINED	**Broadcast OR** Controls the inclusion of broadcast address filtering in the manageability filter decision (OR section).
MULTICAST_AND	26	0b	RW	UNDEFINED	**Multicast AND** Controls the inclusion of Multicast Address filtering in the manageability filter decision (AND section). Broadcast packets are not included by this bit.
ARP_REQUEST_OR	27	0b	RW	UNDEFINED	**ARP Request OR** Controls the inclusion of ARP Request filtering in the manageability filter decision (OR section).
ARP_RESPONSE_OR	28	0b	RW	UNDEFINED	**ARP Response OR** Controls the inclusion of ARP Response filtering in the manageability filter decision (OR section).
NEIGHBOR_DISCOVERY_134_OR	29	0b	RW	UNDEFINED	**Neighbor Discovery 134 OR** Controls the inclusion of Neighbor Discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x86 (134).
PORT_0X298_OR	30	0b	RW	UNDEFINED	**Port 0x298 OR** Controls the inclusion of port 0x298 filtering in the manageability filter decision (OR section).
PORT_0X26F_OR	31	0b	RW	UNDEFINED	**Port 0x26F OR** Controls the inclusion of port 0x26F filtering in the manageability filter decision (OR section).

13.2.2.29.20 Management Decision Filters VSI - PRT_MNG_MDEFVSI[n] (0x00214980 + 0x20*n, n=0...3; RO)

This register is used to define the VSIs that is used to receive packets that matched a specific MDEF. In case of multiple match, the VSI assigned to the MDEF with the highest index is used.

Note: In A0 the lowest index is used.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDEFVSI_2N	15:0	0x0	RW	UNDEFINED	**MDEF VSI 2n** Defines the VSI used for packets matching MDEF 2*n.
MDEFVSI_2NP1	31:16	0x0	RW	UNDEFINED	**MDEF VSI 2n+1** Defines the VSI used for packets matching MDEF 2*n+1.

13.2.2.29.21 Manageability Decision Filters - PRT_MNG_MDEF_EXT[n] (0x00214A00 + 0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
L2_ETHERTYPE_AND	3:0	0x0	RW	UNDEFINED	**L2 EtherType AND** Controls the inclusion of L2 EtherType filtering in the manageability filter decision (AND section).
L2_ETHERTYPE_OR	7:4	0x0	RW	UNDEFINED	**L2 EtherType OR** Controls the inclusion of L2 EtherType filtering in the manageability filter decision (OR section).
FLEX_PORT_OR	23:8	0x0	RW	UNDEFINED	**Flex Port OR** Controls the inclusion of Flex port filtering in the manageability filter decision (OR section). Bit 16 corresponds to flex port 0, and so on.
FLEX_TCO	24	0b	RW	UNDEFINED	**Flex TCO** Controls the inclusion of Flex TCO filtering in the manageability filter decision (OR section). Bit 24 corresponds to Flex TCO filter. ***Note:*** Supported only for Network traffic.
NEIGHBOR_DISCOVERY_135_OR	25	0b	RW	UNDEFINED	**Neighbor Discovery 135 OR** Controls the inclusion of Neighbor Discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x87 (135).
NEIGHBOR_DISCOVERY_136_OR	26	0b	RW	UNDEFINED	**Neighbor Discovery 136 OR** Controls the inclusion of Neighbor Discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x88 (136).
NEIGHBOR_DISCOVERY_137_OR	27	0b	RW	UNDEFINED	**Neighbor Discovery 137 OR** Controls the inclusion of Neighbor Discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x89 (137).
ICMP_OR	28	0b	RW	UNDEFINED	**ICMP OR** Controls the inclusion of ICMP filtering in the manageability filter decision (OR section).
MLD	29	0b	RW	UNDEFINED	**MLD** Controls the inclusion of MLD packets. These are ICMPv6 packets with the following types: 130, 131, 132, 143.
APPLY_TO_NETWORK_TRAFFIC	30	0b	RW	UNDEFINED	**Apply to Network Traffic** 0b = This decision filter does not apply to traffic received from the network. 1b = This decision filter applies to traffic received from the network.
APPLY_TO_HOST_TRAFFIC	31	0b	RW	UNDEFINED	**Apply to Host Traffic** 0b = This decision filter does not apply to traffic received from the host. 1b = This decision filter applies to traffic received from the host.

13.2.2.29.22 Port to MDEF Set Mapping - GL_SWT_PRT2MDEF[n] (0x00216018 + 0x4*n, n=0...31; RO)

For all the registers in the manageability section that are per-port, should be per MDEF set assigned by this register to virtual ports.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MDEFIDX	2:0	000b	RW	UNDEFINED	**MDEF Index** Mapping from port to MDEF set. The selection between port and virtual port is done according to GL_SWT_SWIDFVIDX.*PORT_TYPE* field.
RESERVED	30:3	0x0	RSV	N/A	Reserved.
MDEFENA	31	0b	RW	UNDEFINED	**MDEF Enable** Enables MDEF for this port.

13.2.2.30 PF - Malicious Prevention Registers

13.2.2.30.1 Malicious VF Driver Detected on Tx TDPU - VP_MDET_TX_TDPU[VF] (0x00040000 + 0x4*VF, VF=0...255; RWC)

Malicious detect per VF. Hardware sets to '1' upon malicious event for corresponding VF. Writing '1' to this CSR clears the malicious indication.

Field definitions are the same as those defined in Section 13.2.2.30.2.

13.2.2.30.2 Malicious PF Driver Detected on Tx TDPU - PF_MDET_TX_TDPU (0x00040800; RWC)

Malicious detect per VF. Hardware sets to '1' upon malicious event for corresponding VF. Writing '1' to this CSR clears the malicious indication.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALID	0	0b	RWC	DYNAMIC	**Valid** A malicious event has been detected by the Tx Dat processing unit on this function.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.30.3 Malicious VF Driver Detected on Tx TCLAN - VP_MDET_TX_TCLAN[VF] (0x000FB800 + 0x4*VF, VF=0...255; RW1C)

Field definitions are the same as those defined in Section 13.2.2.30.4.

13.2.2.30.4 Malicious PF Driver Detected on Tx TCLAN - PF_MDET_TX_TCLAN (0x000FC000; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALID	0	0b	RW1C	DYNAMIC	**Valid** A malicious event has been detected by the TCLAN unit on this function
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.30.5 Malicious Driver Tx Event Details - GL_MDET_TX_TCLAN (0x000FC068; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
QNUM	14:0	0x0	RO	DYNAMIC	**Queue Number** Absolute queue ID on which the event was detected.
VF_NUM	22:15	0x0	RO	DYNAMIC	**VF Number** Absolute VF number on which the event was detected.
PF_NUM	25:23	000b	RO	DYNAMIC	**PF Number** PF/parent PF number on which the event was detected.
RESERVED	30:26	0x0	RSV	N/A	Reserved.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALID	31	0b	RW1C	DYNAMIC	**Valid** Indicates that an event has been captured.

13.2.2.30.6 Malicious PF Driver Detected on Tx TCLAN - VM_MDET_TX_TCLAN[n] (0x000FC348 + 0x4*n, n=0...767; RW1C)

Field definitions are the same as those defined in Section 13.2.2.30.4.

13.2.2.30.7 RLAN Malicious Events - GLRLAN_MDET (0x00294200; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.30.8 Malicious Driver Rx Checks Enabled - GL_MDCK_RX (0x0029422C; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DESC_ADDR	0	1b	RW	UNDEFINED	Enable malicious event: descriptor fetch failed. For proper operation this flag must be active.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.30.9 Malicious PF Driver Detected on Rx - PF_MDET_RX (0x00294280; RW1C)

This register records a malicious event detected on the Rx-Queues. Once read, driver must write 0xFFFF to clear.

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALID	0	0b	RW1C	DYNAMIC	**Valid** A malicious event has been detected on this function.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.30.10 Malicious VF Driver Detected on Rx - VP_MDET_RX[VF] (0x00294400 + 0x4*VF, VF=0...255; RW1C)

This register records a malicious event detected on the Rx-Queues. Once read, driver must write 0xFFFF to clear.

Field definitions are the same as those defined in Section 13.2.2.30.9.

13.2.2.30.11 Malicious Driver Rx Event Details - GL_MDET_RX (0x00294C00; RW1C)

This register records the details of the first Rx event detected.

Field	Bit(s)	Init.	Type	CFG Policy	Description
QNUM	14:0	0x0	RO	DYNAMIC	**Queue Number** Absolute queue ID on which the event was detected.
VF_NUM	22:15	0x0	RO	DYNAMIC	**VF Number** Absolute VF number on which the event was detected.
PF_NUM	25:23	000b	RO	DYNAMIC	**PF Number** PF/parent PF number on which the event was detected.
MAL_TYPE	30:26	0x0	RO	DYNAMIC	**Malicious Type** ID of the event that has been recorded.
VALID	31	0b	RW1C	DYNAMIC	**Valid** Indicates that an event has been captured.

13.2.2.30.12 Malicious VF Driver Detected on Tx PQM - VP_MDET_TX_PQM[VF] (0x002D2000 + 0x4*VF, VF=0...255; RW1C)

This register records a malicious event detected on the Tx-Queues. Once read, driver must write 0xFFFF to clear.

Field definitions are the same as those defined in Section 13.2.2.30.13.

13.2.2.30.13 Malicious PF Driver Detected on Tx PQM - PF_MDET_TX_PQM (0x002D2C80; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
VALID	0	0b	RW1C	DYNAMIC	**Valid** A malicious event has been detected by the PQM unit on this function.
RESERVED	31:1	0x0	RSV	N/A	Reserved.

13.2.2.30.14 Malicious Driver Tx Command Checks PQM Configuration 1 - GL_MDCK_CFG1_TX_PQM (0x002D2DF4; RW)

This register includes configuration which are used by PQM malicious detection (hardware) checks.

Field	Bit(s)	Init.	Type	CFG Policy	Description
SSO_MAX_DATA_LEN	7:0	0xFF	RW	UNDEFINED	**SSO Max Data Length** Max Data Length in 64-bytes resolution up to 16K-64 bytes.
SSO_MAX_PKT_CNT	13:8	0x3F	RW	UNDEFINED	**SSO Max Packet Count** Max number of packets incorporated in the Quanta.
RESERVED	15:14	00b	RSV	N/A	Reserved.
SSO_MAX_DESC_CNT	21:16	0x3F	RW	UNDEFINED	**SSO Max Descriptor Count** Max number of descriptor incorporated in the Quanta.
RESERVED	31:22	0x0	RSV	N/A	Reserved.

13.2.2.30.15 Malicious Driver Tx Command Checks Enable PQM - GL_MDCK_EN_TX_PQM (0x002D2DFC; RW)

This register indicates which of PQM Tx malicious detection (hardware) checks are enabled.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PCI_DUMMY_COMP	0	1b	RW	UNDEFINED	**PCI Dummy Completion** Enable detection of PCI Dummy Completion (for a QD Fetch Request)
PCI_UR_COMP	1	1b	RW	UNDEFINED	**PCI Unsupported Request Completion** Enable detection of PCI "Unsupported Request" Completion (for a QD Fetch Request).
RESERVED	2	0b	RSV	N/A	Reserved.
RCV_SH_BE_LSO	3	1b	RW	UNDEFINED	Empty Q fetch (initiated by PQMMNG after 1st Quanta was delivered to PQMMNG by DBL) and LSO QD is expected in completion. Completion is received however received QD is NOT LSO.
Q_FL_MNG_EPY_CH	4	1b	RW	UNDEFINED	**Queue Empty** In fetch command (initiated by PQMMNG) force_fetch is set (Q is full PQMMNG wise) but PQMQDC concluded that the Q is empty.
Q_EPY_MNG_FL_CH	5	1b	RW	UNDEFINED	**Queue Full** In fetch command (initiated by PQMMNG) force_fetch is clear (Q is empty PQMMNG wise) but PQMQDC concludes that the Q is not empty.
LSO_NUMDESCS_ZERO	6	1b	RW	UNDEFINED	**LSO Number of Descriptors Zero** Enable detection of LSO QD whose Number of Descriptors is zero.
LSO_LENGTH_ZERO	7	1b	RW	UNDEFINED	**LSO Length Zero** Enable detection of LSO QD whose Length is zero.
LSO_MSS_BELOW_MIN	8	1b	RW	UNDEFINED	**LSO MSS Below Minimum** Enable detection of LSO QD whose MSS is below GL_MDCK_CFG2_TX_PQM.*LSO_MIN_MSS*.
LSO_MSS_ABOVE_MAX	9	1b	RW	UNDEFINED	**LSO MSS Above Maximum** Enable detection of LSO QD whose MSS is above GL_MDCK_CFG2_TX_PQM.*LSO_MAX_MSS*.
LSO_HDR_SIZE_ZERO	10	1b	RW	UNDEFINED	**LSO Header Size Zero** Enable detection of LSO QD whose Header Size is zero.
RCV_CNT_BE_LSO	11	1b	RW	UNDEFINED	Enable detection of LSO QD for a Q which is LSO disabled.
SKIP_ONE_QT_ONLY	12	1b	RW	UNDEFINED	**Skip One Quanta Only** The first Quanta of a LSO QD that is composed of multiple Quantas is delivered to hardware. The first Quanta is scheduled and hardware fetches LSO QD so it can schedule the other Quantas of the same LSO QD. During processing of the fetched LSO QD, hardware concludes it is a single Quanta (which has already been scheduled) although DBL suggested it is multiple Quantas.
LSO_PKTCNT_ZERO	13	1b	RW	UNDEFINED	**LSO Packet Count Zero** Enable detection of LSO DBL whose First Quanta Number of Segments is zero.
SSO_LENGTH_ZERO	14	1b	RW	UNDEFINED	**SSO Length Zero** Enable detection of SSO QD whose Length is zero.
SSO_LENGTH_EXCEED	15	1b	RW	UNDEFINED	**SSO Length Exceeded** Enable detection of SSO QD whose Length exceeds GL_MDCK_CFG1_TX_PQM.*SSO_MAX_DATA_LEN*.

Field	Bit(s)	Init.	Type	CFG Policy	Description
SSO_PKTCNT_ZERO	16	1b	RW	UNDEFINED	**SSO Packet Count Zero** Enable detection of SSO QD whose Packet Count is zero.
SSO_PKTCNT_EXCEED	17	1b	RW	UNDEFINED	**SSO Packet Count Exceeded** Enable detection of SSO QD whose Packet Count exceeds GL_MDCK_CFG1_TX_PQM.*SSO_MAX_PKT_CNT*.
SSO_NUMDESCS_ZERO	18	1b	RW	UNDEFINED	**SSO Number of Descriptors Zero** Enable detection of SSO QD whose Number of Descriptors is zero.
SSO_NUMDESCS_EXCEED	19	1b	RW	UNDEFINED	**SSO Number of Descriptors Exceeded** Enable detection of SSO QD whose Number of Descriptors exceed minimum of {Remain-Ring-Length and GL_MDCK_CFG1_TX_PQM.*SSO_MAX_DESC_CNT*}.
TAIL_GT_RING_LENGTH	20	1b	RW	UNDEFINED	**Tail Greater Than Ring Length** Enable detection of DBL whose Tail is greater than Ring Length. Applicable for both QD and Legacy Interfaces.
RESERVED_DBL_TYPE	21	1b	RW	UNDEFINED	**Reserved Doorbell Type** Enable detection of DBL whose *Type* field is Reserved (2'b11), which is considered malicious.
ILLEGAL_HEAD_DROP_DBL	22	1b	RW	UNDEFINED	**Illegal Head Drop Doorbell** Enable detection of Head Drop DBL over Comms Queue for which Head Drop is disabled.
LSO_OVER_COMMS_Q	23	1b	RW	UNDEFINED	**LSO Over Comms Queue** Enable detection of LSO DBL over Comms Queue for which LSO is disabled.
ILLEGAL_VF_QNUM	24	1b	RW	UNDEFINED	**Illegal VF Queue Number** Enable detection of VF-TYPE DBLQ element that is associated with illegal Q number.
QTAIL_GT_RING_LENGTH	25	1b	RW	UNDEFINED	**Queue Tail Greater Than Ring Length** Enable detection of DBL whose QDTail is greater than Ring Length. Applicable for QD Interface.
RESERVED	31:26	0x0	RSV	N/A	Reserved.

13.2.2.30.16 Malicious Driver Tx Event Details PQM - GL_MDET_TX_PQM (0x002D2E00; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PF_NUM	2:0	000b	RO	DYNAMIC	**PF Number** PF/parent PF number on which the event was detected.
RESERVED	3	0b	RSV	N/A	Reserved
VF_NUM	11:4	0x0	RO	DYNAMIC	**VF Number** Absolute VF number on which the event was detected.
QNUM	25:12	0x0	RO	DYNAMIC	**Queue Number** Absolute queue ID on which the event was detected.
RESERVED	30:26	0x0	RSV	N/A	Reserved.
VALID	31	0b	RW1C	DYNAMIC	**Valid** Indicates that an event has been captured.

13.2.2.31 PF - Rx QoS Registers

Rx QoS configuration registers.

13.2.2.31.1 DCB Receive RDMA Pipe Monitor Status - PRTDCB_RRDMAPMS (0x00122120; RW)

Meaningless when GLDCB_RSPMC.*RPM_MODE* is not set to 00b.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RDMARPPM	17:0	0x0	RW	UNDEFINED	**RDMA Receive Per-Port Pipe Monitor** Current amount of bytes accounted by the Per-Port Rx RDMA Pipe Monitor. It is expressed in byte units of Layer2 packet lengths, including preamble, IPG, and CRC. Writing to this field has the effect of loading a new current value into the Rx RDMA Pipe Monitor count, which is used by Rx-ETS algorithm.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.31.2 DCB Receive per Port Pipe Monitor Control - PRTDCB_RPPMC (0x00122240; RW)

Meaningless when GLDCB_RSPMC.*RPM_MODE* is not set to 00b.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.31.3 DCB Receive Pacing Control - GLDCB_RPCC (0x00122260; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RESERVED	31:0	0x0	RSV	N/A	Reserved.

13.2.2.31.4 DCB Receive LAN Pipe Monitor Status - PRTDCB_RLANPMS (0x00122280; RW)

Meaningless when GLDCB_RSPMC.*RPM_MODE* is not set to 00b.

Field	Bit(s)	Init.	Type	CFG Policy	Description
LANRPPM	17:0	0x0	RW	UNDEFINED	**LAN Receive Per-Port Pipe Monitor** Current amount of bytes accounted by the Per-Port Rx LAN Pipe Monitor. It is expressed in byte units of Layer2 packet lengths, including preamble, IPG, and CRC. Writing to this field has the effect of loading a new current value into the Rx LAN Pipe Monitor count, which is used by Rx-ETS algorithm.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.31.5 DCB Receive per TC PFC Timer Queue - GLDCB_RTCTQ[n] (0x001222C0 + 0x4*n, n=0...31; RO)

One register per UP. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RXQNUM	10:0	0x0	RO	N/A	**Rx-Queue Number** Returns the Rx-Queue number (which had not enough available Rx-Descriptors) that caused the PFCTIMER of the Port/TC to time out. The queue index reported in this register is the absolute queue index in the device space, which is different than the queue index used for the Tx-Queue and Rx-Queue registers. The value is meaningful only when the corresponding bit in PFDCB_RUPTI is set.
RESERVED	15:11	0x0	RSV	N/A	Reserved.
IS_PF_Q	16	0b	RO	UNDEFINED	**Is PF Queue** Set to 1b if the queue belongs to a PF.
RESERVED	31:17	0x0	RSV	UNDEFINED	Reserved.

13.2.2.31.6 DCB Receive per TC PFC Timer Status - GLDCB_RTCTS[n] (0x00122340 + 0x4*n, n=0...31; RW)

One register per UP. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFCTIMER	13:0	0x0	RW	UNDEFINED	**PFC Timer** Current value of the count-down PFC Timer of TC n in Rx, where n is the register index in the array. The amount is expressed in milliseconds. Writing to this field has the effect of loading a new current timer value, which can be useful for diagnostic purposes.
RESERVED	31:14	0x0	RSV	N/A	Reserved.

13.2.2.31.7 DCB Receive Shared Pipe Monitor Status - GLDCB_RSPMS (0x001223C0; RW)

Meaningless when GLDCB_RSPMC.*RPM_MODE* is not set to 00b.

Field	Bit(s)	Init.	Type	CFG Policy	Description
RSPM	17:0	0x0	RW	UNDEFINED	**Receive Shared Pipe Monitor** Current amount to bytes accounted by the Rx Shared Pipe Monitor. It is expressed in byte units of Layer2 packet lengths, including preamble, IPG, and CRC. Writing to this field has the effect of loading a new current value into the Rx Shared Pipe Monitor count, which is used by Rx-ETS algorithm. It is for debugging purposes only and must be avoided during normal operations.
RESERVED	31:18	0x0	RSV	N/A	Reserved.

13.2.2.31.8 DCB Receive Shared Pipe Monitor Control - GLDCB_RSPMC (0x001223C4; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RSPM	7:0	0x70	RW	UNDEFINED	**Receive Shared Pipe Monitor** Depth of the shared Pipe Monitor applied over the Rx-Pipe, for all ports and LAN/RDMA pipes altogether. It is expressed in KB units of Layer2 packet lengths, including preamble, IPG, and CRC. Meaningful only when *RPM_MODE* is set to 01b. Max allowed value = 0xEF. Unused by SWR/RPRS (used only in RCB instance of this CSR).
RPM_MODE	9:8	0x0	RW	UNDEFINED	**Receive Pipe Monitor Mode** 00b = Per Port Pipe Monitor. 01b = Shared Pipe Monitor. 10b = No Pipe Monitor. Pipes are filled up to their maximum capacity. 11b = Reserved.
PRR_MAX_EXP	13:10	0xB	RW	UNDEFINED	**Port Round-Robin Maximum Exponent** Maximum Exponent M used to compute the Max Credits that a Port can accumulate. Max Credits = (2^M) x PRTDCB_RPRRC.*BWSHARE*.
PFCTIMER	27:14	0x800	RW	UNDEFINED	**PFC Timer** Value in milliseconds loaded into the per-UP PFC Timer in Rx. The timer is loaded every time the device waits for software to free Rx-Descriptors before dropping a packet destined to a no-drop Rx-Queue. There is one such timer per UP and per port, which all are loaded with the same value. Unused by SWR/RPRS (used only in RCB instance of this CSR).
RESERVED	30:28	0x0	RSV	N/A	Reserved.
RPM_DIS	31	0b	RW	UNDEFINED	**Rx-Pipe Monitor(s) Disable** This bit controls all the Rx-Pipe monitors. 0b = 0b - Enabled 1b = Disabled Unused by SWR/RPRS (used only in RCB instance of this CSR).

13.2.2.31.9 DCB Receive Manageability Pipe Monitor Control - GLDCB_RMPMC (0x001223C8; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RSPM	5:0	0x9	RW	UNDEFINED	**Receive Shared Pipe Monitor** Depth of the Manageability Pipe Monitor applied over the Rx-Pipe, for all ports and LAN/RDMA pipes altogether. It is expressed in KB units of Layer2 packet lengths, including preamble, IPG, and CRC. It monitors all the bytes in transit between RPB and the shared 24 KB manageability input queue (included), but excluding the frame currently added into the pipe. Default setting is 9 KB = trunc(12 KB - 2.2 KB), assuming max frame size is for FCoE. Meaningful only when *RMPM_DIS* is set to 0b. Max allowed value = 0xEF.

Field	Bit(s)	Init.	Type	CFG Policy	Description
MIQ_NODROP_MODE	10:6	0x0	RW	UNDEFINED	**Manageability Input Queue No-Drop Mode** This is a bitmap. When bit n is set to 1b, Manageability Input Queue n is operated in no-drop mode. Any manageability packet fetched from RPB that is destined to this queue is NOT be dropped until it has reached the EMP. ***Note:*** Manageability packets mapped to a PB queue that is operated in drop mode can still be dropped if the RPB queue is congested. When bit n is set to 0b, Manageability Input Queue n is operated in drop mode. Manageability packets fetched from RPB that are destined to this queue can be dropped under congestion conditions.
RESERVED	30:11	0x0	RSV	N/A	Reserved.
RPM_DIS	31	0b	RW	UNDEFINED	**Rx-Pipe Monitor Disable** 0b = Enabled 1b = Disabled

13.2.2.31.10 DCB Receive Manageability Pipe Monitor Status - GLDCB_RMPMS (0x001223CC; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
RMPM	15:0	0x0	RO	N/A	**Receive Manageability Pipe Monitor** Current amount to bytes accounted by the Rx Manageability Pipe Monitor. It is expressed in byte units of Layer2 packet lengths, including preamble, IPG, and CRC.
RESERVED	31:16	0x0	RSV	N/A	Reserved.

13.2.2.31.11 DCB Receive per TC PFC Timer Indication - GLDCB_RTCTI (0x001223D0; RW1C)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PFCTIMEOUT_TC	31:0	0x0	RW1C	DYNAMIC	**PFC Time-out TCs** Bitmap where a bit set to 1b means that the PFC Timer corresponding to the Port/TC has timed out. For up to 4 link topology: Bits 0-7 are for port 0, TC 0 to 7. Bits 8-15 are for port 1, TC 0 to 7. Bits 16-23 are for port 2, TC 0 to 7. Bits 24-31 are for port 3, TC 0 to 7. For more than 4 link topology: Bits 00-03 are for port 0, TC 0 to 3. Bits 04-07 are for port 1, TC 0 to 3. Bits 08-11 are for port 2, TC 0 to 3. Bits 12-15 are for port 3, TC 0 to 3. Bits 16-19 are for port 4, TC 0 to 3. Bits 20-23 are for port 5, TC 0 to 3. Bits 24-27 are for port 6, TC 0 to 3. Bits 28-31 are for port 7, TC 0 to 3. Writing a bit with 1b restarts the corresponding PFC Timer.

13.2.2.31.12 RCB Configuration Change on the Fly Counter - GLRCB_CFG_COTF_CNT[n] (0x001223D4 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRKR_COTF_CNT	5:0	0x0	ROCV	N/A	**Marker Change on-the-Fly Counter** Counts cfg_cotf markers originating on same configuration. Counter is incremented when cfg_cotf marker of configuration index correspond to counter index is selected by DCB arbiter in RCB and dropped. Counter is cleared on read.
RESERVED	31:6	0x0	RSV	N/A	Reserved.

13.2.2.31.13 RCB Configuration Change on the Fly Status - GLRCB_CFG_COTF_ST (0x001223F4; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MRKR_COTF_ST	7:0	0x0	RO	N/A	**Marker Change on-the-Fly Status** Bit i reflects the status of the counter. 0b = Counter is either idle or has not yet reached threshold. 1b = Counter has reached threshold and is waiting to be cleared. Bit i is set when the correspond counter reaches threshold. Bit i is cleared when the correspond counter is read.
RESERVED	31:8	0x0	RSV	N/A	Reserved.

13.2.2.31.14 Rx PM Dedicated Pool Size - GLRPRS_PMCFG_DPS[n] (0x00200308 + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
DPS	19:0	0xFF	RW	UNDEFINED	**Dedicated Pool Size** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.15 Rx PM Dedicated Pool High Watermark - GLRPRS_PMCFG_DHW[n] (0x00200388 + 0x4*n, n=0...15; RO)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DHW	19:0	0xFF	RW	UNDEFINED	**Dedicated Pool High Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.16 Rx PM Dedicated Pool Low Watermark - GLRPRS_PMCFG_DLW[n] (0x002003C8 + 0x4*n, n=0...15; RO)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	CFG Policy	Description
DLW	19:0	0xFF	RW	UNDEFINED	**Dedicated Pool Low Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.17 Rx PM Shared Pool Size - GLRPRS_PMCFG_SPS[n] (0x00200408 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SPS	19:0	0xFF	RW	UNDEFINED	**Shared Pool Size** Number of bytes/commands allocated to the shared pool.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.18 Rx PM Shared Pool High Watermark - GLRPRS_PMCFG_SHW[n] (0x00200448 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SHW	19:0	0xFF	RW	UNDEFINED	**Shared Pool High Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.19 Rx PM Shared Pool Low Watermark - GLRPRS_PMCFG_SLW[n] (0x00200468 + 0x4*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
SLW	19:0	0xFF	RW	UNDEFINED	**Shared Pool Low Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.20 TC Pool Config - GLRPRS_PMCFG_TC_CFG[n] (0x00200488 + 0x4*n, n=0...31; RO)

Field definitions are the same as those defined in Section 13.2.2.31.23.

13.2.2.31.21 Rx PM TC High Watermark - GLRPRS_PMCFG_TCHW[n] (0x00200588 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCHW	19:0	0xFF	RW	UNDEFINED	**TC High Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.22 Rx PM TC Low Watermark - GLRPRS_PMCFG_TCLW[n] (0x00200608 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
TCLW	19:0	0xFF	RW	UNDEFINED	**TC Low Watermark** It is expressed in bytes or commands according to usage.
RESERVED	31:20	0x0	RSV	N/A	Reserved.

13.2.2.31.23 TC Pool Config - GLSWT_PMCFG_TC_CFG[n] (0x00204900 + 0x4*n, n=0...31; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
D_POOL	3:0	0x0	RW	UNDEFINED	**Dedicated Pool** Index of dedicated pool TC belongs to.
RESERVED	15:4	0x0	RSV	N/A	Reserved.
S_POOL	18:16	000b	RW	UNDEFINED	**Shared Pool** Index of shared pool TC belongs to.
RESERVED	31:19	0x0	RSV	N/A	Reserved.

13.2.3 BAR3 Registers Summary

13.2.3.1 PF - MSI-X Table Registers Summary

Table 13-41. PF - MSI-X Table Registers Summary

Offset / Alias Offset	Abbreviation	Name	Section Reference
0x00000000 + 0x10*n, n=0...2047	MSIX_TADD[n]	MSI-X Message Address Low	13.2.4.1.1
0x00000004 + 0x10*n, n=0...2047	MSIX_TUADD[n]	MSI-X Message Address High	13.2.4.1.2
0x00000008 + 0x10*n, n=0...2047	MSIX_TMSG[n]	MSI-X Message Data	13.2.4.1.3
0x0000000C + 0x10*n, n=0...2047	MSIX_TVCTRL[n]	MSI-X Vector Control	13.2.4.1.4
0x00008000 + 0x4*n, n=0...63	MSIX_PBA[n]	MSI-X PBA Structure	13.2.4.1.5

13.2.4 Detailed Register Descriptions - PF BAR3

13.2.4.1 PF - MSI-X Table Registers

13.2.4.1.1 MSI-X Message Address Low - MSIX_TADD[n] (0x00000000 + 0x10*n, n=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIXTADD10	1:0	00b	RW	UNDEFINED	**Message Address 1:0** For proper DWord alignment, software must always write zeros to these two bits. Otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.
MSIXTADD	31:2	0x0	RW	UNDEFINED	**Message Address** System-specified message lower address. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the DWord-aligned address (AD[31:02]) for the memory write transaction. This field is read/write.

13.2.4.1.2 MSI-X Message Address High - MSIX_TUADD[n] (0x00000004 + 0x10*n, n=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIXTUADD	31:0	0x0	RW	UNDEFINED	**Message Upper Address** System-specified message upper address bits. If this field is zero, Single Address Cycle (SAC) messages are used. If this field is non-zero, Dual Address Cycle (DAC) messages are used. This field is read/write.

13.2.4.1.3 MSI-X Message Data - MSIX_TMSG[n] (0x00000008 + 0x10*n, n=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MSIXTMSG	31:0	0x0	RW	UNDEFINED	**Message Data** System-specified message data. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write.

13.2.4.1.4 MSI-X Vector Control - MSIX_TVCTRL[n] (0x0000000C + 0x10*n, n=0...2047; RW)

Field	Bit(s)	Init.	Type	CFG Policy	Description
MASK	0	1b	RW	UNDEFINED	**Mask Bit** When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1b (entry is masked).
RESERVED	31:1	0x0	RSV	N/A	Reserved. After reset, the state of these bits must be 0b. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other Vector Control bits. If software modifies the value of these reserved bits, the result is undefined.

13.2.4.1.5 MSI-X PBA Structure - MSIX_PBA[n] (0x00008000 + 0x4*n, n=0...63; RO)

Field	Bit(s)	Init.	Type	CFG Policy	Description
PENBIT	31:0	0x0	RO	N/A	**MSI-X Pending Bits** Each bit is set to 1b when the appropriate interrupt request is set, and cleared to 0b when the appropriate interrupt request is cleared.

13.3 Device Registers - VF

13.3.1 VF Registers Mapping in the PF Space

Table 13-42. VF Registers Mapping in the PF Space

Abbreviation	Virtual Address	Physical Address
VFGEN_RSTAT	0x00008800	0x00074000 + 0x4*VF, VF=0...255

13.3.2 BAR0 Registers Summary

Table 13-43. VF - General Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00008800	VFGEN_RSTAT	VF Reset Status	13.3.3.1.1
0x0000E400	PFPCI_VF_FLUSH_DONE	VF Flush Done	13.3.3.1.2

Table 13-44. VF - Interrupt Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00002800 + 0x4*n + 0x40*m, n=0...15, m=0...2	VFINT_ITRN[n,m]	VF Interrupt Throttling N	13.3.3.2.1
0x00002C00 + 0x4*n + 0x100*m, n=0...63, m=0...2	VFINT_ITRN_64[n,m]	VF Interrupt Throttling N_64	13.3.3.2.2
0x00003800 + 0x4*n, n=0...63	VFINT_DYN_CTLN[n]	VF Interrupt Dynamic Control N	13.3.3.2.3
0x00004C00 + 0x4*n, n=0...2	VFINT_ITR0[n]	VF Interrupt Throttling Zero	13.3.3.2.4
0x00005C00	VFINT_DYN_CTL0	VF Interrupt Dynamic Control Zero	13.3.3.2.5

Table 13-45. VF - Control Queues Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00006000	VF_MBX_ARQBAH	VF Mailbox Receive Queue Base Address High	13.3.3.3.1
0x00006400	VF_MBX_ATQH	VF Mailbox Transmit Head	13.3.3.3.2
0x00006800	VF_MBX_ATQLEN	VF Mailbox Transmit Queue Length	13.3.3.3.3
0x00006C00	VF_MBX_ARQBAL	VF Mailbox Receive Queue Base Address Low	13.3.3.3.4
0x00007000	VF_MBX_ARQT	VF Mailbox Receive Tail	13.3.3.3.5
0x00007400	VF_MBX_ARQH	VF Mailbox Receive Head	13.3.3.3.6
0x00007800	VF_MBX_ATQBAH	VF Mailbox Transmit Queue Base Address High	13.3.3.3.7
0x00007C00	VF_MBX_ATQBAL	VF Mailbox Transmit Queue Base Address Low	13.3.3.3.8
0x00008000	VF_MBX_ARQLEN	VF Mailbox Receive Queue Length	13.3.3.3.9
0x00008400	VF_MBX_ATQT	VF Mailbox Transmit Tail	13.3.3.3.10

Table 13-46. VF - LAN Transmit and Receive Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00000000 + 0x4*DBQM, DBQM=0...255	QTX_TAIL[DBQM]	Transmit Queue Doorbell	13.3.3.4.1
0x00002000 + 0x4*QRX, QRX=0...255	QRX_TAIL[QRX]	Receive Queue Tail Update	13.3.3.4.2

Table 13-47. VF - Protocol Engine Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x00008C00	VFPE_IPCONFIG0	Protocol Engine VF IP Config 0	13.3.3.5.1
0x00009800	VFPE_CCQPHIGH	Protocol Engine VF Create CQP High	13.3.3.5.2
0x00009C00	VFPE_CQPERRCODES	Protocol Engine VF CQP Error Codes	13.3.3.5.3
0x0000A000	VFPE_CQPTAIL	Protocol Engine VF CQP Tail	13.3.3.5.4
0x0000A400	VFPE_AEQALLOC	Protocol Engine VF AEQ Allocate	13.3.3.5.5
0x0000A800	VFPE_TCPNOWTIMER	Protocol Engine VF TCP Now Timer	13.3.3.5.6
0x0000AC00	VFPE_CCQPLOW	Protocol Engine VF Create CQP Low	13.3.3.5.7
0x0000B000	VFPE_CQACK	Protocol Engine VF CQ Ack	13.3.3.5.8
0x0000B400	VFPE_CQARM	Protocol Engine VF CQ Arm	13.3.3.5.9
0x0000B800	VFPE_CCQPSTATUS	Protocol Engine VF Create CQP Status	13.3.3.5.10
0x0000BC00	VFPE_CQPDB	Protocol Engine VF CQP Doorbell	13.3.3.5.11
0x0000C000	VFPE_WQEALLOC	Protocol Engine VF WQE Allocate Register	13.3.3.5.12

Table 13-48. VF - Large VF Access Registers Summary

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x0000F000	VF_MBX_CPM_ATQBAL	VF CPM Mailbox Transmit Queue Base Address Low	13.3.3.6.1
0x0000F010	VF_MBX_CPM_ATQBAH	VF CPM Mailbox Transmit Queue Base Address High	13.3.3.6.2
0x0000F020	VF_MBX_CPM_ATQLEN	VF CPM Mailbox Transmit Queue Length	13.3.3.6.3
0x0000F030	VF_MBX_CPM_ATQH	VF CPM Mailbox Transmit Head	13.3.3.6.4
0x0000F040	VF_MBX_CPM_ATQT	VF CPM Mailbox Transmit Tail	13.3.3.6.5
0x0000F050	VF_MBX_CPM_ARQBAL	VF CPM Mailbox Receive Queue Base Address Low	13.3.3.6.6
0x0000F060	VF_MBX_CPM_ARQBAH	VF CPM Mailbox Receive Queue Base Address High	13.3.3.6.7
0x0000F070	VF_MBX_CPM_ARQLEN	VF CPM Mailbox Receive Queue Length	13.3.3.6.8
0x0000F080	VF_MBX_CPM_ARQH	VF CPM Mailbox Receive Head	13.3.3.6.9

Table 13-48. VF - Large VF Access Registers Summary [continued]

Offset/Alias Offset	Abbreviation	Name	Section Reference
0x0002E000 + 0x4*QRX, QRX=0...255	VFQRX_TAIL[QRX]	Global Receive Queue Tail	13.3.3.6.46
0x00030000 + 0x4*DBQM, DBQM=0...255	VFQTX_COMM_DBELL[DBQM]	Transmit Comm Scheduler Queue Doorbell	13.3.3.6.47

13.3.3 Detailed Register Descriptions - VF BAR0

13.3.3.1 VF - General Registers

This section describes the registers allocated to a VF for generic control and status. These registers are tied to the VF and are not dependent of any resource allocation.

13.3.3.1.1 VF Reset Status - VFGEN_RSTAT (0x00008800; RW)

Field definitions are the same as those defined in Section 13.2.2.1.1.

13.3.3.1.2 VF Flush Done - PFPCI_VF_FLUSH_DONE (0x0000E400; RO)

Field definitions are the same as those defined in Section 13.2.2.3.24.

13.3.3.2 VF - Interrupt Registers

13.3.3.2.1 VF Interrupt Throttling N - VFINT_ITRN[n,m] (0x00002800 + 0x4*n + 0x40*m, n=0...15, m=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.2.2 VF Interrupt Throttling N_64 - VFINT_ITRN_64[n,m] (0x00002C00 + 0x4*n + 0x100*m, n=0...63, m=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.2.3 VF Interrupt Dynamic Control N - VFINT_DYN_CTLN[n] (0x00003800 + 0x4*n, n=0...63; RW)

Field definitions are the same as those defined in Section 13.2.2.15.10.

13.3.3.2.4 VF Interrupt Throttling Zero - VFINT_ITR0[n] (0x00004C00 + 0x4*n, n=0...2; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.2.5 VF Interrupt Dynamic Control Zero - VFINT_DYN_CTL0 (0x00005C00; RW)

Field definitions are the same as those defined in Section 13.2.2.15.10.

13.3.3.3 VF - Control Queues Registers

VF exposed control queues.

13.3.3.3.1 VF Mailbox Receive Queue Base Address High - VF_MBX_ARQBAH (0x00006000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.61.

13.3.3.3.2 VF Mailbox Transmit Head - VF_MBX_ATQH (0x00006400; RW)

Field definitions are the same as those defined in Section 13.2.2.22.58.

13.3.3.3.3 VF Mailbox Transmit Queue Length - VF_MBX_ATQLEN (0x00006800; RW)

Field definitions are the same as those defined in Section 13.2.2.22.57.

13.3.3.3.4 VF Mailbox Receive Queue Base Address Low - VF_MBX_ARQBAL (0x00006C00; RW)

Field definitions are the same as those defined in Section 13.2.2.22.60.

13.3.3.3.5 VF Mailbox Receive Tail - VF_MBX_ARQT (0x00007000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.64.

13.3.3.3.6 VF Mailbox Receive Head - VF_MBX_ARQH (0x00007400; RW)

Field definitions are the same as those defined in Section 13.2.2.22.63.

13.3.3.3.7 VF Mailbox Transmit Queue Base Address High - VF_MBX_ATQBAH (0x00007800; RW)

Field definitions are the same as those defined in Section 13.2.2.22.56.

13.3.3.3.8 VF Mailbox Transmit Queue Base Address Low - VF_MBX_ATQBAL (0x00007C00; RW)

Field definitions are the same as those defined in Section 13.2.2.22.55.

13.3.3.3.9 VF Mailbox Receive Queue Length - VF_MBX_ARQLEN (0x00008000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.62.

13.3.3.3.10 VF Mailbox Transmit Tail - VF_MBX_ATQT (0x00008400; RW)

Field definitions are the same as those defined in Section 13.2.2.22.59.

13.3.3.4 VF LAN Transmit and Receive Registers

13.3.3.4.1 Transmit Queue Doorbell - QTX_TAIL[DBQM] (0x00000000 + 0x4*DBQM, DBQM=0...255; RW)

Field definitions are the same as those defined in Section 13.2.2.25.27.

13.3.3.4.2 Receive Queue Tail Update - QRX_TAIL[QRX] (0x00002000 + 0x4*QRX, QRX=0...255; RW)

Field definitions are the same as those defined in Section 13.2.2.26.22.

13.3.3.5 VF - Protocol Engine Registers

13.3.3.5.1 Protocol Engine VF IP Config 0 - VFPE_IPCONFIG0 (0x00008C00; RW)

Field definitions are the same as those defined in Section 13.2.2.28.23.

13.3.3.5.2 Protocol Engine VF Create CQP High - VFPE_CCQPHIGH (0x00009800; RW)

Field definitions are the same as those defined in Section 13.2.2.28.22.

13.3.3.5.3 Protocol Engine VF CQP Error Codes - VFPE_CQPERRCODES (0x00009C00; RO)

Field definitions are the same as those defined in Section 13.2.2.28.24.

13.3.3.5.4 Protocol Engine VF CQP Tail - VFPE_CQPTAIL (0x0000A000; RO)

Field definitions are the same as those defined in Section 13.2.2.28.2.

13.3.3.5.5 Protocol Engine VF AEQ Allocate - VFPE_AEQALLOC (0x0000A400; RW)

Field definitions are the same as those defined in Section 13.2.2.28.7.

13.3.3.5.6 Protocol Engine VF TCP Now Timer - VFPE_TCPNOWTIMER (0x0000A800; RO)

Field definitions are the same as those defined in Section 13.2.2.28.25.

13.3.3.5.7 Protocol Engine VF Create CQP Low - VFPE_CCQPLOW (0x0000AC00; RW)

Field definitions are the same as those defined in Section 13.2.2.28.21.

13.3.3.5.8 Protocol Engine VF CQ Ack - VFPE_CQACK (0x0000B000; RW)

Field definitions are the same as those defined in Section 13.2.2.28.6.

13.3.3.5.9 Protocol Engine VF CQ Arm - VFPE_CQARM (0x0000B400; RW)

Field definitions are the same as those defined in Section 13.2.2.28.5.

13.3.3.5.10 Protocol Engine VF Create CQP Status - VFPE_CCQPSTATUS (0x0000B800; RO)

Field definitions are the same as those defined in Section 13.2.2.28.20.

13.3.3.5.11 Protocol Engine VF CQP Doorbell - VFPE_CQPDB (0x0000BC00; RW)

Field definitions are the same as those defined in Section 13.2.2.28.1.

13.3.3.5.12 Protocol Engine VF WQE Allocate Register - VFPE_WQEALLOC (0x0000C000; RW)

Field definitions are the same as those defined in Section 13.2.2.28.18.

13.3.3.6 VF - Large VF Access Registers

13.3.3.6.1 VF CPM Mailbox Transmit Queue Base Address Low - VF_MBX_CPM_ATQBAL (0x0000F000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.65.

13.3.3.6.2 VF CPM Mailbox Transmit Queue Base Address High - VF_MBX_CPM_ATQBAH (0x0000F010; RW)

Field definitions are the same as those defined in Section 13.2.2.22.66.

13.3.3.6.3 VF CPM Mailbox Transmit Queue Length - VF_MBX_CPM_ATQLEN (0x0000F020; RW)

Field definitions are the same as those defined in Section 13.2.2.22.67.

13.3.3.6.4 VF CPM Mailbox Transmit Head - VF_MBX_CPM_ATQH (0x0000F030; RW)

Field definitions are the same as those defined in Section 13.2.2.22.68.

13.3.3.6.5 VF CPM Mailbox Transmit Tail - VF_MBX_CPM_ATQT (0x0000F040; RW)

Field definitions are the same as those defined in Section 13.2.2.22.69.

13.3.3.6.6 VF CPM Mailbox Receive Queue Base Address Low - VF_MBX_CPM_ARQBAL (0x0000F050; RW)

Field definitions are the same as those defined in Section 13.2.2.22.70.

13.3.3.6.7 VF CPM Mailbox Receive Queue Base Address High - VF_MBX_CPM_ARQBAH (0x0000F060; RW)

Field definitions are the same as those defined in Section 13.2.2.22.71.

13.3.3.6.8 VF CPM Mailbox Receive Queue Length - VF_MBX_CPM_ARQLEN (0x0000F070; RW)

Field definitions are the same as those defined in Section 13.2.2.22.72.

13.3.3.6.9 VF CPM Mailbox Receive Head - VF_MBX_CPM_ARQH (0x0000F080; RW)

Field definitions are the same as those defined in Section 13.2.2.22.73.

13.3.3.6.10 VF CPM Mailbox Receive Tail - VF_MBX_CPM_ARQT (0x0000F090; RW)

Field definitions are the same as those defined in Section 13.2.2.22.74.

13.3.3.6.11 VF CPM Sideband Transmit Queue Base Address Low - VF_SB_CPM_ATQBAL (0x0000F100; RW)

Field definitions are the same as those defined in Section 13.2.2.22.145.

13.3.3.6.12 VF CPM Sideband Transmit Queue Base Address High - VF_SB_CPM_ATQBAH (0x0000F110; RW)

Field definitions are the same as those defined in Section 13.2.2.22.146.

13.3.3.6.13 VF CPM Sideband Transmit Queue Length - VF_SB_CPM_ATQLEN (0x0000F120; RW)

Field definitions are the same as those defined in Section 13.2.2.22.147.

13.3.3.6.14 VF CPM Sideband Transmit Head - VF_SB_CPM_ATQH (0x0000F130; RW)

Field definitions are the same as those defined in Section 13.2.2.22.148.

13.3.3.6.15 VF CPM Sideband Transmit Tail - VF_SB_CPM_ATQT (0x0000F140; RW)

Field definitions are the same as those defined in Section 13.2.2.22.149.

13.3.3.6.16 VF CPM Sideband Receive Queue Base Address Low - VF_SB_CPM_ARQBAL (0x0000F150; RW)

Field definitions are the same as those defined in Section 13.2.2.22.150.

13.3.3.6.17 VF CPM Sideband Receive Queue Base Address High - VF_SB_CPM_ARQBAH (0x0000F160; RW)

Field definitions are the same as those defined in Section 13.2.2.22.151.

13.3.3.6.18 VF CPM Sideband Receive Queue Length - VF_SB_CPM_ARQLEN (0x0000F170; RW)

Field definitions are the same as those defined in Section 13.2.2.22.152.

13.3.3.6.19 VF CPM Sideband Receive Head - VF_SB_CPM_ARQH (0x0000F180; RW)

Field definitions are the same as those defined in Section 13.2.2.22.153.

13.3.3.6.20 VF CPM Sideband Receive Tail - VF_SB_CPM_ARQT (0x0000F190; RW)

Field definitions are the same as those defined in Section 13.2.2.22.154.

13.3.3.6.21 VF HLP Mailbox Transmit Queue Base Address Low - VF_MBX_HLP_ATQBAL (0x00020000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.75.

13.3.3.6.22 VF HLP Mailbox Transmit Queue Base Address High - VF_MBX_HLP_ATQBAH (0x00020010; RW)

Field definitions are the same as those defined in Section 13.2.2.22.76.

13.3.3.6.23 VF HLP Mailbox Transmit Queue Length - VF_MBX_HLP_ATQLEN (0x00020020; RW)

Field definitions are the same as those defined in Section 13.2.2.22.77.

13.3.3.6.24 VF HLP Mailbox Transmit Head - VF_MBX_HLP_ATQH (0x00020030; RW)

Field definitions are the same as those defined in Section 13.2.2.22.78.

13.3.3.6.25 VF HLP Mailbox Transmit Tail - VF_MBX_HLP_ATQT (0x00020040; RW)

Field definitions are the same as those defined in Section 13.2.2.22.79.

13.3.3.6.26 VF HLP Mailbox Receive Queue Base Address Low - VF_MBX_HLP_ARQBAL (0x00020050; RW)

Field definitions are the same as those defined in Section 13.2.2.22.80.

13.3.3.6.27 VF HLP Mailbox Receive Queue Base Address High - VF_MBX_HLP_ARQBAH (0x00020060; RW)

Field definitions are the same as those defined in Section 13.2.2.22.81.

13.3.3.6.28 VF HLP Mailbox Receive Queue Length - VF_MBX_HLP_ARQLEN (0x00020070; RW)

Field definitions are the same as those defined in Section 13.2.2.22.82.

13.3.3.6.29 VF HLP Mailbox Receive Head - VF_MBX_HLP_ARQH (0x00020080; RW)

Field definitions are the same as those defined in Section 13.2.2.22.83.

13.3.3.6.30 VF HLP Mailbox Receive Tail - VF_MBX_HLP_ARQT (0x00020090; RW)

Field definitions are the same as those defined in Section 13.2.2.22.84.

13.3.3.6.31 VF PSM Mailbox Transmit Queue Base Address Low - VF_MBX_PSM_ATQBAL (0x00021000; RW)

Field definitions are the same as those defined in Section 13.2.2.22.85.

13.3.3.6.32 VF PSM Mailbox Transmit Queue Base Address High - VF_MBX_PSM_ATQBAH (0x00021010; RW)

Field definitions are the same as those defined in Section 13.2.2.22.86.

13.3.3.6.33 VF PSM Mailbox Transmit Queue Length - VF_MBX_PSM_ATQLEN (0x00021020; RW)

Field definitions are the same as those defined in Section 13.2.2.22.87.

13.3.3.6.34 VF PSM Mailbox Transmit Head - VF_MBX_PSM_ATQH (0x00021030; RW)

Field definitions are the same as those defined in Section 13.2.2.22.88.

13.3.3.6.35 VF PSM Mailbox Transmit Tail - VF_MBX_PSM_ATQT (0x00021040; RW)

Field definitions are the same as those defined in Section 13.2.2.22.89.

13.3.3.6.36 VF PSM Mailbox Receive Queue Base Address Low - VF_MBX_PSM_ARQBAL (0x00021050; RW)

Field definitions are the same as those defined in Section 13.2.2.22.90.

13.3.3.6.37 VF PSM Mailbox Receive Queue Base Address High - VF_MBX_PSM_ARQBAH (0x00021060; RW)

Field definitions are the same as those defined in Section 13.2.2.22.91.

13.3.3.6.38 VF PSM Mailbox Receive Queue Length - VF_MBX_PSM_ARQLEN (0x00021070; RW)

Field definitions are the same as those defined in Section 13.2.2.22.92.

13.3.3.6.39 VF PSM Mailbox Receive Head - VF_MBX_PSM_ARQH (0x00021080; RW)

Field definitions are the same as those defined in Section 13.2.2.22.93.

13.3.3.6.40 VF PSM Mailbox Receive Tail - VF_MBX_PSM_ARQT (0x00021090; RW)

Field definitions are the same as those defined in Section 13.2.2.22.94.

13.3.3.6.41 Transmit Comm Scheduler Queue Doorbell - VFQTX_COMM_DBLQ_DBELL[DBLQ] (0x00022000 + 0x4*DBLQ, DBLQ=0...3; RW)

Field definitions are the same as those defined in Section 13.2.2.25.29.

13.3.3.6.42 VF Interrupt Dynamic Control - VFINT_DYN_CTL[n] (0x00023000 + 0x1000*n, n=0...7; RW)

Field definitions are the same as those defined in Section 13.2.2.15.10.

13.3.3.6.43 VF Interrupt Throttling 0 - VFINT_ITR_0[n] (0x00023004 + 0x1000*n, n=0...7; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.6.44 VF Interrupt Throttling 1 - VFINT_ITR_1[n] (0x00023008 + 0x1000*n, n=0...7; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.6.45 VF Interrupt Throttling 2 - VFINT_ITR_2[n] (0x0002300C + 0x1000*n, n=0...7; RW)

Field definitions are the same as those defined in Section 13.2.2.15.7.

13.3.3.6.46 Global Receive Queue Tail - VFQRX_TAIL[QRX] (0x0002E000 + 0x4*QRX, QRX=0...255; RW)

Field definitions are the same as those defined in Section 13.2.2.26.22.

13.3.3.6.47 Transmit Comm Scheduler Queue Doorbell - VFQTX_COMM_DBELL[DBQM] (0x00030000 + 0x4*DBQM, DBQM=0...255; RW)

Field definitions are the same as those defined in Section 13.2.2.25.27.

13.3.4 BAR3 Registers Summary

Table 13-49. VF - MSI-X Table Registers Summary

Offset / Alias Offset	Abbreviation	Name	Section Reference
0x00000000 + 0x10*n, n=0...2047	MSIX_TADD[n]	MSI-X Message Address Low	Section 13.3.5.1.1
0x00000004 + 0x10*n, n=0...2047	MSIX_TUADD[n]	MSI-X Message Address High	Section 13.3.5.1.2
0x00000008 + 0x10*n, n=0...2047	MSIX_TMSG[n]	MSI-X Message Data	Section 13.3.5.1.3
0x0000000C + 0x10*n, n=0...2047	MSIX_TVCTRL[n]	MSI-X Vector Control	Section 13.3.5.1.4
0x00008000 + 0x4*n, n=0...63	MSIX_PBA[n]	MSI-X PBA Structure	Section 13.3.5.1.5

13.3.5 Detailed Register Descriptions - VF BAR3

13.3.5.1 VF - MSI-X Table Registers

13.3.5.1.1 MSI-X Message Address Low - MSIX_TADD[n] (0x00000000 + 0x10*n, n=0...64; RW)

Field definitions are the same as those defined in Section 13.2.4.1.1.

13.3.5.1.2 MSI-X Message Address High - MSIX_TUADD[n] (0x00000004 + 0x10*n, n=0...64; RW)

Field definitions are the same as those defined in Section 13.2.4.1.2.

13.3.5.1.3 MSI-X Message Data - MSIX_TMSG[n] (0x00000008 + 0x10*n, n=0...64; RW)

Field definitions are the same as those defined in Section 13.2.4.1.3.

13.3.5.1.4 MSI-X Vector Control - MSIX_TVCTRL[n] (0x0000000C + 0x10*n, n=0...64; RW)

Field definitions are the same as those defined in Section 13.2.4.1.4.

13.3.5.1.5 MSI-X PBA Structure - MSIX_PBA[n] (0x00008000 + 0x4*n, n=0...2; RO)

Field definitions are the same as those defined in Section 13.2.4.1.5.

NOTE: ***This page intentionally left blank.***

Chapter 14 PCIe Programming Interface

14.1 Overview

The E810 supports the following configuration register sets:

- PCI basic configuration registers (see Section 14.2).
- PCI and PCIe capabilities in the PCI configuration space (see Section 14.3).
  - Includes the PCIe capability structure (see Section 14.3.5).
- PCIe capabilities residing in the PCIe extended configuration Space (see Section 14.4).
- SR-IOV VF configuration space (see Section 14.5).

14.1.1 Functions Mapping

The E810 is a multi-function device with the following characteristics:

- Up to eight8 physical functions (PFs)
- Up to 256 SR-IOV Virtual Functions (VFs)
  - Each PF can be allocated a different number of VFs in the range {0,...,256-1} as long as the total number of VFs does not exceed 256.

The following rule applies regarding allocation of PCI functions to LAN ports:

- Each PCI function is associated with a single LAN port as indicated in the PFGEN_PORTNUM.*PORT_NUM* register field.

Note: NVM programming notes:

Set PFGEN_PORTNUM_CAR in NVM POR auto-load section.

Set PFGEN_PORTNUM in NVM CORER auto-load section.

The number of enabled physical functions might be deducted from the PFPCI_STATUS1.*FUNC_VALID* bits (one per PF). See Section 4.5.4 on how enabled functions are determined.

The ARI capability enables interpretation of the device number part of the RID as part of the function number inside a device. Thus, a single device can span more than eight physical or virtual functions. Table 14-1 and Table 14-2 map the physical functions to PCI Requester ID.

Table 14-1. RID per PF - ARI Mode

PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
PF 7	B,0,7	B,00000,111	PF #7

Table 14-2. RID per PF - non-ARI Mode

PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
PF 7	B,0,7	B,00000,111	PF #7

The Requester ID of a PF (bus, device, and function numbers) is captured in the PF_FUNC_RID register.

14.1.1.1 Support for Dynamic Changes

The E810 captures the bus number and device number per each configuration write request. However, a dynamic change of the bus number or device number is not supported. Rather, the PCIe link should be quiescent prior to such a change, including reception of all completion for previous requests.

14.1.2 Supported Features

Table 14-3 lists the PCI and PCIe capabilities supported per PCI function type. Some capabilities do not necessarily appear with each function or in all cases. See Section 14.3 and Section 14.4 for details on specific capabilities.

Table 14-3. PCI Capabilities Supported by Function

PCI Capability	PFs	VFs	Section Reference
PCI Configuration	Mandatory	Mandatory	14.2
Power Management	Yes	Yes	14.3.1
MSI	Yes	No	14.3.2
MSI-X	Yes	Yes	14.3.3
Vital Product Data (VPD)	Yes	No	14.3.4
PCIe	Yes	Yes	14.3.5
Advanced Error Reporting (AER)	Yes	Yes	14.4.1
Device Serial Number	Yes	No (N/A)	14.4.2
Alternative RID Interpretation (ARI)	Yes	Yes	14.4.3
Single Root I/O Virtualization (SR-IOV)	Yes	No (N/A)	14.4.4
TPH Requester	Yes	Yes	14.4.5
Access Control Services (ACS)	Yes	Yes	14.4.6
Secondary PCIe	Yes	No (N/A)	14.4.7
Data Link Feature	Yes	No (N/A)	14.4.8
Process ID (PASID)	Yes	No (N/A)	14.4.9
Physical Layer 16.0 GT/s Extended Capability	Yes	No (N/A)	14.4.10
Lane Margining at the Receiver Capability	Yes	No (N/A)	14.4.11

14.2 PCI Configuration Space

Configuration registers are assigned one of the attributes listed in Table 14-4.

14.2.1 Register Attributes

Table 14-4 lists the register attributes used in this section.

Table 14-4. Register Attribute Descriptions

Type	Description
RO	**Read-Only register** Register bits are read-only and cannot be altered by software.
RW	**Read/Write register** Register bits are read/write and can be either set or reset.
RW1C	**Read-only status, Write 1b to Clear status register.** Writing a 0b to RW1C bits has no effect.
ROS	**Read-only register with Sticky bits** Register bits are read-only and cannot be altered by software. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed below are also not reset on PERST# when aux power consumption is enabled.
RWS	**Read/Write register with Sticky bits** Register bits are read/write and can be either set or cleared by software to the desired state. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed below are also not reset on PERST# when aux power consumption is enabled.
RW1CS	**Read-only status, Write 1b to Clear status register** Register bits indicate status when read,. A set bit, indicating a status event, can be cleared by writing a 1b to it. Writing a 0b to RW1C bits has no effect. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed in the sections that follow are also not reset on PERST# when aux power consumption is enabled.
HwInit	**Hardware Initialized** Register bits are initialized by firmware or hardware mechanisms, such as pin strapping or serial NVM. Bits are read-only after initialization and can only be reset (for write-once by firmware) with the PWRGOOD signal.
RsvdP	**Reserved and Preserved** Reserved for future read/write implementations;. Software must preserve value read for writes to these bits.
RsvdZ	**Reserved and Zero** Reserved for future RW1C implementations;. Software must use 0b for writes to these bits.

14.2.2 Reset Rules

Reset of the PCI configuration space (including any capability lists) is per the PCIe specification. Several cases require special attention.

14.2.2.1 Sticky Registers

The following sticky register fields are also not reset on PERST# when aux power consumption is enabled (AUX_PWR pin is set).

- PME-related fields:
  - Power Management Capabilities register — *PME_En* bit.
  - Power Management Capabilities register — *PME_Status* bit.
  - Device Control register — *Aux Power PM Enable* bit.
  - The function Requester ID.
- AER-related fields:
  - Uncorrectable Error Status register.
  - Uncorrectable Error Mask register.
  - Uncorrectable Error Severity register.
  - Correctable Error Status register.
  - Correctable Error Mask register.
  - Advanced Error Capabilities and Control register.
  - Header log.
- Physical Layer 16.0 GT/s related fields:
  - Physical Layer 16.0 GT/s Status Register
  - 16.0 GT/s Local Data Parity Mismatch Status Register
  - 16.0 GT/s First Re-timer Data Parity Mismatch Status Register
  - 16.0 GT/s Second Re-timer Data Parity Mismatch Status Register

14.2.2.2 Reset on FLR

The following registers are not affected by FLR:

- The *Max Payload Size* field in the Device Control register.
- The *Active State Link PM Control* field in the Link Control register.
- The *Common Clock Configuration* field in the Link Control register.
- The *Extended Sync* field in the Link Control register.
- The *Link Equalization Request* field in the Link Status 2 register.

14.2.3 PCI Configuration Space Summary

Table 14-5 lists the PCI configuration registers, while their detailed description is given in the sections that follow. Fields that have meaningful default values are indicated in parenthesis — (**value**).

The PCI configuration space from address 0x40 on is allocated for PCI capability structures as described in Section 14.3. However, the region of 0x98-0x9F (8 bytes) is dedicated to an address/data port, which provides access to the device I/O address space (see Section 13.1.1.6 for more details).

Table 14-5. PCI Configuration Space - PF

Section	Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
Mandatory PCI Register	0x0	Device ID		Vendor ID	
	0x4	Status Register		Command Register	
	0x8	Class Code (0x020000/0x010000)			Revision ID
	0xC	Reserved	Header Type (0x0/0x80)	Latency Timer	Cache Line Size (0x10)
	0x10	Base Address Register 0			
	0x14	Base Address Register 1			
	0x18	Base Address Register 2			
	0x1C	Base Address Register 3			
	0x20	Base Address Register 4			
	0x24	Base Address Register 5			
	0x28	CardBus CIS Pointer (0x0000)			
	0x2C	Subsystem ID		Subsystem Vendor ID	
	0x30	Expansion ROM Base Address			
	0x34	Reserved			Cap Ptr (0x40)
	0x38	Reserved			
	0x3C	Max Latency (0x00)	Min Grant (0x00)	Interrupt Pin (0x01...0x04)	Interrupt Line (0x00)

14.2.4 Sharing Among PCI Functions

The E810 supports multiple PCI functions. As each function exposes a PCIe configuration space, each register and each field is either shared among the functions or is replicated per each PCI function. This section summarizes configuration sharing of the fixed PCI configuration space. See the description of each PCI capability structure for configuration sharing within it. Also, the description of each field describes special considerations regarding configuration sharing.

Table 14-6. Configuration Sharing of PCI Configuration Space

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Vendor ID	Vendor ID	X			14.2.5.1
Device ID	Device ID		X		14.2.5.2
Command Register	I/O Access Enable		X	Issue UR per PF if disabled.	14.2.5.3
	Memory Access Enable		X	Issue UR per PF if disabled.	
	Bus Master Enable		X		
	Parity Error Response		X	Enables certain error reporting per PF.	
	SERR# Enable		X	Controls error reporting per PF.	
	Interrupt Disable		X	Selection of interrupt method per PF.	
Status Register	Interrupt Status		X		14.2.5.4
	Capabilities List	X		Hard-wired to 1b.	
	Data Parity Reported / Master Data Parity Error		X	Reports poisoned packets per PF.	
	Signaled Target Abort		X	Reports Completer Abort per PF.	
	Received Target Abort		X	Reports receiving a Completer Abort per PF.	
	Received Master Abort		X	Reports receiving an UR per PF.	
	Signaled System Error		X	Reports Fatal / non-fatal message per PF.	
	Detected Parity Error		X	Reports receiving a poisoned TLP per PF.	
Revision Register		X			14.2.5.5
Class Code Register			X	Per function type.	14.2.5.6
Cache Line Size Register			X	Does not affect device behavior.	14.2.5.7
Latency Timer		X		Hard-wired to 0x00 in PCIe.	14.2.5.8
Header Type Register		X			14.2.5.9
BARs	Memory BAR		X		14.2.6
	I/O BAR		X		
	MSI-X BAR		X	See MSI-X capability.	
I/O Bar Mapping	IOADDR, IODATA		X		14.2.6.1
Subsystem Vendor ID		X			14.2.5.10
Subsystem ID			X		14.2.5.11
Expansion ROM		X		Each PF has its own BAR.	14.2.6.2
Cap_Ptr Register		X			14.2.5.12
Interrupt Line Register			X	Just store the register value.	14.2.5.13
Interrupt Pin Register			X	Separate interrupt number (A-D) per PF.	14.2.5.14
Min Grant		X			14.2.5.15
Max Latency		X			

14.2.5 Mandatory PCI Configuration Registers - Except BARs

14.2.5.1 Vendor ID Register (0x0; RO)

This is a read-only register that has the same value for all PCI functions.

- Vendor ID is loaded from the NVM if the GLPCI_CAPSUP.*LOAD_DEV_ID* bit is set.
- The value for all PFs is loaded from the NVM GLPCI_VENDORID.*VENDOR_ID* field.

14.2.5.2 Device ID Register (0x2; RO)

This is a read-only register that identifies individual E810 PCI functions. All functions have the same default value of 0x1590 for the E810-CAM2/CAM1 (25x25 mm package) and 0x1598 for the E810-XXVAM2 (21x21 mm package), and can be auto-loaded from the NVM during initialization with different values for each function as well as the dummy function (see Section 4.5.4.1 for dummy function details).

Device ID is loaded from the NVM according to the following rules:

- The Device ID is loaded from the NVM if the GLPCI_CAPSUP.*LOAD_DEV_ID* bit is set.
- The value of each PF is loaded to the respective PFPCI_DEVID.*PF_DEV_ID* field.

Table 14-7 describes the values set in this register from NVM according to the different PHY connections.

Table 14-7. Device IDs and Branding Strings

Device ID	Interface	Branding String
0x1590	Default Device ID (E810-CAM2/CAM1)	Intel® Ethernet Connection E810-C
0x1598	Default Device ID (E810-XXVAM2)	Intel® Ethernet Connection E810-XXV
0x1889	Default Virtual function device ID	Intel® Ethernet Adaptive Virtual Function
0x1591	backplane (E810-CAM2/CAM1)	Intel® Ethernet Controller E810-C for backplane
0x1599	backplane (E810-XXVAM2)	Intel® Ethernet Controller E810-XXV for backplane
0x1592	QSFP (E810-CAM2/CAM1)	Intel® Ethernet Controller E810-C for QSFP
0x159A	QSFP (E810-XXVAM2)	Intel® Ethernet Controller E810-XXV for QSFP
0x1593	SFP (E810-CAM2/CAM1)	Intel® Ethernet Controller E810-C for SFP
0x159B	SFP (E810-XXVAM2)	Intel® Ethernet Controller E810-XXV for SFP
0x1594	10GBASE-T (E810-CAM2/CAM1)	Intel® Ethernet Controller E810-C/X557-AT 10GBASE-T
0x159C	10GBASE-T (E810-XXVAM2)	Intel® Ethernet Controller E810-XXV/X557-AT 10GBASE-T
0x1595	1GBASE-T (E810-CAM2/CAM1)	Intel® Ethernet Controller E810-C 1GbE
0x159D	1GBASE-T (E810-XXVAM2)	Intel® Ethernet Controller E810-XXV 1GbE
0x1596-7	Reserved for future use (E810-CAM2/CAM1)	
0x159E-F	Reserved for future use (E810-XXVAM2)	

14.2.5.3 Command Register (0x4; RW)

Shaded bits are not used by this implementation and are hard-wired to 0b. Each function has its own Command register (see Table 14-6).

Bits	Init.	Type	Description
0	0b	RW (see comment)	**I/O Access Enable** This bit is RO if an I/O BAR is not supported by the device.
1	0b	RW	**Memory Access Enable**
2	0b	RW	**Enable Mastering** Also named Bus Master Enable (BME). • LAN functions RW field. • Dummy function RO as zero field.
3	0b	RO	**Special Cycle Monitoring** Hard-wired to 0b.
4	0b	RO	**MWI Enable** Hard-wired to 0b.
5	0b	RO	**Palette Snoop Enable** Hard-wired to 0b.
6	0b	RW	**Parity Error Response**
7	0b	RO	**Wait Cycle Enable** Hard-wired to 0b.
8	0b	RW	**SERR# Enable**
9	0b	RO	**Fast Back-to-Back Enable** Hard-wired to 0b.
10	0b	RW	**Interrupt Disable** When set, devices are prevented from generating legacy interrupt messages. RO as 0b for a dummy function.
15:11	0x0	RO	Reserved.

14.2.5.4 Status Register (0x6; RO)

Shaded bits are not used by this implementation and are hard-wired to 0b. Each function has its own Status register.

Bits	Init.	Type	Description
0	0b	RO	**Immediate Readiness** Not supported in the E810.
2:1	00b		Reserved.
3	0b	RO	**Interrupt Status**[1]
4	1b	RO	**New Capabilities** Indicates that a device implements extended capabilities. The E810 sets this bit and implements a capabilities list to indicate that it supports PCI and PCIe capabilities.
5	0b		**66 MHz Capable** Hard-wired to 0b.
6	0b		Reserved.
7	0b		**Fast Back-to-Back Capable** Hard-wired to 0b.
8	0b	RW1C	**Data Parity Reported**

Bits	Init.	Type	Description
10:9	00b		**DEVSEL Timing** Hard-wired to 0b.
11	0b	RW1C	**Signaled Target Abort**
12	0b	RW1C	**Received Target Abort**
13	0b	RW1C	**Received Master Abort**
14	0b	RW1C	**Signaled System Error**
15	0b	RW1C	**Detected Parity Error**

1. The *Interrupt Status* field is a RO field that indicates that an interrupt message is pending internally to the device.

14.2.5.5 Revision Register (0x8; RO)

The default revision ID of this device is 0x00 for A0 step. The default value is readable through the GLPCI_DREVID register. The value in the Revision register is a logic XOR between the default value and a value loaded from the NVM, reflected via the GLPCI_REVID register.

The default Revision ID for each E810 SKU is:

- E810-C in 25x25 mm package, B0 Step: 0x01
- E810-XXV in 21x21 mm package, A0 Step: 0x01

14.2.5.6 Class Code Register (0x9; RO)

The class code is a read-only value that identifies the device functionality:

- Class Code = 0x020000 (Ethernet adapter) if NVM->*Storage Class* = 0b.
- Class Code = 0x010000 (SCSI storage device) if NVM->*Storage Class* = 1b.

In the dummy function, the class code equals to 0xFF0000.

The device default value is the class code of an Ethernet adapter. The value is overwritten from the NVM. It is loaded to the RO PFPCI_CLASS register.

14.2.5.7 Cache Line Size Register (0xC; RW)

This field is implemented by PCIe devices as a read/write field for legacy compatibility purposes, but has no impact on any PCIe device functionality. All functions are initialized to the same value of 0x00 (specification required).

14.2.5.8 Latency Timer (0xD; RO)

Not used. Hard-wired to 0b.

14.2.5.9 Header Type Register (0xE; RO)

This indicates if a device is single- or multi-function:

- **0x00** — A single function is enabled.
- **0x80** — At least two functions are enabled.

Notes:

- Dummy functions are considered as regular functions in this regard.
- SR-IOV VFs are not counted in the setting of the Header Type register.
- Functions might be disabled during the power on reset flow (through strapping pins, SMASH/CLP commands, NC-SI commands) affecting this bit. See Section 4.5.4.

14.2.5.10 Subsystem Vendor ID Register (0x2C; RO)

This value is loaded from the NVM if the GLPCI_CAPSUP.*LOAD_SUBSYS_ID* bit is set. A value of 0x8086 is the default for this field. It can be read through the GLPCI_SUBVENID register.

14.2.5.11 Subsystem ID Register (0x2E; RO)

This value is loaded from the NVM if the GLPCI_CAPSUP.*LOAD_SUBSYS_ID* bit is set. Each PF is loaded to the respective PFPCI_SUBSYSID.*PF_SUBSYS_ID* field.

14.2.5.12 Capabilities Pointer Register (0x34; RO)

The *Capabilities Pointer* field (Cap_Ptr) is an 8-bit field that provides an offset in the E810's PCI configuration space for the location of the first item in the capabilities linked list. The E810 supports this field and implements a capabilities list. Its value is 0x40, which is the address of the first entry: PCI power management.

14.2.5.13 Interrupt Line Register (0x3C; RW)

Read/write register programmed by software to indicate which of the system interrupt request lines the E810's interrupt pin is bound to. Refer to the PCI definition for more details.

14.2.5.14 Interrupt Pin Register (0x3D; RO)

Read-only register. A value of 0x1...0x4 indicates that this function implements a legacy interrupt on INTA#...INTD# respectively. Loaded from the NVM. It can be read through the RO PFPCI_CNF register. Device default value is 0x0.

If only a single function is enabled, the *Interrupt Pin* field of the enabled function reports INTA# usage.

Reports a value of 0x0 (function uses no legacy interrupt message) for a dummy function.

14.2.5.15 MIN_GNT and MAX_LAT (0x3E; RO)

Not used. Hard-wired to 0b.

14.2.6 Mandatory PCI Configuration Registers - BARs

14.2.6.1 Memory and I/O BARs (0x10 - 0x27; RW)

BARs are used to map E810 register space of the device functions. The E810 has a memory BAR, an I/O BAR (optional) an MSI-X BAR as listed in Table 14-8. The BARs location and sizes are listed in Table 14-9. The fields within each BAR are then listed in Table 14-10.

Table 14-8. E810 BAR Description

Mapping Windows	Mapping Description
Memory BAR	The internal registers memories, Protocol Engine doorbells, and external Flash devices are accessed as direct memory-mapped offsets from the BAR. Software can access a DWord or 64 bits.
I/O BAR	All internal registers and memories can be accessed using I/O operations. There are two 4-byte registers in the I/O mapping window: Addr Reg and Data Reg accessible as DWord entities. The I/O BAR is supported depending on the NVM configuration. Device default value is that an I/O BAR is not supported. The state of the I/O BAR is exposed in the PFPCI_CNF register. This BAR is not present in dummy functions.
MSI-X BAR	The MSI-X vectors and PBA structures are accessed as direct memory-mapped offsets from the MSI-X BAR. Software can access DWord entities. This BAR is not present in dummy functions.

Table 14-9. E810 Base Address Setting in 64-bit BARs Mode

BAR	Addr	31 5	4	3	2	1	0
0	0x10	Memory CSR + FLASH BAR Low: 31:24 = RW 23:18 = RW or 0b 17:4 = 0b		0/1	1	0	0
1	0x14	Memory CSR + FLASH BAR High (RW)					
2	0x18	IO BAR (RW — 31:5) (optional)	0	0	0	0	1
3	0x1C	MSI-X BAR Low (RW — 31:15; RO 0b — 14:4)		0/1	1	0	0
4	0x20	MSI-X BAR High (RW)					
5	0x24	Reserved (RO — 0)					

Table 14-10. Base Address Registers Fields

Field	Bits	Type	Description
Memory and I/O Space Indication	0	RO	**Memory and I/O Space Indication** 0b = Indicates memory space. 1b = Indicates I/O.
Memory Type	2:1	RO	**Memory Type** This field is loaded from the NVM. Hardware default is 64-bit.
Prefetch Memory	3	RO	**Prefetch Memory** 0b = Non-prefetchable space. 1b = Prefetchable space. This bit is loaded from NVM. This bit should be set only on systems that do not generate prefetchable cycles. Device default is 1b (prefetchable). It is exposed in the GLPCI_LBARCTRL register.

Table 14-10. Base Address Registers Fields [continued]

Field	Bits	Type	Description	
Address Space (low register for 64-bit memory BARs)	31:4	RW	**Address Space** The length of the RW bits and RO 0b bits depend on the mapping window sizes. Initial value of the RW fields is 0x0.	
			Mapping Window	RO bits
			Memory space for CSRs, PE doorbells, and Flash memory access and 4K pages.	16:4 for 128 KB 17:4 for 256 KB and so on...
			MSI-X space is 32 KB.	14:4
			I/O space size is 32 bytes.	4:0

14.2.6.2 Expansion ROM Base Address Register (0x30; RW)

This register is used to define the address and size information for boot-time access to the optional Flash memory. This register returns a zero value for functions without an Expansion ROM window and for dummy functions.

The Expansion ROM BAR is disabled through the PFPCI_CNF.*EXROM_DIS* register field.

Field	Bits	Init.	Type	Description
En	0	0b	RW	**Enable** 0b = Disables Expansion ROM access. 1b = Enables Expansion ROM access.
Reserved	10:1	0x0	R	Reserved. Always read as 0x0. Writes are ignored.
Address	31:11	0x0	RW	**Address** The number of bits that are not hard-wired to 0b is determined by the value of the GLPCI_LBARCTRL.*EXROM_SIZE* register field, loaded from the NVM.

14.3 Capabilities in PCI Configuration Space

The first entry of the PCI capabilities link list is pointed to by the Cap_Ptr register. Table 14-11 lists the capabilities supported by the E810 that reside in the PCI configuration space.

Table 14-11. PCI Capabilities List

Address Range	Item	Cases Where Capability Does Not Exist	Next Pointer	Section Reference
0x40 - 0x4F	Power Management	• None (always exists).	0x50 / 0xA0	14.3.1
0x50 - 0x6F	MSI	• Dummy function.	0x70 / 0xA0	14.3.2
0x70 - 0x8F	MSI-X	• PFPCI_CNF.MSI_EN is 0b. • Dummy function.	0xA0	14.3.3
0xA0 - 0xDF	PCIe	• None (always exists).	0xE0 / 0x00	14.3.5
0xE0 - 0xEF	VPD	• VPD Enable bit (GLPCI_CAPCTRL.VPD_EN) is cleared. • Dummy function.	0x00	14.3.4

14.3.1 PCI Power Management Capability

Table 14-12. PCI Power Management Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x40	Power Management Capabilities		Next Pointer	Capability ID (0x01)
0x44	Data	Bridge Support Extensions	Power Management Control and Status	

Table 14-13 lists the sharing of the Power Management Capability registers among the different PCI functions.

Table 14-13. Sharing the Power Management Capability Registers

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Capability ID		X			14.3.1.1
Next Pointer			X		14.3.1.2
Power Management Capabilities	PME_Support	X			14.3.1.3
	D2_Support	X			
	D1_Support	X			
	AUX Current	X			
	DSI	X			
	PME Clock	X		Hard-wired to 0b.	
	Version	X			

Table 14-13. Sharing the Power Management Capability Registers [continued]

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Power Management Control / Status	PME_Status		X		14.3.1.4
	Data_Scale	X			
	Data_Select		X		
	PME_En		X		
	No_Soft_Reset	X			
	PowerState		X		
Data Register			X		14.3.1.6

14.3.1.1 Capability ID Register (0x40; RO)

This field equals 0x01, indicating the linked list item as being the PCI Power Management registers.

14.3.1.2 Next Pointer Register (0x41; RO)

This field provides an offset to the next capability item in the capability list. See Table 14-11 for possible values of the next pointer register.

14.3.1.3 Power Management Capabilities - PMCR (0x42; RO)

This register describes the device functionality during the power management states as listed in the following table.

Bits	Init.	Type	Description
2:0	011b	RO	**Version** The E810 complies with the PCI PM specification revision 1.2.
3	0b	RO	**PME_Clock** Disabled. Hard-wired to 0b.
4	0b	RO	**Immediate Readiness** Immediate_Readiness_on_Return_to_D0 (not supported in the E810).
5	1b	RO	**DSI** The E810 requires its device driver to be executed following a transition to the D0 uninitialized state.
8:6	000b	RO	**AUX Current** Required current defined in the Data register.
9	0b	RO	**D1_Support** The E810 does not support the D1 state.
10	0b	RO	**D2_Support** The E810 does not support the D2 state.
15:11	0x0	RO	**PME_Support** This 5-bit field indicates the power states in which the function can generate a PME event. If GLPCI_CAPSUP.*WAKEUP_EN* is set, the condition functionality values are as follows: 01001b = No AUX Pwr PME at D0 and D3hot 11001b = AUX Pwr PME at D0, D3hot, and D3cold Otherwise zero. ***Note:*** For dummy function, this field is RO - zero.

14.3.1.4 Power Management Control/Status Register - PMCSR (0x44; RW)

This register is used to control and monitor power management events in the device.

Bits	Init.	Type	Description
1:0	00b	RW	**PowerState** This field is used to set and report the power state of a function as follows: 00b = D0 01b = D1 (cycle ignored if written with this value) 10b = D2 (cycle ignored if written with this value) 11b = D3
2	0b	RO	Reserved for PCIe.
3	1b	RO	**No_Soft_Reset** This bit is always set to 1b to indicate that the E810 does not perform an internal reset upon transition from D3hot to D0 via software control of the *PowerState* bits. Configuration context is maintained when performing the soft reset. Upon transition from the D3hot to the D0 state, an initialization sequence is not needed to return the E810 to the D0 Initialized state.
7:4	0x0	RO	Reserved.
8	0b (at power up)	RWS	**PME_En** Writing a 1b to this register enables wake-up.
12:9	0x0	RW	**Data_Select** This 4-bit field is used to select which data is to be reported through the Data register and *Data_Scale* field.
14:13	00b	RO	**Data_Scale** This field indicates the scaling factor that is used when interpreting the value of the Data register. This field is loaded from the NVM (through the GLPCI_PWRDATA.*DATA_SCALE* register) for legal values of Data_Select [0, 3, 4, 7, (and 8 for function 0)]. The normal value is 01b (indicating 0.1 watt/units). Reserved (00b) for any other values of Data_Select.
15	0b (at power up)	RW1CS	**PME_Status** This bit is set to 1b when the function detects a wake-up event independent of the state of the *PME_En* bit. Writing a 1b clears this bit.

14.3.1.5 PMCSR_BSE Bridge Support Extensions Register (0x46; RO)

This register is not implemented in the E810; values set to 0x00.

14.3.1.6 Data Register (0x47; RO)

This optional register is used to report power consumption and heat dissipation. The reported register is controlled by the *Data_Select* field in the PMCSR, while the power scale is reported in the *Data_Scale* field in the PMCSR. The data for this field is loaded from the NVM with a default value of 0x00. It is exposed through the GLPCI_PWRDATA register.

The values for E810 functions are as follows (the relevant column is selected based on the value of the *Data_Select* field):

Field	D0 (Consume/ Dissipate)	D3 (Consume/ Dissipate)	Common
Data_Select	(0x0/0x4)	(0x3/0x7)	(0x8)
Function 0	Loaded from NVM	Loaded from NVM	Multi-function value: Loaded from the NVM Single-function value: 0x00
Other functions	Loaded from NVM	Loaded from NVM	0x00

Note: For other *Data_Select* values the Data register output is reserved (0x00).

14.3.2 MSI Capability

This structure is enabled when the PFPCI_CNF.*MSI_EN* bit is set for the function.

Table 14-14. MSI Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x50	Message Control (0x0080)		Next Pointer	Capability ID (0x05)
0x54	Message Address			
0x58	Message Upper Address			
0x5C	Reserved		Message Data	
0x60	Mask Bits			
0x64	Pending Bits			

Table 14-15 lists configuration sharing of the MSI Capability registers among the different PCI functions.

Table 14-15. Configuration Sharing of the MSI Capability

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Capability ID		X			14.3.2.1
Next Pointer			X		14.3.2.2
Message Control	MSI Enable		X		14.3.2.3
	Multiple Messages Capable	X			
	Multiple Message Enable		X		
	64-bit Capable	X			
	MSI per-vector masking	X			
Message Address Low			X		14.3.2.4
Message Address High			X		14.3.2.5
Message Data			X		14.3.2.6
Mask Bits			X		14.3.2.7
Pending Bits			X		14.3.2.8

14.3.2.1 Capability ID Register (0x50; RO)

This field equals 0x05, indicating that the linked list item as being the MSI registers.

14.3.2.2 Next Pointer Register (0x51; RO)

This field provides an offset to the next capability item in the capability list. See Table 14-11 for possible values of the next pointer register.

14.3.2.3 Message Control Register (0x52; RW)

Bits	Init.	Type	Description
0	0b	RW	**MSI Enable** 1b = Message Signaled Interrupts — The E810 generates an MSI for interrupt assertion instead of INTx signaling.
3:1	000b	RO	**Multiple Messages Capable** The E810 indicates a single requested message per function.
6:4	000b	RW	**Multiple Message Enable** Software writes to this field to indicate the number of allocated vectors. Since the E810 requests a single vector in the *Multiple Message Capable* field, software is expected to write 000b to this field.
7	1b	RO	**64-bit Capable** 1b = Indicates that the E810 is capable of generating 64-bit message addresses.
8	1b[1]	RO	**MSI per-vector masking** 0b = Indicates that the E810 is not capable of per-vector masking. 1b = Indicates that the E810 is capable of per-vector masking.
15:9	0x0	RO	Reserved. Reads as 0x0.

1. Value loaded from the NVM.

14.3.2.4 Message Address Low Register (0x54; RW)

Written by the system to indicate the lower 32 bits of the address to use for the MSI memory write transaction. The lower two bits always return 0b regardless of the write operation.

14.3.2.5 Message Address High Register (0x58; RW)

Written by the system to indicate the upper 32 bits of the address to use for the MSI memory write transaction.

14.3.2.6 Message Data Register (0x5C; RW)

Written by the system to indicate the lower 16 bits of the data written in the MSI memory write DWord transaction. The upper 16 bits of the transaction are written as 0b.

14.3.2.7 Mask Bits Register (0x60; RW)

The Mask Bits and Pending Bits registers enable software to disable or defer message sending on a per-vector basis. Because the E810 only supports one message, only bit 0 of these registers are implemented.

Bits	Init.	Type	Description
0	0b	RW	**MSI Vector 0 Mask** If set, the E810 is prohibited from sending MSI messages.
31:1	0x0	RO	Reserved.

14.3.2.8 Pending Bits Register (0x64; RW)

Bits	Init.	Type	Description
0	0b	RO	**MSI Message** If set, the E810 has a pending MSI message.
31:1	0x0	RO	Reserved.

14.3.3 MSI-X Capability

More than one MSI-X capability structure per function is prohibited, though a function is permitted to have both an MSI and an MSI-X capability structure.

In contrast to the MSI capability structure, which directly contains all of the control/status information for the function's vectors, the MSI-X capability structure instead points to an MSI-X table structure and an MSI-X Pending Bit Array (PBA) structure, each residing in memory space.

A BAR is allocated for the MSI-X structures, described in Section 14.2.6. A BAR Indicator Register (BIR) indicates which BAR, and a QWord-aligned offset indicates where the structure begins relative to the-base address associated with the BAR. The BAR is 64 bits.

The number of MSI-X vectors per PF (denoted as N) varies with the number of physical and virtual functions as set from NVM.

The MSI-X BAR is 32 KB long.

The location and size of the MSI-X vector table and the MSI-X pending bits table are determined as follows:

- MSI-X vector table:
  - The MSI-X table structure (Section 14.3.3.2) typically contains multiple entries, each consisting of several fields: Message Address, Message Upper Address, Message Data, and Vector Control. Each entry is capable of specifying a unique vector.
  - Starts at offset 0x0000 from start of BAR.
  - Contains the MSI-X vectors for the PF. The number of entries in the table (N) is set from NVM. The maximum value of N is 2048 per PF.
  - The vectors start with the Vector 0 (one per PF), followed by the other vectors allocated to the PF.

- MSI-X Pending Bits table:
  - The PBA structure (Section 14.3.3.2.2) contains the function's pending bits, one per table entry, organized as a packed array of bits within QWords. The last QWord is not necessarily fully populated.
  - Starts at offset 0x8000 (32 KB) from start of BAR.
  - Contains the pending bits for the PF. The PF can be allocated a multiple of 64-bit registers. The total number of 32-bit registers is per the number of MSI-X vectors. The maximum number of registers is 8 (for the case of 256 vectors).
  - The bits start with the Vector 0 bit (one per PF), followed by bits for the other vectors allocated to the PF.

To request service using a given MSI-X table entry, a function performs a DWord memory write transaction using:

- The contents of the Message Data field entry for data.
- The contents of the Message Upper Address field for the upper 32 bits of the address.
- The contents of the Message Address field entry for the lower 32 bits of the address.

A memory read transaction from the address targeted by the MSI-X message produces undefined results.

The MSI-X table and MSI-X PBA are permitted to co-reside within a naturally aligned 4 KB address range, though they must not overlap with each other.

14.3.3.1 Capability Structure

Table 14-16. MSI-X Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	Message Control (0x00090)		Next Pointer	Capability ID (0x11)
0x74	Table Offset			
0x78	PBA Offset			

Table 14-17 lists configuration sharing of the MSI-X capability registers among the different PCI functions.

Table 14-17. Configuration Sharing of the MSI-X Capability

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Capability ID		X			14.3.3.1.1
Next Pointer			X		14.3.3.1.2

MSI-X Pending Bit Array	PBA BIR		X		14.3.3.1.5
	PBA Offset		X		
MSI-X Table			X		14.3.3.2.1
MSI-X PBA Structure			X		14.3.3.2.2

14.3.3.1.1 Capability ID Register (0x70; RO)

This field equals 0x11, indicating that the linked list item as being the MSI-X registers.

14.3.3.1.2 Next Pointer Register (0x71; RO)

This field provides an offset to the next capability item in the capability list. See Table 14-11 for possible values of the next pointer register.

14.3.3.1.3 Message Control Register (0x72; RW)

Bits	Init.	Type	Description
10:0	0xFF (256 vectors)	RO	**Table Size** System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. This field is loaded from the NVM. It is reflected in the GLPCI_CNF2.*MSI_X_PF_N* CSR field.
13:11	000b	RO	Reserved. Always returns 000b on a read. A write operation has no effect.
14	0b	RW	**Function Mask** 0b = Each vector's *Mask* bit determines whether the vector is masked or not. 1b = All of the vectors associated with the function are masked, regardless of their per-vector *Mask* bit states. Setting or clearing the MSI-X *Function Mask* bit has no effect on the state of the per-vector *Mask* bits.
15	0b	RW	**MSI-X Enable** 0b = The function is prohibited from using MSI-X to request service. 1b = If 1b and the MSI *Enable* bit in the MSI Message Control register is 0b, the function is permitted to use MSI-X to request service and is prohibited from using its INTx# pin. System configuration software sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a function's service request.

14.3.3.1.4 MSI-X Table Offset Register (0x74; RW)

Bits	Init.	Type	Description
2:0	0x3	RO	**Table BIR** Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X table into the memory space. While BIR values 0...5 correspond to BARs 0x10:0x24, respectively.
31:3	0x000	RO	**Table Offset** Used as an offset from the address contained in one of the function's BARs to point to the base of the MSI-X table. The lower three *Table BIR* bits are masked off (set to 0b) by software to form a 32-bit QWord-aligned offset. ***Note:*** This field is read only.

14.3.3.1.5 MSI-X Pending Bit Array - PBA Offset (0x78; RW)

Bits	Init.	Type	Description
2:0	0x3	RO	**PBA BIR** Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X PBA into the memory space. While BIR values: 0...5 correspond to BARs 0x10:0x24, respectively.
31:3	0x200	RO	**PBA Offset** Used as an offset from the address contained in one of the functions BARs to point to the base of the MSI-X PBA. The lower three *PBA BIR* bits are masked off (set to 0b) by software to form a 32-bit QWord-aligned offset. ***Note:*** This field is read only.

14.3.3.2 PF MSI-X Table Structure

The MSI-X table is made of two structures:

- MSI-X Vector Table
- MSI-X Pending Bits Table

Both are described in the sections that follow and in more detail in Chapter 13.

14.3.3.2.1 MSI-X Vector Table

DWord3 - MSIXTVCTRL	DWord2 - MSIXTMSG	DWord1 - MSIXTUADD	DWord0 - MSIXTADD	Entry Number	BAR 3 - Offset
Vector Control	Msg Data	Msg Upper Address	Msg Lower Address	0	Base (0x0000)
Vector Control	Msg Data	Msg Upper Address	Msg Lower Address	1	Base + 1*16
Vector Control	Msg Data	Msg Upper Address	Msg Lower Address	2	Base + 2*16
...	...	...	...	...	
Vector Control	Msg Data	Msg Upper Address	Msg Lower Address	(N-1)	Base + (N-1)*16

14.3.3.2.2 MSI-X Pending Bits Table

Field	Bits	Init.	Description
PENBIT	31:0	0x0	**MSI-X Pending Bits** Each bit is set to 1b when the appropriate interrupt request is set and cleared to 0b when the appropriate interrupt request is cleared. See Section 9.1.1.3 for more details.

14.3.4 VPD Capability

The E810 supports access to a VPD structure stored in the NVM using the following set of registers. A single VPD structure is provided, accessible through any of the physical functions.

Initial values of the configuration registers are marked in parenthesis.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0xE0	VPD Address		Next Pointer	Capability ID (0x03)
0xE4	VPD Data			

14.3.4.1 Capability ID Register (0xE0; RO)

This field equals 0x3, indicating the linked list item as being the VPD registers.

14.3.4.2 Next Pointer Register (0xE1; RO)

Offset to the next capability item in the capability list. See Table 14-11 for possible values of the next pointer register.

14.3.4.3 VPD Address Register (0xE2; RW)

Word-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate.

Bits	Init.	Type	Description
14:0	X	RW	**Address** DWord-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate. The two LSBs are RO as zero.
15	0b	RW	**F** A flag used to indicate when the transfer of data between the VPD Data register and the storage component completes. The Flag register is written when the VPD Address register is written. 0b = Read. Set by hardware when data is valid. 1b = Write. Cleared by hardware when data is written to the NVM. The VPD address and data should not be modified before the action is done.

14.3.4.4 VPD Data Register (0xE4; RW)

VPD read/write data.

Bits	Init.	Type	Description
31:0	X	RW	**VPD Data** VPD data can be read or written through this register. The LSB of this register (at offset 4 in this capability structure) corresponds to the byte of VPD at the address specified by the VPD Address register. The data read from or written to this register uses the normal PCI byte transfer capabilities. Four bytes are always transferred between this register and the VPD storage component. Reading or writing data outside of the VPD space in the storage component is not allowed. In a write access, the data should be set before the address and the flag is set.

14.3.5 PCIe Capability Structure

The E810 implements the PCIe capability structure linked to the legacy PCI capability list for endpoint devices as follows:

Table 14-18. PCIe Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0xA0	PCIe Capabilities Register (0x0002)		Next Pointer	Capability ID (0x10)
0xA4	Device Capabilities			
0xA8	Device Status		Device Control	
0xAC	Link Capabilities			
0xB0	Link Status		Link Control	
0xB4	Reserved			
0xB8	Reserved		Reserved	
0xBC	Reserved			
0xC0	Reserved		Reserved	
0xC4	Device Capabilities 2			
0xC8	Reserved		Device Control 2	
0xCC	Link Capabilities 2 Register			
0xD0	Link Status 2		Link Control 2	
0xD4	Reserved			
0xD8	Reserved		Reserved	

Table 14-19 lists configuration sharing of the PCIe Capability registers among the different PCI functions.

Table 14-19. Configuration Sharing of the PCIe Capability

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Capability ID		X			14.3.5.1
Next Pointer			X		14.3.5.2
PCIe Capabilities		X			14.3.5.3
Device Capabilities	Max Payload Size Supported	X			14.3.5.4
	Phantom Functions Supported	X		Not supported.	
	Extended Tag Field Supported	X			
	Endpoint L0s Acceptable Latency	X			
	Endpoint L1 Acceptable Latency	X			
	Function Level Reset Capability	X			

Table 14-19. Configuration Sharing of the PCIe Capability [continued]

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Device Control	Correctable Error Reporting Enable		X		14.3.5.5
	Non-Fatal Error Reporting Enable		X		
	Fatal Error Reporting Enable		X		
	Unsupported Request Reporting Enable		X		
	Enable Relaxed Ordering		X

	Active State Link PM Support	X			
	L0s Exit Latency	X			
	L1 Exit Latency	X			
	Clock Power Management	X			
	Port Number	X			

Table 14-19. Configuration Sharing of the PCIe Capability [continued]

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Link Control	Active State Link PM Control		X	Same policy for all PFs (Logical AND of the PF's bits). In ARI mode, use value in Function 0.	14.3.5.8
	Read Completion Boundary (RCB)		X		
	Common Clock Configuration		X	Same policy for all PFs (Logical AND of the PF's bits) In ARI mode, use value in Function 0.	
	Extended Sync		X	Same policy for all PFs (Logical OR of the PF's bits).	
Link Status	Current Link Speed	X			14.3.5.9
	Negotiated Link Width	X			
	Slot Clock Configuration	X			
Device Capabilities 2	Completion Timeout Ranges Supported	X			14.3.5.10
	Completion Timeout Disable Supported	X			
	TPH Completer Supported	X			
	Extended Fmt Field Supported	X			
	OBFF Supported	X			
Device Control 2	Completion Timeout Value		X	Completion timeout decision per PF or use the largest configured value among PFs.	14.3.5.11
	Completion Timeout Disable		X	Completion timeout mechanism enabled per PF.	
	IDO Request Enable		X		
	IDO Completion Enable		X		
	OBFF Enable		X	PF0 only. RsvdP on other functions.	
Link Capabilities 2		X			14.3.5.12
Link Control 2		X		PF0 only. RsvdP on other functions.	14.3.5.13
Link Status 2		X			14.3.5.14

14.3.5.1 Capability ID Register (0xA0; RO)

This field equals 0x10, indicating that the linked list item as being the PCIe Capabilities registers.

14.3.5.2 Next Pointer Register (0xA1; RO)

Offset to the next capability item in the capability list. See Table 14-11 for possible values of the next pointer register.

14.3.5.3 PCIe Capabilities Register (0xA2; RO)

The PCIe Capabilities register identifies PCIe device type and associated capabilities.

Bits	Init.	Type	Description
3:0	0x2	RO	**Capability Version** Indicates the PCIe capability structure version. The E810 supports PCIe version 2 (loaded from NVM). It is reflected in the GLPCI_CAPSUP register.
7:4	0x0/0x9	RO	**Device/Port Type** Indicates the type of PCIe functions. All functions are native PCI functions with a value of 0x0 if *strap_gbe_pci_endpoint_type* strap is set to native, and Root Complex Integrated Endpoint is set to RCIE.
8	0b	RO	**Slot Implemented** The E810 does not implement slot options. Therefore, this field is hard-wired to 0b.
13:9	0x0	RO	**Interrupt Message Number** This field is hard-wired to 0x0 and is assumed to be irrelevant for endpoints.
15:14	00b	RO	Reserved.

14.3.5.4 Device Capabilities Register (0xA4; RO)

This register identifies the PCIe device-specific capabilities.

Bits	Init.	Type	Description
2:0	010b	RO	**Max Payload Size Supported** This field indicates the maximum payload that the E810 can support for TLPs. Set according to the *strap_gbe_imps* strap. If *strap_gbe_imps* strap = 111b, the default is 000b (128 bytes)
4:3	00b	RO	**Phantom Function Supported** Not supported by the E810.
5	1b	RO	**Extended Tag Field Supported** Maximum supported size of the *Tag* field. The E810 supports an 8-bit *Tag* field for all functions.
8:6	011b	RO	**Endpoint L0s Acceptable Latency** This field indicates the acceptable latency that the E810 can withstand due to the transition from L0s state to the L0 state. All functions share the same value loaded from the NVM. The default value of 011b denotes a maximum 512 ns.
11:9	110b	RO	**Endpoint L1 Acceptable Latency** This field indicates the acceptable latency that the E810 can withstand due to the transition from L1 state to the L0 state. The default value of 110b denotes a maximum of 64 µs. All functions share the same value loaded from the NVM. It is reflected in the GLPCI_PMSUP register.
12	0b	RO	Hard-wired in the E810 to 0b for all functions.
13	0b	RO	Hard-wired in the E810 to 0b for all functions.
14	0b	RO	Hard-wired in the E810 to 0b for all functions.
15	1b	RO	**Role Based Error Reporting** Hard-wired in the E810 to 1b for all functions.
17:16	00b	RO	Reserved.
25:18	0x0	RO	**Slot Power Limit Value** Hard-wired in the E810 to 0x0 for all functions.
27:26	00b	RO	**Slot Power Limit Scale** Hard-wired in the E810 to 0b for all functions.
28	1b	RO	**Function Level Reset Capability** A value of 1b indicates the Function supports the optional Function Level Reset (FLR) mechanism.

Bits	Init.	Type	Description
31:29	000b	RO	Reserved.

14.3.5.5 Device Control Register (0xA8; RW)

This register controls the PCIe-specific parameters.

Bits	Init.	Type	Description
0	0b	RW	**Correctable Error Reporting Enable** Enable error report.
1	0b	RW	**Non-Fatal Error Reporting Enable** Enable error report.
2	0b	RW	**Fatal Error Reporting Enable** Enable error report.
3	0b	RW	**Unsupported Request Reporting Enable** Enable error report.
4	1b	RW	**Enable Relaxed Ordering** If this bit is set, the E810 is permitted to set the *Relaxed Ordering* bit in the *Attribute* field of write transactions that do not need strong ordering. Refer to Section 3.1.2.7.2 for more details.
7:5	000b (128 bytes)	RW	**Max Payload Size** This field sets the maximum TLP payload size for E810 functions. As a receiver, the E810 must handle TLPs as large as the set value. As a transmitter, the E810 must not generate TLPs exceeding the set value. In ARI mode, *Max Payload Size* is determined solely by the field in Function 0 (even when it is a dummy function), while it is meaningless in the other function(s).
8	1b	RW	**Extended Tag Field Enable** The E810 uses 8-bit tags when this bit is set, and a 5-bit tag when disabled.
9	0b	RO	**Phantom Functions Enable** Not implemented in the E810.
10	0b	RWS	**Auxiliary Power PM Enable** When set, enables the E810 to draw AUX power independent of PME AUX power. The E810 is a multi-function device, and is therefore allowed to draw AUX power if at least one of the functions has this bit set.
11	0b	RO	**Enable No Snoop** Hard-wired to 0b, as the E810 never sets the no snoop attribute in a TLP.
14:12	010b	RW	**Max Read Request Size** This field sets maximum read request size for the E810 as a requester. 000b = 128 bytes 001b = 256 bytes 010b = 512 bytes 011b = 1024 bytes 100b = 2048 bytes 101b = 4096 bytes 110b = Reserved 111b = Reserved
15	0b	RW	**Initiate FLR** A write of 1b initiates FLR to the function. The value read by software from this bit is always 0b.

14.3.5.6 Device Status Register (0xAA; RW1C)

This register provides information about PCIe device-specific parameters.

Bits	Init.	Type	Description
0	0b	RW1C	**Correctable Detected** Indicates status of correctable error detection.
1	0b	RW1C	**Non-Fatal Error Detected** Indicates status of non-fatal error detection.
2	0b	RW1C	**Fatal Error Detected** Indicates status of fatal error detection.
3	0b	RW1C	**Unsupported Request Detected** Indicates that the E810 received an unsupported request. This field is separate per PF. However, in the case where an error cannot be associated with a PF, this bit is set in all PFs and VFs.
4	0b	RO	**Aux Power Detected** If Aux Power is detected, this field is set to 1b. It is a strapping signal from the periphery and is identical for all functions. Resets on LAN Power Good and PE_RST_N only.
5	0b	RO	**Transaction Pending** Indicates whether the E810 has ANY transactions pending. Transactions include completions for any outstanding non-posted requests for all used traffic classes.
6	0b	RO	**Emergency Power Reduction Detected** Not supported in the E810.
15:7	0x0	RsvdZ	Reserved.

14.3.5.7 Link Capabilities Register (0xAC; RO)

This register identifies PCIe link-specific capabilities.

Bits	Init.	Type	Description
3:0	0x4	RO	**Maximum Link Speed** This field indicates the supported Link speed of the associated port. The encoding is the binary value of the bit location in the supported link speeds vector (in the Link Capabilities 2 register) that corresponds to the maximum link speed. For example, a value of 0011b in this field indicates that the maximum link speed is that corresponding to bit 2 in the supported link speeds vector, which is 8.0 GT/s. Multi-function devices associated with an upstream port must report the same value in this field for all functions.
9:4	0x10	RO	**Maximum Link Width** Indicates the maximum link width. The E810 supports x1, x4, x8, and x16 link width. This field is loaded from the NVM and is reflected in the GLPCI_LINKCAP register. Defined encoding: 000000b = Reserved 000001b = x1 000010b = Reserved 000100b = x4 001000b = x8 001100b = x12 010000b = x16 100000b = x32

Bits	Init.	Type	Description
11:10	10b	RO	**Active State Link PM Support** Indicates the level of the active state of power management supported in the E810. Defined encodings are: 00b = No ASPM support. 01b = L0s Entry supported. 10b = L1 supported. 11b = L0s and L1 supported. All functions share the same value loaded from the NVM.
14:12	100b	RO	**L0s Exit Latency** Indicates the exit latency from L0s to L0 state. 000b = Less than 64 ns. 001b = 64 ns – 128 ns 010b = 128 ns – 256 ns 011b = 256 ns – 512 ns 100b = 512 ns – 1 µs 101b = 1 µs – 2 µs 110b = 2 µs – 4 µs 111b = Reserved. All functions share the same value loaded from the NVM.
17:15	010b	RO	**L1 Exit Latency** Indicates the exit latency from L1 to L0 state. 000b = Less than 1 µs 001b = 1 µs - 2 µs 010b = 2 µs - 4 µs 011b = 4 µs - 8 µs 100b = 8 µs - 16 µs 101b = 16 µs - 32 µs 110b = 32 µs - 64 µs 111b = More than 64 µs All functions share the same value loaded from the NVM.
18	0b	RO	**Clock Power Management** Not supported.
19	0b	RO	**Surprise Down Error Reporting Capable** Hard-wired to 0b.
20	0b	RO	**Data Link Layer Link Active Reporting Capable**
21	0b	RO	**Link Bandwidth Notification Capability** Hard-wired to 0b (not applicable to end-points).
22	1b	HwInit	**ASPM Optionality Compliance** Software is permitted to use the value of this bit to help determine whether to enable ASPM or to run ASPM compliance tests.
23	0b	RO	Reserved.
31:24	0x0	HwInit	**Port Number** The PCIe port number for the given PCIe link. This field is set in the link training phase. The field is set through the *gbe_DeviceNumberN* strap.

14.3.5.8 Link Control Register (0xB0; RO)

This register controls PCIe link-specific parameters.

Bits	Init.	Type	Description
1:0	00b	RW	**Active State Link PM Control** This field controls the active state PM enabled on the link. Link PM functionality is determined by the lowest common denominator of all functions. Defined encodings are: 00b = PM Disabled. 01b = L0s Entry Supported. 10b = L1 Entry Enabled. 11b = L0s and L1 Supported. In ARI mode, the ASPM is determined solely by the field in Function 0 (even when it is a dummy function), while it is meaningless in the other function(s)
2	0b	RsvdP	Reserved.
3	0b	RW	**Read Completion Boundary**
4	0b	RO	**Link Disable** Reserved for endpoint devices. Hard-wired to 0b.
5	0b	RO	**Retrain Link** Not applicable for endpoint devices. Hard-wired to 0b.
6	0b	RW	**Common Clock Configuration** When set, indicates that the E810 and the component at the other end of the link are operating with a common reference clock. A value of 0b indicates that they are operating with an asynchronous clock. This parameter affects the L0s exit latencies. In ARI mode, the common clock configuration is determined solely by the field in Function 0 (even when it is a dummy function), while it is meaningless in the other function(s).
7	0b	RW	**Extended Sync** When set, this bit forces the transmission of additional ordered sets when exiting the L0s state and when in the recovery state. For multi-function devices, if any function has this bit set, the component must transmit the additional ordered sets when exiting L0s or when in recovery.
8	0b	RO	**Enable Clock Power Management** Not supported. Hard-wired to 0b.
9	0b	RO/RsvdP	**Hardware Autonomous Width Disable** When set to 1b, this bit disables hardware from changing the link width for reasons other than attempting to correct an unreliable link operation by reducing link width. Not supported - Function 0 is hard-wired to 0b (RO). Other functions are RsvdP.
10	0b	RO	**Link Bandwidth Management Interrupt Enable** Not applicable to endpoints. Hard-wired to 0b.
11	0b	RO	**Link Autonomous Bandwidth Interrupt Enable** Not applicable to endpoints. Hard-wired to 0b.
13:12	00b	RsvdP	Reserved.
15:14	00b	RO	**DRS Signaling Control** Not applicable to endpoints. Hard-wired to 0b.

14.3.5.9 Link Status Register (0xB2; RO)

This register provides information about PCIe link-specific parameters.

Bits	Init.	Type	Description
3:0	Undefined	RO	**Current Link Speed** This field indicates the negotiated link speed of the given PCIe link. The encoded value specifies a bit location in the supported link speeds vector (in the Link Capabilities 2 register) that corresponds to the current link speed. For example, a value of 0010b in this field indicates that the current Link speed is that corresponding to bit 1 in the supported link speeds vector, which is 5.0 GT/s.
9:4	Undefined	RO	**Negotiated Link Width** Indicates the negotiated width of the link. Relevant encodings for the E810 are: 000001b = x1 000010b = x2 000100b = x4 001000b = x8 010000b = x16
10	0b	RO	Undefined.
11	0b	RO	**Link Training** Indicates that link training is in progress. This field is not applicable, is reserved for endpoint devices, and is hard-wired to 0b.
12	1b	HwInit	**Slot Clock Configuration** When set, indicates that the E810 uses the physical reference clock that the platform provides at the connector. This bit must be cleared if the E810 uses an independent clock. The *Slot Clock Configuration* bit is loaded from the NVM.
13	0b	RO	**Data Link Layer Link Active** Not supported in the E810. Hard-wired to 0b.
14	0b	RO	**Link Bandwidth Management Status** Not supported in the E810. Hard-wired to 0b.
15	0b	RO	**Link Autonomous Bandwidth Status** This bit is not applicable and is reserved for endpoints.

The following registers are supported only if the capability version is two and above.

14.3.5.10 Device Capabilities 2 Register (0xC4; RO)

This register identifies the PCIe device-specific capabilities.

Bits	Init.	Type	Description
3:0	0x3	RO	**Completion Timeout Ranges Supported** This field indicates the E810's support for the optional completion timeout programmability mechanism. Four time value ranges are defined: • Range A: 50 µs to 10 ms • Range B: 10 ms to 250 ms • Range C: 250 ms to 4 s • Range D: 4 s to 64 s Bits are set according to the following values to show the timeout value ranges that the E810 supports. 0000b = Completion timeout programming not supported. The E810 must implement a timeout value in the range of 50 µs to 50 ms. 0001b = Range A. 0010b = Range B. 0011b = Ranges A and B. 0110b = Ranges B and C. 0111b = Ranges A, B and C. 1110b = Ranges B, C and D. 1111b = Ranges A, B, C and D. All other values are reserved.
4	1b	RO	**Completion Timeout Disable Supported** ***Note:*** For dummy functionality, a completion timeout is not relevant as a dummy function because it never sends non-posted requests.
5	0b	RO	**ARI Forwarding Supported** Applicable only to Switch Downstream Ports and Root Ports. Must be 0b for other function types.
10:6	0x0	RO	**Not supported** Hard-wired to 0x0.
11	0b	RO	**LTR Mechanism Supported** A value of 1b indicates support for the optional Latency Tolerance Reporting (LTR) mechanism. For a multi-Function device associated with an Upstream Port, each Function must report the same value for this bit. ***Note:*** Value loaded from NVM as 0b (LTR is not supported by this product). It is reflected in the GLPCI_CAPSUP register.
13:12	00b	RO	**TPH Completer Supported** Value indicates Completer support for TPH or Extended TPH. This capability is not supported.
15:14	00b	R0	**LN System CLS** Applicable only to Root Ports and RCRBs. Must be 00b for all other Function types.
16	1b	RO	**10-Bit Tag Completer Supported** 0b = The Function does not support 10-Bit Tag Completer capability. 1b = The Function supports 10-Bit Tag Completer capability. Supported by the E810.
17	0b	RO	**10-Bit Tag Requester Supported** 0b = The Function does not support 10-Bit Tag Requester capability. 1b = The Function supports 10-Bit Tag Requester capability. Not supported by the E810.

Bits	Init.	Type	Description
19:18	00b	HwInit	**OBFF Supported** 00b = OBFF not supported. 01b = OBFF supported using Message signaling only. 10b = OBFF supported using WAKE# signaling only. 11b = OBFF supported using WAKE# and Message signaling. Loaded from NVM with a value of 00b (OBBF is not supported in this product). The value loaded from NVM is reflected in the GLPCI_PMSUP register.
20	1b	RO	**Extended Fmt Field Supported** 0b = The Function supports a 2-bit definition of the *Fmt* field. 1b = The Function supports the 3-bit definition of the *Fmt* field.
21	1b	RO	**End-End TLP Prefix Supported** Indicates whether End-End TLP Prefix support is offered by a Function.
23:22	1b	RsvdP	**Max End-End TLP Prefixes** Indicates the maximum number of End-End TLP Prefixes supported by this Function.
25:24	00b	RO	**Emergency Power Reduction Supported** Not supported in the E810.
26	0b	RO	**Emergency Power Reduction Initialization Required** N/A for the E810.
31:27	0x0	RsvdP	Reserved.

14.3.5.11 Device Control 2 Register (0xC8; RW)

This register controls the PCIe-specific parameters.

Bits	Init.	Type	Description
3:0	0x0	RW	**Completion Timeout Value** For devices that support completion timeout programmability, this field enables system software to modify the completion timeout value. Defined encodings: 0000b = Default range: 50 µs to 50 ms. ***Note:*** It is strongly recommended that the completion timeout mechanism not expire in less than 10 ms. Values available if Range A (50 µs to 10 ms) programmability range is supported: 0001b = 50 µs to 100 µs. 0010b = 1 ms to 10 ms. Values available if Range B (10 ms to 250 ms) programmability range is supported: 0101b = 16 ms to 55 ms. 0110b = 65 ms to 210 ms. Values available if Range C (250 ms to 4 s) programmability range is supported: 1001b = 260 ms to 900 ms. 1010b = 1 s to 3.5 s. Values available if the Range D (4 s to 64 s) programmability range is supported: 1101b = 4 s to 13 s. 1110b = 17 s to 64 s. Values not defined are reserved. Software is permitted to change the value of this field at any time. For requests already pending when the completion timeout value is changed, hardware is permitted to use either the new or the old value for the outstanding requests and is permitted to base the start time for each request either on when this value was changed or on when each request was issued. Specifically, FLR clears this field to its default, so that completions are expected to return by the default time. ***Note:*** For dummy function, this field is RO - zero.

Bits	Init.	Type	Description
4	0b	RW	**Completion Timeout Disable** When set to 1b, this bit disables the completion timeout mechanism. Software is permitted to set or clear this bit at any time. When set, the completion timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued. ***Note:*** For dummy function, this field is RO - zero.
5	0b	RO	**ARI Forwarding Enable** Applicable only to switch devices.
7:6	00b	RO	Not supported. Hard-wired to 00b.
8	0b	RW	**IDO Request Enable** If this bit is Set, the Function is permitted to set the ID-Based Ordering (*IDO*) bit (Attribute[2]) of Requests it initiates.
9	0b	RW	**IDO Completion Enable** If this bit is Set, the Function is permitted to set the ID-Based Ordering (*IDO*) bit (Attribute[2]) of Completions it returns
10	0b	RO	**LTR Mechanism Enable** When Set to 1b, this bit enables Upstream Ports to send LTR messages. For a multi-function device, the bit in Function 0 is RW, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is RsvdP. If LTR is not supported, this bit is RO with a value of 0b.
11	00b	RO	**Emergency Power Reduction Request** Not supported by the E810.
12	0b	RW	**10-bit Tag Requester Enable**
14:13	00b	RW/RsvdP	**OBFF Enable** 00b = Disabled. 01b = Enabled using Message signaling [Variation A]. 10b = Enabled using Message signaling [Variation B]. 11b = Enabled using WAKE# signaling. For a multi-function device, the field in Function 0 is of type RW, and only Function 0 controls the component's behavior. In all other Functions of that device, this field is of type RsvdP.
15	0b	RsvdP	**End-End TLP Prefix Blocking** Not applicable to endpoints (RsvdP).

14.3.5.12 Link Capabilities 2 Register (0xCC; RO)

Bits	Init.	Type	Description
0	0b	RsvdP	Reserved.
7:1	0x01	RO	**Supported Link Speeds Vector** This field indicates the supported Link speed(s) of the associated Port. For each bit, a value of 1b indicates that the corresponding Link speed is supported. Otherwise, the Link speed is not supported. Bit definitions are: Bit 1 = 2.5 GT/s Bit 2 = 5.0 GT/s Bit 3 = 8.0 GT/s Bit 4 = 16.0 GT/s Bits 7:5 = RsvdP Multi-function devices associated with the same Upstream Port must report the same value in this field for all Functions. This field is loaded from NVM and is reflected in the GLPCI_LINKCAP register.
8	0b	RO	**Crosslink Supported** When set to 1b, this bit indicates that the associated Port supports crosslinks. It is recommended that this bit be Set in any Port that supports crosslinks even though doing so is only required for Ports that also support operating at 8.0 GT/s or higher Link speeds.

Bits	Init.	Type	Description
0	0b	RsvdP	Reserved.
15:9	0x0	RO	**Lower SKP OS Generation Supported Speeds Vector** If this field is non-zero, it indicates that the Port, when operating at the indicated speed(s), supports SRIS and also supports software control of the SKP Ordered Set transmission scheduling rate. Bit definitions within this field are: Bit 0 = 2.5 GT/s Bit 1 = 5.0 GT/s Bit 2 = 8.0 GT/s Bit 3 = 16.0 GT/s Bits 6:4 = RsvdP
22:6	0x0	RO	**Lower SKP OS Reception Supported Speeds Vector** If this field is non-zero, it indicates that the Port, when operating at the indicated speed(s), supports SRIS and also supports receiving SKP OS at the rate defined for SRNS while running in SRIS. Bit definitions within this field are: Bit 0 = 2.5 GT/s Bit 1 = 5.0 GT/s Bit 2 = 8.0 GT/s Bit 3 = 16.0 GT/s Bits 6:4 = RsvdP
23	1b	RO	**Re-timer Presence Detect Supported** When set to 1b, this bit indicates that the associated Port supports detection and reporting of re-timer presence. This bit must be set to 1b in a Port when the *Supported Link Speeds Vector* of the Link Capabilities 2 register indicates support for a Link speed of 16.0 GT/s or higher. It is permitted to be set to 1b regardless of the supported Link speeds.
24	1b	RO	**Two Re-timers Presence Detect Supported** When set to 1b, this bit indicates that the associated Port supports detection and reporting of two re-timers presence. This bit must be set to 1b in a Port when the *Supported Link Speeds Vector* of the Link Capabilities 2 register indicates support for a Link speed of 16.0 GT/s or higher. It is permitted to be set to 1b regardless of the supported Link speeds if the *Re-timer Presence Detect Supported* bit is also set to 1b.
30:25	0x0	RsvdP	Reserved.
31	0b	RO	**DRS Supported** When set, indicates support for the optional Device Readiness Status (DRS) capability. Not supported by the E810.

14.3.5.13 Link Control 2 Register (0xD0; RWS)

Bits	Init.	Type	Description
3:0	0x4 (Func 0) 0x0 (else)	RWS (Func 0) RsvdP (else)	**Target Link Speed** This field is used to set the target compliance mode speed when software is using the *Enter Compliance* bit to force a link into compliance mode. The encoding is the binary value of the bit in the *Supported Link Speeds Vector* (in the Link Capabilities 2 register) that corresponds to the desired target Link speed. All other encodings are Reserved. For example, 5.0 GT/s corresponds to bit 1 in the *Supported Link Speeds Vector*, so the encoding for a 5.0 GT/s target Link speed in this field is 0010b If a value is written to this field that does not correspond to a speed included in the *Supported Link Speeds* field, the result is undefined. The default value of this field is the highest link speed supported by the E810 (as reported in the *Supported Link Speeds* field of the Link Capabilities register).

Bits	Init.	Type	Description
4	0b	RWS (Func 0) RsvdP (else)	**Enter Compliance** Software is permitted to force a link to enter compliance mode at the speed indicated in the *Target Link Speed* field by setting this bit to 1b in both components on a link and then initiating a hot reset on the link. The default value of this field following a fundamental reset is 0b.
5	0b	RWS (Func 0) RsvdP (else)	**Hardware Autonomous Speed Disable** When set to 1b, this bit disables hardware from changing the link speed for reasons other than attempting to correct unreliable link operation by reducing link speed.
6	0b	RO	**Selectable De-Emphasis** This bit is not applicable and reserved for endpoints.
9:7	000b	RWS (Func 0) RsvdP (else)	**Transmit Margin** This field controls the value of the non-de-emphasized voltage level at the Transmitter pins. Encodings: 000b = Normal operating range. 001b = 800-1200 mV for full swing and 400-700 mV for half-swing. 010b = (n-1) — Values must be monotonic with a non-zero slope. The value of n must be greater than 3 and less than 7. At least two of these must be below the normal operating range of n: 200-400 mV for full-swing and 100-200 mV for half-swing. 111b = (n) Reserved.
10	0b	RWS (Func 0) RsvdP (else)	**Enter Modified Compliance** When this bit is set to 1b, the device transmits modified compliance pattern if the LTSSM enters Polling.Compliance state. The default value of this bit is 0b.
11	0b	RWS (Func 0) RsvdP (else)	**Compliance SOS** When set to 1b, the LTSSM is required to send SOS periodically in between the (modified) compliance patterns. This bit is applicable when the Link is operating at 2.5 GT/s or 5 GT/s data rates only. The default value of this bit is 0b.
15:12	0x0	RWS (Func 0) RsvdP (else)	**Compliance Preset/De-Emphasis** For 8.0 GT/s Data Rate: This field sets the Transmitter Preset in Polling.Compliance state if the entry occurred due to the *Enter Compliance* bit being 1b. For 5.0 GT/s Data Rate: This field sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the *Enter Compliance* bit being 1b. When the Link is operating at 2.5 GT/s, the setting of this bit field has no effect. Defined Encodings are: 0001b -3.5 dB 0000b -6 dB For a multi-function device associated with an Upstream Port, the bit field in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit field is of type RsvdP. This bit field is intended for debug, and compliance testing purposes. The default value of this field is 0000b.

14.3.5.14 Link Status 2 Register (0xD2; RW)

Bits	Init.	Type	Description
0	0b	RO	**Current De-emphasis Level** When the link is operating at 5 GT/s speed, this bit reflects the level of de-emphasis. It is undefined when the Link is not operating at 5.0 GT/s speed. Encodings: 0b = -6 dB 1b = -3.5 dB ***Note:*** Same value must be reported for all functions.
1	0b	ROS/RsvdZ	**Equalization Complete** When set to 1b, this bit indicates that the Transmitter Equalization procedure has completed. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
2	0b	ROS/RsvdZ	**Equalization Phase 1 Successful** When set to 1b, this bit indicates that Phase 1 of the Transmitter Equalization procedure has successfully completed. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
3	0b	ROS/RsvdZ	**Equalization Phase 2 Successful** When set to 1b, this bit indicates that Phase 2 of the Transmitter Equalization procedure has successfully completed. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
4	0b	ROS/RsvdZ	**Equalization Phase 3 Successful** When set to 1b, this bit indicates that Phase 3 of the Transmitter Equalization procedure has successfully completed. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
5	0b	RW1C/RsvdZ	**Link Equalization Request** This bit is Set by hardware to request the Link equalization process to be performed on the Link. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
6	0b	RWS (Func 0) RsvdZ (else)	**Re-timer Presence Detected**
7	0b	RWS (Func 0) RsvdZ (else)	**Two Re-timer Presence Detected**
9:8	00b	RO	**Crosslink Resolution**
15:10	0x0	RsvdZ	Reserved.

14.4 PCIe Extended Configuration Space

PCIe configuration space is located in a flat memory-mapped address space. PCIe extends the configuration space beyond the 256 bytes available for PCI to 4096 bytes. The E810 decodes an additional four bits (bits 27:24) to provide the additional configuration space as shown. PCIe reserves the remaining four bits (bits 31:28) for future expansion of the configuration space beyond 4096 bytes.

The configuration address for a PCIe device is computed using a PCI-compatible bus, device, and function numbers as follows:

31 28	27 20	19 15	14 12	11 2	1 0
0000b	Bus #	Device #	Fun #	Register Address (offset)	00b

PCIe extended configuration space is allocated using a linked list of optional or required PCIe extended capabilities following a format resembling PCI capability structures. The first PCIe extended capability is located at offset 0x100 in the device configuration space. The first DWord of the capability structure identifies the capability/version and points to the next capability.

The E810 supports the following PCIe extended capabilities:

Table 14-20. Extended Capabilities List

Address Range	Item	Cases Where Capability Does Not Exist	Next Pointer	Section Reference
0x100 - 0x144	Advanced Error Reporting (AER)	• None (always present).	Any of the below / 0x000	14.4.1
0x150 - 0x158	Device Serial Number	• NVM is not valid.	Any of the below / 0x000	14.4.2
0x148 - 0x14C	Alternative RID Interpretation (ARI)	• ARI Enabled bit in NVM is set to 0b	Any of the below / 0x000	14.4.3
0x160 - 0x19C	Single Root I/O Virtualization (SR-IOV)	• The global SR-IOV Enable bit in NVM is set to 0b (exposed via the GLPCI_CAPSUP.*IOV_EN* bit). • This is a dummy function. • The per-PF SR-IOV Enable bit is set to 0b (PF_VT_PFALLOC.*VALID* is cleared).	Any of the below / 0x000	14.4.4
0x1A0 - 0x1A8	TPH Requester	• TPH Enabled bit in NVM is set to 0b. • This is a dummy function.	Any of the below / 0x000	14.4.5
0x1B0 - 0x1B4	Access Control Services (ACS)	• ACS Enabled bit in NVM is set to 0b. • A single PF is enabled and SR-IOV is disabled.	Any of the below / 0x000	14.4.6
0x1C0 - 0x1C4	Reserved.			
0x1D0 - 0x1FA	Secondary PCI Express	• Secondary PCIe Enabled bit in NVM is set to 0b. • Function is not Function 0.	0x200 / 0x000	14.4.7
0x200 - 0x208	Data Link Feature	• GLPCI_CAPSUP.*DLFE_EN* is cleared.	0x210 / 0x000	14.4.8
0x210 - 0x23C	Physical Layer 16.0 GT/s Extended Capability	• GLPCI_CAPSUP.GEN4_EXT_EN is cleared. • Function is not function 0.	0x250 / 0x000	14.4.10
0x250 - 0x294	Lane Margining at the Receiver Capability	• GLPCI_CAPSUP.GEN4_MARG_EN is cleared. • Function is not function 0.	0x2D0 / 0x000	14.4.11
0x2D0 - 0x2D4	PASID	• GLPCI_CAPSUP.PASID_EN is cleared. • This is a dummy function.	0x000	14.4.9

14.4.1 Advanced Error Reporting (AER) Capability

The PCIe advanced error reporting capability is an optional extended capability to support advanced error reporting. The tables that follow list the PCIe advanced error reporting extended capability structure for PCIe devices.

Table 14-21. AER Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x100	Next Capability Pointer	Version (0x1)	AER Capability ID (0x0001)	
0x104	Uncorrectable Error Status			
0x108	Uncorrectable Error Mask			
0x10C	Uncorrectable Error Severity			
0x110	Correctable Error Status			
0x114	Correctable Error Mask			
0x118	Advanced Error Capabilities and Control Register			
0x11C - 0x128	Header Log			
0x12C	RsvdP (Root Error Command)			
0x130	RsvdZ (Root Error Status)			
0x134	RsvdP (Error Source Identification Register)			
0x138 - 0x144	TLP Prefig Log Registers = 0x0 (not implemented)			

Table 14-22 summarizes configuration sharing of the AER Capability registers among the different PCI functions.

Table 14-22. Configuration Sharing of the AER Capability

14.4.1.1 Advanced Error Reporting Enhanced Capability Header Register (0x100; RO)

Bits	Init.	Type	Description
15:0	0x1	RO	**Extended Capability ID** PCIe extended capability ID indicating advanced error reporting capability.
19:16	0x2	RO	**Version Number** PCIe advanced error reporting extended capability version number.
31:20	See description	RO	**Next Capability Offset** Next PCIe extended capability offset. See Table 14-20 for possible values of the next capability offset.

14.4.1.2 Uncorrectable Error Status Register (0x104; RW1CS)

The Uncorrectable Error Status register reports error status of individual uncorrectable error sources on a PCIe device. An individual error status bit that is set to 1b indicates that a particular error occurred. Software can clear an error status by writing a 1b to the respective bit. Register is cleared by LAN_PWR_GOOD.

Bits	Init.	Type	Description
0	0b	RO	Reserved.
3:1	000b	RsvdZ	Reserved.
4	0b	RW1CS	**Data Link Protocol Error Status**
5	0b	RO	**Surprise Down Error Status**
11:6	0x0	RsvdZ	Reserved.
12	0b	RW1CS	**Poisoned TLP Received Status**
13	0b	RW1CS	**Flow Control Protocol Error Status**
14	0b	RW1CS	**Completion Timeout Status**
15	0b	RW1CS	**Completer Abort Status**
16	0b	RW1CS	**Unexpected Completion Status**
17	0b	RW1CS	**Receiver Overflow Status**
18	0b	RW1CS	**Malformed TLP Status.**
19	0b	RW1CS	**ECRC Error Status**
20	0b	RW1CS	**Unsupported Request Error Status**
21	0b	RO	**ACS Violation Status** Not supported. Hard-wired to 0b.
22	0b	RO	**Uncorrectable Internal Error Status** Not supported. Hard-wired to 0b.
23	0b	RO	**Multicast Blocked TLP Error Status** Not supported. Hard-wired to 0b.
24	0b	RO	**AtomicOp Egress Blocked Status** Not supported. Hard-wired to 0b.
25	0b	RO	**TLP Prefix Blocked Error Status** Not supported. Hard-wired to 0b.
26	0b	RO	**Poisoned TLP Egress Blocked Error Status** Not supported. Hard-wired to 0b.
31:27	0x0	RsvdP	Reserved.

14.4.1.3 Uncorrectable Error Mask Register (0x108; RWS)

The Uncorrectable Error Mask register controls reporting of individual uncorrectable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. Note that there is a mask bit per bit of the Uncorrectable Error Status register.

Bits	Init.	Type	Description
0	0b	RO	Reserved.
3:1	000b	RsvdP	Reserved.
4	0b	RWS	**Data Link Protocol Error Mask**
5	0b	RO	Reserved.
11:6	0x0	RsvdP	Reserved.
12	0b	RWS	**Poisoned TLP Received Mask**
13	0b	RWS	**Flow Control Protocol Error Mask**
14	0b	RWS	**Completion Timeout Mask**
15	0b	RWS	**Completer Abort Mask**
16	0b	RWS	**Unexpected Completion Mask**
17	0b	RWS	**Receiver Overflow Mask**
18	0b	RWS	**Malformed TLP Mask**
19	0b	RWS	**ECRC Error Mask**
20	0b	RWS	**Unsupported Request Error Mask**
21	0b	RO	**ACS Violation Mask** Not supported. Hard-wired to 0b.
22	0b	RO	**Uncorrectable Internal Error Mask** Not supported. Hard-wired to 0b.
23	0b	RO	**Multicast Blocked TLP Error Mask** Not supported. Hard-wired to 0b.
24	0b	RO	**AtomicOp Egress Blocked Mask** Not supported. Hard-wired to 0b.
25	0b	RO	**TLP Prefix Blocked Error Mask** Not supported. Hard-wired to 0b.
26	0b	RO	**Poisoned TLP Egress Blocked Error Mask** Not supported. Hard-wired to 0b.
31:27	0x0	RsvdP	Reserved.

14.4.1.4 Uncorrectable Error Severity Register (0x10C; RWS)

The Uncorrectable Error Severity register controls whether an individual uncorrectable error is reported as a fatal error. An uncorrectable error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered non-fatal.

Bits	Init.	Type	Description
0	0b	RO	Reserved.
3:1	000b	RsvdP	Reserved.
4	1b	RWS	**Data Link Protocol Error Severity**
5	0b	RO	Reserved.
11:6	0x0	RsvdP	Reserved.
12	0b	RWS	**Poisoned TLP Received Severity**

20	0b	RWS	**Unsupported Request Error Severity**
21	0b	RO	**ACS Violation Severity** Not supported. Hard-wired to 0b.
22	0b	RO	**Uncorrectable Internal Error Severity** Not supported. Hard-wired to 0b.
23	0b	RO	**Multicast Blocked TLP Error Severity** Not supported. Hard-wired to 0b.
24	0b	RO	**AtomicOp Egress Blocked Severity** Not supported. Hard-wired to 0b.
25	0b	RO	**TLP Prefix Blocked Error Severity** Not supported. Hard-wired to 0b.
26	0b	RO	**Poisoned TLP Egress Blocked Error Severity** Not supported. Hard-wired to 0b.
31:27	0x0	RsvdP	Reserved.

14.4.1.5 Correctable Error Status Register (0x110; RW1CS)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b it indicates that a particular error occurred. Software can clear an error status by writing a 1b to the respective bit. Register is cleared by LAN_PWR_GOOD.

Bits	Init.	Type	Description
0	0b	RW1CS	**Receiver Error Status**
5:1	0x0	RsvdZ	Reserved.
6	0b	RW1CS	**Bad TLP Status**
7	0b	RW1CS	**Bad DLLP Status**
8	0b	RW1CS	**REPLAY_NUM Rollover Status**
11:9	000b	RsvdZ	Reserved.
12	0b	RW1CS	**Replay Timer Timeout Status**
13	0b	RW1CS	**Advisory non-Fatal Error Status**
15:14	00b	RO	Reserved.
31:16	0x0	RsvdZ	Reserved.

14.4.1.6 Correctable Error Mask Register (0x114; RWS)

The Correctable Error Mask register controls reporting of individual correctable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. There is a mask bit per bit in the Correctable Error Status register.

Bits	Init.	Type	Description
0	0b	RWS	**Receiver Error Mask**
5:1	0x0	RsvdP	Reserved.
6	0b	RWS	**Bad TLP Mask**
7	0b	RWS	**Bad DLLP Mask**
8	0b	RWS	**REPLAY_NUM Rollover Mask**
11:9	000b	RsvdP	Reserved.
12	0b	RWS	**Replay Timer Timeout Mask**
13	1b	RWS	**Advisory non-Fatal Error Mask**
15:14	00b	RO	Reserved.

14.4.1.7 Advanced Error Capabilities and Control Register (0x118; RO)

Bits	Init.	Type	Description
4:0	0x0	ROS	**Vector** Vector pointing to the first recorded error in the Uncorrectable Error Status register. This is a read-only field that identifies the bit position of the first uncorrectable error reported in the Uncorrectable Error Status register.
5	1b	RO	**ECRC Generation Capable** If set, this bit indicates that the function is capable of generating ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
6	0b	RWS	**ECRC Generation Enable** When set, ECRC generation is enabled.
7	1b	RO	**ECRC Check Capable** If set, this bit indicates that the function is capable of checking ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
8	0b	RWS	**ECRC Check Enable** When set, ECRC checking is enabled.
9	0b	RO	**Multiple Header Recording Capable** Not Supported. Hard-wired to 0b.
10	0b	RO	**Multiple Header Recording Enable** Not Supported. Hard-wired to 0.
11	0b	RsvdP	**TLP Prefix Log Present** Not supported. Hard-wired to 0b.
12	0b	RO	**Completion Timeout Prefix/Header Log Capable** Not supported in the E810.
15:13	000b	RsvdP	Reserved.

14.4.1.8 Header Log Register (0x11C - 0x128; ROS)

The Header Log register captures the header for the transaction that generated an error. This register is 16 bytes.

Bits	Init.	Type	Description
127:0	0x0	ROS	**Header Log Register** Header of the packet in error.

14.4.2 Serial Number

The PCIe device serial number capability is an optional extended capability that can be implemented by any PCIe device. The device serial number is a read-only 64-bit value that is unique for a given PCIe device.

Serial Number capability is implemented for Function 0; all other functions return the same device serial number value as that reported by Function 0.

The capability is disabled when the MAC Address in the GLPCI_SERL and GLPCI_SERH registers is 0x00...0 (indicating that the NVM is not valid or a proper MAC Address was not loaded).

Table 14-23. Serial Number Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x150	Next Capability Pointer	Version (0x1)	Serial ID Capability ID (0x0003)	
0x154	Serial Number Register (Lower DWord)			
0x158	Serial Number Register (Upper DWord)			

Table 14-24 summarizes configuration sharing of the Serial Number Capability registers among the different PCI functions.

Table 14-24. Configuration Sharing of the Serial Number Capability

	Capability Version	X			
	Next Capability Offset		X		
Serial Number Registers		X		See comment above.	14.4.2.2

14.4.2.1 Device Serial Number Enhanced Capability Header Register (0x150; RO)

Bits	Init.	Type	Description
15:0	0x3	RO	**PCIe Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. The extended capability ID for the device serial number capability is 0x0003.
19:16	0x1	RO	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the capability structure present. ***Note:*** Must be set to 0x1 for this version of the specification.
31:20	See description	RO	**Next Capability Offset** This field contains the offset to the next PCIe capability structure or 0x000 if no other items exist in the linked list of capabilities. See Table 14-20 for possible values of the next capability offset.

14.4.2.2 Serial Number Registers (0x154 - 0x158; RO)

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit Extended Unique Identifier (EUI-64). The register at offset 0x154 holds the lower 32 bits and the register at offset 0x158 holds the higher 32 bits. The following figure details the allocation of register fields in the Serial Number register. The table that follows provides the respective bit definitions.

Bits	Type	Description
63:0	RO	**PCIe Device Serial Number** This field contains the IEEE defined 64-bit EUI-64. This identifier includes a 24-bit company ID value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer.

The serial number uses the Ethernet MAC Address according to the following definition:

Field	Company ID			Extension Identifier				
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
	Most Significant Byte Most Significant Bit						Least Significant Byte Least Significant Bit	

The serial number can be constructed from the 48-bit Ethernet MAC Address in the following form:

Field	Company ID			MAC Label		Extension identifier		
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
	Most Significant Bytes Most Significant Bit						Least Significant Byte Least Significant Bit	

In this case, the MAC label is 0xFFFF.

For example, assume that the Company ID is (Intel) 00-A0-C9 and the Extension Identifier is 23-45-67 (MAC Address of 00-A0-C9-23-45-67). In this case, the 64-bit serial number is:

Field	Company ID			MAC Label		Extension Identifier		
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
	00	A0	C9	FF	FF	23	45	67
	Most Significant Byte Most Significant Bit						Least Significant Byte Least Significant Bit	

The Ethernet MAC Address for the Serial Number capability is loaded from NVM (not the same field that is loaded from NVM into the Station MAC Address registers). It is reflected in the GLPCI_SERL and GLPCI_SERH registers. In the above example:

- GLPCI_SERL = C9-23-45-67
- GLPCI_SERH = 00-00-00-A0

Note: The official document that defines EUI-64 is:
http://standards.ieee.org/regauth/oui/tutorials/EUI64.html

14.4.3 Alternate Routing ID Interpretation (ARI) Capability Structure

To allow more than eight functions per endpoint without requesting an internal switch, as is usually needed in virtualization scenarios, the PCI-SIG defines a new capability that allows a different interpretation of the Bus, Device, and Function fields. The capability is exposed when the GLPCI_CAPSUP.*ARI_EN* bit is set from NVM.

This capability should not be exposed in Root Complex Integrated endpoints, and the GLPCI_CAPSUP.*ARI_EN* bit should be set accordingly.

The ARI capability structure is as follows:

Table 14-25. ARI Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x148	Next Capability Pointer	Version (0x1)	ARI Capability ID (0x000E)	
0x14C	ARI Control Register		ARI Capability Register	

Table 14-26 summarizes configuration sharing of the ARI Capability registers among the different PCI functions.

Table 14-26. Configuration Sharing of the ARI Capability

Field	Sub-Field	Shared?	Replicated?	Comments	Section Reference
Enhanced Capability Header Register	Extended Capability ID	X			14.4.3.1
	Capability Version	X			
	Next Capability Offset		X		
ARI capability Register	Next Function Pointer		X		14.4.3.2

14.4.3.1 PCIe ARI Header Register (0x148; RO)

Field	Bits	Init.	Type	Description
ID	15:0	0xE	RO	**PCIe Extended Capability ID** PCIe extended capability ID for the alternative RID interpretation.
Version	19:16	0x1	RO	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 0x1 for this version of the specification.
Next Capability Offset	31:20	See description	RO	**Next Capability Offset** This field contains the offset to the next PCIe extended capability structure. See Table 14-20 for possible values of the next capability offset.

14.4.3.2 PCIe ARI Capability Register (0x14C; RO)

Field	Bits	Init.	Type	Description
M	0	0b	RO	**MFVC Function Groups Capability (M)** Applicable only for Function 0. Must be 0b for all other Functions. If 1b, indicates that the ARI Device supports Function Group level arbitration via its Multi-Function Virtual Channel (MFVC) Capability structure. Not supported in the E810.
A	1	0b	RO	**ACS Function Groups Capability (A)** Applicable only for Function 0. Must be 0b for all other functions. If 1b, indicates that the ARI device supports function group level granularity for ACS P2P Egress Control via its ACS capability structures. Not supported in the E810.
Reserved	7:2	0x0	RsvdP	Reserved.

Field	Bits	Init.	Type	Description
NFN	15:8	See description[1]	RO	**Next Function Number** This field contains the pointer to the next physical function configuration space or 0x0000 if no other items exist in the linked list of functions. Function 0 is the start of the link list of functions. Functions can be disabled during the Power-On-Reset flow (through strapping pins, SMASH/CLP commands, NC-SI commands) affecting this field.
M_EN	16	0b	RO	**MFVC Function Groups Enable (M)** Applicable only for Function 0. Must be hard-wired to 0b for all other Functions. When set, the ARI Device must interpret entries in its Function Arbitration Table as Function Group Numbers rather than Function Numbers. Not supported in the E810.
A_EN	17	0b	RO	**ACS Function Groups Enable (A)** Applicable only for Function 0. Must be hard-wired to 0b for all other Functions. When set, each Function in the ARI Device must associate bits within its Egress Control Vector with Function Group Numbers rather than Function Numbers. Not supported in the E810.
Reserved	19:18	00b	RO	Reserved.
FGN	22:20	000b	RO	**Function Group Number** Not supported in the E810.
Reserved	31:23	0x0	RsvdP	Reserved.

1. If function zero is a dummy function, this register should keep its attributes according to the function number. Disabled functions are skipped.

14.4.4 SR-IOV Capability Structure

This is a structure used to support the SR-IOV capabilities reporting and control. The capability is exposed when the GLPCI_CAPSUP.*IOV_EN* bit is set from NVM and the PF_VT_PFALLOC.*VALID* is set.

The following tables shows the implementation of this structure in the E810.

Table 14-27. SR-IOV Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x160	Next Capability Offset	Version (0x1)	SR-IOV Capability ID (0x0010)	
0x164	SR-IOV Capabilities			
0x168	SR-IOV Status		SR-IOV Control	
0x16C	Total VFs (RO)		Initial VFs (RO)	
0x170	Reserved	Function Dependency Link (RO)	Num VFs (RW)	
0x174	VF Stride (RO)		First VF Offset (RO)

14.4.4.1 PCIe SR-IOV Header Register (0x160; RO)

Field	Bits	Init.	Type	Description
ID	15:0	0x10	RO	**PCIe Extended Capability ID** PCIe extended capability ID for the SR-IOV capability.

Field	Bits	Init.	Type	Description
Version	19:16	0x1	RO	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 0x1 for this version of the specification.
Next Pointer	31:20	0x0	RO	**Next Capability Offset** This field contains the offset to the next PCIe extended capability structure or 0x000 if no other items exist in the linked list of capabilities. See Table 14-20 for possible values of the next capability offset.

14.4.4.2 PCIe SR-IOV Capabilities Register (0x164; RO)

Field	Bits	Init.	Type	Description
VFMC	0	0b	RO	**VF Migration Capable** Migration Capable Device running under Migration Capable MR-PCIM. RO as zero in the E810. Not supported in the E810.
ARI CHP	1	1b (lowest SR-IOV-enabled function) 0b (else)	RO	**ARI Capable Hierarchy Preserved** If set, the *ARI Capable Hierarchy* bit is preserved across certain power state transitions. Only present in lowest SR-IOV-enabled function. Read-only zero in other PFs.
VF10B	2	0x0	RO	**VF 10-Bit** VF 10-Bit Tag Requester Supported - not supported.
Reserved	20:3	0x0	RO	Reserved.
IMN	31:21	0x0	RO	**VF Migration Interrupt Message Number** Indicates the MSI/MSI-X vector used for the interrupts. Not supported in the E810.

14.4.4.3 PCIe SR-IOV Control Register (0x168; RW)

Field	Bits	Init.	Type	Description
VFE	0	0b	RW	**VF Enable** Manages the assignment of VFs to the associated PF. If *VF Enable* is set to 1b, VFs must be enabled, associated with the PF, and exists in the PCIe fabric. When enabled, VFs must respond to and can issue PCIe transactions following all other rules for PCIe functions. If set to 0b, VFs must be disabled and not visible in the PCIe fabric; VFs cannot respond to or issue PCIe transactions. In addition, if *VF Enable* is cleared after having been set, all of the VFs must no longer: • Issue PCIe transactions • Respond to configuration space or memory space accesses. The behavior must be as if an FLR was issued to each of the VFs. Specifically, VFs must not retain any context after *VF Enable* has been cleared. Any errors already logged via PF error reporting registers, remain logged. However, no new VF errors are logged after VF Enable is cleared.
VF ME	1	0b	RO	**VF Migration Enable** Enables/Disables VF Migration Support. Not supported in the E810.
VF MIE	2	0b	RO	**VF Migration Interrupt Enable** Enables/Disables VF Migration State Change Interrupt Not supported in the E810.

Field	Bits	Init.	Type	Description
VF MSE	3	0b	RW	**Memory Space Enable for Virtual Functions** VF MSE controls memory space enable for all VFs associated with this PF as with the *Memory Space Enable* bit in a functions PCI command register. The default value for this bit is 0b. When *VF Enable* is 1b, virtual function memory space access is permitted only when *VF MSE* is set. VFs must follow the same error reporting rules as defined in the base specification if an attempt is made to access a virtual functions memory space when *VF Enable* is 1b and *VF MSE* is zero. ***Note:*** Virtual functions memory space cannot be accessed when *VF Enable* is zero. Thus, VF MSE is "don't care" when *VF Enable* is zero. However, software can choose to set VF MSE after programming the VF BARn registers, prior to setting *VF Enable* to 1b.
VF ARI	4	0b	RW (lowest SR-IOV-enabled function) ROS (else)	**ARI Capable Hierarchy** The E810 can locate VFs in function numbers 8 to 255 of the captured bus number. If either *ARI Capable Hierarchy Preserved* or *No_Soft_Reset* are set, a power state transition of this PF from D3hot to D0 does not affect the value of this bit
Reserved	15:5	0x0	RO	Reserved.
VFMIS	16	0b	RO	**VF Migration Status** Indicates a VF Migration In or Migration Out Request has been issued by MR-PCIM. To determine the cause of the event, software can scan the VF State Array. Not implemented in the E810.
Reserved	31:17	0x0	RO	Reserved.

14.4.4.4 PCIe SR-IOV Initial/Total VFs Register (0x16C; RO)

Field	Bits	Init.	Type	Description
InitialVFs	15:0	See Section 14.5.1.1	RO	**Initial VFs** Indicates the number of VFs that are initially associated with the PF. If *VF Migration Capable* is cleared, this field must contain the same value as *TotalVFs*. In the E810 this parameter is equal to the TotalVFs in this register.
TotalVFs	31:16	See Section 14.5.1.1	RO	**Total VFs** Defines the maximum number of VFs that can be associated with the PF. This field is derived from the PF_VT_PFALLOC.*FIRSTVF* and PF_VT_PFALLOC register fields loaded from NVM.

14.4.4.5 PCIe SR-IOV Num VFs Register (0x170; RW)

Field	Bits	Init.	Type	Description
NumVFs	15:0	0x0	RW	**Num VFs** Defines the number of VFs software has assigned to the PF. Software sets *NumVFs* to any value between one and the *TotalVFs* as part of the process of creating VFs. *NumVFs* VFs must be visible in the PCIe fabric after both *NumVFs* is set to a valid value and *VF Enable* is set to 1b.
FDL	23:16	0x0 (Func 0)[1] 0x1 (Func 1) ... 0xn (Func n)	RO	**Function Dependency Link** Defines dependencies between physical functions allocation. In the E810 there are no constraints.
Reserved	31:24	0x0	RO	Reserved.

1. Applies to dummy function as well.

14.4.4.6 PCIe SR-IOV VF RID Mapping Register (0x174; RO)

Field	Bits	Init.	Type	Description
FVO	15:0	0x100 + FirstVF - PF#	RO	**First VF offset** Defines the Requester ID (RID) offset of the first VF that is associated with the PF that contains this capability structure. The first VFs 16-bit RID is calculated by adding the contents of this field to the RID of the PF containing this field. The content of this field is valid only when *VF Enable* is set. If *VF Enable* is 0b, the contents are undefined. If the *VF ARI* bit is set, this field changes to 0x8 + *FirstVF* - PF#. This field is derived from the PF_VT_PFALLOC.*FIRSTVF* register field loaded from NVM.
VFS	31:16	0x1[1]	RO	**VF stride** Defines the Requester ID (RID) offset from one VF to the next one for all VFs associated with the PF that contains this capability structure. The next VFs 16-bit RID is calculated by adding the contents of this field to the RID of the current VF. The contents of this field is valid only when *VF Enable* is set and *NumVFs* is non-zero. If *VF Enable* is 0b or if *NumVFs* is zero, the contents are undefined.

1. See Section 14.5.1.1.

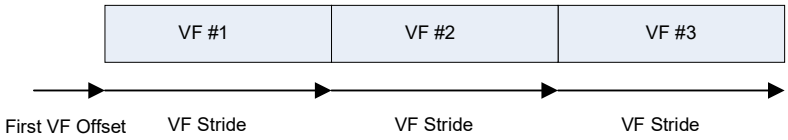

Figure 14-1. VF Stride

14.4.4.7 PCIe SR-IOV VF Device ID Register (0x178; RO)

All Virtual functions have the same default value of 0x1889, and can be auto-loaded from the NVM.

The VF Device ID is loaded from NVM according to the following rules:

- Device ID is loaded from NVM if the GLPCI_CAPSUP.*LOAD_DEV_ID* bit is set.
- The Device ID value of all VFs associated with a given PF is loaded to the respective PFPCI_DEVID.*VF_DEV_ID* field.

14.4.4.8 PCIe SR-IOV Supported Page Size Register (0x17C; RO)

Field	Bits	Init.	Type	Description
Supported Page Size	31:0	0x553	RO	**Supported Page Size** For PFs that support the stride-based BAR mechanism, this field defines the supported page sizes. This PF supports a page size of 2^(n+12) if bit n is set. For example, if bit 0 is set, the Endpoint (EP) supports 4 KB page sizes. Endpoints are required to support 4 KB, 8 KB, 64 KB, 256 KB, 1 MB, and 4 MB page sizes. All other page sizes are optional.

14.4.4.9 PCIe SR-IOV System Page Size Register (0x180; RW)

Field	Bits	Init.	Type	Description
Page Size	31:0	0x1	RW	**System Page Size** This field defines the page size the system uses to map the VFs' memory addresses. Software must set the value of the *System Page Size* to one of the page sizes set in the *Supported Page Size* field. As with *Supported Page Sizes*, if bit n is set in *System Page Size*, the VFs are required to support a page size of 2^(n+12). For example, if bit 1 is set, the system is using an 8 KB page size. The results are undefined if more than one bit is set in *System Page Size*. The results are undefined if a bit is set in System Page Size that is not set in *Supported Page Size*. When *System Page Size* is set, the VFs are required to align all BAR resources on a *System Page Size* boundary. Each BAR size, including VF BARn Size (described later) must be aligned on a *System Page Size* boundary. Each BAR size, including VF BARn Size must be sized to consume a multiple of *System Page Size* bytes. All fields requiring page size alignment within a function must be aligned on a *System Page Size* boundary. *VF Enable* must be zero when *System Page Size* is set. The results are undefined if *System Page Size* is set when *VF Enable* is set.

14.4.4.10 PCIe SR-IOV BAR 0 - Low Register (0x184; RW)

Field	Bits	Init.	Type	Description
Mem	0	0b	RO	**Memory** 0b = Indicates memory space.
Mem Type	2:1	10b	RO	**Memory Type** Indicates the address space size. 10b = 64-bit. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register.
Prefetch Mem	3	0b	RO	**Prefetch Memory** 0b = Non-prefetchable space. 1b = Prefetchable space. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register.
Memory Address Space	31:4	0x0	RW	**Memory Address Space** Which bits are RW bits and which are RO to 0x0 depend on the memory mapping window size.

14.4.4.11 PCIe SR-IOV BAR 0 - High Register (0x188; RW)

Field	Bits	Init.	Type	Description
BAR0 - MSB	31:0	0x0	RW	**BAR0 MSB** MSB part of BAR0.

14.4.4.12 PCIe SR-IOV BAR 2 Register (0x18C; RO)

Field	Bits	Init.	Type	Description
BAR2	31:0	0x0	RO	**BAR2** This BAR is not used.

14.4.4.13 PCIe SR-IOV BAR 3 - Low Register (0x190; RW)

Field	Bits	Init.	Type	Description
Mem	0	0b	RO	**Memory** 0b = Indicates memory space.
Mem Type	2:1	10b	RO	**Memory Type** Indicates the address space size. 10b = 64-bit. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register.
Prefetch Mem	3	0b	RO	**Prefetch Memory** 0b = Non-prefetchable space. 1b = Prefetchable space. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register.
Memory Address Space	31:4	0x0	RW	**Memory Address Space** Which bits are RW bits and which are RO to 0x0 depend on the memory mapping window size. The size is a maximum between 16 KB and the page size.

14.4.4.14 PCIe SR-IOV BAR 3 - High Register (0x194; RW)

Field	Bits	Init.	Type	Description
BAR4 - MSB	31:0	0x0	RW	**BAR4 MSB** MSB part of BAR3.

14.4.4.15 PCIe SR-IOV BAR 5 Register (0x198; RO)

Field	Bits	Init.	Type	Description
BAR5	31:0	0x0	RO	**BAR5** This BAR is not used.

14.4.4.16 PCIe SR-IOV VF Migration State Array Offset Register (0x19C; RO)

Field	Bits	Init.	Type	Description
BIR	2:0	000b	RO	**BIR** Indicates which PF BAR contains the VF Migration State Array. Not implemented in the E810.
Offset	31:3	0x0	RO	**Offset** Offset, relative to the beginning of the BAR of the start of the migration array. Not implemented in the E810.

14.4.5 TPH Requester Capability

The TPH Requester capability is an optional extended capability to support TLP Processing Hints. The capability is exposed when the GLPCI_CAPSUP.*TPH_EN* bit is set from NVM.

Table 14-29 lists the TPH extended capability structure for PCIe devices.

Table 14-29. TPH Requester Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1A0	PCI Express Extended Capability Header			
0x1A4	TPH Requester Capability Register			
0x1A8	TPH Requester Control Register			

Table 14-30 summarizes configuration sharing of the TPH Requester Capability registers among the different PCI functions.

Table 14-30. Configuration Sharing of the TPH Requester Capability

Field	Sub-field	Shared?	Replicated?	Comments	Section Reference
Enhanced Capability Header Register	Extended Capability ID	X			14.4.5.1
	Capability Version	X			
	Next Capability Offset		X		
TPH Requester Capability		X			14.4.5.2
TPH Requester Control			X		14.4.5.3
TPH ST Table			X	The Steering Table Upper fields are not supported.	

14.4.5.1 TPH Requester Extended Capability Header (0x1A0; RO)

Bits	Init.	Type	Description
15:0	0x17	RO	**Extended Capability ID** PCIe extended capability ID indicating TPH capability.
19:16	0x1	RO	**Capability Version** PCIe TPH extended capability version number.
31:20	See description	RO	**Next Capability Offset** This field contains the offset to the next PCIe capability structure. See Table 14-20 for possible values of the next capability offset.

14.4.5.2 TPH Requester Capability Register (0x1A4; RO)

Bits	Init.	Type	Description
0	1b	RO	**No ST Mode Supported** If set indicates that the Function supports the No ST Mode of operation.
1	0b	RO	**Interrupt Vector Mode Supported** Cleared to indicates that the E810 does not support Interrupt Vector Mode of operation.
2	1b	RO	**Device Specific Mode** Set to indicate that the E810 supports Device Specific Mode of operation.
7:3	RsvdP	RO	Reserved.
8	0b	RO	**Extended TPH Requester Supported** Cleared to indicate that the function is not capable of generating requests with Extended TPH TLP Prefix
10:9	00b	RO	**ST Table Location** Value indicates if and where the ST Table is located. Defined Encodings are: 00b = ST Table is not present. 01b = ST Table is located in the TPH Requester Capability structure. 10b = ST Table is located in the MSI-X Table structure. 11b = Reserved. ST Table is not supported.
15:11	0x0	RsvdP	Reserved.
26:16	0x0	RO	**ST Table Size** System software reads this field to determine the *ST_Table_Size* N, which is encoded as N-1. For example, a returned value of 00000000011b indicates a table size of 4. The value in this field is undefined since the E810 does not support an ST Table
31:27	0x0	RsvdP	Reserved.

14.4.5.3 TPH Requester Control Register (0x1A8; RW)

Bits	Init.	Type	Description
2:0	000b	RW	**ST Mode Select** Indicates the ST mode of operation selected. Defined encodings are: 000b = No Table Mode 001b = Interrupt Vector Mode (not supported by the E810) 010b = Device Specific Mode All other values are reserved. The default value of 000b indicates No Table mode of operation.
7:3	0x0	RsvdP	Reserved.
9:8	00b	RW	**TPH Requester Enable** Controls the ability to issue Request TLPs using either TPH or Extended TPH. Defined Encodings are: 00b = The E810 is not permitted to issue transactions with TPH or Extended TPH as Requester. 01b = The E810 is permitted to issue transactions with TPH as Requester and is not permitted to issue transactions with Extended TPH as Requester. 10b = Reserved. 11b = The E810 is permitted to issue transactions with TPH and Extended TPH as Requester (the E810 does not issue transactions with Extended TPH). The default value of this field is 00b.
31:10	0x0	RsvdP	Reserved.

14.4.6 ACS Extended Capability Structure

The ACS Extended Capability defines a set of control points within a PCI Express topology to determine whether a TLP should be routed normally, blocked, or redirected. The capability is exposed when the GLPCI_CAPSUP.*ACS_EN* bit is set from NVM.

The ACS Capability structure is shared and exposed to all PFs.

Table 14-31 lists the PCIe ACS extended capability structure for PCIe devices.

Table 14-31. ACS Extended Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1B0	PCI Express Extended Capability Header			
0x1B4	ACS Control Register (0x0)		ACS Capability Register (0x0)	

14.4.6.1 ACS Extended Capability Header (0x1B0; RO)

Bits	Init.	Type	Description
15:0	0x0D	RO	**PCI Express Extended Capability ID** PCIe extended capability ID indicating ACS capability.
19:16	0x1	RO	**Capability Version** PCIe ACS extended capability version number.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.6.2 ACS Capability Register (0x1B4; RO)

Bits	Init.	Type	Description
0	0b	RO	**ACS Source Validation (V)** Hard-wired to zero, not supported in the E810.
1	0b	RO	**ACS Translation Blocking (B)** Hard-wired to zero, not supported in the E810.
2	0b	RO	**ACS P2P Request Redirect (R)** Hard-wired to zero, not supported in the E810.
3	0b	RO	**ACS P2P Completion Redirect (C)** Hard-wired to zero, not supported in the E810.
4	0b	RO	**ACS Upstream Forwarding (U)** Hard-wired to zero, not supported in the E810.
5	0b	RO	**ACS P2P Egress Control (E)** Hard-wired to zero, not supported in the E810.
6	0b	RO	**ACS Direct Translated P2P (T)** Hard-wired to zero, not supported in the E810.
7	0b	RsvdP	Reserved.
15:8	0x0	RO	**Egress Control Vector Size** Hard-wired to zero, not supported in the E810.

14.4.6.3 ACS Control Register (0x1B6; RO)

Bits	Init.	Type	Description
0	0b	RO	**ACS Source Validation Enable (V)** Hard-wired to zero, not supported in the E810.
1	0b	RO	**ACS Translation Blocking Enable (B)** Hard-wired to zero, not supported in the E810.
2	0b	RO	**ACS P2P Request Redirect Enable (R)** Hard-wired to zero, not supported in the E810.
3	0b	RO	**ACS P2P Completion Redirect Enable (C)** Hard-wired to zero, not supported in the E810.
4	0b	RO	**ACS Upstream Forwarding Enable (U)** Hard-wired to zero, not supported in the E810.
5	0b	RO	**ACS P2P Egress Control Enable (E)** Hard-wired to zero, not supported in the E810.
6	0b	RO	**ACS Direct Translated P2P Enable (T)** Hard-wired to zero, not supported in the E810.
15:7	0x0	RsvdP	Reserved.

14.4.7 Secondary PCI Express Extended Capability

The Secondary PCI Express Extended Capability structure is required for all Ports and RCRBs that support a Link speed of 8.0 GT/s or higher. For Multi-Function Upstream Ports, this capability must be implemented in Function 0 and must not be implemented in other Functions. The capability is exposed when the GLPCI_CAPSUP.*SEC_EN* bit is set from NVM.

Table 14-32 lists the Secondary PCI Express extended capability structure for PCIe devices.

Table 14-32. Secondary PCI Express Extended Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1D0	PCI Express Extended Capability Header			
0x1D4	Link Control 3 Register			
0x1D8	Lane Error Status Register			
0x1DC	Equalization Control Register (Sized by Maximum Link Width)			
---	...			
0x1FA	...			

14.4.7.1 Secondary PCIe Extended Capability Header (0x1D0; RO)

Bits	Init.	Type	Description
15:0	0x19	RO	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Secondary PCI Express Extended Capability is 0019h.

Bits	Init.	Type	Description
19:16	0x1	RO	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.7.2 Link Control 3 Register (0x1D4; RW)

Bits	Init.	Type	Description
0	0b	RsvdP	**Perform Equalization** When this bit is 1b and a 1b is written to the Link Retrain register with Target Link Speed set to 8.0 GT/s, the Downstream Port must perform Transmitter Equalization. This bit is RW for Upstream Ports when *Crosslink Supported* is 1b. This bit is not applicable and is RsvdP for Upstream Ports when the *Crosslink Supported* bit is 0b. The default value is 0b.
1	0b	RsvdP	**Link Equalization Request Interrupt Enable** When Set, this bit enables the generation of interrupt to indicate that the *Link Equalization Request* bit has been set. This bit is RW for Upstream Ports when *Crosslink Supported* is 1b. This bit is not applicable and is RsvdP for Upstream Ports when the *Crosslink Supported bit* is 0b. The default value for this bit is 0b.
8:2	0x0	RsvdP	Reserved.
15:9	0x0	RW	**Enable Lower SKP OS Generation Vector** When the Link is in L0 and the bit in this field corresponding to the current Link speed is set, SKP Ordered Sets are scheduled at the rate defined for SRNS, overriding the rate required based on the clock tolerance architecture. Bit definitions within this field are: Bit 0 = 2.5 GT/s Bit 1 = 5.0 GT/s Bit 2 = 8.0 GT/s Bit 3 = 16.0 GT/s Bits 6:4 = RsvdP
31:16	0x0	RsvdP	Reserved.

14.4.7.3 Lane Error Status Register (0x1D8; RW1CS)

The Lane Error Status register consists of a 32-bit vector, where each bit indicates if the corresponding PCI Express Lane detected an error.

Bits	Init.	Type	Description
7:0	0x0	RW1CS	**Lane Error Status Bits** Each bit indicates if the corresponding Lane detected a Lane-based error. A value of 1b indicates that a Lane based-error was detected on the corresponding Lane Number. The default value of this field is 0b. This field is intended for debug purposes only.
31:8	0x0	RsvdZ	Reserved.

14.4.7.4 Lane Equalization Control Register (0x1DC - 0x1FA; RO)

The Equalization Control register consists of control fields required for per Lane equalization and number of entries in this register are sized by Maximum Link Width.

15	0
Lane (0) Equalization Control Register	
Lane (1) Equalization Control Register	
...	
Lane (Maximum Link Width - 1) Equalization Control Register	

Lane ((Maximum Link Width – 1):0) Equalization Control Register:

Bits	Init.	Type	Description
3:0	0x0	RsvdP	**Downstream Port Transmitter Preset** For an Upstream Port if *Crosslink Supported* is 0b, this field is RsvdP.
6:4	000b	RsvdP	**Downstream Port Receiver Preset Hint** For an Upstream Port if *Crosslink Supported* is 0b, this field is RsvdP.
7	0b	Rsvd	Reserved.
11:8	0xF	RO	**Upstream Port Transmitter Preset** Field contains the Transmit Preset value sent or received during Link Equalization. Since crosslink is not supported, the field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. The default value is 1111b.
14:12	111b	HwInit/RO	**Upstream Port Receiver Preset Hint** Field contains the Receiver Preset Hint value sent or received during Link Equalization. Field usage varies as follows: Since crosslink is not supported, the field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. The default value is 111b.
15	0b	Rsvd	Reserved.

14.4.8 Data Link Feature Extended Capability

Note: This feature should be enabled only in stand alone devices where there is a direct connection to Gen4 PCIe interface.

Table 14-33. Data Link Feature Extended Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x200	Data Link Feature - Extended Capability Header			
0x204	Data Link Feature - Capabilities Register			
0x208	Data Link Feature - Status Register			

14.4.8.1 Data Link Feature Extended Capability Header (0x200; RO)

Bits	Init.	Type	Description
15:0	0x0025	RO	**PCI Express Extended Capability ID** PCIe extended capability ID indicating Data Link feature capability.
19:16	0x1	RO	**Capability Version** PCIe Data Link feature extended capability version number.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.8.2 Data Link Feature Capabilities Register (0x204; RO)

Bits	Init.	Type	Description
22:0	0x1	RO	**Local Data Link Feature Supported** This field contains the Feature Supported value used when this Port sends a Data Link Feature DLLP. Defined features are: Bit 0 = Local Scaled Flow Control Supported This bit indicates that this Port supports the Scaled Flow Control Feature. Bits 22:1 = RsvdP
30:23	0x1	RO	Reserved.
31	1b	RO	**Data Link Feature Exchange Enable** If Set, this bit indicates that this Port will enter the DL_Feature negotiation state.

14.4.8.3 Data Link Feature Status Register (0x208; RO)

Bits	Init.	Type	Description
22:0	0x0	RO	**Remote Data Link Feature Supported** These bits indicate that the Remote Port supports the corresponding Data Link Feature. These bits capture all information from the Feature Supported field of the Data Link Feature DLLP even when this Port does not support the corresponding feature. This field is Cleared on entry to state DL_Inactive. Features currently defined are: Bit 0 = Remote Scaled Flow Control Supported This bit indicates that the Remote Port supports the Scaled Flow Control Feature. Bits 22:1 = Undefined.
23	0b	RO	**Remote Data Link Feature Ack** This bit indicates that the Remote Port has received this Port's Data Link Feature DLLP. This bit captures the Feature Ack bit of the Data Link Feature DLLP. This bit is Cleared on entry to state DL_Inactive.
30:24	0x1	RO	Reserved.
31	1b	RO	**Remote Data Link Feature Supported Valid** This bit indicates that the Port has received a Data Link Feature DLLP in state DL_Feature and that the Remote Data Link Feature Supported and Remote Data Link Feature Ack fields are meaningful. This bit is Cleared on entry to state DL_Inactive

14.4.9 PASID Capability

Note: When PASID is enabled, SR-IOV is disabled (no support for concurrent PASID and SRIOV in the same system).

Note: PASID capability is not exposed in dummy functions.

Table 14-34. PASID Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x2D0	PASID Extended Capability Header			
0x2D4	PASID - Capabilities Register		PASID - Control Register	

14.4.9.1 PASID Extended Capability Header (0x2D0; RO)

Bits	Init.	Type	Description
15:0	0x1B	RO	**PCI Express Extended Capability ID** PCIe extended capability ID indicating PASID capability.
19:16	0x1	RO	**Capability Version** PCIe PASID extended capability version number.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.9.2 PASID Capabilities Register (0x2D4; RO)

Bits	Init.	Type	Description
0	0b	RsvdP	Reserved.
1	0b	RO	**Execute Permission Supported** 0b = The Endpoint never sets the *Execute Requested* bit. 1b = The Endpoint supports sending TLPs that have the *Execute Requested* bit set. Set to zero.
2	0b	RO	**Privileged Mode Supported** 0b = The Endpoint never sets the *Privileged Mode Requested* bit. 1b = The Endpoint supports operating in Privileged and Non-Privileged modes, and supports sending requests that have the *Privileged Mode Requested* bit set. Set to zero.
7:3	0x0	RsvdP	Reserved.
12:8	0x14 (20d)	RO	**Max PASID Width** Indicates the width of the PASID field supported by the Endpoint. The value n indicates support for PASID values 0 through 2n-1 (inclusive). The value 0 indicates support for a single PASID (0). The value 20 indicates support for all PASID values (20 bits). This field must be between 0 and 20 (inclusive).
15:13	0x0	RsvdP	Reserved.

14.4.9.3 PASID Control Register (0x2D6; RW)

Bits	Init.	Type	Description
0	0b	RW	**PASID Enable** 0b = The Endpoint is not permitted to do so. 1b = The Endpoint is permitted to send and receive TLPs that contain a PASID TLP Prefix.
1	0b	RsvdP	**Execute Permission Enable** Ignored, as *Execute Permission Supported* bit is cleared.
2	0b	RsvdP	**Privileged Mode Enable** Ignored, as *Privileged Mode Supported* bit is cleared.
15:3	0x0	RsvdP	Reserved.

14.4.10 Physical Layer 16.0 GT/s Capability

Table 14-35. Physical Layer 16.0 GT/s Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0

14.4.10.1 Physical Layer 16.0 GT/s Extended Capability Header (0x210; RO)

Bits	Init.	Type	Description
15:0	0x0026	RO	**PCI Express Extended Capability ID** PCIe extended capability ID indicating Physical Layer 16.0 GT/s Extended capability.
19:16	0x1	RO	**Capability Version** PCIe Data Link feature extended capability version number.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.10.2 Physical Layer 16.0 GT/s Capabilities Register (0x214; RsvdP)

Bits	Init.	Type	Description
31:0	0x0	RsvdP	Reserved.

14.4.10.3 Physical Layer 16.0 GT/s Control Register (0x218; RsvdP)

Bits	Init.	Type	Description
31:0	0x0	RsvdP	Reserved.

14.4.10.4 Physical Layer 16.0 GT/s Status Register (0x21C; RW1CS)

This register is valid only in function 0, and returns zero in other functions.

Bits	Init.	Type	Description
0	0b	ROS	**Equalization 16.0 GT/s Complete**
1	0b	ROS	**Equalization 16.0 GT/s Phase 1 Successful**
2	0b	ROS	**Equalization 16.0 GT/s Phase 2 Successful**
3	0b	ROS	**Equalization 16.0 GT/s Phase 3 Successful**
4	0b	RW1CS	**Link Equalization Request 16.0 GT/s**
31:5	0x0	RsvdZ	Reserved.

14.4.10.5 16.0 GT/s Local Data Parity Mismatch Status Register (0x220; RW1CS)

Bits	Init.	Type	Description
15:0	0x0	RW1CS	**Local Data Parity Mismatch Status** Each bit indicates if the corresponding lane detected a data parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding lane.
31:16	0x0	RsvdZ	Reserved.

14.4.10.6 16.0 GT/s First Re-timer Data Parity Mismatch Status Register (0x224; RW1CS)

Bits	Init.	Type	Description
15:0	0x0	RW1CS	**First Re-timer Data Parity Mismatch Status** Each bit indicates if the corresponding lane detected a data parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding lane.
31:16	0x0	RsvdZ	Reserved.

14.4.10.7 16.0 GT/s Second Re-timer Data Parity Mismatch Status Register (0x228; RW1CS)

Bits	Init.	Type	Description
15:0	0x0	RW1CS	**Second Re-timer Data Parity Mismatch Status** Each bit indicates if the corresponding lane detected a data parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding lane.
31:16	0x0	RsvdZ	Reserved.

14.4.10.8 Physical Layer 16.0 GT/s Status 2 Register (0x22C; RsvdZ)

Bits	Init.	Type	Description
31:0	0x0	RsvdZ	Reserved.

14.4.10.9 16.0 GT/s Lane Equalization Control Register (0x230 - 0x23C; HWInit)

These registers define the control fields required for per-lane 16.0 GT/s equalization. A byte is allocated to each lane as follows:

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x230	Lane 3	Lane 2	Lane 1	Lane 0
0x234	Lane 7	Lane 6	Lane 5	Lane 4
0x238	Lane 11	Lane 10	Lane 9	Lane 8
0x23C	Lane 15	Lane 14	Lane 13	Lane 12

Each byte is defined as follows:

Bits	Init.	Type	Description
3:0	0xF	HwInit	**Downstream Port 16.0 GT/s Transmitter Preset**
7:4	0xF	HwInit	**Upstream Port 16.0 GT/s Transmitter Preset**

14.4.11 Lane Margining at the Receiver Capability

Table 14-36. Lane Margining at the Receiver Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x250	Lane Margining at the Receiver Extended Capability Header			
0x254	Capabilities Register		Status Register	
0x258 - 0x294	Lane n - Status Register		Lane n - Control Register	

14.4.11.1 Lane Margining at the Receiver Capability Header (0x250; RO)

Bits	Init.	Type	Description
15:0	0x0027	RO	**PCI Express Extended Capability ID** PCIe extended capability ID indicating Lane Margining at the Receiver Capability.
19:16	0x1	RO	**Capability Version** PCIe Data Link feature extended capability version number.
31:20	See description	RO	**Next Capability Offset** See Table 14-20 for possible values of the next capability offset.

14.4.11.2 Lane Margining at the Receiver Capabilities Register (0x254; RO)

Bits	Init.	Type	Description
0	HwInit	RO	**Margining uses Driver Software**
15:1	0x0	RsvdP	Reserved.

14.4.11.3 Lane Margining at the Receiver Status Register (0x256; RO)

Bits	Init.	Type	Description
0	HwInit	RO	**Margining Ready**
1	HwInit	RO	**Margining Software Ready**
15:2	0x0	RsvdP	Reserved.

14.4.11.4 Margining Lane #n Control Register (0x258 + 4*n; RW)

Bits	Init.	Type	Description
2:0	000b	RW	**Receiver Number**
5:3	111b	RW	**Margin Type**
6	0b	RW	**Usage Model**
7	0b	RO	Reserved.
15:8	0x9C	RW	**Margin Payload**

14.4.11.5 Margining Lane #n Status Register (0x25A + 4*n; RO)

Bits	Init.	Type	Description
2:0	000b	RO	**Receiver Number Status**
5:3	000b	RO	**Margin Type Status**
6	0b	RO	**Usage Model Status**
7	0b	RO	Reserved.
15:8	0x0	RO	**Margin Payload Status**

14.5 Virtual Functions

14.5.1 Overview

14.5.1.1 VF to PF Allocation

The E810 supports up to 256 VFs. These VFs can be distributed arbitrarily among the different PFs. The distribution is done by NVM settings as the *TotalVFs* parameter should be stable at enumeration time.

For each of the potential Physical Functions (PFs), the following parameters are defined in the NVM:

- PCIe Configuration Space Control 1.*SR-IOV enable* — Should SR-IOV be exposed for this function?
- Per PF, First VF and Last VF — What is the first VF and the last VF allocated to each function (out of 256). Can be any number between 0 and 256-1.

From these parameters the following parameters are derived in the SR-IOV capability structure (see Section 14.4.4 for details):

- The SR-IOV structure is part of the configuration space of a PF only if the GLPCI_CAPSUP.*IOV_EN* bit is set in the NVM and PF_VT_PFALLOC.*VALID* field is set for this function.
- InitialVFs = TotalVFs = PF_VT_PFALLOC.*LASTVF*[n] - PF_VT_PFALLOC.*FIRSTVF* [n] +1
- First VF Offset = PF_VT_PFALLOC.*FIRSTVF* [n]+ 8 - PF# for ARI mode and PF_VT_PFALLOC.*FIRSTVF* [n]+ 256 - PF# for non ARI mode.

  Note: The First VF offset formula is defined so that the RID of a VF is fixed no matter which PF it belongs to.

- VF stride = 1

The First VF and last VF allocated to a PF can be read from the PF_VT_PFALLOC registers.

14.5.1.2 Bus-Device-Function Layout

The Requester ID allocation of the VF is done using the First VF Offset field and the VF stride in the IOV structure and is used to do the enumeration of the VFs.

14.5.1.2.1 ARI Mode

The ARI capability allows interpretation of the “Device” part of the Requester ID as part of the “Function” part.

The allocation of VFs to PF is flexible, there is no relationship between the PF RID and the associated VFs RID.

When the hierarchy is ARI-capable (VF ARI in SR-IOV Control register is set), the allocation is as follows:

Table 14-37. RID per VF - ARI Mode

VF#/PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	
PF 1	B,0,1	B,00000,001	
PF 2	B,0,2	B,00000,010	
...	...	...	
PF 7	B,0,7	B,00000,111	
VF 0	B,1,0	B,00001,000	
VF 1	B,1,1	B,00001,001	
VF 2	B,1,2	B,00001,010	
...	...	...	
VF 247	B,31,7	B,11111,111	
VF 248	B+1.0.0	B+1,0000,000	
...	...	...	
VF 255	B+1,0,7	B+1,00000,111	

14.5.1.2.2 Non-ARI Mode

When the hierarchy is not ARI-capable (VF ARI in SR-IOV Control register is cleared), a non-zero PCI Device Number in the first bus can not be used. Thus, a second bus is needed to provide enough Requester IDs. In this mode the RID layout is as follows:

Table 14-38. RID per VF - non-ARI Mode

VF#/PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	
PF 1	B,0,1	B,00000,001	
PF 2	B,0,2	B,00000,010	
...	...	...	
PF 7	B,0,7	B,00000,111	
VF 0	B+1,0,0	B+1,00000,000	
VF 1	B+1,0,1	B+1,00000,001	
VF 2	B+1,0,2	B+1,00000,010	
...	...	...	
VF 255	B+1,31,7	B+1,11111,111	

14.5.1.3 Configuration Space Overview

The configuration space reflected to each of the VF is a sparse version of the physical function configuration space. Table 14-39 describes the behavior of each register in the VF configuration space.

Table 14-39. VF PCIe Configuration Space

Section	Offset	Name	VF behavior	Notes
PCI Mandatory Registers	0	Vendor ID	RO — 0xFFFF	
	2	Device ID	RO — 0xFFFF	
	4	Command	Per VF	See Section 14.5.2.3.
	6	Status	Per VF	See Section 14.5.2.4.
	8	RevisionID	RO as PF	
	9	Class Code	RO as PF	
	C	Cache Line Size	RO — 0x0	
	D	Latency Timer	RO — 0x0	
	E	Header Type	RO — 0x0	
	F	Reserved	RO — 0x0	
	10 — 27	BARs	RO — 0x0	Emulated by VMM.
	28	CardBus CIS	RO — 0x0	Not used.
	2C	Sub Vendor ID	RO as PF	
	2E	Sub System	RO — Same value for all VFs of each PF	See Section 14.5.2.5.
	30	Expansion ROM	RO — 0x0	Emulated by VMM.
	34	Cap Pointer	RO — 0x70	Next = MSI-X capability.
	3C	Int Line	RO — 0x0	
	3D	Int Pin	RO — 0x0	
	3E	Max Lat/Min Gnt	RO — 0x0	
MSI-X Capability	70	MSI-X Header	RO — 0xA011	Next = PCIe capability.
	72	MSI-X Message Control	Per VF	See Section 14.5.3.1.1.
	74	MSI-X Table Address	RO	See Section 14.5.3.1.2
	78	MSI-X PBA Address	RO	See Section 14.5.3.1.3

Table 14-39. VF PCIe Configuration Space [continued]

Section	Offset	Name	VF behavior	Notes
PCIe Capability	A0	PCIe Header	RO — 0x0010	Next = Last capability.
	A2	PCIe Capabilities	RO — as PF	
	A4	PCIe Dev Cap	RO — as PF	
	A8	PCIe Dev Ctrl	RW	As PF apart from FLR — See Section 14.5.3.2.1.
	AA	PCIe Dev Status	Per VF	See Section 14.5.3.2.2.
	AC	PCIe Link Cap	RO — as PF	
	B0	PCIe Link Ctrl	RO — 0x0	
	B2	PCIe Link Status	RO — 0x0	
	C4	PCIe Dev Cap 2	RO — as PF	
	C8	PCIe Dev Ctrl 2	RO — 0x0	
	D0	PCIe Link Ctrl 2	RO — 0x0	
	D2	PCIe Link Status 2	RO — 0x0	
AER Capability	100	AER — Header	RO — 0x15010002	Next = ARI structure.
	104	AER — Uncorr Status	Per VF	See Section 14.5.3.3.1.
	108	AER — Uncorr Mask	RO — 0x0	
	10C	AER — Uncorr Severity	RO — 0x0	
	110	AER — Corr Status	Per VF	See Section 14.5.3.3.2.
	114	AER — Corr Mask	RO — 0x0	
	118	AER — Cap/Ctrl	RO	See Section 14.5.3.3.3.
	11C - 128	AER — Error Log	Shared two logs for all VFs	Same structure as in PF. In case of overflow, the header log is filled with ones.
ARI Capability	150	ARI — Header	0x1A01000E	Next = TPH Structure.
	154	ARI — Cap/Ctrl	RO — 0X0	
TPH Requester Capability	1A0	TPH - Header	0x1D010017	Next = ACS Structure.
	1A4	TPH - Capability	RO — 0x00000005	No table reported..
	1A8	TPH - Control	Per VF	Same structure as in PF.
ACS Capability	1D0	ACS - Header	RO — 0x0001000D	Next = Last extended capability.
	1D4	ACS - Capability	RO — 0x00000000	

14.5.2 Mandatory Configuration Space

The IOV specification defines the configuration space of the Virtual functions as a mirror of the Physical function configuration space with the exception of some fields that are implemented per VF.

This section describes the expected handling of the different part of the configuration space for virtual functions. It deals only with the parts relevant to the E810 and describes only changes that are not a trivial implementation of the specification.

14.5.2.1 Legacy PCI Configuration Space

The legacy configuration space is allocated to the PF only and emulated for the VFs. A separate set of BARs and one Bus master enable bit is allocated to the whole set of VFs.

All the legacy error reporting bits are emulated for the VF.

14.5.2.2 Memory BARs Assignment

The IOV specification defines a fixed stride for all the VF BARs, so that each VF can be allocated part of the memory BARs at a fixed stride from the a basic set of BARs. In this method only two decoders per replicated BAR per PF are required, and the BARs reflected to the VF are emulated by the VMM.

The only BARs that are useful for the VFs are BAR0 and BAR3, thus only those are replicated.

Table 14-40 describes the BARs and the stride used for the VFs:

Table 14-40. VF BARs in the E810

BAR	Type	Usage	Requested Size per VF
0	Mem	CSR space	See Section 13.1.2.2
1	Mem	High word of CSR space address	N/A
2	N/A	Not used	N/A
3	Mem	MSI-X	max (16K, page size)
4	Mem	High word of MSI-X space address	N/A
5	N/A	Not used	N/A

14.5.2.3 VF Command Register (0x4; RW)

Bits	Init.	Type	Description
0	0b	RO	**IOAE** I/O Access Enable. RO as zero field.
1	0b	RO	**MAE** Memory Access Enable. RO as zero field.
2	0b	RW	**BME** Bus Master Enable. Disabling this bit prevents the associated VF from issuing any memory or I/O requests. Note that as MSI/MSI-X interrupt messages are in-band memory writes, disabling the bus master enable bit disables MSI/MSI-X interrupt messages as well. Requests other than memory or I/O requests are not controlled by this bit. ***Note:*** The state of active transactions is not specified when this bit is disabled after being enabled. The device can choose how it behaves when this condition occurs. Software cannot count on the device retaining state and resuming without loss of data when the bit is re-enabled. Transactions for a VF that has its *Bus Master Enable* set must not be blocked by transactions for VFs that have their *Bus Master Enable* cleared.
3	0b	RO	**SCM** Special Cycle Enable. Hard-wired to 0b
4	0b	RO	**MWIE** MWI Enable. Hard-wired to 0b.
5	0b	RO	**PSE** Palette Snoop Enable. Hard-wired to 0b.

Bits	Init.	Type	Description
6	0b	RO	**PER** Parity Error Response. Zero for VFs.
7	0b	RO	**WCE** Wait Cycle Enable. Hard-wired to 0b.
8	0b	RO	**SERRE** SERR# Enable. Zero for VFs.
9	0b	RO	**FB2BE** Fast Back-to-Back Enable. Hard-wired to 0b.
10	0b	RO	**INTD** Interrupt Disable. Hard-wired to 0b.
15:11	0x0	RO	Reserved.

14.5.2.4 VF Status Register (0x6; RW)

Bits	Init.	Type	Description
2:0	0x0	RO	Reserved.
3	0b	RO	**IS** Interrupt Status. Hard-wired to 0b.
4	1b	RO	**NC** New Capabilities. Indicates that the E810 VFs implement extended capabilities. E810 VFs implement a capabilities list, to indicate that it supports MSI-X and PCIe extensions.
5	0b	RO	**66E** 66 MHz Capable. Hard-wired to 0b.
6	0b	RO	Reserved.
7	0b	RO	**FB2BC** Fast Back-to-Back Capable. Hard-wired to 0b.
8	0b	RW1C	**MPERR** Data Parity Reported.
10:9	00b	RO	**DEVSEL** DEVSEL Timing. Hard-wired to 0b.
11	0b	RW1C	**STA** Signaled Target Abort.
12	0b	RW1C	**RTA** Received Target Abort.
13	0b	RW1C	**RMA** Received Master Abort.
14	0b	RW1C	**SSERR** Signaled System Error.
15	0b	RW1C	**DSERR** Detected Parity Error.

14.5.2.5 VF Subsystem ID (0x2E; RO)

This value is loaded from NVM if the GLPCI_CAPSUP.*LOAD_SUBSYS_ID* bit is set. Each VF is loaded from the respective PF's NVM PFPCI_SUBSYSID.*VF_SUB_ID* field (in other words, all VFs of a specific PF share the same value).

14.5.3 PCI and PCIe Capabilities

The following capability structures are partially replicated in VFs configuration space:

- PCIe capability structure
- MSI-X capability structure

The following extended capability structures are partially replicated in VFs config space:

Table 14-41. Extended Capabilities List

Address Range	Item	Cases Where Capability Does Not Exist	Next Pointer
0x100 - 0x128	Advanced Error Reporting (AER)	None (always present)	Any of the below / 0x000
0x148 - 0x14C	Alternative RID Interpretation (ARI)	ARI Enabled bit in NVM is set to 0b	Any of the below / 0x000
0x1A0 - 0x1A8	TPH Requester	TPH Enabled bit in NVM is set to 0b	Any of the below / 0x000
0x1B0 - 0x1B4	Access Control Services (ACS)	ACS Enabled bit in NVM is set to 0b	0x000

14.5.3.1 MSI-X Capability

The MSI-X BAR size is max(16K, page size).

The location and size of the MSI-X vector table and the MSI-X Pending Bits table are determined as follows:

- MSI-X vector table
  - The MSI-X table structure (Section 14.3.3.2) typically contains multiple entries, each consisting of several fields: *Message Address*, *Message Upper Address*, *Message Data*, and *Vector Control*. Each entry is capable of specifying a unique vector.
  - Starts at offset 0x0000 from start of BAR.
  - Contains the MSI-X vectors for the VF. The number of entries in the table (N) is set from NVM. The maximum value of N is 65.
  - The vectors start with the “Vector 0” (one per VF), followed by the other vectors allocated to the VF.
- MSI-X Pending Bits table
  - The PBA structure (Section 14.3.3.2.2) contains the function's pending bits, one per table entry, organized as a packed array of bits within QWords. The last QWord is not necessarily fully populated.
  - Starts at half the BAR size (default is offset 0x2000 - 8 KB from start of BAR).
  - Contains the pending bits for the VF. The VF is allocated one 64-bit register for a maximum of 17 bits.
  - The bits start with the “Vector 0” bit (one per VF), followed by bits for the other vectors allocated to the VF.

14.5.3.1.1 VF MSI-X Control Register (0x72; RW)

Bits	Init.	Type	Description
10:0	0x40 (65 vectors)	RO	**TS** Table Size (N-1). N varies with the number of virtual functions as set from NVM. This field is loaded from NVM. It is generated from the VPINT_ALLOC[VF#].*LAST* - VPINT_ALLOC[VF#].*FIRST* fields.
13:11	000b	RO	Reserved.
14	0b	RW	**Mask** Function Mask.
15	0b	RW	**En** MSI-X Enable.

14.5.3.1.2 MSI-X Address Register (0x74; RO)

Bits	Init.	Type	Description
2:0	011b	RO	**Table BIR** Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X table into the memory space. BIR values: 0...5 correspond to BARs 0x10…0x24, respectively.
31:3	0x0	RO	**Table Offset** Used as an offset from the address contained in one of the function's BARs to point to the base of the MSI-X vectors address. The lower three *Table BIR* bits are masked off (set to 0b) by software to form a 32-bit QWord-aligned offset.

14.5.3.1.3 MSI-X PBA Register (0x78; RO)

Bits	Init.	Type	Description
2:0	0x3	RO	**PBA BIR** Indicates which one of a function's BARs, located beginning at 0x10 in configuration space, is used to map the function's MSI-X PBA into memory space. A BIR value of three indicates that the PBA is mapped in BAR 3.
31:3	0x400	RO	**PBA Offset** Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X PBA. The lower three *PBA BIR* bits are masked off (set to zero) by software to form a 32-bit QWord-aligned offset. This value is changed by hardware to be half of the requested BAR size.

14.5.3.2 PCIe Capability Registers

The Device Control and Device Status registers have some fields that are specific per VF.

14.5.3.2.1 VF Device Control Register (0xA8; RW)

Bits	Init.	Type	Description
0	0b	RO	**Correctable Error Reporting Enable** Zero for VFs.
1	0b	RO	**Non-Fatal Error Reporting Enable** Zero for VFs.
2	0b	RO	**Fatal Error Reporting Enable** Zero for VFs.
3	0b	RO	**Unsupported Request Reporting Enable** Zero for VFs.
4	0b	RO	**Enable Relaxed Ordering** Zero for VFs.
7:5	000b	RO	**Max Payload Size** Zero for VFs.
8	0b	RO	**Extended Tag field Enable**
9	0b	RO	**Phantom Functions Enable** Not implemented in the E810.
10	0b	RO	**Auxiliary Power PM Enable** Zero for VFs.
11	0b	RO	**Enable No Snoop** Zero for VFs.
14:12	000b	RO	**Max Read Request Size** Zero for VFs.
15	0b	RW	**Initiate Function Level Reset** Specific to each VF.

14.5.3.2.2 VF Device Status Register (0xAA; RO)

Bits	Init.	Type	Description
0	0b	RW1C	**Correctable Detected** Indicates status of correctable error detection.
1	0b	RW1C	**Non-Fatal Error Detected** Indicates status of non-fatal error detection.
2	0b	RW1C	**Fatal Error Detected** Indicates status of fatal error detection.
3	0b	RW1C	**Unsupported Request Detected** Indicates that the E810 received an unsupported request. This field is separate per VF. However, in the case where an error cannot be associated with a VF, this bit is set in all PFs and VFs.
4	0b	RO	**Aux Power Detected** Zero for VFs.
5	0b	RO	**Transaction Pending** Specific per VF. When set, indicates that a particular function (PF or VF) has issued non-posted requests that have not been completed. A function reports this bit cleared only when all completions for any outstanding non-posted requests have been received.
15:6	0x0	RO	Reserved.

14.5.3.3 AER Registers

The following registers in the AER capability have a different behavior in a VF function.

Note: Unlike the PF AER registers, these registers are not sticky since the VF is reset on FLR and on in-band reset.

14.5.3.3.1 Uncorrectable Error Status Register (0x104; RW1C)

Bits	Init.	Type	Description
3:0	0x0	RO	Reserved.
4	0b	RO	**Data Link Protocol Error Status** Hard-wired to 0b.
5	0b	RO	**Surprise Down Error Status** Hard-wired to 0b.
11:6	0x0	RO	Reserved.
12	0b	RW1C	**Poisoned TLP Status**
13	0b	RO	**Flow Control Protocol Error Status** Hard-wired to 0b
14	0b	RW1C	**Completion Timeout Status**
15	0b	RW1C	**Completer Abort Status**
16	0b	RW1C	**Unexpected Completion Status**
17	0b	RO	**Receiver Overflow Status** Hard-wired to 0b
18	0b	RO	**Malformed TLP Status** Hard-wired to 0b
19	0b	RO	**ECRC Error Status** Hard-wired to 0b
20	0b	RW1C	**Unsupported Request Error Status** When caused by a function that claims a TLP.
21	0b	RO	**ACS Violation Status** Hard-wired to 0b
31:22	0x0	RO	Reserved.

14.5.3.3.2 Correctable Error Status Register (0x110; RW1C)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b, it indicates that a particular error occurred. Software can clear an error status by writing a 1b to the respective bit.

Bits	Init.	Type	Description
0	0b	RO	**Receiver Error Status** Hard-wired to 0b
5:1	0x0	RO	Reserved.
6	0b	RO	**Bad TLP Status** Hard-wired to 0b
7	0b	RO	**Bad DLLP Status** Hard-wired to 0b
8	0b	RO	**REPLAY_NUM Rollover Status** Hard-wired to 0b
11:9	000b	RO	Reserved.
12	0b	RO	**Replay Timer Timeout Status** Hard-wired to 0b
13	0b	RW1C	**Advisory non-Fatal Error Status**
31:14	0x0	RO	Reserved.

14.5.3.3.3 Advanced Error Capabilities and Control Register (0x118; RO)

Bits	Init.	Type	Description
4:0	0x0	ROS	**First Recorded Error** Vector pointing to the first recorded error in the Uncorrectable Error Status register. This is a read-only field that identifies the bit position of the first uncorrectable error reported in the Uncorrectable Error Status register.
5	0b	RO	**ECRC Generation Capable** If set, this bit indicates that the function is capable of generating ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register
6	0b	RO	**ECRC Generation Enable** When set, ECRC generation is enabled. Hard-wired to 0b. The PF setting applies to the VF.
7	0b	RO	**ECRC Check Capable** If set, this bit indicates that the function is capable of checking ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
8	0b	RO	**ECRC Check Enable** When set, ECRC checking is enabled. Hard-wired to 0b. The PF setting applies to the VF.
9	0b	RO	**Multiple Header Recording Capable.** Not supported. Hard-wired to 0b.
10	0b	RO	**Multiple Header Recording Enable** Not supported. Hard-wired to 0b.
11	0b	RsvdP	**TLP Prefix Log Present** Not supported. Hard-wired to 0b.
15:12	0x0	RO	Reserved.

NOTE: ***This page intentionally left blank.***

Chapter 15 Reliability, Diagnostics, and Testability

15.1 Reliability

15.1.1 ECC Support and ECC Error Flow

Memories in the E810 are protected by ECC (ECC bits are added to the memory on write and compare on read). There are two types of ECC errors:

- **Correctable ECC error** — When the memory line has a single bit error, the ECC mechanism corrects it. This is done within the memory shell/wrapper and the flow continues as normal.
- **Uncorrectable ECC error** — When the memory line read has more than a single ECC error, it cannot be recovered by the ECC mechanism. The text that follows describes how the E810 reacts to such an event.

Reporting of ECC errors is as follows:

- The *_ECC_COR_ERR and *_ECC_UNCOR_ERR per-block registers count the occurrence of correctable and uncorrectable errors, respectively (the * symbol stands for the block name).

Uncorrectable errors are handled as follows:

- Device blocks data from going to an external link and blocks any new PCIe master transaction, but the erroneous transaction might reach host memory.
- Recovery then depends on the memory where the error happens:
  - An error takes place in the core or global domains.
    - If the GLGEN_RSTCTL.*ECC_RST_ENA* bit is set to 1b, the E810 generates a GLOBR reset.
  - An error takes place in the EMP.
    - If the GLMNG_WD_ENA.*ECC_RST_ENA* bit is set to 1b, the EMP generates an EMPR reset.
  - An error takes place in FLEEP (Shadow RAM).
    - An ECC error check in the Shadow RAM is enabled via the *Shadow RAM ECC Enable* bit in the NVM.
    - The FLEEP reloads the Shadow RAM from the NVM.
    - If the GLGEN_RSTCTL.*ECC_RST_ENA* bit is set to 1b, the E810 generates a GLOBR reset (which in turn reloads the relevant sections into hardware).
  - An error takes place in the PCIe domain.
    - If an error is in data to be sent out, the TLP is sent with an EDB. Else, the link goes to a link-down state.
    - If the GLMNG_WD_ENA.ECC_RST_ENA bit is set to 1b, the EMP generates an EMPR reset.
    - Else, if the GLGEN_RSTCTL.ECC_RST_EN bit is set to 1b, the E810 generates a GLOBR reset.

15.2 Link Loopback Operations

Loopback operations are supported by the E810 to assist with system and device debug. Loopback operation can be used to test transmit and receive aspects of software device drivers, as well as to verify electrical integrity of the connections between the E810 and the system (such as PCIe bus connections, and so on).

15.3 Firmware Recovery Mode

15.3.1 Overview

Firmware Recovery mode is intended to recover from a fatal failure scenario in which the device is not accessible to the host, meaning firmware is non-responsive.

A PDoS scenario might occur by a misconfiguration done by a malicious software that corrupts device-specific information that is vital for firmware operation and/or its enumeration over the PCIe.

The purpose of the Firmware Recovery mode is to enable the software tools to update or rollback the firmware and/or device configuration so that the fatal error is resolved.

15.3.1.1 Supported Failure Scenarios by Firmware

Possible supported failure scenarios that are covered by firmware:

- Firmware boot failure (for example, fails to authenticate NVM bank).
- Firmware initialization failure on POR/EMPR.
- CORER/GLOBR firmware flow failure.
- Repeated Watchdog reset.
- Repeated Memory exception.

15.3.1.2 Dependencies for Recovery Firmware

Firmware does not run Recovery mode in cases where the error is in one of following firmware components:

- ROM firmware.
- Mini-loader firmware (boot loader).
- Recovery firmware section corrupted or erroneous.

In case any of the above scenarios occur, the device enters Blank Flash Mode (BFP) in which security is off and the entire NVM can be directly accessed by software via CSRs.

15.3.2 Recovery Flows

When firmware detects a failure scenario, it first attempts to automatically rollback to the non-active NVM bank (see Section 15.3.2.1).

If rollback fails or the non-active bank is not valid, firmware attempts recovery (see Section 15.3.2.2). Both flows are run automatically by firmware. Software has no ability to trigger these flows.

Exit from a recovery flow to normal operation mode can be done following successful NVM update flow triggered by the software tool or POR. In normal operation mode, device runs the firmware from the valid NVM bank.

In case of exception or Watchdog timeout, each recovery flow is attempted up to a pre-defined amount of times (3) before firmware decides to try the next recovery flow. Before every attempt, firmware restarts the EMP firmware by issuing a graceful EMPR. Firmware restarts the counting in case firmware is running successfully for a pre-defined (hard-coded) time (five hours).

15.3.2.1 Automatic Rollback

Firmware automatically tries to rollback to "old" operational firmware located in the invalid NVM bank in cases where operational firmware from the valid NVM bank repeatedly enters a PDoS scenario. The invalid NVM bank must pass authentication and other security checks, such as SREV downgrade protection.

After rollback is successful, the banks are swapped, and the "rollback" bank becomes the active bank for the next reset.

15.3.2.2 Recovery Firmware

Recovery firmware is a standalone bank that contains basic functionality to allow software tools to update firmware/NVM and/or device configuration.

The recovery firmware section is separately signed and is upgradeable as part of full NVM bank.

Recovery firmware is invoked automatically by mini-loader firmware in cases where Rollback firmware repeatedly enters a failure scenario.

Recovery firmware is run from the latest active bank disregarding rollback attempt.

15.3.2.2.1 Recovery Firmware Supported Features

15.3.2.2.1.1 Recovery Mode Admin Commands

Recovery firmware supports a reduced set of admin commands, as listed below. Other commands are rejected with BAD_OPCODE error. Admin commands are only supported from PF0 and the "CSR-Based Firmware Admin Queue for Tools" (see Section 9.5.12).

- Section 9.5.13.1, "Get Version (0x0001)"
- Section 9.5.13.4, "Set PF Context (0x0004)"
- Section 9.5.13.5, "Get Expanded AQ Error Reason (0x0005)"
- Section 9.5.13.6, "Request Resource Ownership (0x0008)"
- Section 9.5.13.7, "Release Resource Ownership (0x0009)"

- Section 3.4.10.1, "NVM Read (0x0701)"
- Section 3.4.10.2, "NVM Erase (0x0702)"
- Section 3.4.10.3, "NVM Write (0x0703)"
- Section 3.4.10.8, "NVM Write Activate (0x0707)"

15.3.2.2.1.2 Recovery Mode Admin Command Usage Guidelines

Usage guidelines are as follows:

- The NVM Update and NVM Erase commands support only NVM bank and extended TLV bank.
- The NVM Activate command does not support selected preservation (01) of the PFA.
- The NVM Read command supports NVM bank, Extended TLV bank, and read of the entire flash in flat mode (0x0).
- The NVM update tools can read the EETRACK ID using the NVM Read AQC (0x701). The EETRACK ID is not available in Shadow RAM during recovery.
- Resource request and release commands support only NVM resource (0x1).
- Set PF context supports only PF0.

15.3.2.2.2 Reset Flows

15.3.2.2.2.1 CORER/GLOBR

Recovery firmware performs CORER/GLOBR with no auto-load or initializations.

Firmware acknowledges to software that reset is done and AL is done, as it does in operational firmware.

15.3.2.2.2.2 PFR

Recovery firmware does not perform any device initialization related to data path, and only acknowledges to software that the reset is done, as it does in operational firmware.

15.3.2.2.2.3 PCIR/PERST

Recovery firmware performs minimal configuration to enable AQ communications.

Recovery firmware auto-loads PCIe registers from the PFA inside the "Factory Settings" section instead of active PFA in the SR bank and from the signed EML section.

Firmware acknowledges to software that the reset is done and AL is done, as it does in operational firmware. PCIR registers AL is checked against a white-list that is loaded from the signed EML section.

15.3.2.2.2.4 POR/EMPR

Recovery firmware auto-loads POR registers from PFA inside "Factory Settings" section of active PFA in the SR bank and from the signed EML section.

POR registers AL is checked against a white-list that is loaded from the signed EML section.

15.3.2.2.3 Unsupported Features

Recovery firmware does not support:

- Link
- Traffic
- Manageability (BMC)

Recovery firmware only supports firmware update flows from host.

15.3.3 Operation Mode Software Identification

Firmware indicates operation mode via the *FW_MODES* field (Bits 2:0) in the GL_MNG_FWSM CSR (see Section 13.2.2.29.7). Bits are exclusive.

- Bit 0 = Debug mode indication (0:non-debug mode, 1:debug mode)
- Bit 1 = Recovery mode indication (0:normal mode, 1:recovery mode)
- Bit 2 = Rollback indication (0:normal mode, 1:rollback mode)
- Rollback and recovery indications are valid until next firmware update or next POR. Following firmware update or POR, they are cleared.

NOTE: ***This page intentionally left blank.***

Chapter 16 Electrical/Mechanical Specification

16.1 Introduction

This section describes electrical and mechanical characteristics of the E810, including: Operating Conditions, Power Delivery, Power Dissipation, DC/AC Specifications, Package, and Supported Devices.

16.2 Operating Conditions

16.2.1 Absolute Maximum Ratings

Table 16-1. Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Units
T_j	Junction Temperature Under Bias	-0	115	°C
$T_{storage}$	Storage Temperature Range	-40	115	°C
Vi	3.3V I/O Input Voltage	VSS-0.3	VDDIO33+0.3	V
VDDIO33	3.3V Digital I/O Supply Voltage	VSS-0.3	3.645	V

Notes:

- Stresses above those listed in the table can cause permanent device damage. These values should not be used as limits for normal device operation. Exposure to absolute maximum rating conditions for an extended period of time can affect device reliability.
- Maximum Tj of 125 °C is allowed up to 4% of the time without affecting device reliability.

16.2.2 Recommended Operating Conditions

Table 16-2. Recommended Operating Conditions

Symbol	Parameter	Min	Typical	Max	Units
Tj	Junction Temperature	0		105	°C

Notes:

- For normal device operation, adhere to the limits in this table. Sustained operation of a device at conditions exceeding these values, even if they are within the absolute maximum rating limits, can result in permanent device damage or impaired device reliability.
- Device functionality is not guaranteed if conditions exceed recommended operating conditions.
- External Heat Sink (EHS) is needed for most applications.
- Refer to Chapter 18, "Thermal Design Considerations" for a description of the allowable thermal environment.
- Thermal design power (TDP) is specified at 105 °C junction temperature.

16.3 Power Delivery

16.3.1 Power Supply Specification

Table 16-3. 3.3 V Power Supply Specification

VDDIO33 (3.3V) Parameters				
Title	**Description**	**Min**	**Max**	**Units**
Rise Time	Time from 10% to 90% mark.	0.1	10	ms
Monotonicity	Voltage dip allowed in ramp.	N/A	0	mV
Slope	Ramp rate at any given time between 10% and 90%. Min: 0.8*V (min)/rise time (max) Max: 0.8*V (max)/rise time (min)	24	28,800	V/s
Operational Range	Voltage range for normal operating conditions (+5%, -10%).	2.97	3.465	V
Ripple	Maximum voltage ripple (peak-to-peak).	N/A	VDDIO33 ±200	mV
Overshoot	Maximum overshoot allowed.	N/A	100	mV
Overshoot Settling Time	Maximum overshoot allowed duration. (At that time delta voltage should be lower than 5 mV from steady state voltage.)	N/A	0.05	ms

Note: If ViH tolerance to 3.6 V is required, maintain VDDIO33 between 3.3 V to 3.465 V (3.38 ±2.5%).

Table 16-4. 1.8 V VDDH Power Supply Specification

VDDH Parameters				
Title	**Description**	**Min**	**Max**	**Units**
Rise Time	Time from 10% to 90% mark.	0.1	10	ms
Monotonicity	Voltage dip allowed in ramp.	N/A	0	mV
Slope	Ramp rate at any given time between 10% and 90%. Min: 0.8*V (min)/rise time (max) Max: 0.8*V (max)/rise time (min)	0.33	7120	V/s
Operational Range	Voltage range for normal operating conditions (±10%).	1.62	1.98	V
Ripple	Maximum voltage ripple (peak-to-peak).	N/A	20	mV
Overshoot	Maximum overshoot allowed.	N/A	50	mV
Overshoot Duration	Maximum overshoot allowed duration. (At that time delta voltage should be lower than 5 mV from steady state voltage.)	0	0.05	ms

Table 16-5. 1.1 V AVDDH Power Supply Specification

AVDDH Parameters				
Title	**Description**	**Min**	**Max**	**Units**
Rise Time	Time from 10% to 90% mark.	0.1	10	ms
Monotonicity	Voltage dip allowed in ramp.	N/A	0	mV
Slope	Ramp rate at any given time between 10% and 90%. Min: 0.8*V (min)/rise time (max) Max: 0.8*V (max)/rise time (min)	0.33	7120	V/S
Operational Range	Voltage range for normal operating conditions (±5%)/	1.045	1.155	V
Ripple	Maximum voltage ripple (peak-to-peak). 600 KHz to 20 MHz	N/A	10	mV
Overshoot	Maximum overshoot allowed.	N/A	50	mV
Overshoot Duration	Maximum overshoot allowed duration. (At that time delta voltage should be lower than 5 mV from steady state voltage.)	0	0.05	ms

Table 16-6. 0.9 V AVDD_ETH and AVDD_PCIE Power Supply Specification

AVDD (AVDD_PCIE/AVDD_ETH) Parameters				
Title	**Description**	**Min**	**Max**	**Units**
Rise Time	Time from 10% to 90% mark.	0.1	10	ms
Monotonicity	Voltage dip allowed in ramp.	N/A	0	mV
Slope	Ramp rate at any given time between 10% and 90%. Min: 0.8*V (min)/rise time (max) Max: 0.8*V (max)/rise time (min)	0.33	7120	V/S
Operational Range	Voltage range for normal operating conditions (±5%).	0.855	0.945	V
Ripple	Maximum voltage ripple (peak to peak). 600 KHz to 20 MHz	N/A	2.0	mV
Overshoot	Maximum overshoot allowed.	N/A	50	mV
Overshoot Duration	Maximum overshoot allowed duration. (At that time delta voltage should be lower than 5 mV from steady state voltage.)	0	0.05	ms

Note: In the E810-CAM2/CAM1, AVDD is split for the PCIe and Ethernet interfaces. In the E810-XXVAM2, a single AVDD supplies both interfaces.

Table 16-7. 0.8 V VDD Power Supply Specification

VDD Parameters				
Title	**Description**	**Min**	**Max**	**Units**
Rise Time	Time from 10% to 90% mark.	0.1	10	ms
Monotonicity	Voltage dip allowed in ramp.	N/A	0	mV
Slope	Ramp rate at any given time between 10% and 90%. Min: 0.8*V (min)/rise time (max) Max: 0.8*V (max)/rise time (min)	0.33	7120	V/S
Operational Range	Voltage range for normal operating conditions (0.8 V ±5%).	0.76	0.84	V
Ripple	Maximum voltage ripple (peak to peak).	N/A	20	mV
Overshoot	Maximum overshoot allowed.	N/A	50	mV
Overshoot Duration	Maximum overshoot allowed duration. (At that time delta voltage should be lower than 5 mV from steady state voltage.)	0	0.05	ms

16.3.1.1 Power On/Off Sequence

The following relationships between the application of the different power supplies should be maintained to avoid risk of either latch-up or forward-biased internal diodes:

- The E810 provides an internal Power-On Reset (POR). An alternate external POR (LAN_POWER_GOOD) can be used to extend the reset if necessary.
- The E810 initialization budgets 35 ms from system power-on to LAN_POWER_GOOD (or internal POR) completion. Remaining 65 ms (for the PCIe spec 100 ms system power to PERST# inactive) is allocated to internal initialization.
- The internal POR function monitors VDDH and VDD only. Internal POR signal is held active for 7-10 ms after these supplies reach ~50%.
- Application of power should begin with the 3.3 V (VDDIO33) and 1.8 V (VDDH) supplies ***at the same time***. After 3.3 V reaches 80% of its final value, the digital core 0.8 V supply (VDD) should be enabled and reach its final value within 10 ms.
- 156.25 MHz REFCLK oscillator should be powered with same VDDIO33 used for the E810, but the oscillator's output enable should be held inactive until VDDH is on. Suggest asserting REFCLK OE at the same time as VDD regulator is enabled. This sequence avoids driving a signal into the un-powered clock buffer while enabling REFCLK prior to any analog supply. Allow 10 ms oscillator startup time from 3.3 V to analog supplies enable.
- AVDD_ETH, AVDD_PLL, and REFCLK should be active within 7 ms of VDD regulator enabling to insure that internal clock is active prior to internal POR complete. If this cannot be met, the LAN_POWER_GOOD signal should be used to extend reset. The 35 ms budget must still be met for PCIe timing.
- Use slow rise time on AVDD_ETH to minimize power-on current spike (~3 ms). This allows internal clock and reset to propagate before AVDD has reached its final value.
- AVDD_PCIE and AVDDH can be enabled with AVDD_ETH, or after a slight delay. A small delay (1-3 ms) will mitigate turn on current spikes from these supplies.
- AVDD_PLL should always be sequenced with AVDD_ETH.

Figure 16-1 illustrates a power supply turn-on order with timing that meets the system power-on to PERST# inactive timing in the PCIe CEM specification. Of the 100 ms budget, 65 ms is reserved for internal initialization activity. Power supply delays and rise times are approximate. The key requirement is for power-on reset (whether from the internal POR or LAN_POWER_GOOD) to be complete in 35 ms from system power stable.

For power down, it is recommended to turn off all rails at the same time and allow voltage to decay.

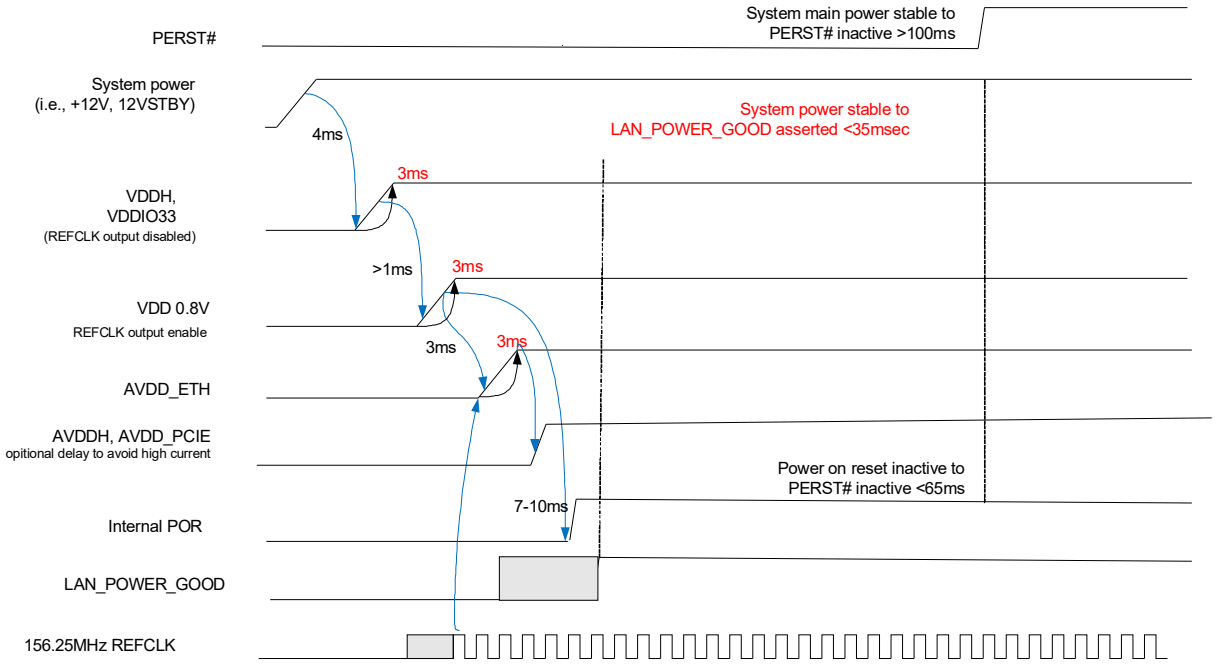

Figure 16-1. Power Supply Sequence

16.3.2 In-Rush Current

Max Load Step (A):

- AVDD = 0.9
- VDD = 5.0

Max Slew Rate (A/µs):

- AVDD = 0.2
- VDD = 2.0

16.4 Power Dissipation

The following tables list the targets for device power consumption. The numbers listed apply to device current and power, and do not include power losses on external components.

Power consumption is listed separately for the E810-CAM2/CAM1 versus the E810-XXVAM2.

Power numbers are provides in two modes:

- **MAX-Power (TDP):** Power consumption of the device specified at maximum recommended operating junction temperature on fast silicon process corner, and nominal power supply voltage. This power should be used for thermal and power supply design.
- **Typical-Power:** Power consumption of the device at nominal operation conditions: typical silicon, nominal power supply voltage, and Tj = 80 °C.

16.4.1 Max Power (TDP) - E810-CAM2/CAM1

Table 16-8. E810-CAM2/CAM1 MAX Power - PCIe Gen 4 and PCIe Gen 3

	Link Speed					
	2x100G PCIe Gen4x16	1x100G/ 2x50G/4x25G PCIe Gen4x16	2x25G PCIe Gen4x8	2x100G PCIe Gen3x16	1x100G/ 2x50G/4x25G PCIe Gen3x16	2x25G PCIe Gen3x8
VDDIO33 (A)	0.02	0.02	0.02	0.02	0.02	0.02
VDDH (A)	0.02	0.02	0.02	0.02	0.02	0.02
AVDDH (A)	0.80	0.50	0.20	0.80	0.50	0.20
AVDD_ETH (A)	3.00	1.80	0.90	3.00	1.80	0.90
AVDD_PCIE (A)	3.904	3.90	2.00	2.60	2.60	1.40
VDD (A)	10.60	10.00	8.80	10.30	9.70	8.50
Power (W)	15.67	13.78	9.97	14.26	12.37	9.19

Notes:

- VCCIO33 current includes on-chip power dissipation only for TDP calculation. System power supply should account for external 3.3 V powered devices, such as LEDs, flash, oscillator, and pluggable modules.
- AVDD_ETH current includes 0.02A for the AVDD_PLL supply.

16.4.2 Typical Power - E810-CAM2/CAM1

16.5 DC/AC Specification

16.5.1 Digital I/O DC Specifications

Table 16-19. Digital Functional 3.3V I/O DC Electrical Characteristics

Symbol	Parameter	Conditions	Min	Max	Units
VOH	Output High Voltage		2.4		V
VOL	Output Low Voltage			0.4	V
IOH	Output High Current		12		mA
IOL	Output Low Current		12		mA
VIH	Input High Voltage		2.0	VDDIO33+300 mV	V
VIL	Input Low Voltage		-0.3	0.8	V
Iil	Input Current[1]	VI=3.3 V / 0V		10	µA
PU	Internal pull-up		10	20	KΩ

1. Input Leakage Current

16.5.1.1 Open Drain I/O DC Specification

This section applies to SMBD, SMBCLK, SMBALRT _N, PE_WAKE_N.

Table 16-20. Open Drain I/O DC Characteristics

Symbol	Parameter	Condition	Min	Max	Units
Vih	Input High Voltage		2.0	VDDIO33 +0.3	V
Vil	Input Low Voltage		-0.2	0.8	V
Ileakage	Output Leakage Current[1]	0 ≤ Vin ≤ VDDIO33 max		100	µA
Vol	Output Low Voltage	@ Ipullup = 4 mA	0.4		V
Cin	Input Pin Capacitance				pF
Ioffsmb	Input leakage Current[1]	VDDIO33 off or floating		100	µA
IOL	Output Current Low		6		mA

1. Device meets this specification whether powered or un-powered.

16.5.1.2 NC-SI I/O DC Specification

Table 16-21. NC-SI I/O DC Characteristics

Symbol	Parameter	Conditions	Min	Typical	Max	Units
Vref[1]	Bus High Reference		3.0	3.3	3.6	V
Vabs	Signal Voltage Range		-0.3		3.765	V
Vil	Input Low Voltage				0.8	V
Vih	Input High Voltage		2.0			V
Vol	Output Low Voltage	Iol = 4 mA, Vref = $Vref_{min}$	0		0.4	V
Voh	Output High Voltage	Iol = -4 mA, Vref = $Vref_{min}$	2.4		Vref	V
Iih	Input High Current	Vin = 3.6 V, Vref = 3.6 V	0		200	µA
Iil	Input Low Current	Vin = 0 V Vref = $Vref_{min}$ to $Vref_{max}$	-20		0	µA
Ioh	Input High Current		12			mA
Iol	Input Low Current		12			mA
Vckm	Clock Midpoint Reference Level				1.4	V
Pin Capacitance	Cin		1.5	1.7		pF
Iz	Leakage Current for Output Signals in High-Impedance State	0 ≤ Vin ≤ Vih_{max} Vref = $Vref_{max}$	-20		20	µA

1. Vref = Bus high reference level. This parameter replaces the term "supply voltage" since actual devices might have internal mechanisms that determine the operating reference for the sideband interface that are different from the devices overall power supply inputs. Vref is a reference point that is used for measuring parameters such as overshoot and undershoot and for determining limits on signal levels that are generated by a device. In order to facilitate system implementations, a device must provide a mechanism (e.g. a power supply pin, internal programmable reference, or reference level pin) to allow Vref to be set to within 20 mV of any point in the specified Vref range. This is to enable a system integrator to establish an interoperable Vref level for devices on the sideband interface. Although the NC-SI spec define the Vrefmax up to 3.6 V, the E810 supports the Vrefmax up to 3.46 V (3.3 V +5%).

16.5.2 Digital I/F AC Specifications

16.5.2.1 Digital I/O AC Specifications

Table 16-22. Digital 3.3 V I/O AC Electrical Characteristics

Parameters	Description	Min	Max	Condition
F_{max}	Maximum Operating Frequency		100 MHz, 300 MHz	100 MHz at 25 pF load. 300 MHz at 8 pF load.
T_{or}	Output Rise Time	0.5 ns	6 ns	
T_{of}	Output Fall Time	0.5 ns	6 ns	

Note: Does not apply to open drain outputs.

16.5.2.2 SMBus and I²C AC Specifications

The E810 meets the SMBus AC specification as defined in the *System Management Bus (SMBus) Specification*, Version 2, Section 3.1.1 (http://www.smbus.org/specs/index.html) and the I²C specification.

The E810 also supports a 400 KHz SMBus and I²C (as a slave), and meets the specifications listed in Table 16-23:

Table 16-23. Support for 400 KHz SMBus

Symbol	Parameter	Min	Typical	Max	Units
F_{SMB}	SMBus Frequency	10		400	KHz
T_{BUF}	Time Between Stop and Start	1.44			µs
$T_{HD,STA}$	Hold Time After Start Condition. After This Period, the First Clock is Generated.	0.48			µs
$T_{SU,STA}$	Start Condition Setup Time	1.6			µs
$T_{SU,STO}$	Stop Condition Setup Time	1.76			µs
$T_{HD,DAT}$	Data in Hold Time	0.32			µs
$T_{SU,DAT}$	Data in Setup Time	0.1			µs
T_{LOW}	SMBClk Low Time	0.8			µs
T_{HIGH}	SMBClk High Time	1.44			µs

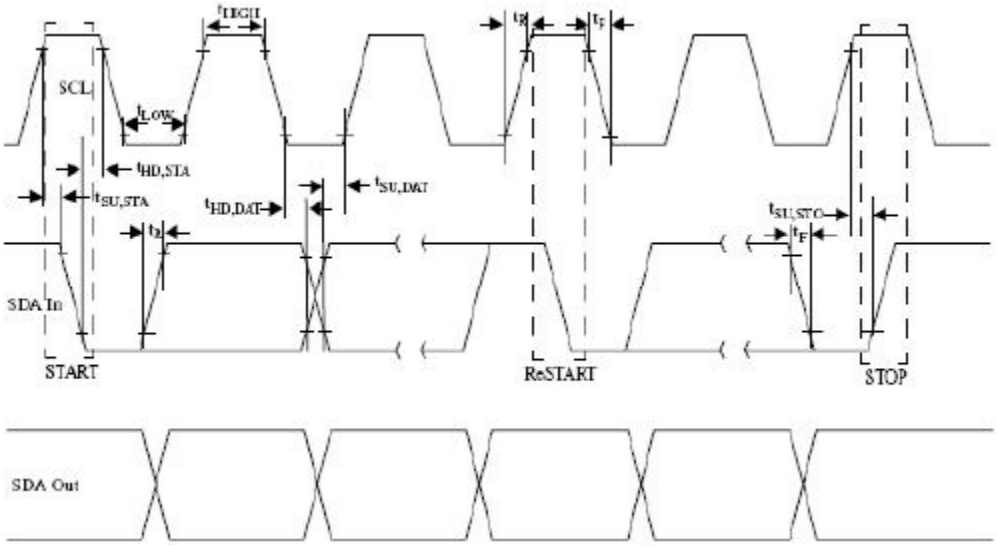

Figure 16-2. SMBus I/F Timing Diagram

16.5.2.3 FLASH AC Specification

The E810 is designed to support a serial Flash. Applicable over recommended operating range with C_{load} = 16 pF (unless otherwise noted). For Flash I/F timing specifications, see Table 16-24 and Figure 16-3.

Note: Table 16-24 applies to FLSH_SI, FLSH_SO, FLSH_SCK and FLSH_CE_N.

Table 16-24. Flash I/F Timing Parameters

Symbol	Parameter	Min	Typical	Max	Units
t_{SCK}	FLSH_SCK Clock Frequency[1]	0		50	MHz
t_{RI}	FLSH_SO Rise Time		3		ns
t_{FI}	FLSH_SO Fall Time		3		ns
t_{WH}	FLSH_SCK High Time[2]		8		ns
t_{WL}	FLSH_SCK Low Time[2]		12		ns
t_{CS}	FLSH_CE_N High Time	10			ns
t_{CSS}	FLSH_CE_N Setup Time	5			ns
t_{CSH}	FLSH_CE_N Hold Time	5			ns
t_{SU}	Data-in Setup Time	2			ns
t_{H}	Data-in Hold Time	3			ns
t_{V}	Output Valid			7	ns
t_{HO}	Output Hold Time	2			ns
t_{DIS}	Output Disable Time			7	ns

1. Nominal 40%:60% high:low duty cycle.
2. Measured at VDDIO33/2.

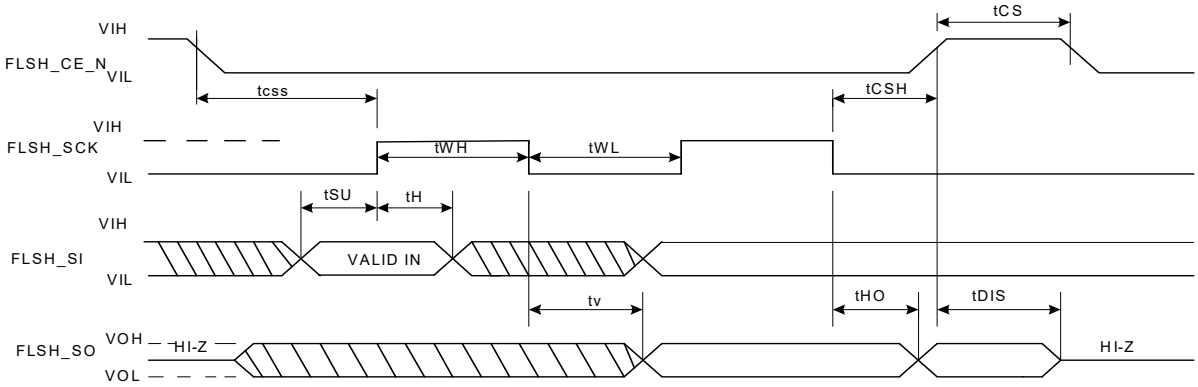

Figure 16-3. Flash I/F Timing Diagram

16.5.2.4 NC-SI AC Specifications

The E810 supports the NC-SI standard as defined in the DMTF *Network Controller Sideband Interface (NC_SI) Specification*. The NC-SI timing specifications can be found in Table 16-25 and Figure 16-4.

Table 16-25. NC-SI Interface AC Specifications

Symbol	Parameter	Min.	Typical	Max	Units
	REF_CLK Frequency		50	50+100 ppm	MHz
	REF_CLK Duty Cycle[1]	35		65	%
T_{co}	Clock-to-Out[2,3] (10 pF ≤ C_{load} ≤ 50 pF)	2.5		12.5	ns
T_{skew}	Skew Between Clocks			1.5	ns
T_{su}	TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER Data Setup to REF_CLK Rising Edge[3]	3			ns
T_{hd}	TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER Data Hold From REF_CLK Rising Edge[3]	1			ns
T_r/T_f	Signal Rise/Fall Time[4]	1		6	ns
T_{ckr}/T_{ckf}	REF_CLK Rise/Fall Time[5]	0.5		3.5	ns
T_{pwrz}	Interface Power-Up High Impedance Interval	2			µs
T_{pwrt}	Power Up Transient Interval (recommendation)			100	ns
V_{pwrt}	Power Up Transient Level (recommendation)	-200		200	mV
T_{pwre}	Interface Power-Up Output Enable Interval			10	ms
$T_{clkstrt}$	EXT_CLK Startup Interval			100	ms

1. REF_CLK duty cycle measurements are made from Vckm to Vckm. Clock skew T_{skew} is measured from Vckm to Vckm of two NC-SI devices and represents maximum clock skew between any two devices in the system.
2. This timing relates to the output pins timing while T_{su} and T_{hd} relate to timing at the input pins.
3. All timing measurements are made between Vckm and Vm. All output timing parameters are measured with a capacitive load between 10 pF and 50 pF.
4. Rise and fall time are measured between points that cross 10% and 90% of Vref (see Table 16-21). The middle points (50% of Vref) are marked as Vckm and Vm for clock and data, respectively.
5. A serial 33 Ω resistor might be required in case of very short trace on the board.

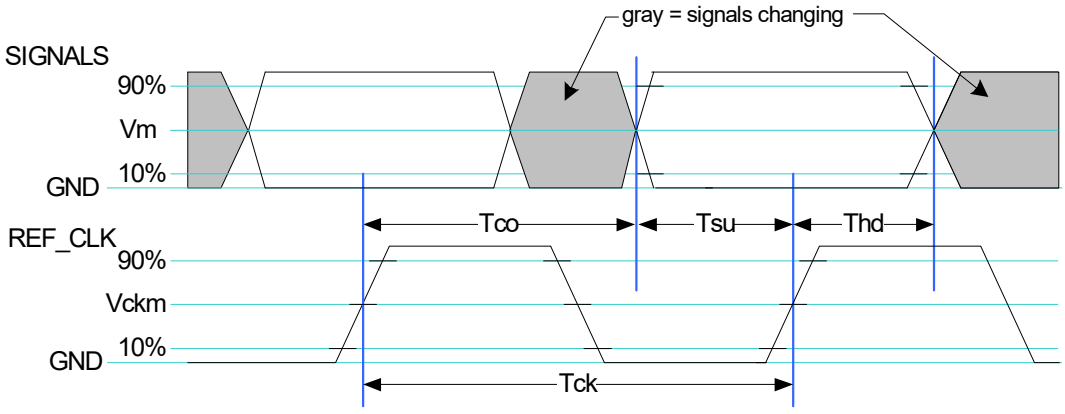

Figure 16-4. NC-SI AC Timing Diagram

16.5.2.5 JTAG AC Specification

The E810 is designed to support the IEEE 1149.1 standard. The following timing specifications are applicable over recommended operating range. For JTAG I/F timing specifications, see Table 16-26 and Figure 16-5.

Table 16-26. JTAG I/F Timing Parameters

Symbol	Parameter	Min	Typical	Max	Units
t_{JCLK}	JTCK Clock Frequency			10	MHz
t_{JH}	JTMS and JTDI Hold Time	10			ns
t_{JSU}	JTMS and JTDI Setup Time	10			ns
t_{JPR}	JTDO Propagation Delay			15	ns

Notes:

- Table 16-26 applies to JTCK, JTMS, JTDI and JTDO.
- Timing measured relative to JTCK reference voltage of VDDIO33/2.

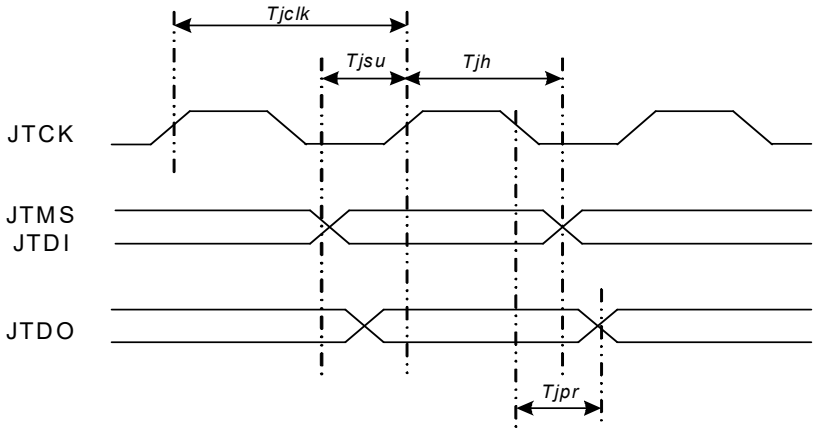

Figure 16-5. JTAG AC Timing Diagram

16.5.2.6 MDIO AC Specification

The E810 is designed to support the MDIO specifications defined in IEEE 802.3 clauses 22 and 45. The following timing specifications are applicable over recommended operating range with C_{load} = 16 pF (unless otherwise noted). For MDIO I/F timing specifications, see Table 16-27, Figure 16-6, and Figure 16-7.

Table 16-27. MDIO I/F Timing Parameters

Symbol	Parameter	Min	Typical	Max	Units
t_{MCLK}	MDC Clock Frequency	2.4		24	MHz
t_{MH}	MDIO Hold Time	10			ns
t_{MSU}	MDIO Setup Time	10			ns
t_{MPR}	MDIO Propagation Delay	10		30	ns

Notes:
- Table 16-27 applies to MDIO0, MDC0, MDIO1 and MDC1.
- Timing measured relative to MDC reference voltage of 2.0 V (Vih).

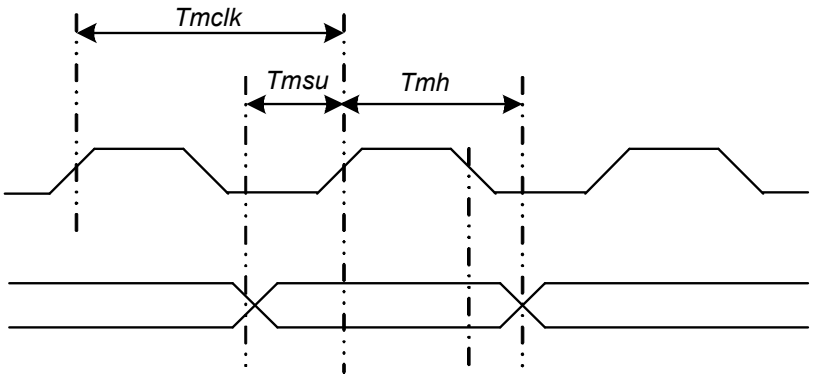

Figure 16-6. MDIO Input AC Timing Diagram

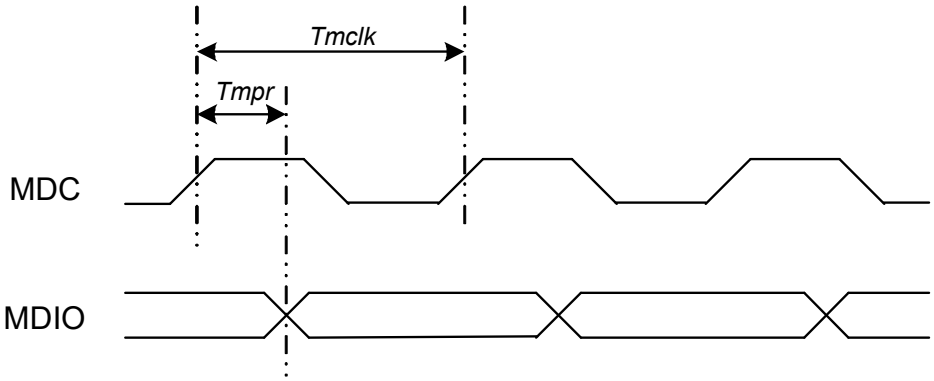

Figure 16-7. MDIO Output AC Timing Diagram

16.5.2.7 Reset Signals

For power-on indication, the E810 can either use an internal power-on circuit that monitors the VDD and VDDH power supplies, or an external reset using the LAN_PWR_GOOD pin. The POR_BYPASS pin defines the reset source. When asserting the POR_BYPASS pin, the E810 uses the LAN_PWR_GOOD pin as power-on indication. Otherwise, the E810 uses a logical OR of the internal power on detection circuit and the LAN_PWR_GOOD pin to generate the internal power-on reset signal.

Note: The timing between the power up sequence and the different reset signals is described in Section 16.3.1.1.

16.5.3 PCIe Interface AC/DC Specification

The E810 PCIe interface supports the PCIe Gen 4.0 electrical specification defined in:

- *PCIe Express Base Specification*, Revision 4.0
- *PCI Express Card Electromechanical Specification*, Revision 4.0

16.5.4 Network Interface AC/DC Specification

The E810 Ethernet interface supports a variety of operating modes, as defined in Section 3.2.2.

16.5.5 Reference Clock Specification

The E810 requires a 156.25 MHz differential reference clock input. The REFCLK input buffer supports HCSL voltage levels and contains internal AC coupling capacitors and 50 Ω termination. Best performance can be achieved by using an HCSL drive oscillator with direct connections to the REFCLK inputs (no other component connected on the circuit board).

Figure 16-8 shows a typical input waveform expected from a 1.8 V HCSL driver.

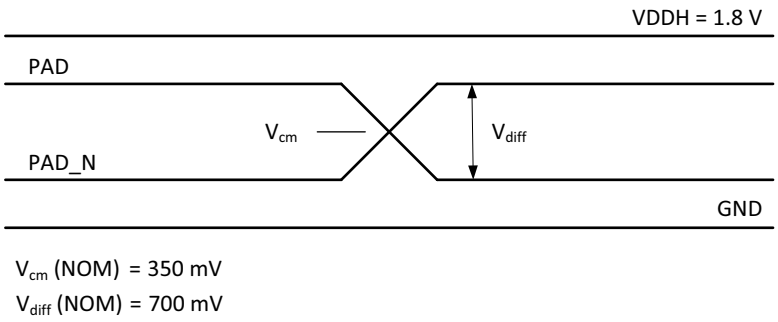

Figure 16-8. Typical HCSL Waveform

The input HCSL signal needs to stay between GND (0 V) and VDDH (1.8 V) range at all times. If the HCSL oscillator logic low V_{OL} = 0 V, the common mode voltage (V_{cm}) measured with respect to GND is half of the differential swing V_{diff}:

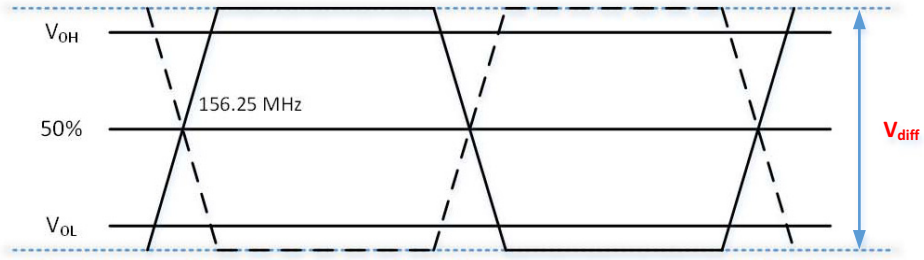
$$V_{cm} = 0.5 * V_{diff}$$

This allows for the HCSL oscillator V_{OL} to be higher than 0 V if needed, but then the max differential swing V_{diff} will need to be reduced:

- If the differential swing V_{diff} = max allowed = 1.2 V, the HCSL oscillator V_{OL} needs to = 0 V.
- If the differential swing V_{diff} < 1.2 V, the HCSL oscillator V_{OL} is allowed to be > 0 V

For example:

If V_{diff} = 800 mV and V_{cm} = 400 mV, the HCSL oscillator V_{OL} max allowed = 200 mV and HCSL oscillator V_{OH} max allowed = 1.0 V.



V_{diff} = differential swing V_{diff} = measured as a single-ended amplitude

Figure 16-9. Differential Swing V_{diff}

Table 16-28. Input Reference Clock Electrical Characteristics

Symbol	Parameter	Min	Typical	Max	Unit	Comments
f	Frequency		156.25		MHz	
Δf	Frequency Variation	-50		+50	ppm

	Phase Noise			-110	dBc/Hz	10 KHz
				-130	dBc/Hz	100 KHz
				-150	dBc/Hz	1 MHz
				-150	dBc/Hz	10 MHz
				-150	dBc/Hz	20 MHz
				-150	dBc/Hz	100 MHz

16.6 Package Characteristics

16.6.1 Mechanical Configuration

The E810 is assembled in 25x25 mm and 21x21 mm FCGBA package with 10-layer substrates. Refer to Section 16.7 for the package mechanical drawings.

Table 16-29. Package Specifications

SKU	Body Size	Ball Count	Ball Pitch	Ball Matrix	Substrate
E810-CAM2/CAM1	25 x 25 mm	668	1 mm	48 x 28	4-2-4
E810-XXVAM2	21 x 21 mm	456	1 mm	40 x 23	4-2-4

16.6.2 Heat Sink Mechanical Load Limits

This section presents guidelines for the maximum loads associated with heat sink to PCB attachment.

For the E810-CAM2/CAM1 (25x25 mm lidded package), loads are applied on the entire raised portion of the lid by a rigid heat sink or rigid actuator that is parallel to the lid plane.

For the E810-XXVAM2 (21x21 mm bare-die package), the heat sink or actuator contact surface is parallel to the die backside surface. Heat sink or actuator touchdown on the die edge or corner is prohibited. Short-term loads act on both the die backside and the exposed substrate. Long-term (heat sink) loads may act solely on the die. A compliant material is used between the heat sink or actuator and the die.

Short-term and long-term loads are applied slowly to prevent dynamic loads from being created. The maximum permissible BGA compression is 15% of the assembled BGA height.

Table 16-30. Mechanical Load Limits

Maximum Load	E810-CAM2/CAM1	E810-XXVAM2
Short-term compressive load (applied for up to two minutes)	30 gm per solder ball. 65 psi on the raised portion of the lid.	30 gm per solder ball. 40 psi on the die and substrate.
Long-term compressive load	15 gm per solder ball. 30 psi on the raised portion of the lid.	15 gm per solder ball.
Dynamic load	30g shock per MIL-STD-810F, Method 516.5 Procedure II.	30g shock per MIL-STD-810F, Method 516.5 Procedure II

16.6.3 Thermal

For complete E810 package thermals, refer to the Flotherm models and Chapter 18, "Thermal Design Considerations".

Table 16-31. Typical Thermal Resistance Parameters

Parameter	E810-CAM2/CAM1	E810-XXVAM2
Thermal resistance, junction to case, Rjc	0.69 C/W	0.15 C/W
Thermal resistance, junction to PCB, Rjb	4.3 C/W	7.4 C/W

16.6.4 Electrical

Package electrical models are part of the IBIS files.

16.8 Devices Supported

16.8.1 Flash

The E810 requires Flash devices with the following characteristics:

- Quad SPI interface
- 24-bits address size
- Nominal 3.3 V power supply and I/O voltage levels
- Max frequency equal or above 66MHz
- Supports Serial Flash Discoverable Parameters (SFDP)
- Minimum density: 16 MB
- *Quad Enable* bit set in the status register by default, or set during the initial programming along with the Flash descriptor.

Table 16-32. Supported Flash Parts

GigaDevice Semiconductor	GD25B127DS

Chapter 17 Design Guidelines

17.1 Introduction

The section shows the Ethernet side interface design requirements for systems using the Intel® Ethernet Controller E810 (E810). The E810 is an integrated device that includes a 100G MAC, a x16 PCIe Gen4 block for upstream connectivity to the host processor, and eight Physical Medium Dependent (PMD) lanes capable of up to 50 Gb/s each. All speeds are dependent on the device SKU, PMD lane, and port configurations.

The E810 topologies support a variety of system configurations for native Ethernet interfaces. This section defines the supported configurations and the information required to design an E810-based system, including pin implementation and electrical specifications.

The E810 architecture allows for 2-port, 4-port, and 8-port mode configurations. These modes connect the root complex to eight PMD lanes accessible downstream. Supported E810 topology configurations are discussed in the sections that follow.

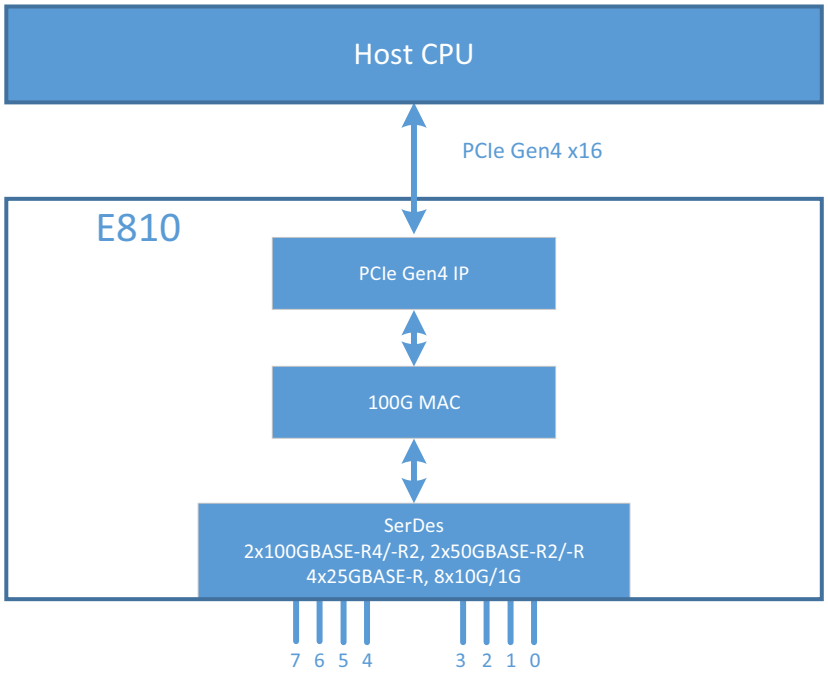

Figure 17-1. E810 Functional Block Diagram

This section shows all of the supported and validated designs for the E810 topology.

17.2 Defined Topologies

The specific product SKU used in the system determines the various configuration options, max device bandwidth, and the number of PMD lanes available. This section shows the permissible E810-CAM2 Dual 100G product configurations using eight PMD lanes with a 100G total bandwidth allocated through the device at any given time. Refer to the E810 SKU offerings for more information.

In the context of this section, groups of four PMDs make up a single "site", and each site is configured based on the chosen E810 Ethernet topology. These are referred to by the configuration names shown in Section 17.2.1.

This section defines "common" topologies. The common configurations represent those that can be implemented natively using the I/O directly from the E810 (for example, 2xSFP28 (50GBASE-R), 4xSFP28 (25GBASE-R), 1xQSFP28 (100GBASE-R4), and 2xQSFP28 (100GBASE-R4)). Within these topologies, the port rates can be individually configured to any lower supported rate.

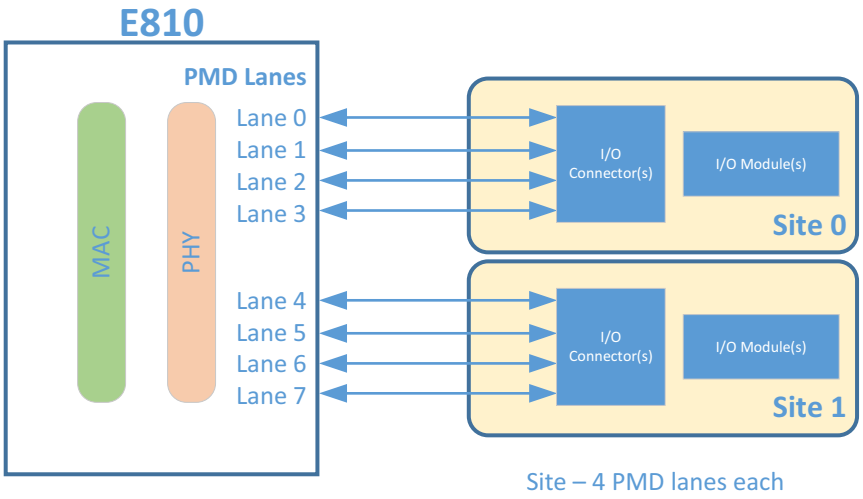

Figure 17-2. E810 Topology Components

Following is a summary of the Ethernet interfaces that the E810 provides:

- PMD lanes:
  - Each lane includes differential pairs for Tx and Rx, for a total of four pins per lane.
  - Eight PMD lanes (up to two sites).
    - Up to eight PMD lanes are available for use depending on the product SKU.
    - The maximum throughput of 100G (Topology restrictions apply. Refer to details in Section 17.2.1.)
    - The PMD lanes are denoted as [0..3] for Site 0, and [4..7] for Site 1. For a 2-port configuration with quad lane PMD modes, the Auto-Negotiation (AN) lanes exist on Lane 0, and Lane 4 by default. For single-lane configurations (e.g. 4-port and 8-port modes), the AN lanes are on a per-lane basis.

- Five MDIO/I^{2}C buses (MDIO/I^{2}C[0:4]) from the E810 that can be independently configured as MDIO or I^{2}C. For this section, the buses are assigned as shown below. The buses are shown in Section 17.2.2 for each I/O configuration.
  - MDC0_SCL0 / MDIO0_SDA0 - I^{2}C management clock and data for QSFP 0 or SFP 0.
  - MDC1_SCL1 / MDIO1_SDA1 - I^{2}C management clock and data for QSFP 1 or SFP 1.
  - MDC2_SCL2 / MDIO2_SDA2 - I^{2}C management clock and data for SFP 2.
  - MDC3_SCL3 / MDIO3_SDA3 - I^{2}C management clock and data for SFP 3.
  - MDC4_SCL4 / MDIO4_SDA4 - I^{2}C management PCA9575 I/O Expander.
- 24 Software Defined Pins (SDP):
  - 24 general purpose software definable pins are driven via the internal I/O Widget in the E810.
  - Application of these pins are defined by the link topology netlist but in general is defined as follows within this section:
    - SDP[0:7] are used as eight GPIOs.
    - SDP[8:19] are generally used as LED pins with a few crossing over for GPIO functions.
    - SDP[20:23] can be used for IEEE 1588 connections.

A summary of the I/O types that the E810 supports is presented below (see Section 17.2.3 for more information on the specific protocols supported on each I/O type):

- I/O Types:
  - SFP (Includes SFP+ and SFP28)
  - QSFP (Includes QSFP+ and QSFP28)

17.2.1 E810 Host Topology Overview

This section shows the most common host topologies that are expected to be used. Table 17-1 provides a high-level summary of the supported common configurations, and Section 17.2.2 provides the overview of each configuration.

The E810 can support up to two quads, with four PMD lanes per quad. Each quad supports multiple speed and multi-lane port configurations using 25G/lane SerDes (1x100G-R4 / 1x50G-R2 / 4x25G / 4x10G / 4x1G), or 50G/lane SerDes (1x100G-R2 / 1x50G-R). The supported common topologies are 2xSFP28 (2x50GBASE-R), 4xSFP28 (4x25GBASE-R), 1xQSFP28, and 2xQSFP28.

Implementations can use a subset of I/Os (for example, 2xSFP28 or 1xQSFP28) as a design option and is described in Section 17.3.1. A 4xSFP28 implementation also supports 2xSFP with 2x50GBASE-R lanes. PMD lanes 0 and 2 must be used for connections supporting 50GBASE-R. A 2xQSFP28 design is a superset of a 1xQSFP28 implementation with breakout capability. A design implementing 2xQSFP28 can still use the breakout capability as long as Site 1 is disabled.

Table 17-1. Supported E810 Common Configurations

			Configuration	
	PMD Lane	Speed	4x SFP	2x QSFP
Site 0	**0**	25G	4x SFP (25G) or 2x SFP (50G) on Lane 0 and 2	1x QSFP and Breakout mode (Site 1 disabled for breakout mode)
	1	25G		
	2	25G		
	3	25G		
Site 1	**4**	25G		1x QSFP
	5	25G		
	6	25G		
	7	25G		
			4-port	2-port, 4-port, 8-port

Key:	SFP LOM Design	QSFP LOM Design	Not supported in the configuration

Note: The bold lane numbers show the auto-negotiation lane for quad lane modes. The E810 supports auto-negotiation on lanes 0 and 4. System designers need to ensure these lanes are mapped to "lane 0" of the QSFP module or link partner to ensure proper connections of the AN channels. For single-lane modes, auto-negotiation occurs on all active lanes.

For each validated E810 configuration above, each PMD lane can be configured with the following speed and port width configurations when using appropriate cable combinations, as depicted in Table 17-2. The E810 supports up to 2x50G PAM4 serial lanes as well as QSFP breakout modes. For details, refer to Section 17.2.2 for configuration options.

Ports shown here with different port counts are supported by the same physical implementation from a hardware perspective, but might require a reboot and/or different NVM or netlist configuration.

Table 17-2. Supported E810 PMD Lanes and Rates for Supported Configuration Topologies

	Site #/PMD#/Supported PMD Rates									
Site	**Site 0**				**Site 1**				**Port Mode**	**Notes/Limitations**

	10G	10G[1]	10G[1]	10G[1]					4	
	1G	1G[1]	1G[1]	1G[1]					4	
	100M	100M[1]	100M[1]	100M[1]					4	

Key:	100G (BASE-R4/-R2)	50G (BASE-R2/-R)	25G	10G	1G/100Mb

Notes:

- All sites can be independently configured for speed and port width based on the supported mode list above via software control.
- Lane numbers denoted with an asterisk (*) show the auto-negotiation lane for quad lane modes. The E810 supports auto-negotiation on lanes 0 and 4. System designers need to ensure these lanes are mapped to "lane 0" of the QSFP module or link partner to ensure proper connections of the AN channels. For single-lane modes, auto-negotiation occurs on all active lanes.

The associated PMD lanes for each mode are called out above. Note that lanes from Quad 1 can be multiplexed over to Quad 0 when the E810 is operating in a 4-port configuration to allow a single QSFP breakout mode. Take note of the following lane speed and port capabilities:

- All 1x50G serial ports are capable of supporting 50G, 25G, 10G, 1G and 100Mb.
- All 1x25G serial ports are capable of supporting 25G, 10G, 1G and 100Mb.
- All 1x10G serial ports are capable of supporting 10G, 1G, and 100Mb.
- QSFP cable configuration support:
  - For 50G/lane configurations, 1x100GBASE-R2 and 2x50GBASE-R breakout are supported.
  - For 25G/lane configurations, 1x100GBASE-R4, 2x50GBASE-R2 and 4x25GBASE-R breakout are supported.

17.2.2 Configuration Topologies

This section presents the supported common configurations for the E810.

17.2.2.1 Configuration - 4x SFP Native

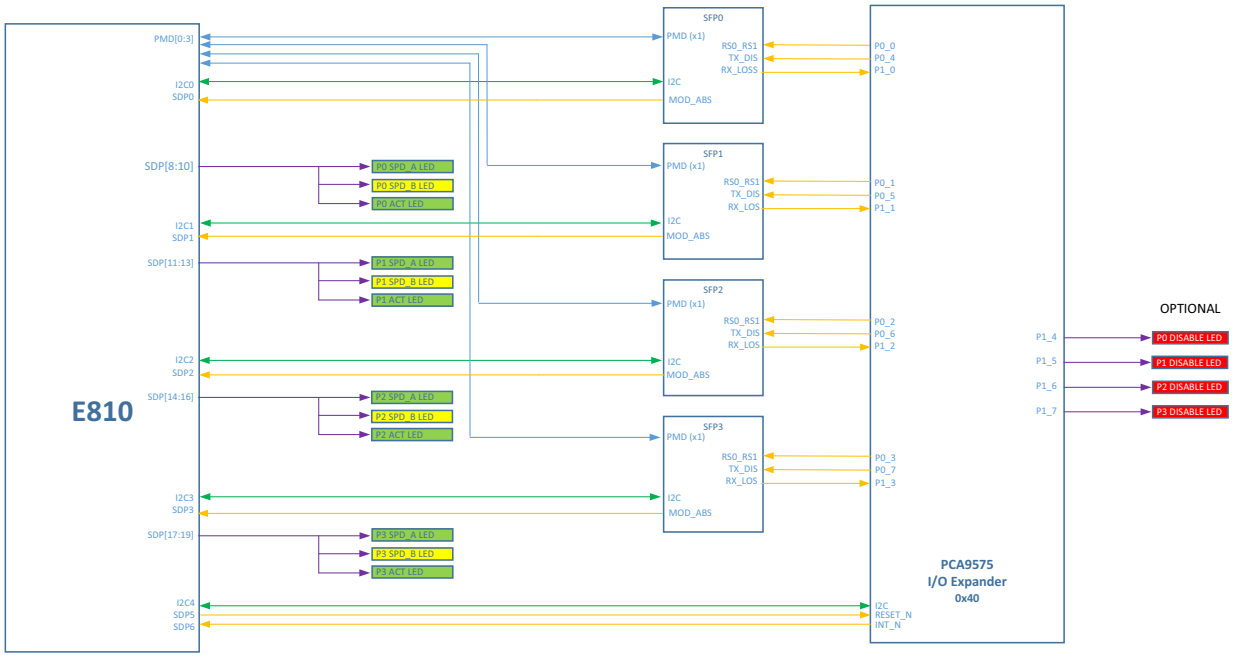

Figure 17-3. Configuration - 4x SFP Native

This configuration uses PMD lanes 0 through 3 to drive four SFP connectors on the host system. A direct I^2C connection as well as Module Absent, LOS, Rate Select, and TX Disable connections are required to each of the SFP connectors. A subset of these signals is supported on the PCA9575 I/O Expander. The link status of each port is indicated by up to three LEDs, for a total of 12 LEDs on the host system (see Section 17.5 for LED usage).

The host supports native SFI, so the E810 PMD lanes can be connected directly to the SFP connector, as shown in Figure 17-3. This figure is provided as a high-level example only, and all connection and design requirements stated within this section must be followed. All other connection requirements, such as pull-up/pull-down resistors, power/ground, LEDs, and so on are detailed in Section 17.3 through Section 17.6.

A 2x50G serial solution can also be implemented. In this case, PMD lane 0 and PMD lane 2 have the 50G serial support (SFP0 and SFP2) and must be used. Lane assignment and low-speed I/O connections for 4x25G and 2x50G modes are shown in Table 17-3.

Table 17-3. PMD Lane Assignment and Low-Speed I/O for 4x25G and 2x50G Modes

Config	Port No.	Ethernet PMD	I²C	E810 SDP/GPIO Name or Port Expander Pin Name	E810 SDP/GPIO Function or I/O Expander Function	E810 SDP/LED Name	E810 SDP/LED Function
4x25G	Port 0	L0	I2C_MDIO_CLK0/DAT0	SDP00	SFP_0_MOD_ABS	SDP08	P0_SPD_A_LED
				Port Expander I/O P1_0	SFP_0_RX_LOS	SDP09	P0_SPD_B_LED
				Port Expander I/O P0_0	SFP_0_RS0_RS1	SDP10	P0_ACT_LED
				Port Expander I/O P0_4	SFP_0_TX_DISABLE	-	-
	Port 1	L1	I2C_MDIO_CLK1/DAT1	SDP01	SFP_1_MOD_ABS	SDP11	P1_SPD_A_LED
				Port Expander I/O P1_1	SFP_1_RX_LOS	SDP12	P1_SPD_B_LED
				Port Expander I/O P0_1	SFP_1_RS0_RS1	SDP13	P1_ACT_LED
				Port Expander I/O P0_5	SFP_1_TX_DISABLE	-	-
	Port2	L2	I2C_MDIO_CLK2/DAT2	SDP02	SFP_2_MOD_ABS	SDP14	P2_SPD_A_LED
				Port Expander I/O P1_2	SFP_2_RX_LOS	SDP15	P2_SPD_B_LED
				Port Expander I/O P0_2	SFP_2_RS0_RS1	SDP16	P2_ACT_LED
				Port Expander I/O P0_6	SFP_2_TX_DISABLE	-	-
	Port3	L3	I2C_MDIO_CLK3/DAT3	SDP03	SFP_3_MOD_ABS	SDP17	P3_SPD_A_LED
				Port Expander I/O P1_3	SFP_3_RX_LOS	SDP18	P3_SPD_B_LED
				Port Expander I/O P0_3	SFP_3_RS0_RS1	SDP19	P3_ACT_LED
				Port Expander I/O P0_7	SFP_3_TX_DISABLE	-	-
2x50G	Port 0	L0	I2C_MDIO_CLK0/DAT0	SDP00	SFP_0_MOD_ABS	SDP08	P0_SPD_A_LED
				SDP02	SFP_0_RX_LOS	SDP09	P0_SPD_B_LED
				SDP05, SDP18	SFP_0_RS0_RS1	SDP10	P0_ACT_LED
				SDP14	SFP_0_TX_DISABLE	-	-
	Port 1	L2	I2C_MDIO_CLK2/DAT2	SDP01	SFP_1_MOD_ABS	SDP11	P1_SPD_A_LED
				SDP03	SFP_1_RX_LOS	SDP12	P1_SPD_B_LED
				SDP06, SDP19	SFP_1_RS0_RS1	SDP13	P1_ACT_LED
				SDP15	SFP_1_TX_DISABLE	-	-

17.2.2.2 Configuration - 2x QSFP Native

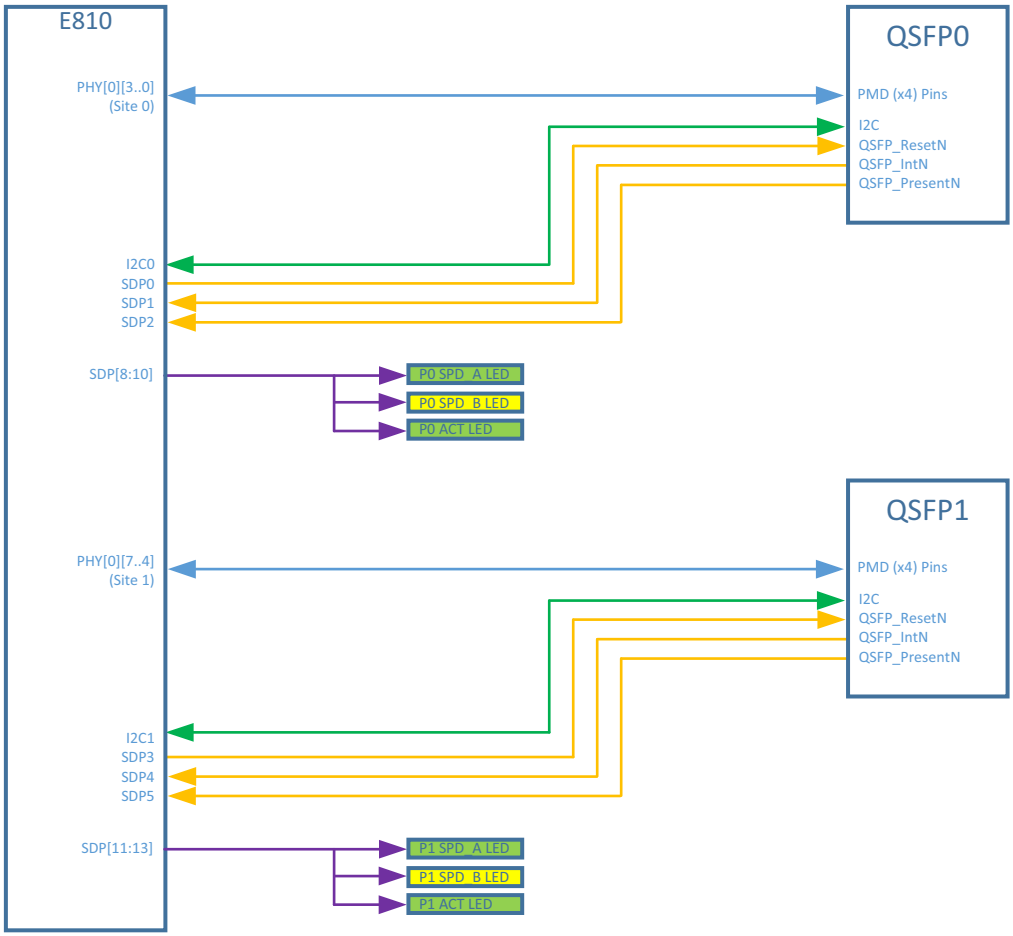

Figure 17-4. Configuration - 2x QSFP Native

This configuration uses PMD lanes 0 through 7 to drive two QSFP connections on the host system. The link status of each QSFP connection is indicated by three LEDs per port by default, for a total of six LEDs on the host system (see Section 17.5 for LED usage).

The E810 can drive a variety of QSFP protocols, so they can be connected directly to the QSFP connectors, as shown in Figure 17-4. This figure is provided as a high-level example only, and all requirements stated within this document must be followed. All connection requirements, such as pull-up/pull-down resistors, power/ground, LEDs, and so on, are detailed in Section 17.3 through Section 17.6.

This configuration supports a variety of link types, and the number of ports is dependent on the link type, since both serial and parallel link modes are available. Each PMD can operate as a single port in a serial link mode, supporting speeds of 10G and 25G, creating four ports from a single site. If the site is in a four-lane parallel link mode, all four PMDs are used to create a single port capable of 100G QSFP protocols. The device also supports the use of one 50G port per quad, with two PMDs supporting this speed. Section 17.2.3 details the variety of link modes available for QSFP connections. This configuration uses all PMD lanes available for E810 systems.

17.2.3 Supported Link Modes and Breakout Modes

The topology configurations presented in the previous section require a wide variety of native link modes from the E810. Table 17-4 provides a high-level summary of the topologies and speeds supported, including the interface to be used in each mode. Table 17-5 provides the supported QSFP breakout modes.

Table 17-4. Supported Ethernet Link Modes

Topology	Speed	Native I/F
SFP+	100M	SGMII
	1G	SGMII
	10G	SFI
SFP28	25G	25G AUI C2M
	25G	25GBASE-CR/CR1
	50G	50GBASE-CR
QSFP28	10G	SFI
	25G	25G AUI C2M
	25G	25GBASE-CR/CR1
	50G	50GBASE-CR/CR2
	50G	50G LAUI-2
	100G	CAUI-4
	100G	100GBASE-CR2/CR4

For QSFP implementations, the following breakout cases are supported:

Table 17-5. Supported QSFP Breakout Modes

Breakout	Lane Speed	Native I/F
4 x 10G	10 Gb/s	SFI
4 x 25G	25 Gb/s	25GBASE-CR/CR1
2 x 50G	25 Gb/s	50GBASE-CR2
2 x 50G	50 Gb/s	50GBASE-CR
2 x 100G	50 Gb/s	100GBASE-CR2

17.2.4 Supported Modules

Refer to Section 3.2.3, “Link Management” for details on specification compliant modules.

17.3 E810 Ethernet Signal Descriptions

The tables in this section show the Ethernet signal assignments on the E810. Annotations are provided where required. This section color codes the I/O pin groups associated with a function and are provided for a quick visual reference only. The color coding is as follows:

Color Code	Definition
SFP	High-Speed Serial (SFP+ and SFP28) related pins.
QSFP	QSFP+ and QSFP28 related pins

17.3.1 E810 High-Speed Serial

This section dictates the PMD connections between the host and the I/O.

Table 17-6. Host High-Speed Interface

	PMD[Lane]	4x SFP	2x QSFP
Site 0	PMD[**0**]	SFP0	QSFP0
	PMD[1]	SFP1	
	PMD[2]	SFP2	
	PMD[3]	SFP3	
Site 1	PMD[**4**]		QSFP1
	PMD[5]		
	PMD[6]		
	PMD[7]		

Note: The bold lane numbers show the auto-negotiation lane for quad lane modes. The E810 supports auto-negotiation on lanes 0 and 4. System designers need to ensure these lanes are mapped to "lane 0" of the QSFP module or link partner to ensure proper connections of the AN channels. For single-lane modes, auto-negotiation occurs on all active lanes.

- For all the supported implementations, the PMD connections always start with "lane 0" regardless of the number of sites implemented in the design.
- A designer might choose to implement a subset of supported sites in a given configuration. In that event, sites are removed, in order, starting with the highest numbered site.
- A designer might also choose to implement a subset of supported lanes for a given configuration.
  - For example, a 4xSFP design requiring only two SFP modules can only implement connectivity on PMD0, and PMD1.
  - The exception is when a designer is implementing two 50GBASE-R interfaces on Site 0 (See the 4xSFP column). In this case, the implemented PMD lanes are 0 and 2 per the E810 architectural definition.
- Sites can directly target an on-board I/O connector (SFP/QSFP).
- Lane numbering for each site is denoted as [0..3] for Site 0, and [4..7] for Site 1.
  - Lane and polarity swapping is dependent on the physical E810 implementation and details are not covered in this section.
  - This section assumes that both lane and polarity swapping are not implemented.

— The lane and polarity swaps are supported in the Link Topology netlist (see Section 3.3.6). Refer to Section 3.2.3, "Link Management" for details.

17.3.2 E810 Management Connections

The following table shows the I^2C and MDIO connection targets across all of the supported topologies.

Table 17-7. Host Management Connections

Pin Name	Ball #	4x SFP	2x QSFP
MDC0_SCL0 MDIO0_SDA0	AB38 AC45	SFP0	QSFP0
MDC1_SCL1 MDIO1_SDA1	Y38 AB42	SFP1	QSFP1
MDC2_SCL2 MDIO2_SDA2	AA39 AB48	SFP2	
MDC3_SCL3 MDIO3_SDA3	AB40 AA45	SFP3	
MDC4_SCL4 MDIO4_SDA4	Y40 Y48		

Note: Table 17-7 shows the superset of pins defined for the host management connections for the E810.

The I^2C SCL/SDA pins are open drain and need to be pulled up to VCC3P3 on the host system using 3.3 KΩ resistors.

A total of five configurable MDIO/I^2C buses are provided by the E810. The following MDIO and I^2C mapping are used:

- MDIO0_I2C0 bus is defined as a dedicated I^2C bus for QSFP 0 or SFP 0.
- MDIO1_I2C1 bus is defined as a dedicated I^2C bus for QSFP 1 or SFP 1.
- MDIO2_I2C2 bus is defined as a dedicated I^2C bus for SFP 2.
- MDIO3_I2C3 bus is defined as a dedicated I^2C bus for SFP 3.
- MDIO4_I2C4 bus is not used and is left as a no connect.

Example - E810 2x QSFP design:

QSFP0 is implemented on PMD lanes 0..3 (Site 0), and QSFP1 is implemented on PMD lanes 4..7 (Site 1). MDIO0_I2C0 is routed to QSFP0, and MDIO1_I2C1 is routed to QSFP1. Both interfaces operate in I^2C mode for module management.

17.3.3 E810 SDP[0:7] (GPIO) Connections

The E810 SDP [0:7] assignments share a common pin-out between all of the supported topologies and are dedicated for GPIO only. All E810 SDP [0:7] pins are defined as push-pull when used as an output.

Table 17-8. Host SDP [0:7] Connections

Pin Name	Ball #	4x SFP	2x QSFP
SDP0	V4	SFP_ModPresN_0	QSFP_ResetN_0
SDP1	T10	SFP_ModPresN_1	QSFP_IntN_0
SDP2	U3	SFP_ModPresN_2	QSFP_PresentN_0
SDP3	U7	SFP_ModPresN_3	QSFP_ResetN_1
SDP4	U11		QSFP_IntN_1
SDP5	W3	PCA9575_Reset_N	QSFP_PresentN_1
SDP6	Y4	PCA9575_Int_N	
SDP7	V10		

The pins noted in Table 17-8 have specific pull-up and pull-down requirements. These requirements are noted in Table 17-9.

Table 17-9. Host SDP[0:7] Pull-Up/Pull-Down Requirements

Signal Name	Host Requirements	Notes
SFP_ModPresN_*	10 KΩ pull up to VCC3P3	SFP ModPresN is tied to GND in the module to indicate presence.
PCA9575_Reset_N	10 KΩ pull-down to GND	Use pull-down on PCA9575 I/O Reset_N to keep I/O Expander in reset until ready to be configured.
PCA9575_Int_N	1 KΩ pull-up to VCC3P3	PCA9575 I/O Expander open drain interrupt pin requires pull-up to VCC3P3.
QSFP_ResetN_*	None	No external pull up resistor required. QSFP reset pin is internally pulled up to VCC3P3 in the module.
QSFP_IntN_*	10 KΩ pull up to VCC3P3	Interrupt pins are open drain and require a pull up.
QSFP_PresentN_*	10 KΩ pull up to VCC3P3	QSFP Present is tied to GND in the module to indicate module presence.

- SFP Module Present signals are located on SDP [0..3] for a 4x SFP implementation.
- I/O Expander Reset_N signal is located on SDP5 for a 4x SFP implementation.
- oI/O Expander Int_N signal is located on SDP6 for a 4x SFP implementation.
- QSFP Reset, Interrupt, and Present pins are assigned in that particular order and are grouped to maximize consistency across QSFP locations.
  - — QSFP0 signals use SDP[0..2].
  - — QSFP1 signals use SDP[3..5].

17.3.4 E810 SDP[8:19] (LED) Connections

The E810 has 12 additional SDPs (SDP[8:19]) for mixed function usage (LED and GPIO) between supported configurations. LED assignments share a common pin-out between the supported configurations, but be aware that the LED pins are not exclusively used for the LED function. These pins are also capable of being defined as GPIO pins. Pin configurations are noted in Table 17-10.

When the pin is used as an LED function, the connection must be connected as open drain with a pull-up on the LED, and the firmware must also be configured as open drain for LED applications. Refer to Section 17.5 for connection details. When the pin is used as a GPIO, the GPIO connection must be configured as push-pull in the firmware.

Table 17-10. Host SDP [8:19] Connections

Pin Name	Ball #	4x SFP	2x QSFP
SDP8	U9	LED0_0_spd_a	LED0_0_spd_ a
SDP9	W7	LED0_1_spd_b	LED0_1_spd_b
SDP10	W9	LED0_2_act	LED0_2_act
SDP11	V8	LED1_0_spd_a	LED1_0_spd_a
SDP12	Y8	LED1_1_spd_b	LED1_1_spd_b
SDP13	W11	LED1_2_act	LED1_2_act
SDP14	AA3	LED2_0_spd_a	
SDP15	Y10	LED2_1_spd_b	
SDP16	AA7	LED2_2_act	
SDP17	AB4	LED3_0_spd_a	
SDP18	V38	LED3_1_spd_b	
SDP19	W39	LED3_2_act	

The pins noted in Table 17-10 have specific pull-up and pull-down requirements. These requirements are noted in Table 17-11.

Table 17-11. Host SDP[8:19] Pull-Up/Pull-Down Requirements

Signal Name	Host Requirements	Notes
LED*		LEDs are connected as active low and are connected to VCC3P3 on the host through a current limiting resistor.

The pin-out description in this section assumes that the default case where three LEDs per LOM port are being used. There is the option to only use two LEDs per port, in which case the LEDn_2_act pin is not used. See Section 17.5 for more information on LED configuration and behavior options.

- SDP [8:10] are associated with QSFP 0, SFP 0.
- SDP [11:13] are associated with QSFP 1, SFP 1.
- SDP [14:16] are associated with SFP2.
- SDP [17:19] are associated with SFP3.

17.3.5 E810 SDP[20:23] (IEEE 1588) Connections

The E810 has four additional SDPs (SDP[20:23]) for IEEE 1588 timing applications. These pins can be used for custom implementations and can be routed out to a header. These pins are not used in standard SFP and QSFP implementations.

17.4 Signal Descriptions

The following sections describe the functional blocks and logical connections. Refer to the block diagrams in Section 17.2.2 for overall connection topologies. Refer to the appropriate sections for details applicable to your design.

17.4.1 High-Speed Serial

This section describes the application of the high-speed serial signals for a SFP/QSFP application.

17.4.1.1 PDM Lanes - Transmit

The transmit PMD signal names are referenced from the host side. Thus, the lane direction is directed towards the connector. This includes the following lanes:

- TX[0:3]_p / TX[0:3]_n
- TX[4:7]_p / TX[4:7]_n

For SFP/QSFP implementations, no series capacitor is required on the board as it is located within the I/O module.

17.4.1.2 PDM Lanes - Receive

The receive PMD signal names are referenced from the host side. Thus, the lane direction is directed towards the E810. This includes the following lanes:

- RX[0:3]_p / RX[0:3]_n
- RX[4:7]_p / RX[4:7]_n

For SFP/QSFP implementations, no series capacitor is required on the board as it is located within the I/O module.

17.4.1.3 SFP High-Speed Serial

For a LOM SFP design, connect the differential signals as follows:

- TX_L0 is connected to SFP0 TD.
- RX_L0 is connected to SFP0 RD.
- TX_L1 is connected to SFP1 TD.
- RX_L1 is connected to SFP1 RD.

- TX_L2 is connected to SFP2 TD.
- RX_L2 is connected to SFP2 RD.
- TX_L3 is connected to SFP3 TD.
- RX_L3 is connected to SFP3 RD.

Take note of the proper polarity connections (positive-to-positive, and negative-to-negative), as shown in Figure 17-5.

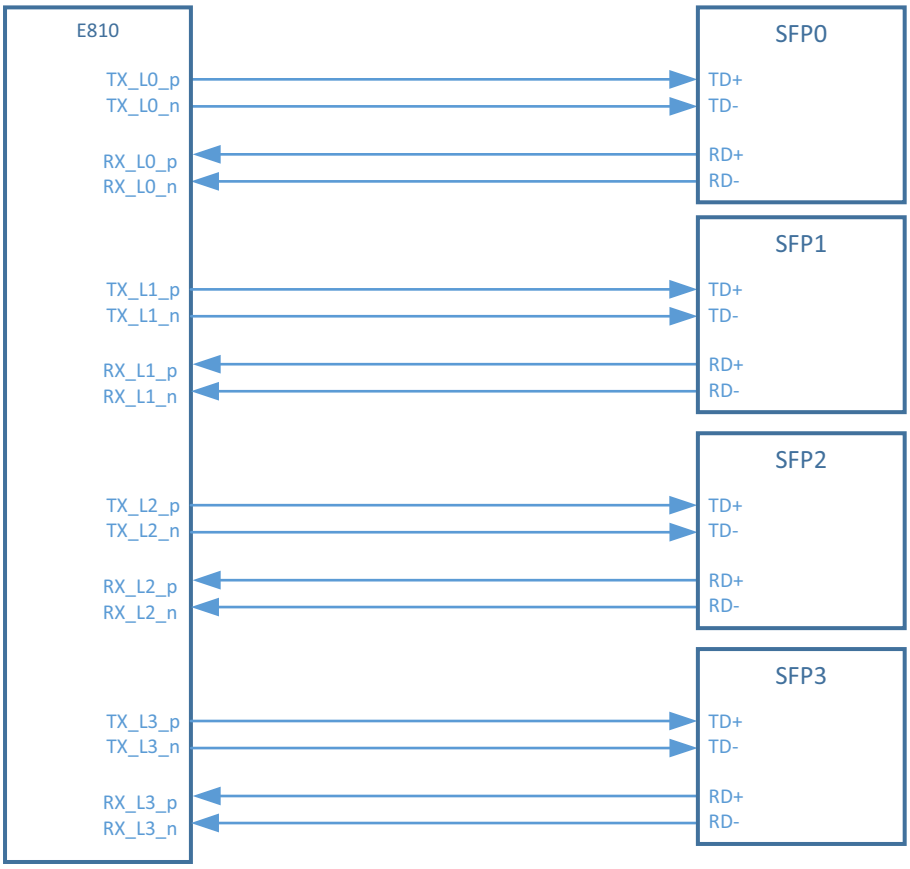

Figure 17-5. LOM SFP High Speed

17.4.1.4 QSFP High-Speed Serial

For a LOM QSFP design, connect the differential signals as follows:

- TX_L[0:3] connects to QSFP TX[1:4]
- RX_L[0:3] connects to QSFP RX[1:4]
- TX_L[4:7] connects to QSFP TX[1:4]
- RX_L[4:7] connects to QSFP RX[1:4]

Take note of the proper polarity and lane order connections, as shown in Figure 17-6.

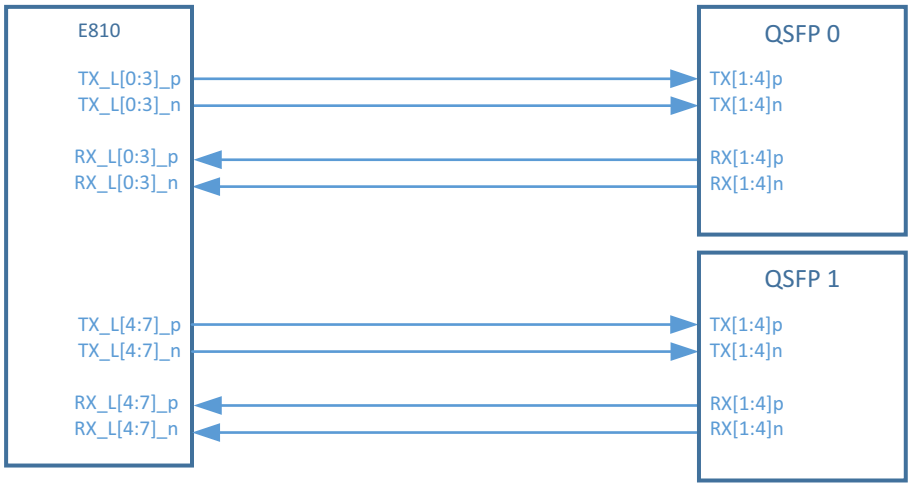

Figure 17-6. LOM QSFP High Speed

17.4.2 SFP and QSFP I/O Module Connections

This section presents the connection guidelines for configurations that implement a SFP or QSFP module(s).

17.4.2.1 SFP Cage Connections

The following connections are required for designs with SFP+/SFP28 cages. This information applies to all SFP designs. Refer to SFF-8431 for more details and specifics about the SFP form factor. Signal directions in this table are from the E810 perspective.

Table 17-12. SFP Interface

Pin Name	SFP Pin #	Type	Description
TD+/-	18, 19	A-out	Transmitter data output (towards module/link partner).
RD+/-	12, 13	A-in	Receiver data input (towards the E810).
I2C_SCL	5	Out, Pu, o/d	2-wire serial interface clock. Connect this pin directly to the E810 SCL pin appropriate for the SFP instance. Pull up to VCC3P3 on the host using a 10 KΩ resistor.
I2C_SDA	4	Inout, Pu, o/d	2-wire serial interface data. Connect this pin directly to the E810 SDA pin appropriate for the SFP instance. Pull up to VCC3P3 on the host using a 10 KΩ resistor.
Mod_ABS	6	In	Module Absent (active high). Grounded in module to indicate module presence. Connect directly between the E810 GPIO pins as defined in Section 17.3 and the SFP connector. This pin must be pulled up to VCC3P3 on the host. This pin must be connected for proper SFP operation in the E810 topology. This pin is akin to the Module Present (active low) signal in the QSFP pin-out.

Table 17-12. SFP Interface [continued]

Pin Name	SFP Pin #	Type	Description
TX Fault	2	Pu, o/d	TX Fault. When high, a laser fault of some kind is detected. Low indicates normal operation. The TX Fault pin is not used in the E810 topology and must be pulled up to VCC3P3 using a 10 KΩ resistor. If the module supports it, the TX Fault feature is available as an optional soft function to control over I^2C. Refer to SFF-8472 Address A0h, Byte 93 for details.
TX Disable	3	Out	TX disable. When high, module transmitter is disabled. When low, module transmitter is enabled. This pin is internally held high to VCC3P3 on the module. This pin must be connected for proper SFP operation in the E810 topology. If the module supports it, the TX Disable feature is also available as an optional soft function to control over I^2C. Refer to SFF-8472 Address A0h, Byte 93 for details.
Rate Select (0,1)	7, 9	Pu	Optional pin in the SFP specification. For dual rate modules, this pin defines module bandwidth control. Low indicates reduced bandwidth, while high indicates full bandwidth. This pin must be connected for proper SFP operation in the E810 topology. The pin is pulled down to ground inside the module. If the module supports it, the Rate Select feature is available as an optional soft function to control over I^2C. Refer to SFF-8472 Address A0h, Byte 93 for details.
LOS	8	Pu, o/d	Loss of signal. When high, indicates loss of signal. Normal operation when low. This pin must be connected for proper SFP operation in the E810 topology and must be pulled up to VCC3P3 using a 10 KΩ resistor. If the module supports it, the LOS the feature is available as an optional soft function to control over I^2C. Refer to SFF-8472 Address A0h, Byte 93 for details.

17.4.2.2 QSFP Cage Connections

The following connections are required for designs with QSFP+/QSFP28 cages. This information applies to all QSFP implementations. Refer to SFF-8665 for more details and specifics about the QSFP form factor. Signal directions in this table are from the E810 perspective.

Table 17-13. QSFP Interface

Pin Name	QSFP Pin #	Type	Description
TX[1..4]p/n	36, 37, 2, 3, 33, 34, 5, 6	A-out	Transmitter data output (towards module/link partner).
RX[1..4]p/n	17, 18, 21, 22, 14, 15, 24, 25	A-in	Receiver data output (towards the E810).
I2C_SCL	11	Out, o/d	2-wire serial interface clock. Pull up to VCC3P3 on the host using a 10 KΩ resistor. Connect this pin directly between the E810 and the QSFP connector.
I2C_SDA	12	Inout, o/d	2-wire serial interface data. Pull up to VCC3P3 on the host using a 10 KΩ resistor. Connect this pin directly between the E810 and the QSFP connector.
ModSelL	8	Out, Pu	Module select. Module responds to host commands when asserted low by the host. For all QSFP designs, ModSelL must be statically held low on the host. Pull down to GND on the host using a 1 KΩ resistor. QSFP modules are required to have a dedicated I^2C connection in the E810 topology. Asserting ModSelL low does not create I^2C addressing conflicts.
ResetL	9	Pu, o/d	Module reset. Module is in reset when held low by the host. ResetL is connected to the host GPIO and described in Section 17.3.3. This pin is internally held high to VCC3P3 on the module. No external pull-up resistor is required.

Table 17-13. QSFP Interface [continued]

Pin Name	QSFP Pin #	Type	Description
ModPrsL	27	Out	Module present. Grounded in module to indicate module presence. ModPrsL is connected to the host GPIO and described in Section 17.3.3. Pull up to VCC3P3 using a 10 KΩ resistor.
IntL	28	Pu	Module interrupt. IntL is connected to the host GPIO and described in Section 17.3.3. Pull up to VCC3P3 using a 10 KΩ resistor.
LPMode	31	Pu, o/d	Low power mode. Module in low power mode when pin is high. Module in high power mode when pin is low. Pin is internally pulled up to VCC3P3 in the module and defaults to low power mode. This pin is not connected on the host, and modules default to low power mode. To enable high power mode, the host must access the module EEPROM interface via I^2C writes. No external pull-up resistor is required.

17.4.3 Reset, Interrupt, and Present

A reset, interrupt, and present pin are presented towards the SFP/QSFP modules to enable device reset, interrupt detection, and presence detection. This section details the connections of the three pins.

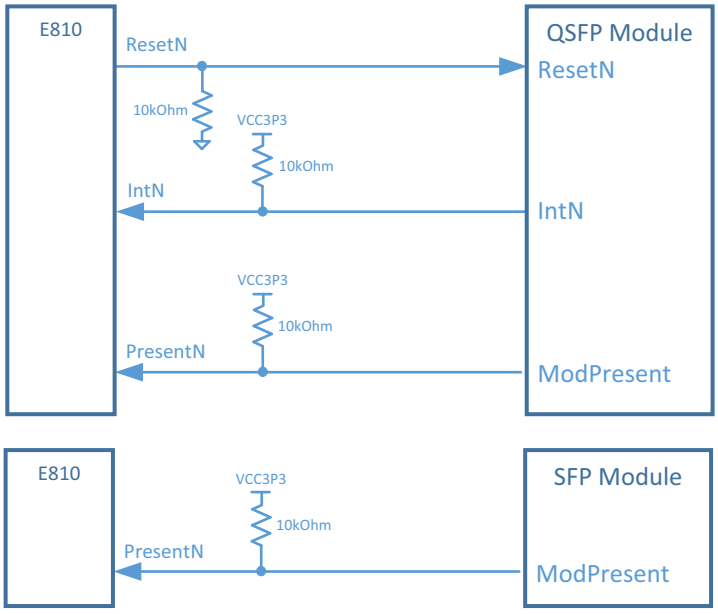

Figure 17-7. Reset, Interrupt, and Present Connection Details for SFP/QSFP Modules

17.4.3.1 ResetN

ResetN is an output pin that is driven by the host. ResetN drives the reset logic on a QSFP. The host must implement a 10 KΩ pull-down resistor on the ResetN line to ensure the device is in reset until the host is ready to initialize the downstream module or PHY.

Note: This signal is not applicable for use on SFP applications.

17.4.3.2 InterruptN

InterruptN is an input pin to the E810 that is driven low by a QSFP. This pin is asserted low when an interrupt event is detected. This pin is open drain and must be pulled up to VCC3P3 with a 10 KΩ resistor on the host.

Note: This signal is not applicable for use on SFP applications.

17.4.3.3 PresentN

PresentN is an input pin to the E810. The host must pull the pin to VCC3P3 using a 10 KΩ pull-up resistor. This pin serves as a SFP/QSFP module presence indication. When PresentN is high, no module is installed. When PresentN is low, a module is installed.

17.4.4 Management Interfaces

An I^2C bus is provided for low speed module identification and configuration for each site. The I^2C bus is a 1:1 mapping between the E810 and each module. Modules do not share an I^2C bus in this topology. The following sections describe the functionality of each of these devices and how they are connected in the E810 architecture.

Each site uses the same basic I^2C device architecture and is presented in Figure 17-8.

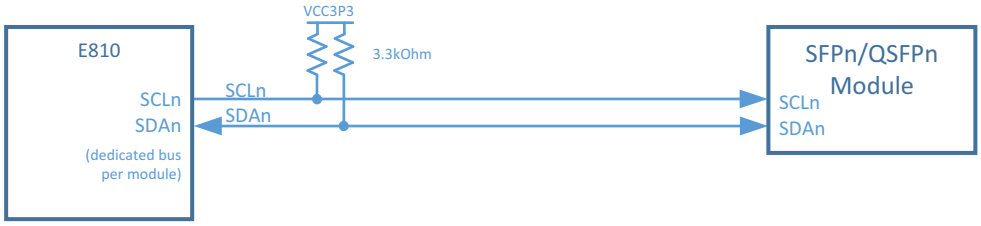

Figure 17-8. Management Interface Connection Details

The E810 Ethernet Hardware Topology defines an I^2C bus for managing SFP and QSFP modules. Per the I^2C bus specification, the SCL and SDA pins are open drain and require a pull up on the host to operate correctly. Pull up the SCL and SDA signals to VCC3P3 through a 3.3 KΩ resistor. The E810 I^2C bus architecture can operate at frequencies of 100 KHz, 400 KHz and 1 MHz at VCC3P3 voltage levels. Refer to the I^2C bus specification for the timing requirements. All SFP and QSFP modules respond to the write/read address pair of 0xA0/0xA1 (8-bit).

17.5 LED Configuration and Behavior

This section defines the default LED configuration and behavior for the various E810 architectures. There are two main design factors to take into consideration regarding LED behavior.

- Link type.
- The number of LEDs per port.

A summary of the available Link Type options is shown in Table 17-14.

Table 17-14. Link Type Options

Link Type	Lanes per Port	Supported Modes
Single PMD	1	1G/10G/25G serial link mode.
Dual PMD	2	50G parallel link mode.
Quad PMD	4	100G parallel link mode.

In general, the default LED configuration has three discrete LEDs per port. There are two speed LEDs and a single link/activity LED. This configuration is discussed in Section 17.5.1.

This section defines the LED colors and implementations that have been designed in and validated on Intel platforms. Refer to the Section 3.2.3, "Link Management" and contact your local Intel PAE representative for support and details on permissible LED configurations.

Up to 24 discrete LEDs can be implemented for any given E810 topology. The total is the sum of LEDs implemented via the E810 LED pins plus any LEDs implemented via LED drivers within a system. This constraint is based on a blink rate of 200 ms on, 200 ms off.

17.5.1 Default LED Behavior - Discrete LED Implementation

The default LED behavior is defined by using three LEDs per port. Native implementations support a three LED configuration (two speed LEDs, and one link/activity LED). A description of each pin is shown in Table 17-15. This implementation works well for the 4xSFPs and is implemented as shown in Table 17-16.

Table 17-15. Default LED Configurations - Discrete LED Implementation

<table>
<tr><th>LED Pin</th><th>LED Color</th><th>Description</th></tr>
<tr><td>Port[0:3]_Spd_A</td><td>Green</td><td>This active low bi-color LED is used as a link and link speed indicator. The expressed color indicates the port link speed. The default color coding is as follows:
<table>
<tr><th>Speed</th><th>Color</th></tr>
<tr><td>Max speed</td><td>Green</td></tr>
<tr><td>Not Max speed</td><td>Yellow</td></tr>
</table></td></tr>
</table>

Table 17-15. Default LED Configurations - Discrete LED Implementation [continued]

LED Pin	LED Color	Description
Port[0:3]_Spd_B	Yellow	The Spd_B indicator is also used for port identification through diagnostic software. When the link is up, this LEDs shall be lit and solid. This indicates that the link is established, there are no local or remote faults, and the link is ready for data packet transmission/ reception. For all single port cage implementations (SFP, QSFP), the LED indication shall operate as follows: • The LED is Green when the port is linked at its maximum speed. • The LED is Yellow when the port is linked but not operating at the highest speed. • The LED is off when no link is present. When a multi-lane cage is configured for dual port or quad port operation (e.g., QSFP breakout), the LED indication shall operate as follows: • The LED is Green when all ports of the multi-lane cage are linked at its maximum speed. • The LED is Yellow when one or more ports of the multi-lane cage are linked, but not operating at the highest speed, or one or more ports are down. • The LED is off when no link is present on all ports of the multi-lane cage.
Port[0:3]_Act	Green	Active low. The LED is illuminated when the signal is low. For all single port cage implementations (SFP, QSFP), the LED indication shall operate as follows: • The LED is off when there is no activity. • The LED should blink when there is activity. When a multi-lane cage is configured for dual port or quad port operation (e.g., QSFP breakout), the LED indication shall operate as follows: • The LED is off when there is no activity on all ports of the multi-lane cage. • The LED should blink when there is activity on one or more ports of the multi-lane cage

Table 17-16. Default LED Configurations - Discrete LED Behavior Matrix

	Speed Indication - 2 LED Pins						
	Max Speed		Not Max Speed		Link Activity - 1 LED Pin		
Port Configuration	Spd_A (Green)	Spd_B (Yellow)	Spd_A (Green)	Spd_B (Yellow)	Link (Green)	No Link (Off)	Activity (Green)
2xSFP (2x50G max)	On (50G)	Off	Off	On (<50G)	Off	Off	Blink
4xSFP28 (4x25G max)	On (25G)	Off	Off	On (<25G)	Off	Off	Blink
1xQSFP28 (1x100G max)	On (100G)	Off	Off	On (<100G)	Off	Off	Blink
1xQSFP28 (1x50G max)	On (50G)	Off	Off	On (<50G)	Off	Off	Blink
4x10GBASE-T (4x10G max)	On (10G)	Off	Off	On (<10G)	Off	Off	Blink
1x1000BASE-T (1x1G max)	On (1G)	Off	Off	On (<1G)	Off	Off	Blink

17.6 Electrical Specifications

17.6.1 Pull-Up/Pull-Down Requirements

The host and site implementations must use pull-up and pull-down resistors on I/O pins to ensure inputs and open drain I/O are in their default states. Refer to the individual signal descriptions shown in Section 17.3, and Section 17.4 for details.

For I^2C and MDIO buses, system designers need to ensure that the pull-up and pull-down values are sufficient for their implementation and that the buses do not exceed the maximum pin bus capacitance values as stated in the respective specifications.

Chapter 18 Thermal Design Considerations

18.1 Introduction

This chapter can be used as an aid when designing a thermal solution for systems implementing the Intel® Ethernet Controller E810-CAM1, the Intel® Ethernet Controller E810-CAM2, and the Intel® Ethernet Controller E810-XXVAM2. This is collectively referred to as the E810 in this chapter unless specific SKU call outs are required.

Properly designed solutions provide adequate cooling to maintain the E810 product case temperature Tcase (or junction) at or below thermal specifications. The E810 should function properly if case temperatures are kept at or below those presented. Ideally this is accomplished by providing a low local ambient temperature airflow and creating a minimal thermal resistance to that local ambient temperature.

By maintaining the case (or junction) temperature at or below the specified limits, a system designer can ensure the proper functionality, performance, and reliability of the E810. Operation outside the functional limits can cause data corruption or permanent damage to the E810.

The simplest and most cost-effective method to improve the inherent system cooling characteristics is through careful chassis design and placement of fans, vents, and ducts. When additional cooling is required, component thermal solutions can be implemented in conjunction with system thermal solutions. The size of the fan or heat sink can be varied to balance size and space constraints with acoustic noise.

18.2 Measuring the Thermal Conditions

This section provides a method for determining the operating temperature of the E810 in a specific system based on the junction and case temperature. Case temperature is a function of the local ambient and internal temperatures of the E810. The junction temperature can be read with the Intel software tools. This document specifies a maximum allowable $T_{J\text{-}MAX}$ and $T_{C\text{-}MAX}$ values for the E810. Refer to Section 18.6 for conversion formula details.

18.3 Thermal Considerations

In a system environment, the temperature of a component is a function of both the system and component thermal characteristics. System-level thermal constraints consist of the local ambient temperature at the component, the airflow over the component and surrounding board, and the physical constraints at, above, and surrounding the component that might limit the size of a thermal enhancement (heat sink).

The component's case/die temperature depends on:

- Component power dissipation
- Size
- Packaging materials (effective thermal conductivity)
- Type of interconnection to the substrate and motherboard
- Presence of a thermal cooling solution
- Power density of the substrate, nearby components, and motherboard

All these parameters are pushed by the continued trend of technology to increase performance levels (higher operating speeds, MHz) and power density (more transistors). As operating frequencies increase and packaging size decreases, the power density increases, and the thermal cooling solution space and airflow become more constrained. The result is an increased emphasis on system design to ensure that thermal design requirements are met for each component in the system.

18.4 Importance of Thermal Management

The thermal management objective is to ensure that all system component temperatures are maintained within functional limits. The functional temperature limit is the range in which the electrical circuits are expected to meet specified performance requirements. Operation outside the functional limit can degrade system performance, cause logic errors, or cause device and/or system damage.

Temperatures exceeding the maximum operating limits might result in irreversible changes in the device operating characteristics.

Note: The E810 has temperature sensors internal to the package, and automatically forces all Ethernet links down when the upper fatal temperature threshold (115 °C) is reached.

Also note that sustained operation at component maximum temperature limit might affect long-term device reliability.

18.5 Packaging Terminology

Table 18-1. Packaging Terminology

Item	Description
BLT	Bond Line Thickness — Final settled thickness of the Thermal Interface Material (TIM) after installation of the heat sink.
CTE	Coefficient of Thermal Expansion — The relative rate a material expands during a thermal event.
FCBGA	Flip Chip Ball Grid Array package — A surface-mount package using a combination of flip chip and BGA structure whose PCB-interconnect method consists of Pb-free solder ball array on the interconnect side of the package. The die is flipped and connected to an organic build-up substrate with C4 bumps. The E810-CAM2/CAM1 package is covered with a lid to protect the on-package capacitors. The E810-XXVAM2 is an exposed die.
Junction	Refers to a P-N junction on the silicon. In this document, it is used as a temperature reference point (for example, Θ_{JB} refers to the "junction" to ambient thermal resistance).
Ambient	Refers to local ambient temperature of the bulk air approaching the component. It can be measured by placing a thermocouple approximately 1 inch upstream from the component edge.
LFM	Linear Feet per Minute — Airflow.
T_A	Local ambient temperature.
T_C	Case temperature — Temperature at geometric center of dies or over mold top surface.
T_J	Junction temperature – Maximum temperature of die active surface, i.e. hot spot.
TDP	Thermal Design Power — The estimated maximum possible/expected power generated in a component by a realistic application. Thermal solutions should be designed to dissipate this power level. TDP is not the peak power that the component can dissipate.
TIM	Thermal Interface Material — A conductive material used between the component and heat sink to improve thermal conduction.
Θ_{JB} (Theta JB)	Thermal resistance junction-to-board, °C/W.
Θ_{JC} (Theta JB)	Thermal resistance junction-to-case, °C/W.
Ψ_{JC} (Psi JC)	Junction-to-case (top of package) thermal characteristic parameter, defined by (T_J - T_C) / TDP. Ψ_{JC} does not represent thermal resistance, but instead is a characteristic parameter that can be used to convert between T_J and T_C when knowing the total TDP. This parameter can vary by environment conditions like heat sink and airflow.

18.6 Thermal Specifications

The following considerations should be made when designing a proper thermal solution for the E810:

- To ensure proper operation of the E810, the thermal solution must maintain a junction temperature at or below 105 °C for functionality, and meet the TDP power specs. The device is tested to 105 °C.
- The E810 is designed to work at up to 115 °C with no reliability issues. However, functionality is not tested and the TDP may exceed the published values. Normal operation is expected to resume when the silicon returns to a max junction temperature of 105 °C.
- The E810 might experience temperature excursions to 125 °C for no more than 4% of the operating lifetime of the product. Functionality is not tested at this temperature, but there is no reliability impact if the device stays within these boundaries. Normal operation is expected to resume when the silicon returns to a max junction temperature of 105 °C.

System-level or component-level thermal enhancements are required to dissipate the generated heat to ensure the junction temperature never exceeds the maximum temperature.

A good heat sink design and system airflow are critical to dissipate the E810's high power. To develop a reliable, cost-effective thermal solution, all the system variables must be considered. Use system-level thermal characteristics and simulations to account for individual component thermal requirements. Good Thermal Interface Material (TIM) between the heat sink and die must be applied correctly. The E810-CAM2/CAM1 and E810-XXVAM2 FloTherm thermal models can be downloaded from rdc.intel.com.

Keep the following in mind when reviewing the data that is included in this document:

- All data is preliminary and is not validated against physical samples.
- Your system design might be significantly different.
- A larger board with more layers might improve the E810 thermal performance.

The relationship between the parameters in Table 18-2 are as follows:

$$\Psi_{JC} = (T_J - T_C) / TDP$$

$$T_{C\text{-}MAX} = T_{J\text{-}MAX} - (\Theta_{JC} * TDP)$$

Table 18-2. E810 Thermal Specifications

Parameter	E810-CAM2	E810-CAM1	E810-XXVAM2	Notes
$T_{J\text{-}MAX}$	105 °C	105 °C	105 °C	
TDP	15.7 W	13.8 W	10.8 W	Max TDP; characterized at T_J = 105 °C. Refer to Section 16.4, "Power Dissipation" for a power down by each power rail and operational conditions.
Θ_{JC}	0.69 °C /W	0.69 °C /W	0.15 °C /W	Thermal resistance junction-to-case.
Θ_{JB}	4.3 °C /W	4.3 °C /W	7.4 °C /W	Thermal resistance junction-to-board.

18.7 Package Mechanical Attributes

The E810 comes in two package sizes:

- **E810-CAM2/CAM1** — 25x25 mm FCBGA with integrated heat spreader (lid).
- **E810-XXVAM2** — 21x21 mm FCBGA with exposed die.

Note: Make sure official drawings are used for your detailed design.

Refer to Section 16.6.2, "Heat Sink Mechanical Load Limits" for the maximum loads for heat sink to PCB attachment.

Chapter 19 Glossary and Acronyms

This section defines terms and acronyms commonly used throughout this specification. Another source for this type information is Section 1.6, which contains some of the acronyms defined in the industry standards (For example, MII, MPA, Verbs, NC-SI, and so on).

Table 19-1. Definition of Terms

Term	Definition
AN	**Auto-Negotiation** — An IEEE Ethernet method for exchanging PHY layer parameters, such as speed and duplex mode, between link partners.
BAR	**Base Address Register** — Standard registers defined in PCI Config space that define how an I/O adapter responds to host memory-mapped I/O requests.
BER	**Bit Error Rate** — The number of bits received in error, divided by the total number of bits received.
BMC	**Baseboard Management Controller** — A BMC is a specialized embedded processor, typically integrated on a server motherboard, that reports the state of the server to the system administrator independent of the state of the server OS.
CEQ	**Completion Event Queue** — The E810 writes Completion events to this shared queue to make it easy for software to determine which CQ has new CQEs.
Completed, Completes, and so on	**Completion** — When an RNIC has performed all functions specified for a given WQ operation, including Placement and Delivery, that WQ operation is said to be "completed". This can be determined by the Consumer through a Work Completion for Signaled Work Requests.
Connection Context	The information needed by the E810 Protocol Engine to track the state of a connection. This can include TCP- and iWARP-related information. The information includes things such as pointers to buffers, pointers to queues, pointers to CQs, sequence numbers, and so on.
Consumer	A software process that communicates with the E810. The Consumer typically consists of an application program or an OS adaptation layer that provides some OS-specific API.
CQ	**Completion Queue** — A sharable queue that can contain one or more Completion Queue Entries. A Completion Queue is used to create a single point of completion notification for multiple Work Queues. The Work Queues associated with a Completion Queue might be from different QPs and of differing queue types (SQs or RQs).
CQE	**Completion Queue Entry** — Info that the E810 writes onto a Completion Queue during the process of performing a Completion.
CRC	**Cyclic Redundancy Check** — An error detecting code commonly used to protect network transmissions.
CSR	**Control/Status Register** — I/O adapter registers typically accessed by the host using memory-mapped I/O requests.
DSI	**Dataplane Switch-mode Interface** — A software API for dataplane applications to allow direct attach of multiple users to device resources.
ECC	**Error-Correcting Code** — A code commonly used to protect network transmissions, which allows both detection and recovery from errors.
EMP	**Embedded Management Processor** — An E810 embedded processor that handles device initialization and also device configuration based on commands received from an Admin Queue, a management interface (like NC-SI), or from a network port.
FLR	**Function-Level Reset** — A capability defined in the *PCI Express Base Specification* that enables software to quiesce and reset a particular PCI Function in a MFD, without affecting the other PCI functions therein.
FPDU	**Framed Protocol Data Unit** — The unit of data created by an MPA sender.

Table 19-1. Definition of Terms [continued]

Term	Definition
FPM	**Function Private Memory** — The E810 uses host memory as backing store for a number of context objects, such as queue state and iWARP objects. These objects are cached in the E810 Host Memory Cache (HMC). Each E810 PF or VF driver allocates host pages for this backing store according to its needs. Host pages are mapped into a virtually contiguous Private Memory address space that the HMC uses for object access. A contiguous portion of Private Memory address space is allocated for each PCI Function, and is referred to as that PCI Function's Function Private Memory (FPM). All of the host pages allocated by a given PF or VF driver are mapped into its FPM.
Frame	A unit composed of headers, data, and footers that are sent or received by a device. Also known as a *Packet*.
FSI	**Financial Services Industry** — The Financial Services Industry includes a broad range of organizations that deal with the management of money, including banks, credit card companies, insurance companies, consumer finance companies, stock brokerages, investment funds, and so on. FSI organizations often require ultra-low-latency access to financial market data such as stock feeds. Market data is typically streamed to, and distributed within these organizations using a publish/subscribe messaging model built on UDP/IP multicast transport.
HPC	**High Performance Computing** — A common term for the compute market of high performance applications.
IPG	**Inter Packet Gap** — A set of idle signals sent over the network to separate packets
IRD	**Inbound RDMA Read Queue Depth** — The maximum number of incoming outstanding RDMA Read Request Messages an E810 QP can handle. The E810 allows IRD to vary on a per QP basis.
ITR	**Interrupt Throttling** — A method of interrupt moderation that guarantees a minimum gap between two consecutive interrupts.
KVM	**Keyboard, Video, Mouse** — Standard bundle of computer user I/O devices.
LACP	**Link Aggregation Control Protocol** — The IEEE protocol that enables the formation of Link Aggregation Groups (aggregation of one or more Ethernet links into a single logical link).
LLDP	**Link Layer Discovery Protocol** — The IEEE protocol that enables a server to advertise its identity, capabilities, and interconnections to other entities on an Ethernet fabric.
LLP	**Lower Layer Protocol** — The protocol layer beneath the protocol layer currently being referenced. For example: • For TCP, the LLP is IP. • For RDMA, the LLP is DDP. • and so on.
LOM	**LAN on Motherboard** — When the E810 is integrated on a server motherboard, it qualifies as a LOM NIC.
LS	**Least Significant** — Lowest order (for example: LS bit = Least significant bit)
MDIO	**Management Data Input/Output Interface** — A standard interface to connect a MAC to a PHY, used to access PHY registers.
MFD	**Multi-Function Device** — A PCI Device with more than one PCI function.
MFP	**Multi-Function per Port** — A PCI Device is classified as an *MFP Device* when it can support more than one PCI Physical Function bound to a single network port. See also *Single-Function per Port (SFP)*.
MR	**Memory Region** — An area of memory that the RDMA Consumer wants the E810 to be able to (locally or locally and remotely) access directly in a logically contiguous fashion. A Memory Region is identified by an STag, a Base TO, and a length. A Memory Region is associated with a Physical Buffer List through the STag.
MSS	**Maximum Segment Size** — The largest amount of data that a network device can handle in a single, unfragmented piece.
MW	**Memory Window** — A subset of a Memory Region, which can be remotely accessed in a logically contiguous fashion. A Memory Window is identified by an STag, a Base TO, and a length, but also references an underlying Memory Region and has Access Rights.
Nearest Bridge Address	A multicast MAC Address used for DCBX exchange.

Table 19-1. Definition of Terms [continued]

Term	Definition
NIC	**Network Interface Controller** — An I/O adapter that enables a computer to communicate over a network.
Non-TPMR Address	**Non-Two-Port MAC Relay Address** — A multicast MAC Address used for CDCP LLDP exchange.
ORD	**Outbound RDMA Read Queue Depth** — The maximum number of outstanding RDMA Read Request Messages that the E810 can initiate from a SQ at the Data Sink. The E810 allows ORD to vary on a per QP basis.
Packet	A unit composed of headers, data, and footers that are sent or received by a device. Also known as a *Frame*.
Page List	A list of physical addresses describing a set of memory pages, which specifies the page size, list of physical addresses, and offset to the start of the memory region within the first page. The starting physical addresses of each page are aligned on power-of-two addresses, and the size of the page is a power of two. Note that it is possible for the starting offset to be an offset into the first page and to be of a byte granularity, and the entire list might have an arbitrary length.
PBL	**Physical Buffer List** — In iWARP terminology, a Physical Buffer List can either be a Block List or a Page List. The E810 does not support Block Lists, so in the context of the E810, PBLs and Page Lists are the same thing.
PD	**Protection Domain** — A mechanism the Protocol Engine uses for tracking the association of Queue Pairs, Memory Windows, and Memory Regions. PDs are intended to be set by a Privileged Consumer to provide protection of one process from accessing another's memory, using the E810 as a proxy.
PF	**Physical Function** — A PCI Function that supports the *PCI-SIG Single Root I/O Virtualization and Sharing Specification*.
PHY Core	The 10/25/40/50/100G PHY connected to the E810.
QP	**Queue Pair** — A pair of queues that allow a Consumer to interact with the E810. The two queues are the Send Queue (sometimes called a Transmit Queue or TQ) and the Receive Queue. Each queue stores a Work Queue Element from the time it is posted until the time it is completed. The E810 LAN Engine and Protocol Engine all use QPs to interact with their various Consumers. Work Queue Elements processed by the different engines can be quite different (for example, LAN packet vs. RDMA message).
Quad	In this document, the term "quad" is defined as the set containing {source IP Address, dest IP Address, source port, dest port} taken from a TCP/IP packet.
Quanta	A configurable amount of bytes consisting of one or more packets.
Registration, Register	**Memory Registration** — The mechanism used to enable direct (local or local and remote) access by the E810 of an RDMA Consumer's Memory Region. The memory registration operation associates a Physical Buffer List to the Steering Tag (STag) returned.
RNIC	**RDMA Network Interface Controller** — The generic term for a device that implements iWARP verbs functionality. The E810 is an RNIC.
RQ	**Receive Queue** — One of the two Work Queues associated with a Queue Pair. The Receive Queue contains Work Queue Elements that describe the Buffers into which data from incoming Send Operation Types is placed.
RSS	**Receive Side Scaling** — A feature of Microsoft Windows OS that distributes receive packet processing to the different processors in a multi-processor system. Received packets are classified by the E810 under OS control into groups of conversations. Each group of conversations is assigned its own receive queue and receiving processor.
Scheduler Quanta	A "quanta" is a configurable amount of bytes consisting of one or more packets. The Scheduler schedules a "quanta" in each scheduling decision.
SDPs	**Software Definable Pins** — E810 device pins that have a high degree of software configurability and programmability. Also called *General purpose I/Os* (GPIOs).
SFP	**Single-Function per Port** — A PCI Device is classified as an SFP device when it can support only one PCI Physical Function bound to a single network port. See also *Multi-Function per Port (MFP)*.
SFP	**Small Form-factor Pluggable** — A small form-factor pluggable (SFP or SFP+) module is a compact, hot-pluggable transceiver that interfaces a network device like the E810 to a fiber optic or copper networking cable.

Table 19-1. Definition of Terms [continued]

Term	Definition
SQ	**Send Queue** — One of the two Work Queues associated with a Queue Pair. The Send Queue contains PostSQ Work Queue Elements that have specific operation types, such as Send Type, RDMA Write, or RDMA Read Type Operations, as well as STag operations such as Bind and Invalidate.
TLV	**Type, Length, Value** — A technique used to encode messages in a data communication protocol. Each message is comprised of three sequential fields: • A Type field, fixed in size and typically ~1 byte, which identifies the specific type of message and the format of information in the Value field. • A Length field, fixed in size and typically ~1 byte, which defines the length of the Value field in octets. • A Value field, variable in size, which contains all of the data specific to this message type. A protocol relevant to the E810 that uses TLV encoding is IEEE Link Layer Discovery Protocol (LLDP).
TOE	**TCP Offload Engine** — The E810 Protocol Engine integrates a TOE, which provides complete TCP/IP transport processing for RDMA connections.
TSO	**Transmit Segmentation Offload** — Also known as Large Send Offload (LSO). This high performance NIC feature allows the host OS to pass large chunks of data payload to the NIC with instructions on how to segment the payload into multiple packets for transmission.
ULP	**Upper Layer Protocol** — The protocol layer above the protocol layer currently being referenced. For example: • For IP, the ULP is TCP. • For RDMA verbs, an example ULP is SDP. • and so on.
VEB	**Virtual Ethernet Bridge** — This is an IEEE EVB term. A VEB is a VLAN Bridge internal to the E810 that bridges the traffic of multiple VSIs over an internal virtual network.
VEPA	**Virtual Ethernet Port Aggregator** — This is an IEEE EVB term. A VEPA multiplexes the traffic of one or more VSIs onto a single E810 Ethernet port. The biggest difference between a VEB and a VEPA is that a VEB can switch packets internally between VSIs, whereas a VEPA cannot.
VF	**Virtual Function** — A VF is a PCI Function that supports the *PCI-SIG Single Root I/O Virtualization and Sharing Specification*. One or more VFs are associated with a single PF. The group of VFs/PFs shares one or more physical resources, such as an Ethernet port. A VF is designed to be programmed by a Virtual Machine, whereas a PF is designed to be programmed by a higher-privileged entity, such as a Hypervisor.
VMDq	**Virtual Machine Devices queues** — A collection of NIC features designed to offload the hypervisor from performing classification and distribution of received packets to the Virtual Machines under its control. There are two versions of VMDq: VMDq1 and VMDq2. VMDq2 is a superset of VMDq1. Its major new features are: internal switching from a Transmit Queue to a Receive Queue, the ability to replicate received multicast and broadcast packets to multiple Receive Queues, the ability to sort received packets based on a combination VLAN tag and MAC Address filter, and anti-spoofing transmit filters.
VMM	**Virtual Machine Monitor** — A software component that allocates/exports/isolates server resources to the Virtual Machines (or System Images). Other terms for VMM in this specification: Hypervisor, Virtualization Intermediary (VI).
VPD	**Vital Product Data** — VPD is defined in the *PCI Local Bus Specification* (this is the conventional PCI specification, not PCIe). VPD is information that uniquely identifies hardware and software elements of a server. The VPD provides a server OS with information on various Field Replaceable Units such as part number, serial number, and so on.
VSI	**Virtual Station Interface** — This is an IEEE EVB term that defines the properties of a virtual machine's (or a physical machine's) connection to the network. Each downstream v-port on an E810 VEB or VEPA defines a VSI. A standards-based definition of VSI properties enables network management tools to perform virtual machine migration and associated network reconfiguration in a vendor-neutral manner.
WoL	**Wake on LAN** — An Ethernet technology that enables a computer to power on or "wake up" upon receipt of a network message, often called a "Magic Packet". Newer specifications in this area call WoL *Advanced Power Management Wake-Up*.
WQ	**Work Queue** — One of either a Send Queue or Receive Queue.
WQE	**Work Queue Element** — A Work Request transformed by software into E810-specific format, and enqueued on a Work Queue.
WR	**Work Request** — A request to the E810 by the Consumer to perform some operation. Gets transformed by software into a Work Queue Element.

Table 19-1. Definition of Terms [continued]

Term	Definition
WRR	**Weighted Round-Robin** — A scheduling or arbitration algorithm that selects amongst requesters in a round-robin fashion, and in which each requester can be programmed to receive a different percentage share of resource bandwidth.
WSP	**Weighted Strict Priority** — A scheduling or arbitration algorithm which selects the requester with highest priority that has not exhausted its programmed percentage share of resource bandwidth.

NOTE: ***This page intentionally left blank.***

Appendix A Factory Parsing Program

A.1 General

The following section describes the factory parsing program embedded into the E810 NVM, in particular the factory-programmed:

- Parse graph
- Protocols and frame formats
- Packet Types

The E810 factory parsing program includes a large set of frame formats that are common in various networking applications. These formats are stored in NVM as the default device programming.

Note: The factory parsing program can be modified or replaced by reprogramming the E810 parser. The device provides reprogramming of any aspect of the parsing policy, including the parse graph, frame formats, and packet types.

A.1.1 Supported Header Length

In general, the device parses headers up to the minimum of first 504 bytes of the packet, or up to 16 detected protocol headers, including payload (hereafter the "parsing depth").

Packets with headers that extend beyond the parsing depth are handled depending on the case:

- When the "next header" is located beyond the parsing depth, the packet is reported as a "partially analyzed" packet.
- When a header is chopped at the parsing depth boundary, the packet is reported as an "abort" (0xFF).

Note: Some types of headers must have a consecutive header (for example, MPLS or VLAN). For such headers, the packet is reported as an abort if there is no trailing header. The last detected protocol will always be reported as "payload".

A.2 Parse Graph

The factory parse graph represents protocol sequences supported by the factory parsing program. Nodes on the parse graph normally correspond to protocol headers such as VLAN, MPLS, IPv4, IPv6, TCP, UDP, VXLAN, and so on. Arcs on the parse graph connect nodes. Traversal over an arc from one node to another node is either unconditional (for example, L2 MAC always after VXLAN) or conditional (for example, IPv4 after L2 MAC if ETYPE = 0x0800).

The factory parse graph supports multiple overlay and tunneling technologies, including:

- MAC-in-MAC
- VXLAN, VXLAN-GPE
- Geneve

- GRE
- NSH (Service Chaining Header)
- MPLSoGRE, MPLSoUDP

Figure A-1 illustrate the E810 factory parse graph.

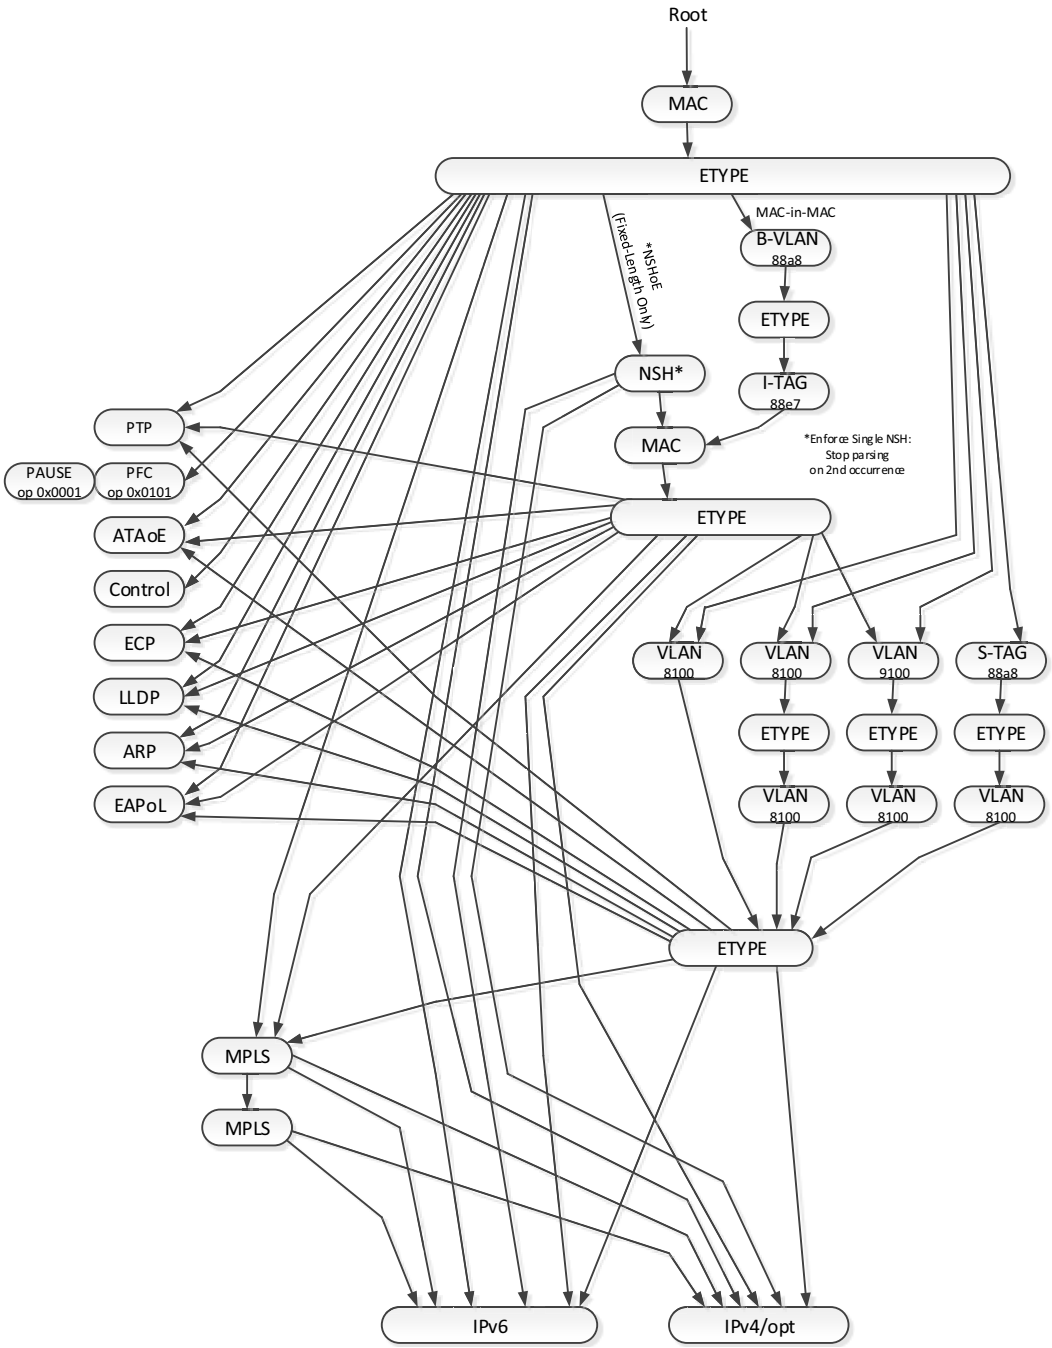

Figure A-1. Factory Parse Graph: L2+ Sections

Note: The parse graph illustrated in Figure A-1 shows the VLAN support for double VLAN mode. When supporting a single VLAN, the second occurrence of a VLAN is omitted from the parse graph.

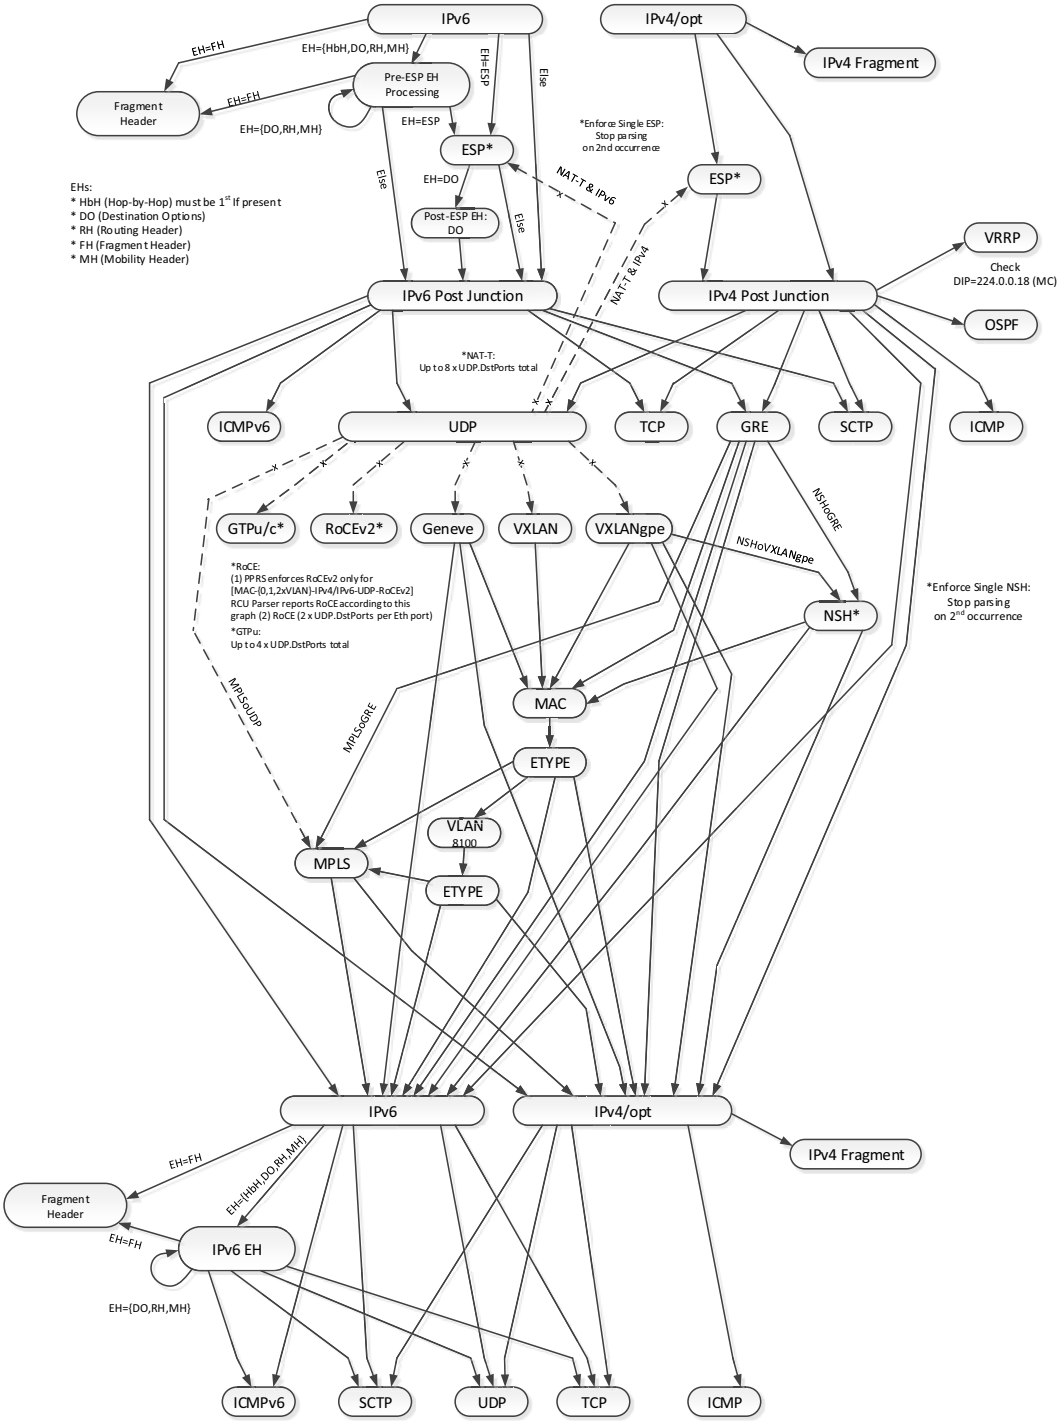

Figure A-2. Factory Parse Graph: L3+ and Inner Sections

Notes:

- The Factory Parse graph represents a superset of multiple common use cases. Some of the sequences listed on the graph are technically feasible but practically non-relevant (for example, MAC-in-MAC with STAG).
- LSO is not supported for GTPu, VRRP, OSPF packets.
- Inner VLAN insertion is not supported with inner MPLS headers.

A.3 PTYPEs

The E810 provides up to 1K programmable PTYPEs (Packet Types) for enumerating traversals over the parse graph. For example, traversal of protocol header sequences such as MAC, IPv6, IPv6, TCP, PAY4 (Payload L4). The PTYPE association of a packet is used by subsequent functions in the pipeline. For example, the ACL classifier might use the PTYPE for selecting a lookup key.

The factory-programmed PTYPEs are detailed in Table A-1.

Notes:

- Unless specifically mentioned, the packet description relates to the inner header structure.
- Table A-1 should not used to deduce which protocol IDs are generated for each PTYPE. The protocol IDs are specified in Table A-2.

Table A-1. Factory-Programmed PTYPEs

PTYPE (Dec)	PTYPE (Hex)	Packet Description	Backward Compatible to X710/XXV710/XL710
L2 Packet Types			
0	0x000	Reserved	No
1	0x001	MAC, PAY	Yes
2	0x002	Reserved	No
3	0x003	Reserved	No
4	0x004	Reserved	Yes
5	0x005	Reserved	Yes
6	0x006	MAC, LLDP	Yes
7	0x007	MAC, ECP	Yes
8	0x008	Reserved	Yes
9	0x009	Reserved	Yes
10	0x00A	MAC, EAPOL	Yes
11	0x00B	MAC, ARP	Yes
12	0x00C	Reserved	No
13	0x00D	Reserved	No
14	0x00E	Reserved	No

144	0x90	MAC, IPv6, GRENAT, MACVLAN, IPv4, TCP, PAY	Yes
145	0x91	MAC, IPv6, GRENAT, MACVLAN, IPv4, SCTP, PAY	Yes
146	0x92	MAC, IPv6, GRENAT, MACVLAN, IPv4, ICMP, PAY	Yes
IPv6 --> GRE/GENEVE/VXLAN --> MAC/VLAN --> IPv6			
147	0x93	MAC, IPv6, GRENAT, MACVLAN, IPv6+IPv6FRAG, PAY	Yes
148	0x94	MAC, IPv6, GRENAT, MACVLAN, IPv6, PAY	Yes
149	0x95	MAC, IPv6, GRENAT, MACVLAN, IPv6, UDP, PAY	Yes
150	0x96	Reserved	No
151	0x97	MAC, IPv6, GRENAT, MACVLAN, IPv6, TCP, PAY	Yes
152	0x98	MAC, IPv6, GRENAT, MACVLAN, IPv6, SCTP, PAY	Yes
153	0x99	MAC, IPv6, GRENAT, MACVLAN, IPv6, ICMP, PAY	Yes
154-254	0x09A-0x0FE	Reserved	Yes
255	0x0FF	Parser Aborted	Yes
IPv4-UDP-GTP			
256	0x100	MAC, IPv4, GTP-C, with TEID	NO
257	0x101	MAC, IPv4, GTP-C, with/out TEID	NO
258	0x102	MAC, IPv4, GTP-U, Message Type = 0xFF	NO
259	0x103	MAC, IPv4, GTP-U, Message Type ≠ 0xFF	NO
260	0x104	Reserved for more IPv4-GTP	NO
261	0x105	Reserved for more IPv4-GTP	NO
262	0x106	Reserved for more IPv4-GTP	NO
263	0x107	Reserved for more IPv4-GTP	NO
IPv6-UDP-GTP			
26	0x108	MAC, IPv6, GTP-C, with TEID	NO
26	0x109	MAC, IPv6, GTP-C, with/out TEID	NO
26	0x10A	MAC, IPv6, GTP-U, Service Type = 0xFF	NO
26	0x10B	MAC, IPv6, GTP-U, Service Type ≠ 0xFF	NO
26	0x10C	Reserved for more IPv6-GTP	NO
26	0x10D	Reserved for more IPv6-GTP	NO
270	0x10E	Reserved for more IPv6-GTP	NO
271	0x10F	Reserved for more IPv6-GTP	NO
Other			
272	0x110	MAC, IPv4, VRRP	NO
273	0x111	MAC, IPv4, OSPF	NO
274	0x112	MAC, IPv6, VRRP	NO
275	0x113	MAC, IPv6, OSPF	NO

Table A-1. Factory-Programmed PTYPEs [continued]

PTYPE (Dec)	PTYPE (Hex)	Packet Description	Backward Compatible to X710/XXV710/XL710
276	0x114	MAC, ATAoE	NO
277	0x115	Reserved	NO
278	0x116	MAC, Control ETYPE 0x8808 (PAUSE, PFC, other control frames)	NO
279-1023		Reserved	No

Notes:
- "GRENAT" means GRE or any UDP tunnel other than UDP-NAT-ESP. This means that several different traversal paths on the parse graph might result in the same PTYPE, yet will each have a different composition of protocol IDs and flags.
- "MAC" is the first MAC protocol in packet.

A.4 Protocol IDs

The E810 provides up to 256 programmable Protocol IDs (Protocol Identification) for enumerating protocol headers or other points of interest in the parse graph.

The factory-programmed Protocol IDs are detailed in Table A-2.

Table A-2. Factory-Programmed Protocol IDs

PTYPE (Dec)	PTYPE (Hex)	Mnemonic	Protocol	Layer	Position	Description
0	0x000	Reserved	-----	-----	-----	Reserved.
1	0x001	MAC.o.[1]	MAC	Outer	1st	Outer or single MAC.
2	0x002	MAC.o.[2]	MAC	Outer	2nd	Outer 2nd MAC (can exist only if inner exists).
3	0x003	Reserved	-----	-----	-----	Reserved.
4	0x004	MAC.i.[L]	MAC	Inner	Last	Inner Last MAC.
5	0x005	Reserved	-----	-----	-----	Reserved.
6	0x006	Reserved	-----	-----	-----	Reserved.
7	0x007	MAC-in-MAC.o.[1]	MAC-in-MAC	Outer	1st	Outer 1st MAC-in-MAC. ***Note:*** This is reported when "STAG+ITAG" (MAC-in-MAC) found. In this case, STAG protID is not reported (even though an "STAG" is found in the pkt).
8	0x008	Reserved	-----	-----	-----	Reserved
9	0x009	ETYPE.o.[L]	ETYPE	Outer	Last	Outer Last ETYPE. ***Note:*** The offset points to the ETYPE field.
10	0x00A	ETYPE.i.[L]	ETYPE	Inner	Last	Inner Last ETYPE. ***Notes:*** The offset points to the ETYPE field
11	0x00B	Reserved	-----	-----	-----	Reserved.
12	0x00C	Reserved	-----	-----	-----	Reserved.
13	0x00D	Reserved	-----	-----	-----	Reserved.
14	0x00E	Reserved	-----	-----	-----	Reserved.

Table A-2. Factory-Programmed Protocol IDs [continued]

PTYPE (Dec)	PTYPE (Hex)	Mnemonic	Protocol	Layer	Position	Description
15	0x00F	Payload	-----	-----	-----	Payload. ***Note:*** Will be reported even if no payload in the pkt.
16	0x010	VLAN.o.[1]	VLAN	Outer	1st	Outer external VLAN. ***Note:*** This is EVLAN (0x8100 or 0x9100) or STAG (0x88a8) (flags distinguish between them)
17	0x011	VLAN.o.[2]	VLAN	Outer	2nd	Outer VLAN. ***Note:*** This is always VLAN (0x8100).
18	0x012	VLAN.i.[1]	VLAN	Inner	1st	Inner 1st VLAN.
19	0x013	Reserved	-----	-----	-----	Reserved.
20	0x014	Reserved	-----	-----	-----	Reserved.

A.5 Frame Formats

The following section details the factory programmed frame formats in the E810.

A.5.1 Layer 2

The following section details the L2 Native Frame formats.

A.5.1.1 Ethernet II (DIX)

The Ethernet II (DIX) frame format is illustrated in Figure A-3.

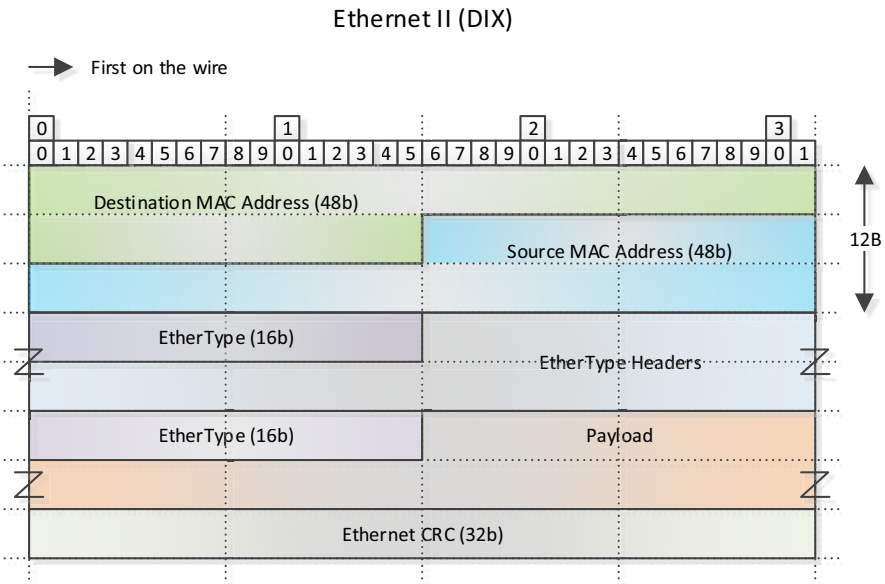

Figure A-3. Ethernet II (DIX) Frame Format

A.5.1.2 EtherTypes (L2 Tags)

Table A-3 lists the factory preset EtherType headers.

Table A-3. Factory Preset EtherTypes

EtherType	Protocol	Notes
0x88A8	B-VLAN (MAC-in-MAC)	Followed by ITag. Note that B-VLAN ETYPE is identical to STag ETYPE.
0x894F	NSHoE	NSH over Ethernet in the outer L2 section of the packet.
0x88A8	STag	IEEE 802.1Q clause 9
0x88E7	ITag	IEEE 802.1Q clause 9.7
0x8100	VLAN	IEEE 802.1Q clause 9
0x9100	VLAN	IEEE 802.1Q clause 9
0x8808	Ethernet Flow Control	PAUSE, PFC
0x8809	LACP	Link Aggregation Control Protocol
0x88F7	PTP (1588)	Precision Time Protocol (PTP) This packet type is not present in the factory parse graph.
0x88CC	LLDP	IEEE P802.1AB
0x8940	ECP	IEEE 802.1Qbg
0x0806	ARP	See Section A.5.3.8.
0x8863	PPPoE (Discovery stage)	
0x8864	PPPoE (Session stage)	
0x888E	EAPoL	IEEE 802.1X
0x88A2	ATAoE	AoE (ATA over Ethernet)

Table A-3. Factory Preset EtherTypes [continued]

EtherType	Protocol	Notes
0x8847	MPLS (Unicast)	According to RFC 5332, this EtherType is also used for MPLS multi-cast packets when the top label was downstream assigned.
0x0800	IPv4	See Section A.5.3.1.
0x86DD	IPv6	See Section A.5.3.2.

A.5.1.3 ATA over Ethernet (AoE)

AoE is used to achieve a very basic level RPC mechanism between a client and an ATA device server. The server accepts commands and generates responses based on a command code in the AoE header.

AoE is not a connection based protocol. Each message sent to a server should be considered unique and unreliable.

The AoE packet format is illustrated in Figure A-4.

Note: Reserved fields have to be set to zero in all messages sent.

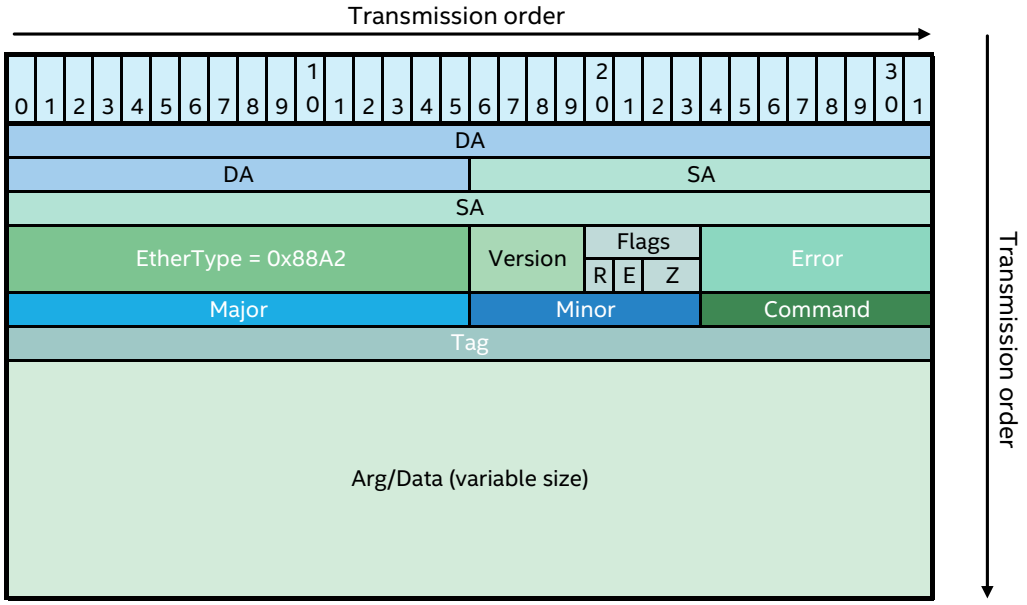

Figure A-4. AoE Frame Format

The AoE frame follows the standard Ethernet MAC header for IEEE 802.3 Ethernet.

- ***EtherType*** — 16-bit field. AoE has a registered Ethernet type of 0x88A2.
- ***Version*** — 4-bit field which defines the AoE header format and also command codes. This field must be set to 0x1.
- Flags:
  - — ***R*** — 1-bit flag that is set for a response message.
  - — ***E*** — 1-bit flag that is set for a response message if the associated command message generated an AoE protocol error.

  - ***Z*** — 2-bit field that is reserved and therefore must be set to zero.

- ***Error*** — 8-bit field. Only relevant when *E* flag is set:
  - Error 1: Unrecognized command code.
  - Error 2: Bad argument parameter.
  - Error 3: Device unavailable – The server can no longer accept ATA commands.
  - Error 4: Config string present – The server cannot set the config string because it is not empty.
  - Error 5: Unsupported version – The server does not recognize the version specified in the *Version* field.
  - Error 6: Target is reserved – Thus, the command cannot be completed.
- ***Major***, ***Minor*** — Each AoE server has a *Major* (16-bit) and a *Minor* (8-bit) address. Before processing the header *Command*, the server must validate its major and minor address with the *Major* and *Minor* fields of the header. To accept to process a command message, these conditions must be valid. The *Major* (minor) field in the header must be equal to the server *Major* (minor) address, or be a suite of ones: 0xffff (0xff). If they are not true, the command messages must be ignored by the server. The server has to supply its major and minor address in every response.
- ***Command*** — 8-bit field that contains the command code for the message. Four commands are defined for this specific version:
  - Command 0: Issue ATA Command
  - Command 1: Query Config Information
  - Command 2: MAC Mask List
  - Command 3: Reserve/Release
  - Commands codes number 240-255 (0xf0-0xff) are reserved for vendor-specific use.
- ***Tag*** — 32-bit field that provides a client with the means to correlate responses with their appropriate commands. It is copied into the response message by the server and otherwise is ignored.
- ***Arg/Data*** — Variable size field. It content serves as an input for the command code.

A.5.1.4 Link Aggregation Control Protocol (LACP)

The Link Aggregation Control Protocol (LACP) provides a standardized method to control the bundling of several ports to form a single logical channel.

The destination address is the Slow Protocols Multicast address (01-80-C2-00-00-02).

The source address in LACP PDUs is the individual MAC Address associated with the port from which the PDU is transmitted.

There are two versions of LACP frames. The first version of the LACP packet format is illustrated in Figure A-5, and the second version frame format is illustrated in Figure A-6.

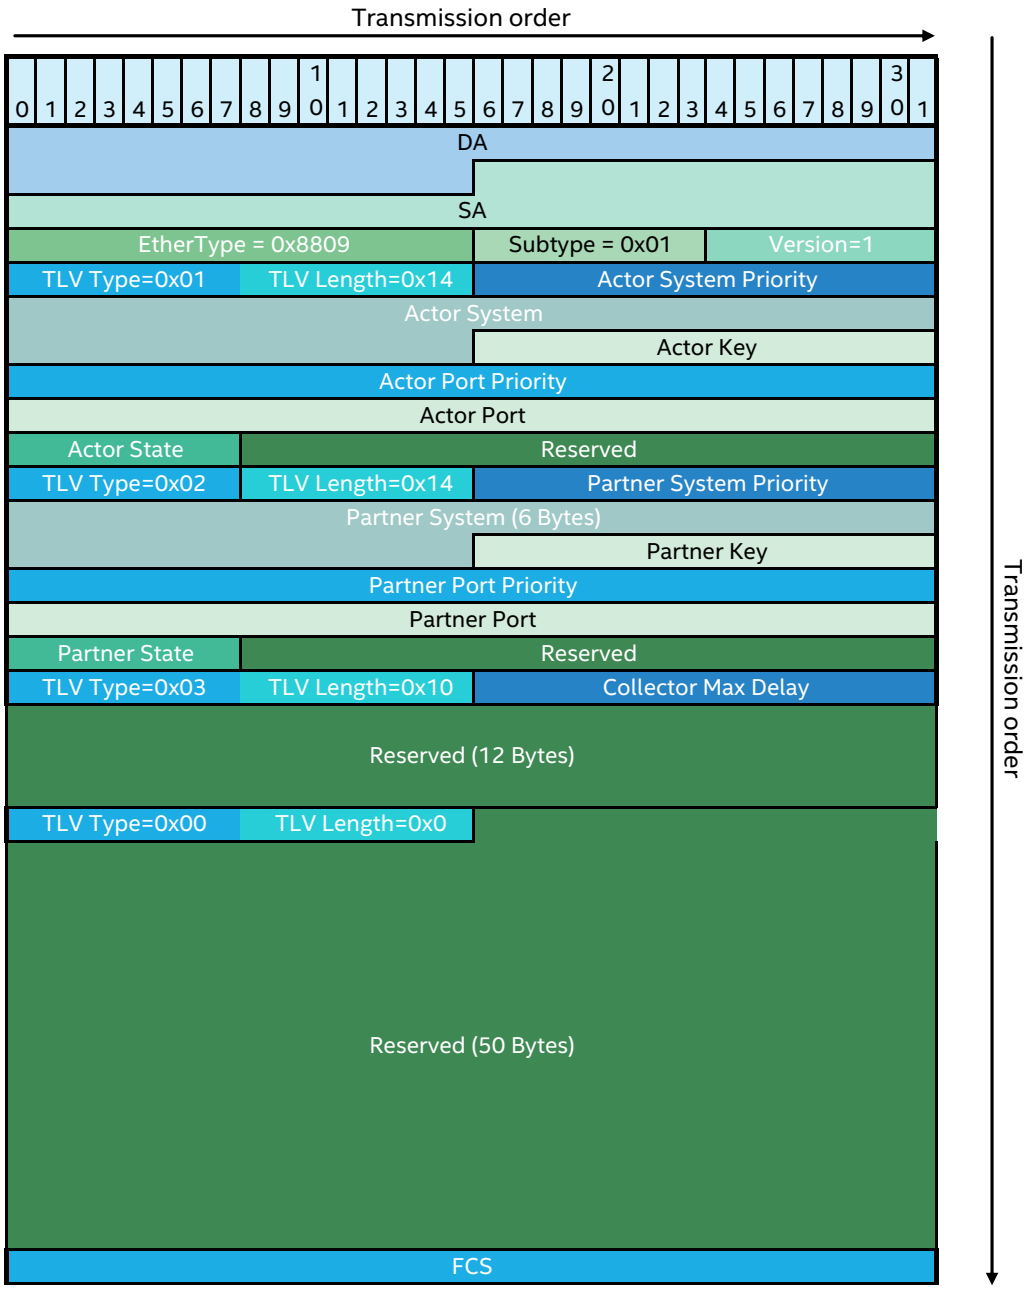

Figure A-5. LACP Version 1 Frame Format

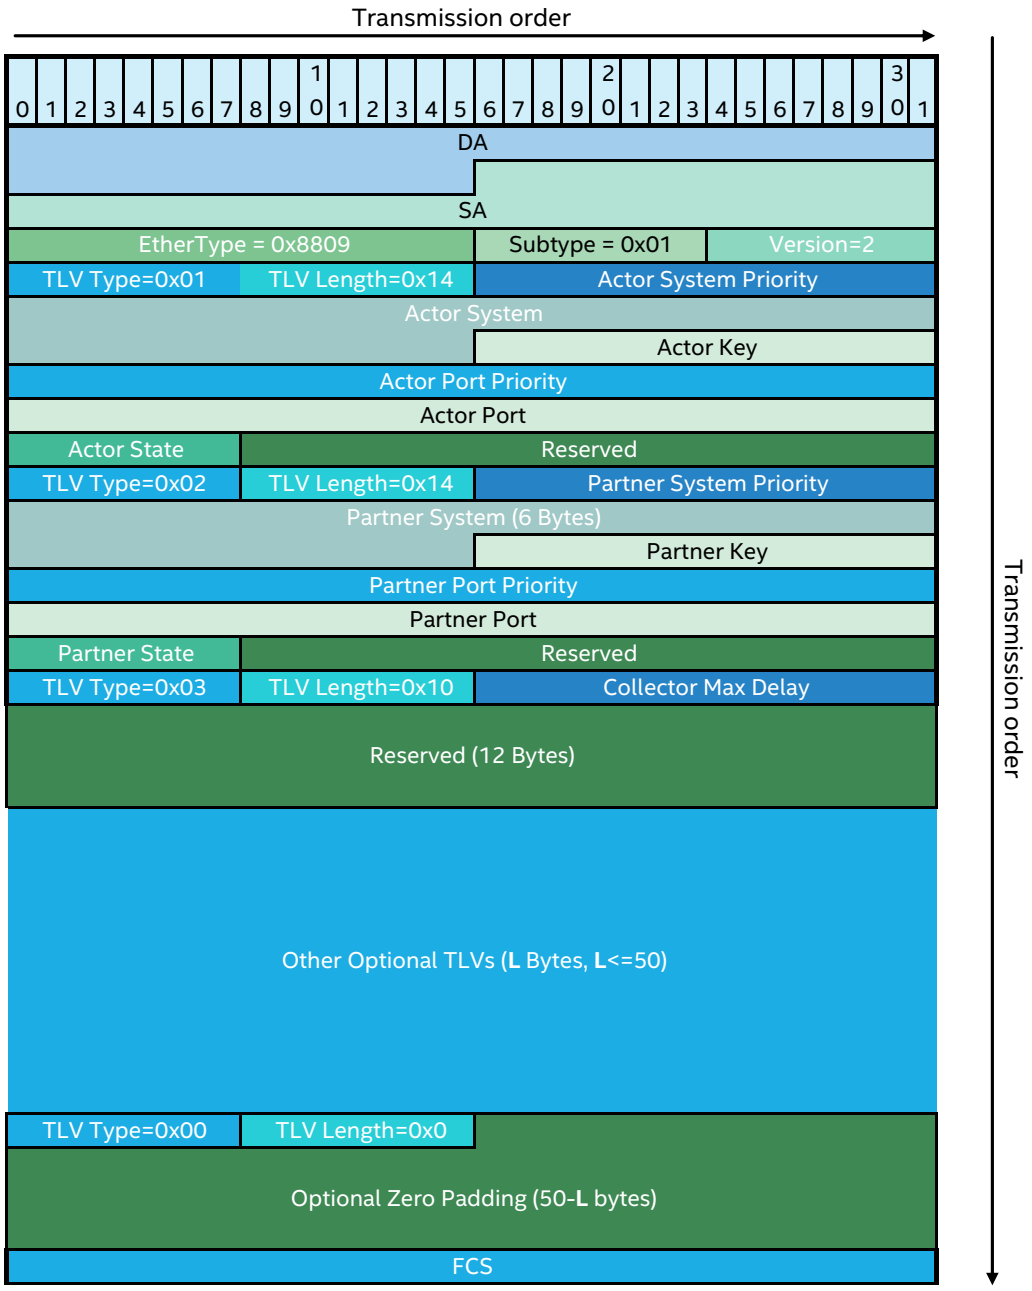

Figure A-6. LACP Version 2 Frame Format

- ***EtherType*** — The EtherType used by LACP is 0x8809.
- ***Subtype*** — 8-bit field that identifies the specific Slow Protocol being encapsulated. The subtype value is: 0x01.
- ***Version*** — 4 bit field. The first version of the LACP standard carries the value 0x01, the second one 0x02.

- ***TLV Type*** (corresponds to the Actor Information) — 8-bit field that indicates the nature of the information carried in this TLV-tuple. It is fixed to the value of 0x01.
- **TLV Length** (of the Actor information) — 8-bit field that indicates the length in bytes of the TLV-tuple. Actor information uses a length value of 20. Thus, *TLV Length* is fixed to 0x14.
- ***Actor System Priority*** — 16-bit (unsigned integer) field that indicates the priority of this System.
- ***Actor System*** — 48-bit address that indicates the MAC Address component of Actor's System ID.
- ***Actor Key*** — 16-bit (unsigned integer) field that indicates the operational key value assigned to the Aggregation Port by the actor.
- ***Actor Port Priority*** — 32-bit (unsigned integer) field that indicates the priority assigned to this Aggregation Port by the Actor (the system sending the PDU; assigned by management or administration policy).
- ***Actor Port*** — 32-bit (unsigned integer) field that indicates the port number assigned to the Aggregation Port by the Actor (the system sending the PDU).
- ***Actor State*** — 8-bit field (see Figure A-7) that defines the Actor's state variables for the Aggregation Port, encoded as individual bits within a single octet.

Figure A-7. State Variables

  - ***LACP_Activity*** — Indicates the Activity control value. For an Active LACP, the flag is set. Otherwise, the flag is cleared (0).
  - ***LACP_timeout*** — Indicates the timeout control value. For short timeout, the flag is set. Otherwise, the flag is cleared (0).
  - ***Aggregation*** — If the flag is set, the system considers this link to be Aggregable, and it is a potential candidate for aggregation. Otherwise, the link is considered to be Individual, and it can be operated only as an individual link.
  - ***Synchronization*** — If the flag is set, the system considers this link to be IN_SYNC (it has been allocated to the correct LAG, the group has been associated with a compatible Aggregator, and the identity of the LAG is consistent with the System ID and operational Key information transmitted). Otherwise, this link is currently OUT_OF_SYNC (it is not in the right LAG).
  - ***Collecting*** — If the flag is set, collection of incoming frames on this link is definitely enabled and it is not expected to be disabled in absence of administrative changes in received protocol information. Otherwise, the flag is cleared (0).
  - ***Distributing*** — If the flag is 0, the distribution of outgoing frames in this link is currently disabled and it is not expected to be enabled in absence of administrative changes or changes in received protocol information. Otherwise, the flag is set (1).
  - ***Defaulted*** — If the flag is set, it indicates that the Actor's Receive machine is using defaulted operational partner information, administratively configured for the partner. Otherwise, the operational partner information in use has been received in a LACPDU.
  - ***Expired*** — If the flag is set, it indicates that the Actor's received machine is in the EXPIRED state. Otherwise, it is not.

    Note: The received values of Defaulted and Expired State (Bits 6 and 7) are not used by LACP, but their values can be useful for diagnosing protocol problems.

- ***Reserved*** — 24-bit field that is not used in the actual protocol (it is reserved for the future extensions of the protocol). On receipt, should be ignored. On transmission, should be set to zeros.
- ***TLV Type*** (corresponds to the Partner information) — 8-bit field that indicates the nature of the information. Set to the value of 0x02.
- ***TLV Length*** (of the Partner information) — 8-bit field that indicates the length in bytes of the TLV-tuple. Actor information uses a length value of 20. Thus, *TLV Length* is fixed to 0x14.
- ***Partner System Priority*** — 16-bit (unsigned integer) field that indicates the priority of the Partner System.
- ***Partner System*** — 48-bit address that indicates the MAC Address component of Partner's System ID.
- ***Partner Key*** — 16-bit (unsigned integer) field that indicates the operational key value assigned to the Aggregation Port associated with this link by the partner.
- ***Partner Port Priority*** — 32-bit (unsigned integer) field that indicates the priority assigned to this Aggregation port by the partner.
- ***Partner Port*** — 32-bit (unsigned integer) field that indicates the port number assigned to the Aggregation Port by the Partner.
- ***Partner State*** — 8 bit field (see Figure A-7) that defines the partners state variables for the Aggregation Port, encoded as individual bits within a single octet, as defined for Actor State.
- ***Reserved*** — 24-bit field that is not used in the actual protocol (it is reserved for the future extensions of the protocol). On receipt, should be ignored. On transmission, should be set to zeros.
- ***TLV Type*** (corresponds to the Collector Information) — 8-bit field that indicates the nature of the information carried in this TLV-tuple. It is fixed to the value of 0x03.
- ***TLV Length*** (of the Collector information) — 8-bit field that indicates the length in bytes of the TLV-tuple. Actor information uses a length value of 16. Thus, *TLV Length* is fixed to 0x10.
- ***Collector Max Delay*** — 16-bit (unsigned integer) field that contains the Collector Max Delay value of the station that transmits the LACPDU. In tens of microseconds. The range of value is 0 to 63,535 tens of microseconds (0.65535s).
- ***Reserved*** — 12-byte field that is not used in the actual protocol (it is reserved for the future extensions of the protocol). On receipt, should be ignored. On transmission, should be set to zeros.
- ***Other Optional TLVs*** — Exists only for the second version of the protocol. Up to 50-byte field. the length is defined in byte by *L*.

  Note: For Long LACPDUs, *L* can be up to 1438. However, the E810 supports headers up to 504 bytes, and therefore does not support Long LACPDUs.
- ***TLV Type*** (corresponds to the Terminator Information) — 8-bit field that indicates the nature of the Terminator information (end of the message) carried in this TLV-tuple. It is fixed to the value of 0x00.
- ***TLV Length*** (of the Terminator information) — 8-bit field that indicates the length in bytes of the TLV-tuple. Terminator information uses a length value of 0. Thus, *TLV Length* is fixed to 0x00. The use of a Terminator Length of 0 is intentional.
- ***Reserved*** — 50 bytes for the first version. On receipt, should be ignored. On transmission, should be set to zeros. This field is not use for Long LACPDUs.
- ***Optional Zero Padding*** — For the second version, it is a 50–L bytes field.
- ***FCS*** — Frame Check Sequence.

A.5.1.5 Point-to-Point Protocol over Ethernet (PPPoE)

The PPPoE frame format is illustrated in Figure A-8.

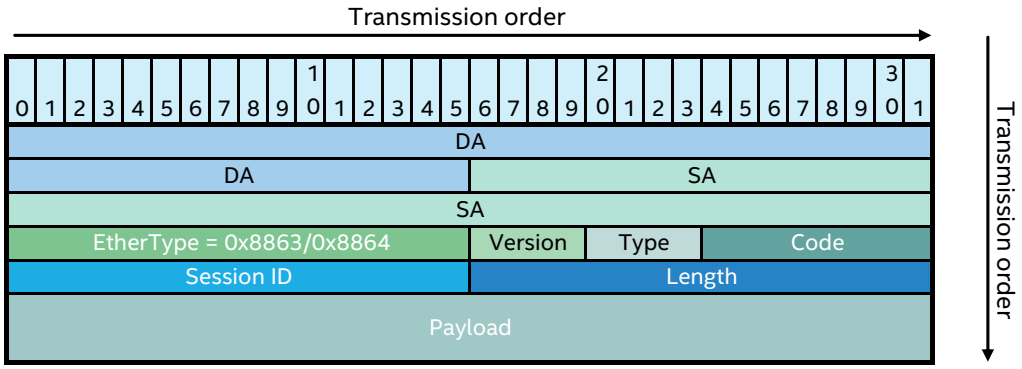

Figure A-8. PPPoE Frame Format

- ***Destination and Source Address*** — 48-bit addresses.

  The destination address contains either a unicast Ethernet destination address, or the Ethernet broadcast address (0xFFFFFFFF). For Discovery packets, the value is either a unicast or broadcast address. For PPP session traffic, this field has to contain the peer's unicast address.

  The source address has to contain the Ethernet MAC Address of the source device.

- ***EtherType*** — 16 bit field that is set to 0x8863 in the case of Discovery Stage or 0x8864 for PPP Session stage.
- ***Version*** — 4-bit field that must be set to 0x1 for this version of the PPPoE specification.
- ***Type*** — 4-bit field that must be set to 0x1 for this version of the PPPoE specification.
- ***Code*** — 8-bit field. May be set to different values (0x09, 0x07, 0x19, 0x65, 0xa7) depending on the type of Discovery packet.
- ***Session ID*** — 16-bit (unsigned) field in network byte order. Session ID takes the value of 0x0000 if the session has not yet been established. Otherwise, it is set to a unique value generated for the current session. For a given PPP session, this value is fixed. For future use, the value 0xffff is reserved.
- ***Length*** — 16-bit field in network byte order which indicates the length of the payload.
- ***Payload*** — Its length depends of the *Length* field.

A.5.1.6 Link Layer Discovery Protocol (LLDP)

The general structure of an LLDP (Link Layer Discovery Protocol) packet is depicted in Figure A-9.

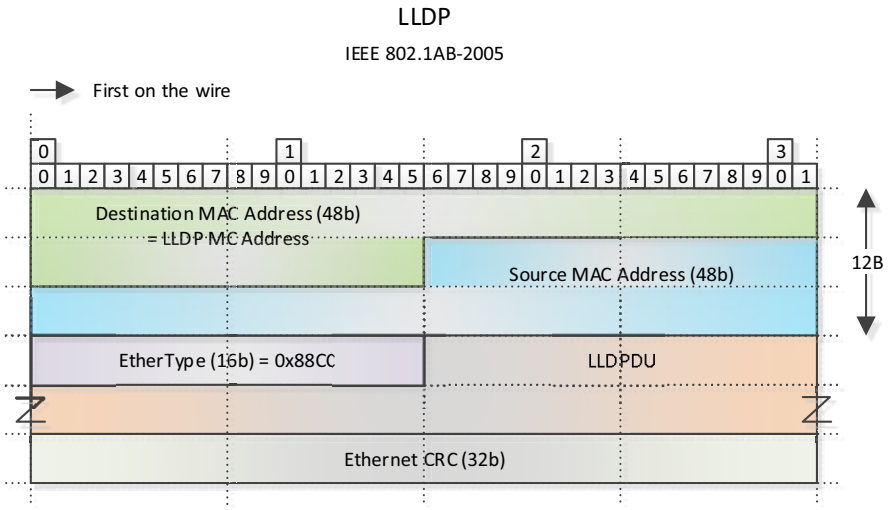

Figure A-9. Structure of LLDP Frame

The LLDPDU contains an ordered sequence of three mandatory TLVs followed by zero or more optional TLVs, plus an End of LLDPDU TLV, as shown in Figure A-10.

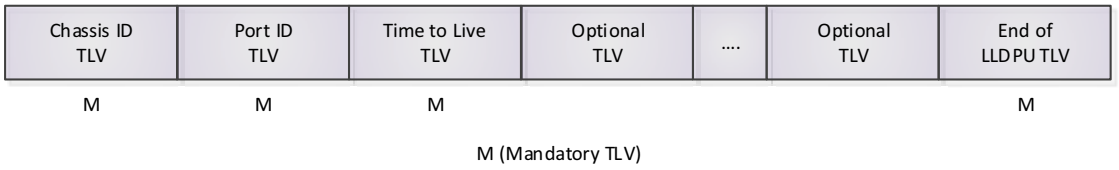

Figure A-10. Structure of LLDP PDU

Each TLV has the structure depicted in Figure A-11.

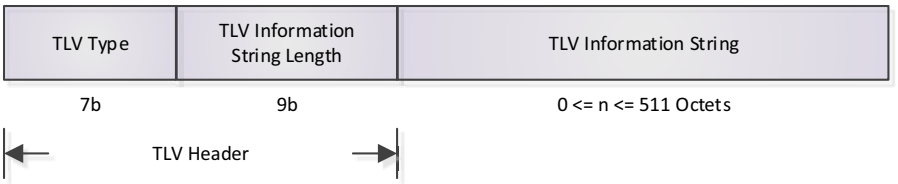

Figure A-11. Structure of an LLDP TLV

The basic format for Organizationally Specific TLVs is shown in Figure A-12.

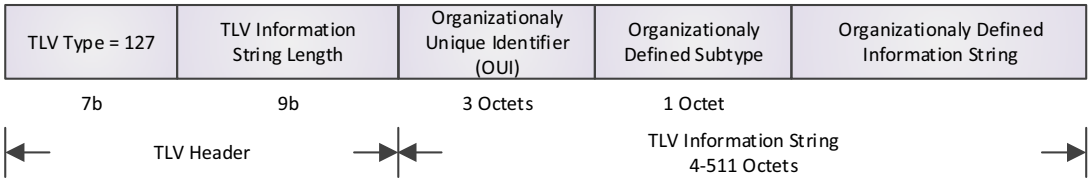

Figure A-12. Structure of LLDP Organizationally Specific TLVs

Table A-4 lists the applicable Organizationally Specific TLVs:

Table A-4. List of Organizationally Specific TLVs

TLV	OUI Value	Subtype Value
DCBX	00-80-C2	09, 0A, 0B, 0C
EEE	00-12-0F	05

Note: The E810 does not parse the TLV sections on LLDP

A.5.1.7 Magic Packets

Magic packets are described in Section 5.3.1.

A.5.1.8 Link Control Packets

Link Control packets are described in Section 3.2.1.5.1. Such packets do not include any L2 tags other than those described therein.

A.5.2 Layer 2.5

A.5.2.1 Multi-Protocol Label Switching (MPLS)

The general structure of an MPLS header is illustrated in Figure A-13.

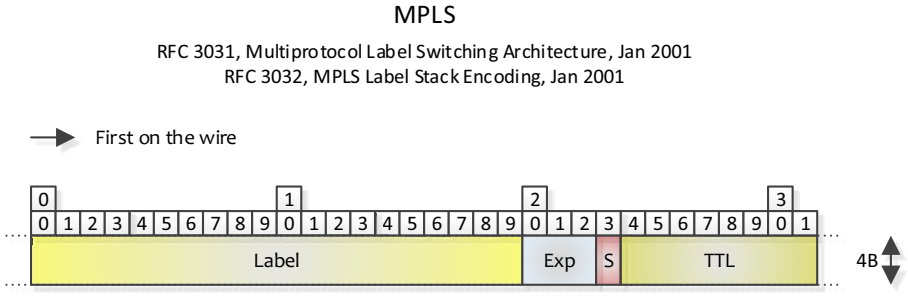

Figure A-13. Structure of MPLS Header

An MPLS header contains one or more repeating sections of:

- ***Label*** (20 bits) — Label value.
- ***Exp*** (3 bits) — QoS TC (Traffic Class) and ECN (Explicit Congestion Notification).
- ***S*** (1 bit) — Bottom-of-Stack flag, if set indicates the last label in the stack.
- ***TTL*** (8 bits) — Time-to-Live.

An MPLS header normally follows the L2 section of the frame, preceding the L3 section (the IP header). The L3 protocol following the last MPLS label is identified by the first nibble as either IPv4 (nibble equals "4") or IPv6 (nibble equals "6").

On top of outer MPLS, the E810 supports MPLSoGRE (MPLS over GRE) and MPLSoUDP (MPLS over UDP).

A.5.3 Layer 3

A.5.3.1 IPv4

The frame format of an IPv4 datagram is illustrated in Figure A-14.

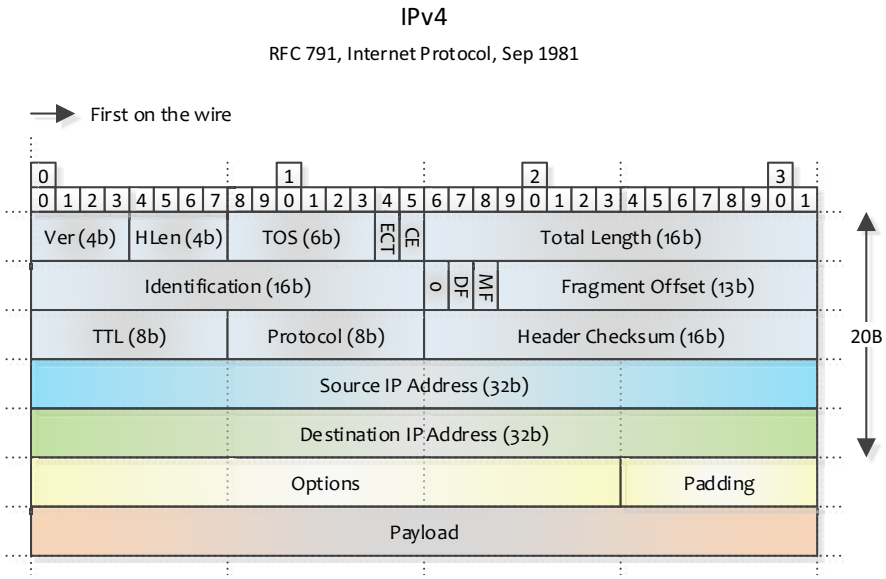

Figure A-14. IPv4 Header Format

- ***Ver*** (Version) (4 bits) — The *Version* field is set to 0x4 for IPv4 header.
- ***HLen*** (Header Length) (4 bits) — The length of the IP header defined in DWord units.
- ***TOS*** (Type of Service) (6 bits) — The *TOS* field is used to indicate the quality of service.
- IP Congestion Flags (2 bits): **CE**, **ECT**
- ***Total Length*** (16 bits) — The *Total Length* is the size of the IP datagram (IP header and payload) in byte units.

- ***Identification*** (16 bits) — The *Identification* field identifies a specific IP packet sent between a source and destination node. The sending host sets the *Identification* field's value, and the field is incremented for successive IP datagrams. The *Identification* field is used to identify multiple fragments of an original IP datagram.
- Fragment Parameters (3 bits):
  - — ***O*** (Fragment Offset) flag
  - — ***DF*** (Disable Fragmentation) flag
  - — ***MF*** (More Fragments) flag
- ***TTL*** (Time-to-Live) (8 bits)— The *TTL* field indicates the number of links that this IP datagram can travel before an IP router discards it.
- ***Protocol*** (Next Header) (8 bits) — The *Protocol* field indicates the next protocol encapsulated within the IP layer.
- ***Header Checksum*** (16 bits) — The *Header Checksum* field is a 16-bit one's complement of the one's complement sum of all 16-bit words in the IP header.
- ***Source and Destination IP Addresses*** — 2 x 32 bit IP Addresses.

Table A-5 describes the processing done to validate IPv4 packets:

Table A-5. IPv4 Packet Structure Validation

Field	Value	Action	Comment
Version/HDR Length	0x4	Check	Check IPv4.
Type of Service	-	Ignore	
Packet Length	-	Ignore	
Identification	-	Ignore	
Fragment Info	-	Ignore	
Time-to-Live	-	Ignore	
Protocol	Multiple	Compare	By the parse graph.
Header Checksum	-	Ignore	Protocol validation does not depend on the header checksum.
Source IP Address	-	Ignore	
Destination IP Address	-	Ignore	

A.5.3.2 IPv6

The frame format of an IPv6 datagram is illustrated in Figure A-15.

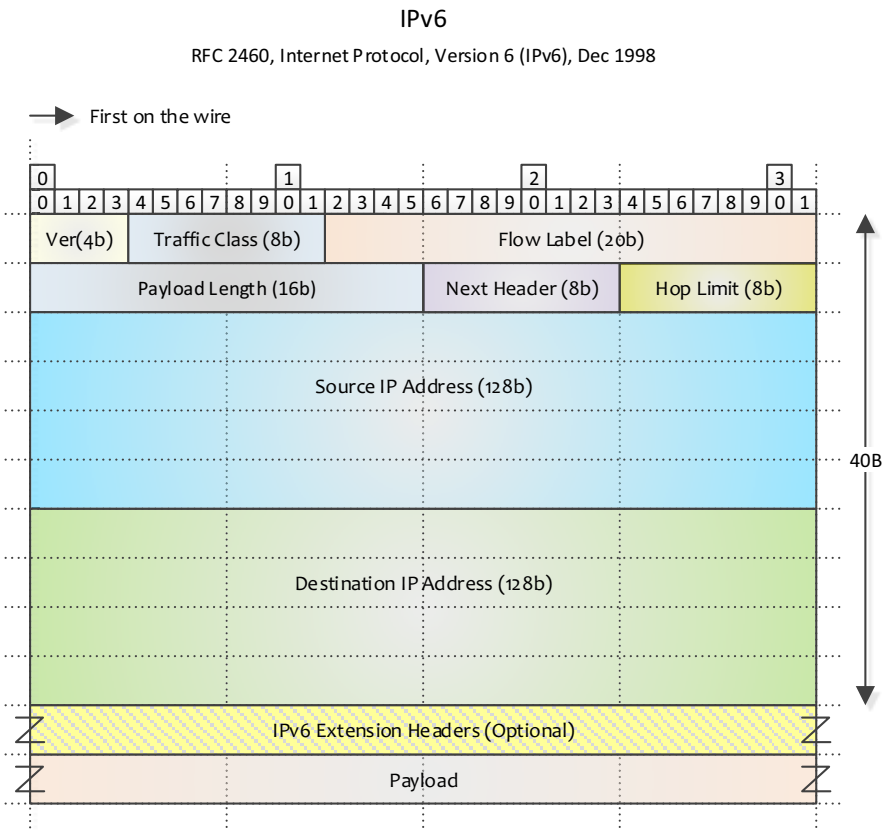

Figure A-15. IPv6 Header Format

- ***Ver*** (Version) (4 bits) — The *Version* field is set to 0x6 for IPv6 header.
- ***Traffic Class*** (8 bits)— The *Traffic Class* is used for QOS support.
- ***Flow Label*** (20 bits) — The *Flow Label* is used for QOS support.
- ***Payload Length*** (16 bits) — The length of the IPv6 payload. That is, the rest of the packet following the IPv6 header, in byte units. Note that any IPv6 extension headers are considered part of the payload.
- ***Next Header*** (Protocol) (8 bits) — The *Next Header* field indicates the next protocol encapsulated within the IP layer.
- ***Hop Limit*** (TTL) (8 bits) — The *Hop Limit* indicates the number of links that this IP datagram can travel before an IP router discards it.
- ***Source and Destination IP Addresses*** — 2 x 128 bit IP Addresses.

Table A-6 describes the processing done to validate IPv6 packets:

Table A-6. IPv6 Packet Structure Validation

Field	Value	Action	Comment
Version	0x6	Check	Check IPv6.
Traffic Class	-	Ignore	
Flow Label	-	Ignore	
Payload Length	-	Ignore	
Next Header	Multiple	Compare	By the parse graph.
Hop Limit	-	Ignore	
Source IP Address	-	Ignore	
Destination IP Address	-	Ignore	

A.5.3.3 IPv6 Extension Headers

The IPv4 option headers that are included as part of the IP header are replaced in IPv6 by separate extension headers per option. Table A-7 lists those most used IPv6 extension and their recommended ordering in the packet. Then these extension headers are illustrated in Figure A-16 through Figure A-21.

Table A-7. IPv6 Extension Headers and Their Recommended Ordering

Header (Protocol)	Next Header Value	Header Length and Header Length Field Offset
Hop-by-Hop Options	0	Variable length field defined in 8-byte units excluding the first 8 bytes.
Routing Header	43	Variable length field defined in 8-byte units excluding the first 8 bytes.
Fragment Header	44	Length is always 8 bytes. The E810 does not continue to parse the rest of the packet.
Encapsulating Security Payload	50	Length is 8 bytes plus variable length of Initial Value plus a trailer. When this header is found, the E810 does not continue to parse the rest of the packet. Applicable to IPv4 as well.
Destination Options	60	Variable length field defined in 8-byte units excluding the first 8 bytes.
Mobility Header	135	Variable length field defined in 8-byte units excluding the first 8 bytes.
No Next Header	59	When no next header type is found, the rest of the packet is not processed.

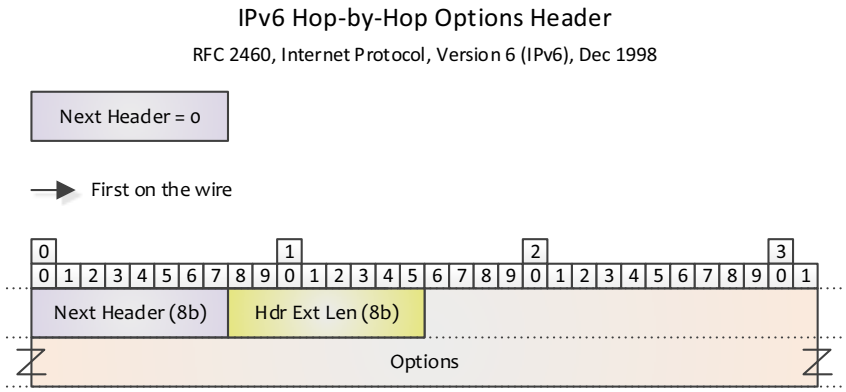

Figure A-16. IPv6 Hop-by-Hop Extension Header

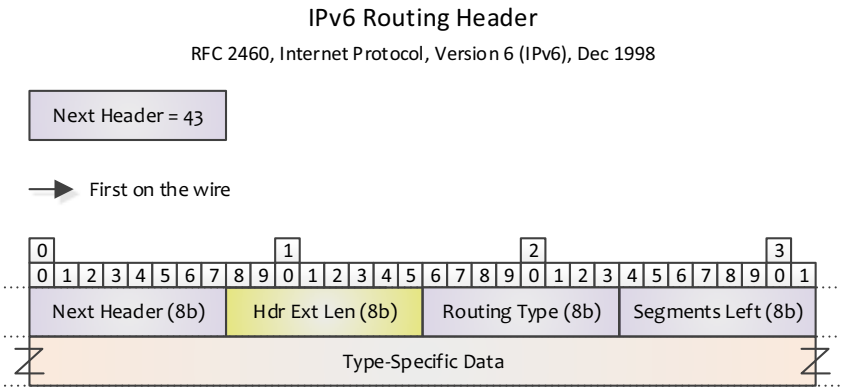

Figure A-17. IPv6 Routing Header

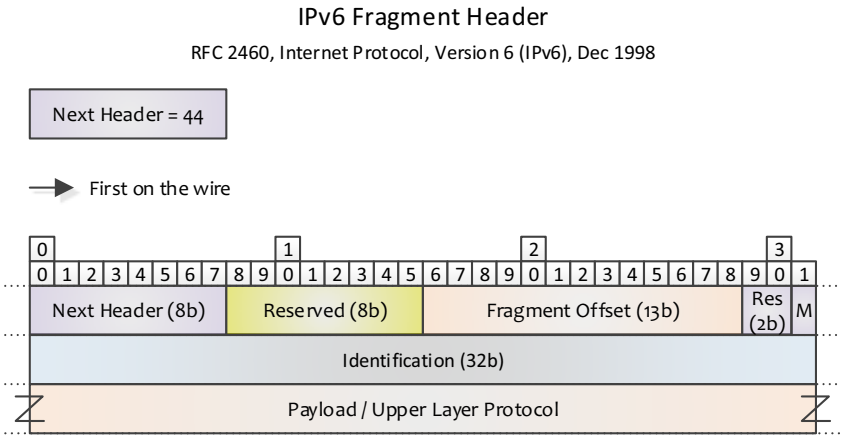

Figure A-18. IPv6 Fragment Header

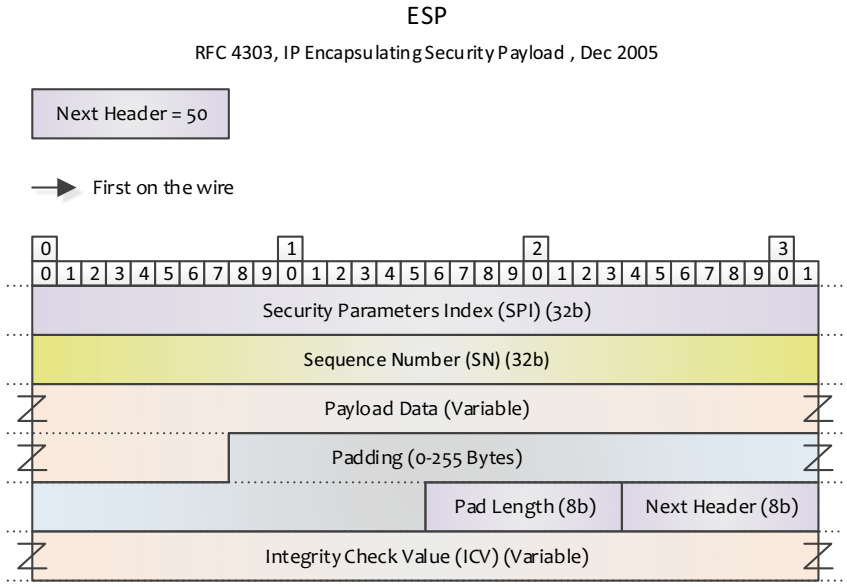

Figure A-19. Encapsulating Security Payload (ESP)

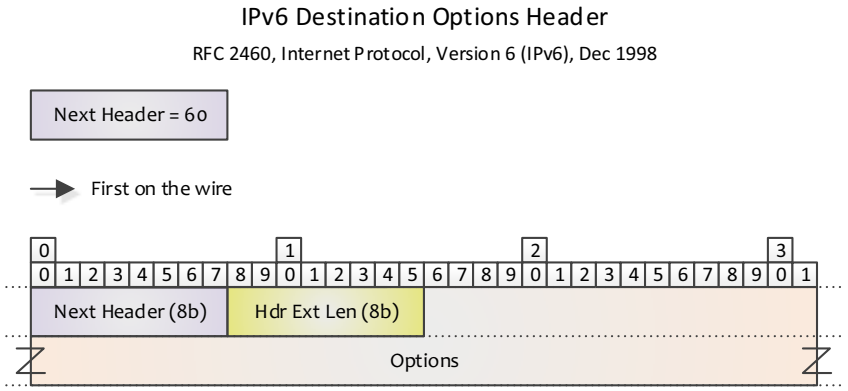

Figure A-20. IPv6 Destination Options

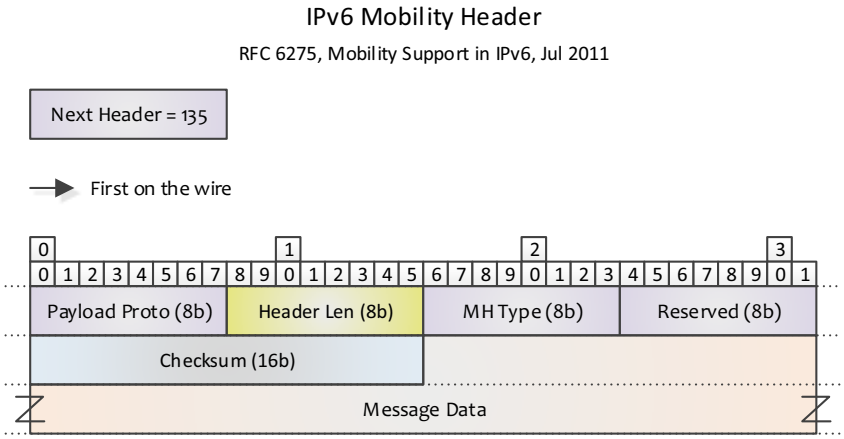

Figure A-21. IPv6 Mobility Header

A.5.3.3.1 Protocol Headers (Next Header)

Table A-8 lists the encoding of the *Next Header Type* field and information on determining each header type's length recognized by the E810.

Table A-8. Header Type Encoding and Lengths

Header (Protocol)	Next Header Value	Header Length and Header Length Field Offset
IPv4	4	Length Field is at bits[7:4], defined in 4-byte units.
IPv6	41	Length is always 40 bytes.
Encapsulating Security Payload	50	Length is 8 bytes plus variable length of Initial Value plus a trailer.
TCP	6	Length field is at Byte 12, Bits [7:4], defined in 4-byte units.
UDP	17	Length is always 8 bytes.
ICMP	1	Length is always 8 bytes.
ICMPv6	58	Length is always 4 bytes.
SCTP	132	Length is always 12 bytes.
VRRP	112	Virtual Router Redundancy Protocol ***Note:*** In Factory Parse Graph only over IPv4.
OSPFv3	89	Open Shortest Path First Version 3 (covered in RFC 5340) ***Note:*** In Factory Parse Graph only over IPv4.
No Next Header	59	When no next header type is found, the rest of the packet is not processed.

A.5.3.4 Internet Control Message Protocol (ICMP)

ICMP packets are used as part of the manageability filtering. The ICMP header structure is illustrated in Figure A-22.

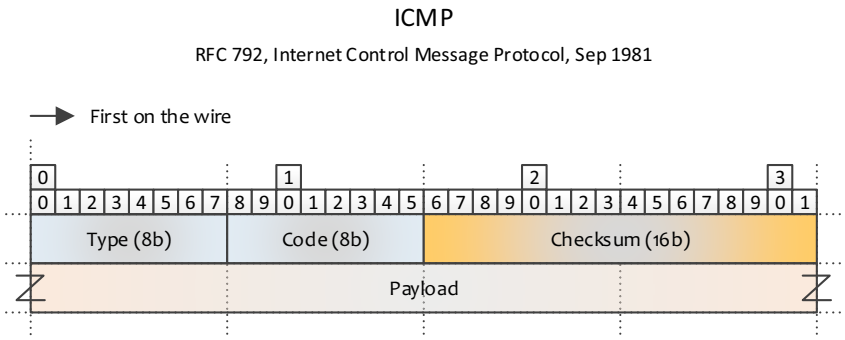

Figure A-22. ICMP Header Structure

Note: The E810 parser does not parse into the ICMP header and only detects the IPv4 *Next Protocol* as ICMP.

Table A-9. ICMP Packet Structure and Processing

Field	Value	Action	Comment
Preceding Protocol Header	IPv4	Check	Enforced by the parse graph.
ICMP type	-	Ignore	
ICMP Code	-	Ignore	
ICMP Header Checksum	-	Ignore	
ICMP Payload	-	Ignore	

A.5.3.5 ICMPv6

ICMPv6 packets are used as part of the manageability filtering and as part of proxy capabilities. The ICMPv6 header structure is illustrated in Figure A-23.

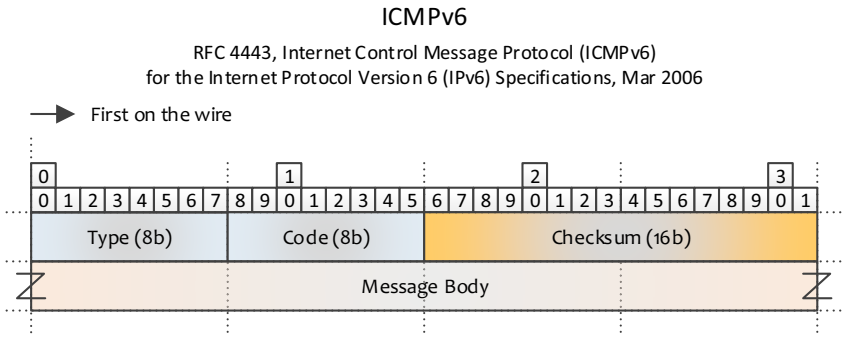

Figure A-23. ICMPv6 Header Structure

Note: The E810 parser detects ICMPv6 by evaluating the *Next Header* field following IPv6 header with optionally more Extension Headers.

The E810 supports the following ICMPv6 packets:

- Neighbor Discovery packets:
  - 0x86 (134d) - Router Advertisement.
  - 0x87 (135d) - Neighbor Solicitation.
  - 0x88 (136d) - Neighbor Advertisement.
  - 0x89 (137d) - Redirect.
- MLD packets:
  - 0x82 (130d) - MLD Query
  - 0x83 (131d) - MLDv1 Report
  - 0x84 (132d) - MLD Done
  - 0x8F (143d) - MLDv2 Report

Table A-10 describes the processing done to validate ICMPv6 packets:

Table A-10. ICMPv6 Packet Structure and Processing

Field	Value	Action	Comment
Preceding L3 Protocol Header	IPv6	Check	Enforced by the parse graph.
Type	0x82, 0x83, 0x84, 0x86, 0x87, 0x88, 0x89, or 0x8F	Compare	Multicast Listener Discovery (MLD) or Neighbor Discovery types.
Code	0x0	Ignore	
Checksum		Ignore	
Message Body		Ignore	

A.5.3.6 Virtual Router Redundancy Protocol (VRRP)

Virtual Router Redundancy Protocol (VRRP), defined in RFC 5798, specifies an election protocol that dynamically assigns responsibility to one of the VRRP routers on a LAN. The "master" router controls the IP Address(es) associated with a virtual router. Forwarded packets are sent to these IP Addresses. VRRP provides a higher availability and reliability of default path without requiring configuration of dynamic routing or router discovery protocols on every end-host.

The purpose of the VRRP packet is to communicate to all VRRP routers the priority and the state of the Master router associated with the Virtual Router ID. VRRP packets are sent encapsulated in IP packets.

- The IPv4 multicast address assigned for VRRP is **224.0.0.18**.
- The IPv6 multicast address assigned for VRRP is **FF02:00:00:00:00:00:00:12**.
- The TTL must be set to **255**.

  Note: A VRRP router receiving a packet with the TTL not equal to 255 MUST discard the packet.
- The IPv4 protocol number/IPv6 Next Header protocol assigned to VRRP is **112**.

Note: The factory parsing configuration must use the next protocol as the only means of detecting a VRRP header and must not perform any validation checks on the header or preceding header related to this protocol.

The VRRP packet format is illustrated in Figure A-24.

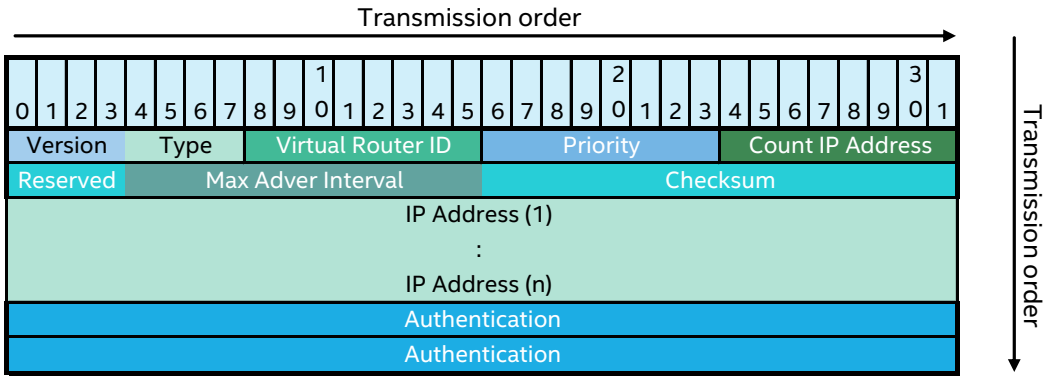

Figure A-24. VRRP Header

- ***Version*** — 4-bit field that specifies the VRRP protocol version of the packet. This specification describes version 3.
- ***Type*** — 4-bit field that specifies the type of the packet. In this version (2), only type number one (ADVERSTISEMENT) is defined. A packet with another type number has to be discarded.
- ***Virtual Router ID*** — 8-bit field that identifies the virtual router this packet is reporting status for. This is a configurable item in the range of 1-255 (decimal). There is no default value.
- ***Priority*** — 8-bit (unsigned integer) field that specifies the sending VRRP router's priority for the virtual router. The higher the value, the higher the priority. For the VRRP router that owns the IP Address(es) associated with the virtual router, priority is 255 (decimal value). This is the "Master".
  - — VRRP routers backing up a virtual router must use priority values, between 1 to 254 (decimal). The default priority value is in this case 100 (decimal).
  - — The priority value zero means that the current Master has stopped participating in VRRP. It is used to effectuate quickly the exchange of master. (We do not have to wait for the current Master to timeout).
- ***Count IP Address*** — 8-bit field that indicates the number of IP Addresses contained in this VRRP advertisement.
- ***Authentication Type*** — 8-bit (unsigned integer) field that identifies the authentication method used. Authentication type is unique on a Virtual Router basis. If a packet has an unknown authentication type or does not match the local authentication, it must be discarded.

  The authentication methods currently defined are:

  - — 0 = No Authentication — VRRP protocol exchanges are not authenticated. The *Authentication Data* field should be set to zero on transmission and ignored on reception.
  - — 1 = Reserved.
  - — 2 = Reserved.

  Types number 1 and 2 are reserved to maintain backward-compatibility with earlier version of VPPR (RFC 2338).

- ***Max Advertisement Interval*** (Adver Int) — 12-bit field that indicates the time interval (in centiseconds) between ADVERTISEMENTS. The default value is 100 centisecond (1 second). It is used for troubleshooting mis-configured routers.
- ***Checksum*** — 16-bit field that is used to detect data corruption in the VRRP message. It is the complement of complement sum of the entire VRRP message starting with the *Version* field (for computing the checksum, the *Checksum* field is set to zero).
- ***IP Address(es)*** — There are one or more IP Addresses associated with the virtual router. Each address length depends on whether it is an IPv4 or IPv6 Address. The number of IP Addresses is specified by the *Count IP Address* field. A mix of IPv4 and IPv6 Addresses is not allowed in the same VRRP header
- ***Authentication Data*** — Two strings of 32 bits each. Currently only used to maintain backward-compatibility with RFC 2338. It should be set to 0 on transmission and ignored at reception.

A.5.3.7 Open Shortest Path First (OSPF)

Open Shortest Path First (OSPF) runs directly over the IP network layer. Thus, OSPF packets are encapsulated just by IP and local data-link headers.

OSPF does not define how to fragment its packets. Rather, it depends on IP fragmentation when transmitting the packets. Therefore, it is recommended to limit the size of packets sent over virtual links to 576 bytes (if it is necessary, can be up to 65,535 bytes, including the IP header).

- One of the important feature of OSPF's IP encapsulation is the use of IP multicast. For that matter, two different IP multicast addresses are used:
  - AllSPFRouters (value address: 224.0.0.5) — Every router running OSPF should be prepared to receive packets from this address. (Hello packets, one of the five types of OSPF packets, are always sent to this destination).
  - AllDRouters (value address: 224.0.0.6) — Designated and Backup Designated Router must be prepared to receive packets destined to this address. Also, certain OSPF packets are sent to those addresses during the flooding procedure.

  Packets sent to multicast addresses are meant to travel a single hop only (IP TTL= 1).
- The IP protocol number assigned to OSPF is **89**.
- Routing protocol packets are sent with IP TOS of 0. The OSPF protocol supports TOS-based routing. All OSPF routing protocol packets are sent using the normal service TOS value of binary 0000.
- OSPF protocol packets should be given precedence over regular IP data traffic (in sending and receiving). Setting the *IP Precedence* field in the IP header to *Internetwork Control* helps implement this objective.

There are five types of OSPF packets. All of them starts start with a common 24-byte header.

The OSPF header format is illustrated in Figure A-25.

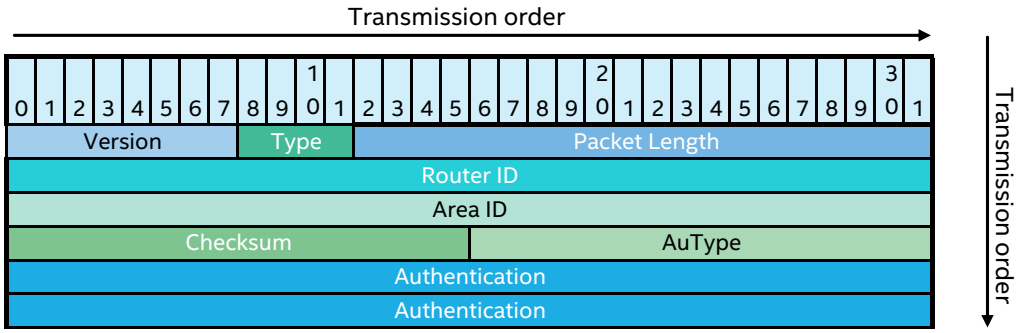

Figure A-25. OSPF Header Format

- ***Version*** — 8-bit field that indicates the version of the protocol. This section describes version 2, which is the only one supported in the factory configuration and is only relevant for IPv4.
- ***Type*** — The type of the OSPF packet: number 1 to 5.
  - — 1 = Hello
  - — 2 = Database Description
  - — 3 = Link State Request
  - — 4 = Link State Update
  - — 5 = Link State Acknowledgment
- ***Packet Length*** — 20-bits field used for the length in bytes of the packet. It includes the standard the standard OSPF header.
- ***Router ID*** — 32-bit field that indicates the Router ID of the packet's source. It is important because in OSPF, source and destination of a routing packet are the two ends of an (potential) adjacency.
- ***Area ID*** — 32 -bit field identifying the area that this packet belongs to. OSPF are associated with a single area. If packets are traveling over a virtual link, the area ID is 0.0.0.0.
- ***Checksum*** — 16-bit that indicates the standard IP checksum of the all packets. It starts with the OSPF packet header and excludes the 64-bit *Authentication* field. It is calculated as the complement of the complement sum of the 16-bit words in the packet (except authentication field). The packet is padded with a zero byte if the packet's length is not an integral number of 16-bit words before summing.
- ***AuType*** — 16-bit field that indicates the authentication scheme.
- ***Authentication*** — 64-bit field used by the authentication scheme.

A.5.3.8 Address Resolution Protocol (ARP)

ARP packets are used as part of the manageability filtering and as part of the proxy capabilities.

Figure A-26 describes the ARP packets structure.

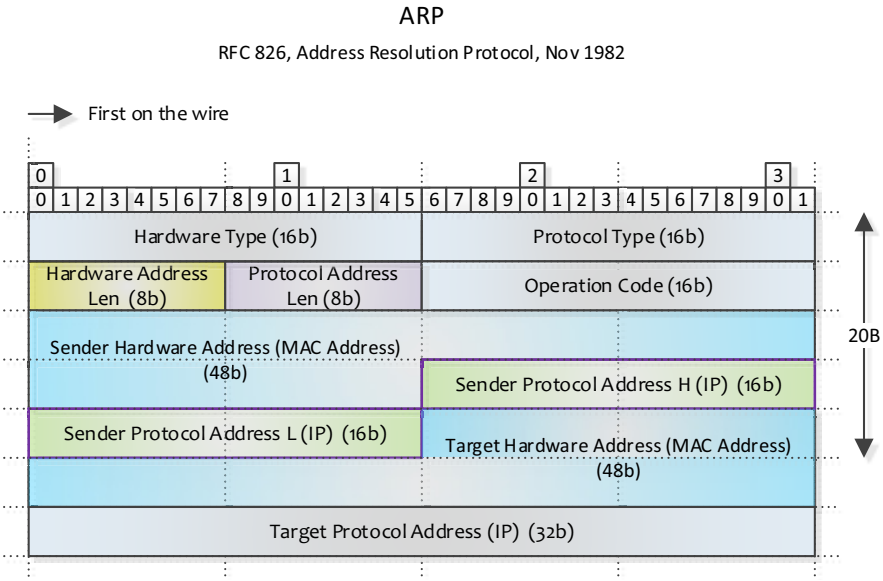

Figure A-26. ARP Packet Structure

Table A-11. ARP Packet Structure and Processing

Field	Value	Action	Comment
Preceding EtherType	0x0806	Compare	ARP.
Hardware Type	0x0001	Compare (by firmware)	Ethernet Hardware type.
Protocol Type	0x0800	Compare (by firmware)	IPv4 Protocol.
Hardware Size	0x06	Compare (by firmware)	MAC Address size in bytes.
Protocol Address Length	0x04	Compare (by firmware)	IPv4 Address size in bytes.
Operation	0x0001/0x0002	Compare (by firmware)	0x0001 = Request 0x0002 = Response
Sender Hardware Address	-	Ignore	
Sender IP Address	-	Ignore	
Target Hardware Address	-	Ignore	
Target IP Address	IP4AT	Compare (by firmware)	Use to decide of an IP match of ARP packets.

Note: The Parser identifies ARP by its ETYPE. Further validation is performed by firmware when processing the ARP packet.

A.5.4 Layer 4

A.5.4.1 User Datagram Protocol (UDP)

The UDP header structure is illustrated in Figure A-27.

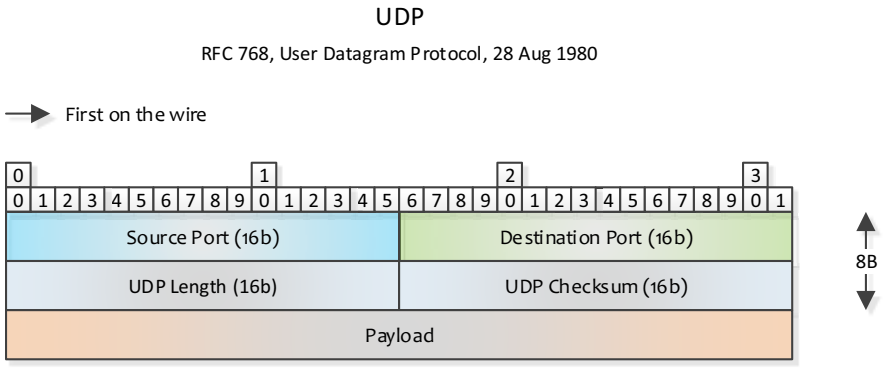

Figure A-27. UDP Packet Format

- ***Source Port*** (16 bits) — Source port number.
- ***Destination Port*** (16 bits) — Destination port number.
- ***UDP Length*** (16 bits) — The length of the entire UDP datagram, including both header and Data fields defined in byte units.
- ***UDP Checksum*** (16 bits) — An optional one's complement of the one's complement sum of all 16-bit words in the header and payload and a "pseudo header" illustrated in the figures above.

On the transmit flow, the OS stack provides the "pseudo header" checksum in the *UDP Checksum* field when requesting from the NIC to offload the checksum calculation.

Table A-12. UDP Header Structure

Field	Value	Action	Comment
Source UDP Port	XXXX	Ignore	Source UDP port number could be any value.
Destination UDP Port	VXLAN Port	Compare	Per the list of supported protocols over UDP.
UDP Length	XXXX	Ignore	Length of the entire datagram including the UDP header.
UDP Checksum	XXXX	Check	Provide an indication if the checksum equals to zero (i.e., no checksum).

Table A-13 lists the factory preset UDP Destination Port values.

Table A-13. Factory Preset UDP Destination Port Values

UDP Destination Port	Protocol	Notes
4789	VXLAN	
4790	VXLAN-gpe	
6081	Geneve	
2152	GTPu (GTPv1-U)	

Table A-13. Factory Preset UDP Destination Port Values [continued]

UDP Destination Port	Protocol	Notes
4791	RoCEv2	IANA assigned The factory parsing program supports up to two configurable UDP ports per physical port for identifying RoCEv2 packets. The value mentioned in this table is the IANA assigned port but the software might use an additional and/or different number (for example, 1021 - the legacy RoCEv2 port).
6635	MPLS over UDP	Covered in RFC 7510

A.5.4.1.1 UDP Pseudo-Header

The UDP pseudo-header structure is illustrated in Figure A-28 and Figure A-29.

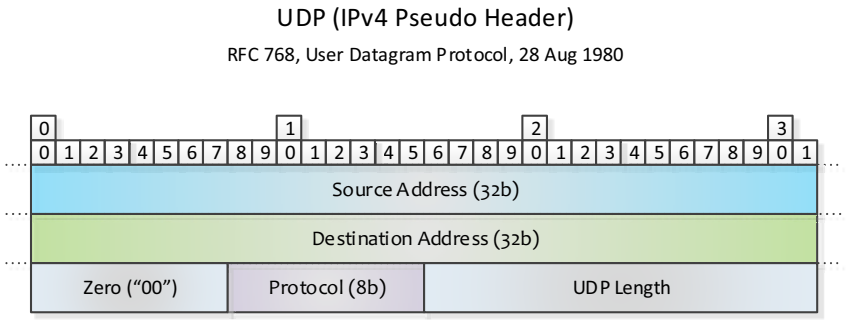

Figure A-28. IPv4 Pseudo-Header for UDP Checksum

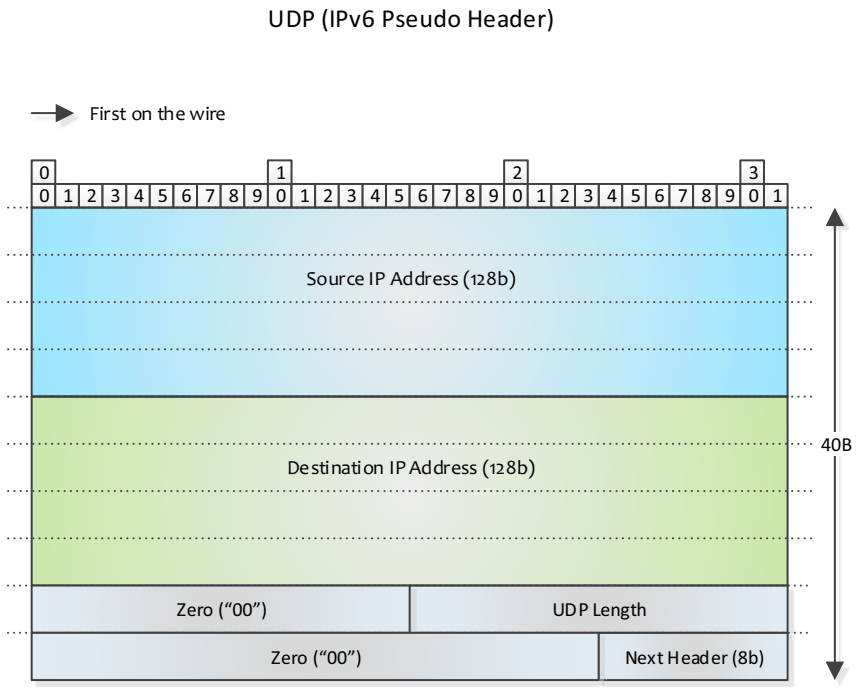

Figure A-29. IPv6 Pseudo-Header for UDP Checksum

A.5.4.2 Transmission Control Protocol (TCP)

The TCP header structure is illustrated in Figure A-30.

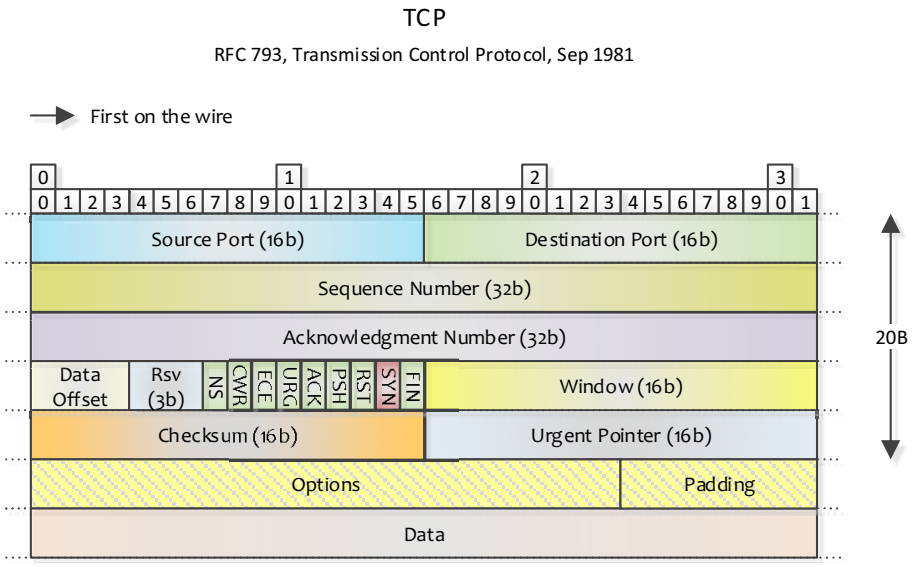

Figure A-30. TCP Packet Format

- ***Source Port*** (16 bits) — Source port number.
- ***Destination Port*** (16 bits) — Destination port number.
- ***Sequence Number*** (32 bits) — The sequence number of the first data octet in this segment (except when SYN is present). If SYN is present the sequence number is the initial sequence number (ISN) and the first data octet is ISN+1.
- ***Acknowledgment Number*** (32 bits) — If the *ACK* control bit is set, this field contains the value of the next sequence number the sender of the segment is expecting to receive. Once a connection is established this is always sent.
- ***Window Size*** (16 bits) — The number of data octets beginning with the one indicated in the *Acknowledgment* field which the sender of this segment is willing to accept.
- TCP Flags (9 bits) — **FIN**, **SYN**, **RST**, **PSH**, **ACK**, **URG**, **ECE**, **CWR**, **NS**.
- ***Header Length*** (4 bits) — The number of DWords in the TCP Header. This indicates where the data begins. The TCP header (including TCP options) is always an integral number of 32 bits long.
- ***Urgent Pointer*** (16 bits) — This field communicates the current value of the urgent pointer as a positive offset from the sequence number in this segment. The *Urgent Pointer* points to the sequence number of the octet following the urgent data. This field is only be interpreted in segments with the *URG* control bit set.
- ***TCP Checksum*** (16 bits) — The *Checksum* field is the 16-bit one's complement of the one's complement sum of all 16-bit words in the header and payload and the "pseudo header" illustrated in the figures above.

  Note: On the transmit flow, the OS stack provides the "pseudo header" checksum in the TCP *Checksum* field when requesting from the NIC to offload the checksum calculation.

A.5.4.2.1 TCP Pseudo-Header

The TCP pseudo-header structure is illustrated in Figure A-31 and Figure A-32.

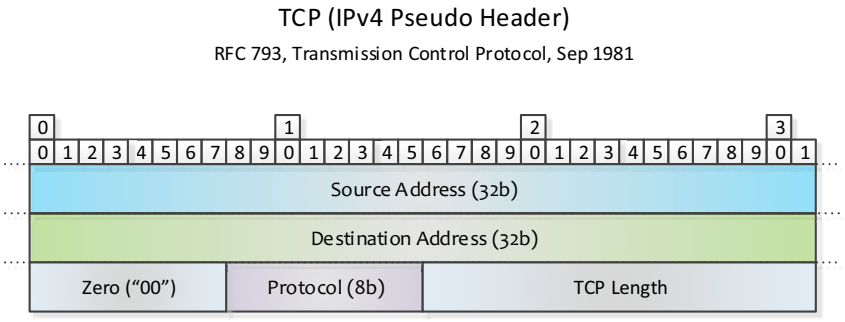

Figure A-31. IPv4 Pseudo-Header for TCP Checksum

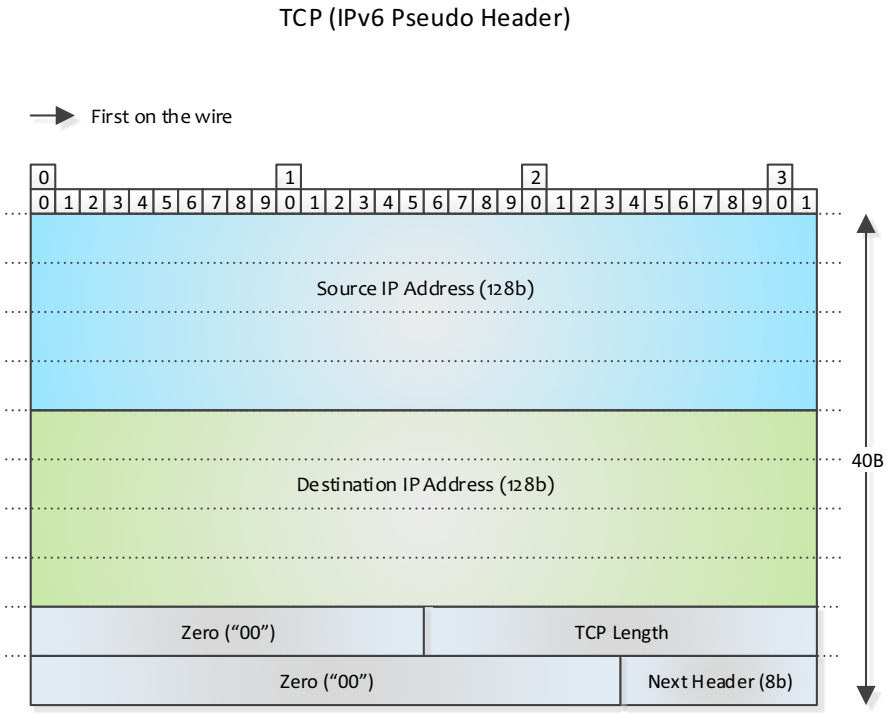

Figure A-32. IPv6 Pseudo-Header for TCP Checksum

A.5.4.3 Stream Control Transmission Protocol (SCTP)

The SCTP header structure is illustrated in Figure A-33.

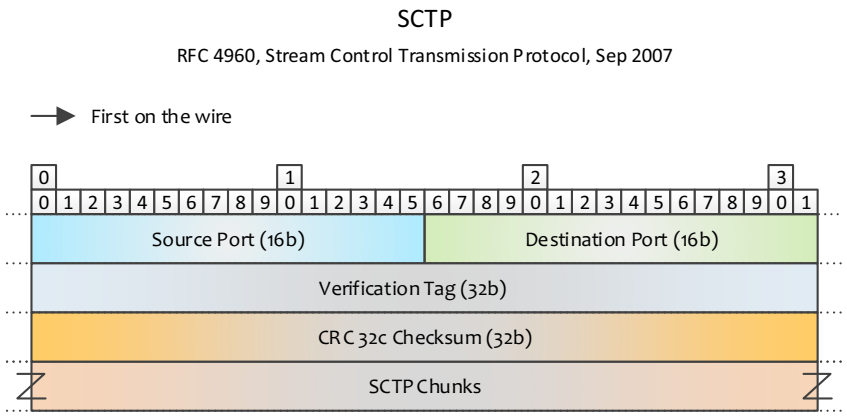

Figure A-33. SCTP Packet Structure

- ***Source Port*** (16 bits) — Source port number.
- ***Destination Port*** (16 bits) — Destination port number.
- ***Verification Tag*** (32 bits) — Random value selected by each endpoint in an association during setup. It is used to discriminate between two successive associations, as well as a protection mechanism against blind attackers.
- ***CRC Integrity*** — CRC32c integrity checksum covering the entire SCTP packet (SCTP header and all chunks). the CRC32c is the same polynomial used for iSCSI as follow: $1 + x + x^2 + x^4 + x^5 + x^7 + x^8 + x^{10} + x^{11} + x^{12} + x^{16} + x^{22} + x^{23} + x^{26} + x^{32}$. The CRC bytes are transmitted on the network in big endian ordering while the MS bytes is first on the wire.

A.5.5 Tunneling and Overlay Networks

The factory parsing program in the E810 supports the following tunneling and overlay networks formats:

- MAC-in-MAC
- IP-in-IP: IPv4/IPv4, IPv4/IPv6, IPv6/IPv4, IPv6/IPv6
- NSH (Service Chaining): NSHoE, NSHoGRE, NSHoVXLANgpe
- VXLAN (MAC-in-UDP), VXLAN-gpe
- GRE
- Geneve
- MPLSoGRE, MPLSoUDP
- IPSEC NAT-T
- GTP

A.5.5.1 Generic Routing Encapsulation (GRE)

The GRE header structure is illustrated in Figure A-34.

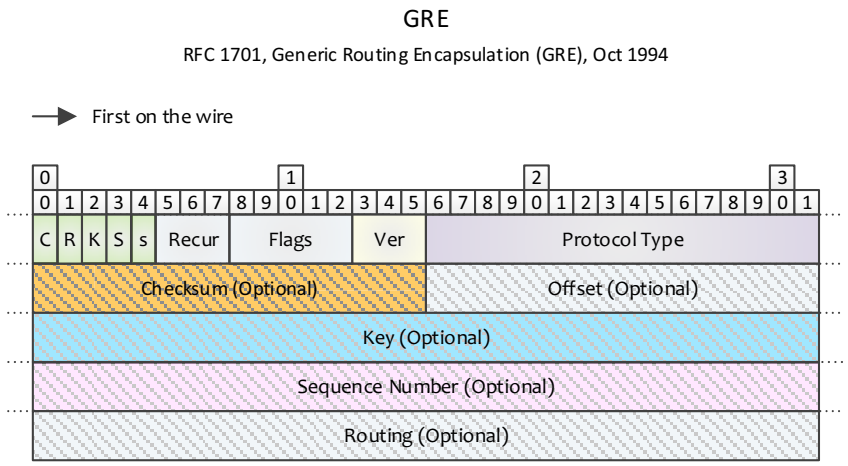

Figure A-34. GRE Header Structure (RFC 1701)

The GRE header is indicated by IP protocol equals to 47 (0x2F). The GRE headers supported by the E810 can be 1, 2, 3 or 4 DWords depending on the flags in the first byte.

- ***C*** (Checksum Present) (1 bit) — When set, it indicates that the *Checksum* field is present and contains valid information. If either the *Checksum Present* bit or the *Routing Present* bit are set, the *Checksum* and *Offset* fields are both present.
- ***R*** (Routing Present) (1 bit) — GRE header with routing header is not supported by the E810. If this flag is found active the header is not recognized by the device.
- ***K*** (Key Present) (1 bit) — If set, the *Key* field is present and contains valid information.
- ***S*** (Sequence Number) (1 bit) — If set then the *Sequence Number* field is present and contains valid information. The E810 ignores this flag other than an indication for the length of this header.
- ***s*** (Strict Source Route) (1 bit) — It is recommended that this bit only be set if all of the Routing Information consists of Strict Source Routes. The E810 ignores this flag.
- ***Recur*** (Recursion Control) (3 bits) — Contains the number of additional encapsulations that are permitted. The E810 supports only GRE header with no recursion headers (Recursion Control equal to zero).
- ***Ver*** (Version) (3 bits) — GRE protocol version. Zero value identifies a GRE header version zero. The E810 supports only zero value. (Note that version 1 is used for PPP protocol.)
- ***Protocol Type*** (16 bits) — Contains the protocol type of the payload packet. In general, the value is the *Ethernet Protocol Type* field for the packet. The following values are supported by the E810. Packet parsing that might have other protocol values is undefined.
  - — IPv4 0x0800
  - — IPv6 0x86DD
  - — MPLS 0x8847 (unicast MPLS)
  - — MAC 0x6558 (MAC-in-GRE)

— NSHoGRE 0x894F

- ***Checksum*** (16 bits) — Contains the IP (one's complement) checksum of the GRE header and the payload packet. This field is not processed by the E810.
- ***Offset*** (16 bits) — Indicates the byte offset from the start of the *Routing* field to the first byte of the active Source Route Entry to be examined. This field is not processed by the E810.
- ***Key*** (32 bits) — Contains a number that was inserted by the encapsulator. It can be used by the receiver to authenticate the source of the packet. The GRE Key is used for VSI classification if enabled by the switch filters.
- ***Sequence Number*** (32 bits) — Contains a number that is inserted by the encapsulator. It can be used by the receiver to establish the order in which packets have been transmitted from the encapsulator to the receiver. This field is not processed by the E810.
- ***Routing*** (variable length) — This field is a list of SREs and is not supported by the E810.

A.5.5.2 Virtual Extensible Local Area Network (VXLAN)

The VXLAN header format is illustrated in Figure A-35.

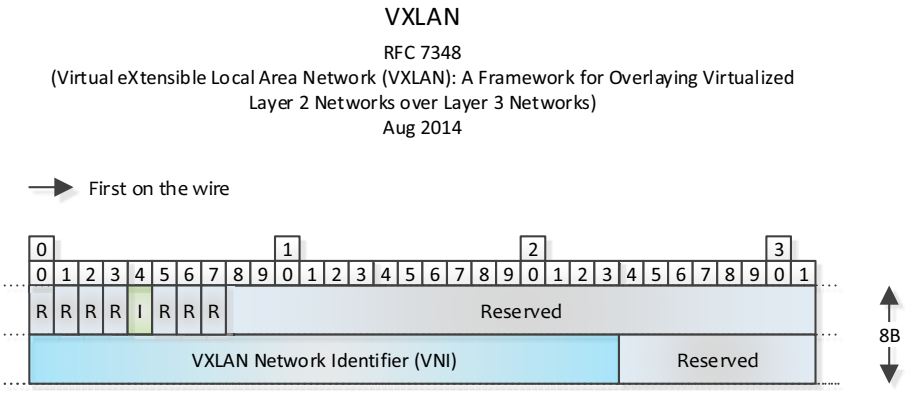

Figure A-35. VXLAN Header Structure

VXLAN comes on top of a UDP header with reserved destination port = 4789 (0x12B5). The E810 allows programming of the VXLAN port.

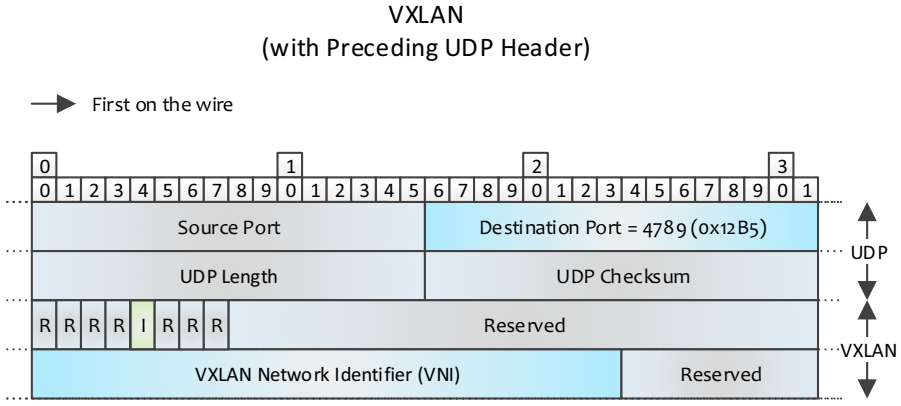

Figure A-36. VXLAN over UDP

Table A-14. VXLAN Header Structure

Field	Value	Action	Comment
Destination UDP Port	VXLAN Port	Compare	The reserved VXLAN port number is programmed by the Add "Tunneling UDP" admin command.
Flags	0x08	Ignore	I = VNI valid indication.
Reserved	XXXX	Ignore	Reserved.
VXLAN Network Identifier	XXXX	Compare	Tenant identifier (used in classification).

A.5.5.3 Generic Protocol Extension for VXLAN (VXLAN-GPE)

The VXLAN-GPE header format is illustrated in Figure A-37.

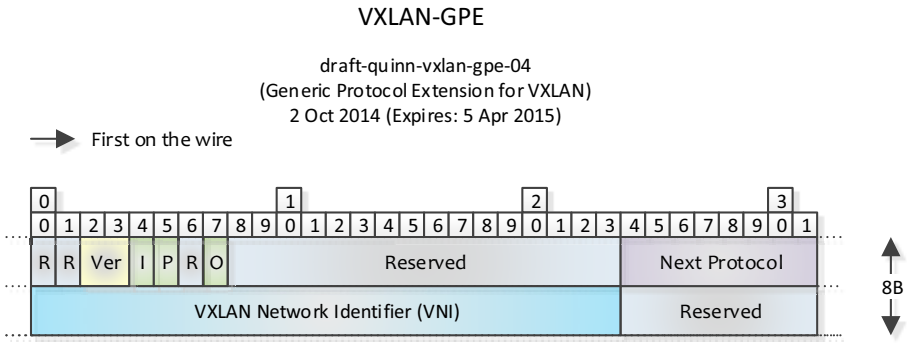

Figure A-37. VXLAN-GPE Header Structure

VXLAN-GPE comes on top of a UDP header with reserved destination port = 4790 (0x12B6). The E810 allows programming of the VXLAN-GPE port.

VXLAN-GPE
(with Preceding UDP Header)

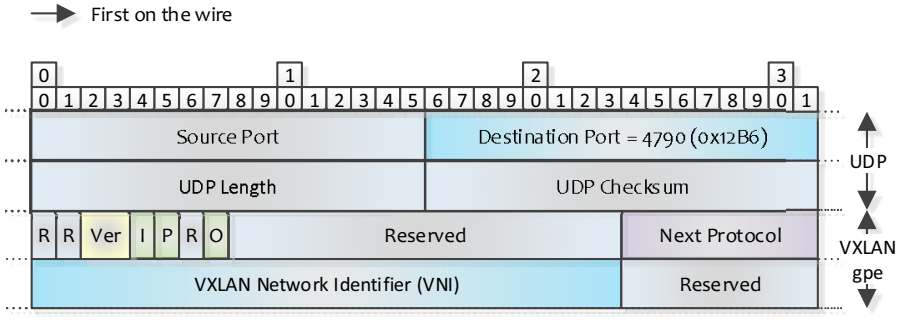

Figure A-38. VXLAN-GPE over UDP

Table A-15. VXLAN-GPE Header Structure

Field	Value	Action	Comment
Destination UDP Port	VXLAN-GPE Port	Compare	The reserved VXLAN port number is programmed by the Add "Tunneling UDP" admin command.
Flags	Ver=0 I=1 P=1 O=Ignore	Compare	Ver = Version = 0 I (Instance) = VNI valid indication = 1 P (Next Protocol) = 1 O (OAM) = Ignore
Reserved	XXXX	Ignore	Reserved.
Next Protocol	XXXX	Check	Next Protocol (according to IETF draft vxlan-gpe-03) 0x1 = IPv4 0x2 = IPv6 0x3 = Ethernet 0x4 = NSH 0x5 = MPLS
VXLAN Network Identifier	XXXX	Compare	Tenant identifier (used in classification).

A.5.5.4 Generic Network Virtualization Encapsulation (Geneve)

The Geneve header format is illustrated in Figure A-39.

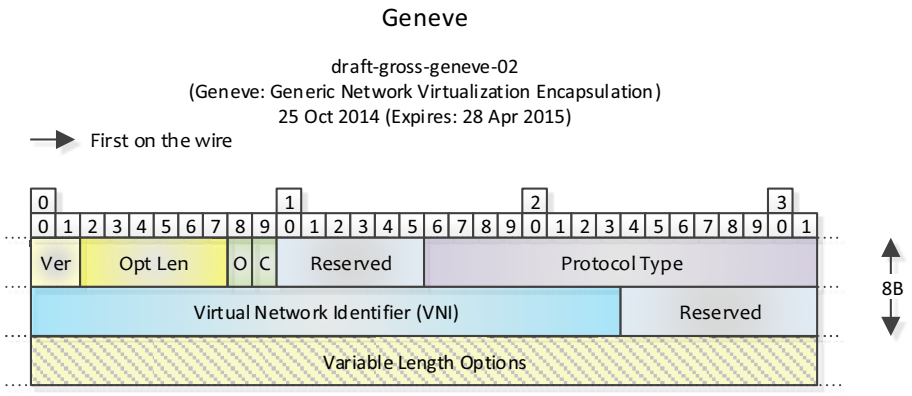

Figure A-39. Geneve Header Structure

Geneve comes on top of a UDP header with destination port = 6081 (0x17C1).

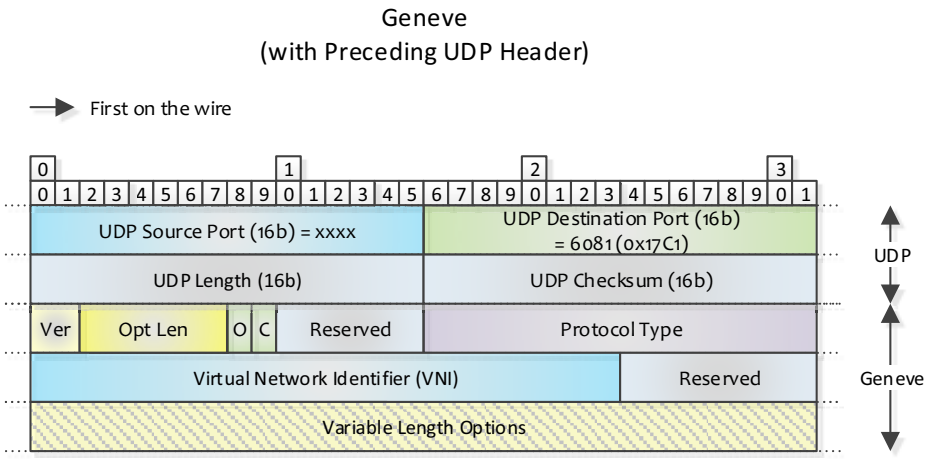

Figure A-40. Geneve over UDP

Table A-16. Geneve Header Structure

Field	Value	Action	Comment
Source UDP Port	XXXX	Ignore	Source UDP port number could be any value.
Destination UDP Port	Geneve Port	Compare	Geneve port number.
UDP Length	xxxx	Ignore	Length of the entire datagram including the UDP header.
UDP Checksum	xxxx	Check	Checksum integrity indication.
Version	00b	Ignore	Geneve version.
O (OAM Frame)	0b	Ignore	
Option Length	Variable	Check	Defines the length of the options fields in 4 byte units. The Parser is using the option length to calculate the total Geneve header length.
C (Critical Options Present)	Variable	Ignore	Expected to be processed by the software stack.
Protocol Type	Variable	Check	Next protocol.
VNI	Variable	Compare	Tenant identifier (used in classification).
Variable Length Options	Variable	Ignore	Length of the *Options* field is defined by the *Option Length* field in this header.

A.5.5.5 RDMA over Converged Ethernet v2 (RoCEv2)

The RoCEv2 packet format is illustrated in Figure A-41.

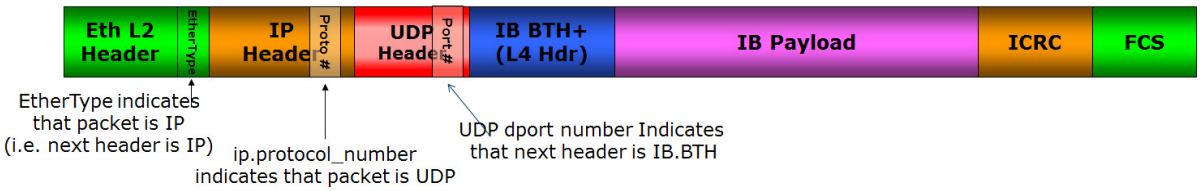

Figure A-41. RoCEv2 Packet Format

The E810 identifies RoCEv2 packets based on their UDP destination port number. Two UDP port numbers are provided per each of the physical Ethernet ports).

A.5.5.6 Network Service Header (NSH)

A Network Service Header (NSH) is used to create network service paths. In addition to path information, this header also carries metadata used by network devices and/or network services.

The NSH basic header structure is shown in Figure A-42.

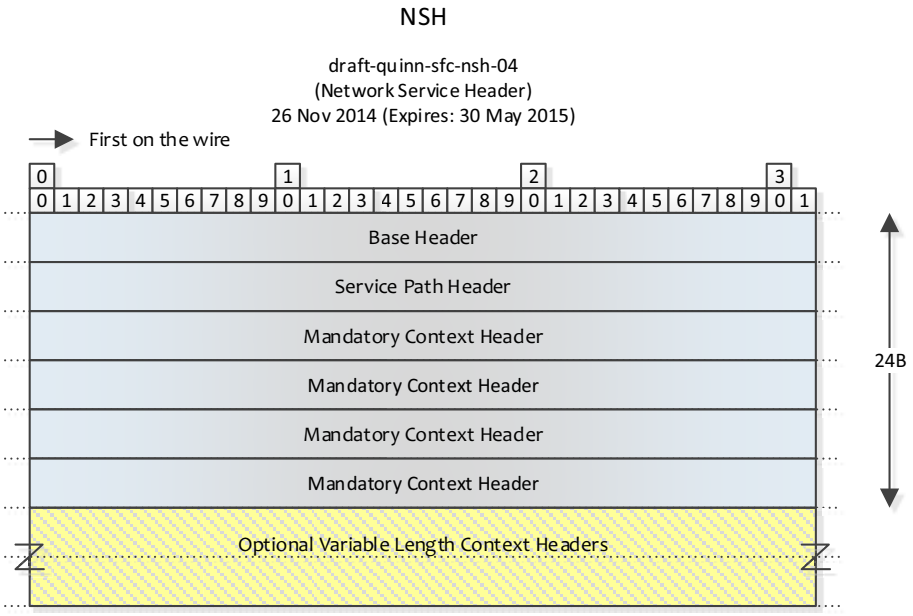

Figure A-42. NSH Basic Header Structure

The NSH header is composed of the following fields:

- ***Base Header*** — Provides information about the service header and service path identification:
  - — Version.
  - — O bit – Indicates that this packet is an operations and management (OAM) packet.
  - — C bit – Context headers MUST be present. When *C* is set, one or more contexts are in use (that is, a value placed in a context is significant). The *C* bit specifies that their ordering and sizing is as specified:
    - Network Platform (32 bits)
    - Network Shared (32 bits)
    - Service Platform (32 bits)
    - Service Shared (32 bits).

    A *C* bit equal to zero indicates that no contexts are in use (although they MUST be present to ensure a fixed size header) and that they can be ignored. If a context header is not in use, the value of that context header MUST be zero.
  - — R bit – All other flag fields are reserved.
  - — Protocol - Indicates the next protocol:
    - 0 = Reserved

  - 1 = IPv4
  - 2 = IPv6
  - 3 = Ethernet
  - 4..253 = Unassigned
- ***Service Index*** — TTL functionality and location within the service path. Service index MUST be decremented by service nodes after performing required services. MAY be used in conjunction with service path for path selection.
- ***Service Path*** — Identifies a service path. Participating node MUST use this identifier for path selection.
- ***Context Headers*** — Carry opaque metadata.
  — Network platform context – Provides platform-specific metadata shared between network nodes.
  — Network shared context – Metadata relevant to any network node such as the result of edge classification.
  — Service platform context – provides service platform specific metadata shared between service functions.
  — Service shared context – Metadata relevant to, and shared, between service functions.
- **TLV section** — Additional variable-size metadata.

Detailed NSH header structure is shown in Figure A-43.

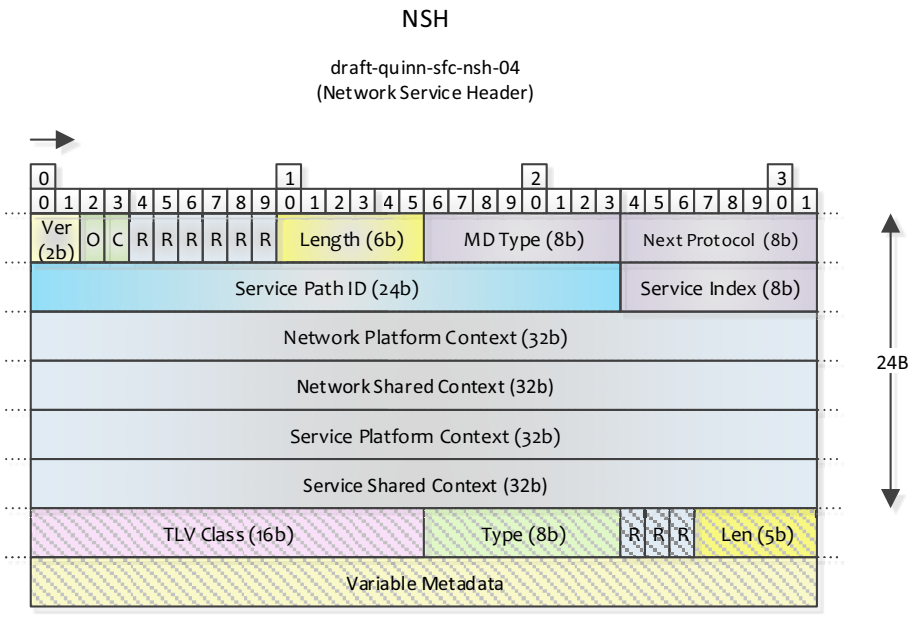

Figure A-43. Detailed NSH Header Structure

Note: The E810 supports only fixed-length NSHoE in the outer L2 section of the packet. Variable length NSH header with TLV extensions is not supported in this section.

A.5.5.7 IPSEC NAT-T

IPSEC NAT-T is identified by 1 of 8 programmable UDP destination port numbers.

The E810 does not provide checksum offload for the NAT header.

The ESP NAT-T header structure is shown in Figure A-44.

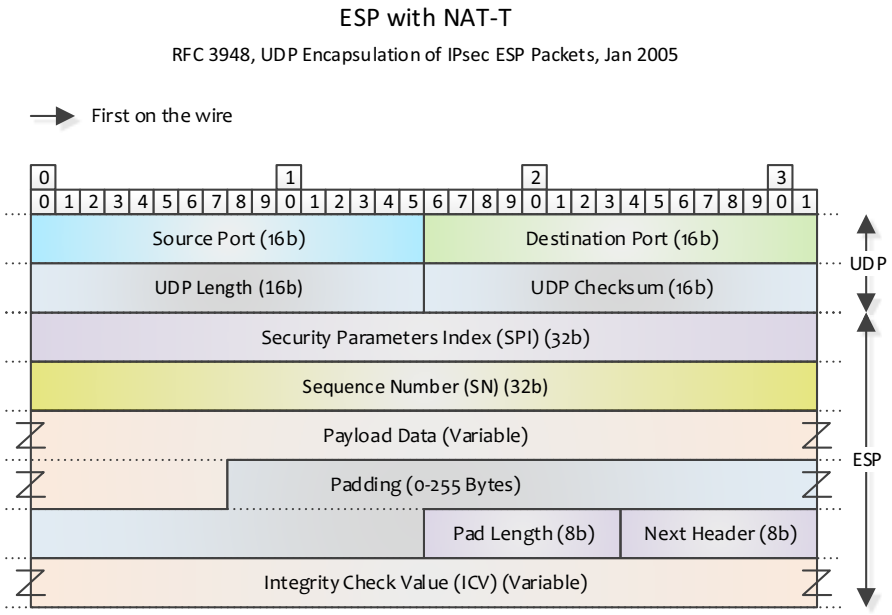

Figure A-44. ESP NAT-T Header Structure

A.5.5.8 GPRS Tunneling Protocol (GTP)

The GPRS Tunneling Protocol is specified by 3GPP.

The E810 factory parsing program supports two versions of the GTP header: GTPv1 and GTPv2, described in sections Section A.5.5.8.1 and Section A.5.5.8.2, respectively.

The protocol is transferred over IP/UDP (see Section A.5.4.1) and has distinct flavors:

- GTP-C packets, used for control, and are identified by UDP port 2123.
- GTP-U packets, used for user data, and are identified by UDP port 2152.

Note: The mentioned UDP port number must be used as the destination port for request messages and as the source port for response messages. There is no GTP-U flavor for GTPv2.

For GTP-U packets, the E810 factory parsing program also identifies whether the packet carries a user data message (G-PDU) or not.

Note: The support provided by the factory parsing program of the E810 for GTP provides the ability of detecting the GTP headers supported in accordance to the overlaying protocols and the *Version* field in the header itself (see each detailed header format sections for details). The E810 does not provide any validity check for the headers themselves, and it is the relevant software client's responsibility to implement the protocol validity checks and relevant error handling suite as mandated by the specifications.

A.5.5.8.1 GTPv1

GTPv1 is specified in 3GPP TS 29.060, and the information below is based on version 14.2.0 published in December, 2016.

The frame format for GTPv1 is described in Figure A-45.

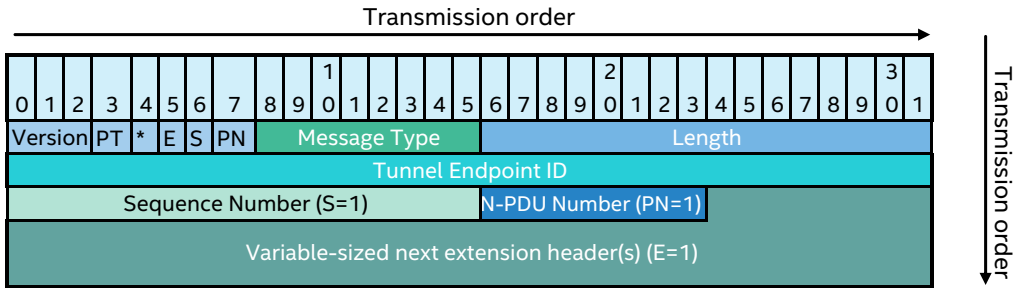

Figure A-45. GTPv1 Header Format

The following fields are always present fields in GTPv1 header:

- ***Version*** — This field is used to determine the version of the GTP protocol. The version number must be set to "1".
- ***PT*** (Protocol Type) — This bit is used as a protocol discriminator between GTP (when PT is "1") and GTP' (when PT is "0"). GTP is described in 3GPP TS 29.060 and the GTP' protocol in 3GPP TS 32.295.
- ***E*** (Extension Header) — This flag indicates the presence of a meaningful value of the *Next Extension Header* field.
  - 0 = The *Next Extension Header* field is either not present, or, if present, must not be interpreted.
  - 1 = The *Next Extension Header* field is present, and must be interpreted, as described below in this section.
- ***S*** (Sequence Number) — This flag indicates the presence of a meaningful value of the *Sequence Number* field.
  - 0 = The *Sequence Number* field is either not present, or, if present, must not be interpreted.
  - 1 = The *Sequence Number* field is present, and must be interpreted, as described below in this section.
- ***PN*** (N-PDU Number) — This flag indicates the presence of a meaningful value of the *N-PDU Number* field.
  - 0 = The *N-PDU Number* field is either not present, or, if present, must not be interpreted.
  - 1 = The *N-PDU Number* field is present, and must be interpreted, as described below in this section.
- ***Message Type*** — This field indicates the type of GTP message. The E810 factory parsing program indicates if the *Message Type* field value is equal to 255 (0xFF) which means the packet is carrying user data (G-PDU).

- ***Length*** — This field indicates the length in octets of the payload. That is, the rest of the packet following the mandatory part of the GTP header (that is the first 8 octets). The *Sequence Number*, the *N-PDU Number* or any Extension headers must be considered to be part of the payload (in other words, included in the length count).
- ***Tunnel Endpoint ID*** (TEID) — This field unambiguously identifies a tunnel endpoint in the receiving GTP-U or GTP-C protocol entity. The receiving end side of a GTP tunnel locally assigns the TEID value the transmitting side has to use. The TEID values are exchanged between tunnel endpoints using GTP-C (or RANAP, over the Iu) messages.

The following fields are optional fields in GTPv1 header:

- ***Sequence Number*** — This field is an optional field in G-PDUs. It is used as a transaction identity for signaling messages having a response message defined for a request message, that is, the *Sequence Number* value is copied from the request to the response message header. In the user plane, an increasing sequence number for T-PDUs is transmitted via GTP-U tunnels, when transmission order must be preserved.
- ***N-PDU Number*** — This field is used at the Inter SGSN Routing Area Update procedure and some inter-system handover procedures (for example, between 2G and 3G radio access networks). This field is used to coordinate the data transmission for acknowledged mode of communication between the MS and the SGSN. The exact meaning of this field depends upon the scenario. For example, for GSM/GPRS to GSM/GPRS, the SNDCP N-PDU number is present in this field.
- ***Next Extension Header Type*** — This field defines the type of Extension Header that follows this field in the GTP-PDU.

A.5.5.8.2 GTPv2

GTPv2 is specified in 3GPP TS 29.274 and the information below is based on version 14.2.0 published in December, 2016.

The frame format for GTPv2 is described in Figure A-46.

Note: GTPv2 is only specified for GTP-C packets.

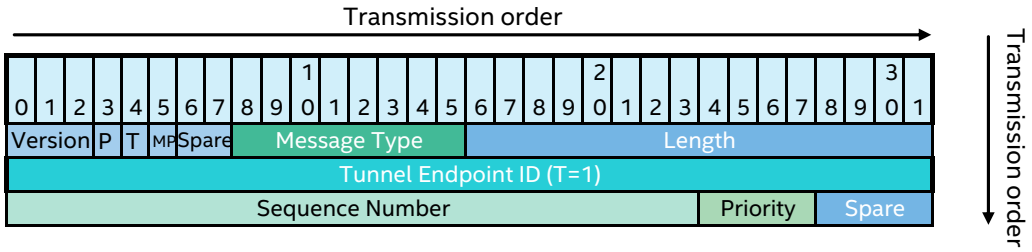

Figure A-46. GTPv2 Header Format

The following fields are always present fields in GTPv2 header:

- ***Version*** — This field is used to determine the version of the GTP protocol. The version number must be set to "2".
- ***P*** (Piggybacking) — When set, another GTPv2-C message is present at the end of this one.
- ***T*** (TEID) — Is set when the header includes a TEID field.
- ***MP*** — When this flag is set, the GTPv2-C header includes a priority field.
- ***Spare*** — Unused. Must be set to "0" by the sender and be ignored by the receiver.

- ***Message Type*** — Set to the unique value for each type of control plane message.
- ***Message Length*** — This field must indicate the length of the message in octets excluding the mandatory part of the GTP-C header (the first 4 octets). The TEID (if present) and the *Sequence Number* must be included in the length count.

  A piggybacked initial message and the preceding triggered response message present in the common IP/UDP packet must have their own length and sequence number in their respective GTP-C headers. The overall length of the IP/UDP packet must indicate the total length of the two GTP-C messages.
- ***Tunnel Endpoint ID*** (TEID) (only exists when T=1) — This field unambiguously identifies a tunnel endpoint in the receiving GTP-C entity. The *Tunnel Endpoint ID* is set by the sending entity in the GTP header of all control plane messages to the TEID value provided by the corresponding receiving entity. If a peer's TEID is not available, the TEID field must be present in a GTPv2-C header, but its value must be set to "0".

  Note: The TEID in the GTP header of a Triggered (or Triggered Reply) message is set to the TEID value provided by the corresponding receiving entity regardless of whether the source IP Address of the initial (or triggered) message and the IP Destination Address provided by the receiving entity for subsequent control plane Initial messages are the same.
- ***Sequence Number*** — Same as in GTPv1.
- ***Priority*** — Relative priority of the GTP-C message. Only relevant if the *MP* flag is set to 1). It must be encoded as the binary value of the Message Priority and it can take any value between 0 and 15, where 0 corresponds to the highest priority and 15 to the lowest priority.

  If the *MP* flag is set to "0" in Octet 1, bits 8 to 5 of octet 12 must be set to "0" by the sending entity and ignored by the receiving entity.
- ***Spare*** — Spare bits. The sending entity must set them to "0" and the receiving entity must ignore them.
