Intel® Ethernet Controller E810

Datasheet

Ethernet Products Group (EPG)

PRODUCT FEATURES

General

- Support both 50Gb/s PAM4 and 25Gb/s NRZ (E810-CAM2/CAM1 only)
- Dynamic Device Personalization (DDP) with fully-programmable pipeline that can add or modify protocols on-demand, allowing for fast-paced innovations
- Application Device Queues (ADQ) feature to increase application predictability, reduce application latency, and improve application throughput
- Support both iWARP and RoCEv2 RDMA, selectable via software per port for low latency, high throughput workload
- Support for 8x10GbE connections for appliance designs (E810-CAM2 only)
- Optimized Tx-Scheduler for steady Tx traffic flow to avoid burst send and in-network congestion
- IEEE 1588 support for precision time measurement
- Enhanced Data Plane Development Kit (DPDK) for Network Functions Virtualization acceleration, advanced packet forwarding, and highly-efficient packet processing
- More resources to support higher density server virtualization deployments: 256 VFs, 768 VSIs
- Flat NVM structure with dual banks to facilitate Any-to-Any NVM update and allow rolling back to previously known good NVM when device cannot load from current active bank
- Extensive test and validation with ecosystem devices including switches, cables and transceivers for interoperability

Three SKUs

- E810-CAM2:25x25mm; PCI Express v4.0/v3.0 x16/x8; 2x100Gb, 2x50Gb, 4x25Gb, 8x10Gb, 50Gb PAM4/25Gb NRZ SerDes
- E810-CAM1:25x25mm; PCI Express v4.0/v3.0 x16/x8; 1x100Gb, 2x50Gb, 4x25Gb, 50Gb PAM4/25Gb NRZ SerDes
- E810-XXVAM2:21x21mm; PCI Express v4.0/v3.0 x8; 1x50Gb, 2x25Gb, 25Gb NRZ SerDes

Storage Networking

- Data Center Bridging (DCB)
- Stateless L3/L4 offloads for iSCSI, NAS, NFS
- Server Message Block (SMB)

NFV and Network Virtualization Overlay (NVO) Support

- Dynamic Device Personalization (DDP) with programmable pipeline for flexible frame format support
- Intelligent Flow Direction: Receiver Side Scaling (RSS), Intel® Ethernet Flow Director, Application Device Queues (ADQ)
- Comprehensive Network Virtualization Overlay protocols support.
- vSwitch Assist
- QoS: Priority-based Flow Control (802.1Qbb); Enhanced Transmission Selection (802.1Qaz); Differentiated Services Code Point (DSCP)

Server Virtualization Support

- SR-IOV: 8 PFs, 256 VFs, 256 Queues per PF, 2K queue pairs total, 768 VSIs
- Adaptive VF driver
- Scalable IO Virtualization (768 VDEVs)
- Programmable Virtual Ethernet Bridging (VEB) with ACL
- Virtual Machine Device Queue (VMDq); Virtual Machine QoS (VMQoS)

Remote Direct Memory Access (RDMA)

- Both iWARP and RoCEv2 support selectable via software per port

Precision Clocks Synchronization

- IEEE 1588 v1 and v2 PTP/802.1AS

Management

- Firmware Management Protocol (FMP)
- MCTP over PCIe and SMBus/I^2C
- PLDM over MCTP; PLDM Monitoring; PLDM Firmware Update; PLDM for RDE
- NET2BMC/OS2BMC

Security

- Hardware-based Root of Trust
- Authentication on Read and Power On; Whitelist approach on NVM update
- Built-in detection of firmware/critical setting corruption with automated device recovery

Revision 2.1
January 2021
613875-003

Revision History

Revision	Date	Notes
2.1	January 22, 2021	Updates include the following: • Updated Table 1-1, "E810 Features Summary" under the Security category. • Added Section 1.4.12.1, "Protect, Detect, and Recover". • Updated Table 1-2, "Standards Supported by the E810" to add Security category. • Updated Section 16.3.1.1, "Power On/Off Sequence". • Updated Table 16-8, "E810-CAM2/CAM1 MAX Power - PCIe Gen 4 and PCIe Gen 3". • Updated Section 16.5.5, "Reference Clock Specification" to enhance HCSL and V_{diff} discussion. • Updated Table 18-2, "E810 Thermal Specifications".
2.0	July 23, 2020	Second public release.
1.9[1]	July 13, 2020	Initial public release.

1. There are no previous publicly-available versions of this document.

Chapter 1 Introduction

1.1 Overview

This document describes the external architecture (including device operation, pin descriptions, register definitions, and so on) for the Intel® Ethernet Controller E810 (E810), a dual-port 100 Gigabit Ethernet (GbE) Network Interface device.

This document is intended as a reference for architects, logic designers, firmware and software device driver developers, board designers, test engineers, or anyone else who might need specific technical or programming information about the E810.

The E810 is Intel's first multi-speed 100 GbE controller supporting rates between 100 Mb/s and 100 Gb/s. The E810's key objective is to enable a scalable Ethernet controller suitable for Enterprise, Cloud, and Communications Service Provider applications.

The key features supported in the E810 include two 100 Gigabit Ethernet ports, 100 Gigabit throughput performance, enhanced programmable packet processing pipeline, virtualization (enhanced SR-IOV support with up to 256 VFs and backward compatibility VF driver support), new features for the communications market (fine grained scheduler, transmit head drop support, adjustment of credits according to different headers, enhanced QoS, and enhanced burst control) and RDMA (iWARP and RoCEv2).

Table 1-1 provides a summary of E810 features. For additional information on supported features, see the *Intel® Ethernet Controller E810 Feature Support Matrix*.

Table 1-1. E810 Features Summary

Category	Features
Host Interface	• Compliance with PCIe 4.0 specification. • Concurrency for 256 non-posted requests.
Network Interface	• Speeds at 2x100 GbE, 2x50 GbE, 4x25 GbE, 8x10 GbE, 8x1 GbE, and 8x100 Mb/s.
Performance	• 100 Gb/s throughput (for each Tx and Rx). • Up to 80 Mpps for Tx and 90 Mpps for Rx. • 100 Gb/s single queue performance.
Software Interface	• Base mode VF compatibility. • Tx/Rx-Queues: — 16K Tx-Queues. — 2K Rx-Queues. — Dynamic allocation of queues to functions and VSIs. • Interrupts: — 2048 interrupts vectors, allocated in a flexible manner to queues and other causes. — Multiple interrupt moderation schemes. — 20M interrupts per second. • Control Queues (also known as Admin Queues): — Mailbox Queues for PF-VF and driver-driver. — Admin Queues for software-firmware control flows. — Sideband Queues for software to access IPs inside the E810. • 256 Tx Doorbell (DB) Queues. • 512 Tx Completion Queues. • Quanta Descriptor (QD) Queue per Tx-Queue. Quanta information is also embedded in the Tx doorbell. • Programmable Rx-Descriptor fields.

Table 1-1. E810 Features Summary [continued]

Category	Features
Packet Processing	• General: — Stages of parsing, switching, ACLs, classification, and packet modification. — Programmable packet processing pipeline. — Multiple control domains. — Profile-based. — Programmable actions. — Propagation of priorities between stages. • Parser: — Parses up to 504 bytes from packet header. — Parse Graph-based. — Session-based parsing. — Programmable parse engine. • Binary Classifier (VEB Switch): — 768 switch ports (VSIs). — Programmable forwarding rules. — Storm control. • ACLs: — 8K programmable TCAM entries. — Tiling capability to n*40-bit width. • Classification Filters: — Hash-based statistical distribution. — Flow Director flow-based classification. — Flow-based identification of iWARP and RoCE flows. — Programmable rules. • Modifier: — Insertion (Tx), removal (Rx), and modification of packet VLANs. — L3 and L4 checksums and CRC.
Virtualization	• Host virtualization via VMQ and SR-IOV. • 256 SR-IOV Virtual Functions (VFs). • Stateless offloads for tunneled packets (network virtualization support). • Malicious VF protection.
RDMA	• iWARP and RoCE v2. • 256K Queue Pairs (QPs). • Send Queue Push Mode. ***Note:*** RDMA is not supported when the E810 is configured for >4-port operation. ***Note:*** Userspace Direct Access (UDA) was intended to provide userspace access queues in a general way, but this feature is not supported in the E810. UDA is available only in the kernel and is limited to iWARP connection setup and error handling. UDA is not available in userspace.
QoS	• WFQ Transmit scheduler with nine programmable layers. • Pipeline sharing and starvation avoidance. • Up to 32 Congestion Domains in the Tx and Rx paths. • QoS via 802.1p PCP or Differentiated services DSCP value. • Rx packet buffer supports at least three no-drop flow control events, shared among ports.
Communication	• Packet shaping. • Packet drops/aging + reporting. • Reduced burstiness - jitter control. • Adjustment of credits per packet based on four different header types. • Concurrent Quanta Descriptors/Legacy Scheduling.
Manageability	• SMBus operating at up to 400 Kb/s. • DMTF-compliant NC-SI 1.1 Interface at 100 Mb/s. • PLDM Types 0, 2, 5, 6 for monitoring and control, firmware update, and Redfish Device Enablement. • MCTP over PCIe and SMBus. • Enterprise-level management schemes via local BMC.

Table 1-1. E810 Features Summary [continued]

Category	Features
Power Management	• Supports PCI power management states D0, D3hot, and D3cold. • APM WoL support in D0, D3hot, and D3cold. ***Note:*** Energy Efficient Ethernet (EEE) is not currently supported in the E810. Some references might remain in this document in the event that it is enabled in the future.
Time Synchronization	• Timestamp with each Rx packet. • Selective timestamps for Tx packets. • IEEE 1588 support.
Security	• Authentication of firmware contents on load from NVM. • Implements NIST 800-193 Platform Firmware Resiliency Guidelines including Protect, Detect, and Recover.

1.2 E810 Full Chip Block Diagram

The E810 is based on a 100G Ethernet controller core block, which is used in multiple Intel products. Figure 1-1 illustrates the relationship between the controller core logic and the I/O and support functions that comprise the full E810 device.

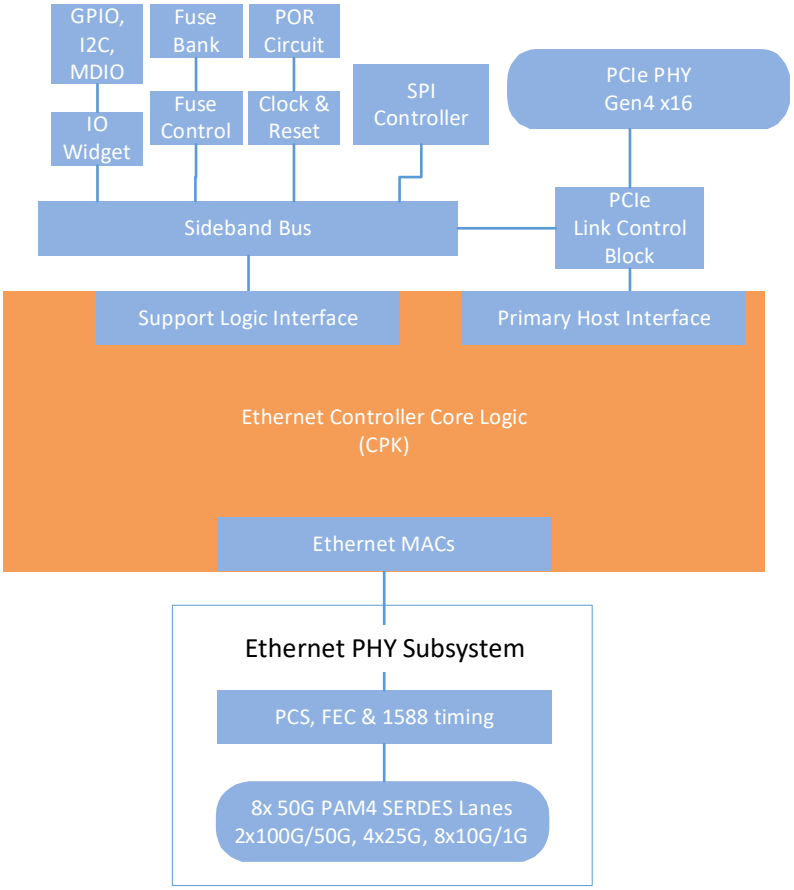

Figure 1-1. E810 Block Diagram

1.3 Controller Core Block Diagram

The controller core block diagram is depicted in Figure 1-2. In this document, references to the controller core are often abbreviated as "CPK", for example, in register bit and NVM field definitions.

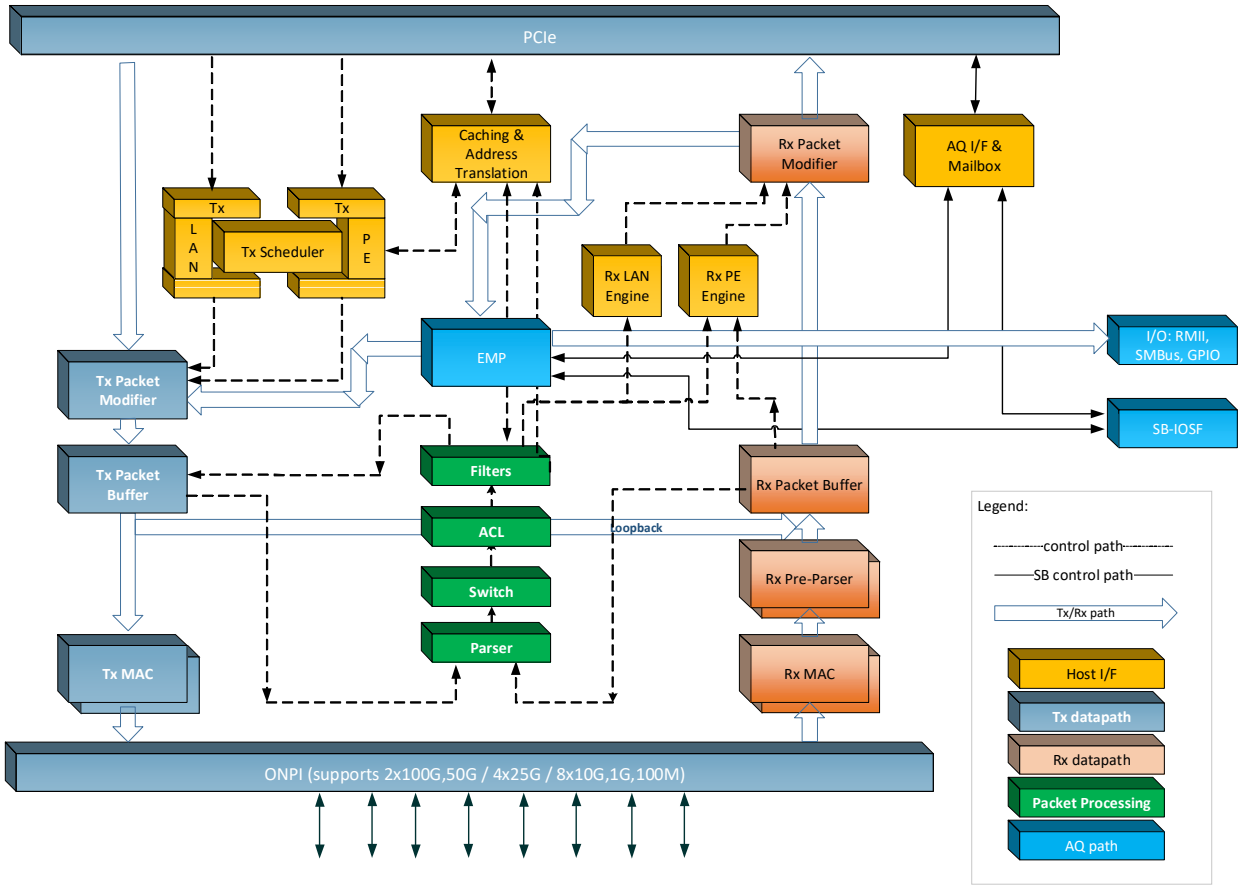

Figure 1-2. Controller Core Block Diagram

The following subsections describe the packet flows.

1.3.1 LAN Traffic Tx Flow

Transmission starts with a "doorbell" from software, indicating one packet or more is waiting in some transmit queue in host memory. If the queue is a LAN queue, the doorbell is registered with the internal Transmit Scheduler (Tx-Scheduler). If the queue is an RDMA queue, the request is registered with the Protocol Engine (PE) scheduler. When the PE scheduler selects a request, the request goes through RDMA protocol processing, at the end of which an internal request is issued to the Tx-Scheduler.

The Tx-Scheduler is responsible for pacing traffic to the network ports. It guarantees bandwidth allocation among requesters, does rate limiting where needed, and paces packets to avoid congestion later in the network.

Once the Tx-Scheduler selects a transmit queue (either from LAN or from RDMA), it services some amount of transmit data (called a "quanta"). Packet data is read from host memory and any packet processing or packet manipulation takes place. These can include partial parsing of the packet, performing Transmit Segmentation Offload (TSO), calculating relevant checksums and CRCs, L2 header manipulations UP enforcement, and inner protocol TTL decrement.

The packet is then passed to the Packet Processing Pipeline, where it queries the on-die switch to identify its destinations. A packet can be forwarded locally to a Host destination (for example VM-VM communication) or to an on-board BMC. The packet also goes through the ACL block, where permissions are checked, and might alter the forwarding decisions made in the switch.

The LAN Controller then forwards the packet to one of the LAN ports and/or to the Receive path. If the destination port is busy, the packet is stored in a local Transmit Buffer. Transmission to a LAN port is done via a 802.3 MAC that interfaces an On-Chip Network Packet Interface (ONPI).

1.3.2 LAN Traffic Rx Flow

Packet reception starts when a packet arrives to any of the ONPI channels. The packet goes through initial processing in the 802.3 MAC and a parsing/processing unit. The parsing/processing unit does some checksum verifications on the packet. The packet is then stored in the on-die Receive Packet Buffer.

The packet header then goes through the Packet Processing stage, where it potentially goes through parsing, switching, ACLs, and classification. If the packet is identified as an RDMA packet, it is passed to the Protocol Engine for protocol processing. If the packet is a LAN packet, it is forwarded to the LAN Engine. Either engine then issues a command to the Rx Modifier. The Rx Modifier fetches the packet from the Receive Packet Buffer, completes any modifications, calculates any required checksums, posts the packet into the respective Host buffer, and terminates the transaction.

1.3.3 Management Flows

Other flows include traffic to or from a system level Baseboard Management Controller (BMC). The E810 serves as a network interface to the BMC. A packet is received from the BMC via PCIe, NC-SI, or SMBus. The Embedded Management Processor (EMP) unit generates a command into the Transmit Pipeline in a similar manner to the Transmit Scheduler as described above. The Tx Modifier fetches the packet from the management interface to be processed as any Host packet.

In a similar manner, a received packet can be forwarded to the BMC once the on-die switch identifies the BMC as its destination. The packet is then forwarded to the management interface to be sent to the BMC.

Host software can also forward a packet to a system BMC. During transmit packet processing, the on-die switch identifies that the destination for the packet is the BMC interface. The E810 then forwards the packet from the transmit path to the receive path as described above. The receive path then processes the packet and forwards it to the management interface to be sent to the BMC.

1.4 Functional Blocks

This section contains a short overview The E810 functional units depicted in Figure 1-2.

1.4.1 Host Interface

The E810 implements a Gen4x16 PCIe 4.0 compliant interface.

The E810 implements a PCIe Transaction layer. The E810's PCIe host interface implements up to eight Physical Functions (PFs), and up to 256 Virtual Functions (VFs). More details on the E810's PCIe features are provided in Section 3.1, while Chapter 14 describes the PCIe programming interface.

1.4.2 Host Memory Objects

The E810 operating system drivers set up a wide variety of host memory objects that are comprehended and manipulated by the E810. All objects are set up in the context of a PCI function.

Described below are the types of memory objects:

- **LAN Transmit (Tx) and Receive (Rx) Queues** — These are ring buffers for submitting commands to the Local Area Network (LAN) engine or posting packets that arrive from the network. Commands take the form of packets/data to be transmitted, descriptors for empty host memory buffers to be filled with received packets/data, and so on. Queues are typically mapped into OS kernel space (or userspace in the case of DSI driver). In a virtualized server, they can be assigned either to the VMM, or to VMs using SR-IOV. The E810 supports up to 16K Tx-Queues and 2K Rx-Queues that can be assigned to PFs or VFs as needed. The queues assigned to a particular PCI function can be used in these important ways:
  - For distributing packet processing work to the different processors in a multi-processor system. On the transmit side, this is done by simply dedicating an independent transmit queue for each CPU to use. On the receive side, packets are classified by the E810 under operating system control into groups of conversations. Each group of conversations is assigned its own receive queue and receiving processor. Microsoft Receive Side Scaling (RSS) is one popular example of this method. ATR using the Flow Director is a another, more precise mechanism to direct Rx packets to queues.
  - For assigning Traffic Class (TC). Transmit queues assigned to different TCs are serviced at different rates by the E810 Transmit Scheduler. Receive queues assigned to different TCs can be serviced at different rates by a Quality of Service (QoS)-enabled operating system and its software device drivers.
  - To associate queues with VMs in VMDq1 or VMDq2 modes, saving packet processing and copying by the VMM
  - To associate DSI queues with different wireless operators, providing a degree of separation between the operators.
- **LAN Auxiliary structures in host memory** — These include:
  - Tx Completion Queues where write-back of transmit events can be done. The 512 Completion Queues allow coalescing of write-back information from multiple transmit queues into a small number of Completion Queues, making it easier for software to collect write-back events.

  - — Tx Doorbell (DB) Queues are used by software to coalesce Tx doorbells ("Tail Write" events) to the device, reducing load on the CPUs. Software can write a Tx DB to one of the 256 DB Queues. Once in a while, software sends an indication (also called doorbell or Tail Write) to the device, indicating that a certain DB Queue has one or more Tx-Queues' doorbells stored in it. The E810 then fetches the Tx-Queue DBs from host memory.
  - — Tx Quanta Descriptor (QD) Queues store auxiliary information on packets stored in Tx-Queues. The information assists the Transmit Scheduler by letting it know how much data is waiting for transmission in a given Tx-Queue. Each Tx-Queue has an associated QD queue.

- **Protocol Engine Queue Pairs (QPs)** — These are ring buffers (one Send Queue, one Receive Queue) for submitting commands to the Protocol Engine. Each Protocol Engine QP can be configured for either RDMA messages or for UDA packets. Commands on RDMA QPs take the form of RDMA messages to be transmitted, descriptors for empty host memory buffers to be filled with received RDMA messages, and so on. Commands on UDA QPs take the form of packets/data to be transmitted, descriptors for empty host memory buffers to be filled with received packets/data, and so on. Protocol Engine QPs are typically mapped into host userspace. In a virtualized server, they can be assigned either to the VMM, or to Virtual Machine userspace using SR-IOV. The E810 supports up to 262,144 Protocol Engine QPs, which are allocated to PFs and VFs as the E810 initializes and drivers load, and are fixed after that.
- **Control Queue (or Admin Queues (AQ)) Pairs** — AQs are used for communication between device drivers, and between a device driver and E810 embedded controllers. Each Admin Queue Pair maps one Admin Transmit Queue (ATQ) and one Admin Receive Queue (ARQ). The ATQ is a ring buffer used by the host driver for submitting commands. The ARQ conveys events to host driver that are not an immediate result of an ATQ command. The host driver posts empty buffers to the ARQ, and the E810 fills them with events. For more details on AQs, see Section 9.5.

1.4.3 LAN Engine

The LAN engine implements the host programming interface for traditional LAN traffic in both virtualized and non-virtualized scenarios. The E810 implements 768 VSIs (virtual ports) used to distribute traffic to PCI physical functions and virtual functions. These VSIs can connect to the host via 16K Tx-Queues and 2K Tx-Queues.

1.4.4 Protocol Engine

The Protocol Engine implements iWARP and RoCEv2 RDMA capability. The Protocol Engine offloads protocol processing from the host, places received data payloads directly into user buffers with no host CPU involvement, and eliminates user-kernel context switching when performing I/O by mapping the RDMA programming interface directly into application address space.

The Protocol Engine implements the latest RDMA features, including Send Queue Push Mode.

1.4.5 Transmit Scheduler

The Transmit Scheduler (Tx-Scheduler) determines the order and timing of packets sent to the network. It receives requests ("doorbells") from LAN and RDMA queues and schedules these for transmission. A scheduling decision allows a given "quanta" of bytes or packets from a given queue or set of queues to be fetched from host memory and sent to the network.

The main capabilities of the Tx-Scheduler are:

- Hierarchical scheduling tree — Scheduling decisions are done by selecting a Queue node while taking in consideration the state of its branch in each layer of the tree. Layers of the tree represent entities that define scheduling attributes, and can be a queue, a set of queues, a VSI, a PCI function, a Traffic Class, a network port, and more. Layers can also represent a network topology, scheduling to prevent congestion in nodes further down the network.
- Scheduling based on Weighted Fair Queuing (WFQ), Strict Priority (SP), and Hybrid algorithms.
- Minimum bandwidth guarantee via Dual-Rate Shapers.
- Rate limiting, including shared rate limiters.
- High-performance fine-grained and accurate scheduling.
- Fully-configurable, flexible topology, including on-the-fly configuration.
- Each scheduler node can be stopped via software-based or hardware-based flow control mechanisms.

For more detail on E810 transmit scheduler features and operation, see Section 8.3.

1.4.6 Tx and Rx Modifiers

The Tx and Rx modifiers perform operations on packet contents in the Tx and Rx pipelines, respectively. The modifiers perform updates to packet headers, such as insertion and removal of L2 tags (for example, VLAN), and calculation (and split in Rx) of header and payload checksums (insertion on Tx and validation on Rx). The Tx modifier also performs TCP Segmentation Offload (TSO).

1.4.7 Ethernet Media Access Controller (MAC)

The E810 integrates IEEE Std 802.3 compliant Ethernet MACs that operate at 100 Mb/s, 1 GbE, 10 GbE, 25 GbE, 50 GbE, and 100 GbE. A total of eight MACs map to the following speeds:

- Two MACs operating at all speeds from 100 GbE and lower.
- Additional two MACs operating at all speeds from 25 GbE and lower.
- Additional four MACs operating at all speeds from 10 GbE and lower.

Therefore, the E810 supports port configurations of 2x100 GbE, 2x50 GbE, 4x25 GbE, 8x10 GbE, 8x1 GbE, and 8x100 Mb/s.

All E810 MACs support transmission and reception of jumbo frames of up to 9728 bytes, and 802.3x flow control frames or 802.3bd priority-based flow control frames. See Section 3.2.1.5 for details.

The E810 implements a set of control signals for the PHY:

- Five independent interfaces for connection to external PHYs. Each interface can be either a Management Data Input/Output (MDIO) or Inter-integrated Circuit (I^2C) interface. These enable host software or E810 firmware to control connected external PHYs, including the ability to read and write PHY registers.
- Eight SDP signals to be used as general purpose I/O. SDPs are typically used to exchange information with or to control external devices (such as PHY devices) under E810 software driver or firmware control. See Section 3.5.1 for more details.

- Three LED indications for maximum 4-ports configuration (total of 12 pins). Each of the LED outputs can be individually configured to select which particular event, state, or activity it indicates. In addition, each LED can be individually configured for output polarity and for blinking versus non-blinking (steady-state) indications. See Section 3.5.1 for more information.

Details on how they are typically connected and used are described in Section 3.2.3.

Admin Queue commands are provided for software device driver control over the integrated PHYs.

1.4.8 Packet Parser

The E810 provides a software programmable Parser capable of supporting a wide range of well-known and proprietary protocols. The Parser examines ingress traffic, retrieves search parameters from the packet and from associated packet context, and then generates additional context based on certain packet attributes. This context is further used by other packet processing modules in the pipeline to associate the packet with a profile, a flow, an action, and so on.

The Parser supports a large set of native frame formats that are common in various networking applications. These formats are provided by the E810 out-of-the-box, not requiring any additional installation or programming. Additional frame formats can be programmed per usage.

1.4.9 VEB Switch (a.k.a. Binary Classifier)

The VEB switch identifies packet destinations for both Tx and Rx, for traffic to/from Host and to/from a manageability port (BMC). For Tx packets, it determines whether the packet goes to an external ONPI port, to a local destination either in the host or to the BMC (via loopback), or to both. For packets arriving from ONPI or from the loopback path, it selects a local destination. A local destination is named a “VSI” and is associated with a PCI function or with an EMP buffer.

The switch makes its forwarding decision based on a set of programmable rules, such as VLAN tag, a destination MAC Address, or a combination of such. Basic forwarding rules are loaded from NVM, and additional rules can be programmed per usage. Dedicated rules identify management traffic to be forwarded to a Baseband Management Controller (BMC).

The switch supports replication of broadcast and multicast packets to multiple VSIs. It also supports mirroring of both Tx and Rx packets. As any other stage in the processing pipeline, the switch generates statistics and can also insert metadata into the pipeline (potentially reaching the Rx-Descriptor).

1.4.10 Access Control Lists (ACLs)

The packet processing pipeline in the E810 provides a programmable Ternary Classifier stage for implementing functions such as Access Control List (ACL), IP Longest Prefix Match (LPM), statistics collection, and so on. The Ternary Classifier is SDN/NFV-enabled, supporting a wide range of network protocols, both standard-based and proprietary. The architecture is fully-programmable, protocol-agnostic, and action-agnostic, capable of adapting to future protocol headers and use cases.

The Ternary Classifier is located following the switch in the packet processor pipeline, as illustrated in Figure 1-2. Since the architecture of the Ternary Classifier is protocol-agnostic and action-agnostic, it can be programmed to serve as a switch extension and thus provide packet forwarding based on programmable rules, augmenting the capabilities of the switch.

1.4.11 Classification Filters

Following forwarding decision in the switch and ACLs stages, the Classification filters perform fine-grain classification of receive packets. The following capabilities are provided:

- **Hash-based classification** — Determines a destination queue in host memory through a hash function over fields in the packet headers. Several hash functions are supported, such as Microsoft RSS.
- **Flow Director** — Provides flow-level classification of packets, including association with a queue in host memory. The E810 provides on-die classification of 16K different flows.
- **Protocol Engine Quad-Hash classification** — Identifies flows to be offloaded in the on-die Protocol Engine.

The Classification Filters are programmable as are other stages in the Packet Processing Pipeline.

1.4.12 Embedded Management Processor (EMP)

The Embedded Management Processor (EMP) unit handles all management duties that cannot be performed by the E810's device drivers, and must be carried out on-chip. This includes performing parts of the E810 power-on sequence, handling AQ commands, initializing E810 Ethernet ports, participating in various fabric configuration protocols like DCBX and other Link Layer Discovery Protocol (LLDP) protocols, filling configuration requests received on one of the E810's BMC management interfaces like NC-SI, and handling special configuration requests received off an Ethernet port.

1.4.12.1 Protect, Detect, and Recover

Zero Trust is a security design strategy centered on the belief that organizations, by default, should not automatically trust anything or anybody inside or outside its perimeters and instead must verify anything and everything trying to connect and gain admittance to its systems before granting access. The Intel® Ethernet 800 Series EMP implements a design philosophy of platform resiliency with three attributes compliant with the NIST Cyber Security Framework, including NIST SP 800-193 Platform Firmware Resiliency Guidelines: Protect, Detect, and Recover.

Intel® Ethernet 800 Series uses signed firmware updates and hardware Root of Trust to protect and verify critical device settings with built-in detection of corruption, and automated device recovery to ensure the device safely returns to its originally programmed state. For details, Section 3.4.9, "NVM Authentication Procedure" and Section 15.3, "Firmware Recovery Mode".

1.4.13 Host Memory Cache (HMC)

The E810's quad hash lookup and Protocol Engine use host memory as a backing store for a variety of context objects. The Host Memory Cache (HMC) is responsible for caching and managing these context objects.

For each RDMA connection, the Protocol Engine uses a QP Context object (TCP/IP connection context that stores, for example, TCP sequence numbers) and Inbound RDMA Read Queue (IRRQ) objects that buffer inbound RDMA Read Requests until their associated Read Responses are scheduled for transmit. For each RDMA Memory Region, the Protocol Engine uses a Memory Region Table Entry (MRTE) object to store region boundary and access rights information, and a set of Physical Buffer List Entry (PBLE) objects to store virtual-to-physical address translations for this region. These and many more Protocol Engine context objects are detailed in Chapter 11.

General information on HMC operation and configuration is provided in Section 9.3.

1.4.14 Various Interfaces

1.4.14.1 Shared Serial Flash Interface

The E810 accesses the NVM via an SPI interface. The NVM device is required for storage of device firmware, device configuration parameters, identifiers that vary per adapter (like MAC Addresses), and register overrides that auto-load automatically after reset. The E810 assumes that at least 10 MB of the NVM are dedicated for these configurations.

More information on the shared serial Flash interface is available in Section 3.4.

1.4.14.2 SMBus Interface

SMBus is an optional interface for pass-through and/or configuration traffic between an external BMC and the E810. The E810's SMBus interface supports standard SMBus at 100 KHz and 400 KHz. Refer to Section 12.3.1.1 for an additional description of the SMBus interface, and Section 2.2.4 for the pin descriptions.

1.4.14.3 NC-SI Interface

NC-SI is an optional interface for pass-through and/or configuration traffic between an external BMC and the E810. Refer to Section 12.3.1.2 for an additional description of the NC-SI interface, Section 2.2.3 for the pin descriptions, and Section 12.6 for NC-SI programming.

1.4.14.4 High-Speed SDPs

On top of the eight SDPs and 12 LEDs slow interfaces accessible via the internal sideband Link, there are also four single-ended high-speed SDPs directly controlled by the E810 controller core. In addition, one differential output is directly connected to the internal clock control unit to create a high-precision clock signal. These SDPs are used for applications like IEEE 1588 that requires more precise timing of the SDPs transitions. See Section 9.7.6.1 for details.

1.5 Conventions

1.5.1 Numbers and Number Bases

Hexadecimal numbers are written with a 0x prefix (like 0xFFFF or 0x1234ABDF). Binary numbers are written with a lowercase 'b' suffix (like 1001b or 10b). Decimal numbers are indicated without any suffix or using a lowercase 'd' suffix (like 4500d).

1.5.2 Byte Ordering

This section defines the internal organization of registers and memory structures that span multiple bytes. A few conventions to start with are:

- **Network Order** — Ethernet always transmits multiple-bytes fields with the Most Significant (MS) byte first.
- **Endian Notation** — Defines how a logical entity (such as a MAC Address) is stored in a given structure (like register or descriptor). Two options exist:
  - Little Endian (LE) notation — The MS byte of the logical entity is mapped to the highest byte address of the structure.
  - Big Endian (BE) notation — The MS byte of the logical entity is mapped to the lowest byte address of the structure.

Following are some examples:

Example 1:

A 32-bit counter is equal 0x01234567 (such as the sequence number in the TCP header). The counter is transferred on the wire as: 01 23 45 67 where 01 is the first byte on the wire and 67 is the last byte.

LE registers store this counter as (in bytes) as follows:

0x01 — Highest byte address
0x23
0x45
0x67 — Lowest byte address

BE registers store this counter as (in bytes) as follows:

0x67 — Highest byte address
0x45
0x23
0x01 — Lowest byte address

Example 2:

An L2 type register that holds the value of IPv4 header is equal 0x0800. The field is transferred on the wire as: 08 00 where 08 is the first byte on the wire.

LE registers store this counter as (in bytes) as follows:

0x08 — Highest byte address
0x00 — Lowest byte address

BE registers store this counter as (in bytes) as follows:

0x00 — Highest byte address
0x08 — Lowest byte address

Example 3:

A 48-bit Ethernet MAC Address equals 0x00112348A9BE. The Ethernet MAC Address is transferred on the wire as: 00 11 23 48 A9 BE where 00 is the first byte on the wire.

LE registers store this counter as (in bytes) as follows:

0x00 — Highest byte address
0x11
0x23
0x48
0xA9
0xBE — Lowest byte address

BE registers store this counter as (in bytes) as follows:

0xBE — Highest byte address
0xA9
0x48
0x23
0x11
0x00 — Lowest byte address

The following rules determine the Endian-ness of E810 structures:

- The general rule is that all structures are defined in LE notation unless defined otherwise. These structures include:
  - Registers.
  - AQ commands.
  - Structures in host memory (including any type of descriptors).
  - NVM.
  - LAN and PE contexts.
- The following structures are in BE notation:
  - Host memory buffers that are received or transmitted.
  - Any structures that contains a MAC Address (see exception for field vector).
  - Quad hash context programming registers (GL_SWT_LOFV_PE, GL_SWT_LOFV_SW and EMP_SWT_LOFV) are each defined in LE, while register 'n' is mapped to words (63 - 2*'n') and (62 - 2 *'n') in the field vector.
  - IP Addresses in Protocol Engine host memory.
- The following structures have a mixed notation:
  - Field vector is presented in mixed BE/LE notation: Words are ordered in BE notation and bytes within the words are presented in LE notation.
  - Type-Length-Value (TLV) structures are stored in the NVM in mixed BE/LE notation: Words are ordered in BE notation and bytes within the words are presented in LE notation.

1.6 Support Documents

Table 1-2 lists industry standards relevant to the E810.

Table 1-2. Standards Supported by the E810

Category	Description
ARP	**Title:** "RFC 826: An Ethernet Address Resolution Protocol (ARP)", November 1982 **Document:** http://www.ietf.org/rfc/rfc0826.txt **Description:** Protocol to convert IP Addresses to Ethernet addresses.
Base	**Title:** "RFC 1071: Computing the Internet Checksum", September 1988 **Document:** http://www.ietf.org/rfc/rfc1071.txt **Description:** This RFC describes how to compute the Internet checksums used in IP, TCP and UDP.
Base	**Title:** "RFC 1180: A TCP/IP Tutorial", January 1991 **Document:** http://www.ietf.org/rfc/rfc1180.txt **Description:** Bare bones tutorial of TCP/IP protocol suite: ARP, IP and TCP and Upper Layer Protocols (ULPs). This is included for informative purposes only.
Base	**Title:** "RFC 1936: Implementing the Internet Checksum in Hardware", April 1996 **Document:** http: //www.ietf.org/rfc/rfc1936.txt **Description:** Techniques for efficiently implementing the Internet checksum in hardware.
DCB	**Title:** "DCB Capability Exchange Protocol Base Specification", Revision 1.01 **Document:** http://www.ieee802.org/1/files/public/docs2008/az-wadekar-dcbxcapability-exchange-discovery-protocol-1108-v1.01.pdf **Description:** Defines CEE DCBX, a pre-standard version of the DCB Capability Exchange Protocol.
DCB	**Title:** "Priority Grouping for DCB Networks (Enhanced Transmission Selection)", Revision 1.01 **Document:** http://www.ieee802.org/1/files/public/docs2008/az-wadekar-etsproposal-0608-v1.01.pdf **Description:** Defines CEE ETS, a pre-standard version of the DCB Enhanced Transmission Selection Protocol
Ethernet	**Title:** "IEEE Standard for Ethernet" (IEEE Std 802.3-2018) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Specifies the Ethernet MAC and PHY layers up to 400 Gb/s. Includes these now superseded docs (among many others): 802.3ae (10 Gb/s base spec), 802.3an (10GBASE-T), 802.3ap (backplane Ethernet, KX, KX4, KR), 802.3ba (100G), 802.3by (25G), 802.3bs (200G/400G), and more.
Ethernet	**Title:** "IEEE Standard for Ethernet – Amendment 3: Media Access Control Parameters for 50 Gb/s and Physical Layers and Management Parameters for 50 Gb/s, 100 Gb/s, and 200 Gb/s Operation" (IEEE Std 802.3cd-2018) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Defines Ethernet MAC for 50 GbE and PHY layers for 50G/100G/200G based upon 50Gb/s PAM4 electrical and optical signaling.
Ethernet	**Title:** "Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications – Amendment 8: MAC Control Frame for Priority-based Flow Control" (IEEE P802.3bd-2011) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Defines a MAC control frame to support 802.1Qbb priority-based flow control.
Ethernet	**Title:** "IEEE Standard for Local and Metropolitan Area Networks – Media Access Control (MAC) Bridges" (IEEE Std 802.1D-2004) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Base specification for Ethernet bridging.
Ethernet	**Title:** "IEEE Standards for Local and Metropolitan Area Networks - Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks" (IEEE Std 802.1Q-2011) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Ethernet VLAN-aware bridge specification.
Ethernet	**Title:** "IEEE Standard for Local and metropolitan area networks— Link Aggregation" (IEEE Std 802.1AX-2008) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Logic and protocols that enable aggregation of one or more Ethernet links into a single logical link. Until recently, link aggregation was defined in the 802.3 specification, but in the 2008 version it was moved to 802.1.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
Ethernet	**Title:** "Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks — Amendment17: Priority-based Flow Control" (IEEE P802.1Qbb-2011) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Priority-based Flow Control (PFC) is one of the specifications that comprise DCB. PFC enables flow control per TC on IEEE 802 point-to-point full duplex links. This is achieved by a mechanism similar to the IEEE 802.3 Annex 31B PAUSE, but operating on individual priorities.
Ethernet	**Title:** "Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks — Amendment 21: Edge Virtual Bridging" (IEEE P802.1Qbg-2012) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** EVB is one of the specifications that comprise DCB. EVB defines many of the virtual switching features on end stations like the E810. This includes definition of things like S-channels, which enable the multiplexing of multiple virtual channels on a single physical LAN, VSIs, VEBs, VEPAs, and so on. It also defines new management infrastructure for administering the new features.
Ethernet	**Title:** "Virtual Bridged Local Area Networks — Bridge Port Extension" (IEEE P802.1BR/D3.3) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** BPE is a dedicated specification describing the bridge port extender element. It specifies the use of E-channels and a multicast replication service to extend bridge ports across multiple physical or virtual devices.
Ethernet	**Title:** "IEEE Standard for Local and metropolitan area networks — Station and Media Access Control Connectivity Discovery" (IEEE Std 802.1AB-2009) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Defines Link Layer Discovery Protocol (LLDP) that enables a server to advertise its identity, capabilities, and interconnections to other entities on an Ethernet fabric.
Ethernet	**Title:** "IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems" (IEEE Std 1588-2008) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Defines a protocol that enables precise synchronization of clocks in systems communicating via packet networks.
Ethernet	**Title:** "SFF-8436 Specification for QSFP+ 4X 10 Gb/s Pluggable Transceiver", Revision 4.9, 8/31/2018 **Document:** Available from https://www.snia.org/technology-communities/sff/specifications **Description:** Defines the Quad Small Form Factor Pluggable (QSFP+) module mechanicals, electrical interface and pin-out, and so on.
Ethernet	**Title:** "SFF-8431 SFP+ 10 Gb/s and Low Speed Electrical Interface", Revision 4.1, 7/6/2009" **Document:** Available from https://www.snia.org/technology-communities/sff/specifications **Description:** Defines the SERDES Framer Interface (SFI) high speed electrical interface to a Small Form-factor Pluggable (SFP+) optical module. Also defines the SFP+ management interface.
Ethernet	**Title:** "RMII™ Specification", Revision 1.2, 3/20/1998 **Document:** http://ebook.pldworld.com/_eBook/-Telecommunications,Networks-/TCPIP/RMII/rmii_rev12.pdf **Description:** Reduced pin count interface used in place of IEEE standard Media Independent Interface (MII). The E810 has an Reduced Media Independent Interface (RMII) based interface for its NC-SI connection.
Ethernet	**Title:** Serial-GMII Specification, rev 1.8, 11/2/2005, published by Cisco Systems **Document:** ftp://ftp-eng.cisco.com/smii/sgmii.pdf **Description:** Reduced pin count interface used in place of IEEE standard Gigabit Media Independent Interface (GMII).
Ethernet	**Title:** "Ethernet Alliance, Ethernet Jumbo Frames", Version 0.1, 11/12/2009 **Document:** http://ethernetalliance.org/wp-content/uploads/2011/10/EA-Ethernet-Jumbo-Frames-v0-1.pdf **Description:** Document describing jumbo frames. Included for informative purposes only.
Ethernet	**Title:** "Extended Frame Sizes for Next Generation Ethernets" **Document:** http://staff.psc.edu/mathis/MTU/AlteonExtendedFrames_W0601.pdf **Description:** Document describing jumbo frames. Included for informative purposes only.
Ethernet	**Title:** "Extended Ethernet Frame Size Support", November 1999 **Document:** https://www.ietf.org/proceedings/48/I-D/kaplan-isis-ext-eth-02.txt **Description:** Document describing jumbo frames. Included for informative purposes only.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
Ethernet (DCB)	**Title:** "Virtual Bridged Local Area Networks — Amendment 18: Enhanced Transmission Selection for Bandwidth Sharing Between Traffic Classes" (IEEE P802.1Qaz-2011) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** ETS is one of the specifications that comprise DCB. ETS enables arbitration of bandwidth between TCs. This specification also defines Data Center Bridging Exchange (DCBX) protocol. DCBX enables configuration of DCB features onto an Ethernet LAN.
Ethernet/IP	**Title:** "RFC 894: A Standard for the Transmission of IP Datagrams over Ethernet Networks", April 1984 **Document:** http://www.ietf.org/rfc/rfc894.txt **Description:** This specifies the method for transmitting IP datagrams over Ethernet.
Ethernet/IP	**Title:** "RFC 1042: A Standard for the Transmission of IP Datagrams over IEEE 802 Networks", February 1988 **Document:** http://www.ietf.org/rfc/rfc1042.txt **Description:** This specifies the method for transmitting IP datagrams over IEEE 802.3 networks. Obsoletes: RFC 948
IP	**Title:** "RFC 791: Internet Protocol", September 1981 **Document:** http://www.ietf.org/rfc/rfc0791.txt **Description:** Base specification for IPv4.
IP	**Title:** "RFC 815: IP Datagram Reassembly Algorithms", July 1982 **Document:** http://www.ietf.org/rfc/rfc0815.txt
IP	**Title:** "RFC 2460: Internet Protocol, Version 6 (IPv6) Specification", December 1998 **Document:** http://www.ietf.org/rfc/rfc2460.txt **Description:** Base specification for IPv6. Obsoletes RFC 1883.
IP	**Title:** "RFC 2474: Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers", December 1998 **Document:** https://tools.ietf.org/html/rfc2474 **Description:** Obsoletes RFC 1349, 1455.
IP	**Title:** "RFC 2710: Multicast Listener Discovery (MLD) for IPv6", October 1999 **Document:** http://www.ietf.org/rfc/rfc2710.txt **Description:** Specifies the protocol used by an IPv6 router to discover the multicast listeners on its directly attached links. MLD is derived from version 2 of IPv4's Internet Group Management Protocol, IGMPv2. This is an important standard for power management.
IP	**Title:** "RFC 3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6", June 2004 **Document:** http://www.ietf.org/rfc/rfc3810.txt **Description:** Updates RFC 2710. This is an important standard for power management.
IP	**Title:** "RFC 2873: TCP Processing of the IPv4 Precedence Field", June 2000 **Document:** http: //www.ietf.org/rfc/rfc2873.txt **Description:** Corrects a conflict between TCP as defined in RFC 793 and DiffServ in handling of the IPv4 precedence field.
IP	**Title:** "RFC 4861: Neighbor Discovery for IP version 6 (IPv6)", September 2007 **Document:** http://www.ietf.org/rfc/rfc4861.txt **Description:** IPv6 nodes use neighbor discovery to discover each other's presence, to determine each other's link-layer addresses, to find routers, and to maintain reachability information. This is an important standard for power management. Obsoletes RFC 2461.
Mgmt	**Title:** "System Management Bus (SMBus) Specification", v3.0, December 20, 2014 **Document:** Available from http://smbus.org/specs/ **Description:** A two-wire interface for communication of management information, based on the principles of operation of I^2C.
Mgmt	**Title:** "DSP0222: Network Controller Sideband Interface (NC-SI) Specification", Version 1.1.0, September 23, 2015 **Document:** http://dmtf.org/sites/default/files/standards/documents/DSP0222_1.1.0.pdf **Description:** Standardizes the sideband communication interface between a NIC (the E810) and a BMC.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
Mgmt	**Title:** "DSP0236: Management Component Transport Protocol (MCTP) Base Specification", Version 1.3.0, November 24, 2016 **Document:** http://dmtf.org/sites/default/files/standards/documents/DSP0236_1.3.0.pdf **Description:** Specifies MCTP protocol.
Mgmt	**Title:** "DSP0237: Management Component Transport Protocol (MCTP) SMBus/I^2C Transport Binding Specification", Version 1.0.0, May 21, 2017 **Document:** http://dmtf.org/sites/default/files/standards/documents/DSP0237_1.1.0.pdf **Description:** Describes the binding of MCTP over SMBus.
Mgmt	**Title:** "DSP0238: Management Component Transport Protocol (MCTP) PCIe VDM Transport Binding Specification", Version 1.0.2, December 7, 2014 **Document:** http://dmtf.org/sites/default/files/standards/documents/DSP0238_1.0.1.pdf **Description:** Describes the binding of MCTP over PCIe.
Mgmt	**Title:** "DSP0239: Management Component Transport Protocol (MCTP) IDs and Codes", Version 1.2.0, August 28, 2012 **Document:** http://dmtf.org/sites/default/files/standards/documents/DSP0239_1.2.0.pdf **Description:** Describes constants used by MCTP specifications.
Mgmt	**Title:** "DSP0240: Platform Level Data Model (PLDM) Base Specification", Version 1.0.0, April 23, 2009 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0240_1.0.0.pdf **Description:** PLDM base specification including the PLDM command format and PLDM control commands.
Mgmt	**Title:** "DSP2041: Platform Level Data Model (PLDM) over MCTP Binding Specification", Version 1.0.0, April 23, 2009 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0241_1.0.0.pdf **Description:** Describes the binding of PLDM over MCTP.
Mgmt	**Title:** "DSP0245 Platform Level Data Model (PLDM) IDs and Codes Specification", Version 1.2.0, November 24, 2016 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0245_1.2.0.pdf **Description:** Constants used for PLDM commands.
Mgmt	**Title:** "DSP0248: Platform Level Data Model (PLDM) for Platform Monitoring and Control Specification", Version 1.1.0, November 8, 2011 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0248_1.1.0.pdf **Description:** Contains the description of PDT, sensors and affecters used in PLDM.
Mgmt	**Title:** "DSP0249: Platform Level Data Model (PLDM) State Set Specification", Version 1.0.0, March 16, 2009 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0249_1.0.0.pdf **Description:** Defines the enums and states used by PLDM.
Mgmt	**Title:** "DSP0261: NC-SI Over MCTP Specification", Version 1.1.0, March 21, 2015 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0261_1.1.0.pdf **Description:** Describes the encapsulation of NC-SI packets in MCTP.
Mgmt	**Title:** "DSP0267: Platform Level Data Model (PLDM) For Firmware Update Specification", Version 1.0.0, November 24, 2016 **Document:** http://www.dmtf.org/sites/default/files/standards/documents/DSP0267_1.0.0.pdf **Description:** Defines messages and data structures for updating firmware.
MPLS	**Title:** "RFC 3031: Multiprotocol Label Switching Architecture", January 2001 **Document:** https://datatracker.ietf.org/doc/rfc3031/ **Description:** MPLS architecture.
MPLS	**Title:** "RFC 3032: MPLS Label Stack Encoding", January 2001 **Document:** https://datatracker.ietf.org/doc/rfc3032/ **Description:** MPLS header.
PCI	**Title:** "PCI Local Bus Specification", Revision 3.0, February 3, 2004 **Document:** Available from www.pcisig.com **Description:** Compliant with select sections, such as Appendix I Vital Product Data.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
PCI	**Title:** "PCI Hot-Plug Specification", Revision 1.1, June 20, 2001 **Document:** Available from www.pcisig.com **Description:** Defines how PCI add-in cards are installed and removed while the system is running.
PCI	**Title:** "PCI Firmware Specification", Revision 3.0, June 20, 2005 **Document:** Available from www.pcisig.com **Description:** Defines the firmware interface for managing PCIe systems in a host computer. Describes the format, contents, and code entry points for Expansion ROMs.
PCI	**Title:** "PCI Express Base Specification", Revision 3.1a, December 7, 2015 **Document:** Available from www.pcisig.com **Description:** Contains the technical details of the PCIe architecture, protocol, link layer, physical layer, and software interface.
PCI	**Title:** "PCI Express Card Electromechanical Specification", Revision 3.0, July 21, 2013 **Document:** Available from www.pcisig.com **Description:** Mechanical and electrical specifications for an Evo card form factor.
Power Mgmt	**Title:** "Magic Packet Technology", November 1995 **Document:** http://support.amd.com/TechDocs/20213.pdf **Description:** Defines a method for waking up a sleeping networked PC using a specific Ethernet frame (a Magic packet).
Power Mgmt	**Title:** "PCI Bus Power Management Interface Specification", Revision 1.2, March 3, 2004 **Document:** Available from www.pcisig.com **Description:** Defines a standard set of PCI peripheral power management hardware interfaces and behavioral policies.
Power Mgmt	**Title:** "Advanced Configuration and Power Interface Specification", Revision 4.0a, April 5, 2010 **Document:** http://www.acpi.info/DOWNLOADS/ACPIspec40a.pdf **Description:** Defines standard interfaces to enable robust OS-directed motherboard device configuration and power management.
Power Mgmt	**Title:** "Standard ECMA-393: proxZZZy for sleeping hosts" 2nd Edition, June 2012 **Document:** www.ecma-international.org/publications/files/ECMA-ST/ECMA-393.pdf **Description:** Defines a low-power proxy that handles key network tasks for a high-power device, thus allowing the high-power device to sleep when not in active use.
RDMA	**Title:** "RFC 5040: A Remote Direct Memory Access Protocol Specification", October 2007 **Document:** http://www.ietf.org/rfc/rfc5040.txt **Description:** LLP is DDP, connects directly to the Host CPU/OS via the E810 System Interface.
RDMA	**Title:** "RFC 5041: Direct Data Placement over Reliable Transports", October 2007 **Document:** http://www.ietf.org/rfc/rfc5041.txt **Description:** LLP is MPA, ULP is RDMAP. DDP protocol provides information to place incoming data directly into a ULP receive buffer without intermediate buffers.
RDMA	**Title:** "RFC 5044: Marker PDU Aligned Framing for TCP Specification", October 2007 **Document:** http://www.ietf.org/rfc/rfc5044.txt **Description:** LLP is TCP, ULP is DDP. MPA is a framing protocol that enables the preservation of ULP record boundaries.
RDMA	**Title:** "RFC 7306: Remote Direct Memory Access (RDMA) Protocol Extensions", June 2014 **Document:** https://tools.ietf.org/html/rfc7306 **Description:** Specifies extensions to the IETF Remote Direct Memory Access Protocol (RDMAP) as specified in RFC 5040.
RDMA	**Title:** "RDMA Protocol Verbs Specification (Version 1.0)", April 2003 **Document:** rdmaconsortium.org/home/draft-hilland-iwarp-verbs-v1.0-RDMAC.pdf **Description:** Verbs describe the Host application/OS interface to an RNIC. This interface is implemented as a combination of the RNIC system interface, its associated firmware, and host software. It provides access to the RNIC queuing and memory management resources, as well as the underlying networking layers.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
RDMA	**Title:** "InfiniBand Architecture Specification Annex A17: RoCEv2" September 2, 2014 **Document:** Available from https://www.infinibandta.org/ibta-specifications-download/ **Description:** This document is an annex to Volume 1 release 1.2.1 of the InfiniBand Architecture.
RDMA	**Title:** "InfiniBand Architecture Specification Volume 1", Release 1.3, March 3, 2015 (subset of this spec that applies to RoCEv2) **Document:** Available from https://www.infinibandta.org/ibta-specifications-download/ **Description:** The InfiniBand Architecture Specification describes a first order interconnect technology for interconnecting processor nodes and I/O nodes to form a system area network.
Security	**Title:** "NIST SP 800-198: Platform Firmware Resiliency Guidelines", May 2018 **Abstract:** https://csrc.nist.gov/publications/detail/sp/800-193/final **Document:** https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-193.pdf **Description:** Provides technical guidelines and recommendations supporting resiliency of platform firmware and data against potentially destructive attacks.
Software	**Title:** Microsoft specification for "Receive Side Scaling" (RSS). **Document:** https://docs.microsoft.com/en-us/windows-hardware/drivers/network/ndis-receive-side-scaling2 **Description:** RSS is a network driver technology that enables the efficient distribution of network receive processing across multiple CPUs in multiprocessor systems.
SR-IOV	**Title:** "Single Root I/O Virtualization and Sharing Specification", Revision 1.1, January 20, 2010 **Document:** Available from www.pcisig.com **Description:** The SR-IOV specification defines extensions to the PCIe specification that enable the VMs in a virtualized server to efficiently share PCI adapter hardware resources.
Statistics	**Title:** "RFC 2819: Remote Network Monitoring Management Information Base", May 2000 **Document:** http://www.ietf.org/rfc/rfc2819.txt **Description:** Defines objects for managing remote network monitoring devices. Includes the popular packet size histogram counters. Obsoletes RFC 1757.
Statistics	**Title:** "RFC 2863: The Interfaces Group MIB", June 2000 **Document:** http://www.ietf.org/rfc/rfc2863.txt **Description:** Describes objects used for managing network interfaces. Obsoletes RFC 2233.
Statistics	**Title:** "RFC 4022: Management Information Base for the Transmission Control Protocol (TCP)", March 2005 **Document:** http://www.ietf.org/rfc/rfc4022.txt **Description:** IP version-independent TCP MIB. Obsoletes RFC 2012, 2452.
Statistics	**Title:** "RFC 4113: Management Information Base for the User Datagram Protocol (UDP)", June 2005 **Document:** http://www.ietf.org/rfc/rfc4113.txt **Description:** Objects for managing implementations of UDP. Obsoletes RFC 2013, 2454.
Statistics	**Title:** "RFC 4293: Management Information Base for the Internet Protocol (IP)", April 2006 **Document:** http://www.ietf.org/rfc/rfc4293.txt **Description:** IP version-independent IP MIB. Obsoletes RFC 2011, 2465, 2466.
Statistics	**Title:** "Microsoft NDIS 6.0 OID_GEN_STATISTICS" **Document:** https://docs.microsoft.com/en-us/windows-hardware/drivers/network/oid-gen-statistics **Description:** Adapter statistics counters defined by Microsoft for NDIS 6.0.
TCP	**Title:** "RFC 793: Transmission Control Protocol", September 1981 **Document:** http://www.ietf.org/rfc/rfc0793.txt **Description:** Base specification for TCP.
TCP	**Title:** "RFC 813: Window and Acknowledgment Strategy in TCP", July 1982 **Document:** http://www.ietf.org/rfc/rfc813.txt
TCP	**Title:** "RFC 896: Congestion Control in IP/TCP Internetworks", January 6, 1984 **Document:** http://www.ietf.org/rfc/rfc896.txt **Description:** Defines the Nagle algorithm, which specifies delaying transmission of small amounts of data when there are Acknowledgments (ACKs) outstanding.

Table 1-2. Standards Supported by the E810 [continued]

Category	Description
TCP	**Title:** "RFC 1323: TCP Extensions for High Performance", May 1992 **Document:** http://www.ietf.org/rfc/rfc1323.txt **Description:** Defines the TCP window scale and timestamp options, Round Trip Time Measurement (RTTM) and Protect Against Wrapped Sequences (PAWS). Obsoletes RFC 1072, 1185.
TCP	**Title:** "RFC 2525: Known TCP Implementation Problems", March 1999 **Document:** http://www.ietf.org/rfc/rfc2525.txt **Description:** This RFC describes implementation issues with various historical TCP/IP stacks. While it is included here for informative purposes only, it does serve as a good check list to avoid known problems. The E810 Protocol Engine is designed to support its recommendations.
TCP	**Title:** "RFC 2923: TCP Problems with Path MTU Discovery", September 2000 **Document:** http://www.ietf.org/rfc/rfc2923.txt **Description:** Discusses problems with existing RFC 1191 implementations that should be avoided. Serves as an implementation checklist.
TCP	**Title:** "RFC 2988: Computing TCP's Retransmission Timer", November 2000 **Document:** http://www.ietf.org/rfc/rfc2988.txt **Description:** Defines the standard algorithm that TCP senders are required to use to compute and manage their retransmission timer.
TCP	**Title:** "RFC 3390: Increasing TCP's Initial Window", October 2002 **Document:** http://www.ietf.org/rfc/rfc3390.txt **Description:** Specifies an optional standard for TCP to increase the permitted initial window from one or two segments to roughly 4 KB. Obsoletes RFC 2414. Updates RFC 2581.
TCP	**Title:** "RFC 3465: TCP Congestion Control with Appropriate Byte Counting (ABC)", February 2003 **Document:** http://www.ietf.org/rfc/rfc3465.txt **Description:** This experimental RFC defines a small modification to the way TCP increases its congestion window. Instead of increasing cwnd by a constant amount for each acknowledgment, cwnd is increased based on the number of previously unacknowledged bytes each ACK covers.
TCP	**Title:** "RFC 3782: The NewReno Modification to TCP's Fast Recovery Algorithm", April 2004 **Document:** http://www.ietf.org/rfc/rfc3782.txt **Description:** Update the fast recovery algorithm that is run after three duplicate ACKs have been received. Changes to the CWND during fast recovery, scheduling additional fast retransmitted packets if the received ACKs do not acknowledge all the data when fast recovery was entered. Obsoletes RFC 2582.
TCP	**Title:** "RFC 5681: TCP Congestion Control", September 2009 **Document:** http://www.ietf.org/rfc/rfc5681.txt **Description:** TCP slow start, congestion avoidance, fast retransmit, and fast recovery algorithms. Obsoletes RFC 2581.
Test	**Title:** "IEEE Standard Test Access Port and Boundary-Scan Architecture" (IEEE Std 1149.1-2001) **Document:** Available from http://standards.ieee.org/getieee802 **Description:** Defines a standard interface through which instructions and test data are communicated to an integrated circuit for component- and circuit board-level testing.
Tunneling	**Title:** "RFC 7637: NVGRE: Network Virtualization using Generic Routing Encapsulation", September 2015 **Document:** http://datatracker.ietf.org/doc/draft-sridharan-virtualization-nvgre/?include_text=1 **Description:** MAC in Generic Routing Encapsulation (GRE) over IP encapsulation.
Tunneling	**Title:** "RFC 7348: Virtual eXtensible Local Area Network (VXLAN): A Framework for Overlaying Virtualized Layer 2 Networks over Layer 3 Networks", August 2014 **Document:** http://datatracker.ietf.org/doc/draft-mahalingam-dutt-dcops-vxlan/?include_text=1 **Description:** MAC in UDP encapsulation.
UDP	**Title:** "RFC 768: User Datagram Protocol", August 28, 1980 **Document:** http://www.ietf.org/rfc/rfc0768.txt **Description:** Base specification for UDP.

Chapter 2 Pin Interface

2.1 Pin Descriptions

This section provides detailed descriptions of E810 signal pins, grouped by function.

- A "_N" following the signal name indicates that the signal is active-low.
- Signal names with a suffix of "_p" and "_n" refer to differential signals.

The buffer types are listed in Table 2-1.

Table 2-1. Buffer Types

Buffer	Description
In	Input is a standard input-only signal.
Out (O)	Totem Pole Output (TPO) is a standard active driver.
t/s	Tri-state is a bi-directional, tri-state input/output pin.
o/d	Open drain enables multiple devices to share as a wire-OR.
A-in	Analog input signals.
A-out	Analog output signals.
A-Inout	Bi-directional analog signals.
HCSL-in	High-Speed Current Steering Logic input signal.
NCSI-in	NC-SI input signal.
NCSI-out	NC-SI output signal.
Pu	Internal pull-up resistor.
Pd	Internal pull-down resistor.
clkobs	Clock observation output.
JTAG	1.8 V JTAG I/O.

2.2 Pin Assignments and Descriptions

The E810 is available in two package options:

- The 25x25 mm, 668-pin, Flip-Chip Ball Grid Array (FCBGA) package contains all the signals needed to implement the maximum product configuration. In particular, 16 lanes of PCIe and eight lanes of Ethernet PMD are exposed. Products based on the Intel® Ethernet Controller E810-CAM1 and the Intel® Ethernet Controller E810-CAM2 use this package.
- The 21x21 mm, 456-pin, Flip-Chip Ball Grid Array (FCBGA) package contains the signals needed to implement eight lanes of PCIe and two lanes of Ethernet PMD for the dual-port 25 GbE or single-port 50 GbE implementation. Products based on the Intel® Ethernet Controller E810-XXVAM2 use this package.

The following sections provide the signal names, pin/ball assignments and signal descriptions. The AC/DC electrical specifications for the signals are described in Chapter 16.

2.2.1 PCIe Interface Pins

This section provides the pin assignment for PCIe interface signals.

Table 2-2. PCIe Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
PE_CLK_p PE_CLK_n	N47 N45	H40 G39	HCSL-in	PCIe Differential Reference Clock In. A 100 MHz differential clock input. This clock is used as the reference clock for the PCIe Tx/Rx circuitry and by the PCIe core PLL to generate clocks for the PCIe core logic.
PET_0_p PET_0_n	L39 L41	E39 E37	A-out	PCIe Serial Data Output. A serial differential output pair running at 16 GT/s, 8 GT/s, 5 GT/s, or 2.5 GT/s. This output carries both data and an embedded clock that is recovered along with data at the receiving end.
PET_1_p PET_1_n	J39 J41	C35 C33	A-out	Same as previous.
PET_2_p PET_2_n	G39 G41	C29 C27	A-out	Same as previous.
PET_3_p PET_3_n	E45 D44	C23 C21	A-out	Same as previous.
PET_4_p PET_4_n	E41 D40	C17 C15	A-out	Same as previous.
PET_5_p PET_5_n	E37 D36	E11 D10	A-out	Same as previous.
PET_6_p PET_6_n	E33 D32	E7 D6	A-out	Same as previous.
PET_7_p PET_7_n	E29 D28	E3 D2	A-out	Same as previous.
PET_8_p PET_8_n	E25 D24	N/A	A-out	Same as previous.
PET_9_p PET_9_n	E21 D20	N/A	A-out	Same as previous.
PET_10_p PET_10_n	E17 D16	N/A	A-out	Same as previous.
PET_11_p PET_11_n	E13 D12	N/A	A-out	Same as previous.
PET_12_p PET_12_n	E9 D8	N/A	A-out	Same as previous.
PET_13_p PET_13_n	E5 D4	N/A	A-out	Same as previous.
PET_14_p PET_14_n	G9 G7	N/A	A-out	Same as previous.
PET_15_p PET_15_n	J9 J7	N/A	A-out	Same as previous.
PER_0_p PER_0_n	L45 L47	C39 B38	A-in	PCIe Serial Data Input. A serial differential input pair running at 16 GT/s, 8 GT/s, 5 GT/s, or 2.5 GT/s This output carries both data and an embedded clock that is recovered along with data at the receiving end.
PER_1_p PER_1_n	J45 J47	A35 A33	A-in	Same as previous.
PER_2_p PER_2_n	G45 G47	A29 A27	A-in	Same as previous.

Table 2-2. PCIe Interface Pins [continued]

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
PER_3_p PER_3_n	B44 A43	A23 A21	A-in	Same as previous.
PER_4_p PER_4_n	B40 A39	A17 A15	A-in	Same as previous.
PER_5_p PER_5_n	B36 A35	B12 A11	A-in	Same as previous.
PER_6_p PER_6_n	B32 A31	B8 A7	A-in	Same as previous.
PER_7_p PER_7_n	B28 A27	B4 A3	A-in	Same as previous.
PER_8_p PER_8_n	B24 A23	N/A	A-in	Same as previous.
PER_9_p PER_9_n	B20 A19	N/A	A-in	Same as previous.
PER_10_p PER_10_n	B16 A15	N/A	A-in	Same as previous.
PER_11_p PER_11_n	B12 A11	N/A	A-in	Same as previous.
PER_12_p PER_12_n	B8 A7	N/A	A-in	Same as previous.
PER_13_p PER_13_n	B4 A3	N/A	A-in	Same as previous.
PER_14_p PER_14_n	G3 G1	N/A	A-in	Same as previous.
PER_15_p PER_15_n	J3 J1	N/A	A-in	Same as previous.
PE_WAKE_N	R47	Y40	o/d	Wake. Pulled to 0b to indicate that a Power Management Event (PME) is pending and the PCIe link should be restored. Defined in the PCIe specifications. 3.3 V tolerant even when device is not powered.
PE_RST_N	R45	W39	In	Power and Clock Good Indication. Indicates that power and PCIe reference clock are within specified values. Defined in the PCIe specifications. Also called PCIe Reset and PERST#.

2.2.2 Ethernet Interface Pins

This section provides the pin assignments for Ethernet interface signals.

Table 2-3. Ethernet Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
REFCLKIN_p REFCLKIN_n	M2 M4	G1 H2	HCSL-in	156.25MHz HCSL differential clock input
RX_L0_p RX_L0_n	AF44 AE45	AA17 AA19	A-in	Serial Data Input for Ethernet PMD lane 0. A serial differential input pair running at up to 26.5625 GBaud. An embedded clock present in this input is recovered along with the data. This lane is used as a receive pair for one of the Ethernet ports. See Section 3.2.2 for lane to port mapping
RX_L1_p RX_L1_n	AF38 AF40	AA23 AA25	A-in	Same as previous, Lane 1.
RX_L2_p RX_L2_n	AF32 AF34	N/A	A-in	Same as previous, Lane 2.
RX_L3_p RX_L3_n	AF26 AF28	N/A	A-in	Same as previous, Lane 3.
RX_L4_p RX_L4_n	AF20 AF22	N/A	A-in	Same as previous, Lane 4.
RX_L5_p RX_L5_n	AF14 AF16	N/A	A-in	Same as previous, Lane 5.
RX_L6_p RX_L6_n	AF8 AF10	N/A	A-in	Same as previous, Lane 6.
RX_L7_p RX_L7_n	AF2 AF4	N/A	A-in	Same as previous, Lane 7.
TX_L0_p TX_L0_n	AG47 AF48	AC17 AC19	A-out	Serial Data Output for Ethernet PMD Lane 0. A serial differential output pair running at up to 26.5625 GBaud. This output carries both data and an embedded clock that is recovered along with data at the receiving end. This lane is used as a transmit pair for one of the Ethernet ports for one of the Ethernet ports. See Section 3.2.2 for lane to port mapping
TX_L1_p TX_L1_n	AH42 AH44	AC23 AC25	A-out	Same as previous, Lane 1.
TX_L2_p TX_L2_n	AH36 AH38	N/A	A-out	Same as previous, Lane 2.
TX_L3_p TX_L3_n	AH30 AH32	N/A	A-out	Same as previous, Lane 3.
TX_L4_p TX_L4_n	AH24 AH26	N/A	A-out	Same as previous, Lane 4.
TX_L5_p TX_L5_n	AH18 AH20	N/A	A-out	Same as previous, Lane 5.
TX_L6_p TX_L6_n	AH12 AH14	N/A	A-out	Same as previous, Lane 6.
TX_L7_p TX_L7_n	AH6 AH8	N/A	A-out	Same as previous, Lane 7.

Table 2-4. External Ethernet PHY Control - MDIO/I²C Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
MDIO0_SDA0	AC45	AC33	T/s, o/d, Pu	Management Data, when configured as an MDIO interface. Bi-directional signal for serial data transfers between the E810 and the PHY management registers. ***Note:*** Tri-state buffer, requires an external pull-up device. I²C Data, when configured as 2-wire management interface. Stable during the high period of the clock (unless it is a start or stop condition). ***Note:*** Open drain buffer requires an external pull-up device. Mapping of MDIO/I²C interfaces is controlled by the topology netlist stored in NVM.
MDC0_SCL0	AB38	W33	O, o/d, Pu	Management Clock, when configured as an MDIO interface. Clock output for accessing the PHY management registers. MDC clock frequency is set to 2.4 MHz (default). I²C Clock, when configured as 2-wire management. One clock pulse is generated for each data bit transferred. Mapping of MDIO/I²C interfaces is controlled by the topology netlist stored in NVM. ***Note:*** This I/O operates as an open drain buffer, and therefore requires an external pull-up device.
MDIO1_SDA1	AB42	AA33	T/s, o/d, Pu	Same as above.
MDC1_SCL1	Y38	R31	O, o/d, Pu	Same as above
MDIO2_SDA2	AB48	AC37	T/s, o/d, Pu	Same as above.
MDC2_SCL2	AA39	U33	O, o/d, Pu	Same as above
MDIO3_SDA3	AA45	AA37	T/s, o/d, Pu	Same as above.
MDC3_SCL3	AB40	Y34	O, o/d, Pu	Same as above
MDIO4_SDA4	Y48	Y38	T/s, o/d, Pu	Same as above.
MDC4_SCL4	Y40	V34	O, o/d, Pu	Same as above

Note: If an I²C interface clock/data pair is disconnected, the pins must be pulled up either by an external pull-up resistor or by enabling the internal pull-up.

2.2.3 NC-SI Interface Pins

This section provides the pin assignment for NC-SI signals.

Table 2-5. NC-SI Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
NCSI_CLK_IN	U39	U37	NCSI-In, Pu	NC-SI Reference Clock Input. Synchronous clock reference for receive, transmit, and control interface. It is a 50 MHz clock ±100 ppm.
NCSI_CRS_DV	U45	T40	NCSI-Out, Pu	Carrier Sense/Receive Data Valid (CRS/DV).
NCSI_RXD_0 NCSI_RXD_1	V46 Y42	U39 N33	NCSI-Out, Pu	Receive Data. Data signals to the BMC.
NCSI_TX_EN	V42	V40	NCSI-In, Pu	Transmit Enable.
NCSI_TXD_0 NCSI_TXD_1	V40 W41	V38 T34	NCSI-In, Pu	Transmit Data. Data signals from the BMC.
NCSI_ARB_IN	U41	T38	NCSI-In, Pu	NC-SI Hardware Arbitration Input. If GL_MNG_HWARB_CTRL.*NCSI_ARB_EN* is cleared, this pin is internally pulled up.
NCSI_ARB_OUT	Y46	P34	NCSI-Out, Pu	NC-SI Hardware Arbitration Output.

Note: If NC-SI is disconnected, external pull-downs should be used for the NCSI_CLK_IN, NCSI_TXD[1:0], and NCSI_TX_EN signals.

2.2.4 SMBus Interface Pins

This section provides the pin assignment for the SMBus interface signals.

Table 2-6. SMBus Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
SMBCLK	AC41	AA31	o/d	SMBus Clock. One clock pulse is generated for each data bit transferred. 3.3 V tolerant when device is not powered.
SMBD	AA37	W31	o/d	SMBus Data. Stable during the high period of the clock (unless it is a start or stop condition). 3.3 V tolerant when device is not powered.
SMBALRT_N	AC39	AC31	o/d	SMBus Alert. Acts as an interrupt pin of a slave device on the SMBus. 3.3 V tolerant when device is not powered.

Note: If the SMBus is disconnected, an external pull-up should be used for the SMBCLK and SMBD pins.

2.2.5 Serial Flash Memory Interface Pins

This section provides the pin assignment for SPI signals for connectivity to Flash memory devices.

Table 2-7. Serial Flash Memory Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
FLSH_SI	W1	U1	t/s, Pu	Serial data output that should be connected to the Serial Input (SI) of the SPI serial Flash memory. With the dual and quad SPI commands, the SI Pin becomes I/O0 in conjunction with other pins providing a 4-bit wide data path to the Flash device. To maintain consistency with the SPI nomenclature, the SI (I/O0) pin is referenced as the SI pin unless specifically addressing the Dual-I/O and Quad-I/O modes in which case it is referenced as I/O0.
FLSH_SO	AA1	W1	In, Pu	Serial data input that should be connected to the Serial Output (SO) from the SPI serial Flash memory. With the dual and quad SPI commands, the SO Pin becomes I/O1 in conjunction with other pins providing a 4-bit wide data path to the Flash device. To maintain consistency with the SPI nomenclature, the SO (I/O1) pin is referenced as the SO pin unless specifically addressing the Dual-I/O and Quad-I/O modes in which case it is referenced as I/O1.
FLSH_IO2 FLSH_IO3	Y2 U1	V2 R1	t/s, Pu	FLSH_IO2 and FLSH_IO3 are only used for quad SPI instructions, providing a 4-bit wide data path to the Flash device.
FLSH_SCK	V2	T2	t/s, Pu	Flash serial clock operates at 50 MHz.
FLSH_CE_N	AB2	Y2	t/s, Pu	Flash chip select output.

2.2.6 General Purpose I/O (GPIO) Pins

This section provides the pin assignment for GPIO signals. The E810 has a total of 24 GPIO pins that can be configured as Software Definable Pins (SDPs), LED drivers or dedicated hardware functions for connecting to external PHYs or IEEE 1588 auxiliary devices. The E810 offers the flexibility to configure any of the GPIO pins to different modes and associated with different ports as described in Section 3.5.

The GPIO pins fall into two categories:

- **GPIO/SDP/LED:** These general purpose software definable pins are driven via the internal I/O expander (the I/O Widget). The terms GPIO and SDP are used somewhat interchangeably in this document. Application of these pins is defined by the link topology netlist. Refer to the reference design section for supported mapping.
- **Direct Timing GPIO:** The E810 has a total of five direct, low latency, GPIOs that can be used for accurate timing applications such as 1588. Four of these GPIOs are single ended, one a differential output. These pins are controlled directly by the controller core to minimize delay and jitter for timing applications.

Table 2-8. GPIO/SDP/LED Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
SDP0 SDP1 SDP2 SDP3 SDP4 SDP5 SDP6 SDP7 SDP8 SDP9 SDP10 SDP11 SDP12 SDP13 SDP14 SDP15 SDP16 SDP17 SDP18 SDP19	V4 T10 U3 U7 U11 W3 Y4 V10 U9 W7 W9 V8 Y8 W11 AA3 Y10 AA7 AB4 V38 W39	T4 P6 R3 V4 R7 U3 AA1 U7 W3 AA3 V8 Y4 AB4 R9 AC3 U9 AC5 AB6 W37 R33	t/s, Pu	General purpose 3.3 V I/Os. Can be used to connect LEDs, low speed optical module interfaces, external PHY control, or other similar usages. The SDP pins can also be configured for use as external interrupt sources. Refer to the reference design section for supported uses.

Table 2-9. Direct Timing GPIO Interface Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
SDP20 SDP21 SDP22 SDP23	AC1 AA9 AB8 AC3	AA9 W7 AA7 AC9	t/s, Pu	General purpose 3.3 V I/Os for 1588 synchronized timing applications. The pins can also be configured for use as external interrupt sources.
CLK_OUT_P CLK_OUT_N	P4 P2	M2 L1	clkobs	0.8 V differential output for 1588 synchronized timing applications.

2.2.7 Miscellaneous Pins

This section provides the pin assignment for other miscellaneous signals.

Table 2-10. Miscellaneous Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
LAN_PWR_GOOD	AA11	Y10	In, Pu	LAN Power Good. A 3.3 V input signal. A transition from low-to-high initializes the E810 into operation. If not used (POR_BYPASS = 0b), an internal Power-on-Reset (POR) circuit triggers the E810 power-up. If the internal POR circuit is used to trigger device power-up, this signal should be connected to 3.3 V. By default, internal POR should be used.
POR_BYPASS	AD2	AB10	In, Pu	Bypass indication as to whether or not to use the internal POR or the LAN_PWR_GOOD pin. 0b = The E810 uses both the internal POR circuit and the LAN_PWR_GOOD pin; the device is held in reset as long as the POR is active or LAN_PWR_GOOD is low. By default, this pin should be pulled down to VSS and the internal POR used unless the power supply sequencing timing requirements, as defined in Chapter 16 could not be met. 1b = The E810 disables the internal POR circuit and uses the LAN_PWR_GOOD pin as a POR indication.
AUX_PWR	AD4	AB12	In, Pu	Auxiliary Power Available. When set, indicates that auxiliary power is available and the E810 should support the $D3_{COLD}$ power state if enabled to do so. This pin is latched at the rising edge of LAN_PWR_GOOD.
MAIN_PWR_OK	AC7	AC11	In, Pu	Main Power OK. Indicates that platform main power is up. Must be connected externally.
PCI_DIS_N	AB10	Y8	In, Pu	This pin is a strapping pin latched while LAN_PWR_GOOD or PE_RST_N or in-band PCIe reset are asserted. If this pin is not connected or driven high during initialization, all PCI functions as configured from NVM are enabled. If this pin is asserted/driven low during initialization, all PCI functions that are allowed to be disabled as configured in NVM are disabled (see Section 4.5 for details).
DEV_DIS_N	AC9	W9	In, Pu	This pin is a strapping option pin latched while LAN_PWR_GOOD or PE_RST_N or in-band PCIe reset are asserted. This pin can be either used as a device disable or for disabling the LAN ports and associated functions based on NVRAM configuration (see Section 4.5 for details). If this pin is not connected or driven high during initialization, all the LAN ports and associated functions as configured from NVRAM are enabled for normal operation. If this pin is asserted/driven low during initialization, the LAN ports and associated functions as configured from NVRAM are disabled. Asserting this pin disables the entire device if all the LAN ports are configured to be disabled. When the entire device is disabled, the PCIe link is in L3 state, the PHY is in power down mode, and the output buffers are tri-stated. (see Section 4.5 for details).
SENSOR_THERM_IN SENSOR_THERM_OUT	M10 M8	J7 J5	Analog	Thermal Diode for use with the integrated thermal sensor. Use with an external thermal sensor is not validated.
OBS_CORE_VDD OBS_CORE_VSS	T24 R23	P22 N21		Power supply observation pins.

2.2.8 Testability and Debug Pins

This section provides the pin assignment for JTAG testability interface signals.Note that the JTAG 1.8 V I/Os internal pull-up/pull-down are not enabled until after core VDD is applied. Therefor, for stable power up, external pull-up/pull-down resistors are required as indicated. Access to the JTAG pins is need for advanced debug. Refer to Section 17, "Design Guidelines" for recommended debug connections.

Table 2-11. Testability and Debug Pins

Signal	Ball # CAM2/CAM1	Ball # XXVAM2	Type	Description
JTCK	R41	K38	JTAG, In, Pu	JTAG Clock Input. Connect pull up resistor to 1.8V for normal operation.
JTDI	P38	K36	JTAG, In, Pu	JTAG Data Input. Connect pull up resistor to 1.8V for normal operation.
JTDO	P42	J37	JTAG, Out	JTAG Data Output. 1.8 V
JTMS	N39	K34	JTAG, In, Pu	JTAG TMS Input. Connect pull up resistor to 1.8 V for normal operation.
JRST_N	R37	L37	JTAG, In, Pd	JTAG Reset Input. 1.8 V I/O. Active low reset for the JTAG port. Connect pull down resistor to VSS for normal operation.
TAP_SEL	P40	L39	JTAG, In, Pd	1.8V I/O. 0b = JTAG interface is connected to Intel TAP. 1b = JTAG interface is connected to manufacturing TAP.
UARTTXD	AA47	AA39	t/s, Pu	Multi-function pin. RSVD pins. UART interface for EMP firmware debug. Transmit data output. This pin can also be configured as an additional SDP from the I/O Widget (IOW).
UARTRXD	AA41	AB38	t/s, Pu	Multi-function pin. RSVD pins. UART interface for EMP firmware debug. Receive data input. This pin can also be configured as an additional SDP from the IOW.
UARTCTS	AB46	Y32	t/s, Pd	Multi-function pin. RSVD pins. UART interface for EMP firmware debug. Clear to send input. This pin can also be configured as an additional SDP from the IOW.
UARTRTS	AC47	AB34	t/s, Pu	Multi-function pin. RSVD pins. UART interface for EMP firmware debug. Request to send output. This pin can also be configured as an additional SDP from the IOW.

2.2.9 Reserved and No-Connect Pins

This section provides the pin assignment for reserved and no-connect pins. Table 2-12 and Table 2-13 contain the reserved and no-connect pins for the E810-CAM2/CAM1 and E810-XXVAM2, respectively.

Table 2-12. Reserved and No-Connect Pins (E810-CAM2/CAM1)

Signal	Ball # CAM2/CAM1	Description
RSVDN37_VDDH RSVDR39_VDDH	N37 R39	Reserved pins. Connect pull up resistor to 1.8 V for normal operation.
RSVDN41_VSS	N41	Reserved pin. Connect pull down resistor to VSS for normal operation.
RSVDN7_NC RSVDN11_NC RSVDP8_NC RSVDP10_NC RSVDR7_NC RSVDR9_NC RSVDR11_NC RSVDT2_NC RSVDT4_NC RSVDT8_NC RSVDT38_NC RSVDT40_NC RSVDT42_NC RSVDT46_NC RSVDT48_NC RSVDU47_NC RSVDV48_NC RSVDW33_NC RSVDW45_NC RSVDW47_NC RSVDAA35_NC	N7 N11 P8 P10 R7 R9 R11 T2 T4 T8 T38 T40 T42 T46 T48 U47 V48 W33 W45 W47 AA35	Reserved pins. Leave unconnected for normal operation.

Table 2-13. Reserved and No-Connect Pins (E810-XXVAM2)

Signal	Ball # XXVAM2	Description
RSVDJ33_VDDH RSVDM40_VDDH	J33 M40	Reserved pins. Connect pull up resistor to 1.8 V for normal operation.
RSVDK40_VSS	K40	Reserved pin. Connect pull down resistor to VSS for normal operation.

Leave unconnected for normal operation.

2.2.10 Power Supply Pins

This section provides the pin assignment for power supply pins. The electrical specifications for the power supply pins are defined in Section 16.3. Table 2-14 and Table 2-15 contain the power supply pins for the E810-CAM2/CAM1 and E810-XXVAM2, respectively.

Table 2-14. Power Supply Pins (E810-CAM2/CAM1)

Signal	Ball # CAM2/CAM1	Type	Description
VDDIO33	P12, P14, T12, T14, T34, T36, V12, V14, V34, V36, Y12, Y14, Y34, Y36	3.3 V	Digital power supply for 3.3 V I/O.
VDDH18	M12, M14, P34, P36	1.8 V	Digital 1.8 V power supply.
AVDDH	Y20, Y22, Y24	1.1 V	Analog power supply for Ethernet SerDes interfaces.
AVDD_ETH	AB14, AB16, AB18, AB20, AB22, AB24, AB26, AB28, AB30, AB32, AB34, AD12, AD14, AD16, AD18, AD20, AD22, AD24, AD26, AD28, AD30, AD32, AD34, AD36	0.9 V	Analog power supply for Ethernet SerDes interfaces.
AVDD_PCIE	F14, F16, F18, F20, F22, F24, F26, F28, F30, F32, F34, H16, H18, H20, H22, H24, H26, H28, H30, H32, K22, K24, K26, K28, K30	0.9 V	Analog power supply for PCIe SerDes interfaces.
AVDD_PLL	AA19, AA23	0.9 V	PLL power supply.
VDD	K20, K32, M16, M18, M20, M22, M24, M26, M28, M30, M32, P16, P18, P20, P22, P24, P26, P28, P30, P32, T16, T18, T20, T22, T26, T28, T30, T32, V16, V18, V20, V22, V24, V26, V28, V30, V32, Y16, Y18, Y26, Y28, Y30, Y32	0.8 V	Digital core logic power supply.
PLLVDD	J17, K18	0.8 V	
VSSA	A5, A9, A13, A17, A21, A25, A29, A33, A37, A41, A45, B2, B6, B10, B14, B18, B22, B26, B30, B34, B38, B42, B46, B48, C1, C3, C5, C7, C9, C11, C13, C15, C17, C19, C21, C23, C25, C27, C29, C31, C33, C35, C37, C39, C41, C43, C45, C47, D2, D6, D10, D14, D18, D22, D26, D30, D34, D38, D42, D46, D48, E1, E3, E7, E11, E15, E19, E23, E27, E31, E35, E39, E43, E47, F2, F4, F6, F8, F10, F12, F36, F38, F40, F42, F44, F46, F48, G5, G11, G13, G15, G17, G19, G21, G23, G25, G27, G29, G31, G33, G35, G37, G43, H2, H4, H6, H8, H10, H12, H14, H34, H36, H38, H40, H42, H44, H46, H48, J5, J11, J13, J15, J21, J23, J25, J27, J29, J31, J33, J35, J37, J43, K2, K4, K6, K8, K10, K12, K34, K36, K38, K40, K42, K44, K46, K48, L35, L37, L43, M34, M36, M38, M40, M42, M44, M46, M48, W21, W23, AA15, AA17, AA21, AA25, AA27, AA29, AA31, AA33, AB12, AB36, AC11, AC13 AC15, AC17, AC19, AC21, AC23, AC25, AC27, AC29, AC31, AC33, AC35, AC37, AD8, AD10, AD38, AD40, AD42, AD44, AD46, AD48, AE1, AE3, AE5, AE7, AE9, AE11, AE13, AE15, AE17, AE19, AE21, AE23, AE25, AE27, AE29, AE31, AE33, AE35, AE37, AE39, AE41, AE43, AE47, AF6, AF12, AF18, AF24, AF30, AF36, AF42, AF46, AG1, AG3, AG5, AG7, AG9, AG11, AG13, AG15, AG17, AG19, AG21, AG23, AG25, AG27, AG29, AG31, AG33, AG35, AG37, AG39, AG41, AG43, AG45, AH4, AH10, AH16, AH22, AH28, AH34, AH40, AH46	0 V	Analog power supply ground.
PLLGND	J19, K16	0 V	
VSS	K14, L1, L3, L5, L7, L9, L11, L13, L15, L17, L19, L21, L23, L25, L27, L29, L31, L33, M6, N1, N3, N5, N9, N13, N15, N17, N19, N21, N23, N25, N27, N29, N31, N33, N35, N43, P6, P44, P46, P48, R1, R3, R5, R13, R15, R17, R19, R21, R25, R27, R29, R31, R33, R35, R43, T6, T44, U5, U13, U15, U17, U19, U21, U23, U25, U27, U29, U31, U33, U35, U37, U43, V6, V44, W5, W13, W15, W17, W19, W25, W27, W29, W31, W35, W37, W43, Y6, Y44, AA5, AA13, AA43, AB6, AB44, AC5, AC43, AD6	0 V	Digital power supply ground.

Table 2-15. Power Supply Pins (E810-XXVAM2)

Signal	Ball # XXVAM2	Type	Description
VDDIO33	M8, M10, M12, M30, M32, P8, P10, P12, P30, P32, T8, T10, T30, T32, V30, V32	3.3 V	Digital power supply for 3.3 V I/O.
VDDH18	H8, H10, H30, H32, K8, K10, K30, K32	1.8 V	Digital 1.8 V power supply.
AVDD	D14, D16, D18, D20, D22, D24, D26, D28, F18, F20, F22, F24, F26, F28, F30, U19, U21, W13, W15, W17, W19, W21, W23, W25, W27	0.9 V	Analog power supply for PCIe and Ethernet SerDes interfaces.
VDD	H12, H18, H20, H22, H24, H26, H28, K12, K14, K16, K18, K20, K22, K24, K26, K28, M14, M16, M18, M20, M22, M24, M26, M28, P14, P16, P18, P20, P24, P26, P28, T12, T14, T16, T18, T22, T24, T26, T28	0.8 V	Digital core logic power supply.
PLLVDD	G15, H16	0.8 V	
VSSA	A5, A9, A13, A19, A25, A31, A37, B2, B6, B10, B14, B16, B18, B20, B22, B24, B26, B28, B30, B32, B34, B36, B40, C1, C3, C5, C7, C9, C11, C13, C19, C25, C31, C37, D4, D8, D12, D30, D32, D34, D36, D38, D40, E1, E5, E9, E13, E15, E17, E19, E21, E23, E25, E27, E29, E31, E33, E35, F2, F4, F6, F8, F10, F32, F34, F36, F38, F40, G19, G21, G23, T20, V12, V14, V16, V18, V20, V22, V24, V26, V28, Y14, Y16, Y18, Y20, Y22, Y24, Y26, Y28, AA13, AA15, AA21, AA27, AB14, AB16, AB18, AB20, AB22, AB24, AB26, AB28, AC15, AC21, AC27	0 V	Analog power supply ground.
PLLGND	G17, H14	0 V	
VSS	F12, F14, F16, G3, G5, G7, G9, G11, G13, G25, G27, G29, G31, G33, G35, G37, H4, H34, H36, H38, J1, J3, J9, J11, J13, J15, J17, J19, J21, J23, J25, J27, J29, J31, J35, J39, K2, L3, L9, L11, L13, L15, L17, L19, L21, L23, L25, L27, L29, L31, L35, M4, M36, N1, N3, N11, N13, N15, N17, N19, N23, N25, N27, N29, N31, N35, P2, P36, R5, R11, R15, R17, R19, R21, R23, R25, R27, R29, R35, T6, T36, U5, U11, U13, U15, U17, U23, U25, U27, U29, U31, U35, V6, V10, V36, W5, W11, W29, W35, Y6, Y12, Y30, Y36, AA5, AA11, AA29, AA35, AB2, AB8, AB30, AB32, AB36, AC7, AC13, AC29, AC35	0 V	Digital power supply ground.

2.2.11 Pull-Up and Pull-Down Resistors

Internal pull-up and pull-down values on 3.3 V I/O pins, where indicated:

- Min: 10 KΩ
- Max: 20 KΩ

Internal pull-up and pull-down values on 1.8 V JTAG I/O pins, where indicated:

- Min: 25 KΩ
- Max: 50 KΩ

2.3 Package Layout

Figure 2-1 and Figure 2-2 show a top view ball map of Intel® Ethernet Controller E810-CAM2/CAM1. Figure 2-3 and Figure 2-4 show a top view ball map of Intel® Ethernet Controller E810-XXVAM2. See Section 16.7 for package mechanical specifications.

Chapter 3 Interconnects

3.1 PCI Express (PCIe)

3.1.1 Features

The E810 supports Rev. 4.0 of the PCIe base specification.

In addition to the capabilities required by the PCIe specifications, the E810 also supports the following optional functionality as described in this section:

- All PCI functions are native PCIe functions.
- Physical Layer:
  - Support for 2.5GT/s, 5GT/s, 8GT/s, and 16GT/s
  - Interface width of 1, 4, 8, or 16 PCIe lanes
  - Full swing and half swing signaling
  - Lane reversal
- Transaction Layer mechanisms:
  - 64-bit and 32-bit memory address spaces
  - Removal of I/O BAR (optional)
  - Relaxed ordering
  - Flow control update timeout mechanism
  - ID-based ordering (IDO)
  - Packet sizes:
    - Maximum payload size: 512B
    - Maximum read request size: 4 KB
  - Extended tags:
    - 10-bit tag as completer
    - 8-bit tag as requester
  - Function-Level Reset (FLR).
- Reliability:
  - Advanced Error Reporting (AER)
  - End-to-End CRC (ECRC) generation and checking
  - Recovery from data poisoning
  - Completion timeout
- Power Management:
  - Wake capability

- DFT and DFM support for high-volume manufacturing.
- The E810 supports the following extended capabilities:
  - AER
  - Device Serial Number (DSN)
  - Alternative RID Interpretation (ARI)
  - Single Root I/O Virtualization (SR-IOV)
  - Access Control Services (ACS)
  - TLP Processing Hints (TPH)
  - Process Address Space ID (PASID)

Table 3-1 lists the new requirements for the PCIe interface in the E810.

Table 3-1. PCIe Interface New Features

Description
General • Support PCIe base specification Ver. 4.0). • Support up to 8 PCI physical functions. ***Note:*** The PCI functions can be used in different manners per usage (for example, allocated to Ethernet ports).
PCI and PCIe Capabilities • PASID support. • Gen4 support.

3.1.2 Transaction Layer

3.1.2.1 Transactions Accepted by the E810

Table 3-2 lists the transactions accepted by the device and their attributes. See Section 3.1.2.8 for the number of credits provided per FC type.

Table 3-2. Transaction Types Accepted by the Transaction Layer

Transaction Type	FC Type	Tx Layer Reaction	Hardware Should Keep Data from Original Packet
Configuration Read Request	NPH	CPLH + CPLD	Requester ID, TAG, attribute.
Configuration Write Request	NPH + NPD	CPLH	Requester ID, TAG, attribute.
Memory Read Request	NPH	CPLH + CPLD	Requester ID, TAG, attribute.
Memory Write Request	PH + PD	-	-
IO Read Request	NPH	CPLH + CPLD	Requester ID, TAG, attribute.
IO Write Request	NPH + NPD	CPLH	Requester ID, TAG, attribute.
Read Completions	CPLH + CPLD	-	-
Message	PH + PD[1]	-	-

1. MCTP messages contain payload.

Flow Control types:

- CPLD — Completion Data Payload
- CPLH — Completion Headers
- NPD — Non-Posted Request Data Payload
- NPH — Non-Posted Request Headers
- PD — Posted Request Data Payload
- PH — Posted Request Headers

3.1.2.2 Size of Target Accesses

3.1.2.2.1 Memory Accesses

Rules for accesses to the CSR space (both memory BAR and MSI-X BAR):

Write accesses:

- CSR writes are 32-bit or 64-bit only.
- Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
- Other accesses (partial writes, larger writes) are handled as completer abort. Data is dropped and an error is generated as per PCIe rules.

Read accesses:

- CSR reads are 32-bit or 64-bit only.

  Note: Some 64-bit reads are handled atomically, such as not interleaved with any other read requests. This applies mainly to reading counters, where all 64 bits need to be read simultaneously. Such registers are explicitly marked in their description.

- Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear-by-read) is also applicable to partial reads. The completion on PCIe adheres to the specification rules regarding the number of bytes reported in the completion.
- Zero-length reads generate a completion, but the register is not accessed and undefined data is returned.
- Larger CSR read requests are handled as unsupported requests. The completion includes a UR status and an error is generated as per PCIe rules.

Rules for accessing the doorbell space in the memory BAR:

Write accesses:

- Write accesses are supported within the limit of the respective PCIe credits.
- A write access that crosses over into the Flash address space is handled as a completer abort.
- Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).

Read accesses:

- Read accesses are replied with stale data. No error indication is provided.

Rules for accessing the Flash space in the memory BAR or the Expansion ROM BAR:

Write accesses:

- Writes to Flash are silently ignored.

Read accesses:

- Reads to Flash are 32 bits wide.
- Partial reads with at least one byte disabled are handled internally as a full read. The completion on PCIe adheres to the specification rules regarding the number of bytes reported in the completion
- Zero-length reads generate a completion, but the Flash is not accessed and undefined data is returned.
- Larger CSR read requests are handled as completer abort. The completion includes a CA status and an error is generated as per PCIe rules.

3.1.2.3 I/O Accesses

Rules for accesses to the I/O BAR:

Write accesses:

- Write accesses are 32 bits wide.
- Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
- Other accesses (partial writes, larger writes) are handled as completer abort. Data is dropped and an error is generated as per PCIe rules.

Read accesses:

- Reads to the I/O BAR are 32 bits wide.
- Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe adheres to the specification rules regarding the number of bytes reported in the completion.
- Larger CSR read requests are handled as completer abort. The completion includes a CA status and an error is generated as per PCIe rules.
- See Section 13.1.1.5 for more details.

3.1.2.3.1 Messages

MCTP messages might contain a payload of up to 64 bytes.

3.1.2.4 Transactions Initiated by the E810

Table 3-3 lists the transactions initiated by the device and their attributes.

Table 3-3. Transaction Types Initiated by the Transaction Layer

Transaction Type	Payload Size	FC Type
Configuration Read Request Completion	DWord	CPLH + CPLD
Configuration Write Request Completion	-	CPLH
IO Read Request Completion	DWord	CPLH + CPLD
IO Write Request Completion	-	CPLH
Read Request Completion	DWord/QWord	CPLH + CPLD
Memory Read Request	-	NPH
Memory Write Request	≤ MAX_PAYLOAD_SIZE	PH + PD
Message	≤ 64 bytes[1]	PH + PD

1. MCTP messages contain payload.

Configuration values:

- MAX_PAYLOAD_SIZE - The value of the *Max Payload Size Supported* field in the Device Capabilities register is loaded from NVM.
  - Hardware default is 512B.
  - System software then programs the actual value into the *Max Payload Size* field of the Device Control register.
    - Non-ARI mode: If not all functions are programmed with the same value, the *Max Payload Size* used for all functions is the minimum value programmed among all functions.
    - ARI mode: *Max Payload Size* is determined solely by the setting in Function 0.
- MAX_READ_REQUEST_SIZE - The E810 supports read requests of up to 4 KB.
  - The actual maximum size of a read request is defined as the minimum {4 KB, *Max Read Request Size* field in the Device Control Register}.
- Extended tags are supported for Memory Read Requests.
- Prefixes can be added to memory read and write requests when PASID is enabled.

Note: If Extended tags are not enabled, the performance of the device might degrade. To ensure usage of extended tags, all functions must enable them in the *Extended Tag Field Enable* field.

3.1.2.4.1 Data Alignment

Requests must never specify an address/length combination that causes a memory space access to cross a 4 KB boundary. Therefore, the E810 breaks requests into 4 KB-aligned requests (if needed). This does not pose any requirement on software. However, if software allocates a buffer across a 4 KB boundary, hardware issues multiple requests for the buffer. Software should consider aligning buffers to a 4 KB boundary in cases where it improves performance.

The general rules for packet alignment are as follows. Note that these apply to all E810 requests:

- The length of a single request does not exceed the PCIe limit of *Max Payload Size* for write, and *Max Read Request Size* for read.
- A single request does not span across different memory pages as noted by the 4 KB boundary alignment previously mentioned.

If a request can be sent as a single PCIe packet and still meets the general rules for packet alignment, it is not broken at the cache line boundary, but rather is sent as a single packet. However, if any of the general rules require that the request be broken into two or more packets, the request is broken at the cache line boundary.

For requests with data payload, if the payload size is larger than (MAX_PAYLOAD_SIZE - CACHELINE_SIZE), the request is broken into multiple TLPs starting at the first cache-line boundary following the (MAX_PAYLOAD_SIZE - CACHELINE_SIZE) bytes. For example, if MAX_PAYLOAD_SIZE = 256B and CACHELINE_SIZE = 64 bytes, a 1 KB request starting at address 0x...10 is broken into TLPs such that the first TLP contains 240 bytes of payload (since 240 bytes + 0x10 = 256 bytes is on the cache-line boundary).

The system cache line size is controlled by the GLPCI_CNF2.*CACHELINE_SIZE* bit, loaded from the NVM *Cache Line Size* field. Note that the Cache Line Size register in the PCI configuration space is not related to the GLPCI_CNF2.*CACHELINE_SIZE* and is solely for software use.

3.1.2.5 Messages

Table 3-4 lists the response to messages sent to the device. Unlisted messages are not supported by the device and are treated as unsupported requests.

Table 3-4. Messages in the E810 (as a Receiver)

Message Code [7:0]	Routing r2r1r0	Message	E810 Response
0x00	011b	Unlock	Silently drop.
0x14	100b	PM_Active_State_NAK	Accepted.
0x19	011b	PME_Turn_Off	Accepted.
0x40 0x41 0x43 0x44 0x45 0x47 0x48	100b	Ignored messages (used to be hot-plug messages)	Silently drop.
0x50	100b	Slot power limit support (has one DWord data)	Silently drop.
0x7E	000b 010b 011b 100b	Vendor_defined type 0	Drop and handle as an unsupported request.
0x7F	100b 000b	Vendor_defined type 1	Silently drop.
0x7F	010b 011b	Vendor_defined type 1. See Section 3.1.2.5.1	Send to MCTP reassembly if Vendor ID = 0x1AB4 (DMTF) and VDM code - 0000b (MCTP). Otherwise, silently drop.

Table 3-5 lists the messages sent by the device.

Table 3-5. Messages in the E810 (as a Transmitter)

Message Code [7:0]	Routing r2r1r0	Message
0x20	100b	Assert INT A
0x21	100b	Assert INT B
0x22	100b	Assert INT C
0x23	100b	Assert INT D
0x24	100b	De-assert INT A
0x25	100b	De-assert INT B
0x26	100b	De-assert INT C
0x27	100b	De-assert INT D
0x30	000b	ERR_COR
0x31	000b	ERR_NONFATAL
0x33	000b	ERR_FATAL
0x18	000b	PM_PME
0x1B	101b	PME_TO_Ack
0x7F	000b 010b 011b	Vendor Defined Messages (VDM); see Section 3.1.2.5.1.

3.1.2.5.1 VDM

The following vendor defined message is supported:

- DMTF
- MCTP

3.1.2.5.1.1 MCTP VDMs

MCTP VDMs are supported as both master and target. The following header fields are involved (see Section 12.7.2.1 for more details):

- Fmt — Set to 11b to indicate a 4-DWord header with data.
- Type:

  [4:3] — Set to 10b to indicate a message.
  [2:0] — Routing r2r1r0 = 000b, 010b or 011b.
- Traffic Class — Set to 000b.
- TLP Digest — Set to 0b (no ECRC).
- Error Present — Set to 0b.
- Attributes[1:0] — Set to 01b (no snoop).
- Tag field — Indicates this is an MCTP packet and the size of padding to DWord alignment added.
- Message code = 0x7F (Type 1 VDM).
- Destination ID — captures the target B/D/F for route by ID. Otherwise, reserved.
- Vendor ID = 0x1AB4 (DMTF).

3.1.2.6 Transaction Attributes

3.1.2.6.1 Traffic Class (TC) and Virtual Channels (VC)

The E810 supports only TC = 0b and VC = 0b (default).

3.1.2.6.2 TLP Processing Hints (TPH)

The E810 supports the TPH capability defined in the PCI Express specification. It does not support extended TPH requests.

Existence of a TPH is indicated on the PCIe link by setting the *TH* bit in the TLP header. Using the PCIe TLP Steering Tag (ST) and Processing Hints (PH) fields, the E810 can provide hints to the root complex about the destination (socket ID) and about data access patterns (locality in cache) when executing DMA memory writes or read operations.

The E810 exposes a PCIe TPH capability structure (see Section 14.4.5) with no steering table.

Required steps to enable TPH usage:

1. For a given function, the *TPH Requester Enable* field in the PCIe configuration TPH Requester Control register should be set to either 01b or 11b, and the *ST Mode Select* field should be set to one of the two supported values: 000b (No Table Mode) or 010b (Device Specific Mode). If this is not the case, the PF driver should not enable the TPH in the transmit and receive queue contexts.
2. Appropriate TPH *Enable* bits in the receive or transmit queue context should be set.
3. Processing hints should be programmed in the GLTPH_CTRL.*Desc_PH* and GLTPH_CTRL.*Data_PH* Processing Hints fields.
4. Steering information should be programed in the *CPUID* fields in the receive or transmit queue context.

The Processing Hints and Steering Tags are set according to the characteristics of the traffic as listed in Table 10-2.

Note: To enable TPH usage, all the memory reads are done without setting any of the byte enable bits.

3.1.2.6.2.1 Steering Tag and Processing Hint Programming

Each type of DMA traffic uses a different policy to define how the steering tag (socket ID) and processing hints are generated:

- The policy for LAN traffic is described in Section 10.3.
- The policy for offloaded traffic is described in Section 11.4.8.
- Accesses to the Host Memory Cache do not use TPH hints.
- Accesses to the admin command queues do not use TPH hints.

3.1.2.6.3 PASID Prefix

Memory read and write transactions can have a PASID prefix added if the transaction is related to a queue from a PASID-enabled VSIs and PASID is enabled in the system.

The PASID prefix is described as follows:

31 29	28	27 24	23	22	21 20	19 0
100	1	0001	E	P	Res	PASID[19:0]

where:

- The *PASID[19:0]* value is extracted from the VSI_PASID.*PASID[19:0]* field.
- E = Execute Privilege = 0
- P = Privileged Mode Requested = 0

The addition of the prefix is controlled by the VSI_PASID.*EN[31]* bit if PASID is enabled in the PASID capability. See Section 14.4.9 for more information.

3.1.2.7 Device Ordering Rules

The E810 meets the PCIe ordering rules as follows:

Deadlock avoidance — The E810 meets the PCIe ordering rules that prevent deadlocks:

- Posted writes overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, master posted writes are allowed to proceed. On the target side, it is acceptable to timeout on stalled read requests to allow later posted writes to proceed.
- Target posted writes overtake stalled target configuration writes.
- Completions overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, completions generated by the E810 are allowed to proceed.

Consistency of data:

- Descriptor/Data Ordering — The E810 insures that a Rx-Descriptor is written back on PCIe only after the data that the descriptor relates to is written to the PCIe link.
- Target NP read requests might pass target posted writes addressing different PCI functions.
- Completions for target reads (memory, I/O, configuration) do not pass previous posted requests. Here are some specific usages of this rule:
  - Flush following a reset (such as FLR, BME, D3 entry, VFE clear) — When the system issues a reset event, it needs to identify when the device stops sending new posted requests from the function(s) under reset. The completion to the config write of these reset events is sent after all requests/completions related to that function(s) are flushed out. The device is expected not to issue any new posted transactions from the function(s) under reset.
  - MSI and MSI-X Ordering Rules — System software can change the MSI or MSI-X tables during run-time. Software expects that interrupt messages issued after the table has been updated are using the updated contents of the tables.
    - Since software does not know when the tables are actually updated in the E810, a common scheme is to issue a read request to the MSI or MSI-X table after an update to the table (a PCI configuration read for MSI and a memory read for MSI-X). Software expects that any message issued following the completion of the read request is using the updated contents of the tables.
    - Once an MSI or MSI-X message is issued using the updated contents of the interrupt tables, any consecutive MSI or MSI-X message does not use the contents of the tables prior to the change.

Independence between target and master accesses:

- The acceptance of a target posted request does not depend upon the transmission of any TLP.
- The acceptance of a target non-posted request does not depend upon the transmission of a non-posted request.
- Accepting a completion does not depend upon the transmission of any TLP.

3.1.2.7.1 Processing of Target Accesses

The E810 meets the specification requirements regarding target accesses as described in Section 3.1.2.7.

In addition, the following behaviors apply:

- Target accesses from different functions might be processed in a different order than the order in which they arrive.
- Completions that belong to requests from different PCI functions might be issued in a different order than the order of the respective requests.

3.1.2.7.2 Relaxed Ordering

The E810 takes advantage of the relaxed ordering rules in PCIe. By setting the relaxed ordering bit in the packet header, the E810 enables the system to optimize performance in the following cases:

- Relaxed ordering for LAN descriptor and data reads — When the E810 issues a read transaction, its split completion has no ordering relationship with the writes from the CPUs (same direction). It should be allowed to bypass the writes from the CPUs.
  - The GLLAN_RCTL_1.*RXDESCRDROEN* bit (loaded from NVM) enables relaxed ordering for Rx-Descriptor reads.
- Relaxed ordering for LAN Rx data writes — When the E810 issues Rx data writes, it also enables them to bypass each other in the path to system memory because software does not process this data until their associated descriptor writes are done.
  - The GLLAN_RCTL_1.*RXDATAWRROEN* bit (loaded from NVM) enables relaxed ordering for Rx data writes.
- The E810 does not relax ordering for the following requests:
  - LAN descriptor writes.
  - LAN Tx head write back.
  - Interrupt messages.
  - MCTP messages.
  - Protocol Engine traffic.
  - HMC requests.
  - EMP requests.
  - Any other requests not previously mentioned.

Relaxed ordering is globally enabled in the E810 by clearing the GLPCI_CNF2.*RO_DIS* bit, originally loaded from NVM. It is further controlled through the *Enable Relaxed Ordering* bit in the PCIe Device Control register (see Section 14.3.5.5).

3.1.2.7.3 ID-Based Ordering (IDO)

ID-based ordering was introduced in the PCIe rev. 2.1 specification. When enabled, the E810 sets IDO in all applicable TLPs defined in the PCIe specification. IDO is not set for MCTP packets.

IDO is enabled when all of the following conditions are met:

- IDO is not disabled from the NVM. Device default is enabled. The value loaded from the NVM is reflected in the GLPCI_CAPSUP register.
- The PCIe *IDO Request Enable* bit (for requests) or the *IDO Completion Enable* bit (for completions) in the Device Control 2 register is set (see Section 14.3.5.11).

3.1.2.8 Flow Control

3.1.2.8.1 Flow Control Rules

The E810 only implements the default Virtual Channel (VC0). A single set of credits is maintained for VC0.

Table 3-6. Flow Control Credits Allocation

Credit Type	Operations	Number of Credits (per Device)
Posted Request Header (PH)	Target write (one unit) Message (one unit)	96 header credit units.
Posted Request Data (PD)	Target write Message	288 data credits units.
Non-Posted Request Header (NPH)	Target read (one unit) Configuration read (one unit) Configuration write (one unit)	Four units (to enable concurrent target accesses).
Non-Posted Request Data (NPD)	Configuration write (one unit)	Four units.
Completion Header (CPLH)	Read completion (N/A)	Infinite (accepted immediately).
Completion Data (CPLD)	Read completion (N/A)	Infinite (accepted immediately).

Rules for FC updates:

- UpdateFC packets are sent immediately when a resource becomes available.
- The E810 follows the PCIe recommendations for frequency of UpdateFC FCPs.
- Specific rules apply in L0 or L0s link state. See the PCIe specification.

3.1.2.8.2 Flow Control Timeout Mechanism

The E810 implements the optional flow control update timeout mechanism. See the PCIe specification.

3.1.2.9 End-to-End CRD (ECRC)

The E810 supports ECRC as defined in the PCIe specification. The following functionality is provided:

- Inserting ECRC in transmitted TLPs:
  - The E810 indicates support for inserting ECRC in the *ECRC Generation Capable* bit of the PCIe Configuration registers. This bit is loaded from the global *ECRC Generation Capable* NVM bit.
  - Inserting ECRC is enabled per function by the *ECRC Generation Enable* bit of the PCIe Configuration registers. VFs follow the behavior of their PF.
  - ECRC is not added to MCTP messages (per the MCTP specification).
- ECRC is checked on all incoming TLPs. A packet received with an ECRC error is dropped. Note that for completions, a completion timeout occurs later (if enabled).
  - The E810 indicates support for ECRC checking in the *ECRC Check Capable* bit of the PCIe Configuration registers. This bit is loaded from the global *ECRC Check Capable* NVM bit.
  - Checking of ECRC is enabled by the *ECRC Check Enable* bit of the PCIe Configuration registers. ECRC checking is done if enabled by at least one physical function (enablement is not done via VFs).
- ECRC errors are reported on all Physical Functions (PFs) enabled for ECRC checking.
- System software can configure ECRC independently per each physical function.

3.1.3 Link Layer

3.1.3.1 ACK/NAK Scheme

NAKs are sent as soon as identified.

ACKs are sent per Section 3.5.3.1 (Table 3-7, Table 3-8, and Table 3-9) in the *PCIe Base Specification*.

3.1.3.2 Supported DLLPs

The following DLLPs are supported by the E810 as a receiver:

- ACK
- NAK
- PM_Request_Ack
- InitFC1-P
- InitFC1-NP
- InitFC1-Cpl
- InitFC2-P
- InitFC2-NP
- InitFC2-Cpl
- UpdateFC-P
- UpdateFC-NP

- UpdateFC-Cpl

The following DLLPs are supported by the E810 as a transmitter:

- ACK
- NAK
- PM_Enter_L1
- PM_Enter_L23
- InitFC1-P
- InitFC1-NP
- InitFC1-Cpl
- InitFC2-P
- InitFC2-NP
- InitFC2-Cpl
- UpdateFC-P
- UpdateFC-NP

Note: UpdateFC-Cpl is not sent because of the infinite FC-Cpl allocation.

3.1.3.3 Transmit EDB Nullifying (End Bad)

A TLP might be signaled as EDB or poisoned if during its transmission from the device, an internal memory error is detected that might corrupt the TLP payload.

3.1.3.4 Retry Buffer

The retry buffer size is 8 KB.

3.1.4 Physical Layer

3.1.4.1 Link Speed

The E810 supports Gen 1 (2.5GT/s), Gen 2 (5GT/s), Gen 3 (8GT/s), and Gen 4 (16GT/s).

The following configuration controls link speed:

- PCIe *Supported Link Speeds* bit — Indicates the link speeds supported by the E810.
- PCIe *Current Link Speed* bit — Indicates the negotiated link speed.
- PCIe *Target Link Speed* bit — Used to set the target compliance mode speed when software is using the *Enter Compliance* bit to force a link into compliance mode. The default value is the highest link speed supported defined by the previous *Supported Link Speeds*.

The E810 does not initiate a hardware autonomous speed change.

The E810 supports entering compliance mode at the speed indicated in the *Target Link Speed* field in the PCIe Link Control 2 register (see Section 14.3.5.13). Compliance mode functionality is controlled via the PCIe Link Control 2 register.

3.1.4.2 Link Width

The E810 supports a maximum link width of x16, x8, x4, or x1.

The maximum link width supported is loaded from the NVM into the *Maximum Link Width* field of the PCIe Link Capabilities register (see Section 14.3.5.7). Hardware default is the x16 link.

During link configuration, the platform and the E810 negotiate on a common link width. The link width must be one of the supported PCIe link widths (x1, x4, x8, x16), such that:

- If maximum link width = x16, the E810 negotiates to either x16, x8, x4, or x1.
- If maximum link width = x8, the E810 negotiates to either x8, x4, or x1.
- If maximum link width = x4, the E810 negotiates to either x4 or x1.
- If maximum link width = x1, the E810 only negotiates to x1.

The E810 does not initiate a hardware autonomous link width change.

3.1.4.3 Lane Configurations

The E810 supports lane reversal and degraded modes.

The following general rules determine how the device reacts in different cases of lanes configuration:

- If lane 0 is found valid, the E810 does not initiate lane reversal. The Link Partner (LP) might initiate lane reversal (to end up with an optimal lane width) and the E810 consents with the lane reversal.
- If lane 0 is found invalid, the E810 initiates lane reversal. Lane reversal succeeds if the LP supports link reversal.
- If the lanes at both ends of the port (such as lanes 0 and 15 for x16, lanes 0 and 7 for x8, lanes 0 and 3 for x4, lane 0 for x1) are invalid, a link is not established.

Note: Some of the configurations or transitions assume lane reversal done by the LP. If the LP does not support a specific transition, the respective configuration is not provided on that system.

Figure 3-1, Figure 3-2, Figure 3-3 and Figure 3-4 depict the initial link width configuration and link degradation options. In Figure 3-2 and Figure 3-3, the upper part of the figures describe link options where the LP and the E810 are aligned. The bottom part of the figures describe link options where the LP and the E810 are reversed in order.

- Figure 3-1 applies when both the LP or the E810 is physically set to x1.
- Figure 3-2 applies when either the LP or the E810 is physically set to x4 and both are not physically set to x8.
- Figure 3-3 applies when either the LP or the E810 is physically set to x8.
- Figure 3-4 applies when either the LP or the E810 is physically set to x16.

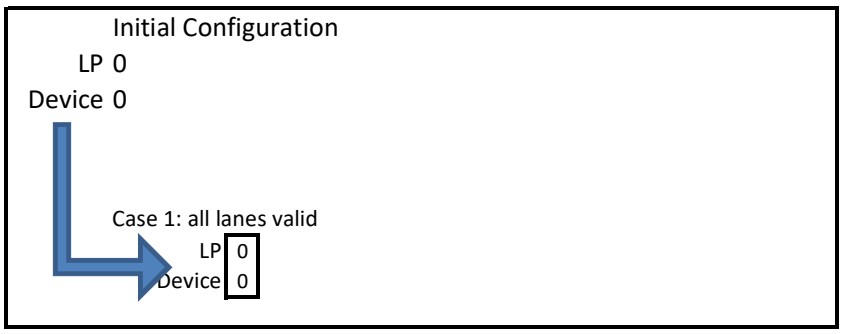

Figure 3-1. Link Width Configurations for a x1 Port

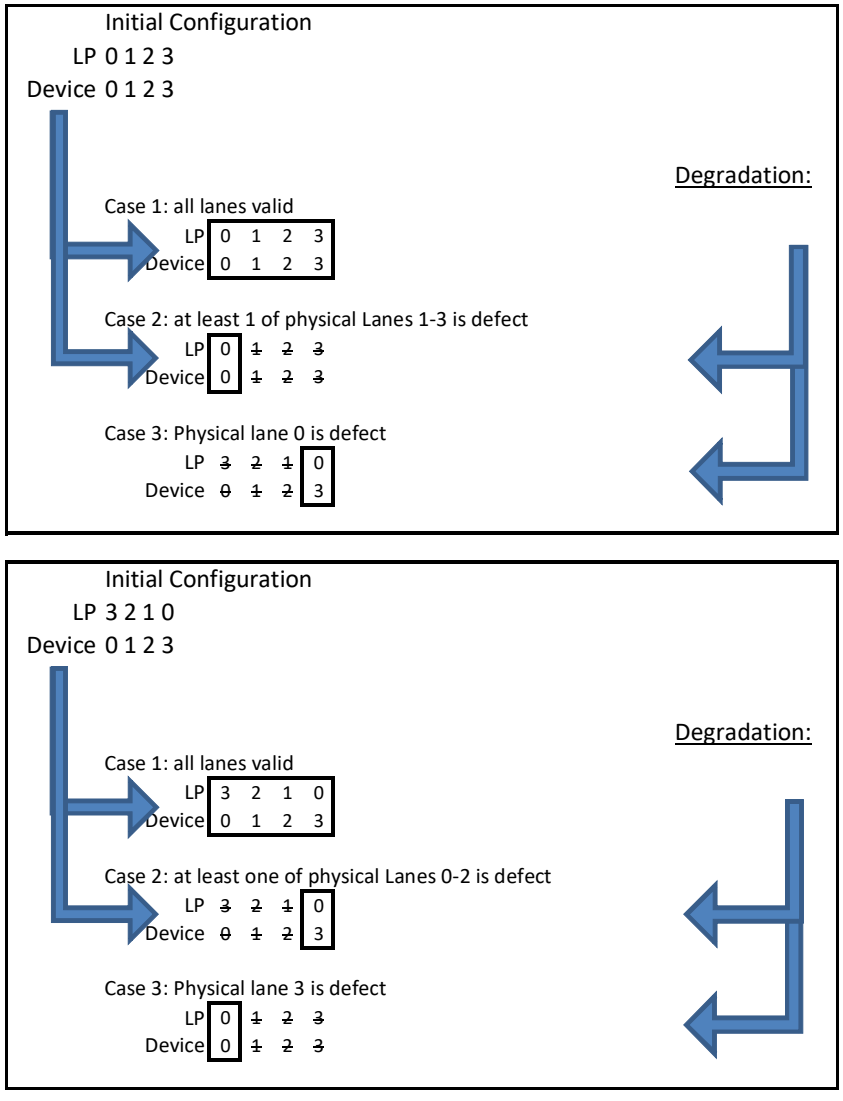

Figure 3-2. Link Width Configurations for a x4 Port

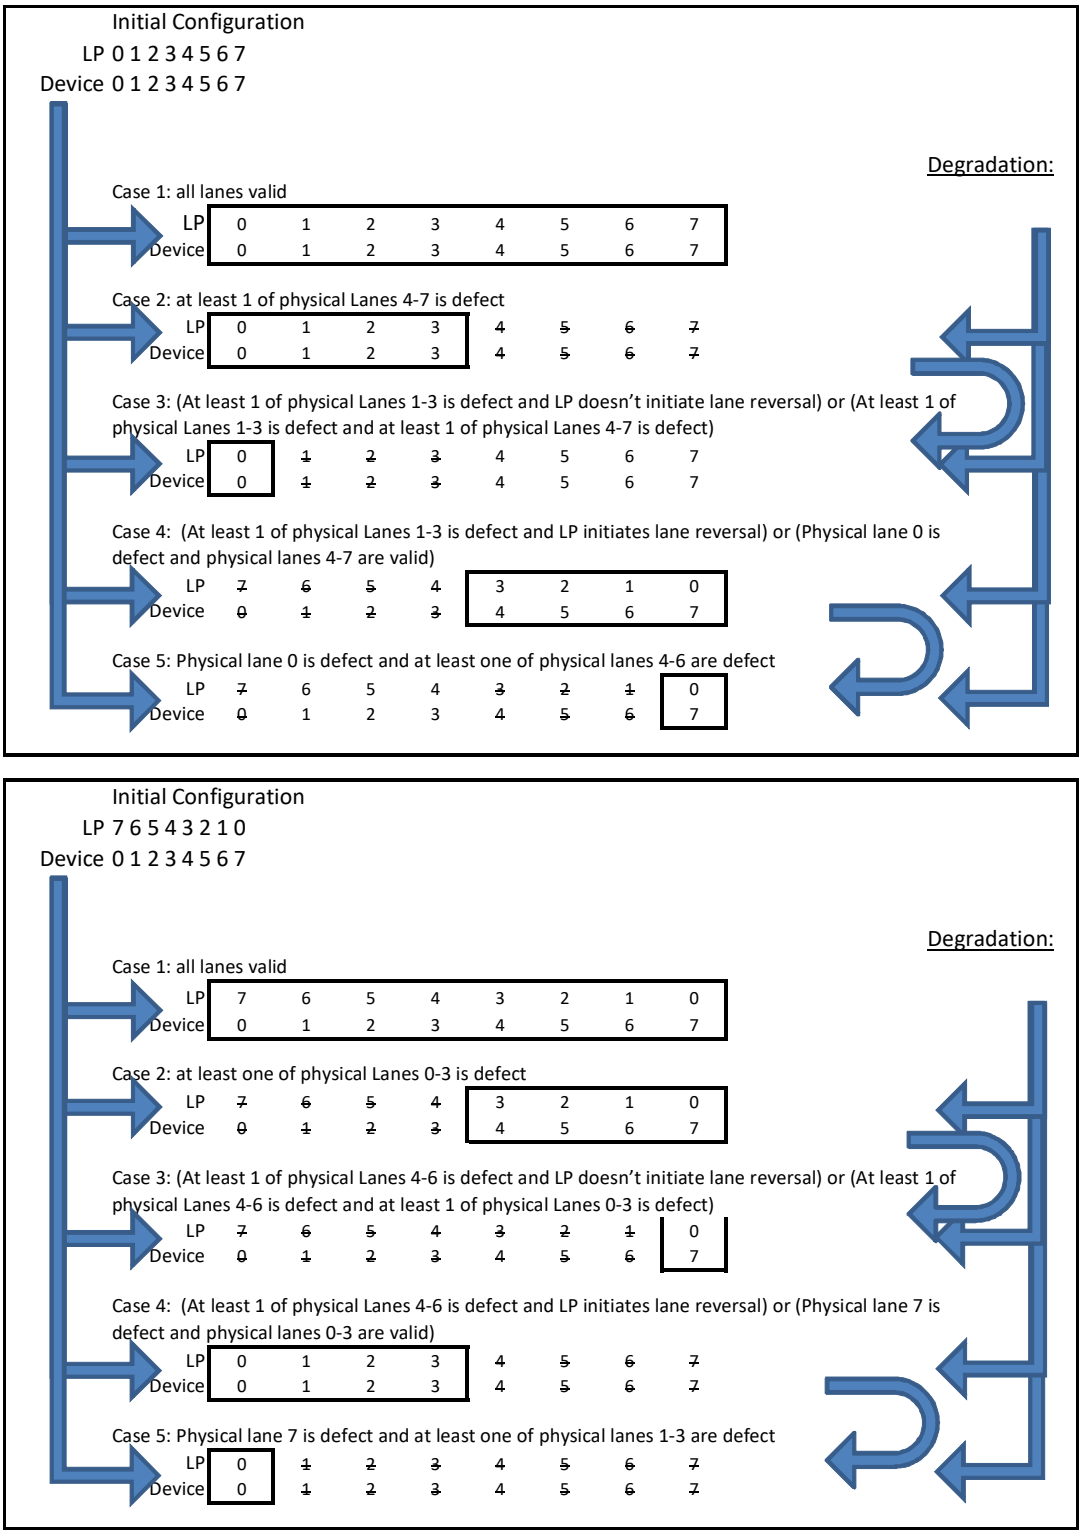

Figure 3-3. Link Width Configurations for a x8 Port

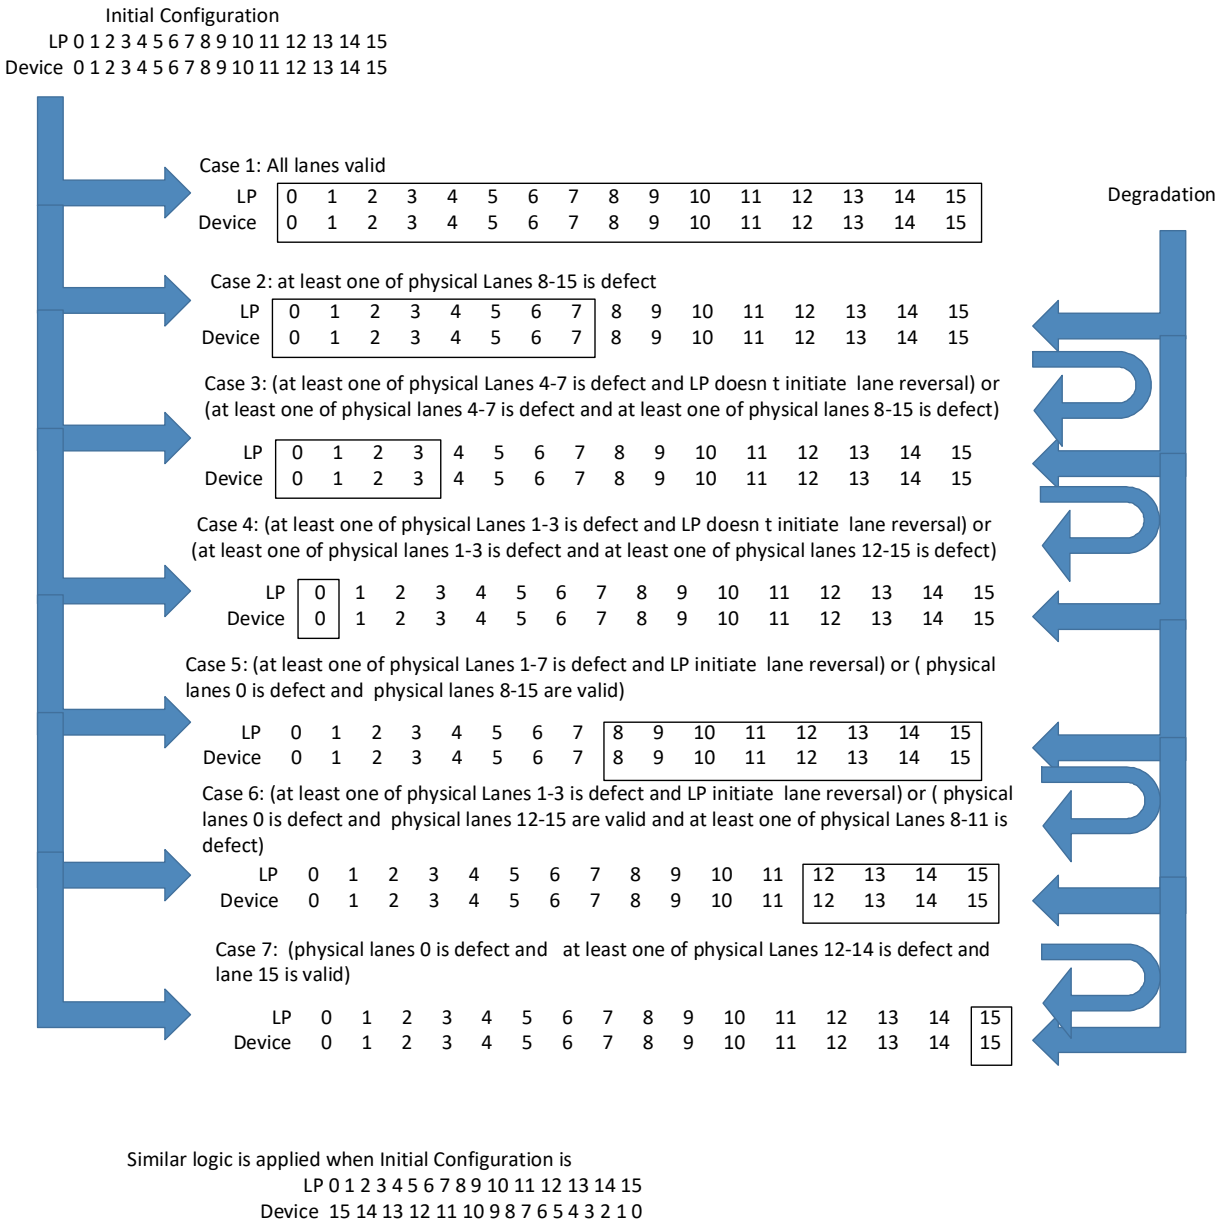

Figure 3-4. Link Width Configurations for a x16 Port

3.1.4.4 Receiver Framing Requirements

This section applies to Gen 3 or Gen 4 operation only, and lists the optional capabilities defined in Section 4.2.2.3.3, "Receiver Framing Requirements" of the *PCIe Base Specification*.

The device implements the optional Gen3 receiver framing error checks other than:

- TLP Token length=0b
- Mixed order sets across lanes (which anyway ending up with recovery)

3.1.5 Error Events and Error Reporting

This section describes error reporting and advanced error reporting.

3.1.5.1 General Description

PCIe defines two error reporting paradigms:

- Baseline capability
- Advanced Error Reporting (AER) capability.

The baseline error reporting capabilities are required of all PCIe devices, and define the minimum error reporting requirements. The AER capability is defined for more robust error reporting, and is implemented with a specific PCIe capability structure. Both mechanisms are supported by the E810, but the AER capability must be enabled in the NVM.

The *SERR# Enable* and the *Parity Error* bits from the Legacy Command register also take part in the error reporting and logging mechanism.

In a multi-function device, PCIe errors that are not related to any specific function within the device are logged in the corresponding status and logging registers of all functions in that device (see Section 6.2.4 in the *PCIe Base Specification*). Figure 3-5 shows, in detail, the flow of error reporting in PCIe. See also Figure 6-2 in the *PCIe Base Specification*.

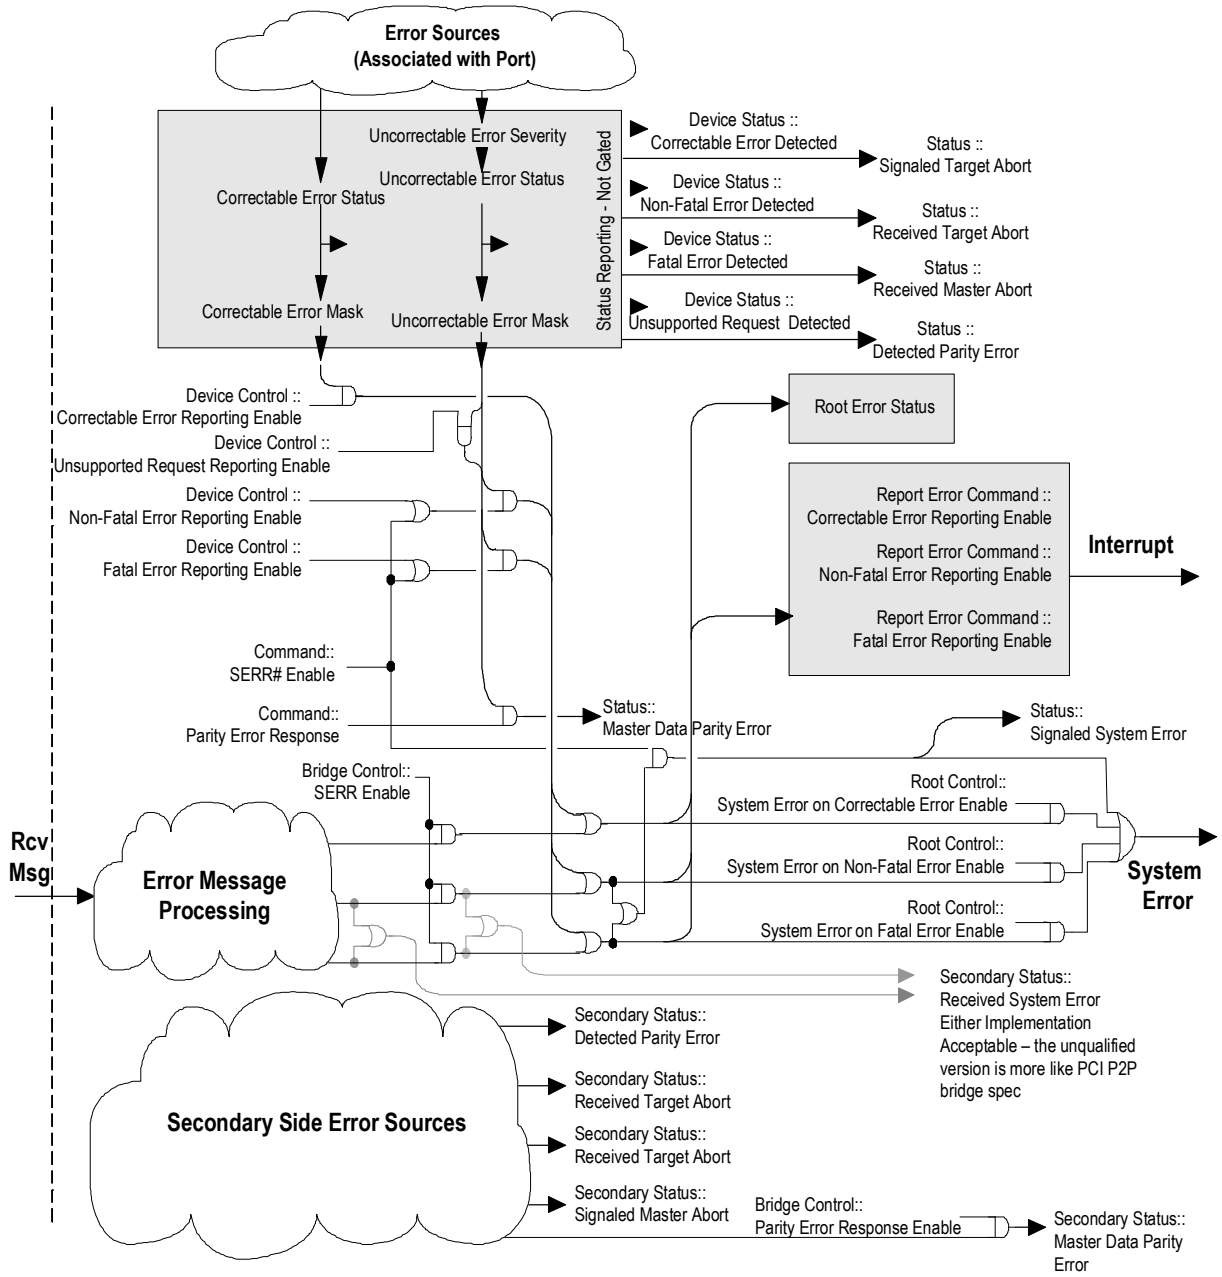

Figure 3-5. Error Reporting Mechanism

3.1.5.2 Error Events

Table 3-7 lists the error events identified by the E810 and the response in terms of logging, reporting, and actions taken. Refer to the PCIe specification for the effect on the PCI Status register.

Table 3-7. Response and Reporting of PCIe Error Events

Error Name	Error Events	Default Severity	Action
Physical Layer Errors			
Receiver Error	8b/10b Decode Errors Packet Framing Error	Correctable Send ERR_CORR	TLP to Initiate NAK, Drop Data DLLP to Drop
Data Link Errors			
Bad TLP	Bad CRC Not Legal EDB Wrong Sequence Number	Correctable Send ERR_CORR	TLP to Initiate NAK, Drop Data
Bad DLLP	Bad CRC	Correctable Send ERR_CORR	DLLP to Drop
Replay Timer Timeout	REPLAY_TIMER expiration	Correctable Send ERR_CORR	Follow LL Rules
REPLAY NUM Rollover	REPLAY NUM Rollover	Correctable Send ERR_CORR	Follow LL Rules
Data Link Protocol Error	Violations of Flow Control Initialization Protocol	Uncorrectable Send ERR_FATAL	
Poisoned TLP Received	TLP With Error Forwarding	Uncorrectable ERR_NONFATAL Log Header	See section Section 3.1.5.4 for more details. If error is defined as non-fatal (default severity): • Treat as an advisory non-fatal error: Send an ERR_COR message. If error is defined as fatal: • Send ERR_FATAL message.
ECRC Check Failed	Failed ECRC check	Uncorrectable ERR_NONFATAL Log Header	See Section 3.1.2.9 for more details. If error is defined as non-fatal (default severity): • Send an ERR_NONFATAL message. If error is defined as fatal: • Send ERR_FATAL message.
Unsupported Request (UR)	Receipt of TLP with unsupported Request Type Receipt of an Unsupported Vendor Defined Type 0 Message Invalid Message Code Wrong Function Number Received TLP Outside BAR Address Range Receipt of a Request TLP during D3hot, other than Configuration and Message requests Reception of packet with unexpected PASID prefix Received Target Access with illegal data size per Section 3.1.2.2	Uncorrectable ERR_NONFATAL Log header (including optional prefix)	Send Completion with UR. If error is defined as non-fatal (default severity): • Treat as an advisory non-fatal error: Send an ERR_COR message. If error is defined as fatal: • Send ERR_FATAL message.

Table 3-7. Response and Reporting of PCIe Error Events [continued]

Error Name	Error Events	Default Severity	Action
Completion Timeout	Completion Timeout Timer Expired	Uncorrectable ERR_NONFATAL	See Section 3.1.5.3 for more details. Log the header of the Request TLP that encountered the error. If error is defined as non-fatal (default severity): • Treat as an advisory non-fatal error: Send an ERR_COR message. If error is defined as fatal: • Send ERR_FATAL message.
Unexpected Completion	Received Completion Without a Request For It (Tag, ID, and so on)	Uncorrectable ERR_NONFATAL Log Header	Discard TLP. If error is defined as non-fatal (default severity): • Treat as an advisory non-fatal error: Send an ERR_COR Message. If error is defined as fatal: • Send ERR_FATAL message.
Receiver Overflow	Received TLP Beyond Allocated Credits	Uncorrectable ERR_FATAL	Receiver Behavior is Undefined
Flow Control Protocol Error	Minimum Initial Flow Control Advertisements Flow Control Update for Infinite Credit Advertisement	Uncorrectable ERR_FATAL	Receiver Behavior is Undefined
Malformed TLP (MP)	Data Payload Exceed Max_Payload_Size Received TLP Data Size Does Not Match Length Field TD field value does not correspond with the observed size PM Messages That Do Not Use TC0. Usage of Unsupported VC Target request crosses a 4KB boundary	Uncorrectable ERR_FATAL Log Header	Drop the Packet, Free FC Credits
Completion with Unsuccessful Completion Status		No Action (already done by originator of completion)	Free FC Credits (no credits for completions)

3.1.5.3 Completion Timeout Mechanism

The E810 supports completion timeout as defined in the PCIe specification.

The E810 controls the following aspects of completion timeout:

- Disabling or enabling completion timeout.
  - The PCIe *Completion Timeout Disable Supported* bit in the Device Capabilities 2 register (Section 14.3.5.10) is hard-wired to 1b to indicate that disabling completion timeout is supported.
  - The PCIe *Completion Timeout Disable* bit in Device Control 2 register (Section 14.3.5.11) controls whether completion timeout is enabled.
- A programmable range of timeout values.
  - The E810 supports all four ranges as programmed in the *Completion Timeout Ranges Supported* field of the Device Capabilities 2 register. The actual completion timeout value is written in the *Completion Timeout Value* field of Device Control 2 register.

The following sequence takes place when completion timeout is detected:

1. The appropriate message is sent on PCIe as listed in Table 3-7.
2. The affected queue or client takes action based on the nature of the original request:
   - If the original request was for Tx packet data, the request and any partial packet completions are dropped.
   - Else, the request is handled same way as malicious requests. An interrupt is issued to the respective PF.
3. Software might identify the source of the event (whether due to TLP poisoning, to a completion timeout, or an actual malicious event) by reading the error reporting counters or the performance and statistics counters.

3.1.5.4 Error Forwarding (TLP Poisoning)

If a TLP is received with an error-forwarding trailer, the packet is dropped and is not delivered to its destination.

The following sequence takes place when a poisoned TLP is received:

1. The appropriate message is sent on PCIe as listed in Table 3-7.
2. If the TLP is a completion, a completion timeout follows at some later time. Processing continues as described in Section 3.1.5.3.

System logic is expected to trigger a system-level interrupt to inform the operating system of the problem. Operating systems can then stop the process associated with the transaction, re-allocate memory to a different area instead of the faulty area, and so on.

3.1.5.5 Completion with Unsuccessful Completion Status

A completion arriving with unsuccessful completion status (either UR or CA) is dropped and not delivered to its destination. A completion timeout follows at some later time. Processing continues as described in Section 3.1.5.3.

3.1.5.6 Error Pollution

Error pollution can occur if error conditions for a given transaction are not isolated to the error's first occurrence. If the PHY detects and reports a receiver error, to avoid having this error propagate and cause subsequent errors at the upper layers, the same packet is not signaled at the data link or transaction layers. Similarly, when the data link layer detects an error, subsequent errors that occur for the same packet are not signaled at the transaction layer.

3.1.5.7 Blocking on Upper Address

The GLPCI_UPADD register blocks master accesses from being sent out on PCIe if the TLP address exceeds some upper limit. Bits [31:1] correspond to bits [63:33] in the PCIe address space, respectively.

When a bit is set in GLPCI_UPADD[31:1], any transaction in which the corresponding bit in its address is set is blocked and not sent over PCIe. If all register bits are cleared, there is no effect (TLPs are sent unconditionally).

Processing a blocked transaction:

- Write transaction:
  - The transaction is dropped.
- Read transaction:
  - The transaction is dropped.
  - Set the exceeded upper address limit (read requests) event in the PCIe errors register (see Section 3.1.6).
  - The affected queue or client takes action based on the nature of the original request. An interrupt is issued to the respective PF. See Section 9.2.2.2.1.

3.1.6 Performance and Statistics Counters

The E810 incorporates counters to track the behavior and performance of the PCIe interconnect.

General characteristics of the counters:

- Software can reset, stop, or start the counters.

The counters are shared by all PCI functions (service mode of sharing).

3.1.6.1 Event Counters - Transaction Layer

Counters operate in one of the following modes:

- **Count mode** — The counter increments when the respective event occurred.
- **Leaky bucket mode** — The counter increments only when the rate of events exceeded a certain value. See Section 3.1.6.1.2 for more details.

The list of events supported by the E810 are listed in Table 3-8.

Table 3-8. PCIe Statistic Events Encoding

Event	Event Mapping (Hex)	Description
Cycles	0x00	Increment on each PCIe clock tick.
Transaction Layer Events		
Bad Request TLPs	0x10	Number of bad TLPs arriving to the transaction layer. These include: • Request caused UR. • Request caused CA. • Malformed TLP.
Bad Completions	0x11	Number of bad completions received. These include: • Unexpected completion. • UR status. • CA status.
Completion Timeout	0x12	Number of completion timeout events.
Poisoned TLP	0x13	Number of TLPs received with poisoned data.
ECRC Check	0x14	Number of TLPs that fail ECRC check.
Link Layer Events		
Retry Buffer Timeout	0x31	Number of replay events that happen due to timeout (does not count replay initiated due to NACK).
Retry Buffer Replay Roll-Over	0x32	Increment when a replay is initiated for more than three times.
Physical Layer Events		
Receive Error	0x50	Increment when one of the following occurs: • Decoder error occurred during training in the PHY. It is reported only when training ends. • Decoder error occurred during link-up or till the end of the current packet (in case the link failed). This error is masked when entering/exiting EI.

3.1.6.1.1 Count Mode

The following CSR fields control operation of the Count mode:

- Four 32-bit counters GLPCI_GSCN_0_3 track events and increment on each occurrence of an event.
  - The four 32-bit counters can also operate in a two 64-bit mode to count long intervals or large payloads.
    - Registers GLPCI_GSCN_0_3[0] and GLPCI_GSCN_0_3[1] form the first 64-bit counter, while registers GLPCI_GSCN_0_3[2] and GLPCI_GSCN_0_3[3] form the second 64-bit counter.
    - The GLPCI_GSCL_1_P.*GIO_64_BIT_EN* selects between 32-bit and 64-bit modes.
- The GLPCI_GSCL_1_P.*GIO_COUNT_EN_[3:0]* bits enable each of the four counters.
  - The enable bits for the two 64-bit counters are GLPCI_GSCL_1_P.*GIO_COUNT_EN_0* and GLPCI_GSCL_1_P.*GIO_COUNT_EN_2*, respectively.
- The GLPCI_GSCL_1_P.*GIO_COUNT_START* bit starts event counting of enabled counters.
- The GLPCI_GSCL_1_P.*GIO_COUNT_STOP* bit stops event counting of running counters.
- The GLPCI_GSCL_1_P.*GIO_COUNT_RESET* bit resets the event counters.

- The GLPCI_GSCL_2 associates an event with each of the four counters.
  - In 64-bit mode, the *GIO_EVENT_NUM_[2,0]* fields are used.

3.1.6.1.2 Leaky Bucket Mode

Each of the counters can be configured independently to operate in a leaky bucket mode. When in leaky bucket mode, the following functionality is provided:

- One of four 16-bit Leaky Bucket Counters (LBC) is enabled via the LBC_ENABLE_[3:0] bits in the PCIe Statistic Control Register #1 (GLPCI_GSCL_1_P).
- The LBC is controlled by the *GIO_COUNT_START*, *GIO_COUNT_STOP*, *GIO_COUNT_RESET* bits in the PCIe Statistic Control Register #1 (GLPCI_GSCL_1_P).
- The LBC increments every time the respective event occurs.
- The LBC is decremented every T μs as defined in the *LBC_TIMER_N* field in the PCIe Statistic Control Register #5...#8 (GLPCI_GSCL_5_8).
- When an event occurs and the value of the LBC meets or exceeds the threshold defined in the *LBC_THRESHOLD_N* field in the PCIe Statistic Control Register #5...#8 (GLPCI_GSCL_5_8), the respective statistics counter increments, and the LBC counter is cleared to zero.

3.1.6.2 Event Counters - Link and Physical Layers

This section describes the performance events for the Link and Physical layers and how to manage the counters associated with these events.

Two events can be counted concurrently. The event counters include two sets of registers, each managing one event counter. Such pairs are documented as <register_name>[1:0].

The following procedures manage the operation of the event counters (when writing to part of the register, ensure that other fields are written with their existing values):

Resetting the counters configuration:

1. Set the XPPERFCON.*GRST* bit.
2. Clear the XPPERFCON.*GRST* bit (otherwise the logic stays in reset)

Setting an event:

1. Write 0x0...0 to the XPPMCL[1:0] registers.
2. Set the XPPMR[1:0].*CENS* field to 0x1.
3. Set the XPPMR[1:0].*CNTMD* field to 0x1.
4. Set the XPPMER[1:0].*XPRSCA* field to 0x1.
5. Set the event according to Table 3-9.

Starting a count:

1. Set the XPPERFCON.*GCE* bit

Stopping a count:

1. Clear the XPPERFCON.*GCE* bit

Reading the count (note: reading the counter clears their values):

1. Read the respective XPPMDH[1:0] and XPPMDL[1:0] register pair in a single 64-bit aligned access.

Table 3-9 defines the Link and Physical Layer events:

Table 3-9. Link and Physical Layer Performance Events

Event	Description	Register Field
Uncorrectable Errors	Counts the total number of Uncorrectable Errors.	XPPMER[1:0].*CNTUCERR*
Correctable Errors	Counts the total number of Correctable Errors.	XPPMER[1:0].*CNTCERR*
Tx L0s State Utilization	Counts the number of entries to L0s on the Tx lanes.	XPPMER[1:0].*TXL0SU*
Rx L0s State Utilization	Counts the number of entries to L0s on the Rx lanes.	XPPMER[1:0].*RXL0SU*
Link Utilization	Counts clocks that a port is receiving data. If one counter counts receiver errors and another counter counts Link Utilization, a bit error rate can be calculated.	XPPMER[1:0].*LNKUTIL*
Recovery State Utilization	Counts the number of entries to Recovery state.	XPPMER[1:0].*RECOVERY*
ASPM L1 State Utilization	Counts the number of entries to ASPM L1 state (that is, initiated by the device)	XPPMER[1:0].*L1*
SW L1 State Utilization	Counts the number of entries to L1 state initiated by software.	XPPMER[1:0].*SWL1*
Tx and Rx L0s Utilization	Counts number of events where both Tx and Rx are in L0s state.	XPPMER[1:0].*RXL0STXL0SU*
NAK DLLP Received	Counts number of received NAK DLLPs.	XPPMER[1:0].*NAKDLLP*

3.1.6.2.1 Bandwidth Counters

The bandwidth counters measure total payload bytes transferred over the PCIe link. Counting is provided per each traffic type (posted, non-posted, completions) per direction (upstream, downstream).

The mechanisms described above hold for the bandwidth counters with the following differences:

Setting an event:

1. Set the XPPMR[1:0].*CENS* field to 0x1.
2. Set the XPPMR[1:0].*EGS* field to 0x2.
3. Set the XPPMER[1:0].*FCCSEL* field to the desired traffic type (posted, non-posted, completions, or all).
4. Set the XPPMER[1:0].*TXRXSEL* field to desired values.
5. Set the XPPMER[1:0].*XPRSCA* field to 0x1.
6. Set the XPPERFCON.*GCE* field to 0x1.

Registers fields used exclusively by the bandwidth counters:

- XPPMER[1:0].*FCCSEL* - Selects the desired traffic type (posted, non-posted, completions, or all).
- XPPMER[1:0].*TXRXSEL* - Selects between monitoring downstream traffic, upstream traffic, or both.

3.2 Ethernet Interconnect

3.2.1 Media Access Control (MAC) Layer

The E810 supports up to eight full-duplex Ethernet MAC ports compliant with IEEE Std802.3-2018 standard (Clause 4 and Annex 4A). The MAC ports can be configured to operate at different speeds, as explained in Section 3.2.1.2.

Each MAC port is associated with a corresponding Media Access Unit (MAU) that provides the physical layer interfaces. The MAUs must be configured to operate with the appropriate physical layer protocols based on the MAC operating speed. Physical layers supported by the E810 for different speeds of operation are explained in Section 3.2.2, "Physical Layer Interface".

3.2.1.1 MAC Features

Table 3-10 lists the E810 Ethernet port features.

Table 3-10. Link Layer Ethernet Port Features

Description
Ethernet Speed and Interfaces: • 100 Gb/s: 2 ports of CGMII • 50 Gb/s: 2 ports of XLGMII • 25 Gb/s: 4 ports of XGMII (boosted to 25G) • 10 Gb/s: 8 ports over XGMII (supporting 10G,1G, 100M) (ONPI 32 bits - reduced clock)
The E810's Maximum Transmit Unit Size (MTU) is 9728 - Ethernet header/CRC = 9728 - 18 = 9710 bytes (jumbo frames). MTU can be further reduced by additional header fields such as Virtual Local Area Network (VLAN) tag(s), and so on.
Full-duplex operation at all supported speeds.
Integrates support for IEEE Std 802.3 Clause 73 Auto-Negotiation for Backplane Ethernet (The auto-negotiation protocol is done by the PHY).

3.2.1.2 MAC Speed Configuration

Table 3-11 lists the possible speed configurations available on each MAC port.

Table 3-11. MAC Port and Possible Speed Configurations

Port	100 Mb/s	1 Gb/s	10 Gb/s	25 Gb/s	50 Gb/s	100 Gb/s
MAC 0	Y	Y	Y	Y	Y	Y
MAC 1	Y	Y	Y	Y	Y	Y
MAC 2	Y	Y	Y	Y	N	N
MAC 3	Y	Y	Y	Y	N	N
MAC 4	Y	Y	Y	N	N	N
MAC 5	Y	Y	Y	N	N	N
MAC 6	Y	Y	Y	N	N	N
MAC 7	Y	Y	Y	N	N	N

When LAN ports are disabled in multi-port system configurations, corresponding PCIe functions must be disabled through the NVM or external disable pins. See Section 4.4 for details on PCI function disable and LAN port disable functionality.

The link speed for each port can be controlled through NVM loaded settings or Link Configuration admin commands (see Section 3.2.4). In some physical interfaces, the final link speed is selected out of the pre-configured options, based on the link auto-negotiation protocol.

The maximum speed enabled depends on the number of enabled ports:

- 2 Ports setting:
  - Each port can be independently configured to 100/50/25/10/1 Gb, 100 Mb, or disabled.
  - In this setting, only Port0 and Port1 can be enabled.
- 4 Ports setting:
  - Each Port can be independently configured to 25/10/1 Gb, 100 Mb, or disabled.
  - In this setting, only Port0, Port1, Port2, Port3 can be enabled.
- 8 Ports setting:
  - Each Port can be independently configured to 10/1 Gb, 100 Mb, or disabled.
  - Some ports can be configured to 25 Gb, depending on other port's configurations (see Table 3-12).
  - In this setting, all ports can be enabled.

Note: The ports maximal speed depends also on the maximal bandwidth SKU. The above speeds assumes 200G SKU.

Note: The number of ports and their speed affect the E810 pipe settings, such as TPB, RPB, DCB, and more. This is done using the adaptive NVM method, when the link topology is configured. See Section 3.3.3.3.

Table 3-12 illustrates the allowed port configurations when the E810 bandwidth is not limited by SKU setting (like 200G max bandwidth SKU).

Table 3-12. Port Configurations

Ports[1]/ Configuration	0	1	2	3	4	5	6	7	
2 ports	100G	100G	-	-	-	-	-	-	2 ports (100G and below)
4 ports	25G	25G	25G	25G	-	-	-	-	4 ports (25G and below)
6 ports - 1	25G	25G	10G	10G	-	-	10G	10G	2x25G + 4x10G
6 ports - 2	10G	10G	25G	25G	10G	10G	-	-	2x25G + 4x10G
6 ports - 3	25G	10G	25G	10G	-	10G	-	10G	2x25G + 4x10G
6 ports - 4	10G	25G	10G	25G	10G	-	10G	-	2x25G + 4x10G
6 ports - 5	25G	10G	10G	25G	-	10G	10G	-	2x25G + 4x10G
6 ports - 6	10G	25G	25G	10G	10G	-	-	10G	2x25G + 4x10G
7 ports - 1	25G	10G	10G	10G	-	10G	10G	10G	1x25G + 6x10G
7 ports - 2	10G	25G	10G	10G	10G	-	10G	10G	1x25G + 6x10G
7 ports - 3	10G	10G	25G	10G	10G	10G	-	10G	1x25G + 6x10G

Table 3-12. Port Configurations [continued]

Ports[1]/ Configuration	0	1	2	3	4	5	6	7	
7 ports - 4	10G	10G	10G	25G	10G	10G	10G	-	1x25G + 6x10G
8 ports	10G	10G	10G	10G	10G	10G	10G	10G	8 ports (10G and below)

1. Port numbers in this table refer to E810 port numbering. See Section 3.2.2.3 for port mapping.

3.2.1.3 Transmit Padding

The minimum frame size for Ethernet as specified by IEEE Std 802.3 standard is 64 bytes. The E810 MAC pads, with zeros, Ethernet packets that are smaller than 64 bytes during transmit. In the E810, transmit packets arrive already padded to the MAC. Refer to the padding rules for transmitted and received packets and loop-back packets in Section 7.12.2.

3.2.1.4 Jumbo Frame Support

The E810 MAC supports transmission and reception of frames of up to 9.5 KB (9728 bytes). Maximum receive and transmit frame size is configured through the *Max Frame Size* field in the Set MAC Config command (see Section 3.2.4.1.2).

3.2.1.5 Ethernet Flow Control (FC)

The E810 supports flow control (pause) as defined in 802.3x (IEEE Std 802.3-2008 Annex 31B), as well as the specific operation of asymmetrical flow control (asymmetric pause) defined by 802.3z (IEEE Std 802.3-2008 Annex 28B). The E810 also supports Priority Flow Control (PFC) as defined in IEEE P802.1Qbb, sometimes referred to as Class Based Flow Control or (CBFC), as part of the DCB architecture.

Note: An E810 port can either be configured to receive 802.3x Link Flow Control (LFC) packets or 802.1Qbb/802.3bd PFC packets. It does not support the reception of both types of packets simultaneously over the same port.

Flow control is implemented to reduce receive buffer overflows, which result in the dropping of received packets. Flow control also allows for local controlling of network congestion levels. This can be accomplished by sending an indication to a transmitting station of a nearly full receive buffer condition at a receiving station.

The implementation of asymmetric flow control allows for one link partner to send flow control packets while being allowed to ignore their reception (for example, not required to respond to PAUSE frames).

The following registers define the basic control functionality. Refer to the registers specified in Section 8.2.4.4 for the other programming related to flow control. In Data Center Bridge (DCB) mode, some of the registers are duplicated per Traffic Class (TC), up to eight duplicate copies of the registers. If DCB is disabled, index [0] of each register is used.

3.2.1.5.1 MAC Control Frames and Reception of Flow Control Frames

3.2.1.5.1.1 MAC Control Frame — Other Than FC

IEEE 802 reserved the EtherType value of 0x8808 for MAC control frames as listed in Table 3-13. The MAC control frame format is specified in IEEE 802.3 Clause 31.

Table 3-13. MAC Control Frame Format

Field	Description
DA	The *Destination Address* field can be an individual or multicast (including broadcast) address. Permitted values for the *Destination Address* field can be specified separately for a specific control opcode such as FC packets.
SA	Port Ethernet MAC Address (6 bytes).
Type	0x8808 (2 bytes).
Opcode	The MAC control opcode indicates the MAC control function.
Parameters	The *MAC Control Parameters* field must contain MAC control opcode-specific parameters. This field can contain none, one, or more parameters up to a maximum of minFrameSize = 20 bytes.
Reserved field = 0x00	The *Reserved* field is used when the MAC control parameters do not fill the fixed length MAC control frame.
CRC	4 bytes.

3.2.1.5.1.1.1 MAC Control Frame Receive Identification

Packets with:

- MAC DA = 01-80-C2-00-00-01.
- EtherType value of 0x8808 are considered to be control frames.

3.2.1.5.1.2 Structure of 802.3x FC Packets

802.3x FC packets are defined by the following three fields (see Table 3-14):

- A match on the 6-byte multicast address for MAC control frames, or a match to the station address of the device. The 802.3x standard defines the MAC control frame multicast address as 01-80-C2-00-00-01.
- A match on the *Type* field. The *Type* field in the FC packet is compared against an IEEE reserved value of 0x8808.
- A match of the MAC control *Opcode* field has a value of 0x0001.

Frame-based flow control differentiates XOFF from XON based on the value of the PAUSE *Timer* field. Non-zero values constitute XOFF frames while a value of zero constitutes an XON frame. Values in the *Timer* field are in units of pause quanta (slot time). A pause quanta lasts 64 byte times, which is converted in to an absolute time duration according to the line speed.

Note: XON frame signals the cancellation of the pause that was initiated by an XOFF frame. For example, a pause for zero pause quanta.

Table 3-14. 802.3x Link Flow Control - Frame Formats

Field	Description
DA	01_80_C2_00_00_01 (6 bytes).
SA	Port Ethernet MAC Address (6 bytes).
Type	0x8808 (2 bytes).
Opcode	0x0001 (2 bytes).
Time	XXXX (2 bytes).
Pad	42 bytes.
CRC	4 bytes.

3.2.1.5.1.2.1 802.3x Frame Receive Identification

Received frames that are identified as control frames (see Section 3.2.1.5.1.1.1) can further be classified as 802.3x if the frames opcode = 0x0001 as listed in Table 3-14.

3.2.1.5.1.3 Priority Flow Control (PFC)

EEDC introduces support for multiple TCs assigning different priorities and bandwidth per TC. LFC stops all the TCs. PFC specified in IEEE P802.1Qbb enables more granular flow control on the Ethernet link in an EEDC environment, as opposed to the PAUSE mechanism defined in 802.3x. The PFC frame format is specified in IEEE P802.3bd.

Table 3-15. Priority Flow Control - Frame Format

Field	Description
DA	01_80_C2_00_00_01 (6 bytes).
SA	Port Ethernet MAC Address (6 bytes).
Type	0x8808 (2 bytes).
Opcode	0x0101 (2 bytes).
Priority Enable Vector	0x00XX (2 bytes).
Timer 0	XXXX (2 bytes).
Timer 1	XXXX (2 bytes).
Timer 2	XXXX (2 bytes).
Timer 3	XXXX (2 bytes).
Timer 4	XXXX (2 bytes).
Timer 5	XXXX (2 bytes).
Timer 6	XXXX (2 bytes).
Timer 7	XXXX (2 bytes).
Pad	26 bytes.
CRC	4 bytes.

Table 3-16. Format of Priority Enable Vector

	ms octet	ls octet
Priority enable vector definition	0	e[7]...e[n]...e[0]
e[n] =1 => time (n) valid e[n] =0 => time (n) invalid		

Each of the eight timers refers to a specific User Priority (UP). For example, Timer 0 refers to UP 0, and so on. The E810 binds a UP (and therefore the timer) to one of its TCs according to the UP-to-TC binding tables. Refer to the PRTDCB_TUP2TC register (Section 13.2.2.17.101) for the binding of received PFC frames to Tx TCs, and to the PRTDCB_RUP2TC register (Section 13.2.2.17.99) for the binding of transmitted PFC frames to Rx TCs.

When a PFC frame is formatted by the E810, the same values are replicated into every *Timer* field and *Priority Enable Vector* bit of all the UPs bound to the concerned TC. These values as configured in the PRTDCB_RUP2TC register.

The following rule is applicable for the case of multiple UPs that share the same TC as configured in the PRTDCB_TUP2TC register. When PFC frames are received with different timer values for the previous UPs, the traffic on the associated TC must be paused by the highest XOFF timer's value.

3.2.1.5.1.3.1 PFC Frame Receive Identification

Received frames that are identified as control frames (see Section 3.2.1.5.1.1.1) can further be classified as PFC if the frames opcode = 0x0101 as listed in Table 3-15.

3.2.1.5.1.4 Operation and Rules

The E810 operates in either LFC mode or in PFC mode. Enabling both modes concurrently is not allowed.

Note: LFC capability must be negotiated between link partners via the auto-negotiation process. PFC capability is negotiated via some higher level protocol (DCBX), and the resolution is usually provided to the software device driver by the EEDC management agent. It is the responsibility of the EMP to reconfigure the LFC settings after the auto-negotiation process is resolved.

Once the receiver has validated the reception of an XOFF or PAUSE frame, the device performs the following:

1. Increment the appropriate statistics register(s).
2. Initialize the pause timer based on the packet's PAUSE *Timer* field (overwriting any current timer's value).
   - In case of PFC, this is done per TC. If several UPs are associated with a TC, the device sets the timer to the maximum value among all enabled timer fields associated with the TC.
3. Disable packet transmission or schedule the disabling of transmission after the current packet completes.
   - In case of PFC, this is done per paused TC.

Resumption of transmission can occur under the following conditions:

- Expiration of the PAUSE timer.
  — In case of PFC, this is done per TC.

- Reception of an XON frame (a frame with its PAUSE timer set to 0b).
  - In case of PFC, this is done per TC.

Both conditions clear the relevant TXOFF status bits in the Transmit Flow Control Status (PRTDCB_TFCS) register and transmission can resume. Hardware records the number of received XON frames.

3.2.1.5.1.5 Timing Considerations

When operating at 100 Gb/s line speed, the E810 does not begin to transmit a (new) frame more than 394 pause_quantum after the reception of a valid XOFF frame that contains a non-zero value of pause_time, as measured at the wires (a pause quantum is 512 bit times).

When operating at 50 Gb/s line speed, the E810 does not begin to transmit a (new) frame more than 394 pause_quantum after the reception of a valid XOFF frame that contains a non-zero value of pause_time, as measured at the wires (a pause quantum is 512 bit times).

When operating at 25 Gb/s line speed, the E810 does not begin to transmit a (new) frame more than 80 pause_quantum after the reception of a valid XOFF frame that contains a non-zero value of pause_time, as measured at the wires (a pause quantum is 512 bit times).

When operating at 10 Gb/s line speed, the E810 must not begin to transmit a (new) frame more than 60 pause quanta after receiving a valid XOFF frame, as measured at the wires. When connected to an external 10GBASE-KR PHY with FEC, or to an external 10GBASE-T PHY, the response time requirement increases to 74 pause quanta because of extra delays consumed by these external PHYs.

When operating at 1 Gb/s line speed, the E810 must not begin to transmit a (new) frame more than two pause quanta after receiving a valid XOFF frame, as measured at the wires.

The IEEE P802.1Qbb draft 2.3, specifies that the tolerated response time for priority XOFF frames is 614.4 ns (equivalent of 12 pause quanta at the link speed of 10 Gb/s). This extra budget in addition to the link delay is aimed to compensate for the fact that the decision to stop new transmissions from a specific TC must be taken earlier in the transmit data path than for the LFC case.

3.2.1.5.2 Transmitting PAUSE Frames

The E810 generates PAUSE packets to insure there is enough space in its receive packet buffers to avoid packet drop. The E810 monitors the fullness of its receive FIFOs and compares it with the contents of a programmable threshold. When the threshold is reached, the E810 sends a PAUSE frame.

The E810 supports both LFC and PFC, but not both concurrently (at the same physical port). When DCB is enabled, it sends only PFC. When DCB is disabled, it sends only LFC.

Note: Similar to the reception of flow control packets previously mentioned, software can enable flow control transmission only after it is negotiated between the link partners (possibly by auto-negotiation).

3.2.1.5.2.1 PFC

Like Rx flow control, Tx flow control operates in either a link 802.3x compliant mode or in PFC mode, but not in both at the same time.

The same flow control mechanism is used for PFC and for 802.3x flow control to determine when to send XOFF and XON packets. When PFC is used in the receive path, Priority PAUSE packets are sent instead of 802.3x PAUSE packets. The format of priority PAUSE packets is described in Section 3.2.1.5.1.2.1.

A specific consideration for generating PFC packets:

- When a PFC packet is sent, the packet sets all the UPs that are associated with the relevant TC (UP-to-TC association in receive is defined in PRTDCB_RUP2TC register).

3.2.1.5.2.2 Operation and Rules

At 10 Gb/s and lower speeds, the *TFCE* field in the Flow Control Configuration (PRTDCB_FCCFG) register enables transmission of PAUSE packets as well as selects between the LFC mode and the PFC mode.

Refer to Section 8.2.1.4.1 for the criteria used by the device for sending a XOFF frame to the neighbor. The E810 sends an additional PAUSE frame if it has previously sent one and the FIFO overflows. This is intended to minimize the amount of packets dropped if the first PAUSE frame did not reach its target.

From the time it has issued a PAUSE frame to the neighbor, the E810 starts counting down in an internal shadow counter used to mirror the pause timeout counter at the partner's end. When this internal counter reaches the value set, then, if the PAUSE condition is still valid (meaning that the buffer(s) fullness is still above the relevant watermarks), an XOFF message is sent again.

Once the receive buffer fullness reaches the relevant low watermarks, the E810 sends an XON message (a PAUSE frame with a timer value of zero). Refer to Section 8.2.1.4.1 for the criteria used by the device for sending a XON frame to the neighbor.

3.2.1.6 Inter Packet Gap (IPG) Control and Pacing

The E810 can limit the packet transmission using one of the following:

- **Programmable fixed IPG extension, per port configuration** — The inter packet gap can be extended by fixed number of 16-bytes words, for all Tx packets. This configuration can enable connection through Bump On the Wire devices that need larger inter packet gap. The *TX_IPG* field of the PRTMAC_TX_PACE[PRT] register specifies the number of 16-bytes words inserted between each consecutive packets.
- **Average data rate limitation, per port configuration** — The gap between packets can be extended in a way that the average data rate is lower than the link speed. This configuration might be used with PHYs that implements line speeds that can not be directly configured to the E810 (for example, 5 Gb/s), but can connect to the E810 with and interface with which the E810 can support its speed (for example, 10 Gb/s). Pacing rate is implemented by extending the IPG. The *TX_PACE* field of register PRTMAC_TX_PACE[PRT] specifies the number of bits added to IPG for each 16 bytes that are transmitted. The total number of bits to be added is accumulated, and when the IPG is inserted between packets, the IPG is extended in 16-bytes granularity, according to the total number of accumulated bits, while the residual is kept to be added at the next gap between packets. To meet the IEEE 802.3 specifications, 12 bytes of minimal inter frame gap are always added to the IPG.

The following examples show how the *TX_PACE* field can be calculated to achieve specific rate.

Example 1:

Assume all transmitted packets are in size of 64 bytes. To achieve a 5 Gb/s data rate when link rate is 10 Gb/s (50%) and packet length is 64 bytes (4 x 16-bytes words), programmers need to add an additional IPG, calculated as follows. The 64-byte packet is transmitted with 12 bytes IPG, and the bandwidth must be reduced by 50%, or add 1 byte for each transmitted byte or IPG byte. Therefore, for each packet 76 bytes must be added. As TX_PACE is added in bit resolution for each of the 4 16-byte words of the packet, the programmer therefore should configure 76*8/4=152 bits in the *TX_PACE* field. The multiplication by 8 is to translate bytes to bits and the division is to calculate the number of bits to be added per 16-byte word.

Example 2:

Now assume all transmitted packets are in size of 65 bytes. To achieve a 5 Gb/s data rate when link rate is 10 Gb/s and packet length is 65 bytes (5 x 16-byte words when rounded up) programmers must add an additional IPG of 65+12=77 bytes. Note that in these case, where the packet length counted in 16-byte words is not an integer, the *TX_PACE* would be added also for a fraction of 16-bytes words transmitted. As *TX_PACE* is added in bit resolution for each of the five 16-byte words of the packet, the programmer therefore should configure 77*8/5=123.2 in the *TX_PACE* field. *TX_PACE* should be rounded up to 124, to ensure transmission at a slightly lower speed, as a slightly higher speed might result in packet loss in some extreme case.

Note: For the two examples above, a fixed packet size is assumed. For the case of variable packet size, if transmission must be ensured in lower than the configured rate, choose the highest *TX_PACE*, as calculated for all packet sizes. Table 3-17 shows the exact number of bits (rounded up to integer value) that needs to be added in order to reach 50% of the line rate.

Table 3-17. Example of TX_IPG Configuration to Achieve 50% of the Data Rate for Different Packet Sizes

Packet Size	Added Bits per 16-Byte Word of the Packet (TX_IPG)
64	152
65	124
66	125
67	127
68	128
69	130
70	132
71	133
72	135
73	136
74	138
75	140
76	141
77	143
78	144
79	146
80	148
81	124
...	
1500	129

Assuming rate must be equal or less than 50% (for example, pacing to 5 Gb/s with line speed of 10 Gb/s), *TX_IPG* should be configured to 152 bits.

Table 3-18 specifies the *TX_IPG* configuration for different pacing speeds with average target rate in 10% steps, assuming evenly-distributed packet size.

Table 3-18. Configurations for Different Pacing Speeds

Pacing Speed (Percentage of Line Rate)	TX_IPG	Pacing Config Field (Bits 6:3) in the Set MAC Config Admin Command
100%	0	0000b
90%	17	1001b
80%	38	1000b
70%	66	0111b
60%	102	0110b
50%	152	0101b
40%	228	0100b
30%	355	0011b
20%	608	0010b
10%	1368	0001b
25%	456	1110b
93% (WAN)	12	1111b

3.2.1.7 MAC Speed Change at Different Power Modes

Auto-negotiation enables establishment of link speed at the Highest Common Denominator (HCD). During certain low power modes, power saving might be more important than link performance. The E810 supports an additional mode of operation, where it can configure the PHY to fixed speed, starting from the lowest speed and checking if the link can be up. This method sets the link speed to the Lowest Common Denominator (LCD) link speed. The link-up process enables the link to come up at any possible speed in cases where power is more important than performance. See further information in Section 5.2.2.

3.2.1.8 MAC Errors

The E810's MAC supports identification of the following erroneous packets:

- **L2 CRC Error** — Packet's FCS check resulted in an error.
- **Undersized or Oversized Packets** — Received frame size is smaller than 64 bytes or larger than the configured max frame size, which was either loaded from the NVM or set using the Set MAC Config command (see Section 3.2.4.1.2).
- **Illegal Byte Error** — Indication that an illegal control byte was received on the interface. An illegal control byte is any value that is not legal. (See IEEE802.3 for legal symbols, such as /I/,/E/,/T/, /D/ , /S/, /Seq/, or /LPI/).
- **Error Byte Error** — Indication that a packet was received with the error control byte (/E/) on the XGMII interface. Indicates that the PCS has encountered an error during the packet's reception.
- **802.3 Length Error** — <Length> field information in the 802.3 header does not match the packet's actual size.

Packets containing any one of the previous errors can be filtered by the device or forwarded to a pre-configured VSI based on the *SBP* flag in the PRT_SBPVSI register.

Note: Packets shorter than 64 bytes are always filtered by the MAC layer and are not affected by the Store Bad Packets (SBP) configuration.

3.2.1.8.1 MAC Error Counters

Table 3-19 lists the different MAC error counters supported by the device.

Table 3-19. MAC Error Counters

Field	Description
CRC Error	Counts the number of packets received with CRC errors that are not fragments.
Illegal Bye Error	Counts the number of packets received with an illegal control byte on the CGMII/XLGMII interface.
Error Byte	Counts the number of packets that were received with an error control byte on the CGMII/XLGMII interface.
Receive Length Error	Counts the number of packets received with error in length field comparison in the 802.3 header.
Receive Undersize	Counts the number of packets with good CRC that are smaller than 64 bytes.
Receive Fragment	Counts the number of packets with bad CRC that are smaller than 64 bytes
Receive Oversize	Counts the number of packet that are larger than the configured max frame size.
MAC Short Packet Discard	Counts the number of packets smaller than 32 bytes that were discarded by the MAC layer.

3.2.2 Physical Layer Interface

3.2.2.1 Introduction

The E810 provides up to eight Ethernet port interfaces. The following sections describe the physical interfaces that the E810 can support and manage through firmware.

Table 3-20. Supported Electrical Modes

Speed	Mode	Spec	Comments
100G	CAUI-4	• IEEE 802.3 Annex 83D/83E	• 4x25G AUI used for chip-to-chip or chip-to-module connectivity. Annex 83D/E provides electrical specs. Clause 82 PCS, Clause 91 RS(528,514) required for support of 100GBASE-SR4, CWMD4, or PSM4 optics.
	100GBASE-KR4	PMD: • IEEE 802.3 Clause 93 PCS: • IEEE 802.3 Clause 82 • IEEE 802.3 Clause 91	• 4x25G used for backplane connectivity. • Uses RS(528,514).
	100GBASE-CR4	PMD: • IEEE 802.3 Clause 92 PCS: • IEEE 802.3 Clause 82 • IEEE 802.3 Clause 91	• 4x25G used for connecting to DA Copper cable. • Uses RS(528,514).
	100GBASE-CR2	PMD: • IEEE 802.3 Clause 136 PCS: • IEEE 802.3 Clause 82 • IEEE 802.3 Clause 91	• 2x50G lanes using PAM4 modulation. Used for connecting to DA Copper cable. • Uses RS(544,514).
	100GBASE-KR2	PMD: • IEEE 802.3 Clause 137 PCS: • IEEE 802.3 Clause 82 • IEEE 802.3 Clause 91	• 2x50G lanes using PAM4 modulation. Used for backplane connectivity. • Uses RS(544,514)
	100GAUI-2	IEEE 802.3 Annex 135F/135G	• 2x50G lane AUI using PAM4 modulation and RS(544,514) for chip-to-chip or chip-to-module connectivity.
	100GAUI-4	IEEE 802.3 Annex 135D/135E	• 4x25G lane AUI using NRZ modulation and RS(544,514) for chip-to-chip or chip-to-module connectivity.

Table 3-20. Supported Electrical Modes [continued]

Speed	Mode	Spec	Comments
50G	50GBASE-KR2	PMD: • IEEE 802.3 Clause 93 like PCS: • IEEE 802.3 Clause 82 like	• Used for Backplane connectivity. • Not specified in IEEE 802.3, KR PMD with 2x25G lanes as specified in 25/50G Ethernet consortium.
	50GBASE-CR2	PMD: • IEEE 802.3 Clause 92 like PCS: • IEEE 802.3 Clause 82 like	• Used for connecting to DA Copper cable. • Not specified in IEEE 802.3, CR PMD with 2x25G lanes as specified in 25/50G Ethernet consortium.
	50GBASE-CR	PMD: • IEEE 802.3 Clause 136 PCS: • IEEE 802.3 Clause 133 • IEEE 802.3 Clause 134 RS-FEC	• 1x50G PAM4 used for connecting to DA Copper cable. • RS(544,514).
	50GBASE-KR	PMD: • IEEE 802.3 Clause 137 PCS: • IEEE 802.3 Clause 133 • IEEE 802.3 Clause 134 RS-FEC	• 1x50G PAM4 used for backplane connectivity. • RS(544,514)
	50GAUI-2	IEEE 802.3 Annex 135D/135E	• 2x25G lane AUI using NRZ modulation and RS(544,514) for chip-to-chip or chip-to-module connectivity.
	50GAUI-1	IEEE 802.3 Annex 135F/135GE	• 1x50G lane AUI using PAM4 modulation and RS(544,514) for chip-to-chip or chip-to-module connectivity.
	LAUI-2	IEEE 802.3 Annex 135B/135C	• 2x25G lane AUI using NRZ modulation and RS(528,514) or no FEC for chip-to-chip or chip-to-module connectivity.
25G	25GAUI	PMD: • 25GAUI C2C Annex 109A • 25GAUI C2M Annex 109B PCS: • IEEE 802.3 Clause 107 PCS, Clause 108 RS-FEC	• 109A used for chip-to-chip connectivity. • 109B used for connecting to optics (generally 25GBASE-SR/LR in SFP28 module with RS(544,514).
	25GBASE-KR	PMD: • IEEE 802.3 Clause 111 PCS • IEEE 802.3 Clause 107 PCS, Clause 108 RS-FEC, Clause 74 BASE-R FEC	• Used for Backplane connectivity. • Auto-negotiated options for use of no FEC, BASE-R FEC, or RS(528,514).
	25GBASE-CR	PMD: • IEEE 802.3 Clause 110 PCS • IEEE 802.3 Clause 107 PCS, Clause 108 RS-FEC, Clause 74 BASE-R FEC	• Used for connecting to DA Copper cable. • Auto-negotiated options for use of no FEC, BASE-R FEC, or RS(528,514).
	25GBASE-CR1/KR1	25G/50G Ethernet Consortium Schedule 3 v1.6.	• 25G CR/KR PMD as specified in 25G/50G Ethernet Consortium Schedule 3 v1.6. Compatible with IEEE 25G CR/KR except for auto-negotiation advertisement.

Table 3-20. Supported Electrical Modes [continued]

Speed	Mode	Spec	Comments
10G	10GBASE-KR	PMD: • IEEE 802.3 Clause 72 PCS: • IEEE 802.3 Clause 49	• Used for Backplane connectivity.
	SFI	PMD: • SFF 8431 PCS: • IEEE 802.3 Clause 49	• Used for connecting to SFP+ module. • Limiting mode for optical and active cables. • Appendix E linear mode for passive copper twin-ax.
1G	1000BASE-KX	PMD: • IEEE 802.3 Clause 70 PCS: • IEEE 802.3 Clause 36	• Used for Backplane connectivity.
	SGMII	PMD: • Cisco SGMII spec PCS: • IEEE 802.3 Clause 36, 37 like	• Used for chip-to-chip connectivity.
100M	SGMII	PMD: • SGMII spec PCS: • IEEE 802.3 Clause 36, 37 like	• Used for chip-to-chip connectivity.

3.2.2.2 MAC/PHY Interface

The E810 provides up to eight Ethernet ports, where there is a 1:1 mapping between the E810 MAC ONPI port and the PHY physical port. The interface modes are illustrated in the following diagrams.

3.2.2.2.1 MAC/PHY Interface Mapping

Figure 3-6 illustrates the default MAC-to-PHY connectivity. The controller core contains eight Ethernet MACs. The MACs are grouped into two sets of four. Within each set of four, one MAC supports all rates up to 100G (MAC0 and MAC1), a second MAC supports all rates up to 25G (MACs2 and MAC3), and the remaining MACs (MAC4-MAC7) support up to 10G.

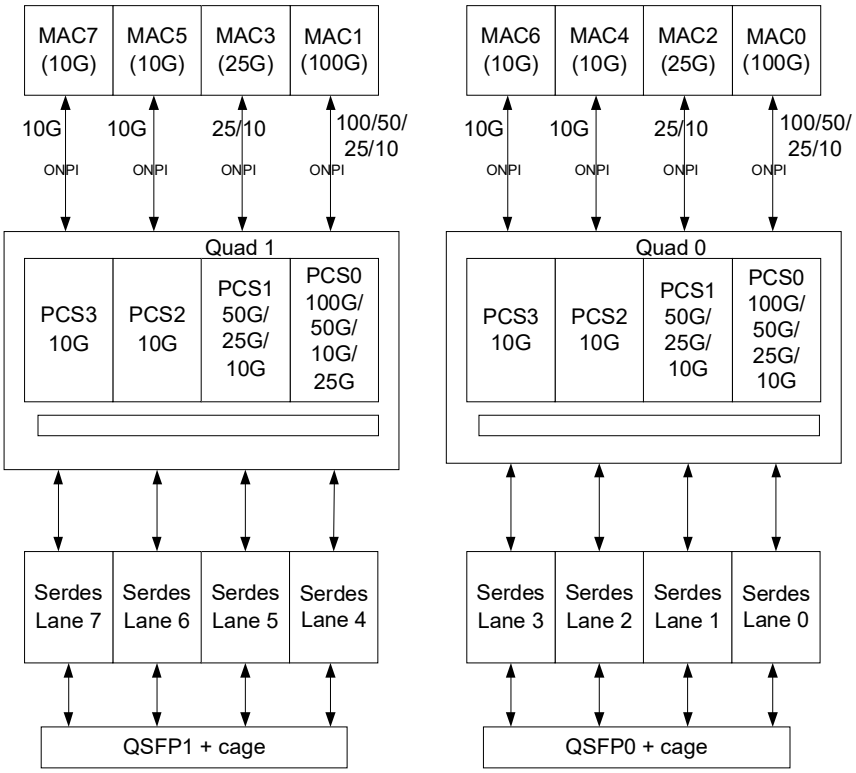

Figure 3-6. E810 - MAC-PCS-SerDes Default Mapping

Each set of four MACs is connected to a single PCS block that supports up to four ports. Within each PCS block is one PCS function (PCS0) that support all rates up to 100G, a second PCS function (PCS1) that supports rates up to 50G, and two PCS functions (PCS2/3) that support up to 10G.

When operating in dual port mode, MAC0 and MAC1 are connected to PCS0 of their respective PCS blocks, and the PCS distributes the data to up to four SerDes lanes needed for 4-lane modes, such as 100GBASE-CR4. This results in MAC0 utilizing SerDes lanes 0-3, while MAC1 utilizes SerDes lanes 4-7.

When operating in quad-port mode, only single lane per port modes are supported. MAC0 and MAC2 connect to PCS0 and PSC1 of the first PCS, while MAC1 and MAC3 connect to PCS0 and PCS1 of the second PCS block. Using the default PCS-to-SerDes mapping, this presents the data from MACs (0,2,1,3) on SerDes lanes 0, 1, 4, and 5 respectively.

To support a “breakout” mode where all four ports utilize the same SerDes quad, multiplexers in the PCS-to-SerDes path direct the data from both PCS blocks to a single SerDes quad. This mode allows a system design to support quad-port 25G in the same QSFP connector as a 100G port.

When working with lane rates of 50G, a 100G port is mapped to two lanes and 50G port is mapped to a single lane. As those rates are only supported by MAC0 and MAC1, both direct and breakout mappings are supported. While working at 100G port rates, the direct mapping maps MAC0 into lane0 and lane1, while MAC1 is mapped into lane4 and lane5. In 50G port rates, the direct mapping maps MAC0 to lane0 and MAC1 into lane4. In 50G port rates, additional breakout mapping can be applied, which maps MAC0 into lane0 and MAC1 into lane1.

The 50G “breakout” mode allows a system design to support two 50G ports using the same QSFP connector that was used when the port is configured to 100G.

3.2.2.3 Port and PMD Mapping

To manage the Ethernet links, E810 firmware must map the port number and PMD (SerDes lane) number along the way of the packet.

3.2.2.3.1 Port and PMD Nomenclature

The term "Logical port" to refers to an Ethernet port link as seen from the host perspective. A logical port is mapped to the E810 Ethernet MAC and to a PCIe physical function (PF). In addition, a logical port is mapped to a single or multiple PMD lanes of the internal PHY, depending on the PMD type. For link management admin commands or link topology commands, the E810 field refers to logical port.

E810 MAC port numbering might be different from logical port numbering, because of physical function mapping and the internal ONPI connection between the E810 controller core and the PHY.

3.2.2.3.2 Port Mapping

Table 3-21. Port Mapping

E810				PHY		
Physical Function (PF) Mapping			MAC Number	ONPI Port Number	PMD Lane Number[1]	
2-Port Default	4-Port Default	8-Port Default			Single Lane	Multi Lane
0	0	0	0	0	0	**0**,1,2,3
	1	1	2	2	1	1
		2	4	4	2	2
		3	6	6	3	3
1	2	4	1	1	4	**4**,5,6,7
	3	5	3	3	5	5
		6	5	5	6	6
		7	7	7	7	7

1. Bold identifies the auto-neg PMD lane

Note: E810 Ports 0-3 support up to 25G. There is a need to map those ports using the same lanes that were used for 100G, for breakout configurations. This mapping is described in Table 3-22.

Table 3-22. Port Mapping (4x25G on the First Quad)

Physical Function (PF)	E810 MAC Number	PHY ONPI Port Number	PMD Number
0	0	0	0
1	2	2	1
2	1	1	2
3	3	3	3

For 50G lane rates, E810 Ports 0-1 are mapped to lanes 0,1,4,5 using the following mapping:

Table 3-23. Port Mapping (50G Lane Rates)

Mode	Physical Function (PF)	E810 MAC Number	PHY ONPI Port Number	PMD Number[1]
2x100G	0	0	0	**0**,1
	1	1	1	**4**,5
2x50G	0	0	0	0
	1	1	1	4
2x50G Breakout	0	0	0	0
	1	1	1	2

1. Bold identifies the auto-neg PMD lane

3.2.2.3.3 Port Mapping - E810-XXVAM2 SKU

The E810-XXVAM2 product in the 21x21 mm package shares the same core features as the E810-CAM2/CAM1 products in the 25x25 mm package, with the exception of limited interfaces. The PCIe interface is limited to Gen4 x8, and the Ethernet interface limited to two ports maximum at 25G and lower speeds, or a single port of 50G, implemented as 2x25G SerDes (that is, 50GBASE-CR2).

Table 3-24. Port Mapping - E810-XXVAM2

Mode	Physical Function (PF)	E810 MAC Number	PHY ONPI Port Number	PMD Number[1]
2x25G	0	0	0	**0**
	1	1	1	**1**
1x50G	0	0	0	**0**,1

1. Bold identifies the auto-neg PMD lane

3.2.2.4 PHY Lane Mapping per Port Mode

In single-lane mode, there is a direct mapping between the PHY ONPI port and the PHY PMD lane. In multi-lane mode, a single PHY ONPI port is mapped to 2 or 4 PMD lanes. The E810 PHY Core supports multi-lane mode at port 0 and port 4. Port 0 can be mapped to PMD lanes 0-2 for a dual-lane mode, or lanes 0-3 for a 4-lane mode. Port 4 can be mapped to PMD lanes 2-3 for a dual-lane mode, or lanes 4-7 for a 4-lane mode.

Table 3-25. E810 PMD Lane Mapping per Port Mode

	Site #/PMD#/Supported PMD Rates									
Site	**Site 0**				**Site 1**				**Port Mode**	**Notes/Limitations**
PMD	**0***	**1**	**2**	**3**	**4***	**5**	**6**	**7**		
QSFP Lane	**1**	**2**	**3**	**4**	**1**	**2**	**3**	**4**		
CFG1.1	50G		50G						2	**CFG1.1:** 4xSFP (2-port and 4-port modes) **Note:** The 4x SFP implementation also supports 2x50GBASE-R on PMD lane 0 and 2. This configuration multiplexes the Site 1 serial lanes to Site 0.
	25G	25G	25G	25G					4	
	10G	10G	10G	10G					4	
	1G	1G	1G	1G					4	
	100M	100M	100M	100M					4	
CFG3.1	100G-R4								2	**CFG3.1:** 1xQSFP (2-port and 4-port modes, including breakout) **Note:** This configuration multiplexes the Site 1 serial lanes to Site 0. Site 0 configuration now effectively supports QSFP and QSFP breakout cables. Site 1 is disabled due to the internal multiplexing structure.
	100G-R2								2	
	50G-R2		50G-R2						2	
	50G		50G						2	
	25G	25G	25G	25G					4	
	10G	10G	10G	10G					4	
	1G	1G	1G	1G					4	
	100M	100M	100M	100M					4	
CFG4.1	100G-R4				100G-R4				2	**CFG4.1:** 2xQSFP (2-port, 4-port, and 8-port modes) **Note:** CFG4.x is a superset of CFG3.x. A system designed with CFG4 can also use the breakout mode described in CFG3 on Site 0. **Note:** For the noted PMD lanes (Note 1), the configuration is only supported with topology resolution when breakout cables are plugged in. This would force the E810 to be configured in a 4-port/8-port mode.
	100G-R2				100G-R2				2	
	50G-R2				50G-R2				2

Key:	100G (BASE-R4/-R2)	50G (BASE-R2/-R)	25G	10G	1G/100M

3.2.3 Link Management

3.2.3.1 Link Management Interfaces

The E810 supports either MDIO or I^2C interfaces for control plane connection between the MAC (master side) and external PHY devices. The MDIO or I^2C interfaces enable both MAC and firmware access to the PHY for monitoring and controlling of the PHYs functionality. E810 MDIO is compliant with the IEEE Std 802.3 Clause 45 as well as IEEE Std 802.3 Clause 22 frame formats and register address space for accessing legacy PHY devices. E810 I^2C is compliant with the I^2C bus specification.

Since I^2C and MDIO interfaces requires 3.3 V pads, the I^2C and MDIO controllers are not implemented within the E810. Instead they are placed in a widget. E810 firmware accesses the I^2C and MDIO controllers via registers.

The E810 supports up to six management interfaces (one per port, in 2-port or 4-port configurations) to control external PHY devices. In configurations where the number of ports is higher than four, each management interface should be shared (that is, a single management interface for a mezzanine card of four ports). When the protocol used is I^2C, an I^2C port replicator might be implemented on the 4-port mezzanine card. Depending on the PHY type to manage, the management interface can be configured for either MDIO or 2-wire management interface.

To manage multi-port PHYs, an I^2C/MDIO interface can be configured to control a quad-port PHY, or two I^2C/MDIO interfaces can be configured to control two dual-port PHYs. The PHY configuration registers for each port are mapped into the respective I^2C/MDIO address space. In configurations in which the number of ports is higher than four, five E810 I^2C/MDIO interfaces can be configured to control up to five quad-port PHYs or mezzanine cards with I^2C port replicator. The sixth I^2C/MDIO interface is usually shared between all devices and mezzanine cards and is used for PHYs, LED controllers, thermal sensor or other devices that can share the I^2C or MDIO bus. For example, in mezzanine card based topology, one I^2C port might be dedicated for each mezzanine card and one MDIO interface can be shared between all cards. The MDIO can be used for PHYs or other devices that can share the bus. The I^2C bus is either replicated, using I^2C port extender at the mezzanine card, or used for devices that can share the I^2C bus. Alternatively, the I^2C bus can be used by single I^2C device.

Note: PHY mezzanine daughter cards are not supported in the E810.

The E810 provides hardware acceleration of MDIO accesses over the 2-wire management interface. The device driver manages the external devices using the admin commands (see Section 3.2.4, "Link Configuration Admin Commands"). The device driver does not have direct access to the MDIO bus except for diagnostic purposes. Firmware performs direct access to MDIO interface, using register read and write commands to the widget, for reading and writing to the PHY device as described in the paragraphs that follow.

Figure 3-7 shows the a basic example of connectivity between the MAC and an external PHY/module for up to four ports.

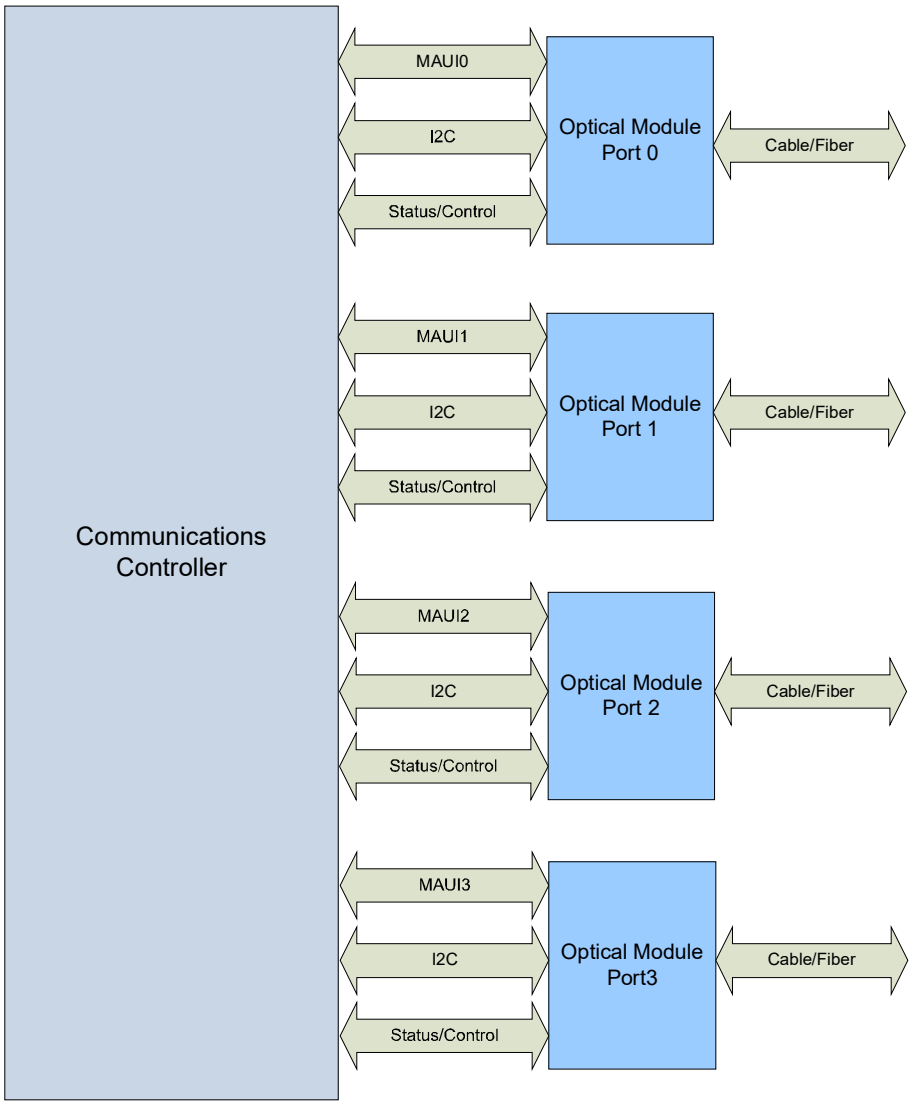

Figure 3-7. Basic PHY/Module Connectivity

3.2.3.2 Link Management Topologies

The E810 supports MDIO and 2-wire management interface (I^2C) for connectivity to external modules, re-timers, and PHYs (for example, SFP+ or QSFP+ optical and direct attached copper PHYs).

The E810 supports up to five management interfaces (one per port - for up to 4-port configurations) to control external PHY devices. Depending on the PHY type to manage these can be configured for either MDIO or 2-wire management interface.

The link topology is described using a netlist in NVM section (see Section 3.3).

Figure 3-8 and Figure 3-9 show the basic examples of connectivity between the MAC and an external module.

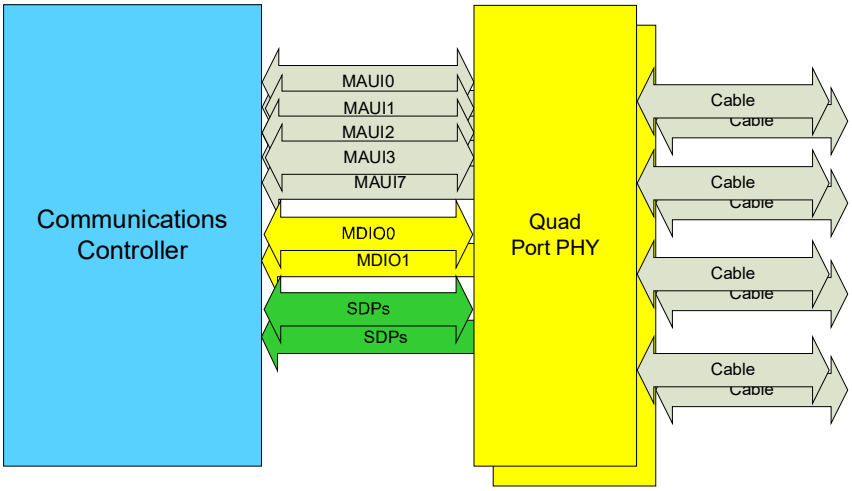

Figure 3-8. Basic Example of Module Connectivity

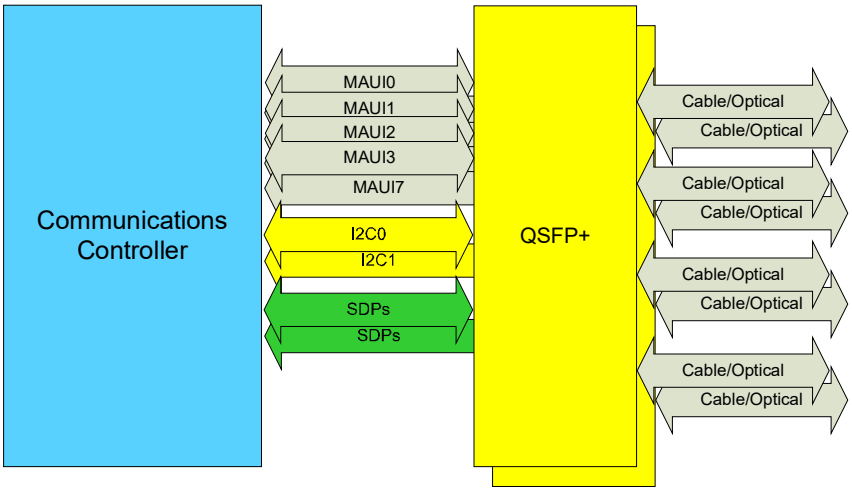

Figure 3-9. Basic Example of Module Connectivity

3.2.3.2.1 The E810's SFP+ Connectivity Scheme (Up to 4 Ports Topologies)

Figure 3-10 and Figure 3-11 illustrate the low speed digital signals used when connecting the E810 to SFP+ modules with topologies of up to four ports.

Note: The diagram illustrates the minimal connectivity required. Additional SDPs can be used to connect to the SFP+ module for direct hardware signaling (for example, *TX_FAULT*). However, these are not mandatory and can be replaced with register access through the I^2C management interface.

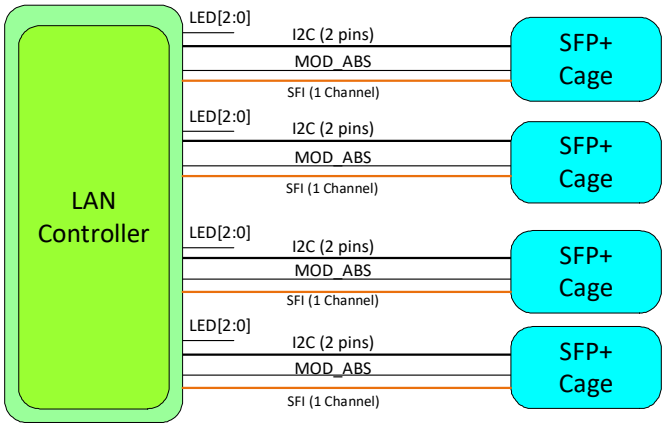

Figure 3-10. Quad 10G SFP+[1]

1. In 4-port configuration, the E810 provides up to 3 LEDs per port.

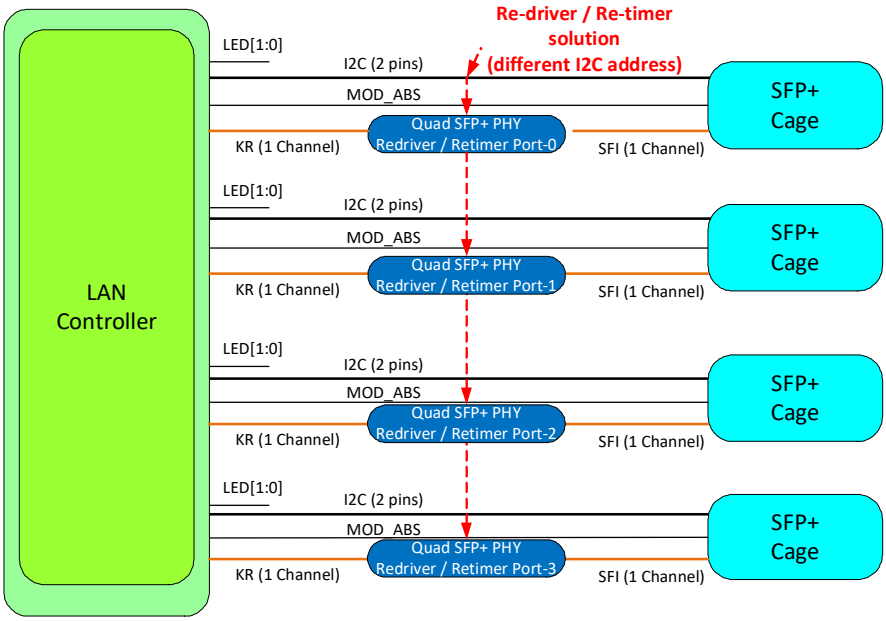

Figure 3-11. Quad 10G SFP+ with Re-driver PHY[1]

1. In 4 port configuration, the E810 provides up to 3 LEDs per port

3.2.3.2.2 The E810's QSFP+ Connectivity Scheme (Up to 8 Ports Topologies)

Figure 3-12 and Figure 3-13 illustrate the low speed digital signals used when connecting the E810 to QSFP+ modules.

Note: The diagrams illustrates the minimal connectivity required. Additional SDPs can be used to connect to the QSFP+ module for direct hardware signaling (for example, ResetL). However, these are not mandatory and can be replaced with register access through the I^2C management interface.

The E810 also supports a mode where an SFP module is inserted in a QSP+ cage using a QSA module adapter.

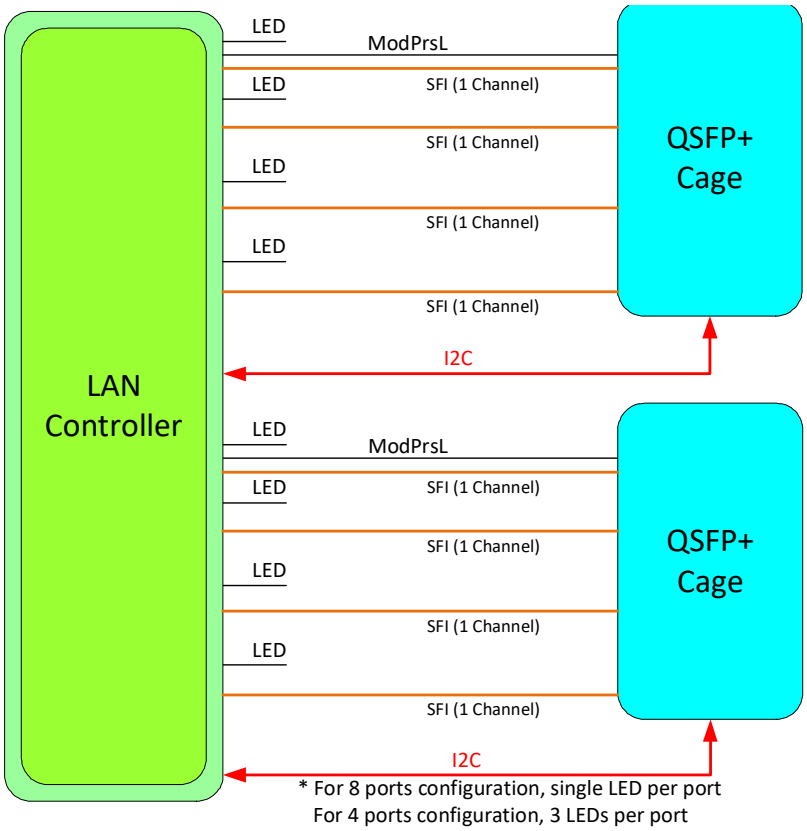

Figure 3-12. Octal 10GDual QSFP+

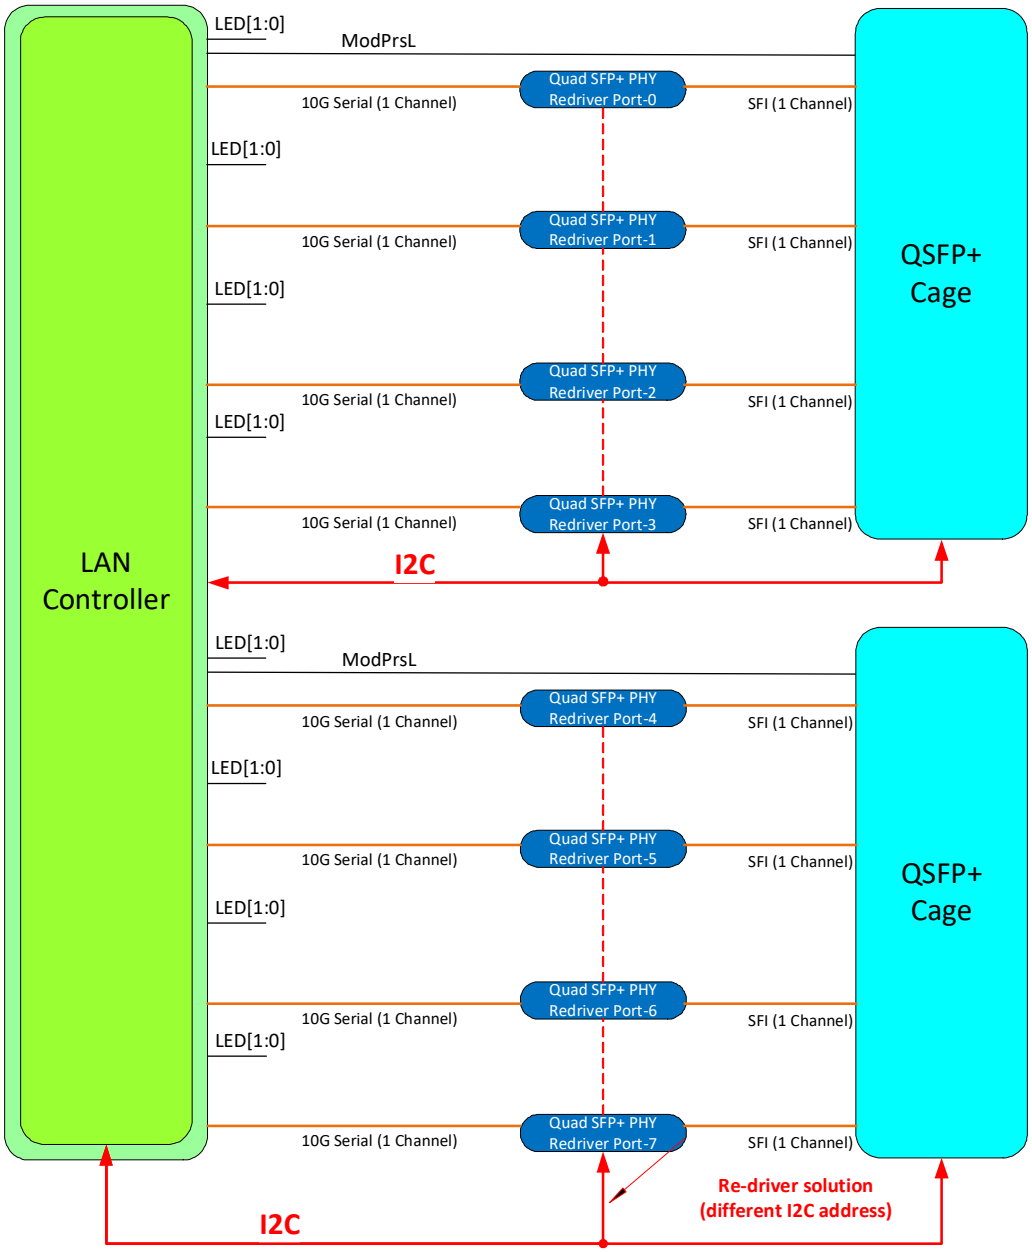

Figure 3-13. Octal 10GDual QSFP+ with Re-driver PHY

3.2.3.2.3 The E810's BASE-T Connectivity Scheme

Figure 3-14 illustrates the low speed digital signals used when connecting the E810 to BASE-T PHYs.

Note: The diagram illustrates the minimal connectivity required. Additional SDPs can be used to connect to the PHY for direct hardware signaling INT. However, these are not mandatory and can be replaced with register access through the MDIO management interface.

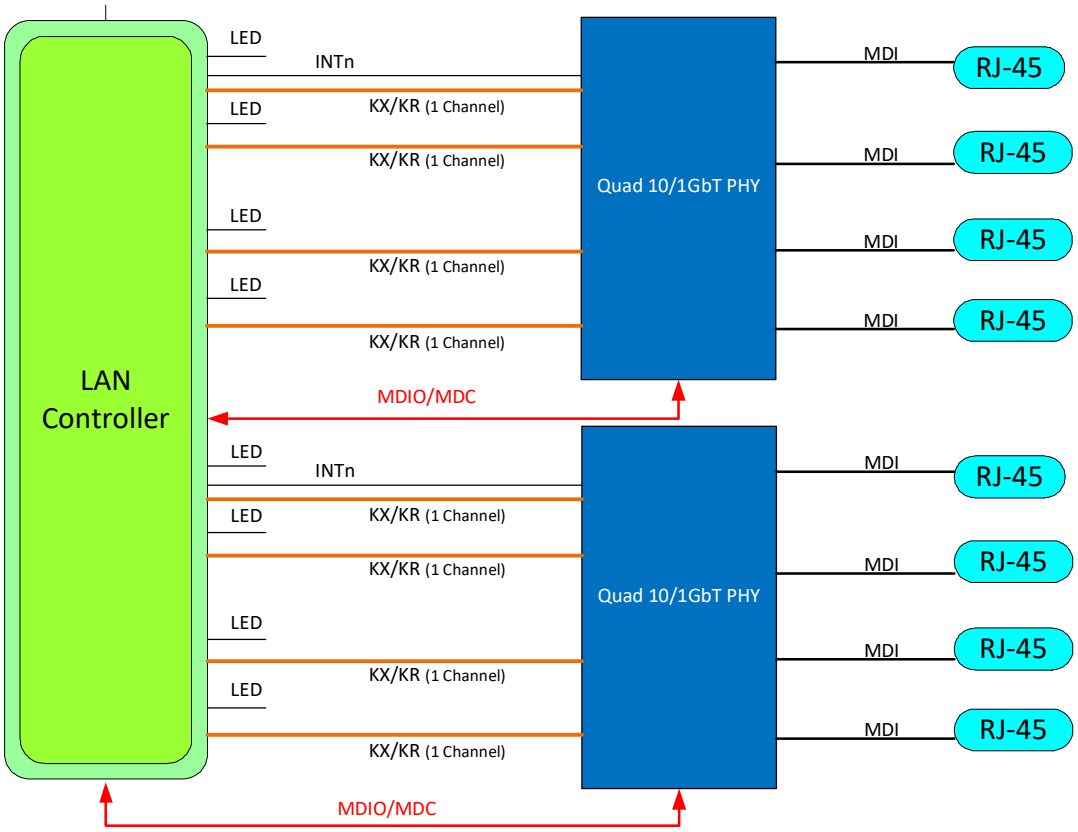

Figure 3-14. Octal 10G/1G BASE-T

Note: The SFP+ module is shown with four SDP pins per port for dedicated hardware functions. The *TX_Disable* bit of the SFP+ module is accessed by software through the I^2C interface. Alternatively, one of the global GPIO pins can be connected to *TX_Disable* pin.

Note: The SFP+ module is shown above with four SDPs. However, the minimum number of SDPs required is only one, which should be connected to the module's *Mod_ABS* pin.

Furthermore, when connecting to a pluggable 1GBASE-T module, the minimum number of SDPs required is two, since an additional SDP is required for connecting to the module *Rx_LOS* signal for accurate link state reporting to the link management firmware. There are, however, specific pluggable BASE-T modules that can be supported without *Rx_LOS*. For specific model numbers please contact Intel support.

3.2.4 Link Configuration Admin Commands

The E810 supports the following admin commands for configuring and managing the link. Software should use the admin commands to configure the link. This includes configuring the MAC and internal/external PHY devices. The firmware provides link configuration and status services to the device driver based on these admin commands.

Software can use the Get Link Status command to find out the current status of the link.

Table 3-26. Link Configuration Admin Commands (0x06xx)

Command	Opcode	Description	Section Reference
Set PHY Config	0x0601	Sets various PHY configuration parameters on the port.	3.2.4.1.1
Set MAC Config	0x0603	Sets various MAC configuration parameters on the port.	3.2.4.1.2
Setup Link and Restart Auto-Negotiation[1]	0x0605	Sets up the link and restarts link establishment. This command applies the latest link configuration as configured with the Set PHY Config (0x0601) command. The command also restarts the link establishment process. For links configured for auto-negotiation, it starts the auto-negotiation process. This operation could bring down the link. This command must be executed to allow the latest link parameters to take effect on the link.	3.2.4.1.3
Get PHY Abilities	0x0600	Gets various PHY abilities supported on the port.	3.2.4.1.4
Get Link Status	0x0607	Gets link status of the port.	3.2.4.1.5
Link Status Event	0x0607	Firmware sends this asynchronous event notification to software when there is a change in status in any of the event causing conditions (such as link up/down or other link error conditions).	3.2.4.1.6
Set Event Mask	0x0613	Sets event mask. Software can mask some or all of the link status event causing conditions.	3.2.4.1.7

1. In SFP mode, the Setup Link and Restart Auto-Negotiation command must be executed by the device driver or any other change in link parameters to take effect on the link. This operation could disrupt the link since the link state might toggle while the link is re-initialized with the new parameters.

3.2.4.1 Link Configuration Commands

This section provides a detailed description of the link configuration admin commands and their structure.

3.2.4.1.1 Set PHY Config (0x0601)

This command is used by the device driver to set the various PHY configuration parameters supported on the port.

This is a indirect command. Set PHY Config command parameters data structure is placed in the data buffer.

Note: This command must be followed by the Setup Link and Restart Auto-Negotiation (0x0605) command for any changes to the link parameters to actually take place. Some parameter settings might take effect immediately with this command execution, as specified below.

Table 3-27. Set PHY Config Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0601	Command opcode.
Datalen	4-5	0x18	Length of the data buffer in bytes.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware. 0 = No error. Command completed successfully. 21 = EMODE. Operation not allowed in current device mode. This error is returned when the command is called with disable link, but the link is configured to be used for manageability. At this case, the link is not configured.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810
Reserved	17-23	Reserved	Value 0x0.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

In the E810, the command is indirect and contains a data buffer. The structure of the data buffer is described in Table 3-28.

Table 3-28. Set PHY Config Command Data Structure

Name	Bytes.Bits	Value	Remarks
PHY Type	0-15	PHY Type	128 bits PHY type (PHY capabilities) supported on port. 128 bits structure, describing capabilities of the outermost PHY, with one bit per PHY capability. PHYs connected to the E810 might be capable of supporting multiple PHY types, indicated using the link topology netlist The software driver uses this command to indicate the capabilities to enable. This structure is identical to the extended PHY capabilities structure, as described in Section 3.3.3.2.1. This parameter is used by the device driver to set the various PHY capabilities to be supported on the port. The port can be configured for a subset of the actual PHY capabilities available on the port. The actual PHY capabilities available are read by the device driver using Get PHY Abilities (0x0600) command. When the link establishment state machine (LESM) is enabled, the E810 tries one of the enabled PHY types that matches the media capabilities and selects this PHY capability when the link is up. When the LESM is disabled, this field should enable only a single value, and then the E810 is forced to operate in that selected mode. Some of the PHY capabilities might require the auto-negotiation feature, which might resolve some of the link parameters, such as speed and FEC, according to the negotiation result with the link partner.
PAUSE Ability	16.0-16.1	Pause Ability	**Bit 16.0:** Tx Link Pause 0b = Disable PAUSE ability. 1b = Enable IEEE 802.3x Tx link PAUSE ability. **Bit 16.1:** Rx Link Pause 0b = Disable PAUSE ability. 1b = Enable IEEE 802.3x Rx link PAUSE ability. Auto-negotiation might have be restarted for this configuration to take effect over the link. This parameter is used by the device driver to set the IEEE 802.3x pause ability of the port. The E810's pause ability can be read using the Get PHY Abilities (0x0600) or Get Link Status (0x0607) commands. The device driver might disable the IEEE 802.3x link PAUSE ability using this command. If the link is already up and configured, the device driver needs to restart auto-negotiation, so the updated PAUSE ability could be advertised to the link partner for the setting to take effect on the link. ***Note:*** When PFC is enabled, firmware turns off the PAUSE ability bits during auto-negotiation regardless of the setting used in the admin command. However, if PFC will be disabled in the future, the last setting of the PAUSE ability bits is used.
Low Power Ability	16.2	Low Power Mode	**Bit 16.2:** Power Mode 0b = High Power mode. 1b = Low Power mode. QSFP+: • This is ignored if NVM loaded <Low Power Ability> = Low Power. When QSFP+ is shared between multiple ports: • Firmware sets the power mode based on the setting of the first (lower power number) port in the group and ignore the settings of the other ports in the group. • The setting of Low Power Ability by one PF automatically changes the Low Power Ability of all PFs sharing the QSFP+. This can result in link loss on all ports. • Firmware identifies which ports are sharing a QSFP+ by looking at the ModPresL SDP and seeing that it is shared between multiple ports.
Enable Link	16.3	Enable Link	**Bit 16.3:** Link Enable 0b = Disable the link. 1b = Enable the link. Device driver should not force link down when port is being used for manageability or WoL.

Table 3-28. Set PHY Config Command Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Reserved	16.4	Reserved	Reserved.
Enable Automatic Link Update	16.5	Enable Automatic Link Update	**Bit 16.5:** Automatic Link Update Enable 0b = The device driver maintains the responsibility for sending the Setup Link and Restart Auto-Negotiation (0x0605) command. 1b = Firmware automatically executes the Setup Link and Restart Auto-Negotiation (0x0605) command following this command. When automatic link update is enabled, the device driver should be aware that a link change event can occur following the Set PHY Config (0x0601) command.
LESM Enable	16.6	LESM Enable	**Bit 16.6:** LESM Enable 1b = Enables the Link Establishment State Machine.
Auto FEC Enable	16.7	Auto FEC Enable	**Bit 16.7:** Auto FEC Enable 1b = Enables the automatic selection of FEC mode.
Low Power Control	17	D3cold LPAN	**Bit 17.0:** D3cold LPAN 0b = Disable D3cold low power auto-negotiation. 1b = Enable D3cold low power auto-negotiation. **Bit 17.3:** AN37 Enable - Clause 37 auto-negotiation enable. 0b = AN37 disabled. 1b = AN37 enabled on 1G links. ***Note:*** The value of *AN37 Enable* bit should be propagated from Get PHY Abilities (0x0600) output to Set PHY Config (0x0601) input for all default Software and firmware flows. **All other bits** = Reserved. Must be zero.
EEE Capability Enable	18-19	EEE Capability	Sets EEE capability for each PHY type supported on the port. One bit per PHY type. These capabilities refers to the outermost PHY connected to the E810 link. The following parameter indicates the bit number. Ignores values for unsupported PHY types. This structure is aligned with the "EEE options 1", in the link topology netlist. See Section 3.3.6.6.8. **Bit 18.0:** EEE is enabled for 100BASE-TX. **Bit 18.1:** EEE is enabled for 1000BASE-T. **Bit 18.2:** EEE is enabled for 10GBASE-T. **Bit 18.3:** EEE is enabled for 1000BASE-KX. **Bit 18.4:** EEE is enabled for 10GBASE-KR. **Bit 18.5:** EEE is enabled for 25GBASE-KR **Bit 18.7:** EEE is enabled for 50GBASE-KR2 **Bit 19.0:** EEE is enabled for 50GBASE-KR-PAM4 **Bit 19.1:** EEE is enabled for 100GBASE-KR4 **Bit 19.2:** EEE is enabled for 100GBASE-KR2-PAM4 **All other bits** = Reserved. Must be zero. This field is used by the device driver to enable the EEE capability of various PHY types supported on the port. The EEE capability of the E810 can be read by the Get PHY Abilities (0x0600) command. The device driver might set EEE capability for a subset of PHY types supported by the E810.
EEER	20-21	EEER Value	Value to program the EEER register. ***Note:*** The EEER register is changed immediately with the execution of this command.

Table 3-28. Set PHY Config Command Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Link FEC Options	22	Link FEC Options	Sets the FEC options to the link. This field is aligned with the FEC options in "Link options 0" of the topology netlist. **Bit 22.0:** FIRE_CODE_10_ABILITY Enable Controls FEC capability advertisement for 10G KR. 0b = FEC disabled. 1b = FEC enabled (advertised). **Bit 22.1:** FIRE_CODE_10_REQUEST Controls FEC capability request for 10G KR. 0b = FEC disabled. 1b = FEC Enabled (requested). **Bit 22.2:** RS_528_REQUEST Controls RS FEC 528 capability request for 25G lanes KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC disabled. 1b = FEC Enabled (requested). **Bit 22.3:** FIRE_CODE_25_REQUEST Controls KR FEC capability request for 25G lanes KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC disabled. 1b = FEC Enabled (requested). **Bit 22.4:** RS_544_REQUEST Controls RS FEC 544 capability request for 25G/50G lanes KR/KR-S/KR1/CR/CR-S/CR1. **Bit 22.5:** Reserved **Bit 22.6:** RS_528_ABILITY Controls RS FEC ability advertisement for 25G KR1/CR1. 0b = FEC disabled. 1b = FEC enabled (advertised). **Bit 22.7:** FIRE_CODE_25_ABILITY Controls KR FEC ability advertisement for 25G KR1/CR1. 0b = FEC disabled. 1b = FEC enabled (advertised).
Module Compliance Enforcement	23.0		0b = Lenient 1b = Strict
Reserved	23.1-23.7	0x0	Reserved. Set to 0x0.

The following structure describes the response by firmware to the Set PHY Config command.

Table 3-29. Set PHY Config Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0601	Command opcode.
Datalen	4-5		Length of the data buffer in bytes.
Return Value/VFID	6-7		Return value. 0x0 = Command success. Returns EPERM code if the operation is not permitted.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Param0	17-19	Reserved	Zeroed by firmware,. Value is ignored.
Param1	20-23	Reserved	Must be 0x0. Value is ignored.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

Note: When *Enable Automatic Link Update* is set to 1b, firmware sends a completion for the Set PHY Config command only after making all the necessary configuration changes and executing the Setup Link and Restart Auto-Negotiation (0x0605) command.

3.2.4.1.2 Set MAC Config (0x0603)

This command is used by the device driver to set the various MAC configuration parameters supported on the port. This status is indicated by the command response.

This is a direct command. The Set MAC Config command parameters data structure is placed in the command descriptor.

Table 3-30. Set MAC Config Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0603	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Set MAC Config	16-31	See Table 3-31	16-byte data structure that holds the Set MAC Config command parameters as listed in Table 3-31.

Table 3-31 lists the data structure of the Set MAC Config command parameters, such as max frame size, and so on.

Table 3-31. Set MAC Config Command Data Structure

Name	Bytes.Bits	Value	Remarks
Max Frame Size	0-1	Max Frame Size	16-bit value used to set the maximum frame size of the Ethernet frame on the port. This parameter is used by the device driver to set the maximum frame size on the port both for Rx and for Tx. This parameter should be set to the maximum expected L2 packet size. It is ~1.5 KB or ~9.5 KB depending if jumbo packets are expected on the link. The firmware should return ERANGE error when the value provided by the software is bigger than the maximal frame size supported by the MAC (9.5K). ***Note:*** The maximal frame size is checked on packets transmitted before the Ethernet CRC is appended to them. For received packets, the check is performed on the packet length that includes the Ethernet CRC.
Reserved	2.0-2.2	Reserved	Must be 0x0
Pacing config	2.3-2.7	Pacing Config	**Bits 2.6-2.3:** This is 4 bit field that allows configuring PACE parameter in the MAC to slow down the effective data rate. For data rate pacing, as defined in Table 3-18. For Fixed IPG pacing, defines the number of 16-byte words added. **Bit 2.7:** Pacing Type 0b = Data rate pacing. 1b = Fixed IPG pacing.
Transmit Timer Priority	3	Transmit Timer Priority	This bitmap field selects the priority <n>, with one bit per priority. The priorities selected here are updated with the *Transmit Time Value* field and the *FC Refresh Threshold* field with the values provided in this command. For additional register description, see Section 3.2.1.5.

Table 3-31. Set MAC Config Command Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Transmit Timer Value	4-5	Transmit Timer Value	This is the priority <n> timer value that is included in the XOFF frames being transmitted, where <n> is selected in the *Transmit Timer Priority* bitmap above. <n> = 0 is used for Link Level FC. For additional register description, see Section 3.2.1.5.
FC Refresh Threshold	6-7	FC Refresh Threshold	This field represents priority <n> FC refresh threshold, that specifies how many slot time before the XOFF expires, a new XOFF is sent. <n> is selected in the *Transmit Timer Priority* bitmap above. When <n> = 0, the value is used for link level flow control. This value is used to calculate the actual refresh period for sending the next pause frame if conditions for a pause state are still valid. For additional register description, see Section 3.2.1.5.
Auto Drop Blocking Packets	8.0		This bit controls the behavior when a no-drop packet is blocking a TC queue. 0b = The PF driver is notified. 1b = The blocking packet is dropped and then the PF driver is notified.
Reserved	8.1-15	Reserved	Must be 0x0.

The following data structure describes the response by firmware to the Set MAC Config command.

Table 3-32. Set MAC Config Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0603	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7		Return value. 0x0 = Command success. Returns EPERM code if the operation is not permitted.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	Reserved	Value 0x0.

3.2.4.1.3 Setup Link and Restart Auto-Negotiation (0x0605)

This command is used by the device driver to setup the link and execute previously-sent Set PHY Config (0x0601) commands, as well as restart the link establishment process. When the link is configured to auto-negotiation mode, the link establishment state machine also starts the auto-negotiation process over the link. This command must be executed for any change in link parameters, such as set link speed (and so on) to take effect.

This is a direct command.

Table 3-33. Restart Auto-Negotiation Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0605	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored. 0 = No error. Command completed successfully. 20 = EMODE. Operation not allowed in current device mode. This error is returned when the command is called with disable link, but the link is configured to be used for manageability. At this case, the link is not configured.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17	Reserved	Must be 0x0. Value is ignored.
Command Flags	18	Command	**Bit 18.1:** Restart Link 1b = Restart the link. **Bit 18.2**[1]**:** Enable Link 0b = Disable link. 1b = Enable link. **All other bits** = Reserved. Must be zero. This command might be executed automatically by firmware, following a Set PHY Config (0x0601) command, with the *Enable Automatic Link Update* bit (16.5) set. In such a case, these bits are assigned by firmware as follows: Bit 18.1 is set to 1. ***Note:*** Bit 18.2 is copied from the *Enable Link* field in the Set PHY Config command.
Reserved	19-31	Reserved	Must be 0x0. Value is ignored.

1. Used by the device driver to enable/disable the link without modifying the other link settings. This is useful at POR when an application needs to have link powered down until the device driver loads.

The following structure describes the response by firmware to the Restart Auto-Negotiation command.

Table 3-34. Restart Auto-Negotiation Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0605	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7		Return value. 0x0 = Command success.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17-31	Reserved	Value 0x0.

3.2.4.1.4 Get PHY Abilities (0x0600)

This command is used by the device driver to find out the various PHY abilities supported on the port.

This is an indirect command.

Table 3-35. Get PHY Abilities Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0600	Command opcode.
Datalen	4-5		Length of the response buffer in bytes. The software driver should supply a buffer with enough space to be filled by firmware
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17	Reserved	Must be 0x0. Value is ignored.
Param0	18-19	Command	First command parameter. **Bit 18.0:** Report Qualified Modules List of qualified modules is part of the response only when this bit is set to 1b. **Bits 18.1-18.2:** Report Mode 00b = **Report Topology Capabilities, without Media:** Report capabilities structure as read from the topology netlist in NVM or ID EEPROM. This report ignores the media that might be connected and limits the capabilities. 01b = **Report Topology Capabilities, with Media:** Report capabilities as read from topology netlist in NVM and ID EEPROM, intersect with the media information, if exists Examples: When the topology includes cage, but it is empty, it reports all possible module types and speeds, just like 00b report mode. When there is specific media connected (that is, a module is populated into the cage), it reports only modes speeds supported by the media or the module. 10b = **Report Active Configuration:** Report the capabilities of the active configuration. The active configuration can be taken from the last software configuration, but it can be modified by firmware (for example when a new module is inserted or NCSI command is executed. When the Override Enable bit is set at the Link Default Override Mask PFA section, the capabilities are taken from the same PFA section. 11b = Reserved. **All other bits** = Reserved.
Reserved	20-23	Reserved	Must be 0x0. Value is ignored.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

Table 3-36 lists the Get PHY Abilities response structure returned by firmware to the Get PHY Abilities command. The response, opcode, and Get PHY Abilities response data structure buffer address are placed in the descriptor. The Get PHY Abilities response data structure is placed in a buffer.

Table 3-36. Get PHY Abilities Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0600	Command opcode.
Datalen	4-5		Set by firmware according to the actual size of the response buffer.
Return Value/VFID	6-7		Return value. EINVAL = Invalid parameters (for example, buffer too small). EIO = Error while accessing the information. EAGAIN = PHY/module interface currently busy, retry.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17-23	Reserved	Reserved. Must be set to 0x0.
Data Address High	24-27	Buffer Address	Buffer address. Buffer content is listed in Table 3-37.
Data Address Low	28-31	Buffer Address	

Table 3-37 lists the format of the buffer content for the Get PHY Abilities reply.

Table 3-37. Get PHY Abilities Command Response Data Structure

Name	Bytes.Bits	Value	Remarks
PHY Type	0-15	PHY Type	See detailed description in Table 3-46.
Pause Ability	16.0:16.1	Pause Ability	**Bit 16.0:** Returns 1b if the port advertises IEEE 802.3x Tx link PAUSE ability. Otherwise, returns 0b. **Bit 16.1:** Returns 1b if the port advertises IEEE 802.3x Rx link PAUSE ability. Otherwise, returns 0b. This parameter can be used by the device driver to determine the IEEE 802.3x PAUSE abilities of the port.
Low Power Ability	16.2	Low Power Ability	**Bit 16.2:** Power Mode 0b = High Power mode. 1b = Low Power mode.
Link Mode	16.3	Link Mode	**Bit 16.3:** Link Mode 0b = Link is disabled. 1b = Link is enabled.
Reserved	16.4		Reserved.
Enable Module Qualification	16.5	Enable Module Qualification	**Bit 16.5:** Module Qualification Returns 1b if a external module or PHY qualification check is enabled.
LESM Enable	16.6	LESM Enable	**Bit 16.6:** LESM Returns 1b if the Link Establishment State Machine is enabled.
Auto FEC Enable	16.7	Auto FEC Enable	**Bit 16.7:** Auto FEC Returns 1b if the automatic selection of FEC mode is enabled.

Table 3-37. Get PHY Abilities Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Low Power Control / AN Modes	17	D3cold LPAN	**Bit 17.0:** D3cold LPAN 0b = D3cold low power auto-negotiation disabled. 1b = D3cold low power auto-negotiation enabled. **Bit 17.1:** 0b = AN28 disabled. 1b = AN28 enabled. **Bit 17.2:** 0b = AN73 disabled. 1b = AN73 enabled. **Bit 17.3:** 0b = AN37 disabled. 1b = AN37 enabled on 1GF PHY Types. **All other bits =** Reserved. Must be zero. ***Note:*** The auto-negotiation enable bits are reserved when Get PHY Abilities (0x0600)" is called with the *Report Active Configuration* parameter indicated, and firmware should return these bits as 0.
EEE Capability	18-19	EEE Capability	Reports EEE capability for each PHY type supported on the port. One bit per PHY type. These capabilities refers to the outermost PHY connected to the E810 link. The following parameter indicates the bit number. This structure is aligned with the "EEE options 1", in the link topology netlist. See Section 3.3.6.6.8. **Bit 18.0:** EEE is enabled for 100BASE-TX. **Bit 18.1:** EEE is enabled for 1000BASE-T. **Bit 18.2:** EEE is enabled for 10GBASE-T. **Bit 18.3:** EEE is enabled for 1000BASE-KX. **Bit 18.4:** EEE is enabled for 10GBASE-KR. **Bit 18.5:** EEE is enabled for 25GBASE-KR **Bit 18.7:** EEE is enabled for 50GBASE-KR2 **Bit 19.0:** EEE is enabled for 50GBASE-KR-PAM4 **Bit 19.1:** EEE is enabled for 100GBASE-KR4 **Bit 19.2:** EEE is enabled for 100GBASE-KR2-PAM4 **All other bits** = Reserved, Must be zero.
EEER	20-21	EEER Value	Content of EEER register.
Current PHY ID/Vendor OUI	22-25	PHY ID/OUI	This parameter is used by the device driver to find out the PHY/module ID connected on the port. If the E810 is connected to an external BASE-T PHY: This 4-byte field returns the {OUI, Manufacturer Model#, Revision ID} as defined in IEEE 802.3, 22.2.4.3.1 PHY Identifier (Registers 2 and 3). **Bytes 23:22:** Register3. **Bytes 25:24:** Register2. If the E810 is connected to an external module: This field returns the three-byte vendor OUI of the module (MSB is padded with zeros).
Current PHY FW version	26-33	PHY Firmware Version	This 8-byte parameter indicates the external outermost PHY firmware version

Table 3-37. Get PHY Abilities Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Link FEC Options	34	Link FEC Options	Returns the FEC options of the link. This field is aligned with the FEC options in "Link options 0" of the topology netlist. See Section 3.3.6.6.5. **Bit 34.0:** FIRE_CODE_10_ABILITY Enable Controls FEC capability advertisement for 10G KR. 0b = FEC Disabled. 1b = FEC Enabled (advertised). **Bit 34.1:** FIRE_CODE_10_REQUEST Controls FEC capability request for 10G KR. 0b = FEC Disabled. 1b = FEC Enabled (requested). **Bit 34.2:** RS_528_REQUEST Controls RS FEC 528 capability request for 25G KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC Disabled. 1b = FEC Enabled (requested). **Bit 34.3:** FIRE_CODE_25_REQUEST Controls KR FEC capability request for 25G KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC Disabled. 1b = FEC Enabled (requested). **Bit 34.4:** RS_544_REQUEST Controls RS FEC 544 capability request for 25G KR/KR-S/KR1/CR/CR-S/CR1. **Bit 34.5:** Reserved **Bit 34.6:** RS_528_ABILITY Controls RS FEC ability advertisement for 25G KR1/CR1. 0b = FEC Disabled. 1b = FEC Enabled (advertised). **Bit 34.7:** FIRE_CODE_25_ABILITY Controls KR FEC ability advertisement for 25G KR1/CR1. 0b = FEC Disabled. 1b = FEC Enabled (advertised).
Module Compliance Enforcement	35.0		0b = Lenient 1b = Strict
Reserved	35.1-35.7	Reserved	Reserved.
Current Module Extended Compliance Code	36	Extended Compliance Code	Returns the extended compliance code of the module as defined in SFP+ (Address 0xA0, Byte 36) specification. This parameter is used by the device driver to find out the module type on the port when connected to external modules.

Table 3-37. Get PHY Abilities Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Current Module Type	37-39	Module Type	Returns the three-byte module ID. First byte: Module identifier. Defined by SFP+ (Address 0xA0, Byte 0) or QSFP+ (Address 128, page 0) specifications. Second byte: The following bits might be set to indicate the supported technologies: 0 = SFP+ Cu Passive 1 = SFP+ Cu Active 4 = 10G BASE-SR 5 = 10G BASE-LR Remaining bits are reserved. Third byte: GbE compliance code. Defined by SFP+ (Address 0xA0, Byte 6) or QSFP+ (Address ess134, page0) specifications. This parameter is used by the device driver to find out the module type on the port when connected to external modules. For example, the E810 might be connected to an SFP+ or QSFP+ optical or direct attached copper modules. The format of the module type returns the ID and Ethernet compliance code fields as defined in the SFP+ or QSFP+ specifications. There is no separate Ethernet compliance code for SFP+ copper modules. It is reported in a separate byte in SFP+ module. However, the E810 uses the unused bits in second byte to report SFP+ direct attach cables.
Qualified Module Count	40		Number of qualified modules to be listed in the following bytes.
Reserved	41-47	Reserved	Reserved.
Qualified Module ID-n	48+n*32 - 79+n*32		This is a list of qualified modules that are supported by the E810 and might be connected. The list contains a 24-byte field per module, based on IEEE Std 802.3 definition of device ID, containing: • Vendor OUI (3 bytes). • Reserved (1 bytes). • Vendor Part# (16 bytes). • Vendor Rev# (4 bytes). • Last 8bytes are reserved.

3.2.4.1.5 Get Link Status (0x0607)

This command is used by the device driver to find out the link status of the port. Firmware returns link status = up when the link is available for transmission/reception. This command also returns other operating parameters of the link, such as negotiated speed, PHY type, and so on.

In the E810 this is an indirect command, and returns the Get Link Status information structure within the buffer.

Table 3-38. Get Link Status Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0607	Command opcode.
Datalen	4-5		Length of the data buffer in bytes.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17	Reserved	Must be 0x0. Value is ignored.
Command Flags	18-19	Command Flags	**Bits 18.1-18.0:** 00b = NOP — LSE notification value is not modified and Get Link Status response returns the most updated value of enable/disable. 01b = Reserved. 10b = Disable link status event notification to software. 11b = Enable link status event notification to software. See Section 3.2.4.1.6 for details on LSE and enabling/disabling LSE events. **All other bits** = Reserved. Must be 0x0. Value is ignored.
Reserved	20-23	Reserved	Must be 0x0. Value is ignored.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

The following structure describes the response by firmware to the Get Link Status command.

Table 3-39. Get Link Status Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0607	Command opcode.
Datalen	4-5		Length of the data buffer in bytes.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17	Reserved	Must be 0x0. Value is ignored.
Command Flags	18-19	Command Flags	**Bit 18.0:** LSE Enable Enable link status event notification to software. Firmware sets this bit to 1b to indicate that LSE is enabled, or sets to 0b if LSE is disabled. See Section 3.2.4.1.6 for further details on LSE and enabling/disabling LSE events. **All other bits** = Reserved. Must be 0, value is ignored.
Reserved	20-23	Reserved	Must be 0x0. Value is ignored.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

Table 3-40 lists the data structure of the Get Link Status command parameters, such as link up/down, negotiated/operating speed, fault conditions, and so on.

Table 3-40. Get Link Status Command Response Data Structure

Name	Bytes.Bits	Value	Remarks
Topology/Media Conflicts	0		Topology and media conflict reporting. **Bit 0.0:** Unresolved topology conflict detected. The mezzanine card topology does not match with the main board topology or multiple port options available, but the automatic conflict resolution bit is turned off. **Bit 0.1:** Unresolved media conflict detects. The detected media does not match with the available topology options or media supports multiple port options, but the automatic conflict resolution bit is turned off. **Bit 0.2:** LOM Topology netlist corrupted. The LOM topology netlist is corrupted and cannot be read from the NVM. **Bit 0.3:** Reserved. **Bit 0.4:** Topology netlist load detected Unreachable port. **Bit 0.5:** Topology netlist load detected Underutilized port. **Bit 0.6:** Topology netlist load detected Underutilized media. **Bit 0.7:** Unsupported Media detected.
Link Configuration Error	1		**Bit 1.0:** Link Configuration Error. Link Configuration Error was detected during attempt to bring the link up. **All other bits** = Reserved.
Link Status	2.0	Function Link Status	**Bit 2.0:** Function Link Status Returns 1b if link status = up, or returns 0b if the link status = down. This parameter indicates if the Link is up and ready for data communication.

Table 3-40. Get Link Status Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Link Fault	2.1:2.4	Link Fault	**Bit 2.1:** Returns 1b if PHY has detected a link fault condition. The fault could be anywhere in the PHY layer and either on transmit or receive local or remote fault. The following bits provide additional information about a link fault condition: **Bit 2.2:** Returns 1b if a transmit link fault condition is detected, 0b otherwise. **Bit 2.3:** Returns 1b if a receive link fault condition is detected, 0b otherwise. **Bit 2.4:** Returns 1b if a remote fault condition detected, 0b otherwise.
External Port Link Status	2.5	Port's Link Status	**Bit 2.5:** Port Link Status Returns 1b if link status = up, or returns 0b if the link status = down.
Media Available	2.6	Media Available	**Bit 2.6:** Media Available Returns 1b if media is available for normal link communication, or returns 0b otherwise. This parameter is used by the device driver to find out if the media is available on the port. When connected to an external module, this command returns if the media is plugged in and is available for normal communication. ***Note:*** This field is not relevant when connecting to an external BASE-T PHY or when connecting to a backplane.
Signal Detect	2.7	Signal Detect	**Bit 2.7:** Signal Detect Returns 1b if a receive signal is detected by the PHY or module, or returns 0b otherwise. In the case of external PHYs, for example, this maps to the global signal detect function in the PHY and in some of the PHYs this maps to energy detect function on the link. In the case of external modules, this maps to the inverse of loss of signal function.
AN Completed	3.0	An Completed	**Bit 3.0:** Auto-Negotiation Completed Returns 1b if auto-negotiation completed successfully, or returns 0b otherwise. This bit is valid only if the currently configured PHY type supports auto-negotiation and auto-negotiation is enabled.
LP AN Ability	3.1	LP AN Ability	**Bit 3.1:** Link Partner Auto-Negotiation Ability Returns 1b if the link partner is able to perform auto-negotiation, or returns 0b otherwise. This bit is valid only if the PHY supports auto-negotiation and auto-negotiation is enabled.
Parallel Detection Fault	3.2	Parallel Detection Fault	**Bit 3.2:** Parallel Detection Fault Returns 1b if the PHY detects parallel detection fault, or returns 0b otherwise. This bit is valid only if the PHY supports auto-negotiation with parallel detection enabled.
FEC Enabled	3.3	FEC Enabled	**Bit 3.3:** FEC Enabled Returns 1b if FEC is enabled on the link, or returns 0b otherwise. For PHY types that supports auto-negotiation, FEC might be enabled on the link during auto-negotiation.
Low Power State	3.4	Low Power State	**Bit 3.4:** Power Mode Returns the Low power configuration as set by the Set PHY Config (0x0601) command 0b = High Power Mode 1b = Low Power Mode

Table 3-40. Get Link Status Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Link Pause Status	3.5:3.6	Link Pause Status	**Bit 3.5:** Returns 1b if Tx link pause is enabled on the link during auto-negotiation, or returns 0b otherwise. **Bit 3.6:** Returns 1b if Rx link pause is enabled on the link during auto-negotiation, or returns 0b otherwise. Link Pause status is reported when the current PHY type supports auto-negotiation. Link pause should be disabled if PFC is enabled on the link. Simultaneous operation of link pause and PFC is not supported.
Qualified Module	3.7	Qualified Module	**Bit 3.7:** Qualified Module When the E810 is connected to an external SFP+/QSFP+ module and module qualification is required, this field indicates if the module is a qualified module whose OUI matches one of the pre-defined qualified modules. 0b = Module was not found in pre-configured list of qualified modules. 1b = Module is qualified.
PHY Temp Alarm	4.0	PHY Temp Alarm	**Bit 4.0:** PHT Temp Alarm Returns 1b if a temperature alarm condition is reported by the PHY, or returns 0b otherwise. Typically, an external PHY generates a temperature alarm condition by signaling a PHY interrupt to firmware. The temperature alarm feature should be enabled in the PHY to generate this condition.
Excessive Link Errors	4.1	Excessive Link Errors	**Bit 4.1:** Excessive Link Errors Returns 1b if an excessive errors over the link condition is reported by the outermost PHY, or returns 0b otherwise
Port Tx Suspended	4.2-4.3	Port Tx Suspended	**Bits 4.2-4.3:** Port Tx Suspended 00b = Port's Tx active. 01b = Port's Tx suspended and drained. 10b = Reserved. 11b = Port's Tx suspended and drained. Blocked TC pipe flushed.
Reserved	4.4-4.7	Reserved	Reserved.
Loopback Enabled Status	5	Loopback Enabled Status	**Bit 5.0:** PHY local loopback enabled. **Bit 5.1:** PHY remote loopback enabled. **Bit 5.2:** MAC local loopback enabled. **Bit 5.3-5.5:** The PHY index of the PHY that is reported to perform loopback. **All other bits** = Reserved. This command reports the first PHY in the chain that perform loopback, starting at the outermost.
Max Frame Size	6-7	Max Frame Size	Maximum frame size set on this port.
KR FEC Enabled	8.0	KR FEC Enabled	**Bit 8.0:** KR FEC Enabled Returns 1 if KR-FEC was negotiated on the link, or returns 0 otherwise. This field is reported when the current PHY type supports auto-negotiation.
RS 528 FEC Enabled	8.1	RS 528 FEC Enabled	**Bit 8.1:** RS 528 FEC Enabled Returns 1 if RS-FEC 528 was negotiated on the link, or returns 0 otherwise. This field is reported when the current PHY type supports auto-negotiation.
RS 544 FEC Enabled	8.2	RS 544 FEC Enabled	**Bit 8.2:** RS 544 FEC Enabled Returns1 if RS-FEC 544 was negotiated on the link, or returns 0 otherwise. This field is reported when the current PHY type supports auto-negotiation.

Table 3-40. Get Link Status Command Response Data Structure [continued]

Name	Bytes.Bits	Value	Remarks
Pacing Config	8.3-8.7	Pacing Config	**Bits 8.3-8.6:** This is 4-bit field that enables configuring an average rate pace parameter or fixed IPG pace parameter in the MAC to slow down the effective data rate as listed in Table 3-18. **Bit 8.7:** Specifies if the pacing is average rate or fixed IPG.
External Device Power Ability	9.0-9.1	External Device Power Class	**Bits 9.0-9.1:** External Device Power Class QSFP+: This field contains the supported power ability of the connected module, as follows (bits order [1:0]): 00b = Power Class 1 Module (Low Power) 01b = Power Class 2 Module (High Power) 10b = Power Class 3 Module (High Power) 11b = Power Class 4 Module (High Power) ***Note:*** If QSFP Power Ability is High Power but <Low Power State> is Low Power then link is disabled. BASE-T (bit 9.0): 0b = Low and high power. 1b = High power only.
Reserved	9.2-9.7	Reserved	Reserved.
Current Link Speed	10-11	Link Speed	Returns operating link speed of the port. The PHY might be capable of many speeds but only one speed is enabled as result of configuration or auto-negotiation. This parameter is an 16-bit field, each bit corresponds to a link speed as follows. Only one bit is set at any given time. **Bit 10.0:** 10 Mb/s **Bit 10.1:** 100 Mb/s **Bit 10.2:** 1000 Mb/s **Bit 10.4:** 5 Gb/s **Bit 10.5:** 10 Gb/s **Bit 10.6:** 20 Gb/s **Bit 10.7:** 25 Gb/s **Bit 11.1:** 50 Gb/s **Bit 11.2:** 100 Gb/s **Bit 11.3:** 200 Gb/s **All other bits** = Reserved, must be zero. This parameter is used by the device driver to find out the operating Link speed on the port. The link might be enabled at one of the link speeds due to the result of auto-negotiation/parallel detection or manually configured by firmware or software when auto-negotiation is disabled. Depending on the device MAC capabilities, some bits might not be set regardless of the PHY because the MAC does not support those speeds.
Reserved	12-15	Reserved	Must b 0x0.
Current PHY type	16-31	PHY Type	This field will have a single bit set to indicate the PHY type per the link's mode of operation. The firmware should report back only the current PHY types and speed, based on topology option or the latest result of the auto-negotiation. The bytes' encoding is identical to PHY type (PHY capabilities) found in Section 3.3.3.2.1. Additionally, this field can set bit 127 in the structure to indicate that the link state is disabled, or bit 126 in the structure to indicate that PHY is in the auto-negotiation state.

3.2.4.1.6 Link Status Event (0x0607)

The Link Status Event (LSE) is generated by firmware to the device driver when there is a change in status in any of the event causing conditions. Event causing conditions listed in Table 3-41 can be individually masked from generating LSE by using the Set Event Mask (0x0613) command. The LSE share the same opcode, command structure and link status response data structure listed in Table 3-39 and Table 3-40. Firmware posts this data structure to the admin receive queue.

The LSE is disabled by default, unless explicitly enabled by software. Software enables an LSE by setting the *LSE Enable* bit when issuing Get Link Status (0x0607) command (see Table 3-38). Firmware disables the LSE immediately after generating an LSE and does not queue further events until LSE is explicitly enabled by software by the Get Link Status command. Firmware also indicates the LSE enabled status through the *LSE Enable* bit in the Get Link Status command response data structure (see Table 3-39).

The LSE is only generated by firmware to respective PF drivers, and it is software's responsibility to communicate relevant link status change events to the VF through appropriate PF-to-VF communication mechanisms. Software is not expected to use any hardware link status interrupt mechanisms. Hardware link status change interrupts are provided only for diagnostic use. Hence, hardware link status interrupts to PFs and VFs should be disabled for normal operation. Software should use the AQ mechanism to get the link status change notifications using the Get Link Status command and LSE.

Table 3-41. Reported Link Events

Event	Description
Link Change	Link state change. For example, the link state changes from link up to link down.
Media Not Available	Event is reported when an external module is pulled out of its cage.
Link Fault	
PHY Temperature Alarm	Event is generated when an external PHY or module generates a temperature alarm interrupt.
Excessive Errors	
Signal Detect Condition	
Auto-Negotiation Completed	
Module Qualification Failure	When working with external modules, firmware might be enabled to perform a validation process where the module ID parameters are compared with a per-configured, NVM loaded, list of qualified modules. If, qualification check is enabled and connected module is not found in the list, then firmware terminates the link initialization process and then generates this event.
Port Tx Suspend	Indicates that the port's Tx data path is temporarily suspended for configuration purposes.
Topology Conflict	Indicates a conflict in the topology netlist, when the port options of the mezzanine card do not match any available port option of the innermost PHY.
Media Conflict	Indicate a conflict in the media options, when the available options that are supported by the media do not intersect with the port options of the innermost to the outermost PHYs.

3.2.4.1.7 Set Event Mask (0x0613)

This command is used by the device driver to mask the event causing conditions of the link status event from firmware. The link status event is generated by firmware to the PF as described in Section 3.2.4.1.6. This is a Direct command.

Table 3-42. Set Event Mask Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0613	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17-23	Reserved	Value 0x0.
Event Mask	24-25	Event Mask	Masks the cause of LSE. The bit mask might be used to mask one or more event causing conditions. Set bit(s) to 1b to mask an event from causing LSE or set to 0b otherwise. The bits are cleared by default. **Bit 24.0:** Reserved. **Bit 24.1:** Mask link up/down condition. **Bit 24.2:** Mask media not available or module not present condition. **Bit 24.3:** Mask link fault condition. **Bit 24.4:** Mask PHY temperature alarm condition. **Bit 24.5:** Mask excessive errors over the link condition. **Bit 24.6:** Mask signal detect (asserted or de-asserted) condition. **Bit 24.7:** Mask auto-negotiation completed condition. **Bit 25.0:** Mask module qualification failure condition. **Bit 25.1:** Mask port Tx suspend. **Bit 25.2:** Mask Topology conflict. **Bit 25.3:** Mask media conflict. **All other bits** = Reserved, Must be zero.
Reserved	26-31	Reserved	Must be 0x0. Value is ignored.

The following structure describes the response by firmware to the Set Event Mask command.

Table 3-43. Set Event Mask Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0613	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16		Logical Port number. This field specifies the logical port number, and is ignored in the E810.
Reserved	17-31	Reserved	Must be 0x0. Value is ignored.

3.3 Link Topology

3.3.1 Overview

In the E810, the Ethernet link management task is performed by firmware, using scripting language to allow flexible programming of each link component. To manage the link, the firmware must know which components are connected to the link, how those components are connected to perform the link, and how each component can be accessed to configure it. The scheme of component connections to perform the link is referred as link topology. The link topology might include internal PHYs (within an SoC), external on-board PHY and re-timers, and additional optical or electrical modules and cables either mounted on board or plugged into a cage (for example, SFP+ or QSFP cages). Firmware must know the type of each device connected to the Ethernet link, the sequence of connections between the devices, how to access each device registers, and how to configure it. Internal PHYs might be connected using the SoC internal bus, while external devices are usually connected using the I^2C bus or MDIO, optionally using I^2C multiplexers at the I^2C path. In addition, some control signals are needed for those devices, (for example, RST_N, PRSNT_N and INTR_N). Those control signals are either connected directly to the SoC SDP, or indirectly using an I^2C port replicator connected at the I^2C tree. Finally, the link management task also includes control of link-related LEDs. Firmware must know how to access the LEDs associated with each Ethernet link. Those LEDs might be connected directly to the SoC or indirectly using an I^2C LED driver.

The way that the internal or external components are connected to the Ethernet link is referred to as the link topology. The topology describes how components connected to the Ethernet link and how to access them for configuration. The topology also includes a description of the low-speed devices, such as I^2C multiplexers and port expanders. Link management tasks must configure those I^2C multiplexers to allow access to link components. In addition, link management task must know the port expander connectivity to access the reset and interrupt signals of the link components, and to know if those components exist on the board.

The topology of the main board is stored within an NVM section. During initialization, firmware should read the topology and initialize all devices accordingly. However, some parts of the topology might change dynamically. For example, if an SFP module is inserted into an SFP cage, firmware must detect this event and configure the link appropriately. In addition, the main board might include connectors to PHY mezzanine cards. The firmware must to detect the card, read its topology, and re-build the topology structure used for accessing the link components. The part of the topology that describes the mezzanine card topology is stored on an EEPROM located on the mezzanine card, and the firmware should know how to access it.

Note: The E810 does not support topologies with mezzanine cards.

This section describes the structure of such topology descriptions and how firmware reads and process the topology.

- Section 3.3.2 defines link topology and illustrates the framework of link topology.
- Section 3.3.3 describes the structures needed for link topology in the platform NVM and the ID EEPROM of each mezzanine card. A high level overview of all link structures including the link topology netlist structures is given.
- Section 3.3.4 discuss two examples for the link topology netlist, for main board topology and mezzanine card topology.
- Section 3.3.6 gives detailed information about the link topology netlist structures.
- Section 3.3.7 discuss sizes, conventions, and constraints of the netlist.
- Section 3.3.8 describes the link topology software interface using admin commands.

3.3.2 Link Topology Definition

The link topology describes any device connected to the Ethernet link (for example, PHY or re-timer). The topology also describes the associated devices used for managing the link devices (for example, I^2C multiplexer). In addition, the associated SDPs and LEDs that are used to indicate link changes are defined within the topology description. Those devices might be located on the motherboard (LAN on Motherboard - LOM) or on a mezzanine card, which is plugged-in into the motherboard. Some links might use LOM topology, while others use mezzanine card topology.

Figure 3-15 illustrates link topology.

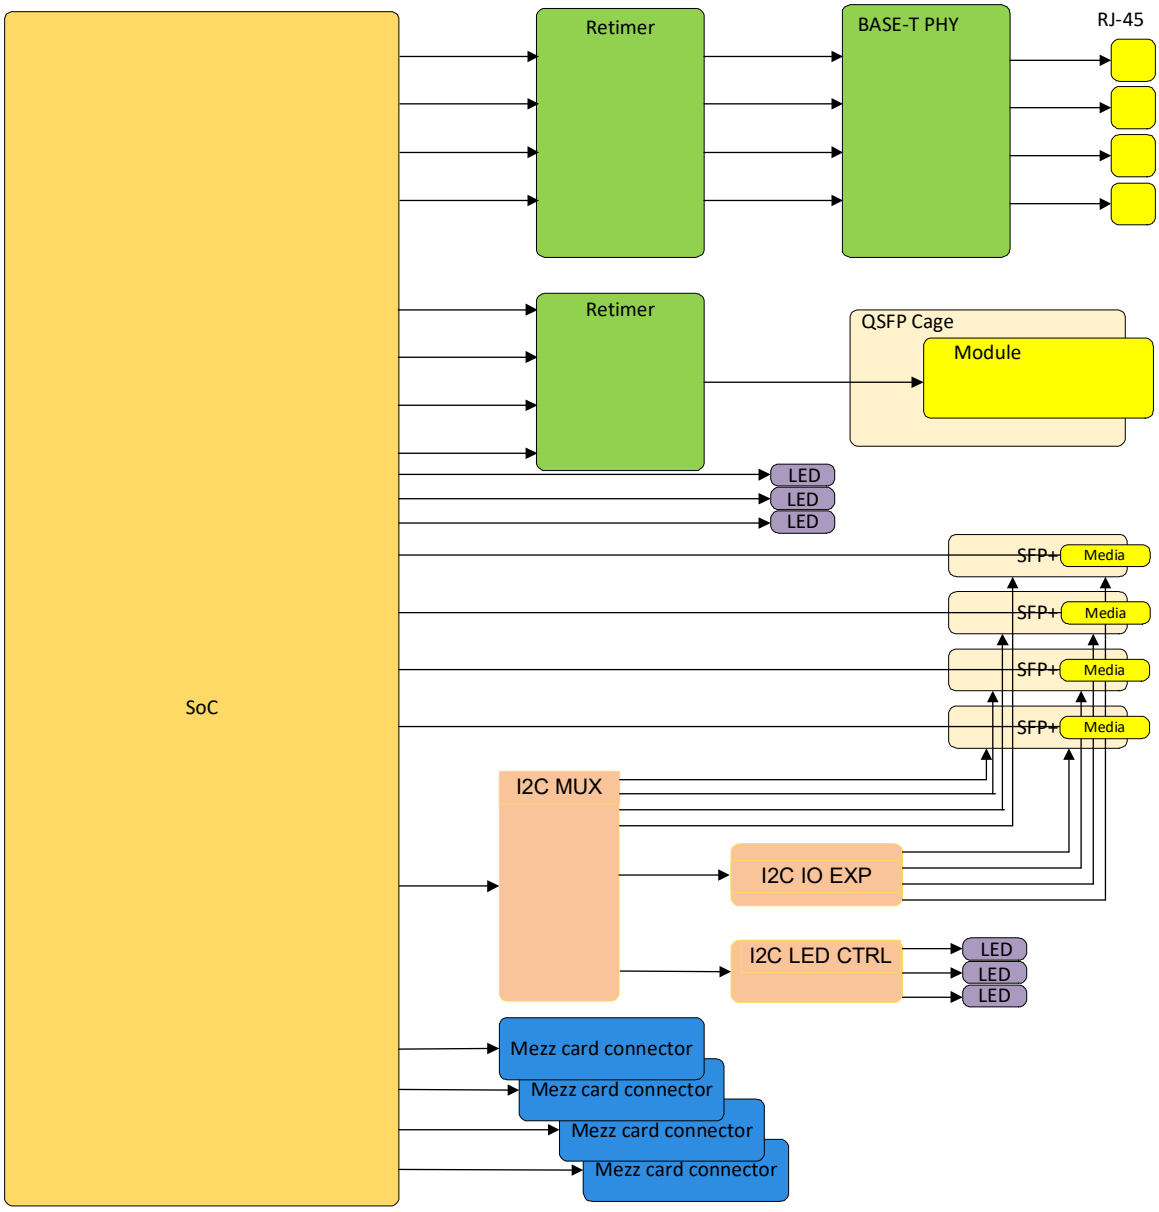

Figure 3-15. Topology Schematic

3.3.3 Topology Structures

The link topology is described using the link topology netlist structure, in both the platform NVM and the mezzanine card ID EEPROM. The E810 registers that are affected by the link topology are modified using the adaptive NVM tables that are stored in the platform NVM.

The link topology netlist describes all topology components and the connection(s) between the, and is composed of several sections. The first on is stored in the link topology NVM section, and describes the motherboard topology. The other topology netlist sections are located in the ID EEPROM of the mezzanine cards, and describe the topology of the mezzanine card. Each mezzanine card ID EEPROM would contain the topology netlist that describes its components.

Some topology-related parameters, referred as link topology capabilities registers, are stored directly as NVM words, and therefore can be modified using adaptive NVM configuration tables. For example, the number of available ports and link speeds is determined by the link topology netlist, and is applied to E810 registers using adaptive NVM. Those parameters are therefore located in the NVM and are subject to adaptive NVM configuration.

The link topology netlist and link topology capabilities sections are also used by the link establishment state machine to bring up the link with the link partner. The NVM stores the adaptive NVM features table, which describes the link topology capabilities registers values and other NVM values, per Ethernet link for a list of predefined link modes.

A mezzanine card ID EEPROM would hold a the link mode configuration for each of the links implemented on the mezzanine card. The link modes configurations for the Ethernet links implemented on the motherboard (that is, LOM links) are also held in the platform NVM.

The topology netlists that are stored at the platform NVM and at the ID EEPROM device of each mezzanine card are merged into one netlist representing the current topology netlist. The NVM section stores the details about the topology components that are on the motherboard, while the ID EEPROM sections stores the details about each mezzanine card topology. A link topology that does not include mezzanine cards, would only have one topology section in the NVM. For a board that is based on mezzanine cards, all topology structures, one from the NVM and one from each mezzanine card, should be merged into the board topology netlist.

This topology structure holds the functionality of the device, the connectivity description of its management interfaces, the way to access its registers and additional information depending on its function. For example, a PHY device would also hold a table that describes how to configure its host-side link, based on the line-side link parameters that were agreed.

At initialization stage, when a module is plugged into a cage and when a mezzanine card is detected, the firmware reads the different topology structures and builds the current topology of the links.

3.3.3.1 High-Speed PHY Chain

One part of the link topology can be viewed as a chain of PHYs, re-timers, and modules that are connected in a chain to perform a link. For the sake of simplicity, we treat all the elements in the chain as PHYs, with two ports: the line port, and the host port, where the line port is the port connected to the chain ended in the line side of the link, and the host port is the port connected to the chain ended at the host.

Figure 3-16 illustrates the PHY chain.

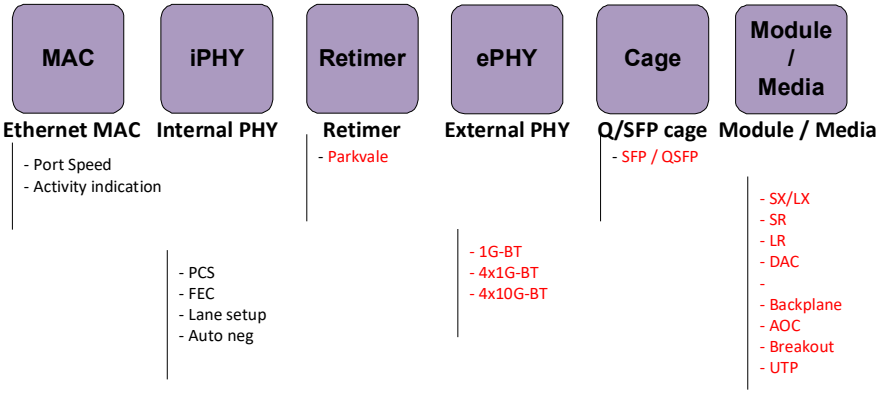

Figure 3-16. High-Speed PHY Chain

Notes:

- Some components in the PHY chain are within the SoC, while others are on the motherboard or mezzanine card.
- Some topologies do not include all components (for example, re-timer or a cage).
- The high speed PHY chain might contain components that are shared between several Ethernet links. For example, an external PHY might support four Ethernet links, or a QSFP cage might be plugged with breakout cable, that creates four different Ethernet links.

3.3.3.2 PHY Capabilities Structures

Ethernet link might work in different speeds and different electrical parameters. In general, each speed is specified with several different electrical specifications, to support different media. Such are short-reach cables (SR), long-reach cables (LR), different types of backplanes, and BASE-T pairs. We use single structure to describe the available modes, while each mode might have additional options that are described in adjacent parameters. The PHY capabilities structure, which is also referred to as PHY_TYPE, is used in several topology structures, admin command parameters, and in PHY configuration scripts as a parameter. For the topology description, it is used as a link topology NVM word, that describes the outermost PHY capabilities. It is also used twice, for each PHY node in the topology structures, to indicate the supported modes at the line side and at the host side.

Some capabilities are valid only for the outermost PHY, while others can be reflected also at the board connection between two PHYs in a chain. Table 3-44 and Table 3-45 describe the PHY capabilities for outermost PHYs, which covers all types of links.

Note: For the sake of readability, these tables are organized with capabilities bit per speed.

To avoid explosion of the topology netlist, we implement two different structures. The extended structure is used for the line side of the outermost PHY, which includes all capabilities. The basic structure used for the host side of the outermost PHY and both line side and host side for the other PHYs in the chain.

The extended structure is implemented as 128-bit words (84 bits used and the rest reserved for future use) and is described in Table 3-46. The basic structure is implemented as 64-bit words (31 bits used and the rest reserved for future use) and is described in Table 3-47. Both PHY capabilities structures are implemented in the topology netlist PHY capabilities section, as described in Section 3.3.6.6.

128 bits for outermost line side. 64 bits for everything else.

			50G-AUI1-AOC / 50G-AUI1-ACC	100G-AUI4-AOC / 100G-AUI4-ACC	200G-AUI8-ACC / 200G-AUI8-AOC	
			50GBASE-AUI2	100G-AUI2		
			50G-AUI2-AOC/ 50G-AUI2-ACC	100G-AUI2-AOC / 100G-AUI2-ACC		
				100GBASE-CR-PAM4		
				100GBASE-KR-PAM4		

Note: As NVM word, the capabilities structure describes the enabled options for the outermost PHY. These link speeds and link options might or might not be supported at the specified device level, or for specific link. The enabled speeds/options in Table 3-44 and Table 3-45 should be selected in such a way that the device would be able to support them. For example, the E810 does not support 2.5G/40G/200G/400G speeds, and therefore those options should not be selected for this device.

3.3.3.3 Link Modes Adaptive NVM Features Tables

The link topology applied by the link topology netlist might affect can E810 CSRs. This is done using adaptive NVM method. The link topology netlist references two types of adaptive NVM features tables.:

- **Global super-feature tables** — Affect E810 configurations that should be modified according to the combination of the valid ports and their corresponding maximal speed.
- **Per-port/Per function features tables** — Affect configurations relevant for the specific port type and speed.

The global super-feature table is applied by the adaptive NVM configuration ID at the innermost PHY attached to the selected port option. There should be a different port option for each valid combination of E810 ports, as described in Table 3-12, "Port Configurations".

Table 3-48 describes the main E810 settings that are affected by the global super-feature.

Table 3-48. Global Super-Feature Affected Settings

Feature	Description
E810 port topology mode	Controls the allocation of E810 resources according to the number of ports and speed of those ports.
Additional DCB configurations	DCB-to-UP translation tables. Congestion domain configurations.
VSI/VEB allocation	Allocations of resources to physical functions (see Section 7.8.10).
Max number of virtual functions allocated to physical function	
Physical function port association	Association of physical function to port (see Section 4.5).

Table 3-49 describes the main E810 settings that are affected by the Per-port feature.

Table 3-49. Per-Port Super Feature Affected Settings

Feature	Description
Port enabling	Enable or disable the port (see Section 4.5).
Port WoL setting	Enable/Disable this port for WoL setting.

Table 3-50 describes the main E810 settings that are affected by the Per-function feature.

Table 3-50. Per-Function Super Feature Affected Settings

Feature	Description
Physical function enabling	Enabling the physical function that is associated with the port (see Section 4.5).
Device ID	

3.3.3.4 Link Topology Netlist

The topology netlist is a description of all components associated with the Ethernet link, a description of the way to control those components and the connectivity between them. The topology netlist includes an entry for each topology device (node), with a description of its interfaces, capabilities, device types, associated configuration, and any information needed to setup this device to bring up the Ethernet link.

Each topology node is composed of several sections. Two sections are common for all topology nodes and are reflected the topology netlist:

- **Node Header Section** — Includes the basic description of the node and pointers to the other sections.
- **Node I/O Section** Includes pointers and descriptions of the node I/Os that connect the node toward the host.

Some topology devices do not need any additional description besides the Node Header Section and the Node I/O Section, while others include additional sections to reflect topology-related properties that are specific to the node. Some nodes need and additional scratch section, which is used by the scripts to store scratch data.

The following basic topology devices contain only the Node Header Section and the Node I/O Section, with some of the nodes also containing also the scratch area (Node Scratch Section):

- GPIO controller node
- MUX controller node
- LED controller node
- ID EEPROM node
- Cage node
- Mezzanine connector node

The Node Header Section and the Node I/o Section that compose the basic topology device structure include the following information:

- **Node Header Section** — Contains information on the following:
  - — Node type, node handle, node address, node part number, and node options.
  - — I/O section pointer.
  - — Port options section pointer — Relevant for PHY, LED, and Temperature sensor nodes and includes Port option count and the pointer to the Port options section.
  - — Line-side analog Port options section pointer — Relevant for PHY nodes and includes the pointer to the analog Port options section.
  - — Host-side analog Port options section pointer — Relevant for PHY nodes and includes the pointer to the analog Port options section.
- **Node I/O Section** — Includes a list of interfaces that are connected to this node. As all topology devices are eventually controlled by the SoC, the link topology netlist is built as a tree, where the roots of the tree are the SoC nodes that represent I/Os that are directly controlled by the SoC firmware. Therefore, it is sufficient that each topology node would list only the interfaces (I/Os) that connect between the node and other nodes that are up in the topology tree. Those I/Os could be either I/Os that are controlled by this node (master I/Os), or I/Os that are used to control this node (slave I/Os). Within the Node I/O Section, each such interface contains the following information:

— Driving node handle — This includes a node handle, used to point to the topology device that this interface is connected to, and the I/O number at that topology device.

— I/O type and driving interface — Contains information about the type of the interface (for example, I^2C, MDIO, SDP, LED), and the function of the interface (for example, when is the type SDP, what is the functionality of that SDP - INT_N / PRESET_N / TX_DISABLE, and so on).

— Other properties of the I/Os, like Polarity, Strapped, Strap value, Interrupt, and Speed. Those properties might be used with the proper I/O type.

For some devices, like the LEDs and the thermal sensors, we need to add an information about the association of the topology device with another topology device, referred as its parent device. The port option selected for the parent device is also applied for the current topology device. Therefore, LED and thermal sensor nodes include additional node parent section.

The LED topology node includes the basic node sections, the node parent section and additional LED configuration section for each port option, with the following information:

- LED link affinity (Lo /High) — Up to 24 bits (lowest 24 bits) are used to associate the Ethernet link with the LED. When the bit is set, the relevant Ethernet link affects the LED. The highest two bits are used to select the logic operation between the ports (AND or OR).
- LED flag (Low / High)
- LED color and condition

The Temperature Sensor node includes the basic node sections, the node parent section, and additional Thermal Sensor Configuration Section for each port option, with the following information:

- Temperature sensor link Affinity (Low / High) — Up to 32 bits are used to associate the Ethernet link with the temperature sensor. Each link should be associated with one temperature sensor.

• Temperature alarm threshold — The threshold temperature for this sensor.

The PHY node includes several sections that are added to the basic node description. A PHY node would include two sections of PMD analog options (one for the host side and one for the line side) and two sections of PMD miscellaneous analog options (one for the host side and one for the line side). The PMD analog options contain configurations and coefficients for the analog side of the PHY lines, while the PMD miscellaneous analog section might contain additional configuration that is PHY-specific.

In addition to the above sections, the PHY node also contains one port option pointer section and port option header sections per port option. Each port option contains several PMDs, with PHY capability section per PMD within the port option. See Section 3.3.6.13 for an example of a PHY node.

The PMD Analog Section contains the following information:

- Coefficients for 1G/5G/10G/25G/50G AUI modes.
- Coefficients for 10G KR, 25G KR/CR and 50G KR modes.
- Link establishment state machine timeouts for 1G/5G/10G/25G/50G AUI modes.
- Link establishment state machine timeouts for 10G KR, 25G KR/CR and 50G KR modes.
- Lane transmit and receive polarity.

The Port Option Pointer Section includes the following information, per Port option:

- A pointer to the relevant port option section.

The Port Option Header Section includes the following information:

- Adaptive NVM Global Super Configuration ID — A pointer to the adaptive NVM super-feature table that sets NVM parameters per-port option.
- Adaptive NVM PHY Configuration ID — A pointer to the adaptive NVM feature table of the relevant PHY that sets NVM parameters per-port option of the PHY.
- Minimum SKU — The minimum SKU that this port option can work with.
- PMD count — The number of PMDs within this port option.
- A pointer to the Node PHY capabilities section per PMD.

The Node PHY Capabilities Section includes the following information:

- Feature IDs and configuration IDs of adaptive NVM tables of the port and the function, relevant for this port option.
- Link options (EEE enable, FEC abilities advertise and request for 25G (cl. 74,91), FEC abilities advertise and request for 10G, PCS enable, Low power mode enable, LPLU enable, Rx and Tx pause, auto-negotiation options (cl. 28, 37,73), LESM enable, Auto FEC enable, host and line lane reversal, and outermost indication).
- PMD width for host side and line side.
- First lane (lane 0) ID for host side and line side.
- EEE TWSysTX timer value.
- PHY capabilities structure for host side and line side per Section 3.3.6.5.5.

Table 3-51 summarize the link topology node structure, for different nodes:

Table 3-51. Link Topology Node Structure

Section	Description	Applies to Node Types	Number of Sections in a Node
Header Section	The header section contains basic information for all node types, such as node type, section length, address and pointers to the other node sections.	All nodes types	One section. Fixed size
I/O Section	The IO section contains information about the connectivity of the node within the topology netlist.	All node types	One section. Size is linear with the number of I/Os.
Led Configuration Section	This section contains information about the configuration of the LED, such as polarity, port affinity and color.	LED nodes	One section. Size is linear with the number of port options of the parent PHY node.
Thermal Configuration Section	This section contains information dealing with the configuration of the thermal sensor, such as port affinity and alarm threshold.	Temperature sensor nodes	One section. Size is linear with the number of port options of the parent PHY node.
PMD Analog Section	This section contains the configuration of the PHY lanes analog side.	PHY nodes	Two section per PHY node, for the host and line side. Size is linear with the number of lanes.
PMD Analog Misc Section	This section contains PHY specific configuration of the PHY lanes analog side.	PHY nodes	Two section per PHY node, for the host and line side. Size is linear with the number of lanes.
Port Option Pointer Section	This section contains the pointers for all PMD options within a single PHY node.	PHY nodes	One section per PHY node. Size is linear with the number of port options.

Table 3-51. Link Topology Node Structure [continued]

Section	Description	Applies to Node Types	Number of Sections in a Node
Port Option Header Section	This section contains the number of PMDs per port option and pointers to Node PHY capabilities section.	PHY nodes	Each PHY node has sections for each port option. Size is linear with the number of PMDs within the port option.
Node PHY Capabilities Section	This section contains the configuration of the PHY in a specific port option.	PHY nodes	Each port option has sections for each PMD. Size is fixed.

3.3.3.5 Link Topology NVM Section

In addition to the link topology netlist, there is an additional NVM section for link topology parameters that might be updated by the link topology firmware. The following parameters are included in this section.

Table 3-52. Link Topology NVM Section

Parameter	Word/Bit Offset	Description
Netlist Map Version	0x2 / Bits [15:8]	The version of the netlist field definition
Load Mode	0x2 / Bit 0	Netlist Loading Mode — Controls the steps taken at the netlist load time. Valid only for the motherboard's netlist. Two modes defined: 0x0 = Normal mode — the active port options are loaded. 0x1 = resolution mode — The active port options of the non-innermost nodes are updated and then the active port options are loaded. The update is performed based on matching the active port option of the connected innermost PHY. If the port option was forced, the active option is not updated.
Netlist Version	0x3 / Bits [15:0]	The version of the netlist.
Active Port Option	0x4-0x13 / Bits [3:0] and Bits [11:8]	The active port option selected for each PHY in the netlist. Up to 32 PHYs are supported, where each word holds the active option for two PHYs. The first is in Bits [3:0] and the second is in Bits [11:8].
Forced	0x4-0x13 / Bit 4 and Bit 12	Indicates that the active port option is forced. 0x0 = Not forced — Port option is not forced. The active port option can be chosen based on automatic topology or media conflict resolution. 0x1 = Forced — Port option is forced to the value in the *Active Port Option* field. When the netlist is read from NVM and mezzanine cards, the innermost PHY port option is selected based on the current active port option.

3.3.4 Link Topology Use Cases

This section illustrates the resulting link topology netlist, with a specific use case. We take our use cases from the *NAC Hardware Topology Design Specification* document, focusing on one topology for the main board and one for a mezzanine card. The following use cases are taken:

- A main board (or LAN on motherboard - LOM) use case, where all link topology components are on the motherboard. We focus on "CFG3.x - 1xQSFP + CEI".
- A mezzanine card use case. A typical mezzanine card with PHYs, re-timers, LED controllers, and I/O expander is shown. We focus on "CEI CFG2 - PKVL 4x SFP".

3.3.4.1 LOM Use Case

Figure 3-17 describes typical LAN on motherboard use case. Figure 3-18 describes the resulting topology data structures.

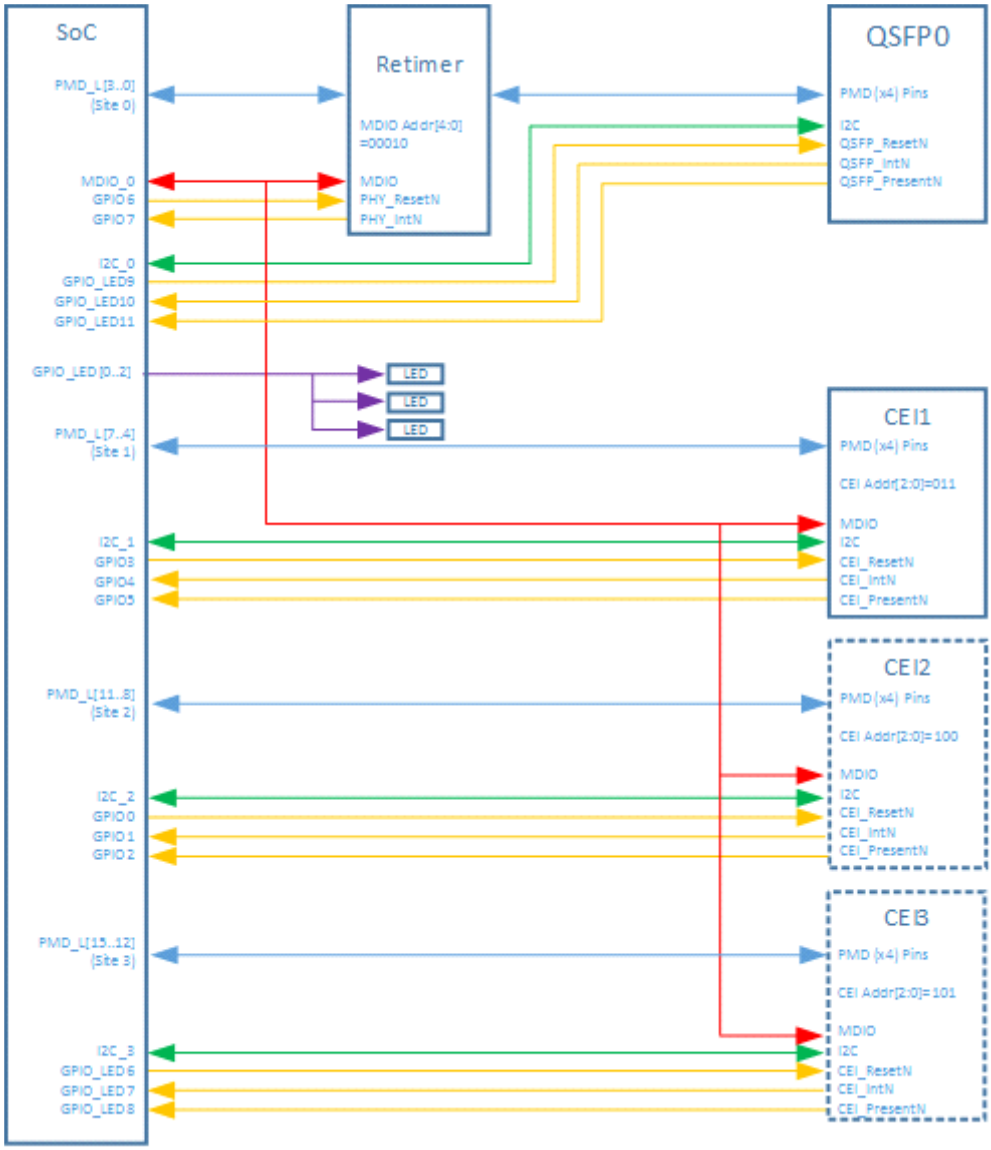

Figure 3-17. LOM Topology Use Case

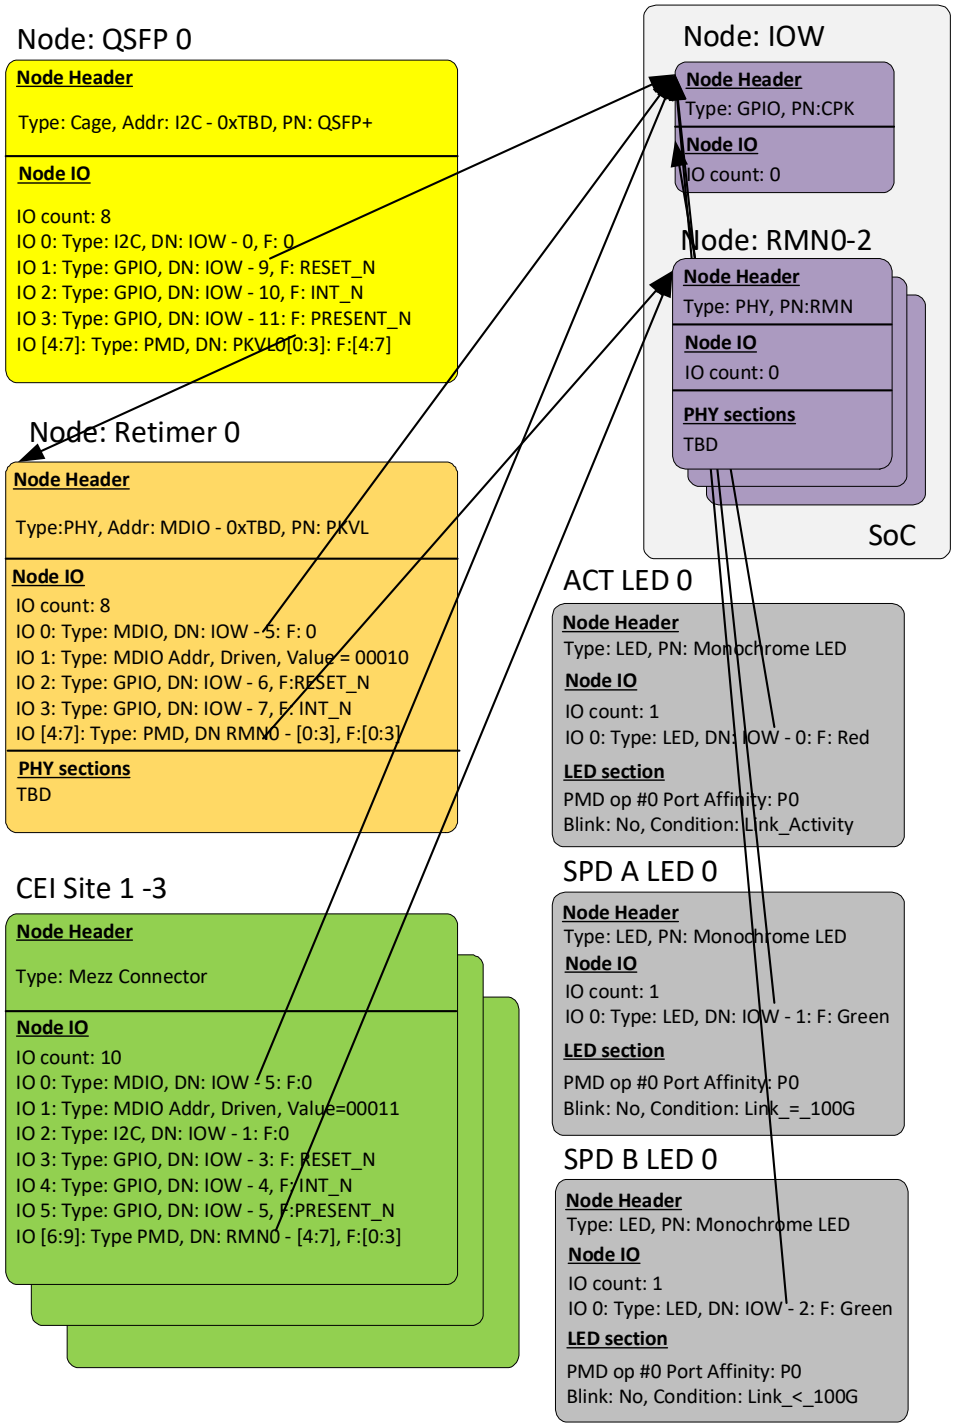

Figure 3-18. LOM Topology Use Case Data Structures

3.3.4.2 Mezzanine Card Use Case

Figure 3-19 describes typical Mezzanine card use case. Figure 3-20 describes the resulting topology data structures.

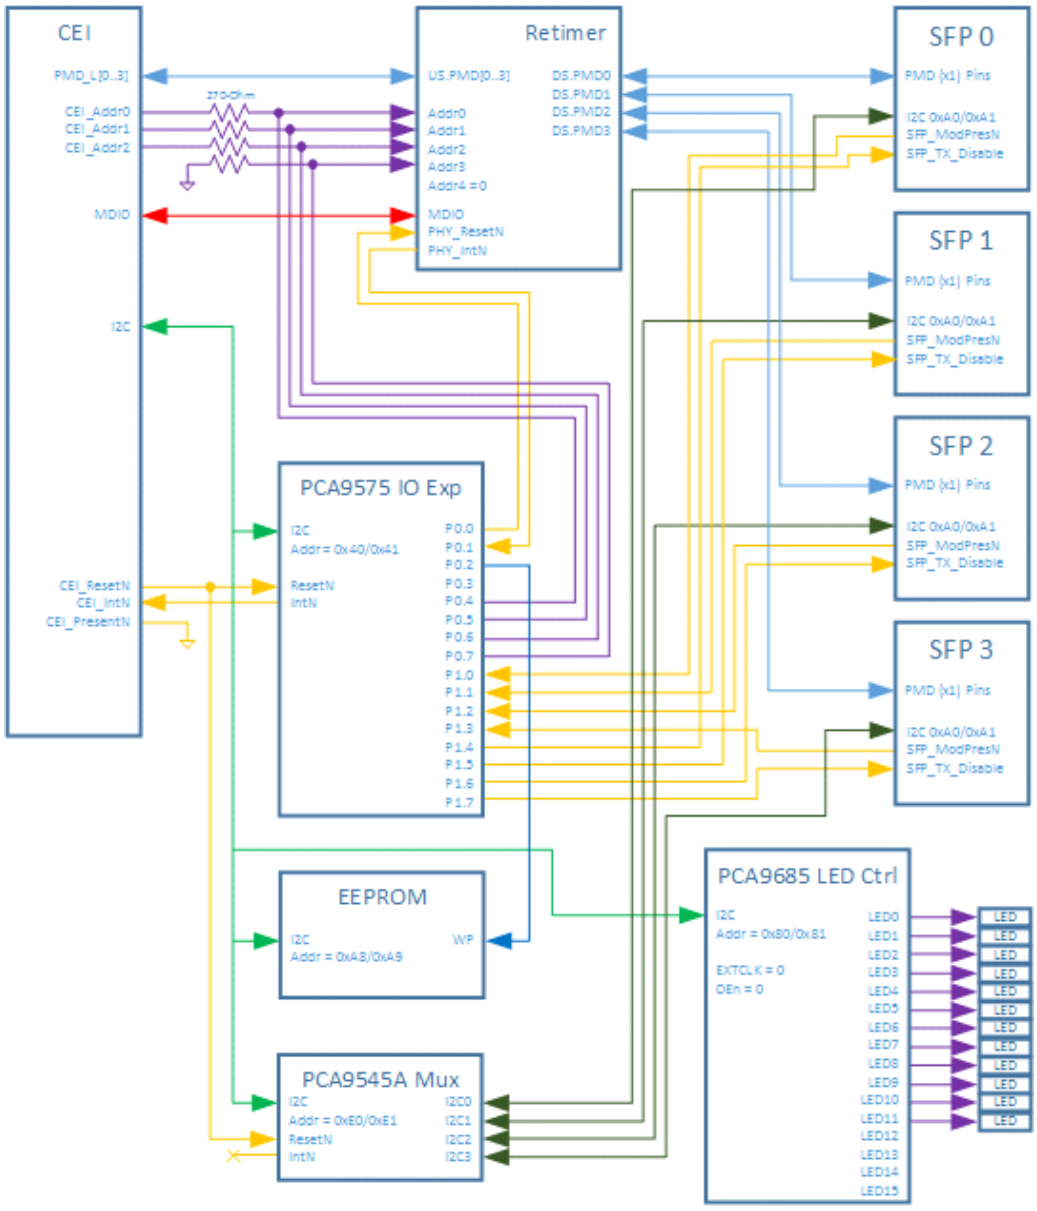

Figure 3-19. Mezzanine Card Topology Use Case

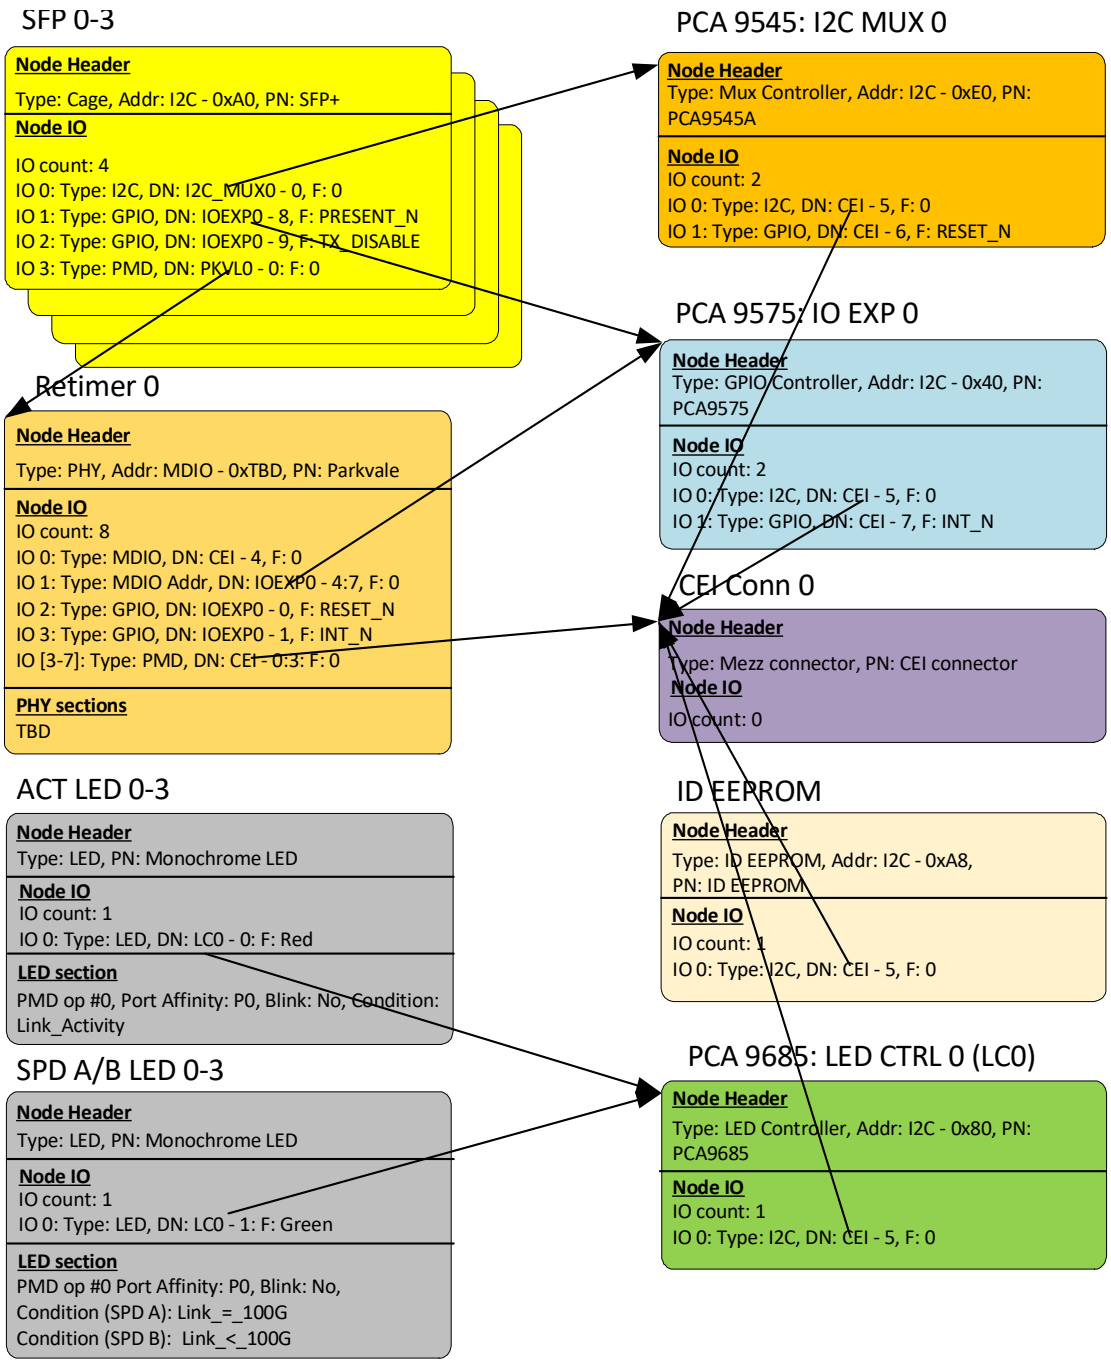

Figure 3-20. Mezzanine Card Topology Use Case Data Structures

3.3.5 Topology Initialization

At boot time, or when an interrupt for card insertion or module insertion is triggered, firmware should check the signature of all mezzanine cards. When a card is detected, it should compare the OCP ID and version against a local copy of the currently-populated mezzanine cards. Any change in the card should trigger a topology structures build.

3.3.6 Topology Netlist

This section defines the structure of the topology netlist module of the NVM and the mezzanine ID EEPROM. The module begins with a header followed by DWord aligned blocks describing the netlist nodes in the following order: PHY Nodes, GPIO Controller Nodes, MUX Controller Nodes, LED Controller Nodes, LED Nodes, Temperature Sensor Nodes, ID EEPROM Node, Cage Nodes, and Mezzanine Connector Nodes.

For each of the nodes the netlist contains a block with separate sections dedicated to different features of the node. Presence of certain sections depends on the node type.

Note: This section defines the topology netlist for several products, therefore some entries include descriptions of values that are not supported in the current product. Those values are usually marked in the Magenta color.

3.3.6.1 Topology Netlist Header

This section describes the length of the Topology Netlist Section and the number of nodes it holds.

Word Offset	Description	Section Reference
0x0000	Module Length	3.3.6.1.1
0x0001	Node Count	3.3.6.1.2
0x0002	Netlist Map Version and CRC	3.3.6.1.3
0x0003	Netlist Version	3.3.6.1.4
0x0004 + n*2 (0x0004 for n=0)	Node Handle (for Node 0)	3.3.6.1.5
0x0005 + n*2 (0x0005 for n=0)	Node Block Offset (for Node 0)	3.3.6.1.6
0x0004 + n*2 (0x0006 for n =1)	Node Handle (for Node 1)	3.3.6.1.5
0x0005 + n*2 (0x0007 for n =1)	Node Block Offset (for Node 1)	3.3.6.1.6
...	...	...
0x0004 + (Node Count - 1)*2	Node Handle for last node (n = Node Count -1)	3.3.6.1.5
0x0005 + (Node Count - 1)*2	Node Block Offset for last node (n = Node Count -1)	3.3.6.1.6
0x0004 + Node Count*2	First Word (Offset 0x0) of the Netlist Identifier Block	

Word Offset	Description	Section Reference
…	…	…
0x0033 + Node Count*2	Last Word (0ffset 0x2F) of the Netlist Identifier Block	3.3.6.1.30

Netlist Identifier Block:

Word Offset	Description	Section Reference
0x0000	Module ID - Netlist Identifier Block	3.3.6.1.7
0x0001	Module Length - Netlist Identifier Block	3.3.6.1.8
0x0002	Base Release Version - Major Low Word- Netlist Identifier Block	3.3.6.1.9
0x0003	Base Release Version - Major High Word - Netlist Identifier Block	3.3.6.1.10
0x0004	Base Release Version - Minor Low Word - Netlist Identifier Block	3.3.6.1.11
0x0005	Base Release Version - Minor High Word - Netlist Identifier Block	3.3.6.1.12
0x0006	Base Release Version: Type Low Word - Netlist Identifier Block	3.3.6.1.13
0x0007	Base Release Version: Type High Word - Netlist Identifier Block	3.3.6.1.14
0x0008	Base Release Version: Revision Low Word - Netlist Identifier Block	3.3.6.1.15
0x0009	Base Release Version: Revision High Word - Netlist Identifier Block	3.3.6.1.16
0x000A - 0x0019	Netlist Binary Hash Word - Netlist Identifier Block	3.3.6.1.17
0x001A	Netlist Origin Flags: Low - Netlist Identifier Block	3.3.6.1.18
0x001B	Netlist Origin Flags: High - Netlist Identifier Block	3.3.6.1.19
0x001C	Netlist Modification Date: Year - Netlist Identifier Block	3.3.6.1.20
0x001D	Netlist Modification Date: Day/Month - Netlist Identifier Block	3.3.6.1.21
0x001E	Netlist Modification Date: Time - Netlist Identifier Block	3.3.6.1.22
0x001F	ETT Version Used for Netlist Compile: Major - Netlist Identifier Block	3.3.6.1.23
0x0020	ETT Version Used for Netlist Compile: Minor - Netlist Identifier Block	3.3.6.1.24
0x0021	ETT Version Used for Netlist Compile: Revision - Netlist Identifier Block	3.3.6.1.25
0x0022	ETT Version Used for Netlist Compile: Patch - Netlist Identifier Block	3.3.6.1.26
0x0023 - 0x002C	Full git Netlist SHA-1 Hash Word - Netlist Identifier Block	3.3.6.1.27
0x002D	Customer IANA: Low Word - Netlist Identifier Block	3.3.6.1.28
0x002E	Customer IANA: High Word - Netlist Identifier Block	3.3.6.1.29
0x002F	Customer Netlist Version Word - Netlist Identifier Block	3.3.6.1.30

The section is not accessible through the GETNODEATTR action.

3.3.6.1.1 Module Length (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Module Length		Module length in double words. Does not include the first DWord that contains the *Module Length* field itself and the N*ode Count* field.

3.3.6.1.2 Node Count (0x0001)

Bits	Field Name	Default NVM Value	Description
15:10	Reserved		Reserved.
9:0	Node Count		The number of nodes captured in the topology netlist.

3.3.6.1.3 Netlist Map Version and CRC (0x0002)

Bits	Field Name	Default NVM Value	Description
15:8	Netlist Map Version	0x01	The version of the netlist field definition. This field changes every time there is a change in the definition of the netlist, like fields, structures, or nodes are added, removed, or modified.
7:0	CRC8		CRC-8-CCITT: Start Section -> Word offset = 0x0004 End Section -> Word offset = Module Length

3.3.6.1.4 Netlist Version (0x0003)

Bits	Field Name	Default NVM Value	Description
15:0	Netlist Version	1	The version of the netlist. This field changes when the content of a tracked netlist changes. That is, the values of some of the fields in the netlist change.

3.3.6.1.5 Node Handle (0x0004 + n*2)

Bits	Field Name	Default NVM Value	Description
15:10	Reserved		Reserved.
9:0	Node Handle		Unique identifier of the node in the topology. Matches the *Node Handle* field inside the corresponding Node Header Section. See Section 3.3.6.2.2.

3.3.6.1.6 Node Block Offset (0x0005 + n*2)

Bits	Field Name	Default NVM Value	Description
15:0	Node Block Offset		The word offset of the node section relative to the beginning of the module.

Note: The next nodes are referenced with Net-list Identifier Block offset, which is equal to Node Block Offset + 0x0004 + NodeCount * 2.

3.3.6.1.7 Module ID - Netlist Identifier Block + 0x0000

Bits	Field Name	Default NVM Value	Description
15:0	Module ID	0x0000	Module ID.

3.3.6.1.8 Module Length - Netlist Identifier Block + 0x0001

Bits	Field Name	Default NVM Value	Description
15:0	Module Length	0x0000	Module length in double words. Does not include the *Module Length* field.

3.3.6.1.9 Base Release Version: Major Low Word - Netlist Identifier Block + 0x0002

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Major Low Word	0x0000	Low word of the Base Release version: Major value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.10 Base Release Version: Major High Word - Netlist Identifier Block + 0x0003

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Major High Word	0x0000	High word of the Base Release version: Major value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.11 Base Release Version: Minor Low Word - Netlist Identifier Block + 0x0004

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Minor Low Word	0x0000	Low word of the Base Release version: Minor value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.12 Base Release Version: Minor High Word - Netlist Identifier Block + 0x0005

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Minor High Word	0x0000	High word of the Base Release version: Minor value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.13 Base Release Version: Type Low Word - Netlist Identifier Block + 0x0006

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Type Low Word	0x0000	Low word of the Base Release version: Type value. Each unique netlist from Intel has a different Type value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.14 Base Release Version: Type High Word - Netlist Identifier Block + 0x0007

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Type High Word	0x0000	High word of the Base Release version: Type value. Each unique netlist from Intel will have a different Type value. Stored in BCD (binary coded decimal). Similar to NVM version.

3.3.6.1.15 Base Release Version: Revision Low Word - Netlist Identifier Block + 0x0008

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Revision Low Word	0x0000	Low word of the Base Release revision. This is updated by ETT on any change to the template. Automatic by ETT.

3.3.6.1.16 Base Release Version: Revision High Word - Netlist Identifier Block + 0x0009

Bits	Field Name	Default NVM Value	Description
15:0	Base Release Version: Revision High Word	0x0000	High word of the Base Release revision. This is updated by ETT on any change to the template. Automatic by ETT.

3.3.6.1.17 Netlist Binary Hash Word: Netlist Identifier Block + 0x000A-0x0019

Bits	Field Name	Default NVM Value	Description
15:0	Hash Value of Netlist	0x0000	Hash of Netlist complied binary. Inserted by ETT. It should be the SHA3 256 bit hash of the netlist where the Hash Field is set to all zeros. The binary hash should be calculated assuming that both the binary hash field and the CRC8 field in the netlist header is zero. And once the binary hash is injected, the CRC8 for the netlist header should be calculated as the final step for the netlist binary compilation.

3.3.6.1.18 Netlist Origin Flags Low: Netlist Identifier Block + 0x001A

Bits	Field Name	Default NVM Value	Description
15:3	Reserved	0x0000	Reserved.
2	Intel Created Custom		0b = Not custom. 1b = Intel-created net for use with a customer netlist by OEM.
1	Intel Factory Created		0b = Not created by Intel factory. 1b = Intel factory-created net for use as a reference netlist.
0	Netlist Origin	0	0b= Intel-created and unmodified by customer. 1b= Customer modified netlist. ETT must set this bit on any customer change of the netlist.

3.3.6.1.19 Netlist Origin Flags High: Netlist Identifier Block + 0x001B

Bits	Field Name	Default NVM Value	Description
15:0	Reserved	0x0000	Reserved.

3.3.6.1.20 Netlist Modification Date: Year - Netlist Identifier Block + 0x001C

Bits	Field Name	Default NVM Value	Description
15:0	Netlist Modification Date: Year	0x0000	Year of the last netlist modification in BCD (binary coded decimal). Set by ETT on any Intel or customer modification of the netlist. Example: 0x2019 = 2019.

3.3.6.1.21 Netlist Modification Date: Day/Month - Netlist Identifier Block + 0x001D

Bits	Field Name	Default NVM Value	Description
15:8	Netlist Modification Date: Day	0x00	Day of the month of last netlist modification in BCD (binary coded decimal). Set by ETT on any Intel or customer modification of the netlist. Example: 0x20 = 20th day of the month.
7:0	Netlist Modification Date: Month	0x00	Numerical representation of the Month of last netlist modification in BCD (binary coded decimal). Set by ETT on any Intel or customer modification of the netlist. Example: 0x11 = the 11th months, which is November.

3.3.6.1.22 Netlist Modification Date: Time - Netlist Identifier Block + 0x001E

Bits	Field Name	Default NVM Value	Description
15:0	Netlist Modification Date: Time	0x0000	Time of the last netlist modification in BCD (binary coded decimal). Set by ETT on any Intel or customer modification of the netlist. Example: 0x1300 is 1:00 pm.

3.3.6.1.23 ETT Version Used for Netlist Compile: Major - Netlist Identifier Block + 0x001F

Bits	Field Name	Default NVM Value	Description
15:0	ETT Major Version Used for Netlist Compile	0x0000	Major version of ETT used to compile the most recent version of the netlist. This should be inserted and updated on any netlist change by Intel or customer.

3.3.6.1.24 ETT Version Used for Netlist Compile: Minor - Netlist Identifier Block + 0x0020

Bits	Field Name	Default NVM Value	Description
15:0	ETT Minor Version Used for Netlist Compile	0x0000	Minor version of ETT used to compile the most recent version of the netlist. This should be inserted and updated on any netlist change by Intel or customer.

3.3.6.1.25 ETT Version Used for Netlist Compile: Revision - Netlist Identifier Block + 0x0021

Bits	Field Name	Default NVM Value	Description
15:0	ETT Revision Version Used for Netlist Compile	0x0000	Revision version of ETT used to compile the most recent version of the netlist. This should be inserted and updated on any netlist change by Intel or customer.

3.3.6.1.26 ETT Version Used for Netlist Compile: Patch - Netlist Identifier Block +0x0022

Bits	Field Name	Default NVM Value	Description
15:0	ETT Patch Version Used for Netlist Compile	0x0000	Patch version of ETT used to compile the most recent version of the netlist. This should be inserted and updated on any netlist change by Intel or customer.

3.3.6.1.27 Full git Netlist SHA-1 Hash Word - Netlist Identifier Block + 0x0023-0x002C

Bits	Field Name	Default NVM Value	Description
15:0	Full Git Hash Value	0x0000	Full git commit hash of netlist. Should be set by ETT when committing changes to git.

3.3.6.1.28 Customer IANA: Low Word - Netlist Identifier Block + 0x002D

Bits	Field Name	Default NVM Value	Description
15:0	Customer IANA - Low Word	0x0157	Customer IANA low. Intel to set Intel IANA 0x0157. Customer to fill in their IANA.

3.3.6.1.29 Customer IANA: High Word - Netlist Identifier Block + 0x002E

Bits	Field Name	Default NVM Value	Description
15:0	Customer IANA - High Word	0x0000	Customer IANA high. Intel to set Intel IANA 0x0000. Customer to fill in their IANA.

3.3.6.1.30 Customer Netlist Version Word - Netlist Identifier Block + 0x0002F

Bits	Field Name	Default NVM Value	Description
15:0	Customer Netlist Version	0x0000	Customer version that customer can set in customer ETT. Template images from Intel would set this to 0.

3.3.6.2 Node Header Section

This section describes the structure of the Node Header Section, detailing the node type, node block length, node handle and node part number. Based on node type where applicable, the number of I/Os, port options, Module Qualification options, firmware download options and conflict resolution options are also defined.

Word Offset	Description	Section Reference
0x0000	Node Type and Node Section Length	3.3.6.2.1
0x0001	Node Handle	3.3.6.2.2
0x0002	Node Address	3.3.6.2.3
0x0003	Node Part Number and Node Options	3.3.6.2.4
0x0004	Node I/O Section Pointer	3.3.6.2.5
0x0005	Node Port Options Section Pointer	3.3.6.2.6
0x0006	Node PMD Line Analog Section Pointer	3.3.6.2.7
0x0007	Node PMD Host Analog Section Pointer	3.3.6.2.8

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x0000. The Node Address within Attribute ID 0x0001 can also be modified through the SETNODEATTR action.

3.3.6.2.1 Node Type and Section Length (0x0000)

Bits	Field Name	Default NVM Value	Description
15:12	Node Type		Defines the node type. Valid values are: 0x0 = PHY device 0x1 = GPIO Controller (Port Expander) 0x2 = MUX Controller (Bus Expander) 0x3 = LED Controller (LED Driver) 0x4 = LED 0x5 = Temperature Sensor 0x6 = Cage (SFP, SFP28, QSFP, QSFP28) 0x7 = Mezzanine Connector 0x8 = ID EEPROM 0x9-0xF = Reserved
11:0	Node Section Length		Node section length in double words. Does not include the first double word, the *Node Section Length* field itself.

3.3.6.2.2 Node Handle (0x0001)

Bits	Field Name	Default NVM Value	Description
15:10	Reserved		Reserved.
9:0	Node Handle		Unique identifier of the node in the topology. Values must be assigned sequentially from 0 to Node Count - 1. Bit 9 = Board Type — Identifies if the node is on the motherboard or a mezzanine card. 0b = LOM 1b = Mezzanine Card For LOM: Bit 8:0 = Unique node identifier within the context of the motherboard. For Mezzanine Cards: Bit 8:6 = Mezzanine card number. Populated by firmware during the mezzanine discovery flow. The value in the mezzanine topology is always 3'b0. Bit 5:0 = Unique node identifier within the context of the mezzanine card.

3.3.6.2.3 Node Address (0x0002)

Bits	Field Name	Default NVM Value	Description
15:14	Reserved		Reserved.
13:12	Bus Address Type		Defines whether the bus address is absolute or relative to the mezzanine card (CEI) slot. 00b = Reserved 01b = Absolute address. The uniqueness of the address is ensured by the topology. 10b = Relative address. The address must be updated on board initialization to avoid conflicts. 11b = Reserved. Not applicable to LED nodes.
11:10	Bus Type		Defines the bus type. Valid options are: 00b = SoC internal bus 01b = I^2C 10b = MDIO 11b = Reserved Not applicable to LED nodes.
9:0	Bus Address		For all node types other than LED: The bus address that the node can be accessed at. The range of valid addresses depends on the bus type. For SoC internal bus, the assignment is as follows: 0x000 = PHY Core 0 0x001 = PHY Core 1 0x002 = PHY Core 2 0x003 = I/O Widget 0x004-0x3FF - Reserved For I^2C, the field represents the 7-bit or 10-bit address of the I^2C attached node: 0x000-0x07F = For 7-bit addressable I^2C devices, the 3 high MSB should be set to 0x0. 0x000-0x3FF = For 10-bit addressable I^2C devices. For MDIO, the field represents the 5-bit Port Address: 0x000-0x01F = 5bit MDIO Port Address. 0x020-0x3FF = Reserved.

3.3.6.2.4 Node Part Number and Node Options (0x0003)

Bits	Field Name	Default NVM Value	Description
15:8	Node Part Number		The part number assigned to each of the POR devices supported by the topology and link management. The defined part numbers are: 0x00 = I/O Widget (Node type - GPIO controller) 0x10 = CEI Connector (Node type - mezzanine connector) 0x11 = SFP+ Cage (Node type - Cage) 0x12 = SFP28 Cage (Node type - Cage) 0x13 = QSFP+ Cage (Node type - Cage) 0x14 = QSFP28 Cage (Node type - Cage) 0x15 = Monochrome LED (Node type - LED) 0x16 = RGB LED (Node type - LED) 0x20 = PCA9545A \ PCA9546A (Node type - MUX controller) 0x21 = PCA9575 (Node type - GPIO controller) 0x22 = PCA9685 (Node type - LED controller) 0x23 = PCA9552 (Node type - LED controller) 0x30 = PHY Core (Node type - PHY) 0x31 = C827 (Node type - PHY) 0x32 = X557-AT4 (Node type - PHY) 0x33 = 88E1543 (Node type - PHY) 0x34 = 88E1512 (Node type - PHY) 0x35 = 88E1514 (Node type - PHY) 0x36 = E810 internal PHY (Node type - PHY) 0x37 = X557-AT2 (Node type - PHY) 0x43 = AT24C32 (ID EEPROM 32K bit) (Node type - ID EEPROM) 0x44 = SFPx Module Temperature Sensor 0x45 = QSFPx Module Temperature Sensor All other values are reserved.
7:4	Reserved		Reserved.
3	Module Qualification Enable		Module qualification enable. 0b = Pluggable module qualification is disabled for the cage. 1b = Pluggable module qualification is enabled for the cage. Valid for Cage nodes only. Reserved for all other node types.
2	Innermost PHY		Defines whether the PHY is the innermost PHY: 0b = The PHY has host side PMD connections to another PHY node. 1b = The PHY has host side connections to the MAC. Valid for PHY nodes only. Reserved for all other node types.
1	Auto Conflict Resolution		Auto conflict resolution. depending on the node type, enables automatic Topology or Media Conflict resolution. Applicable to Innermost PHY and Cage nodes only: • When set on an Innermost PHY node, it enables automatic Topology Conflict resolution. • When set on a Cage node, it enables automatic Media Conflict resolution. Valid for PHY and Cage nodes only. Reserved for all other node types.
0	FW Download Enable		Firmware download enable. 0b = The PHY load its firmware from a dedicated EEPROM/Flash after reset. 1b = The PHY firmware should be downloaded from NVM at initialization Valid for PHY nodes only. Reserved for all other node types.

3.3.6.2.5 Node I/O Section Pointer (0x0004)

Bits	Field Name	Default NVM Value	Description
15:12	I/O Count		The number of host side I/O connections of the node. This defines the length of the Node I/O Section.
11:0	Node I/O Section Offset		The word offset of the Node I/O Section relative to the beginning of the node section.

3.3.6.2.6 Node Port Options Section Pointer (0x0005)

Bits	Field Name	Default NVM Value	Description
15:12	Port Option Count		Defines the number of Port Options supported by the node. This defines the number Node PHY Port Options. The LED node and Thermal sensor LED inherit the number of Port Options from their Parent PHY node. Not applicable to nodes of type other than PHY. For those nodes this field is reserved and must be 0x0.
11:0	Node Port Options Section Offset		For PHY nodes: The word offset of the Node Port Options Section relative to the beginning of the node section. For LED nodes: The word offset of the first Node LED Configuration Section relative to the beginning of the node section. For Temperature Sensor nodes: The word offset of the Node Thermal Configuration Section relative to the beginning of the node section. Not applicable to any other node types.

3.3.6.2.7 Node PMD Line Analog Section Pointer (0x0006)

Bits	Field Name	Default NVM Value	Description
15:12	Line Lane Count		The number of line side lanes on the PHY node.
11:0	Node PMD Line Analog Section Offset		The word offset of the Node PMD Line Analog Section relative to the beginning of the node section.

3.3.6.2.8 Node PMD Host Analog Section Pointer (0x0007)

Bits	Field Name	Default NVM Value	Description
15:12	Host Lane Count		The number of host side lanes on the PHY node.
11:0	Node PMD Host Analog Section Offset		The word offset of the Node PMD Host Analog Section relative to the beginning of the node section.

3.3.6.3 Node I/O Section

This section describes the structure of the Node I/O Section, detailing the I/O connections of a topology node.

Word Offset	Description	Section Reference
0x0000 + n*2	Driving Node Handle	3.3.6.3.1
0x0001 + n*2	I/O Type and Driving Interface	3.3.6.3.2

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x2000.

3.3.6.3.1 Driving Node Handle (0x0000 + n*2)

Bits	Field Name	Default NVM Value	Description
15:10	Driving I/O Number		The number of the interface with the specified *I/O Type* on the device pointed to by Driving Node Handle to which the connection leads.
9:0	Driving Node Handle		Unique identifier of the node in the topology to which the I/O is connected.

3.3.6.3.2 I/O Type and Driving Interface (0x0001 + n*2)

Bits	Field Name	Default NVM Value	Description
15	Driven	1b	Defines if the I/O is strapped to a certain value or is driven by another node in the topology. 0b = The I/O is strapped to a value defined by the *Value* field. 1b = The I/O is driven by the device identified by the Driving Node Handle. Only applicable to I/Os with *I/O Type* of GPIO and MDIO Address. ***Note:*** For I/Os that use inverted I/O function (e.g. RESET_N or INT_N) and the I/O is defined as "Driven", it is driven to the inverse of the *Value* field.
14	Value		For driven I/Os, defines the default value. For strapped I/Os, defines the static value of the I/O is configured to. Only applicable to I/Os with *I/O Type* of GPIO and MDIO Address.
13	Polarity		Polarity configuration for the I/O. 0b = The signal is active low. 1b = The signal is active high. Only applicable to I/Os with *I/O Type* of GPIO.
12:11	Interrupt		Interrupt configuration for the I/O. 00b = No interrupt. 01b = Interrupt on rising edge. 10b = Interrupt on falling edge. 11b = Interrupt on change (rising or falling edge). Only applicable to I/Os with *I/O Type* of GPIO.

Bits	Field Name	Default NVM Value	Description
10:8	I^2C/MDIO Speed		The bus speed. For I^2C, the I/O Widget supports the following speeds: 000b = 100 kHz 001b = 400 kHz 010b = 1 MHz All other values are reserved. For MDIO, the I/O Widget supports the following speeds: 000b = 2.441 MHz All other values are reserved. Only applicable to I/Os with *I/O Type* of I^2C Bus and MDIO Bus.
7:5	I/O Type		The type of the I/O. The defined I/O types are: 000b = PMD 001b = I^2C Bus 010b = MDIO Bus 011b = GPIO 100b = MDIO Address All other values are reserved.
4:0	I/O Function / I/O Number		I/O Function: For I/Os with *I/O Type* of GPIO defines the specific use of the GPIO 0x00 = GPIO 0x01 = RESET_N 0x02 = INT_N 0x03 = PRESENT_N 0x04 = TX_DISABLE 0x05 = MODSEL_N 0x06 = LPMODE 0x07 = TX_FAULT 0x08 = RX_LOSS 0x09 = RS0 0x0A = RS1 0x0B = EEPROM_WP 0x0C = LED/LED.Red 0x0D = LED.Green 0x0E = LED.Blue 0x0F-0x1F = Reserved I/O Number: For I/Os with *I/O Type* of PMD, I^2C Bus, MDIO Bus, and MDIO Address, defines the index of the I/O on the node.

The I/O connections are grouped by *I/O Type*. For a given I/O connection, on the node describing the connection, the I/O Number/Function is used to identify the interface within the group. On the node identified by the Driving Node Handle, the driving I/O (located within the group with matching *I/O Type*) is pointed to by the Driving I/O Number.

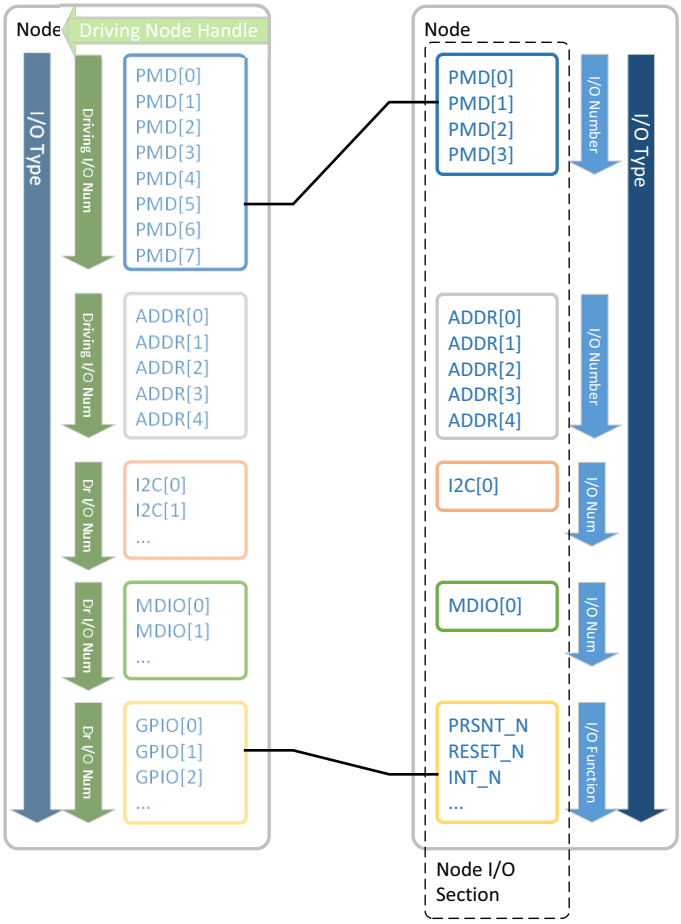

Figure 3-21. I/O Numbering Convention

3.3.6.4 Node Port Option Pointer Section

This section describes the structure of the Node Port Option Pointer Section, detailing the available Port Options.

Word Offset	Description	Section Reference
0x0000 + n	Port Option Pointer	3.3.6.4.1

The section is not accessible through the GETNODEATTR action.

3.3.6.4.1 Node Port Option Pointer (0x0000 + n)

Bits	Field Name	Default NVM Value	Description
15:12	Reserved		Reserved.
11:0	Port Option Pointer		The Port Option's word offset relative to the beginning of the node section.

3.3.6.5 Node Port Option Header Section

This section describes the structure of the Node Port Option Header Section, detailing the available Port Options.

Word Offset	Description	Section Reference
0x0000	Adaptive NVM Global (per Port Option) Super Configuration ID	3.3.6.5.1
0x0001	Adaptive NVM PHY Configuration ID	3.3.6.5.2
0x0002	Minimum SKU	3.3.6.5.3
0x0003	Adaptive NVM PF-to-Port mapping Configuration ID	3.3.6.5.4
0x0004	PMD Count and PHY Capabilities [0] Pointer	3.3.6.5.5
0x0005 + n - 1	PHY Capabilities [n] Pointer	3.3.6.5.6

The section is not accessible through the GETNODEATTR action.

3.3.6.5.1 Adaptive NVM Global (per Port Option) Super Configuration ID (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Adaptive NVM Global (per port option) Super Configuration ID		Global adaptive NVM Super Configuration ID [15:0]. Used to identify the adaptive NVM configuration needed to apply to configure the controller for this Port Option (E810 port mode - 2/4/8 ports; DCB Configuration - pipe monitors, RPB thresholds, VSI/VEB allocation, and so on). See Section 3.3.3.3.

3.3.6.5.2 Adaptive NVM PHY (per Innermost PHY) Super Configuration ID (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Adaptive NVMPHY Configuration ID (per Innermost PHY)		Adaptive NVM PHY Configuration ID[15:0]. Used to identify the adaptive NVM configuration ID needed to apply to configure the PHY for the innermost PHY at this Port Option). See Section 3.3.3.3.

3.3.6.5.3 Minimum SKU (0x0002)

Bits	Field Name	Default NVM Value	Description
15:12	Adaptive NVM RDMA & MTU Global Super Configuration ID		Adaptive NVM RDMA & MTU Global Super Configuration ID - Used to identify the adaptive NVM configuration ID for super feature ID (0xF0FD). This super feature controls the RDMA setting together with the MTU setting. The value here must match the number of ports defined in the port option.
11:8	Reserved		Reserved.
7	Required Lane Speed		Maximum lane speed required. 0b = 50G serial required. 1b = 25G serial required.
6:4	Reserved		Reserved.

Bits	Field Name	Default NVM Value	Description
3:2	Required Bandwidth		Specificities the Required bandwidth for this port option: 00b = 200 Gb/s required. 01b = 100 Gb/s required. 10b = 50 Gb/s required. 11b = 25 Gb/s required.
1:0	Required Ports		Number of ports required: 00b = 8 ports required. 01b = 4 ports required. 10b = 2 ports required. 11b = 1 port required.

3.3.6.5.4 Adaptive NVM PF-to-Port Mapping Configuration ID (0x0003)

Bits	Field Name	Default NVM Value	Description
15:0	Adaptive NVM PF to Port Mapping Configuration ID		This is the adaptive NVM configuration ID that selects the relevant PF-to-port mapping using the adaptive NVM PF-to-port mapping feature ID.

3.3.6.5.5 PMD Count and PHY Capabilities Pointer (0x0004)

Bits	Field Name	Default NVM Value	Description
15:12	PMD Count		The number of PMDs within the Port Option.
11:0	PHY Capabilities [0] Pointer		The PHY Capabilities Section's word offset relative to the beginning of the Node Port Option Header Section.

3.3.6.5.6 Capabilities Pointer (0x0005 + n - 1)

Bits	Field Name	Default NVM Value	Description
15:12	Reserved		Reserved.
11:0	PHY Capabilities [n] Pointer		The PHY Capabilities Section's word offset relative to the beginning of the Node Port Option Header Section.

3.3.6.6 Node PHY Capabilities Section

This section describes the structure of the Node PHY Capabilities Section, detailing the PHY capabilities for a PHY for a given Port Option. It is used within the PHY node, as described in Section 3.3.6.13.

Word Offset	Description	Section Reference
0x0000	Per-Port Adaptive NVM Configuration ID	3.3.6.6.1
0x0001	Per-Function Adaptive NVM Configuration ID	3.3.6.6.2
0x0002	Per-Port/Function Adaptive NVM Feature ID	3.3.6.6.3
0x0003	PMD Width	3.3.6.6.4
0x0004	Link Options 0	3.3.6.6.5
0x0005	Link Options 1	3.3.6.6.6
0x0006	EEE Options 0	3.3.6.6.7
0x0007	EEE Options 1	3.3.6.6.8
0x0008	Host Side PMD Capabilities 0	3.3.6.6.9
0x0009	Host Side PMD Capabilities 1	3.3.6.6.10
0x000A	Host Side PMD Capabilities 2	3.3.6.6.11
0x000B	Host Side PMD Capabilities 3	3.3.6.6.12
0x000C	Line Side PHY Capabilities (PHY Types) 0	3.3.6.6.13
0x000D	Line Side PHY Capabilities (PHY Types) 1	3.3.6.6.14
0x000E	Line Side PHY Capabilities (PHY Types) 2	3.3.6.6.15
0x000F	Line Side PHY Capabilities (PHY Types) 3	3.3.6.6.16
0x0010	Line Side PHY Capabilities (PHY Types) 4	3.3.6.6.17
0x0011	Line Side PHY Capabilities (PHY Types) 5	3.3.6.6.18
0x0012	Line Side PHY Capabilities (PHY Types) 6	3.3.6.6.19
0x0013	Line Side PHY Capabilities (PHY Types) 7	3.3.6.6.20

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x4000. Attribute ID 0x4006-4009 (Line Side PHY Capabilities 4-7) are only defined for PMDs with the *Outermost PMD* bit set.

3.3.6.6.1 Per-Port Adaptive NVM Configuration ID (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Per Port Adaptive NVM Configuration ID		Per port adaptive NVM Configuration ID [15:0]. Used to identify the adaptive NVM Configuration ID needed to apply to configure the port associated with the PMD. The field applies to the Innermost PHY node only and is reserved for all other nodes.

3.3.6.6.2 Per-Function Adaptive NVM Configuration ID (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Per Function Adaptive NVM Configuration ID		Per function adaptive NVM Configuration ID [15:0]. Used to identify the adaptive NVM feature needed to apply to configure the port associated with the PMD (PF assignment). The field applies to the Innermost PHY node only and is reserved for all other nodes.

3.3.6.6.3 Per-Port/Function Adaptive NVM Feature ID (0x0002)

Bits	Field Name	Default NVM Value	Description
15:8	Port Feature ID		Port Feature ID. Used to specify the adaptive NVM feature ID of the port.
7:0	Function Feature ID		Function Feature ID. Used to specify the adaptive NVM feature ID of the function.

3.3.6.6.4 PMD Width (0x0003)

Bits	Field Name	Default NVM Value	Description
15:12	Host PMD Width		The number of lanes assigned to the Host side PMD. The Host side PMD's lanes will range from PHY Node Lane [Host PMD Lane 0] to PHY Node Lane [Host PMD Lane 0 + Host PMD Width - 1].
11:8	Host PMD Lane 0		The number of the Host side PMD's Lane 0 on the PHY Node.
7:4	Line PMD Width		The number of lanes assigned to the Line side PMD. The Line side PMD's lanes will range from PHY Node Lane [Line PMD Lane 0] to PHY Node Lane [Line PMD Lane 0 + Line PMD Width - 1].
3:0	Line PMD Lane 0		The number of the Line side PMD's Lane 0 on the PHY Node.

3.3.6.6.5 Link Options 0 (0x0004)

Bits	Field Name	Default NVM Value	Description
15	Rx PAUSE		Controls Link Flow control Rx PAUSE default for this link. 0b = Rx PAUSE is disabled by default. 1b = Rx PAUSE is enabled by default.
14	Tx PAUSE		Controls Link Flow control Tx PAUSE default for this link. 0b = Tx PAUSE capability is disabled by default. 1b = Tx PAUSE capability is enabled by default.
13	AN Clause 37 Enable		Controls Clause 37 auto-negotiation for the line side PMD. 0b = Clause 37 auto-negotiation is disabled. 1b = Clause 37 auto-negotiation is enabled.
12	AN Clause 73 Enable		Controls Clause 73 auto-negotiation for the line side PMD. 0b = Clause 73 auto-negotiation is disabled. 1b = Clause 73 auto-negotiation is enabled.
11	AN Clause 28 Enable		Controls Clause 28 auto-negotiation for the line side PMD. 0b = Clause 28 auto-negotiation is disabled. 1b = Clause 28 auto-negotiation is enabled.

Bits	Field Name	Default NVM Value	Description
10:8	Reserved		Reserved.
7	CL74_ConFEC_Abl		Controls KR FEC (Fire Code FEC) ability advertisement for 25G KR1/CR1. 0b = KR FEC is not supported. 1b = KR FEC is supported.
6	CL91_ConFEC_Abl		Controls RS FEC ability advertisement for 25G KR1/CR1. 0b = RS FEC is not supported. 1b = RS FEC is supported.
5	Reserved		Reserved.
4	RS FEC 544 Request		Controls RS FEC 544 capability request for 25G/50G/100G KR/KR-S/KR1/CR/CR-S/CR1. 0b = RS FEC is not requested. 1b = RS FEC is requested.
3	25G KR FEC Request		Controls KR FEC (Fire Code FEC) capability request for 25G KR/KR-S/KR1/CR/CR-S/CR1. 0b = KR FEC is not requested. 1b = KR FEC is requested.
2	RS FEC 528 Request		Controls RS FEC 528 capability request for 25G KR/KR-S/KR1/CR/CR-S/CR1. 0b = RS FEC is not requested. 1b = RS FEC is requested.
1	10G KR FEC Request		Controls FEC (Fire Code FEC) capability request for 10G KR. 0b = FEC is not requested. 1b = FEC is requested.
0	10G KR FEC Enable		Controls FEC (Fire Code FEC) capability advertisement for 10G KR. 0b = FEC is disabled. 1b = FEC is enabled and is advertised.

3.3.6.6.6 Link Options 1 (0x0005)

Bits	Field Name	Default NVM Value	Description
15:12	Max LPLU Speed		Max LPLU speed. Limits the maximum speed that can be enabled using Low Power Link Up (LPLU) algorithm for BASE-T PHYs. 0x0 = 10M 0x1 = 100M 0x2 = 1G 0x3 = Reserved 0x4 = 5G 0x5 = 10G 0x6-0xF = Reserved ***Note:*** This option is valid when LPLU is enabled (See bit 3 - LPLU enable).
11	Disable automatic Link on Start-Up		This bit, when set, disables the automatic link on start-up. When the port is defined as manageability port, the LESM ignores this bit and tries to start the link anyway.
10	Reserved		Reserved.
9	Flow Control ASM_DIR Capability		Controls Link Flow control ASM_DIR (A6) ability to advertise. 0b = 0ASM_DIR is advertised as 0. 1b = ASM_DIR is advertised as 1.
8	Flow Control PAUSE capability		Controls Link Flow control PAUSE (A5) ability to advertise. 0b = PAUSE is advertised as 0. 1b = PAUSE is advertised as 1.

Bits	Field Name	Default NVM Value	Description
7	PCS Enable	1b	Controls the PCS of the PMD. • PCS is disabled, the PHY is operating in a transparent re-timer mode. • PCS is enabled.
6	LESM Auto FEC Enable	1b	Controls the FEC options for the Link Establishment State Machine (LESM). This option is valid, when the LESM is enabled. 0b = LESM uses the default FEC mode based on the current media. 1b = LESM automatically detects the link partner's FEC type. This might include FEC types not specifically supported by the spec.
5	LESM Enable	1b	Controls the Link Establishment State Machine for the PMD. 0b = LESM is disabled. 1b = LESM is enabled.
4	Low Power Mode	0b	Controls the Low Power Mode for the module. 0b = The device is allowed to operate at high power. 1b = The device must operate in low power mode. Pluggable modules are only allowed to operate at their lowest power level.
3	LPLU Support Enable	0b	Enables or disables the Low Power Link-up (LPLU) support for the PMD. 0b = LPLU support is disabled. 1b = LPLU support is enabled.
2	Host Lane Reversal Enable	0b	Controls lane reversal on the host side of the PMD. 0b = The lane order is normal. 1b = The lane order needs to be reversed.
1	Line Lane Reversal Enable	0b	Controls lane reversal on the line side of the PMD. 0b = The lane order is normal. 1b = The lane order needs to be reversed.
0	Outermost PMD		Defines whether the PMD is the outermost PMD. 0b = The PMD has no outside of box connections. 1b = The PMD has outside of the box connection on the line side.

3.3.6.6.7 EEE Options 0 (0x0006)

Bits	Field Name	Default NVM Value	Description
15:0	EEE_TWsysTX		EEE_TWsysTX. See Section 5.3.1.

3.3.6.6.8 EEE Options 1 (0x0007)

Bits	Field Name	Default NVM Value	Description
15:11	Reserved		Reserved.
10	EEE Enable 100GBASE-KR2-PAM4	0b	Controls the EEE functionality for 100GBASE-KR2-PAM4. 0b = EEE is disabled. 1b = EEE is enabled.
9	EEE Enable 100GBASE-KR4	0b	Controls the EEE functionality for 100GBASE-KR4. 0b = EEE is disabled. 1b = EEE is enabled.
8	EEE Enable 50GBASE-KR-PAM4	0b	Controls the EEE functionality for 50GBASE-KR-PAM4. 0b = EEE is disabled. 1b = EEE is enabled.

Bits	Field Name	Default NVM Value	Description
7	EEE Enable 50GBASE-KR2	0b	Controls the EEE functionality for 50GBASE-KR2. 0b = EEE is disabled. 1b = EEE is enabled.
6	Reserved		Reserved.
5	EEE Enable 25GBASE-KR	0b	Controls the EEE functionality for 25GBASE-KR. 0b = EEE is disabled. 1b = EEE is enabled.
4	EEE Enable 10GBASE-KR	0b	Controls the EEE functionality for 10GBASE-KR. 0b = EEE is disabled. 1b = EEE is enabled.
3	EEE Enable 1000BASE-KX	0b	Controls the EEE functionality for 1000BASE-KX. 0b = EEE is disabled. 1b = EEE is enabled.
2	EEE Enable 10GBASE-T	0b	Controls the EEE functionality for 10GBASE-T. 0b = EEE is disabled. 1b = EEE is enabled.
1	EEE Enable 1000BASE-T	0b	Controls the EEE functionality for 1000BASE-T. 0b = EEE is disabled. 1b = EEE is enabled.
0	EEE Enable 100BASE-TX	0b	Controls the EEE functionality for 100BASE-TX. 0b = EEE is disabled. 1b = EEE is enabled.

3.3.6.6.9 Host Side PMD Capabilities 0 (0x0008)

Host-side PMD capabilities are mapped based on line side link speed.

Bits	Field Name	Default NVM Value	Description
15	50GBASE-KR2		
14:13	Reserved		Reserved.
12	25G-AUI-C2C		
11	25GBASE-KR1		
10	25GBASE-KR-S		
9	25GBASE-KR		
8	10G-SFI-C2C		
7	10GBASE-KR/CR1		
6	10G-SFI-DA		
5	5GBASE-KR		
4:3	Reserved		Reserved.
2	1G-SGMII		
1	1000BASE-KX		
0	100M-SGMII		

3.3.6.6.10 Host Side PMD Capabilities 1 (0x0009)

Host-side PMD capabilities are mapped based on line side link speed.

Bits	Field Name	Default NVM Value	Description
15:14	Reserved		Reserved.
13	200G-AUI8		
12	200G-AUI4		
11	200GBASE-KR4-PAM4		
10	100G-AUI2		
9	Reserved		Reserved.
8	100GBASE-KR2-PAM4		
7	100GBASE-KP4-PAM4		
6	100G-AUI4		
5	100G-CAUI4		
4	100GBASE-KR4		
3	50G-AUI1		
2	50GBASE-KR-PAM4		
1	50G-AUI2		
0	50G-LAUI2		

3.3.6.6.11 Host Side PMD Capabilities 2 (0x000A)

Host-side PMD capabilities are mapped based on line side link speed.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.6.12 Host Side PMD Capabilities 3 (0x000B)

Host-side PMD capabilities are mapped based on line side link speed.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.6.13 Line Side PHY Capabilities (PHY Types) 0 (0x000C)

The following table defines the Line Side PHY Capabilities for the outermost PMD. If the *Outermost PMD* bit is not set, the Line Side PHY Capabilities match the Host Side PHY Capabilities structure. See Section 3.3.6.6.9.

Bits	Field Name	Default NVM Value	Description
15	10GBASE-LR		
14	10GBASE-SR		
13	10G-SFI-DA		
12	10GBASE-T		
11	5GBASE-KR		
10	5GBASE-T		
9:7	Reserved		Reserved.
6	1G-SGMII		
5	1000BASE-KX		
4	1000BASE-LX		
3	1000BASE-SX		
2	1000BASE-T		
1	100M-SGMII		
0	100BASE-TX		

3.3.6.6.14 Line Side PHY Capabilities (PHY Types) 1 (0x000D)

The following table defines the Line Side PHY Capabilities for the outermost PMD. If the *Outermost PMD* bit is not set, the Line Side PHY Capabilities match the Host Side PHY Capabilities structure. See Section 3.3.6.6.10.

Bits	Field Name	Default NVM Value	Description
15:14	Reserved		Reserved.
13	25G-AUI-C2C		
12	25G-AUI-AOC/ACC		
11	25GBASE-KR1		
10	25GBASE-KR-S		
9	25GBASE-KR		
8	25GBASE-LR		
7	25GBASE-SR		
6	25GBASE-CR1		
5	25GBASE-CR-S		
4	25GBASE-CR		
3	25GBASE-T		
2	10G-SFI-C2C		
1	10G-SFI-AOC/ACC		
0	10GBASE-KR/CR1		

3.3.6.6.15 Line Side PHY Capabilities (PHY Types) 2 (0x000E)

The following table defines the Line Side PHY Capabilities for the outermost PMD. If the *Outermost PMD* bit is not set, the Line Side PHY Capabilities match the Host Side PHY Capabilities structure. See Section 3.3.6.6.11.

Bits	Field Name	Default NVM Value	Description
15	50GBASE-LR		
14	50GBASE-FR		
13	50GBASE-SR		
12	50GBASE-CP		
11	50G-AUI2		
10	50G-AUI2-AOC/ACC		
9	50G-LAUI2		
8	50G-LAUI2-AOC/ACC		
7	50GBASE-KR2		
6:5	Reserved		
4	50GBASE-CR2		
3:0	Reserved		Reserved.

3.3.6.6.16 Line Side PHY Capabilities (PHY Types) 3 (0x000F)

The following table defines the Line Side PHY Capabilities for the outermost PMD. If the *Outermost PMD* bit is not set, the Line Side PHY Capabilities match the Host Side PHY Capabilities structure. See Section 3.3.6.6.12.

Bits	Field Name	Default NVM Value	Description
15	100GBASE-DR		
14	100GBASE-SR2		
13	100GBASE-CR2-PAM4		
12	100GBASE-KP4-PAM4		
11	Reserved		Reserved.
10	100G-AUI4		
9	100G-AUI4-AOC/ACC		
8	100G-CAUI4		
7	100G-CAUI4-AOC/ACC		
6	100GBASE-KR4		
5	100GBASE-LR4		
4	100GBASE-SR4		
3	100GBASE-CR4		
2	50G-AUI1		
1	50G-AUI1-AOC/ACC		
0	50GBASE-KR-PAM4		

3.3.6.6.17 Line Side PHY Capabilities (PHY Types) 4 (0x0010)

The following table defines the Line Side PHY Capabilities for the outermost PMD. Not defined for PMDs with the *Outermost PMD* bit not set.

Bits	Field Name	Default NVM Value	Description
15	400GBASE-FR8	0b	
14	200G-AUI8	0b	
13	200G-AUI8-AOC/ACC	0b	
12	200G-AUI4	0b	
11	200G-AUI4-AOC/ACC	0b	
10	200GBASE-KR4-PAM4	0b	
9	200GBASE-DR4	0b	
8	200GBASE-LR4	0b	
7	200GBASE-FR4	0b	
6	200GBASE-SR4	0b	
5	200GBASE-CR4-PAM4	0b	
4	100G-AUI2		
3	100G-AUI2-AOC/ACC		
2:1	Reserved		Reserved.
0	100GBASE-KR2-PAM4		

3.3.6.6.18 Line Side PHY Capabilities (PHY Types) 5 (0x0011)

The following table defines the Line Side PHY Capabilities for the outermost PMD. Not defined for PMDs with the *Outermost PMD* bit not set.

Bits	Field Name	Default NVM Value	Description
15:4	Reserved		Reserved.
3	400G-AUI8	0b	
2	400G-AUI8-AOC/ACC	0b	
1	400GBASE-DR4	0b	
0	400GBASE-LR8	0b	

3.3.6.6.19 Line Side PHY Capabilities (PHY Types) 6 (0x0012)

The following table defines the Line Side PHY Capabilities for the outermost PHY. Not defined for PMDs with the *Outermost PHY* bit not set.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved	0x0	Reserved.

3.3.6.6.20 Line Side PHY Capabilities (PHY Types) 7 (0x0013)

The following table defines the Line Side PHY Capabilities for the outermost PHY. Not defined for PMDs with the *Outermost PHY* bit not set.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved	0x0	Reserved.

3.3.6.7 Node PMD Analog Section

This section describes the structure of the Node PMD Analog Section, detailing the analog configuration of a PHY Lane.

Word Offset	Description	Section Reference
0x0000 + n*14	1G/5G C2C Coefficients Low	3.3.6.7.1
0x0001 + n*14	Polarity and 1G/5G C2C Coefficients High	3.3.6.7.2
0x0002 + n*14	10G C2C Coefficients Low	3.3.6.7.3
0x0003 + n*14	10G C2C Coefficients High	3.3.6.7.4
0x0004 + n*14	10G C2M Coefficients Low	3.3.6.7.5
0x0005 + n*14	10G C2M Coefficients High	3.3.6.7.6
0x0006 + n*14	25G C2C Coefficients Low	3.3.6.7.7
0x0007 + n*14	25G C2C Coefficients High	3.3.6.7.8
0x0008 + n*14	25G C2M Coefficients Low	3.3.6.7.9
0x0009 + n*14	25G C2M Coefficients High	3.3.6.7.10
0x000A + n*14	50G C2C Coefficients Low	3.3.6.7.11
0x000B + n*14	50G C2C Coefficients High	3.3.6.7.12
0x000C + n*14	50G C2M Coefficients Low	3.3.6.7.13
0x000D + n*14	50G C2M Coefficients High	3.3.6.7.14

Notes: There is no standard definition for how the device must implement the coefficient values set in this section. The values set in this section of the netlist are PHY-specific, and must align with the definition conventions for the PHY which they are specifying, as well as the PHY-specific script which configures the device.

C2C Coefficients are used for link modes directly connecting PHY devices, such as 10G SFI DA and 25G AUI C2C. C2M coefficients are used for link modes that use a module, such as 10GBASE-LR and 25G-AUI AOC/ACC

This section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x6800 for the line side and 0x7000 for the host side.

3.3.6.7.1 1G/5G C2C Coefficients Low (0x0000 + n*14)

Defines the transmit equalizer settings for 1G/5G serial AUI/C2C interfaces.

Note: It is important to understand that each PHY uses its own definition for TXFFE values, including format and sign. It is required that the values saved in the netlist align with the format used by the specific PHY they are defining. Therefore, there is no standardized way that the coefficients are defined in this section. The convention used must also align with the script that manages the link up process for that individual PHY. Overriding TXFFE values should only be done by an advanced user with specific knowledge of how the PHY should be configured for the given mode, such as tuning the coefficients based on conformance testing results.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for C2C 1G/5G speeds.
7:0	C[1][7:0]		Post-Cursor value for C2C 1G/5G speeds.

3.3.6.7.2 Polarity and 1G/5G C2C Coefficients High (0x0001 + n*14)

Defines the lane polarity and transmit equalizer settings for 1G/5G serial AUI/C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15	Rx Polarity	0b	Lane Rx Polarity control. 0b = Normal Rx polarity. 1b = Inverted Rx polarity.
14	Tx Polarity	0b	Lane Tx Polarity control. 0b = Normal Tx polarity. 1b = Inverted Tx polarity.
13	TXFFE Override 50G AUI-C2M		TXFFE Override 50G AUI-C2M control. 0b = Use silicon default TXFFE values for AUI-C2M PHY modes with 50G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2M PHY modes with 50G lane speeds.
12	TXFFE Override 50G AUI-C2C		TXFFE Override 50G C2C control. 0b = Use silicon default TXFFE values for AUI-C2C PHY modes with 50G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2C PHY modes with 50G lane speeds.
11:10	Reserved		Reserved.
9	TXFFE Override Enable		TXFFE Override Enable control. 0b = Always silicon default TXFFE values for all PHY modes. 1b = Use netlist defined TXFFE values for PHY modes based on the TXFFE Override bit corresponding to each mode.
8	TXFFE Override 1G/5G		TXFFE Override 1G/5G control. 0b = Use silicon default TXFFE values for PHY modes with 1G/5G lane speeds. 1b = Use netlist defined TXFFE values for PHY modes with 1G/5G lane speeds.
7:0	C[-1][7:0]		Pre-Cursor value for C2C 1G/5G speeds.

3.3.6.7.3 10G C2C Coefficients Low (0x0002 + n*14)

Defines the transmit equalizer settings for 10G serial C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2C 10G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2C 10G speeds.

3.3.6.7.4 10G C2C Coefficients High (0x0003 + n*14)

Defines the transmit equalizer settings for 10G serial AUI-C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:9	Reserved		Reserved.
8	TXFFE Override 10G AUI-C2C		TXFEE Override 10G AUI-C2C control. 0b = Use silicon default TXFFE values for AUI-C2C PHY modes with 10G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2C PHY modes with 10G lane speeds.
7:0	C[-1][7:0]		Pre-Cursor value for 10G speeds.

3.3.6.7.5 10G C2M Coefficients Low (0x0004 + n*14)

Defines the transmit equalizer settings for 10G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2M 10G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2M 10G speeds.

3.3.6.7.6 10G C2M Coefficients High (0x0005 + n*14)

Defines the transmit equalizer settings for 10G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:9	Reserved		Reserved.
8	TXFFE Override 10G AUI-C2M		TXFFE Override 10G AUI-C2M control. 0b = Use silicon default TXFFE values for AUI-C2M PHY modes with 10G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2M PHY modes with 10G lane speeds.
7:0	C[-1][7:0]		Pre-Cursor value for C2M 10G speeds.

3.3.6.7.7 25G C2C Coefficients Low (0x0006 + n*14)

Defines the transmit equalizer settings for 25G serial AUI-C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2C 25G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2C 25G speeds.

3.3.6.7.8 25G C2C Coefficients High (0x0007 + n*14)

Defines the transmit equalizer settings for 25G serial AUI-C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:9	Reserved		Reserved.
8	TXFFE Override 25G AUI-C2C		TXFFE Override 25G AUI-C2C control. 0b = Use silicon default TXFFE values for AUI-C2C PHY modes with 25G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2C PHY modes with 25G lane speeds.
7:0	C[-1][7:0]		Pre-Cursor value for AUI-C2C 25G speeds.

3.3.6.7.9 25G C2M Coefficients Low (0x0008 + n*14)

Defines the transmit equalizer settings for 25G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2M 25G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2M 25G speeds.

3.3.6.7.10 25G C2M Coefficients High (0x0009 + n*14)

Defines the transmit equalizer settings for 25G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:9	Reserved		Reserved.
8	TXFFE Override 25G AUI-C2M		TXFFE Override 25G AUI-C2M control. 0b = Use silicon default TXFFE values for AUI-C2M PHY modes with 25G lane speeds. 1b = Use netlist defined TXFFE values for AUI-C2M PHY modes with 25G lane speeds.
7:0	C[-1][7:0]		Pre-Cursor value for AUI-C2M 25G speeds.

3.3.6.7.11 50G C2C Coefficients Low (0x000A + n*14)

Defines the transmit equalizer settings for 50G serial AUI-C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2C 50G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2C 50G speeds.

3.3.6.7.12 50G C2C Coefficients High (0x000B + n*14)

Defines the transmit equalizer settings for 50G serial AUI-C2C interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[-2][7:0]		Pre-Cursor 2 (C[-2]) value for AUI-C2C 50G speeds.
7:0	C[-1][7:0]		Pre-Cursor 1 (C[-1]) value for AUI-C2C 50G speeds.

3.3.6.7.13 50G C2M Coefficients Low (0x000C + n*14)

Defines the transmit equalizer settings for 50G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[0][7:0]		Cursor value for AUI-C2M 50G speeds.
7:0	C[1][7:0]		Post-Cursor value for AUI-C2M 50G speeds.

3.3.6.7.14 50G C2M Coefficients High (0x000D + n*14)

Defines the transmit equalizer settings for 50G serial AUI-C2M interfaces.

Bits	Field Name	Default NVM Value	Description
15:8	C[-2][7:0]		Pre-Cursor 2 (C[-2]) value for AUI-C2M 50G speeds
7:0	C[-1][7:0]		Pre-Cursor 1 (C[-1]) value for AUI-C2M 50G speeds

3.3.6.8 Node PMD Analog Misc Section

An extension of the Node PMD Analog Section, this section contains PHY device specific lane configuration. The section is located immediately at after the Node PMD Analog Section for both the host and line sides.

Word Offset	Description	Section Reference
0x0000	PMD Analog Misc Length	3.3.6.8.1
0x0001	Auto-neg LESM Timeout	3.3.6.8.2
0x0002	1G/5G/10G serial AUI LESM Timeout	3.3.6.8.3
0x0003	25G/50G serial AUI LESM Timeout	3.3.6.8.4

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x8800 for the line side and 0x9000 for the host side.

3.3.6.8.1 PMD Analog Misc Length (0x0000)

Bits	Field Name	Default NVM Value	Description
15:8	Reserved		Reserved.
7:0	PMD Analog Misc Length		The length of the PMD analog miscellaneous section in words.

3.3.6.8.2 Auto-Neg LESM Timeout (0x0001)

Bits	Field Name	Default NVM Value	Description
15:8	Auto-Neg LESM Timeout		Auto-negotiation LESM timeout defined in 200 ms increments.
7:0	Reserved		Reserved.

3.3.6.8.3 1G/5G/10G Serial AUI LESM Timeout (0x0002)

Bits	Field Name	Default NVM Value	Description
15:8	10G Serial AUI LESM Timeout		10G AUI LESM timeout defined in 200 ms increments.
7:0	1G/5G Serial AUI LESM Timeout		1G/5G AUI LESM timeout defined in 200 ms increments.

3.3.6.8.4 25G/50G Serial AUI LESM Timeout (0x0003)

Note: This parameter applies to all link modes that are using 50G serial signaling. For example, 100G implemented as 2x50G.

Bits	Field Name	Default NVM Value	Description
15:8	50G Serial AUI LESM Timeout		50G AUI LESM Timeout defined in 200 ms increments.
7:0	25G Serial AUI LESM Timeout		25G AUI LESM Timeout defined in 200 ms increments.

3.3.6.9 Node LED Configuration Section

This section describes the structure of the Node LED Configuration Section, detailing the configuration of an LED for a given Port Option. The length of the section is dependent on the number of conditions defined for the LED to indicate. See Section 3.3.6.9.3.

Word Offset	Description	Section Reference
0x0000	Port Option Port Affinity Low	3.3.6.9.1
0x0001	Port Option Port Affinity High	3.3.6.9.2
0x0002 + n*1	Port Option Color and Condition [n], where n = 0:3	3.3.6.9.3

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0xA000.

3.3.6.9.1 Port Option Port Affinity Low (0x0000)

Defines the port affinity of the LED for a given Port Option.

If the netlist describes the LOM, the ports are referring to Physical MAC Ports. If the netlist describes a mezzanine card, the ports are referring to PHY Ports within the context of the mezzanine card. These, during the mezzanine card topology detection, are re-mapped into the Physical MAC Ports within the context of the system in which the mezzanine card was inserted. Therefore, when accessed through the GETNODEATTR action, the *Port Affinity* bits always refer to Physical MAC Ports.

Bits	Field Name	Default NVM Value	Description
15	Port 15		If set, the LED is associated with Port 15
14	Port 14		If set, the LED is associated with Port 14
13	Port 13		If set, the LED is associated with Port 13
12	Port 12		If set, the LED is associated with Port 12
11	Port 11		If set, the LED is associated with Port 11
10	Port 10		If set, the LED is associated with Port 10
9	Port 9		If set, the LED is associated with Port 9
8	Port 8		If set, the LED is associated with Port 8
7	Port 7		If set, the LED is associated with Port 7
6	Port 6		If set, the LED is associated with Port 6
5	Port 5		If set, the LED is associated with Port 5
4	Port 4		If set, the LED is associated with Port 4
3	Port 3		If set, the LED is associated with Port 3
2	Port 2		If set, the LED is associated with Port 2
1	Port 1		If set, the LED is associated with Port 1
0	Port 0		If set, the LED is associated with Port 0

3.3.6.9.2 Port Option Port Affinity High (0x0001)

Bits	Field Name	Default NVM Value	Description
15:14	Logic Operator	10b	The logic operator to be used between port flags. 00b = Reserved 10b = AND 10b = OR 11b = Reserved
13:9	Reserved		Reserved.
8	Port ID		If set, the LED is used for port identification based on software request.
7:4	Reserved		Reserved.
3	Port 19		If set, the LED is associated with Port 19.
2	Port 18		If set, the LED is associated with Port 18.
1	Port 17		If set, the LED is associated with Port 17.
0	Port 16		If set, the LED is associated with Port 16.

3.3.6.9.3 Port Option Color and Condition [n] (0x0004 + n*1)

The state of the LED is controlled by four conditions defined separately for each Port Option. The conditions are prioritized: Condition[0] being the highest in priority and Condition[3] the lowest. The true condition with the highest priority defines the Color and Blink configuration of the LED.

To allow for more flexibility, two adjacent conditions can be combined through the defined Logic Operator. If the expression Condition[i] <Operator[i]> Condition[i+1] is true, the LED is configured with the Color and Blink configuration associated with Condition[i].

Bits	Field Name	Default NVM Value	Description
15:14	Reserved		Reserved.
13:11	Blink		Blink configuration for the LED. 000b = No Blink 001b = Blink 010b = Blink on MAC Activity All other values are reserved. Blinking results in a cadence of 200 ms on / 200 ms off.

Bits	Field Name	Default NVM Value	Description
10:8	Color		Defines the color of an RGB LED. The color is mixed though driving the associated Red, Green and Blue LEDs with the appropriate PWM signals through a PCA9585 LED controller. The possible colors are as follows: 000b = SKIP — Skip Condition: The LED state should be driven based on the result of evaluating the next condition. 001b = RED 010b = ORANGE 011b = YELLOW 100b = GREEN 101b = BLUE 110b = PURPLE 111b = Reserved  Colors are only supported if the Node Part Number is RGB LED. The node has three I/Os defined, and they all are driven by the same PCA9585 LED controller.
7:6	Logic Operator		The logic operator to be used between Condition[i] and Condition[i+1]. 00b = NONE 01b = AND 10b = OR 11b = Reserved The field is ignored for Condition[3].

Bits	Field Name	Default NVM Value	Description
5:0	Condition		Defines the condition in which the LED should be asserted. Valid conditions are: 0x00 = FALSE 0x01 = TRUE 0x02 = LINK 0x03 = LINK_ACTIVITY 0x04 = MAC_ACTIVITY 0x05 = FILTER_ACTIVITY 0x06 = INVALID_MEDIA 0x07 = LINK_LESS_THAN_1G 0x08 = Reserved 0x09 = LINK_LESS_THAN_5G 0x0A = LINK_LESS_THAN_10G 0x0B = LINK_LESS_THAN_25G 0x0C = Reserved 0x0D = LINK_LESS_THAN_50G 0x0E = LINK_LESS_THAN_100G 0x0F = LINK_LESS_THAN_200G 0x10 = LINK_LESS_THAN_400G 0x11 = LINK_100M 0x12 = LINK_1G 0x13 = Reserved 0x14 = LINK_5G 0x15 = LINK_10G 0x16 = LINK_25G 0x17 = Reserved 0x18 = LINK_50G 0x19 = LINK_100G 0x1A = LINK_200G 0x1B = LINK_400G 0x1C = NO_LINK 0x1E:0x1F = Reserved 0x20 = TEMP_WARN_N 0x21 = TEMP_CRIT_N 0x22 = FAN_ON_AUX 0x23:0x3F - Reserved

3.3.6.10 Node Thermal Configuration Section

This section describes the structure of the Node Thermal Configuration Section, detailing the configuration of the temperature sensor.

Word Offset	Description	Section Reference
0x0000	Min and Max Readable Value	3.3.6.10.1
0x0001	Tolerance and Hysteresis	3.3.6.10.2
0x0002	Resolution Low	3.3.6.10.3
0x0003	Resolution High	3.3.6.10.4
0x0004	Offset Low	3.3.6.10.5
0x0005	Offset High	3.3.6.10.6
0x0006	Normal Max and Warning High Thresholds	3.3.6.10.7
0x0007	Critical High and Fatal High Threshold	3.3.6.10.8
0x0008 + n*2	Temperature Sensor Port Affinity Low	3.3.6.10.9
0x0009 + n*2	Temperature Sensor Port Affinity High	3.3.6.10.10

The section is accessible through the GETNODEATTR action starting at the DWord-aligned Attribute ID offset 0xC000. The Temperature Sensor Port Affinity is replicated for each Port Option of the associated Parent PHY node. Only the copy with the same index as the Parent PHY's active Port Option is loaded to RAM and accessible through GETNODEATTR.

Note: For SFP and QSFP standard sensors, E810 firmware follows the standard and should not modify parameters from the netlist. The firmware should not take (i.e. ignore) the critical thresholds from the netlist, where SFP or QSFP standard sensor is defined. Instead, it should use the thresholds as read from the module itself (SFF-8436 defines them in bytes 128-129)

3.3.6.10.1 Min and Max Readable Value (0x0000)

Bits	Field Name	Default NVM Value	Description
15:8	Max Readable Value	0xFF	Thermal Sensor max readable value.
7:0	Min Readable Value	0x00	Thermal Sensor max readable value.

3.3.6.10.2 Tolerance and Hysteresis (0x0001)

Bits	Field Name	Default NVM Value	Description
15:8	Hysteresis	0x02	Thermal Sensor Hysteresis (°C).
7:0	Tolerance	0x01	Thermal Sensor *plusTolerance* and *minusTolerance* (°C).

3.3.6.10.3 Resolution Low (0x0002)

Bits	Field Name	Default NVM Value	Description
15:0	Resolution [15:0]	0x0000	Lower two bytes of the Thermal Sensor resolution. The field uses a real32 representation. ***Note:*** The available resolution is 0.125 °C, but the supported value is 1 °C. ***Note:*** For the internal thermal sensor definition, the resolution is not taken from the netlist, but it is set to the NVM default.

3.3.6.10.4 Resolution High (0x0003)

Bits	Field Name	Default NVM Value	Description
15:0	Resolution [31:16]	0x3F80	Higher two bytes of the Thermal Sensor resolution. The field uses a real32 representation. ***Note:*** The available resolution is 0.125 °C, but the supported value is 1 °C. ***Note:*** For the internal thermal sensor definition, the resolution is not taken from the netlist, but it is set to the NVM default.

3.3.6.10.5 Offset Low (0x0004)

Bits	Field Name	Default NVM Value	Description
15:0	Offset [15:0]	0x0000	Lower two bytes of the Thermal Sensor offset. The field uses a real32 representation.

3.3.6.10.6 Offset High (0x0005)

Bits	Field Name	Default NVM Value	Description
15:0	Offset [31:16]	0x0000	Higher two bytes of the Thermal Sensor offset. The field uses a real32 representation.

3.3.6.10.7 Normal Max and Warning High Thresholds (0x0006)

Bits	Field Name	Default NVM Value	Description
15:8	Warning High		Warning High - High temperature warning threshold (°C).
7:0	Normal Max		Normal Max - Maximum normal temperature threshold (°C).

3.3.6.10.8 Critical High and Fatal High Thresholds (0x0007)

Bits	Field Name	Default NVM Value	Description
15:8	Fatal High		Fatal High - Fatal temperature alarm threshold (°C). ***Note:*** For any thermal sensor, this threshold must be set between the "Internal Thermal Sensor Minimum Threshold" and "Internal Thermal Sensor Maximum Threshold" NVM parameters.
7:0	Critical High		Critical High - Critical temperature alarm threshold (°C).

3.3.6.10.9 Temperature Sensor Port Affinity Low (0x0008 + n*2)

This section describes the port affinity of the temperature sensor. Each bit, if set, indicates the temperature sensor is associated with the respective port.

If the netlist describes the LOM, the ports are referring to Physical MAC Ports. If the netlist describes a mezzanine card, the ports are referring to PHY Ports within the context of the mezzanine card. These, during the mezzanine card topology detection, are re-mapped into the Physical MAC Ports within the context of the system into which the mezzanine card was inserted. Therefore, when accessed through the GETNODEATTR action, the Port Affinity bits will always refer to Physical MAC Ports.

Bits	Field Name	Default NVM Value	Description
15	Port 15		If set, the temperature sensor is associated with Port 15
14	Port 14		If set, the temperature sensor is associated with Port 14
13	Port 13		If set, the temperature sensor is associated with Port 13
12	Port 12		If set, the temperature sensor is associated with Port 12
11	Port 11		If set, the temperature sensor is associated with Port 11
10	Port 10		If set, the temperature sensor is associated with Port 10
9	Port 9		If set, the temperature sensor is associated with Port 9
8	Port 8		If set, the temperature sensor is associated with Port 8
7	Port 7		If set, the temperature sensor is associated with Port 7
6	Port 6		If set, the temperature sensor is associated with Port 6
5	Port 5		If set, the temperature sensor is associated with Port 5
4	Port 4		If set, the temperature sensor is associated with Port 4
3	Port 3		If set, the temperature sensor is associated with Port 3
2	Port 2		If set, the temperature sensor is associated with Port 2
1	Port 1		If set, the temperature sensor is associated with Port 1
0	Port 0		If set, the temperature sensor is associated with Port 0

3.3.6.10.10 Temperature Sensor Port Affinity High (0x0009 + n*2)

Bits	Field Name	Default NVM Value	Description
15:8	Sensor Location		Defines the location of the sensor.
7:4	Reserved		Reserved.
3	Port 19		If set, the temperature sensor is associated with Port 19.
2	Port 18		If set, the temperature sensor is associated with Port 18.
1	Port 17		If set, the temperature sensor is associated with Port 17.
0	Port 16		If set, the temperature sensor is associated with Port 16.

3.3.6.11 Node Parent Section

This section describes the structure of a node's parent node section. LED and Temperature Sensor nodes might be associated with a PHY node as they might contain different configuration for all Port Options of the specified PHY node. Used by firmware to select which configuration section to load.

Word Offset	Description	Section Reference
0x0000	Parent Node Handle	3.3.6.11.1
0x0001	Reserved	3.3.6.11.2

3.3.6.11.1 Parent Node Handle (0x0000)

Bits	Field Name	Default NVM Value	Description
15:11	Reserved		Reserved.
10	Parent Valid	1b	Indicates whether the Parent Node ID is valid. 0b = The node does not have a parent node. The Parent Node Handle field should be ignored. 1b = The node is associated with a parent node. The parent node is identified by the Parent Node Handle.
9:0	Parent Node Handle		The node handle of the parent node.

3.3.6.11.2 Reserved (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12 Node Scratch Section

This section describes the structure of the Node Scratch Section. Used by scripts to store node-related temporary variables. This section is implemented only in EMP firmware RAM and is not stored in the NVM. The exact use of the scratch section is subject to script implementation and it is beyond the scope of this specification. The section must be initialized to 0x0000 on POR, EMPR, and script engine reset.

Word Offset	Description	Section Reference
0x0000	Scratch 0	3.3.6.12.1
0x0001	Scratch 1	3.3.6.12.2
0x0002	Scratch 2	3.3.6.12.3
0x0003	Scratch 3	3.3.6.12.4
0x0004	Scratch 4	3.3.6.12.5
0x0005	Scratch 5	3.3.6.12.6

The section is accessible through the GETNODEATTR and SETNODEATTR action starting at the DWord-aligned Attribute ID offset 0x3800.

3.3.6.12.1 Scratch 0 (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12.2 Scratch 1 (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12.3 Scratch 2 (0x0002)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12.4 Scratch 3 (0x0003)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12.5 Scratch 4 (0x0004)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.12.6 Scratch 5 (0x0005)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

3.3.6.13 PHY Node

This section describes the block structure of a PHY node. The block contains several sections of variable length: the Node I/O Section, host and line side PMD Analog Sections, host and line side PMD Analog Misc Sections, Port Option Pointer Section, Port Option Header Sections, and the Node PHY Capabilities Sections.

A PHY can support multiple Port Options. The number of the supported Port Options is defined by the *Port Option Count* field in the Node Header Section. The netlist captures the Port Options in order of decreasing priority.

For each of these options, the Node PHY Options Header Section captures the number of PMDs available. For each of the PMDs in a given Port Option the node includes a Node PHY Capabilities Section.

The Adaptive NVM Pointer of the active Port Option on the innermost PHY node identifies the Adaptive NVM Feature required to configure the controller for the current Port Option. The active Port Option of all connected PHY nodes is selected as a function of the active Port Option of the innermost PHY. The active Port Option of the PHY node identified by the Parent PHY Handle of an LED node determines the active Port Option of the LED node.

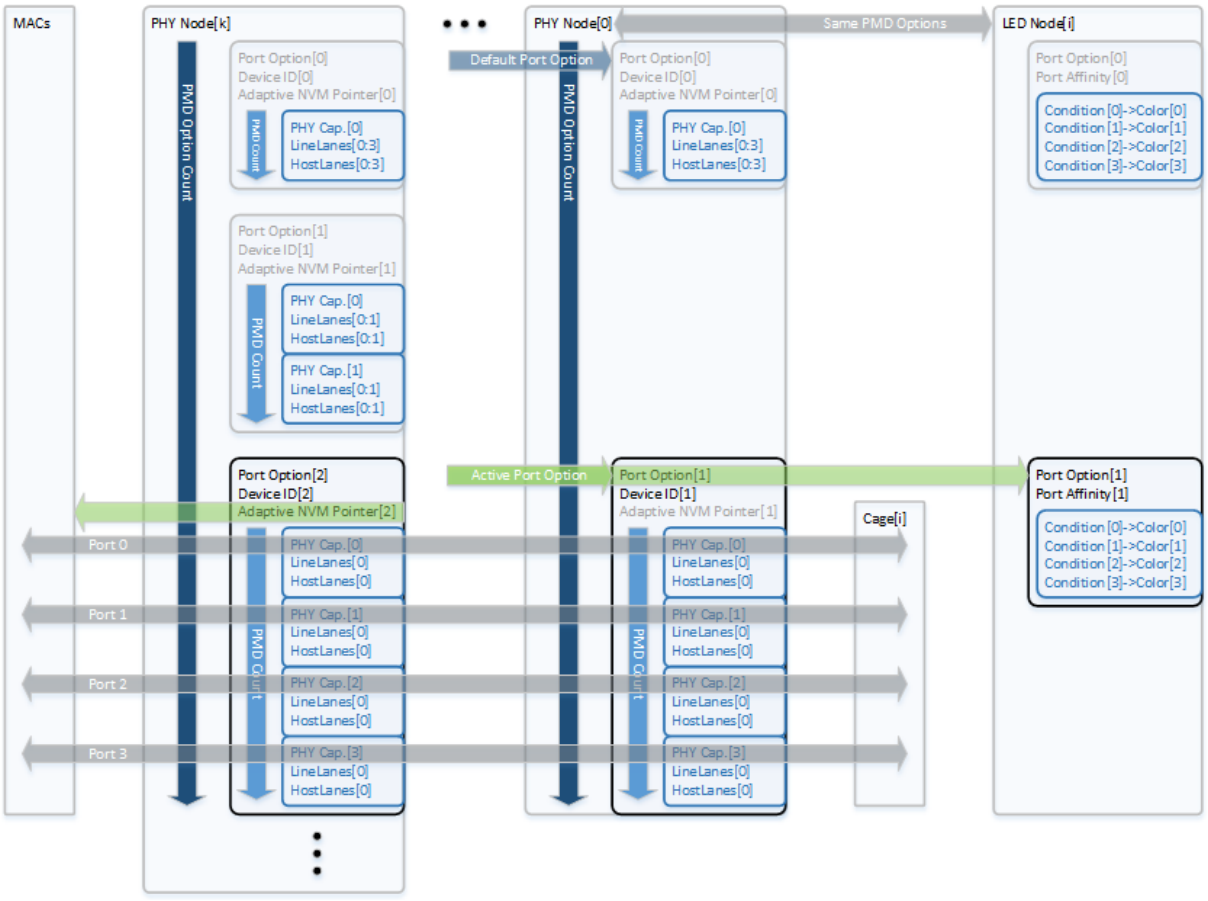

Figure 3-22. Port Options

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
	0x6800	PMD Line Analog Section	3.3.6.7
	0x8800	PMD Line Analog Misc Section	3.3.6.8
	0x7000	PMD Host Analog Section	3.3.6.7
	0x9000	PMD Host Analog Misc Section	3.3.6.8
	N/A	Port Option Pointer Section	3.3.6.4
	N/A	Port Option Header Section [0:Port Option Count]	3.3.6.5
	0x4000	PHY Capabilities Section [0:PMD Count - 1][0:Port Option Count]	3.3.6.6

The Node I/O Section should define the following I/Os: I^2C or MDIO, Int_N, Reset_N, PMD[0:n]. Additionally if the *Bus Address Type* defined in the Node Header Section is Relative Address ADDR[0:4] can also be defined.

3.3.6.14 GPIO Controller Node

This section describes the block structure of a GPIO Controller node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
N/A	0x3800	Node Scratch Section	3.3.6.12

The Node I/O Section should define the following I/Os: I^2C, Int_N, and Reset_N.

3.3.6.15 MUX Controller Node

This section describes the block structure of an MUX Controller node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
N/A	0x3800	Node Scratch Section	3.3.6.12

The Node I/O Section should define the following I/Os: I^2C and Reset_N.

3.3.6.16 LED Controller Node

This section describes the block structure of an LED Controller node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
N/A	0x3800	Node Scratch Section	3.3.6.12

The Node I/O Section should define the following I/Os: I^2C and Reset_N.

3.3.6.17 LED Node

This section describes the block structure of an LED node. The block contains two or more sections of variable length: the Node I/O Section and the Node LED Configuration Section.

An LED node can have one or three I/O connections. The number is reflected by the *I/O Count* field of the Node Header Section (Section 3.3.6.2). If the LED is a monochrome indicator, the I/O Section defines a single I/O (*I/O Type* LED) and if the LED is an RGB color indicator then the I/O Section defines three I/Os (I/O types LED.Red, LED.Green, and LED.Blue).

The LED can have a different configuration for each of the Port Options of the PHY it is associated with. Therefore the LED Node block contains a Node LED Configuration Section for each of the Port Options of the PHY with which the LED is associated. When the Parent Node Handle is valid, the number of the Port Options captured in the Node Header Section (Section 3.3.6.2) must match the number of Port Options defined for the PHY node with which the LED is associated. Otherwise, the number of Port Options in the node header should be 1.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
0x000A / 0x000E	N/A	Node Parent Section	3.3.6.11
0x000C + n*6 / 0x00010 + n*6	0xA000	Node LED Configuration Section. n - port option index	3.3.6.9
N/A	0x3800	Node Scratch Section	3.3.6.12

3.3.6.18 Temperature Sensor Node

This section describes the block structure of an Temperature Sensor node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
0x000C	N/A	Node Parent Section	3.3.6.11
0x0010	0xC000	Node Thermal Configuration Section	3.3.6.10

The Temperature Sensor node can have a different configuration for each of the Port Options of the PHY with which it is associated. Therefore, the Temperature Sensor node block contains a Node Thermal Configuration Section for each of the Port Options of the PHY with which the Temperature Sensor is associated. When the parent node handle is valid, the number of the Port Options captured in the Node Header Section (Section 3.3.6.2) must match the number of Port Options defined for the PHY node with which the Temperature Sensor is associated. Otherwise, the number of Port Options in the node header should be 1.

The Node I/O Section should define the following I/Os: I^2C, Int_N, and Reset_N.

3.3.6.19 ID EEPROM Node

This section describes the block structure of an ID EEPROM node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3

The Node I/O Section should define the following I/Os: I^2C and EEPROM_WP.

3.3.6.20 Cage Node

This section describes the block structure of an Cage node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3
N/A	0x3800	Node Scratch Section	3.3.6.12

The Node Header Section should indicate a *Bus Type* of I^2C and the *Bus Address* should be 0xA0.

For an SFP+ or SFP28 cage, the following I/Os must be defined: I^2C, Present_N. Optionally, the following I/Os could be also defined: TX_Disable.

For a QSFP+ or QSFP28 cage, the following I/Os must be defined: I^2C, Present_N, Reset_N, Int_N. Optionally, the following I/Os could be also defined: Modsel_N, LPMode.

3.3.6.21 Mezzanine Connector Node

This section describes the block structure of an Mezzanine Connector node. The block contains one section of variable length: the Node I/O Section.

Word Offset	Attribute ID	Description	Section Reference
0x0000	0x0000	Node Header Section	3.3.6.2
0x0008	0x2000	Node I/O Section	3.3.6.3

The Node Header Section should indicate a *Bus Type* of I^2C and the *Bus Address* should be 0xA8.

Setting the path to this mezzanine connector and using this bus allows for reading the mezzanine card's ID EEPROM.

For a CEI mezzanine connector, part of the motherboard topology, the following I/Os must be defined: I^2C, Present_N, Int_N, Reset_N, MDIO, ADDR[0:2], and PMD[0:3].

When the topology of a mezzanine card is discovered, the connections with the motherboard are determined by matching the I/O types of the mezzanine connector from the mezzanine card topology with the I/Os of the mezzanine connector of the motherboard topology according to the below in Figure 3-23.

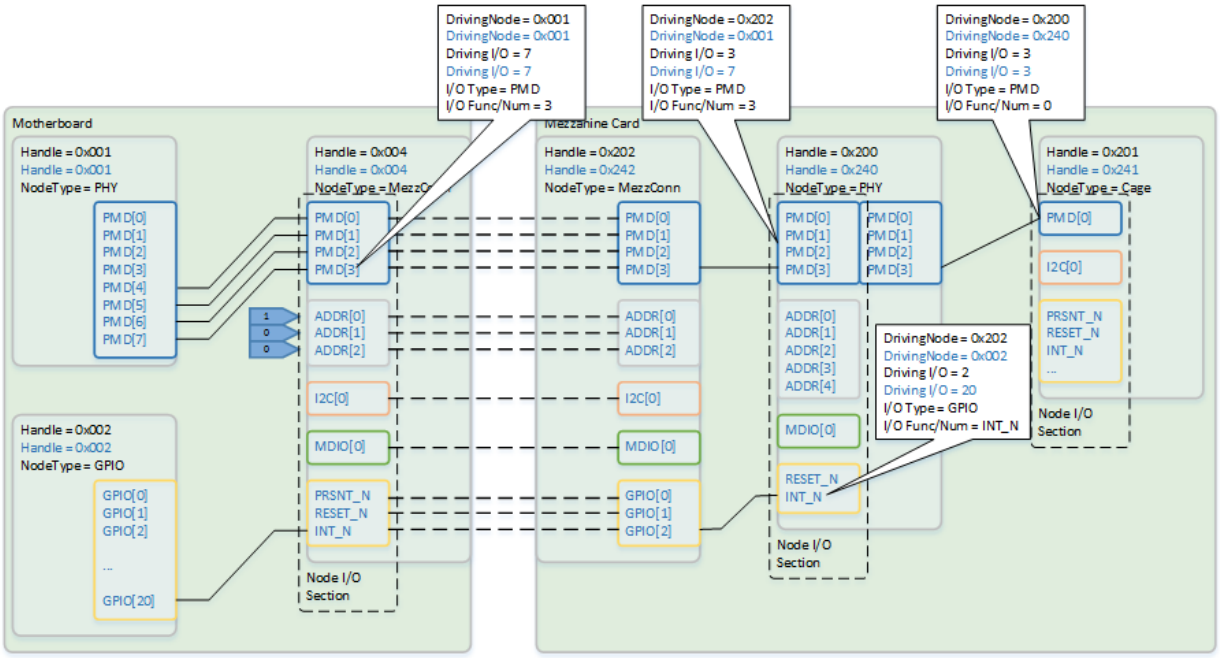

Figure 3-23. Mezzanine Connector Mapping

3.3.7 Topology Netlist Constraints and Conventions

The topology netlist describes design-specific configuration and connections between various motherboard or mezzanine card components, referred to as nodes.

The E810 link management engine imposes the following constraints:

3.3.7.1 Netlist Size Constraints

- The maximum size of the netlist supported in EMP firmware RAM is 12 KB, including the motherboard and all potential mezzanine cards. For PHY and LED nodes, this includes only the currently-active Port Option.
- The maximum size of the motherboard netlist in the NVM is 28 KB.
- The maximum size of the mezzanine card netlist in the IDEEPROM is 4 KB.
- The maximum size of the motherboard netlist in RAM is 12 KB. For all PHY and LED nodes, this includes only the currently-active Port Option.
- The maximum size of the mezzanine card netlist in RAM is 2 KB. For all PHY and LED nodes, this includes only the currently-active Port Option.

3.3.7.2 Node Constraints

- The maximum number of nodes supported on a motherboard is 128.
- The maximum number of nodes supported on a mezzanine card is 32.
- The maximum number of nodes of Mezzanine Connector type supported on a motherboard is 5.
- The maximum number of nodes of Mezzanine Connector type supported on a mezzanine card is 1.
- The maximum depth of cascaded PHY nodes (PHY chain length) is 4.

3.3.7.3 Node I/O Constraints

- The maximum number of I/O connections supported on the motherboard is 384.
- The maximum number of I/O connections supported on a mezzanine card is 64.
- The maximum number of I/O connections supported on a node is 16.
- The maximum number of I/O connections of a given I/O type to a node is 64.
- The maximum number of I/O connections with I/O Type of PMD supported on a motherboard is 40.
- The maximum number of I/O connections with I/O Type of PMD supported on a mezzanine card is 8.
- The maximum number of I/O connections with I/O Type of PRESENT_N supported on a motherboard is 20.
- The maximum number of I/O connections with I/O Type of PRESENT_N supported on a mezzanine card is 4.
- The maximum number of I/O connections with I/O Type of INT_N supported on a motherboard is 16.
- The maximum number of I/O connections with I/O Type of INT_N supported on a mezzanine card is 4.
- Each node can have up to one I/O connection with I/O type GPIO and a given I/O Function / I/O Number.
- All I/O connections to the a specific driving I/O on any given node must have matching configuration. For example, all I/O connections with *I/O Type* of GPIO and *I/O Function* of RESET_N connecting to the same driving GPIO input must have matching Polarity and Default Value configuration.
- With the exception of I/O connections with *I/O Type* of I^2C Bus, MDIO Bus and GPIO with *I/O Function* of RESET_N must be dedicated point to point connections. Another exception to this rule is GPIO signal driving the rate select pins of modules (RS0 and RS1).
- If a node is accessible through an I^2C or MDIO, the connection must be described by the first entry in the I/O connections.
- On each board the I^2C attached MUX Controllers, GPIO Controllers, and LED Drivers must have a shared reset signal. Each of these nodes must have and I/O connection with *I/O Type* of GPIO and *I/O Function* of RESET_N pointing to the same driving I/O on the same driving node.
- PHY nodes must not share their reset signal with other devices. The driving I/O on the driving node pointed to by a PHY node's I/O connection with *I/O Type* of GPIO and *I/O Function* of RESET_N must not have more than one connection to it.

- Mezzanine cards that implements more than one PHY, should not share their reset signal.
- The maximum number of MDIO/I^2C I/Os on the I/O Widget node is 16.
- The maximum number of MDIO/I^2C I/Os on a Mux node is 62.

3.3.7.4 Node I/O Conventions

3.3.7.4.1 I/O Widget

- Pins MDC[0:4]/SCL[0:5], MDIO[0:4]/SDA[0:4] are referred to as MDIO[0:4] or I^2C[0:4], depending on the *I/O Type* of the connected I/O connection.
- Pins GPIO[0:31] are referred to as GPIO[0:31].

3.3.7.4.2 PCA9545A

- Pins SD0 and SC0 defined in Chapter 6 of the PCA9545A Datasheet are referred to as I^2C[0].
- Pins SD1 and SC1 defined in Chapter 6 of the PCA9545A Datasheet are referred to as I^2C[1].
- Pins SD2 and SC2 defined in Chapter 6 of the PCA9545A Datasheet are referred to as I^2C[2].
- Pins SD3 and SC3 defined in Chapter 6 of the PCA9545A Datasheet are referred to as I^2C[3].

3.3.7.4.3 PCA9575

- Pins P0_0 through P0_7 defined in Table 3 of the PCA9575 Datasheet are referred to as GPIO[0:7].
- Pins P1_0 through P1_7 defined in Table 3 of the PCA9575 Datasheet are referred to as GPIO[8:15].

3.3.7.4.4 PCA9685

- Pins LED0 through LED15 defined in Table 3 of the PCA9685 Datasheet are referred to as GPIO[0:15].

3.3.7.4.5 C827

- Pins LIP0, LIN0, LOP0, and LON0 defined in Table 2 of the C827 Datasheet are referred to as PMD[0].
- Pins LIP1, LIN1, LOP1, and LON1 defined in Table 2 of the C827 Datasheet are referred to as PMD[1].
- Pins LIP2, LIN2, LOP2, and LON2 defined in Table 2 of the C827 Datasheet are referred to as PMD[2].
- Pins LIP3, LIN3, LOP3, and LON3 defined in Table 2 of the C827 Datasheet are referred to as PMD[3].
- Pins HIP0, HIN0, HOP0, and HON0 defined in Table 2 of the C827 Datasheet are referred to as PMD[0].

- Pins HIP1, HIN1, HOP1, and HON1 defined in Table 2 of the C827 Datasheet are referred to as PMD[1].
- Pins HIP2, HIN2, HOP2, and HON2 defined in Table 2 of the C827 Datasheet are referred to as PMD[2].
- Pins HIP3, HIN3, HOP3, and HON3 defined in Table 2 of the C827 Datasheet are referred to as PMD[3].

3.3.7.5 PHY Node Constraints

- The maximum number of lanes on line or host side of a PHY node is 8.
- The maximum number of Port Options supported for a PHY node is 16.
- The E810 has one PHY node defined for each of the three PHY Cores.
- The first two PHY Core nodes allow for a total of eight line-side lanes, while the third one only four line-side lanes. None of the PHY Core nodes have host-side lanes. Therefore, the *Host Lane Count* is 0, the Node PMD Host Analog Section Pointer is ignored, and the corresponding Node PMD Analog Section does not exist.
- The netlist must capture the PHY nodes in a well defined order. All PHY nodes must be preceded by the PHY nodes that it has host side connections to (I/O Connections with *I/O Type* of PMD). This results in the innermost PHY nodes needing to be captured first.
- All I/O connections with *I/O Type* of PMD from any PHY node must connect to the same node.

3.3.7.6 GPIO Controller Node Constraints

- • The E810 has one GPIO Controller node defined for the I/O Widget.
- The netlist must capture the GPIO nodes in a well-defined order. The first node captured by the netlist must be the I/O Widget with a node handle equal to 0.

3.3.7.7 LED Node Constraints

- All I/O connections of an LED node must be to the same driving node.
- The parent PHY node of a LED node, should be described in the netlist prior to the description of the LED node.

3.3.7.8 Temperature Node Constraints

- The parent PHY node of a Temperature node, should be described in the netlist prior to the description of the Temperature node.

3.3.7.9 Cage Node Constraints

- The I/O connection with *I/O Type* of I^2C must point to an I^2C interface dedicated to the cage. All cages must have dedicated I^2C interfaces. The MODSEL_N pin of the QSFP cages must be asserted low through a strapping.

3.3.8 Link Topology Admin Commands

Most components of the link topology are accessed by the device firmware, either directly or using PHY configuration scripts. However, sometimes there is a need for direct access of the software driver, or tools driver to the link topology components. As link topology components are owned by the firmware, any such access should be coordinated and conducted thorough firmware admin command, where the firmware can synchronize and control the required access.

The following link topology firmware admin commands are defined:

Table 3-53. Link topology Admin Commands

Command	Opcode	Description	Section Reference
Set Port Identification LED	0x06E9	Set the LED used for identification of this port.	3.3.8.1

3.3.8.1 Set Port Identification LED (0x06E9)

The Set Port Identification LED admin command is used to set the LED that is used to identify the port as indicated in the topology structures (see Section 3.3.6.9.2). The software driver should provide the Logical Port Number.

Table 3-54. Set Port Identification LED Admin Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x06E9	Command opcode.
Datalen	4-5	0x0	No external buffer for this command.
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Logical Port Number	16-17		Software uses this field to send the logical port number. Software might mark the logical port number as not valid. In this case, firmware might use the port that is owned by the function. **Byte 16**: Logical Port number This field specifies the port number, and it is used when the physical function owns more than one port or when the physical function owns single port, but the *Logical Port number is valid* bit (Bit 17.0) is turned on. **Bit 17.0:** Logical Port number is valid **All other bits** = Reserved.
Set Indent Mode	18		**Bit 18.0:** Set the LED into identification mode 0b = The LED is configured to its original mode (by the netlist). 1b = The LED is configured to identification mode and will blink. **All other bits** = Reserved.
Reserved	19-31		Reserved. Set to zero.

3.4 Non-Volatile Memory (NVM)

3.4.1 General Overview

The following conditions specific to the E810 induced an approach to NVM access:

- LAN and RDMA traffic can be handled only if the EMP code runs.
- For flexibility reasons, the main EMP code is retrieved from the NVM and not from ROM.
- Unless authenticated, the EMP/PE firmware code presents a potential security threat for the system:
  - Modification/tampering firmware code is presently undetectable to the rest of the system.
  - The E810's various virtualization capabilities (like SR-IOV with VFs and PFs) can virtually reach into any VM or VMM address space.
  - A malicious firmware is capable of sending out the harvested data from the server to unauthorized recipients via DMA reads … again, undetected. The host CPU is not involved in this process.
  - A malicious firmware is capable of injecting malware into the host, bypassing other platform-level access control.
- The E810 controller core IP is part of several products with specific NVM needs, while the NVM design is common for all of them and consequently it has to meet the most strict requirements.

3.4.1.1 Requirements on NVM Access

The basic requirements from NVM access in the E810 include the following:

- Guarantee that only Intel-provided firmware code (EMP, PE, PHY) is run and device-critical data is used by the E810.
  - The firmware code and device-critical data is cryptographically signed and authenticated prior to execution.
  - The Intel ECSS/EDSS is used for signing.
  - PKCS #1 v2.2 format with 2048-bit RSA keys and SHA-256 hash is used for signing EMSA-PKCS1-v1.5.
- Protect NVM image against compromised supply chains and at least partial protection against physical tampering. Full protection against physical tampering is not required at the moment but can be requested in future.
  - It implies security on read approach, where the firmware ROM code is the Root of Trust and the authentication is done at every step of the Chain of Trust. That is, ROM-Miniload-NVM image.
  - Authentication is only performed at POR/EMPR resets and it is not required on every NVM access.
  - The hash value of the public key is stored in fuses, while the public key is part of the NVM image.
- Compromised key revocation is supported, while only level two keys can be revoked by providing a new CA certificate. The key for CA authentication can not be changed in the field.

- Protection against rollback to the NVM version with known security issues is provided.
  - This is achieved by guaranteeing that the NVM image security revision is not decreased during NVM update.
  - A way to override the security revision rollback protection with BMC manageability commands is provided.
- Initial NVM programming is responsible to program blank fuses encoding the hash of the public verification key if fuses are not configured as part of the packaging process.
- The ROM firmware supports blank Flash programming mode, where the Flash can be written by host software, and then subsequently verified on device reset. Blank Flash programming mode assumes known good device initialization parameters are built into the ROM.
- Protect NVM update flow from power failure before completion. This implies the image-update procedure of modules uses a double-bank policy.
- Meet the boot time requirements described in PCIe specification.
- Reduce the surface for security attacks and protect as much NVM content a possible taking the "white list" approach. Consequently, only a small PFA area with system-specific settings surviving NVM update is unprotected by design.
- Provide a simple way to update NVM shifting responsibility for system specific configuration preservation to the device firmware. This is required to support the update over PLDM DMTF emerging standard and any to any NVM update.
- Prevent a malicious software from causing permanent damage to the system, and to the NVM (and the E810 in particular) so that Flash parts or NICs are not returned to Intel. It implies some countermeasure be taken against a malicious software that would excessively write access the Flash to precipitate its wear-out.

3.4.1.2 Operational Limitations

The NVM protection method selected in the E810 relies on authenticating key sections on initial load, also known as authenticate on read. Protected modules are authenticated before their first usage following a power-on reset, in addition to validating image updates prior to committing an update. NVM protection is implemented using a ROM-based firmware digital signature authentication algorithm, which uses fuse-encoded hashes of the public verification keys. Authenticating images on every initial load greatly reduces the possibility of unwanted modification to device firmware being introduced from compromised supply chains or physical tampering.

There is small set of PCIe-related time-critical CSRs, which are auto-loaded speculatively without authentication. This content is verified later at initialization time. If the verification fails, the NVM content is fixed and the error is reported to the software (using GL_MNG_FWSW CSR), with the request to initiate a corresponding reset.

In normal operating mode, NVM write accesses are access controlled by the EMP firmware and cannot be performed directly from the host to the NVM device via the memory-mapped accesses. Memory-mapped NVM access remains available for NVM read accesses only. For simplicity and flexibility reasons, NVM write accesses (except for VPD) can be initiated only via an admin command or following a BMC command, which are both handled by the EMP.

The ROM-based EMP firmware supports a blank Flash programming mode in the event the initial EMP firmware loader detects either a blank, corrupt, or invalid NVM image. In blank Flash programming mode, the host software program can program an image directly to the Flash device without any security limitations, nor is the EMP firmware involved. The host software has direct access to the SPI Flash controller with the same permission as the EMP firmware in the blank Flash programming mode.

When the host debug mode is entered via a dedicated JTAG code (0x3E), the host can remove address protection of the PF space and write into the register that controls the blank Flash programming mode.

Note: This is not an error flow. Thus, the main firmware is loaded, the auto-load process still occurs, and the state of the device might not be the hardware default state.

3.4.2 External Flash

In the E810, the LAN controller core is the main client of the internal SPI controller. The E810's full Flash image must also contain a descriptor for the SPI controller as described below.

The SPI controller is responsible for the following tasks:

- Perform arbitration between the different clients.
- Manage the access control to the different regions.
- Reflect a zero-base address to each of the clients such as each client's first address is address zero.
- Enable access for a software tool for global blank Flash programming.

Note: **External Flash must have Descriptor for SPI controller preprogrammed.** The External Flash used by the device must have Descriptor for SPI controller pre-programmed in the Flash for the device to function. Until the Flash contains this information, Software Tools cannot program an NVM image.

3.4.2.1 E810 NVM Regions

In the E810, the NVM uses a 16 or 32 MB Flash and contains the following regions:

- **Descriptor region** — The first 4 KB of the Flash that contains the following data:
  - — Signature
  - — Content section (3 DWords)
  - — Component section
  - — Region section
  - — Masters section
  - — Soft-Straps

  Presence of the descriptor region is a requirement of the SPI Controller block. This region must be pre-programmed before the host or firmware can access the Flash device via the SPI controller. This programming can be done off-line during the manufacturing process, or via the host interface using the "bit bang" mode.
- **Core region** — The core NVM used by the IP as described in Section 6.3. It is mapped as region 3 and has a size of 8-10 MB.

3.4.3 Shadow RAM

NVM modules that meet one of these criteria must also be mirrored internally into a Shadow RAM that is loaded once after POR:

- Software must be able to partially update the module without being forced to rewrite the entire module (like SMBus address, VPD, and so on).

  Unlike an EEPROM, Flash devices require rewriting an entire sector even if it comes to updating a single byte. The partial update is first performed against the Shadow RAM. Later on, the E810 commits the entire updated Shadow RAM into the Flash.

- On device-level resets (in contrast to function-level resets), the module (or parts of it) is auto-loaded by the E810 into registers that are mapped to the host memory BAR.

  Auto-load done after PCIe fundamental resets (POR and PERST#) must be completed within a bounded time, and cannot wait for the delays involved by a sector erase operation (hundreds of milliseconds) that could have been initiated just before. Flash read accesses are suspended until a Flash sector erase operation completes. NVM auto-load performed further to device-level resets are done from the internal Shadow RAM into the registers, without involving Flash read cycles.

The E810 maintains the first 32 x 4 KB sectors of the Flash area allocated to it for the configuration content that must be mirrored into the Shadow RAM. These sectors are organized in two equally-sized banks, each one capable of containing the PFA of the Shadow RAM contents (See Figure 3-24, this includes also the init module). These banks are referred to as the basic NVM banks. At any time one of these two banks must be valid or else the E810 is set by hardware default and enters into blank Flash programming mode (refer to Section 3.4.4.2).

Following a Power-on Reset (POR), the E810 firmware copies the valid Persistent Shadow RAM bank of the Flash device and Non-persistent Shadow RAM area of the valid NVM Bank into the internal Shadow RAM (see Figure 3-24 and Figure 3-25), which is made resilient to device-level resets that might occur later on. The valid bank is the lowest indexed bank with the validity field content read as 01b. The NVM *Validity* field is located at NVM Control Word 1. At any time, the valid bank is referred to as the current basic bank, while the other is referred as the next basic bank. Any further accesses of software to this section of the NVM are directed to the internal Shadow RAM. Modifications made to the Persistent Shadow RAM area content are then copied by the E810 into the next bank of the NVM, flipping circularly the valid Persistent Shadow RAM bank between bank 0 and bank 1 of the Flash.

This mechanism also provides a way for software to protect an image-update procedure from power-down events by establishing a dual-bank policy even when performing a module partial update.

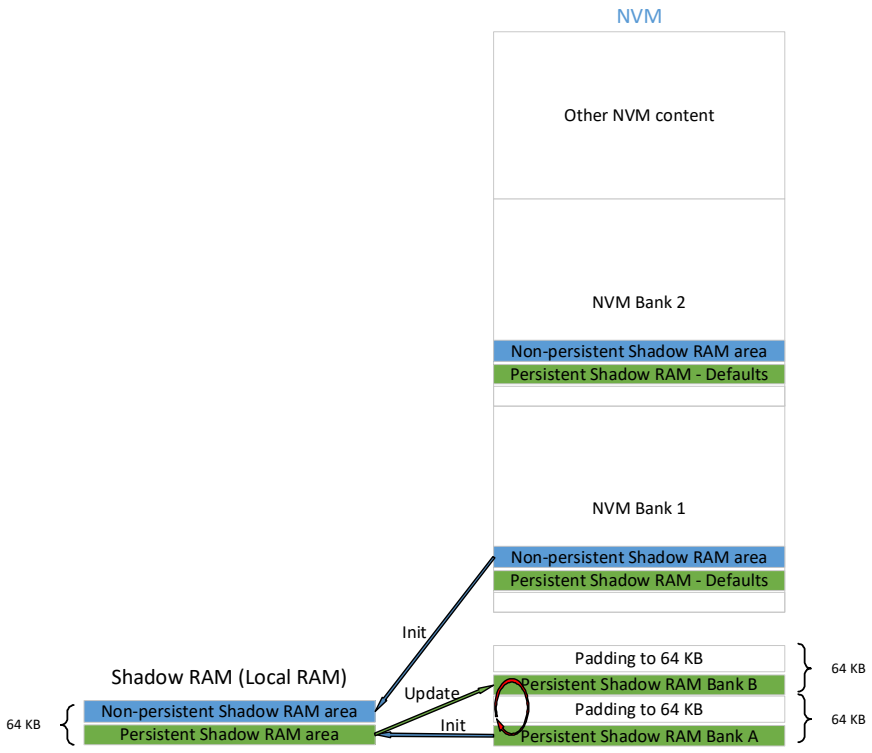

Figure 3-24. NVM Shadow RAM

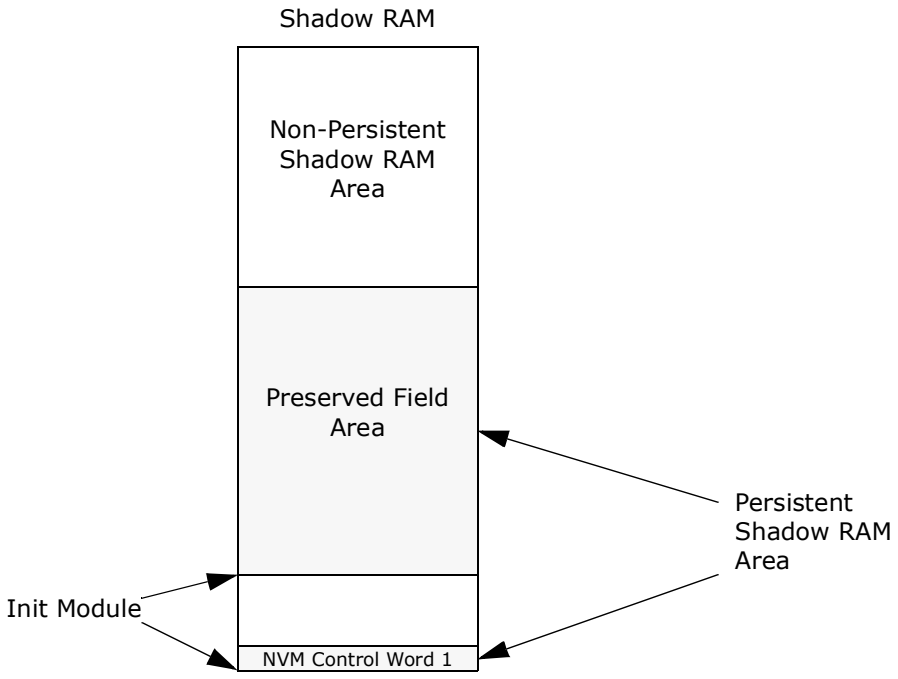

Figure 3-25. Shadow RAM Structure

3.4.4 NVM Access Modes

The NVM is connected to the device through SPI. Every access method eventually uses the SPI.

The NVM is accessed in multiple ways according to the entity and the state of the NVM image. following are the different access modes.

- SPI access mode
- Normal access mode
  - — Through admin commands.
  - — VPD register set
  - — Memory map
- Blank Flash programming mode.

3.4.4.1 Normal Mode

For BIOS read accesses and VPD accesses, any read or write access to the NVM by the host must be preceded by taking ownership of the NVM resource via the Request Resource Ownership admin command (see Section 9.5.13.6). This prevents the following situations:

- Reading a module that is currently being modified by another entity.
- Concurrent modifying a module contents.

3.4.4.1.1 Normal Read Access

Memory-mapped read accesses to the NVM do not require the EMP to be involved. EMP is involved when the read is performed via the NVM Read admin command.

Available read accesses are as follows:

- An NVM Read admin command from the PF.
- VPD register set.
- Memory mapped read via the memory/Option ROM BAR. To save host memory addresses, memory BAR access to the NVM is not always available. It is enabled/disabled by setting the *Flash_Expose* bit in the NVM (or setting the GLPCI_LBARCTRL.*FLASH_EXPOSE* CSR bit).

3.4.4.1.2 Normal Write Access

Write accesses to the NVM are controlled by the EMP.

Two accesses are provided:

- An NVM Update admin command from the PF.
- VPD register set. The EMP asserts the *Done* bit.

NVM write access attempts performed via the memory/Option ROM BARs are not performed by the E810, although PCIe transactions are completed normally.

3.4.4.2 Blank Flash Programming Mode

The E810 enters local blank Flash programming mode based on the following:

- When a blank Flash is detected. It means that the NVM *Blank Validity* field (NVM Control Word 1) read from the two basic banks is not equal to 01b.
- When the EMP image read at initialization time does not belong to the E810.
- When the ROM code fails to authenticate the mini-loader image.
- When the mini-loader fails to authenticate the whole NVM bank.
- When the GLNVM_FLA.*LOCKED* bit is cleared. This bit can be cleared from the PF space if host debug mode is entered. It is recommended that Flash programming platforms at manufacturing sites be provided with the JTAG as a back-up means.

This mode is not safe and must be used only at manufacturing time and/or as a last resort to recover from initial mis-configurations. Only host access to the Flash and Shadow RAM is guaranteed when in this mode.

It is not recommended to enter this mode at run-time because no resource ownership taking is required prior to accessing the NVM. Also, taking resource ownership requires an operational EMP, which is not the case when in this mode.

When the E810 is in this mode (see conditions in the previous list), the EMP/PE codes are not loaded from the NVM and the EMP/PE remains disabled. The E810 is not able to exchange any kind of traffic over the lines and no admin command can be posted. The E810 is in an unknown operational state where only the Flash programming flow is operational.

3.4.5 NVM Update Flows

The flows described in this section affect only normal programming mode. When in the Blank Flash Programming mode, refer to the NVM access procedures described in Section 3.4.8.

It is firmware's responsibility to keep track of Shadow RAM consistency between Internal RAM and Flash. If GLOBR/CORER occurs while Shadow RAM is inconsistent, EMPR is triggered, which eventually results in coherent Shadow RAMs by rolling-back the internal RAM changes.

It is assumed that an NVM update sequence does not last beyond the NVM ownership timeout for a write of three minutes (refer to Table 9-46). Failing to complete an update (by setting *LAST* bit in the command flag) within that time, results in EMPR which causes a roll-back of the non-completed update.

The firmware is responsible to re-compute and update the software checksum (PFA section with *TLV Type* = 0x3F) each time the Shadow RAM content is changed.

3.4.5.1 Flash High-Level Map

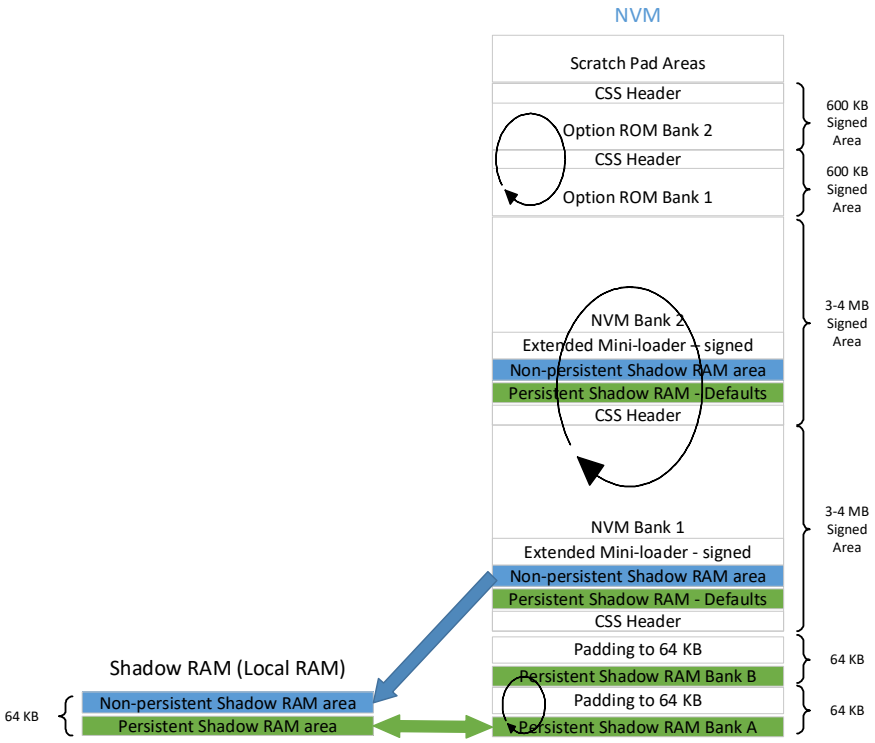

Figure 3-26. Flash High-Level Map

Figure 3-26 shows the high level mapping of the NVM in the E810, while the exact mapping is given in Chapter 6. It is made of the following areas:

- **Two Basic Persistent Shadow RAM Banks A,B** — It contains a modifiable content. including NVM Control Word 1 (offset 0x00) along with the Preserved Fields Area (PFA) that includes the VPD area and other modules to be preserved upon a new image release. It might also contain other content for convenience, which is overwritten with the clean copy of the Shadow RAM at POR. The current valid bank is mirrored into the internal Shadow RAM at POR events. Changes that are made in the Shadow RAM are finally dumped into the next bank, which becomes the current valid, and so forth, cyclically. Refer to Section 3.4.5.3 and Section 3.4.5.4, and Section 3.4.5.6 for the Shadow RAM update flows.
- **Two Authenticated NVM Banks** — They contain the basic NVM image from which specific images are created. One of the banks is valid, and the other is used for updating. Each area contains:
  - — A clean copy of the Shadow RAM area, with default values in the Preserved Field Area.
  - — The mini-loader image signed along with the time critical configurations.
  - — EMP Image area, containing the code to be run by EMP embedded processor.
  - — PE Image area, containing the code to be run by the Protocol Engine.
  - — PHY Configuration scripts.
  - — Parts CORER and GLOBR reset register auto-load sections, which are not modifiable by the Adaptive NVM features.

  - — EMP Global and Setting modules, containing basic configurations common to all images.
  - — Adaptive NVM metadata, which is a data structure containing the metadata required to modify an image to match a given configuration.
  - — PHY Analog modules (internal Ethernet PHY microcode and configuration) loaded by the E810 at power-up events only.
  - — PE Settings module, containing defaults to PE registers.
  - — Recovery Mode firmware image, separately signed. See Section 15.3.

  See Section 3.4.5.6 for the update flow of the signed area.

- **Two Expansion/Option ROM Areas (OROM area)** — It contains pre-boot code and settings read by BIOS. Refer to Section 3.4.5.5 for the update flow. Pre-boot code is authenticated by BIOS at initialization time before being executed. Pre-boot code is also internally authenticated on update. One of the banks is valid, and the other is used for updating.
- **Netlist Module** — A pair of RW modules used to store the netlist structure.
- **Scratch Pads** — A set of RW areas that are not double banked, where software and firmware can store data for logging and debug.

Refer to Section 6.3 for the detailed NVM map.

3.4.5.2 Generic Flows

This section describes the flows that are used as building blocks by other flows.

3.4.5.2.1 Shadow Ram Dump

1. The firmware sets internal bit indicating Flash and Shadow RAM are inconsistent.
2. The firmware erases the next bank. It erases the contents of the next basic bank sectors.
3. The firmware copies first part of the Shadow RAM (from the first word until the end of the PFA) into the next bank sector with the exception of the *Validity* field, which is left as all ones.
4. The firmware checks the Flash write. The new bank content is read and checked to be identical to the Shadow RAM contents. This can be done in the course of writing to the Flash using previous step.
   a. If not identical (such as Flash defect), exit the flow. Refer to Section 9.5.13.7.
   b. If the check was successful (identical), the EMP validates the new bank and invalidates the old bank.
      1. The *Validity* field of the new bank is set to 01b. The EMP checks that the *Validity* field is read as written in the Flash. If not, then go to the previous sub-step.
      2. The EMP toggles the state of the *BANK1VAL* bit in the GLNVM_GENS register to indicate that the non-valid bank became the valid one and vice versa.
      3. The current (old) bank is invalidated by setting its *Validity* field to 00b.
      4. Firmware clears internal bit indicating Flash and Shadow RAM are inconsistent.

3.4.5.3 VPD Update

3.4.5.3.1 First VPD Area Programming

The VPD capability is exposed on the PCIe interface only if the GLPCI_CAPCTRL.*VPD_EN* bit is set to 1b, regardless to any other sanity check that is performed on the VPD area contents.

The VPD area and VPD pointer must be written on a blank Flash and must contain a valid contents from this first programming. If VPD tags were modified, it is required to issue a PCIe reset before write accessing the VPD area from PCIe configuration space.

3.4.5.3.2 VPD Area Update from PCIe Configuration Space

The flow described on this section is used once the VPD area contents and pointer have been already programmed in the NVM and loaded into the E810.

1. A PF VPD software performs a VPD write. It sets write offset/data into VPD register set of the relevant PF configuration space, setting the *VPD* Flag (bit 15 in VPD Address register 0x0E2).
2. Hardware notifies the EMP. It issues an internal VPD access interrupt to the EMP to notify it of the VPD access and of the PF affected.
3. The EMP checks that the VPD write is allowed. It checks that the write offset points to the VPDRW area (and not to a VPD RO area).
   — If not, the EMP clears the *VPD* Flag in the PF configuration space to notify PF VPD software that the transaction completed and then exits the flow.
4. EMP writes the change into Shadow RAM.
5. The EMP completes the VPD access to software. The EMP clears the *VPD* Flag in the PF configuration space to notify PF VPD software that the access completed.
6. The EMP dumps the Shadow RAM to Flash.
   a. The EMP takes ownership over the NVM resources for a write.
   b. EMP performs the dump as described in Section 3.4.5.2.1.
   c. If the Flash is busy by a previous sector erase operation, Flash erase is blocked by the wear-out protection mechanism (lack of credits) or if NVM ownership is held by software, it might indicate that the flow needs to be restarted from step 1 at this stage by successive VPD write accesses initiated by VPD software.
   d. The EMP releases the NVM ownership.

Notes: Users must be made aware that dumping the VPD change into the Flash might take a few hundredths of a millisecond after the VPD transaction completes to software (by clearing the *VPD* flag). As a result, they must wait few seconds before they can shut down the system.

If the VPD write access is attempted by the host when the E810 has just started a Shadow RAM dump (Step 6), then it might be that the write request times out.

3.4.5.4 Updating Items in the Preserved Fields Area (PFA)

Figure 3-27 describes the PFA update flow:

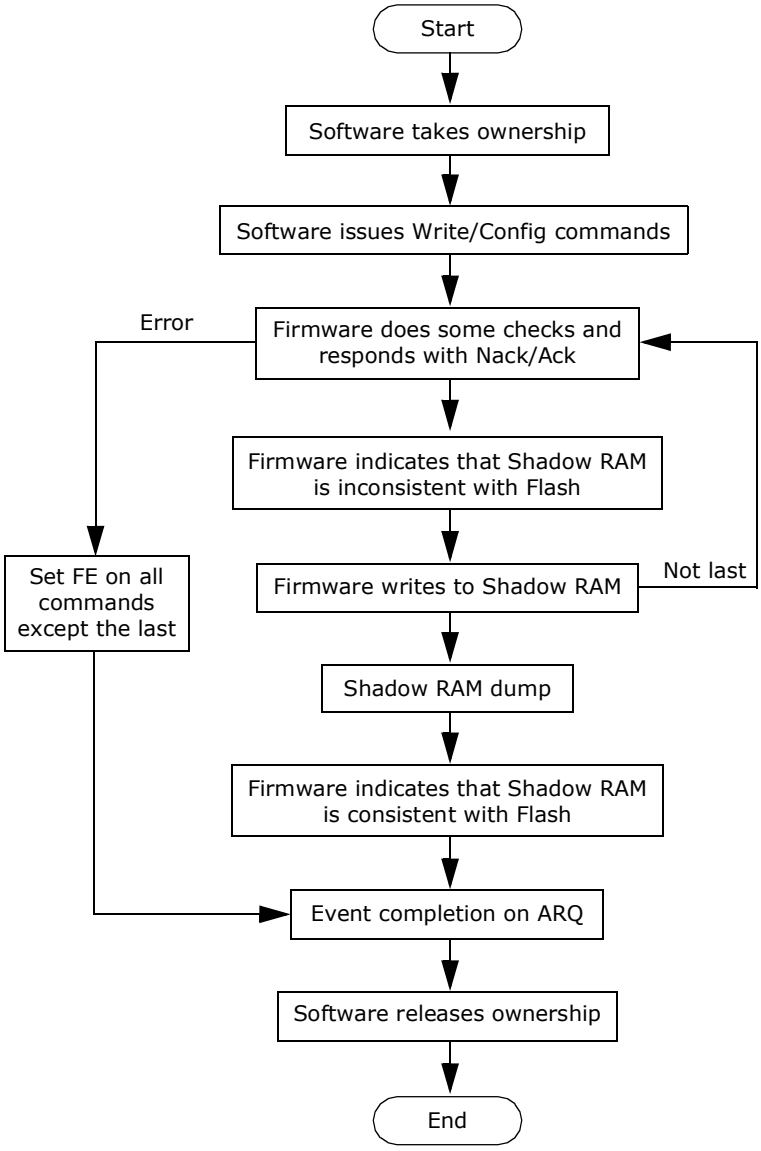

Figure 3-27. PFA Update Flow

The update flow detailed description is as follows:

1. Software takes ownership over the NVM resource for a write (see Section 9.5.13.6).
2. Software issues one or several NVM Write commands or NVM Config Write commands. For NVM Write admin command see Section 3.4.10.3. For NVM Config Write admin command see Section 3.4.10.5.

3. In update flows, if the *Last Command* bit is cleared in the command, it means that the command belongs to a complex NVM update operation made of several elementary NVM update commands that are posted in the Admin Queue. In between completions of elementary commands in a chain, other commands can be posted by a PF, besides other NVM-related commands. The entire NVM change is committed to the Flash part only once the last NVM command of the sequence is processed.

   The Flush on Error (FE) bit must be set for all the commands of a sequence, with the exception of the last one.

4. The firmware checks that the command is valid and posts a response to software. It performs the following command validity checks and posts a response (ACK/NACK) to software. If one check fails, the EMP flushes the remaining NVM update commands (if any) of the sequence and exits the flow. Otherwise, if no error is encountered, the EMP runs the command (NVM update) or schedules the NVM command to run in a separate thread, resuming from the next step.

   - The pointer points to a section within the PFA area. The start/end offsets, once applied to the module's location in the basic bank, do not lead to addresses beyond the PFA size. In case of "Dynamic NVM Update" command, the offset/length must be within the selected module.

5. The firmware sets internal bit, indicating Flash and Shadow RAM are inconsistent.
6. The firmware writes the change into Shadow RAM.
7. If the *Last Command* bit is set in the command, the firmware dumps the Shadow RAM to Flash (see Section 3.4.5.2.1). Otherwise, it completes the command to software and exits the flow. When the next command is posted by software the flow continues from Step 2.
8. The firmware clears internal bit, indicating Flash and Shadow RAM are inconsistent.
9. The firmware posts an event completion on ARQ to software.

   - If the NVM ownership timeout for write ends before reaching this step, the EMP flushes the remaining NVM update commands (if any) of the sequence, reporting a timeout error status.

10. In config write flows, the software should initiate a Shadow RAM dump by sending a NVM Write Activate command with no activation bits set.
11. Software releases NVM ownership (see Section 9.5.13.7).
12. Software initiates a reset for loading the modifications into the E810.

3.4.5.4.1 Limitations on PFA Updates/Handling

To allow seamless upgrade and downgrade updates, the following limitations and assumptions are made as to how PFA can be modified:

- When new TLVs are added, they must be added at the end of the PFA, replacing part of the padding TLV.
- Firmware ignores unknown TLVs and does not treat their presence as an error.
- Reserved fields in existing TLVs must not be reused.
- The size of TLVs must not change between versions. One exception is the ANVM feature selection TLV, which may expand into the next padding area.
- TLVs are never removed from PFA, even if no longer used.

3.4.5.5 Scratch Pads Update

The following flow supports only the full module replacement without the double-bank policy. The following NVM modules are affected by this flow:

- Firmware Scratch Pad Area (pointed by NVM word 0x50)
- Link Topology Scratch Pad Area (pointed by NVM word 0x4B)

Figure 3-28 shows the non-authenticated module update flow:

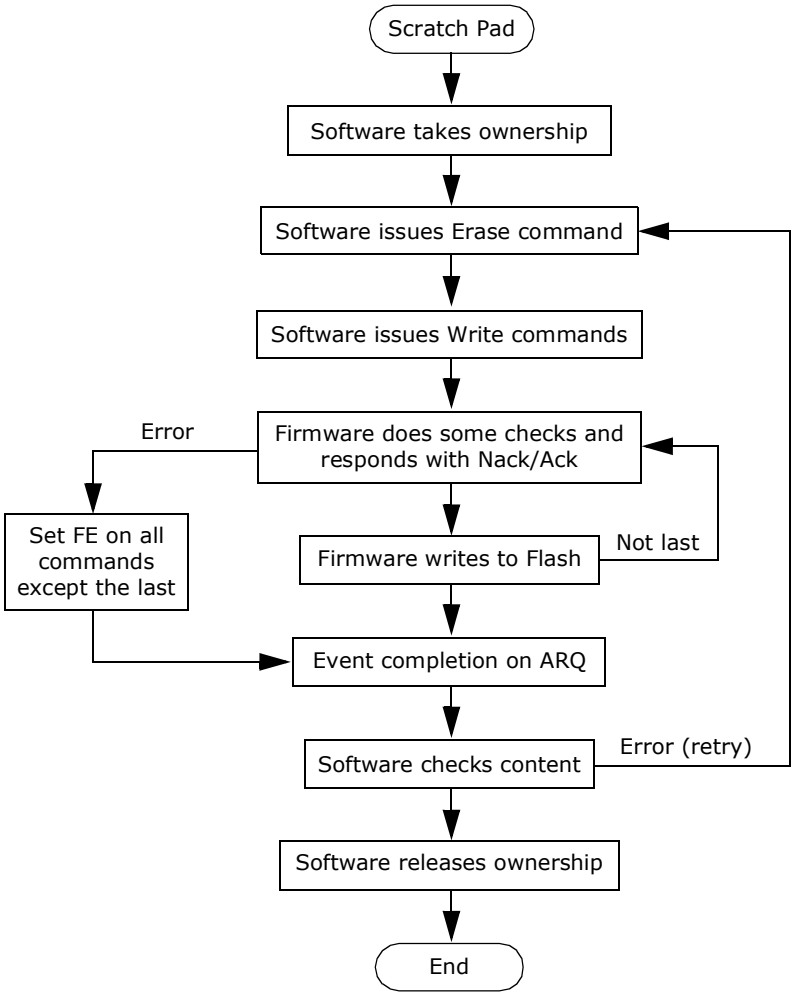

Figure 3-28. Non-Authenticated Module Update Flow

The flow details are below:

1. Software takes ownership over the NVM resource for a write (see Section 9.5.13.6).
2. Software issues a single NVM Erase command to the EMP, providing the following parameters (see Section 3.4.10.2):
   - Address in the NVM of the pointer to the relevant scratch pad area of one of the modules previously listed.

3. Software issues one or several NVM Write commands to the EMP, providing the following parameters (see Section 3.4.10.3):
   - Address in the NVM of the pointer to one of the modules previously listed.
   - Offset inside the module.
   - Buffer in host memory.
   - Buffer length (maximum supported is 4 KB).

   The *Flush on Error* (FE) bit must be set for all the commands of a sequence with the exception of the last one.
4. The firmware checks that the command is valid and posts a response to software. It performs the following command validity checks and posts a response (ACK/NACK) to software. If one check fails, the firmware flushes the remaining NVM update commands (if any) of the sequence and exits the flow. Otherwise, if no error is encountered, the EMP schedules the NVM command to run in a separate thread, resuming from the next step.
   a. The pointer location belongs to one of the modules in the list.
   b. The offset and length, once applied to the relevant area, do not lead to addresses beyond the device's NVM area size.
   c. The offset and length, once applied to the relevant area, do not spread over two consecutive 4 KB sectors.
5. The firmware posts an event completion on ARQ to software.
   - If the NVM ownership timeout for write ends before reaching this step, the EMP flushes the remaining NVM update commands (if any) of the sequence, reporting a timeout error status.
6. Software releases NVM ownership (see Section 9.5.13.7).
7. Software takes ownership over the NVM resource for a read (see Section 9.5.13.6).
8. Software reads from Flash the contents of the new module to check that it has been correctly recorded into the Flash.
   - In case it was not, Software re-does the flow.
9. Software releases NVM ownership (see Section 9.5.13.7).
10. Software initiates a device reset (PCIR, CORER, or GLOBR) for loading the modifications into the E810.

3.4.5.6 Updating a Double Bank Module

The following flow supports only the full bank replacement via a double-bank policy. The following banks are affected by this flow:

- **NVM** — Word 0x42 holds the 1st NVM bank pointer and word 0x43 holds the NVM bank size. The valid bank is indicated by a bit in Control Word 1. The 2nd NVM bank is right after the 1st NVM bank and has the same size.
- **OROM** — Word 0x44 holds the 1st OROM bank pointer and word 0x45 holds the OROM bank size. The valid bank is indicated by a bit in Control Word 1. The 2nd OROM bank is right after the 1st OROM bank and has the same size.
- **Netlist** — Word 0x46 holds the 1st TLV bank pointer and word 0x47 holds the netlist bank size. The valid bank is indicated by a bit in Control Word 1. The 2nd netlist bank is right after the 1st netlist bank and has the same size. This module is not authenticated.

Figure 3-29 shows the double banked modules update flow:

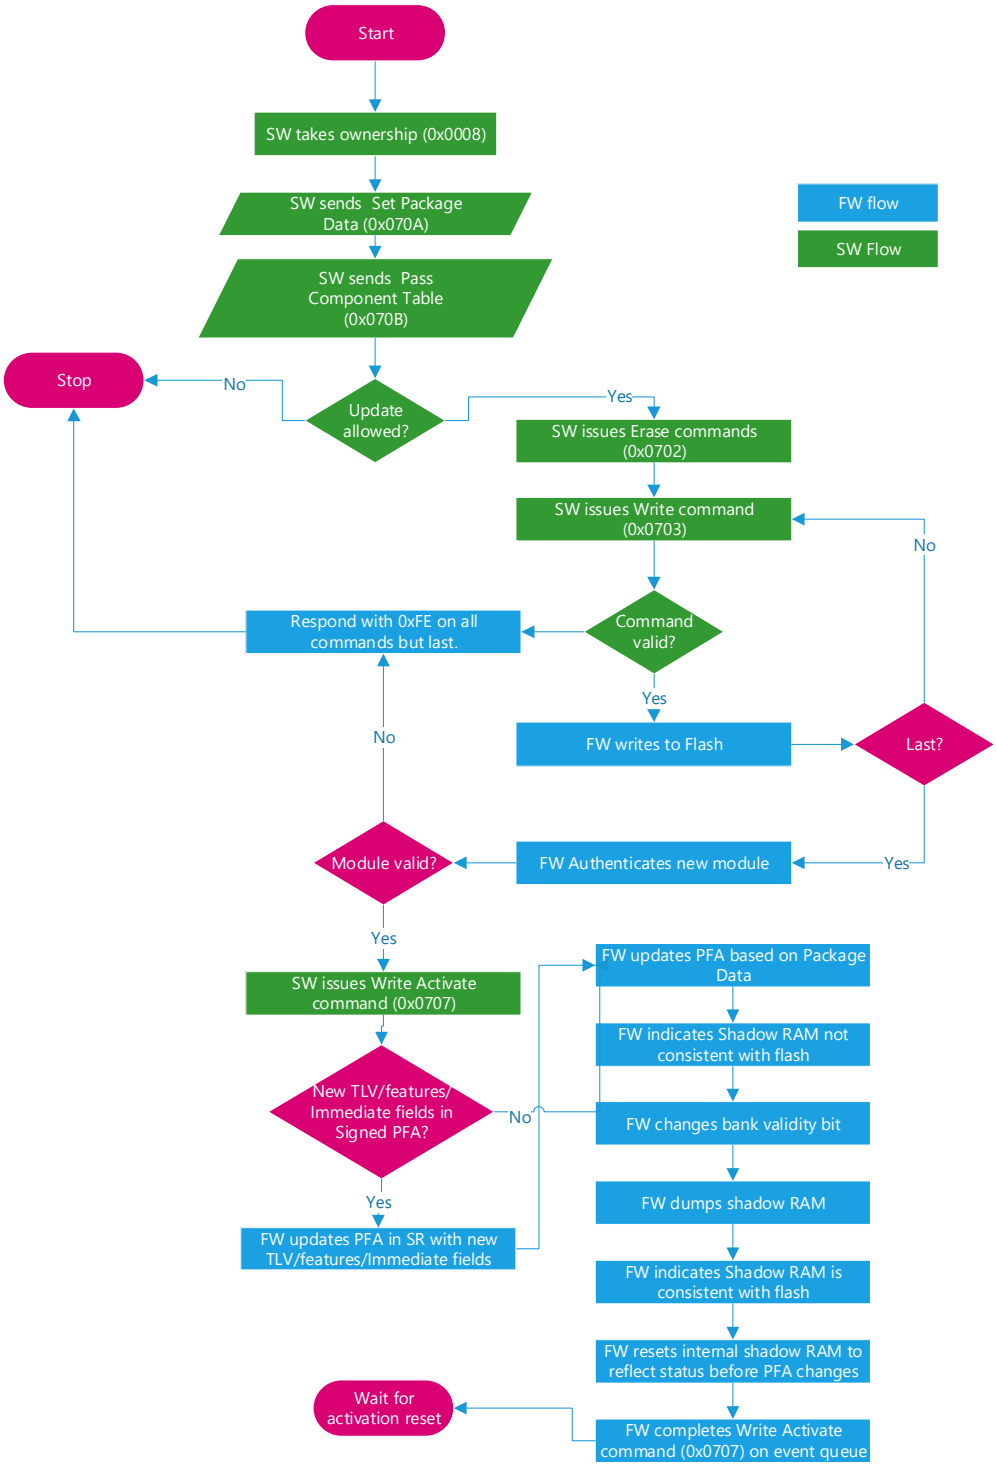

Figure 3-29. Authenticated Module Update Flow

The detailed flow is described as follows:

1. Software Tools verifies that the source/destination NVM images are compatible:
   a. Takes ownership on the NVM (see Section 9.5.13.6) and reads valid NVM sections through admin commands (see Section 3.4.10.1).
   b. Send a Set Package Data (0x070A) command to provide package metadata to firmware.
   c. Send a Pass Component Table (0x070B) command to check if images are compatible.
   d. If the images are not compatible, Software Tools notifies users of the error and exits the flow.

   Note: This step is not performed by EEUpdate, LANConf and NUR-a tools, which are not using config files. These tools are used by OEMs and Hardware manufacturers only (not end-users), who refer to Intel documentation for compatibility check.
2. If not done previously, software takes ownership over the NVM resource for a write (see Section 9.5.13.6).
3. Software issues a single NVM Erase command to the EMP, providing the following parameters (see Section 3.4.10.2):
   - TypeId of the module to be replaced.

   Firmware knows to erase the non valid bank.
4. Software issues several NVM Write commands to the EMP, providing the following parameters (see Section 3.4.10.3):
   - TypeId of the module to be replaced.
   - Offset inside the module.
   - Buffer in host memory.
   - Buffer length (maximum supported is 4 KB).

   If the *Last Command* bit is cleared in the command, it means that the command belongs to a complex NVM update operation made up of several elementary NVM Write commands that are posted in the Admin Queue. In between completions of elementary commands in a chain, other commands can be posted by a PF, besides other NVM-related commands. The entire non-valid bank must always be written.

   The *Flush on Error* (FE) bit must be set for all commands of a sequence with the exception of the last one.
5. The firmware checks that the command is valid and posts a response to software. It performs the following command validity checks and posts a response (ACK/NACK) to software. If one check fails, the EMP flushes the remaining NVM Update commands (if any) of the sequence and then exits the flow. Otherwise, if no error is encountered, the EMP schedules the NVM command to run in a separate thread, resuming from the next step.
   a. The module TypeID belongs to one of the banks in the list.
   b. The offset and length, once applied to the relevant non valid bank area, do not lead to addresses beyond the non valid bank area size.
   c. The offset and length, once applied to the relevant non valid bank area, do not spread over two consecutive 4 KB sectors.
6. The firmware writes the non valid bank area. The firmware writes the change required by the (elementary) command into it. If the last bit is cleared, the firmware posts an event completion on ARQ to software and completes the command. The flow continues from Step 4 for the next (elementary) command of the sequence.

7. If the *Last* flag is set, the firmware performs the following security checks and authenticates the next NVM bank. It reads the new bank from the Flash and authenticates its signature according to the procedure described in Section 3.4.9. If one of the security check fails or if authentication fails, firmware posts an error event on ARQ to **Software Tools** (either the *Public Key Check Failed* or the *Module Signature Check Failed* bit). The flow goes to Step 22.
   a. The *lad_srev* in the destination is equal or greater than the one in the source.
   b. The *Blank NVM Device ID* field in the destination corresponds to the E810 device ID (0x1590).
   c. The *lad_module_id* in the destination corresponds to bank currently being updated.
   d. In case of PLDM firmware update, GFID match is checked, as described in Section 3.4.5.6.1.
   e. These checks are not done for the netlist module.

   Note: Note that before authenticating the Option ROM module, the module must be appended with the last 330 words of the module's area, as the CSS header has been moved to the module's trailer. See Section 6.1.5.2 for more details.
8. Firmware posts an event completion on ARQ to software.
   a. Where applicable, software driver must save *RESET_FLAG* as returned by this command.
9. Software driver can release NVM ownership, or keep it until NVM Write Activate is completed.

   Note: An attempt to write to a ready double bank at this stage results in rollback of the previous write so that authentication must be done again on new write completion.
10. A Write command that modifies PFA TLV configuration (including VPD) can be called with the *Last* bit cleared to activate (dump to Flash) in the same time of the Bank Update Activation command. However, it is recommended to use the package data provided in the Get Package Data command to request PFA modifications.
11. If not already taken, software driver takes ownership over the NVM resource for a write.
12. Software driver sends an NVM Write Activate Command and states which modules need activation by setting a flag per module (NVM Bank, OROM, Topology Netlist). Shadow RAM Bank is written by default and does not require setting any flag. Only banks that were written completely (that is, the *Last* bit was set) can be activated. Firmware posts a fail response to the command if one of the following checks fails:
    a. All specified banks were written.
    b. If an NVM bank was written, it is also activated.
13. Firmware sets internal bit indicating that Flash and Shadow RAM are inconsistent.
14. If the command was issued from ACQ: From this point until command completion (Step 21), in case of a CORER/GLOBR/PFR, firmware triggers EMPR.
15. Firmware parses the content of the package data provided by the Set Package Data command and modifies the PFA accordingly.
16. Depending on preservation mode, firmware overwrites current PFA with the default PFA from the image (no preservation), replaces selected PFA fields in current PFA with the default ones from the image (selective preservation), copies the factory setting region to the PFA (restore to factory settings), or makes no changes to current PFA (full preservation).
17. In case of NVM module update, firmware compares the TLVs present in signed version of the PFA with the ones in the actual PFA. If a TLV is present in the signed PLA and is not the actual PFA, it is added to the actual PFA, replacing part of the padding TLV. It also checks if new features or new immediate fields are added to the PFA version of the signed NVM. If there are new features or immediate fields, they are copied with their default values to the PFA in the Shadow RAM.

a. If features changed, the firmware runs the ANVM flow to ensure that any affected PFA TLVs are updated.

Note: From this point until initiating the reset that will switch to the new firmware, NVM Write (0x703) to PFA or to any of the double banks is rejected.

18. The firmware changes the valid bit indication in Control Word 1.
19. The firmware dumps the Shadow RAM to Flash (see Section 3.4.5.2.1).
20. Firmware clears internal bit indicating that Flash and Shadow RAM are inconsistent.
21. The firmware posts an event completion on ARQ to software. It posts a completion/response to the last admin command of the sequence.
22. Software releases NVM ownership (see Section 9.5.13.7).
23. At this stage, if a new update is needed, the software can revert to previous state by using the NVM Write Active command with revert flag set. After that it can restart the flow for a new image.
24. Software checks the *RESET_FLAG* field.
25. Software Tools checks the value of the *RESET_FLAG* field in the event posted by firmware:
    - If *RESET_FLAG* == PERST, Software Tools notifies the user to reboot the system since it no ability to issue a PERST cycle (it can only ask the OS to do so).
    - If *RESET_FLAG* == POR, Software Tools notifies the users to reboot the system (to initiate a PERST cycle) as before.

    Note: In PLDM firmware update case, firmware sends feedback to BMC with the requested reset to activate the update.
26. Software may choose to activate the new Firmware in two ways:
    - Wait for the next PERST event — On the next PERST event, firmware also resets itself by issuing an EMPR cycle. In this case, the PERST can take a longer time to complete and might violate PCIe rules.
    - Send a NVM Update EMPR command, and then request for an immediate PERST event. In this case, the NVM Update EMPR command creates an EMPR, and the PERST will be faster and compliant with the PCIe rules. **The software should not initiate any NVM change between the two resets.**
27. Auto-load (driven by new Firmware) occurs from the new SR contents.
28. Software Tools checks that the destination map 'EETrackID' was loaded in Internal SR to verify that there was no spurious reset during update, causing ROM to load the wrong Shadow RAM bank.
    a. In case the original map 'EETrackID' is read from Internal SR, **Software Tools** restarts the flow from the beginning.
29. (New) firmware loads the new firmware code and other NVM settings into its Internal RAM.

Note: Contents of the old module cannot be erased by a software command prior to completing this flow.

3.4.5.6.1 GFID Handling

GFID is used to identify if two images are compatible. If the GFID of the current image is the same as the GFID of the new image, the new image can be used to upgrade the current one. In some cases, it is needed to allow a split of a single family of images to multiple families. As GFIDs must be defined as part of the first image released, a mechanism to move from one GFID to another is needed. Hence each image contains two GFIDs: an original GFID and a current one. The following algorithm is used to define if an image can be updated based on the two GFIDs in the current (Adapter) and next (Update) images:

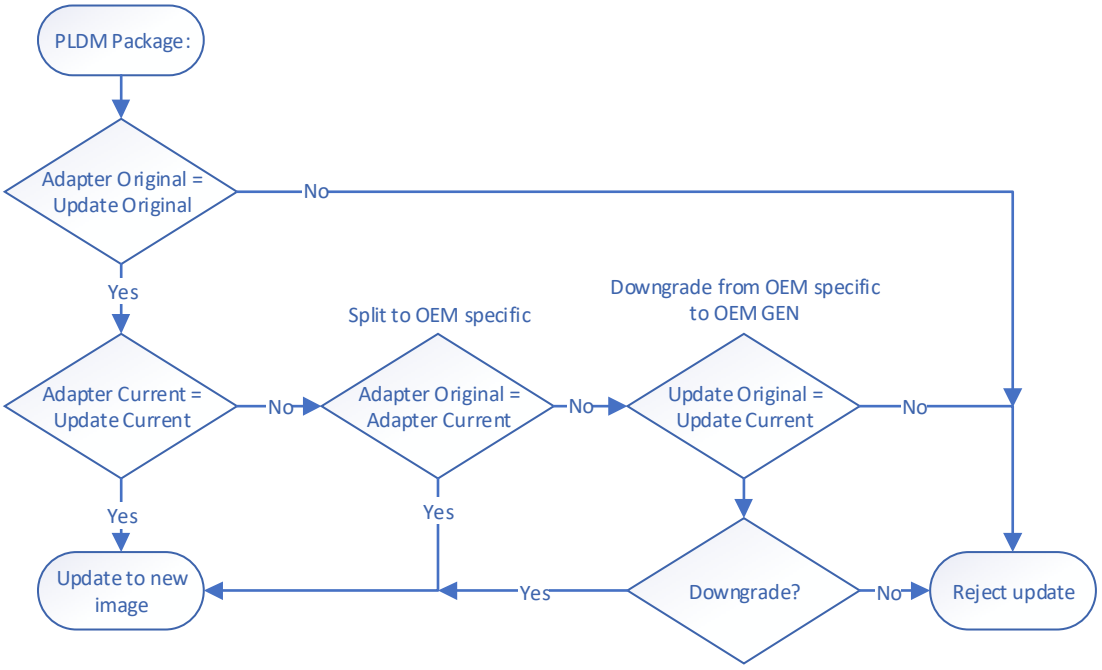

Figure 3-30. GFID Handling Flow

The GFIDs are stored in the non-PFA part of the Shadow RAM for the current image and in the package data of the PLDM header for the new image.

3.4.5.6.2 Recovery from Reset During Flash Update

In case a spurious reset occurs (other than POR) before the update sequence is fully completed, the following flow is used to recover:

1. Firmware issues a graceful EMPR cycle, notifying **Software Tools** about the event.
2. **Software Tools** report to user that the update has failed. Software is notified by interrupt on the fact the firmware was reset.
3. User restarts the flow from the beginning.

3.4.5.7 Flash Wear-Out Protection

This mechanism prevents Flash part wearing out by malicious software. This mechanism blocks excessive Flash erase operations.

Assuming a typical Flash device endurance is ~100,000 erase/program cycles and the required system lifespan is 10 years, a Flash erase can happen every 10 (years)*365(days/year)*24(hours)*60(minutes)/100,000 = ~53 minutes.

The E810 does not have access to the real-time clock, and its clocks do not survive a POR reset. As a result, the algorithm has some limitations related to POR resets. Assuming a POR is not a frequent event that can not be initiated by malicious software, it does not pose a problem.

Note: An entry to the Sx power state is equivalent to power-on reset for the systems with no AUX power.

The simple algorithm described in Figure 3-31 is credit-based. Separate credits are counted for every erase unit. To avoid credit counter proliferation, the number of erase units is limited to the following blocks, while more blocks can be added in future if there is such a need:

- Two NVM Banks
- Two OROM Banks
- Two persistent SR Banks
- Two TLV Extension Banks
- Link topology Scratch Pad Area
- Firmware Scratch Pad Area

It is noted that limiting the number of units requires modification of the NVM update flows to allow only the whole unit erase at a time, blocking the per-sector erase operations. To simplify system validation and Flash content update after the first power-on of the system, there are initial credits assigned to each unit.

The recommended values for the initial and maximal credits are 2000 (2%) and 5000 (5%), correspondingly. These values are stored in the signed part of the NVM image.

The algorithm is presented in Figure 3-31.

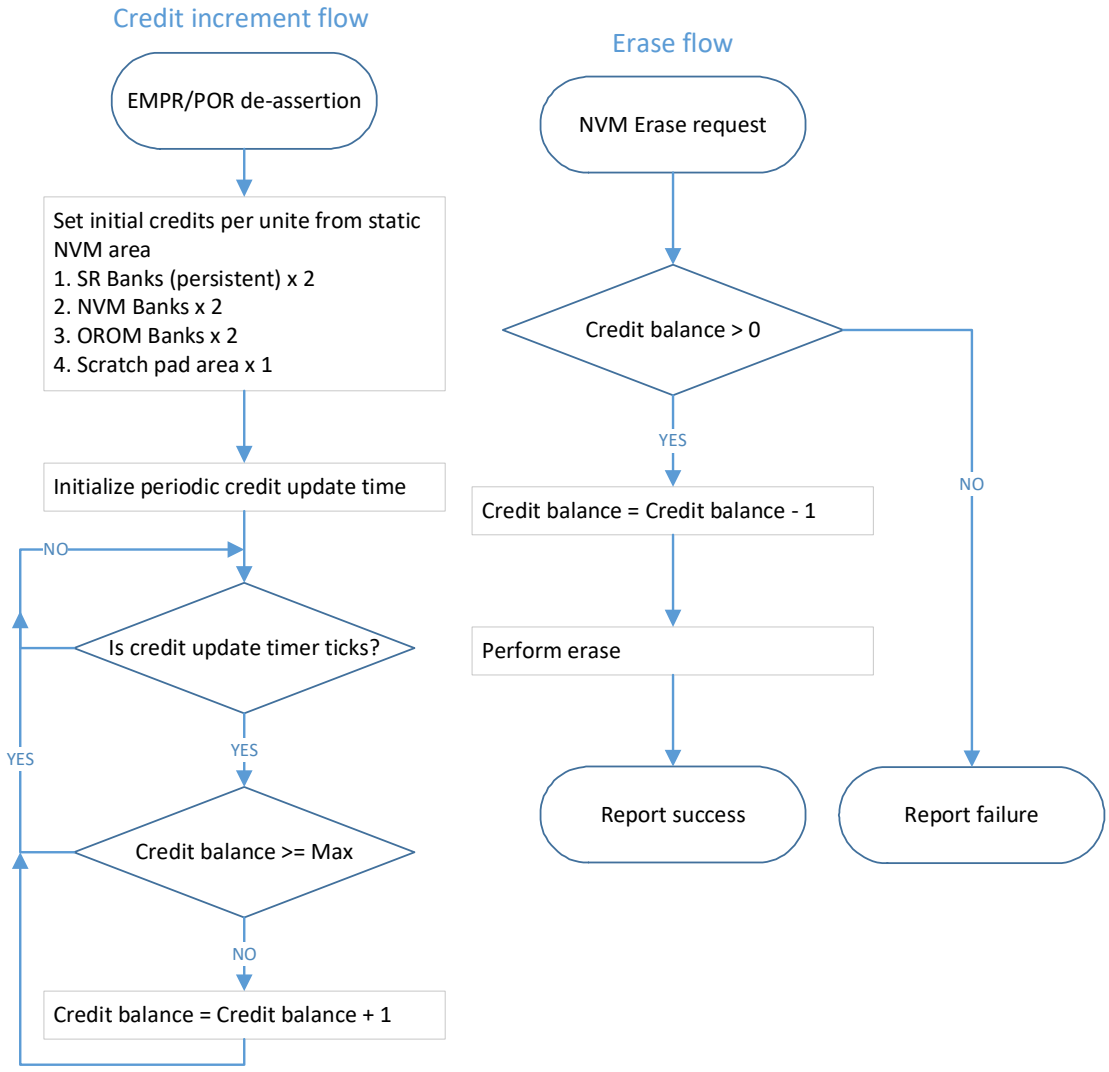

Figure 3-31. Flash Wear-Out Protection Algorithm[1]

1. Credit update time is once per hour.

3.4.5.8 Save Factory Settings AQC

This section describes the flow executed by the Save Factory Settings Command (see Section 3.4.10.9).

3.4.5.8.1 Save Factory Settings Flow

The following flow is run by the Save Factory Settings admin command (opcode 0x0708) and can be used by manufacturing tools to modify the image before programming the device.

- Word pointer to PFA in internal Shadow RAM (iSR) is located at iSR word offset 0x40.
- PFA word size is at first PFA word.
- Word pointer to netlist is located at iSR word offset 0x46.
- Netlist word size is at second netlist word.
- Word pointer to Factory Settings is located at iSR word offset 0x61

Flow:

1. Verify PFA checksum.
2. Check that Factory Settings (FS) password is “0xFFFF”.
3. Setup a variable to keep FS size within limits in init module word offset 0x62.
4. Copy PFA content from iSR to Factory settings PFA area (offset 32B from address in word 0x61).
5. Copy netlist content from valid netlist bank to Factory Settings netlist area (offset 32B + PFA size from address in word 0x61).
6. Set FS header fields located at the first 32 bytes of Factory Settings:
   - password = 0x2811
   - Size = 32B + PFA size + netlist size
   - TLV_Extension_Offset = 32B + PFA size
   - TLV_Extension_Size = netlist size
   - CIR_AL_Offset = PCIR AL section byte offset relative to PFA start. TLV 0x133.
   - POR_AL_Offset = POR AL section byte offset relative to PFA start. TLV 0x118.
   - PCI_Serial_ID_MAC_Offset = PCI Serial ID MAC section byte offset relative to PFA start. TLV 0x133.
   - Set all reserved bytes to '0'

3.4.6 NVM Clients and Low-Level Interfaces

There are several clients that can access the NVM to different address ranges via different access modes, methods, and low-level interfaces. The various clients to the NVM are hardware, Software Tools (BIOS, and so on), drivers, EMP, PE, BMC (via EMP), and VPD software.

Table 3-55 lists the different accesses to the NVM.

Table 3-55. Clients and Access Types to the NVM

Client	NVM Access Method	Accessed Programmed Against	Logical Byte Address Range	NVM Access Interface (CSRs or Other)
VPD Software	Parallel (32-bits)	Shadow RAM	0x000000 - 0x0003FF from VPD module beginning	VPD Address and Data registers. Any write access is immediately pushed by the E810 into the Flash.
PF Software	Parallel via Memory (CSR) BAR (32-bit read)	Flash Part	0x000000 - 0xFFFFFF	The address is relative to the beginning of the Flash. See Section 13.1.2.1 for details of the Flash offset within the CSR BAR.
	Parallel via Option ROM BAR (32-bit read only).	Flash Part	0x020000 - 0xFFFFFF	This logical address range is relative to the beginning of the Option ROM module.
	Via AQC	Flash Part/ Shadow RAM	0x000000 - 0x00FFFF	NVM Read, NVM Erase, and NVM Write admin commands as described in Section 3.4.10.

3.4.6.1 Memory-Mapped Host Interface

The Flash is read by the E810 each time the host CPU performs a read operation to a memory location that is within the Flash address mapping, or upon boot via accesses in the space indicated by the Option ROM Base Address register. Accesses to the Flash are based on a direct decode of CPU accesses to a memory window defined in either:

- **Memory CSR + Flash Base Address register (PCIe Control register at offset 0x10)** — The Flash address space is exposed to the host memory BAR when the *Flash Expose* bit is set in the NVM (or the GLPCI_LBARCTRL.*FLASH_EXPOSE* CSR bit is set), or when the E810 is in blank Flash programming mode. The Flash size exposed is 16 MB. Refer to Section 13.1.1.2 for more details.
- **The Option ROM Base Address register (PCIe Control register at offset 0x30)** — The OROM module address space is exposed to the Option ROM BAR if the Flash is not blank and the Expansion ROM base address register contains a valid (non-zero) base memory address. Otherwise the BAR is not exposed. The Flash size exposed is retrieved from the GLPCI_LBARCTRL.*EXROM_SIZE* CSR field, and is 1 MB by default. The E810 is responsible to map read accesses via the Option ROM BAR to the physical NVM. Write attempts to the Flash through this BAR are not performed, and are silently dropped. The offset in the NVM of the Option ROM module is defined by the PCIe expansion/ Option ROM pointer (Flash word address 0x05). This pointer is loaded by the E810 from the Flash before enabling any access to the Option ROM memory space.
  - When modifying the PXE driver section pointer in the NVM, it is required to issue a PCIe reset on which the updated offset is sampled by hardware.
  - If there is no valid NVM validity field in the two basic banks, the Option ROM BAR is disabled.

The E810 controls accesses to the Flash when it decodes a valid access. Out of range memory-mapped read access returns arbitrary data.

Refer to Section 3.1.2.2.1 for details on memory/Option ROM BAR access rules.

Notes:

- Flash read accesses are assembled by the E810 each time the access is greater than a byte-wide access.
- The E810 byte reads to the Flash take about 2 to 30 µs. The E810 continues to issue retry accesses during this time.
- During normal operation, the host avoids memory-mapped accesses to the first two basic banks of the Flash because it might be non-coherent with the Shadow RAM contents.

Prior to initiating an NVM read cycle via memory-mapped access, PF software is required to take ownership over the NVM resources. Refer to Section 9.5.13.6.

3.4.7 Flash Access Contention

Flash read accesses initiated through PFs might occur concurrently to the firmware modifying the NVM contents. The E810 does not synchronize between the different entities accessing the Flash, so contentions caused from one entity reading and the other modifying the same locations is possible.

To avoid such a contention between software and firmware accesses, these entities are required to make use of the NVM ownership take/release flows for any read or write access to NVM (see Section 9.5.13.6 and to Section 9.5.13.7 for more details). This is also useful to avoid the timeout of the PCIe transaction made to a memory mapped Flash address while the Flash is currently busy with a long sector erase operation.

However, two software entities cannot use the NVM ownership acquire/release mechanisms: BIOS reading through Expansion ROM BAR and VPD software. A BMC requesting firmware update via PLDM firmware update also does not require a semaphore.

- Since VPD software accesses only the VPD module, which is located in the first valid bank of the NVM, VPD accesses are always performed against Shadow RAM first. In this case, the firmware must take/release ownership over the NVM as if it was the originator of the Flash access. It is then the responsibility of hardware/firmware to update the NVM according to the Flash update sequence described in Section 3.4.5.3.
- No contention can occur between BIOS and any other software entity (VPD included) as it accesses the NVM while the operating system is down.
- The firmware takes care of the semaphore ownership for PLDM firmware updates.

However, since BIOS cannot take ownership over the NVM resource, it might be that the Flash part is not accessible when BIOS attempts reading it. This might occur if a Flash erase operation was performed just before PCIe reset. In such a case, read accesses via the Option ROM BAR returns 0xDEADBEEF.

- It is assumed that the Option ROM signature check performed by BIOS fails in this case.
- The firmware must avoid initiating sector erase operations at boot time.
- It is assumed and recommended that users do not attempt to update the NVM contents via the BMC while the system is rebooting.
- The BMC delays PERST# de-assertion or boot running until after the BMC completes any OOB accesses to Flash memory. It is required to route the wake-up signal from the standby button to the BMC and not to the chipset. The BMC issues a system reboot signal to the chipset only after any NVM write access completes.
- If a system reboot is issued by a local user running on the host, there is no technical way to avoid contention in this case.

Note: It is the user's responsibility when accessing the NVM remotely via the BMC to ensure that another user is not currently initiating a local host reboot there.

- The firmware's responsibility to take NVM ownership on the BMC account prior to performing any NVM read or write access, which is needed for handling an NC-SI command. The NVM ownership is released by the firmware together with completing the NC-SI command. If NVM ownership is not free when processing the NC-SI command, the command completes with a Package Not Ready status.

3.4.8 NVM Access Procedures

Any software read/write or firmware write flow described in this section (except flows executed by VPD software or by BIOS or to flows executed when in blank Flash programming mode) must be preceded by taking NVM ownership. Anytime software is taking NVM ownership, it must re-read the pointers to the module it plans to access because they might have been modified by the firmware in between two ownership takings.

Refer to Section 9.5.13.6 and Section 9.5.13.7 for the NVM ownership taking/releasing procedures as well for the associated timeouts.

3.4.8.1 Auto-Load

This section describes only the auto-load/init tasks relative to NVM. Firmware is solely responsible for all auto-loads and initialization flows described in this section.

Firmware initialization performed at power-up and EMPR events consists for three steps, while DIGEST updating (discussed in Section 3.4.8.1.2) is done at each step:

1. ROM flow:
   a. Find a valid NVM content.
   b. Load the Extended mini-loader to the local RAM and authenticate it.
   c. Jump to the mini-loader code entry point.
2. Mini-loader flow:
   a. Auto-load time-critical NVM section, which is a part of the Extended mini-loader and the persistent Shadow RAM bank. Starting from this point, mini-loader is ready to handle time-critical PCIe auto-loads.
   b. Read the Shadow RAM content to the local RAM from the NVM.
   c. Read the whole NVM bank to the local RAM and authenticate it. The EMP firmware is placed in the local RAM at this moment, while most of the other content is discarded after the authentication.
   d. Jump to the EMP Firmware entry point.
3. EMP Firmware flow:
   a. Perform auto-load on every PCIe, CORER, and GLOBR resets.
   b. Initialize all firmware code being ready to handling all runtime events.
   c. Report initialization completion to the host software.

Simplified NVM Bank and Extended mini-Loader maps are shown in Figure 3-32 for better understanding of the initialization flows.

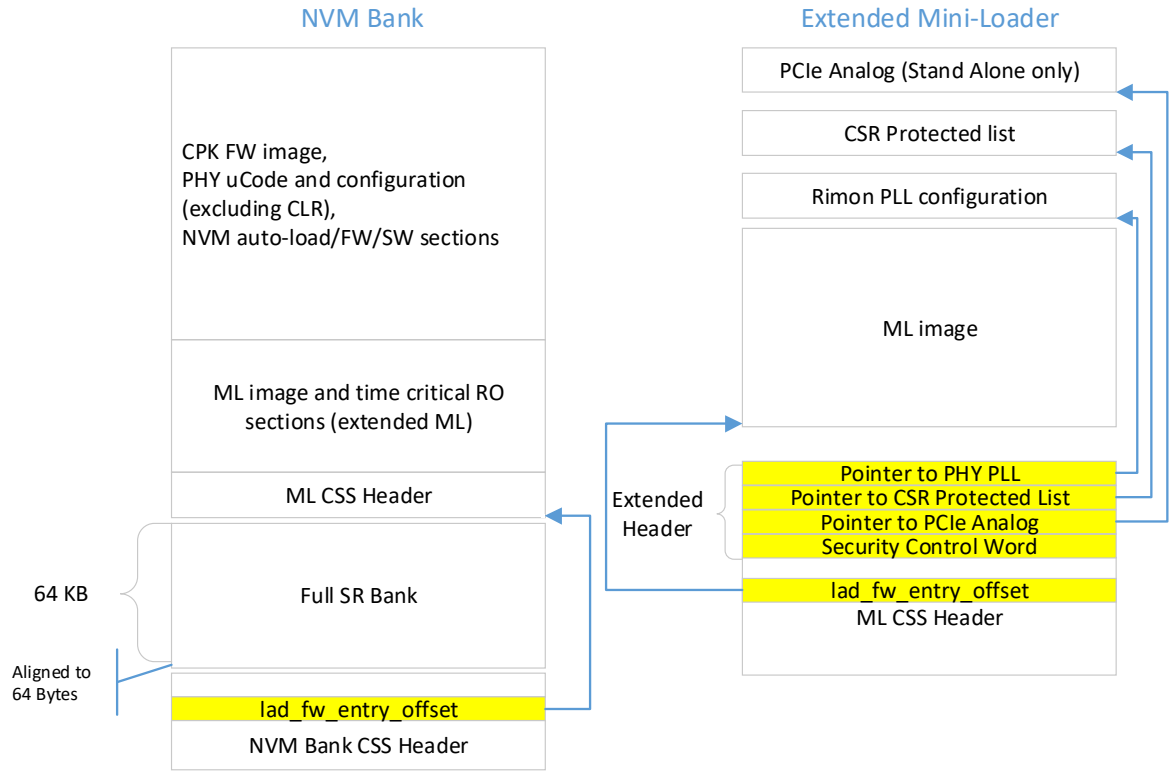

Figure 3-32. Simplified NVM Bank and Extended Mini-Loader Maps

3.4.8.1.1 EMP Firmware Init Flow

The firmware is ready to PERST de-assertion handing during the flow. Such an event must be handled within 20 ms.

1. Run the adaptive NVM initialization flow using feature selections in PFA on the Shadow RAM copy in RAM. No Shadow RAM dump is required since the same initialization occurs after every POR reset.
2. Proceed initialization firmware initialization.

3.4.8.1.2 Firmware Measurement for Remote Attestation

A new *Controller Firmware Management System Architecture Specification* requires performing of remote attestation to prove the firmware identity. The EMP firmware is required to expose firmware measurement to the host software. This measurement is represented by the cryptographic identity of all firmware components.

Two 32-byte DIGEST registers (GL_MNG_SHA_EXTEND in Section 13.2.2.29.3 and GL_MNG_SHA_EXTEND_ROM in Section 13.2.2.29.5) are implemented in the E810 for this purpose. Another GL_MNG_SHA_EXTEND_STATUS register (Section 13.2.2.29.4) exposes the measurement status.

Note: The GL_MNG_SHA_EXTEND_ROM and GL_MNG_SHA_EXTEND are writable only once after each EMP reset.

Firmware flow:

1. The E810 ROM locates the E810 mini-loader.
   a. If the mini-loader is not found[1], the E810 ROM sets GL_MNG_SHA_EXTEND_ROM to the ROM version, sets GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 001b, sets GL_MNG_SHA_EXTEND_STATUS.*FW_HALTED*, sets GL_MNG_SHA_EXTEND_STATUS.*DONE*, and moves to blank Flash programming.
2. If mini-loader is found, the mini-loader header contains a SHA256 hash of the mini-loader and signature over the hash. The E810 ROM authenticates mini-loader.
   a. If the authentication is successful, the E810 ROM writes the mini-loader hash value to the GL_MNG_SHA_EXTEND_ROM register and sets GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 010b. In this case, the computed mini-load hash matches what is in the header, and the ROM loads the mini-loader and passes control to it.
   b. If the authentication fails, the E810 ROM writes the computed mini-loader hash value to the GL_MNG_SHA_EXTEND_ROM register, sets GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 010b, sets GL_MNG_SHA_EXTEND_STATUS.*FW_HALTED*, sets GL_MNG_SHA_EXTEND_STATUS.*DONE*, and halts.
3. The E810 mini-loader locates the E810 firmware header. If the firmware is not found, the E810 mini-loader sets GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 011b, sets GL_MNG_SHA_EXTEND_STATUS.*FW_HALTED*, sets GL_MNG_SHA_EXTEND_STATUS.*DONE*, and moves to blank Flash programming.
4. Firmware header contains a SHA256 hash of the firmware image. Note that the E810 mini-loader is contained within firmware. The E810 mini-loader authenticates the complete firmware image.
   a. If the authentication is successful, the E810 mini-loader writes the firmware hash value to the GL_MNG_SHA_EXTEND register. In this case, the computed firmware hash matches what is in the header. The E810 mini-loader sets the following:
      - GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 100b
      - GL_MNG_SHA_EXTEND_STATUS.*DONE*
   b. If the authentication fails, the E810 mini-loader writes the computed firmware hash value to the GL_MNG_SHA_EXTEND register. The E810 mini-loader sets the following, then halts:
      - GL_MNG_SHA_EXTEND_STATUS.*STAGE* to 100b
      - GL_MNG_SHA_EXTEND_STATUS.*FW_HALTED*
      - GL_MNG_SHA_EXTEND_STATUS.*DONE*

Software flow:

1. Poll the GL_MNG_SHA_EXTEND_STATUS.*DONE* until set.
2. Keep value of GL_MNG_SHA_EXTEND_STATUS
3. Read the GL_MNG_SHA_EXTEND and GL_MNG_SHA_EXTEND_STATUS registers.
4. Reread the GL_MNG_SHA_EXTEND_STATUS register and check the value is the same as saved. If not, the firmware might have been reset during the read process.

   Note: The complete read flow should complete within 100 ms to guarantee that a full reset cycle did not occur in between.
5. If GL_MNG_SHA_EXTEND_STATUS.*FW_HALTED*, the firmware load did not succeed.
6. The GL_MNG_SHA_EXTEND_STATUS.*STAGE* indicates the latest firmware stage authenticated.

1. If the RSA key verification fails, this is considered as if mini-loader is not found.

3.4.8.2 VPD Accesses

The VPD module (VPD area) is mapped into the valid basic bank and it is thus mirrored in Shadow RAM. It is accessed by VPD software via the PCIe VPD capability structure. Refer to Section 3.4.5.3 for more details.

3.4.9 NVM Authentication Procedure

The NVM update integrity feature ensures that only Intel-approved firmware code (or another protected NVM module) is able to run on E810 devices after manufacturing. This procedure is performed by mini-loader and ROM-code on every initial program load and by a RAM-based firmware each time an attempt is made to update one of the protected modules. Refer to NVM update flows in Section 3.4.5 for more details. The OROM image is not authenticated by EMP on initial program load. It is authenticated only on OROM updates.

Integrity validation of NVM updates is provided by means of a digital signature. The digital signature is a SHA256 hash computed over the protected content (256 bits long) that is then encrypted by a 2048-bit RSA encryption using an Intel private key. This digital signature is stored in what is called the manifest in the NVM module image. Also stored in the manifest is the corresponding RSA modulus (public key) and RSA exponent to be used to decrypt the digital signature. Refer to Section 6.1.5 for more details.

To verify the authenticity of the digital signature of the mini-loader, EMP ROM must first verify that the SHA256 hash of the RSA Modulus and RSA Exponent fields in the new module loaded are identical to those retrieved from fuses. If the hash of the RSA *Modulus* and *Exponent* fields match the value in the fuses, EMP decrypts the digital signature using the 2048-bit RSA Modulus and Exponent fields stored in the manifest to extract the expected SHA256 hash of content (stored hash). EMP then performs an independent SHA256 hash over the protected content (computed hash). If the stored hash matches the computed hash, the digital signature is accepted and the NVM module update is applied.

When the mini-loader authenticates the digital signature of the full firmware or the recovery firmware, or when authentication occurs as part of a firmware update, the key hash in the authenticated firmware is compared with the one of three key hash values stored in the extended mini-loader:

- NVM Key hash (used for NVM and recovery)
- OS package key hash
- OROM key hash

NVM updates are validated prior to invalidating the old NVM configuration, such that the old NVM configuration is still usable if the update fails to validate. After the new NVM is successfully verified, the updated image is committed to the E810's Flash by the EMP.

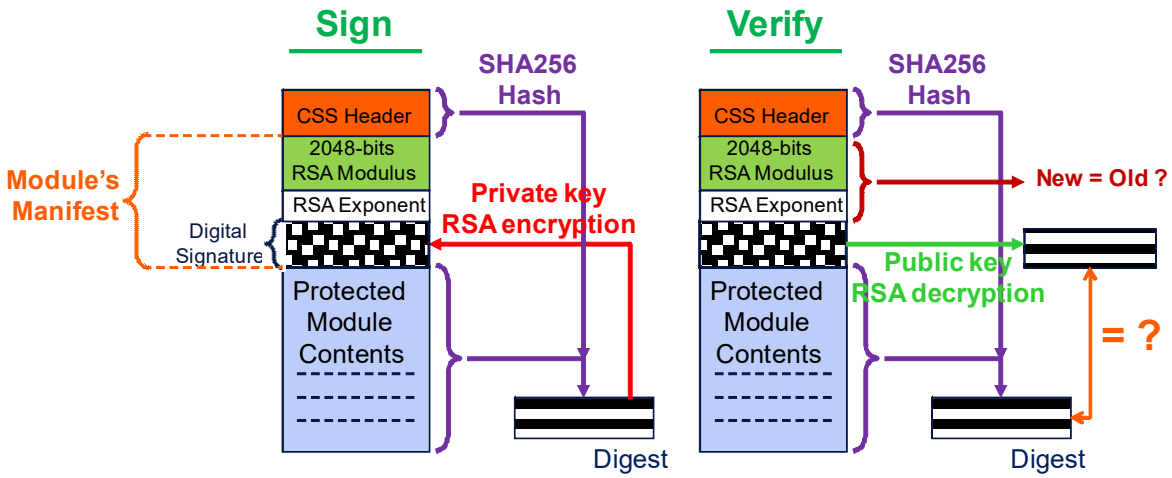

Figure 3-33. Sign and Verify Procedures for Authenticated NVM Modules

3.4.9.1 Digital Signature Algorithm Details (Not Updated with CA Certificate)

As previously mentioned, the digital signature generation is a hash computation followed by an RSA encryption. This is performed within Intel as part of the NVM update image generation process and not performed by Intel software in the field, nor by the E810.

The algorithms used are described in the following locations:

- PKCS #1 v2.2: Encoding method - EMSA-PKCS1-v1_5:

  https://tools.ietf.org/html/rfc8017

- SHA family definition:

  http://nvlpubs.nist.gov/nistpubs/FIPS/NIST.FIPS.180-4.pdf

- SHA usage with digital signatures:

  http://csrc.nist.gov/publications/nistpubs/800-107/NIST-SP-800-107.pdf

- SHA validation vectors:

  http://csrc.nist.gov/groups/STM/cavp/documents/shs/SHAVS.pdf

Note: The protected module contents shown in Figure 3-33 starts with the CSS header, skips the RSA Pubic key, RSA exponent and Encrypted SHA256 hash, continues from the E810's Blank NVM Device ID word of the NVM header described in Section 6.1.5.2, and ends at the offset defined by the size field in the CSS header.

3.4.9.2 Intel Key Generation and Intel Code Signing System

The integrity of NVM digital signatures requires not only robust private RSA key generation but also continued protection of these private keys into the indefinite future as well as a method to generate new signed images using the existing private keys.

Intel's CSS follows the PKCSv2.2 format with 2048-bit RSA keys and SHA-256 hash - RSA-PSS. The CSS algorithm requires a standard manifest header to appear at the beginning of all signed modules.

The manifest header (represented in C syntax) is as follows:

```
typedef struct _CssHeader {
  uint32 moduleType;          // Reserved CSS field.
  uint32 headerLen;           // Reserved CSS field.
  uint32 headerVersion;       // Reserved CSS field.
  uint32 moduleID;            // Reserved CSS field.
  uint32 moduleVendor;        // Reserved CSS field.
  uint32 date;                // Reserved CSS field.
  uint32 size;                // In DWords - Reserved CSS field.
  uint32 keySize;             // Reserved CSS field.
  uint32 modulusSize;         // Reserved CSS field.
  uint32 exponentSize;        // Reserved CSS field.
  uint32 lad_srev;            // Internal security revision field.
  uint32 reserved;            // Reserved for future use.
  uint32 lad_fw_entry_offset;// ND-specific offset from start of CSS header of the
                                firmware code in WORDS.
  int32 reserved;             // Mandatory field, in use by previous project.
  uint32 lad_image_unique_id;// Internal unique identifier for the specific NVM image
                                version.
                              // Taken from NVM Software Reserved Words 22, 23 (a.k.a.
                                 EETRACK ID). N/A for mini-loader CSS header.
  uint32 lad_module_id;       // Internal and per device unique identifier for NVM
                                 module. Is one of the following values:
  * 0x5 for Option ROM
  * 0x6 NVM Bank
  uint32 reserved[16];        // Mandatory field, but free for use.
} CssHeader;
```

The CSS header must be placed at the beginning of the integrity-checked data. Software Tools are also required to pre-process raw NVM images to prepend the manifest prior to CSS tool chain submission. All fields marked Reserved CSS Field must be zero when submitting to the CSS tool chain.

The E810 CSS header includes a Security Revision (*lad_srev*) field. This field is monotonically updated for each and every security-related update to the NVM. If a security exploit is detected and an updated NVM image is released with an incremental security revision, the E810 does not allow an NVM image roll-back to an earlier version because this might expose previously known vulnerabilities. Security version checking can be temporarily disabled by manageability command.

There are four instances of the Security Revision (lad_srev) field:

- NVM module Security Revision
- Extended Mini-loader Security Revision
- Recovery Firmware Security Revision
- OROM Security Revision

The following policy applies:

- NVM module Security Revision and Recovery Firmware Security Revision should increase together.
- Extended Mini-Loader Security Revision need not increase even if others changes.
- OROM Security Revision can increase independently of the others.

Notes:

- Not all NVM updates need to have an incremental security revision. A roll back of updates to non-security related parameters (such as firmware patches where the Security Revision field is equal to the existing image) are allowed.
- The size field gives the entire module size including the CSS header itself. It is expressed in DWords.

The usage of SREV is optional, and users should opt in for the SREV to take effect. Opting in is done by updating the matching Min Srev value in the MinSrev TLV.

Note: Only the NVM Module and OROM module Min Srev are represented in the MinSrev TLV, as the Recovery Firmware Security Revision is always the same as the NVM module Security Revision, and the Extended Mini-loader Security Revision is always lower or equal to the NVM module Security Revision.

3.4.9.3 Protected Modules

Any data that is modified in the field (either by the OEM during manufacturing or by the end user) cannot be included in the signed region of the NVM. The E810 cannot generate a signed image by itself because the private key is not available to it to generate the digital signature in the NVM.

Only the following NVM modules require authentication in the E810. Each module is with its own digital signature:

- Option ROM
- NVM bank

3.4.9.4 Software Requirements

A software tool must prepare NVM images for the CSS signing step, pre-pending the CSS manifest, and applying an Intel security revision field. After receiving the signed image, the tool merges the excluded fields back into the NVM image and performs an internal integrity check to verify that the merge was successful (such as a software computation of the digital signature passes).

SVTools (LANConf) MUST implement an NVM update image integrity check option in software prior to applying NVM updates to hardware. SVTools might integrate capabilities to generate self-signed NVM images to assist in the SV and debug process by developers.

CELO (or equivalent manufacturing diagnostics tool) must implement a test to check the GLNVM_FLA.*LOCKED* bit state as part of manufacturing qualification. If after the NVM is programmed, and the E810 powers up with the GLNVM_FLA.*LOCKED* bit not set, an inappropriate NVM image has been loaded during manufacturing (an NVM image with incorrect Flash opcodes). This represents a critical error. With GLNVM_FLA unlocked, unauthorized in-the-field updates can bypass designed firmware integrity checks.

Host software device drivers might implement an interface enabling a network administrator to perform an internal verification check of the signed NVM image. Using Windows drivers, this would take the form of an OID, which reports a SUCCESS or INVALID_PARAMETER. Using Linux, an **ethtool** command extension is advised to enable command line interrogation of the NVM content using the hash value built into the hardware, as well as the saved CSS manifest in the NVM image.

3.4.9.5 Manufacturing Requirements

3.4.9.5.1 Factory Settings Preservation Flow

Manufacturing information should be stored at the end of board manufacturing to the 'Factory Settings' section that is read only to software and is located outside of NVM banks. This section includes the active PFA, active Topology Netlist and a 32B header.

Update of this section can be done only once, by firmware via the Save Factory Settings AQC (see Section 3.4.10.9 or by Software Tools in Blank Flash Programming mode.

The AQC will fail with EMODE error if the 'Factory Settings' section is not entirely erased.

This section will never be modified in any NVM update.

The entire active PFA can be reset to factory settings by software via the NVM Write Activate Command AQC (see Section 3.4.10.8) using preservation mode 10b.

Software default to recover PFA & netlist should be 'return to factory settings'.

If software uses the 'return to signed default' option, following the update, firmware is required to restore MAC Addresses from factory settings at the next firmware load.

After recovery has been completed and normal mode firmware is running, software can do additional updates to modify PFA.

3.4.9.5.2 End-of-Line Verification

OEMs must execute CELO (or an equivalent manufacturing diagnostics tool) to verify the GLNVM_FLA.*LOCKED* bit state (as described in Section 3.4.9.4).

3.4.10 NVM Access Admin Commands and Events

NVM access commands are not supported when the E810 is in the blank Flash programming mode. They are available only to the PFs once it has acquired NVM ownership via the commands described in Section 9.5.13.6.

Table 3-56. NVM Access Admin Commands and Events

Command	Opcode	Description	Section Reference
NVM Read	0x0701	Read a segment from the NVM into a host buffer.	3.4.10.1
NVM Erase	0x0702	Erase consecutive 4 KB sectors of the Flash.	3.4.10.2
NVM Write	0x0703	Write a segment of the NVM from a host buffer.	3.4.10.3
NVM Config Read	0x0704	Read feature selections.	3.4.10.4
NVM Config Write	0x0705	Program Feature Selections.	3.4.10.5
NVM Checksum	0x0706	Update PFA checksum.	3.4.10.7
NVM Write Activate	0x0707	Activate new NVM.	3.4.10.8
Save Factory Settings	0x0708	Save factory settings	3.4.10.9
NVM Update EMPR	0x0709	Reset after new firmware update.	3.4.10.10
Set Package Data	0x070A	Provide package data to firmware.	3.4.10.11
Pass Component Table	0x070	Check if new module is compatible with current one.	3.4.10.12

Note: All parameters in the admin commands are defined in little endian.

3.4.10.1 NVM Read (0x0701)

This command is useful especially if the host memory-mapped access to the NVM was not enabled with the intent to save memory address space.

Table 3-57. NVM Read Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0701	Command opcode.
Datalen	4-5		Length in bytes of command buffer
Return Value/VFID	6-7		Return value. Zeroed by the device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Offset	16-18		Offset in the module, which is expressed in bytes from the pointed module's beginning. This is the byte offset of the first byte returned in the data buffer.
Command Flags	19		NVM Access Admin Command Parameters **Bit 19.0:** Last Command Bit Used to notify EMP that this is the last admin command of a sequence. **Bit 19.7:** Read from Flash When Bit 7 is set, the read is done directly from the Flash and not from Shadow RAM. Relevant only if access address is below 64 KB. Ignored otherwise, so above 64 KB the read is always from the Flash, only when Module_TypeID is zero. **All other bits** = Reserved. Must be zeroed. Only one Module type is read at a time. For PFA TLVs only the length+data portion of the TLV is read (not the *TLV Type*). See Table 6-5 for TypeID values.
Module_TypeID	20-21		A value of 0x0000 means that the command is performed over the Flash part seen as a flat memory.
Length	22-23		Length of the section to be read, which is expressed in bytes from the offset in the module. A value of 0xFFFF means the last byte to be returned is the last byte of the module (if byte 17 was not set to 0x0000). In any case, a (single) read command is limited up to 4 KB.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

Table 3-58. NVM Read Response

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0701	Command opcode.
Datalen	4-5		Number of bytes the were read. If a value of 0xFFFF was set in the admin command (and if byte 17 was not set to 0x0000), this field returns the length from the offset to the module's end unless it is above 4K.
Return Value	6-7		Return value. 0x0 = No error (success). EPERM = The module pointer location specified in the command does not permit the required operation. The word contents is not a pointer. EINVAL = Out of range offset/length (beyond the module's size). EIO = Flash defect. EBUSY = The PF is not permitted to post this command because it does not own the NVM resource. This error code is also returned if the PF attempts to post a command while another NVM command is in process.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Offset	16-18		Offset in the module, copied from the command.
Reserved	19		Reserved.
Module_TypeID	20-21		*Module_TypeID* copied from the command.
Length	22-23		Length in bytes of command buffer.
Data Address High	24-27		Address of command buffer. The buffer contains the read data.
Data Address Low	28-31		

3.4.10.2 NVM Erase (0x0702)

This command is used to erase the contents of 4 KB Flash sectors.

Table 3-59. NVM Erase Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0702	Command opcode.
Datalen	4-5		Must be zeroed by the software device driver.
Return Value/VFID	6-7		Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-18		Reserved.
Command Flags	19		NVM Access Admin Command Parameters **Bit 19.0:** Last Command Bit Used to notify the EMP that this is the last admin command of a sequence. **All other bits** = Reserved. Must be zeroed.
Module_TypeID	20-21		The only valid TypeIDs are: • 1st NVM Bank Pointer (0x42): Non-valid bank erase. • 1st OROM Bank Pointer (0x44): Non-valid bank erase. • 1st TLV Extension Bank Pointer (0x46): Non-valid bank erase. • One of the scratch pad pointers (0x4B, 0x50, 0x59).
Reserved	22-31		Reserved.

This is an asynchronous command. The EMP reads the command from the ATQ and writes back an immediate completion, intended only as an ACK/NACK that the command has been addressed by the EMP. The EMP checks the validity of the command and returns an error (NACK) on the ATQ completion if it is unable to process the command. If successful (ACK), the EMP then schedules the NVM Erase operation to be performed by a lower priority thread, which can be preempted by other AQ commands.

Once completed, the EMP posts a completion event on the ARQ. Software must hold the NVM resource lock while performing this operation and must release it once the full NVM operations complete (assuming the erase is part of an update sequence).

Software must not post another NVM command while this command is in process. For example, during the time between posting the request on the ATQ and receiving the completion event on the ARQ.

Table 3-60. NVM Erase Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0702	Command opcode.
Datalen	4-5		Reserved.
Return Value	6-7		Return value. 0x0 = No error (success). EPERM = The module pointer location specified in the command does not permit the required operation. The word contents is not a pointer to a next bank area. EBUSY = The PF is not permitted to post this command because it does not own the NVM resource. This error code is also returned if the PF attempts to post a command while another NVM command is in process. EACCESS = Attempt to erase a non erasable area.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31		Reserved.

Table 3-61. NVM Erase Completion (on ARQ)

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0702	Command opcode.
Datalen	4-5		Reserved
Return Value	6-7		Return value. 0x0 = No error (success).
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-17	0x0	Reserved. Must be zeroed
Reserved	19		Reserved.
Module_TypeID	20-21		Copied from the command.
Length	22-23		Copied from the command. If a value of 0xFFFF was set in the admin command, this field returns the length from the offset to the module's end in 4 KB units.
Reserved	24-31		Reserved.

3.4.10.3 NVM Write (0x0703)

This command is used to write the data given by the attached buffer into a specified location in the NVM. Erasing the relevant sector(s) by posting NVM erase command(s) (see Section 3.4.10.2) is required prior to posting this command.

For double bank updates (like Module_TypeId = 0x42, 0x44, 0x46), the command must be followed by the NVM Write Activate command for a bank update to take effect.

Table 3-62. NVM Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0703	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7		Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Offset	16-18		Offset, which is expressed in bytes from the pointed module's beginning. This is the byte offset of the first byte to be written. Offset of zero points to the section length. However the length is not overwritten.
Command Flags	19		NVM Access Admin Command Parameters **Bit 19.0:** Last Command Bit Used to notify EMP that this is the last admin command of a sequence. ***Note:*** Setting the *Last* bit causes a Shadow RAM dump, but it is recommended to use the NVM Write Activate to achieve this. **Bit 19.6:** Allow Special Update Set to allow change of MinSrev TLV. **All other bits** = Reserved. Must be zeroed.

Table 3-62. NVM Write Command [continued]

Name	Byte.Bit	Value	Remarks
Module_TypeID	20-21		Module TypeID The only valid init module pointers are: • 0x00: Flat memory view • 1st NVM bank pointer (0x42): Non-valid bank. • 1st OROM bank pointer (0x44): Non-Valid Bank. • 1st TLV Extension Bank Pointer (0x46): Non-valid bank. • One of the scratch pad pointers: — Firmware scratch pad pointer (0x50) — Link Topology scratch pad pointer (0x4B) • PFA TypeIDs not included in the list below (see Table 6-5). A value of 0x00 here means that the command is performed over the Shadow RAM part seen as a flat memory. No reset or pointer switch is initiated by the E810 in such a case. A flat write attempt to the first 64 KB of the Flash is performed against the Shadow RAM first, and then dumped to the next Shadow RAM bank in the Flash (see Section 3.4.5.4). A flat write (0x00) attempt to a Shadow RAM area other than within the PFA, or words listed below or out side the Shadow RAM is rejected as well. The following PFA TLV sections cannot be updated by this AQC: • Immediate values • Feature configuration • POR auto-load section • PCIR auto-load section • TLVs Header • VPD when the VPD_WRITE_ENABLE is cleared • RDMA control • HII port/PF disable • Padding TLV • Software Checksum The MinSrev module can be updated only if *Allow Special Update* is set. The following checks are applied when the MinSrev module is updated: • MinSrev valid is not cleared (1 → 0). • If MinSrev valid and Current MinSrev <= Srev in signed image, then check that Current MinSrev < New Srev <= Srev in signed image. • If Current MinSrev valid and Current MinSrev > Srev in signed image OR Current MinSrev NOT valid, then check that New NVM Srev <= NVM Srev in signed image. ***Note:*** Srev in signed image = Srev of the new image if exists - if not of current image. ***Note:*** MinSrev can not be updated in recovery mode. In debug mode, a value of 0x00 writes to the entire Flash seen as flat memory without any protection. Only one module is updated at a time. For TLVs only the data portion of the TLV is updated.
Length	22-23		Length of the section to be written, which is expressed in bytes from the offset in the module. A (single) write command is limited up to 4 KB and must not spread over two (consecutive) 4 KB sectors. Also, attempting to write a RO word invalidates the entire command.Length is truncated to size of TLV in bytes +2.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

This is an asynchronous command. EMP reads the command from the ATQ and writes back an immediate completion, intended only as an ACK/NACK that the command has been addressed by the EMP. The EMP checks the validity of the command and returns an error (NACK) on the ATQ completion if it is unable to process the command. If successful (ACK), the EMP then schedules the NVM write operation to be performed by a lower priority thread, which can be preempted by other AQ commands.

Once completed, the EMP posts a completion event on the ARQ. Software must hold the NVM resource lock while performing this operation and must release it once NVM operations complete.

Software must not post another NVM command while this command is in process. For example, during the time between posting the request on the ATQ and receiving the completion event on the ARQ.

Table 3-63. NVM Write Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0703	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success). EPERM = The module type specified in the command does not permit the required operation. The word contents is not a pointer, or an attempt to write a RO module or word, or command is received not at the right place in the flow. EINVAL = Out of range offset/length (beyond the relative free area module's limits), or write spread over two (consecutive) sectors. EBUSY = The PF is not permitted to post this command because it does not own the NVM resource. This error code is also returned if the PF attempts to post a command while another NVM command is in process. EACCESS = Attempt to write to read only area or authentication failure.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31		Reserved.

Table 3-64. NVM Write Completion (on ARQ)

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0703	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success). EIO = Flash defect. EACCES = Security check failed: • Public key check failed. • Module digest (CRC) check failed. • Module security revision check failed. • Device ID check failed. • Module ID check failed. EINVAL = Invalid parameters
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Offset	16-18		Copied from the command.
Response Flags	19		RESET_FLAG **Bit 19.0:** A reset flag to indicate the type of reset required to get the NVM bank update effective. 0b = POR 1b = PERST **All other bits** = Reserved ***Note:*** Relevant only for NVM Bank update.
Module_TypeID	20-21		*Module_TypeID* that was used for this update
Length	22-23		Copied from the command.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

3.4.10.4 NVM Config Read (0x0704)

This admin command reads currently configured feature/super-feature selections and immediate field values/entries. The features/fields to be read are specified in the command's buffer. It can also be used for reading all features or fields. In case one buffer is not enough Feature or field iteration is used. The next *Feature_ID*/*Field_ID* to read are returned in the command response in this case.

Table 3-65. NVM Config Read Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0704	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7		Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command Flags	16		NVM access admin command parameters. **Bit 16.0:** Single/Multiple elements. 0b = Only a single *Feature_ID*/*Field_ID* is read. 1b = *Feature_ID*/*Field_ID* iteration is used. **Bit 16.1:** Feature/Field 0b = Feature selections are read. 1b = Immediate fields are read. **All other bits** = Reserved. Must be set to zero.
Reserved	17	0x0	Reserved. Must be set to zero.
Element Count	18-19	0x0	The number of features/fields returned. Zeroed by driver, written by firmware.
Feature_ID/ Field_ID	20-21	See description	Single *Feature_ID*/*Field_ID* when Bit 16.0 is 0b. *Feature_ID* when Bit 16.1 is 0b. *Field_ID* when Bit 16.1 is 1b. Iterator: *Feature_ID*/*Field_ID* to start reading from (iterator) when Bit 16.0 is 1b. ***Note:*** When Bit 16.0 is 0b, *Feature_ID*/*Field_ID* = 0 is not valid. When Bit 16.0 is 1b, it indicates that the command reads the data starting from the first *Feature_ID*/*Field_ID* in the array.
Reserved	22-23		Reserved.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

Table 3-66. NVM Config Read Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0704	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success).
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command Flags	16		NVM access admin command parameters. **Bit 16.0:** Single/Multiple elements. 0b = Only a single *Feature_ID*/*Field_ID* is read. 1b = *Feature_ID*/*Field_ID* iteration is used. **Bit 16.1:** Feature/Field 0b = Feature selections are read. 1b = Immediate fields are read. **All other bits** = Reserved. Must be set to zero.
Reserved	17	0x0	Reserved. Must be set to zero.
Element Count	18-19	See description	The number of features/fields returned.
Feature_ID/Field_ID	20-21	See description	Same as the command.
Reserved	22-23		Reserved.
Data Address High	24-27		Address of command buffer. See Section 3.4.10.6.
Data Address Low	28-31		

3.4.10.5 NVM Config Write (0x0705)

This admin command writes the feature selections and the values of the immediate fields provided in the attached command buffer to the NVM.

After this command is completed, an NVM Write Activate (0x0707) must be called to make the configuration persistent.

Table 3-67. NVM Config Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0705	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7	0x0	Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command Flags	16		NVM Access Admin Command Parameters **Bit 16.0:** Reserved. **Bit 16.1:** Feature/Field 0b = Feature selections are written. 1b = Immediate fields are written. **Bit 16.2:** Add New Configuration 0b = Existing configuration. 1b = New configuration added. **All other bits** = Reserved. Must be set to zero.
Reserved	17	0x0	Reserved. Must be set to zero.
Element Count	18-19	0x0	The number of features/fields in the command buffer.
Reserved	20-23	0x0	Reserved. Must be set to zero.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

Table 3-68. NVM Config Write Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0705	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success).
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31		Reserved.

3.4.10.6 NVM Config Read/Write Command Buffer

Described below is the format of the command buffer attached to the NVM Config Read Response and to the NVM Config Write commands. The buffer can either be filled with Feature Selection fields or Immediate Field fields, depending on Bit 16.1 in the command.

Table 3-69. Feature Buffer for NVM Config Read/Write

Parameter	Bytes.Bits	Description
Feature_ID	0-1	Feature_ID
Feature Flags	2-3	Feature options for NVM_Config_Read only. Reserved for NVM_Config_Write. **Bit 0:** OEM only (is set). **Bits 1:2:** Reserved. **Bit 3:** If set the Feature fields are mapped in DWORD-wise, otherwise are WORD. **Bit 4:** Should be set when using a POR CSR. **Bit 5:15:** Reserved.
Feature selection/Field Value	4-5	Configured feature selection for NVM Config Read. Requested feature selection for NVM Config Write.

Table 3-70. Immediate Buffer for NVM Config Read/Write

Parameter	Bytes.Bits	Description
Field_ID	0-1	Field_ID
Field flags	2-3	Field options for NVM Config Read. Reserved for NVM Config Write.
Field Value	4-5	Field value.

3.4.10.7 NVM Update Checksum (0x0706)

This admin command recalculates/verifies the PFA checksum. This command is used by software once it fixed a corrupted PFA or to check the validity of the PFA after reset.

Table 3-71. NVM Update Checksum Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0706	Command opcode.
Datalen	4-5	0x0	Length in bytes of command buffer.
Return Value/VFID	6-7	0x0	Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command Flags	16		**Bit 17.0:** Verify Checksum **Bit 17.1:** Recalculate Checksum **All other bits** = Reserved. ***Note:*** Only one bit of the above can be set in a command. ***Note:*** After a recalculate action, the software must initiate a Shadow RAM dump.
Reserved	17-31	0x0	Reserved. Must be set to zero.

Table 3-72. NVM Update Checksum Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0706	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7	0x0	Return value. 0x0 = No error (success). INVAL = Both 17.0 and 17.1 bits are set.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-17		Reserved.
Checksum	18-19	0x0	A value of 0xBABA indicates a valid checksum. Returned only if *Verify Checksum* flag was set in command.
Reserved	20-31		Reserved.

3.4.10.8 NVM Write Activate (0x0707)

This admin command updates the control word with the required banks' validity bits and dumps the Shadow RAM to Flash.

It must be called after NVM Write AQ Command was successfully completed in order for the new bank(s) to be updated.

If no flag is set, this command acts as an SR-dump command.

Table 3-73. NVM Write Activate Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0707	Command opcode.
Datalen	4-5	0x0	Length in bytes of command buffer.
Return Value/VFID	6-7	0x0	Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-17	0x0	Reserved. Must be set to zero.
Command Flags 2	18	0x0	**Bit 18.0:** Set to Elevate next PERST to EMPR. Clear has no effect. **All other bits** = Reserved. Must be set to zero.
Command Flags	19	0x0	**Bit 19.0:** Reserved. **Bits 19.2-19.1:** Preservation Mode (relevant only if Bit 3 is set): 00b = No preservation — Notify EMP to avoid any field preservation during NVM bank update. Returns to the values in the copy of the PFA stored in the signed NVM module. 01b = Preserve all (Default) — Used to notify EMP to preserve all the necessary customization fields during NVM bank update. 10b = Return to factory settings. 11b = Preserve Only Selected Fields — Used to notify EMP to preserve only the immediate fields and section marked as such during NVM bank update. The following sections are currently included: • PCI Serial ID • PF MAC Addresses TLV • MNG MAC Address TLV section • HLP MAC Address TLV section • SMBus addresses • MinSrev **Bit 19.3:** 0b = Keep current NVM Bank. 1b = Switch to invalid NVM Bank **Bit 19.4:** 0b = Keep current NV OROM Bank. 1b = Switch to invalid OROM Bank **Bit 19.5:** 0b = Keep current EXT TLV Bank. 1b = Switch to invalid EXT TLV Bank **Bit 19.6:** 0b = No event. 1b = Revert Last Activate. **Bit 19.7:** Reserved. ***Note:*** If Bits 3:5 are clear, Shadow RAM is dumped and swapped with no validity bits change.
Reserved	20-31	0x0	Reserved. Must be set to zero.

Table 3-74. NVM Write Activate Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0707	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success). EPERM = Returned when at least one of the specified bank(s) is not in the expected state for being updated, or command is received not at the right place in the flow. EMODE = NVM module not included in activation.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31		Reserved.

Table 3-75. NVM Write Activate Completion (on ARQ)

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0707	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value	6-7		Return value. 0x0 = No error (success). 0xC = EBUSY - Unavailable resource. 0xA = EACCES - Not available for activation (no image was loaded successfully). 0x15 = EMODE - Internal firmware error.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31	0x0	Reserved.

3.4.10.9 Save Factory Settings (0x0708)

This admin command saves the PFA, active Topology Netlist, and 32B header to a permanent read-only NVM location. This command should be executed at the end of product manufacturing after NVM content has been programmed, including MAC Addresses. For more information refer to Section 3.4.9.5.1, "Factory Settings Preservation Flow".

Table 3-76. Save Factory Settings Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0708	Command opcode.
Datalen	4-5	0x0	Length in bytes of command buffer.
Return Value/VFID	6-7	0x0	Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31	0x0	Reserved. Must be set to zero.

Table 3-77. Save Factory Settings Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0707	Command opcode.
Datalen	4-5	0x0	Length in bytes of command buffer.
Return Value	6-7	0x0	Return value. 0x0 = No error (success). EACCESS = Save Factory Settings command was previously executed.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31	0x0	Reserved.

3.4.10.10 NVM Update EMPR (0x0709)

This admin command allows the software the request an EMPR after a successful reset to allow activation of the new firmware.

Table 3-78. NVM Update EMPR Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0709	Command opcode.
Datalen	4-5	0x0	
Return Value/VFID	6-7	0x0	Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31	0x0	Reserved. Must be set to zero.

Table 3-79. NVM Update EMPR Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0709	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7		Return value. 0x0 = No error (success). EMODE = No successful update pending. Reset not allowed. EPERM = Command is received not at the right place in the flow.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31	0x0	Reserved.

3.4.10.11 Set Package Data (0x070A)

This command is equivalent to the reception of a PLDM FW Update *GetPackageData* command. This command assumes that any package data is smaller than 4K and hence is contained within a single command. This command should be sent as part of the NVM update as the first command in the flow.

Table 3-80. NVM Set Package Data Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x070A	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7		Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-18		Reserved.
Command Flags	19		**Bit 19.0:** Delete PackageData If set, the current PackageData stored by firmware is deleted. If this bit is set, buffer size is zero. **All other bits** = Reserved. Must be set to zero.
Reserved	20-23		Reserved.
Data Address High	24-27		Address of command buffer. The buffer contains the PackageData.
Data Address Low	28-31		

Table 3-81. NVM Set Package Data Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x070A	Command opcode.
Datalen	4-5		
Return Value	6-7		Return Value. 0x0 = No error (success). EPERM = NVM update is not allowed (between activate and reset or lock-down). EINVAL = Error in parsing of the content of the package data. EBUSY = The PF is not permitted to post this command because it does not own the NVM resource. This error code is also returned if the PF attempts to post a command while another NVM command is in process. EACCESS = Attempt to request an update of a RO area.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-18		Reserved.
Flags	19		**Bit 19.0:** Skipped Entries If set, some of the update requests will be skipped due to unknown PFA TLVs or unknown VPD keys. **All other bits** = Reserved.
Reserved	20-23		Reserved.

Table 3-81. NVM Set Package Data Response [continued]

Name	Byte.Bit	Value	Remarks
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

3.4.10.11.1 Buffer of NVM Set Package Data Command

The content of the buffer is the *PackageData* as read by the tool from the PLDM header. The size of this buffer is up to 1 KB.

The content is as follows:

- Byte [0].Bit 0 — PFA Preserve (default mode). Should be set to zero.
- Byte [0].Bits [7:1] — Reserved
- Byte[1] — Reserved
- TLV as follows:
  - — Type — 2 bytes:
    - GFID - 0x1
  - — Length — 2 bytes:
    - 36 words
  - — Value:
    - 17:0 = Current GFID
    - 35:18 = Original GFID
- The following set of TLVs as needed:
  - — Type — 2 bytes:
    - TLV + Offset update - 0x10 // used to update TLVs
  - — Length — 2 bytes:
    - According to size of value (in words)
  - — Value:
    - uint16: TLV number
    - uint16: Offset in words (offset 0 is the beginning of the TLV data)
    - uint16: Data length in words
    - Variable: Data
- The following set of TLVs as needed:
  - — Type — 2 bytes:
    - VPD Key update - 0x11 // Used to update VPD entries
  - — Length — 2 bytes:
    - According to size of value (in words)

— Value:

- uint16: VPD key (ascii - e.g. V2 = 0x5632 (ascii('V'), ascii('2')))
- uint16: Data length (in bytes) // should match current VPD entry size - error otherwise

  Note: If Data Length is odd, add a pad byte at end of data to make the TLV word aligned.

- Variable: Data

Notes:

- The TLVs can be in any order.
- Although this command is received at the beginning of the update flow, the actual programming of the PFA happens at the end (before the activation).
- The treatment of a PackageData received via *GetPackageData* PLDM firmware update command should be the same as described above.
- For all changes received via this package, regular PFA protection applies as defined in NVM Write admin command. The MinSrev can be changed according to the regular checks.
- After updating the VPD, the checksum in the VPD RV tag should be updated.
- If a modification of an unknown PFA tag or VPD key is requested, the command is accepted, and this tag/key is ignored. This is indicated via the *Skipped Entries* flag.
- To be able to modify parts of the VPD RO tag, the *VPD Write Enable* bit in NVM should be set. If not set, and modifications of the RO VPD area are requested the command will fail.
- If command 0x070A is received more than once, the last version is retained, even if faulty.
- If unknown TLVs or PFA TLVs with wrong size or VPD keys with wrong size are part of the PackageData, the command will fail.
- An NVM Write Activate command (0x0707) or PLDM *CancelUpdate* or PLDM *ActivateFirmware* or PLDM timeout will invalidate the content received in this command. For a new update, the command should be sent again.

3.4.10.12 Pass Component Table (0x070B)

This command is equivalent to the reception of a PLDM firmware Update *PassComponentTable* command. This command is sent once per component. This command should be sent as part of the NVM update only after the Set Package Data command is sent and before the update actually starts. The E810 assumes these commands are going to be sent until the *TransferFlag* is set to *End* or *StartAndEnd*.

Table 3-82. NVM Pass Component Table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x070B	Command opcode.
Datalen	4-5		Length in bytes of command buffer.
Return Value/VFID	6-7		Must be zeroed by the software device driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-18		Reserved.
TransferFlag	19		Possible values: 0x1 = Start 0x2 = Middle 0x4 = End 0x5 = StartAndEnd ***Note:*** This *TransferFlag* is ignored by firmware for now.
Reserved	20-23		Reserved.
Data Address High	24-27		Address of command buffer. Contains the component table.
Data Address Low	28-31		

Table 3-83. NVM Pass Component Table Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x070B	Command opcode.
Datalen	4-5		
Return Value	6-7		Return Value. 0x0 = No error (success). EPERM = NVM update is not allowed (between activate and reset or lock-down). EBUSY = The PF is not permitted to post this command because it does not own the NVM resource. This error code is also returned if the PF attempts to post a command while another NVM command is in process. EINVAL = Wrong parameters.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.

Table 3-83. NVM Pass Component Table Response [continued]

Name	Byte.Bit	Value	Remarks
ComponentResponse	16		*ComponentResponse* as described in DSP0267: 0 = Component can be updated - *ComponentResponseCode* must be set to 0x00. 1 = Component might not be updatable - A *ComponentResponseCode* greater than zero must be provided to explain the reason why the component cannot be updated, or if a flag is required to be set in *UpdateOptionFlags* field within the *UpdateComponent* request. 2 = Component should not be updated with this image (this is not part of the DSP0267 spec, but provides more information to host). The matching *ComponentResponseCodes* are denoted below. All other values reserved. This value reflects the update status this module.
ComponentResponseCode	17		*ComponentResponseCode* as defined in DSP0267 and as described in Section 12.8.4.2.4: 0x00 = Component can be updated. 0x01 = Component comparison stamp is identical to the firmware component comparison stamp in the FD. The device accepts such an update, but the software should reflect this to the user. 0x02 = Component comparison stamp is lower than the firmware component comparison stamp in the FD (downgrade). The device accepts such an update, but the software should reflect this to the user. 0x03 = Invalid component comparison stamp. The device rejects the request and returns a *ComponentResponse* = 2. Returned, among others, if GFID does not match. 0x04 = Component has conflict with another component provided in a separate *PassComponentTable* command. 0x05 = Prerequisites for this component have not been met. Returned if 0x70A was not sent before this command. The device rejects the request and returns a *ComponentResponse* = 2. 0x06 = Component is not supported on FD. The device rejects the request and returns a *ComponentResponse* = 2. 0x07 = Security restrictions prevent component from being downgraded. Should include Srev check. The device rejects the request and returns a *ComponentResponse* = 2. 0x08 = Incomplete component image set was received. Not used. 0x09 = Reserved. 0x0A = Component version string is identical to the firmware component version string in the FD. The device accepts such an update, but the software should reflect this to the user. 0x0B = Component version string is lower to the firmware component version string in the FD. The device accepts such an update, but the software should reflect this to the user. All other values are reserved.
Reserved	18-23		Reserved.
Data Address High	24-27		Address of command buffer.
Data Address Low	28-31		

3.4.10.12.1 Buffer of NVM Pass Component Table Command

The buffer of NVM Pass Component Table command contains the Component Table as passed to the device by the PassComponentTable PLDM firmware command as described in DSP0267 *PassComponentTable* command and described in Table 3-84. For more information, see Section 12.8.5

Table 3-84. Component

Type	Name	Format/Value
uint16	**ComponentClassification**	Should be 0x000A - Firmware for all components.
uint16	**ComponentIdentifier**	NVM = 0x6 OROM = 0x5 Topology Net List = 0x8
uint8	**ComponentClassificationIndex**	0x0 - Not used.
uint32	**ComponentComparisonStamp**	MajorMinor Major = 16 bit Minor = 16 bit NVM bank comparison stamp = 31:25: DevStarterVersion Major (0-99) 24:18: DevStarterVersion Minor (0-99) 17:0: EETrackID OROM bank comparison stamp = CIVD if Combo - Combo Image Version Low/High in CIVD Section. In case of no OROM, the version reported is all zeros. Net list comparison stamp = BaseReleaseVersion.Major/Minor (32 bit value copied from Netlist identifier block).
enum8	**ComponentVersionStringType**	ASCII = 1
uint8	**ComponentClassificationIndex**	The length, in bytes, of the ComponentVersionString.
Variable	**ComponentVersionString**	See section Section 12.8.5.2.1.

3.4.11 VPD Support

The Flash image can contain an area for VPD. This area is managed by the OEM vendor and does not influence the behavior of hardware. The VPD area is stored in the PFA with a *TLV Type* of 0x2F. A value of 0b in the GLPCI_CAPCTRL.*VPD_EN* register bit means VPD is not supported and the VPD capability does not appear in the configuration space. The register bit must be set to 1b in NVM only once the VPD area has been programmed. Refer to Section 3.4.5.3.1.

The maximal VPD area size provisioned in Shadow RAM is 1 KB, but it can be smaller. The VPD block is built from a list of resources. A resource can be either large or small. The structure of these resources are listed in Table 3-85 and Table 3-86.

Table 3-85. Small Resource Structure

Offset	Content
0	Tag = 0xxx,xyyyb (Type = Small(0), Item Name = xxxx, length = yy bytes)
1-n	Data

Table 3-86. Large Resource Structure

Offset	Content
0	Tag = 1xxx,xxxxb (Type = Large(1), Item Name = xxxxxxx)
1:2	Length
3-n	Data

The E810 parses the VPD structure during the auto-load process following PCIe reset to detect the read-only and read/write area boundaries. The E810 assumes the following VPD fields with the limitations listed:

Table 3-87. VPD Structure Tags

Tag	Length (Bytes)	Data	Resource Description
0x82	Length of identifier string	Identifier	Identifier string.
0x90	Length of RO area	RO data	VPD-R list containing one or more VPD keywords.
0x91	Length of RW area	RW data	VPD-W list containing one or more VPD keywords. This part is optional.
0x78	n/a	n/a	End tag.

VPD structure limitations:

- The structure must start with a tag = 0x82.
- The structure must end with a tag = 0x78 before the Shadow RAM's end. The tag must also be word-aligned.
- If the E810 does not detect a value of 0x82 in the first byte of the VPD area, or if no end tag is detected, or if the structure does not follow the information listed in Table 3-87, it assumes the area is not programmed:
  - Any read/write access through the VPD registers set are ignored.
  - EMP considers the VPD area as an empty module and thus allows NVM Update commands to be performed over the area pointed by the VPD area pointer, up to the start of another RO module.
  - The VPD pointer itself remains RO.
- The RO area and RW area are both optional and can appear in any order. A single area is supported by per-tag type. Refer to Appendix I in the PCI 3.0 specification for details of the different tags.
- If a VPD-W tag is found, the area defined by its size is writable via the VPD structure.
- The VPD area can be accessed through the PCIe configuration space VPD capability structure listed in Table 3-87. Write accesses to a RO area or any accesses outside of the VPD area via this structure are ignored. If the *VPD Write Enable* field is set to 1b in the NVM Security Control word and the entire VPD area can be modified via the NVM Update AQ command. Otherwise, the command is completed with an error status.
- VPD area must be mapped into the first valid basic bank of the Flash.
- VPD software does not check the NVM ownership before attempting to access the Flash via dedicated VPD registers (refer to Section 14.3.4). VPD software write access is recorded in the Flash immediately once the Flash part is available (such as not busy by a previous sector erase operation). Refer to Section 3.4.5.3 for more details.

3.5 General Purpose I/O (GPIO) and LED

The E810 provides two types of GPIOs:

- Low latency GPIOs, that are directly controlled by the device registers.
- Standard GPIOs that are provided by an I/O Widget.

Four direct, low latency GPIOs are connected directly to single-ended 3.3 V IO pads, plus one differential output. In addition to the direct low latency GPIOs, the E810 controls an I/O Widget that provides an additional 20 GPIOs, which can be used either as SDPs or LEDs.

In total the E810 provides the following:

- Four direct low latency single-ended GPIOs, plus one differential output, mostly used for TimeSync application.
- An additional 20 GPIOs, controlled using an I/O Widget. The I/O Widget IP is able to provide up to 32 general-purpose GPIO pins. However, the following SDP/LED are externally connected.
  - 8 SDP pins, mostly for allowing direct control of SFP modules (for example, the MOD_ABS pin).
  - 12 LED pins that can be divided into 3 LEDs per port in 4 SFP+ configuration.

Note: The I/O Widget generates LEDs and SDPs with the same feature set, so the division to 12 LEDs and 8 SDPs is provided only as an example to typical low port count application

3.5.1 E810 I/O Widget SDP and LED

The E810 controls an I/O Widget, which provides 8 SDPs and 12 LEDs. The I/O Widget is accessed using register access commands.

The eight widget SDPs are used for Ethernet link management purposes, as follows:

- Directly controlling link topology components, such as external PHY or re-timer. This is mostly used in low port count applications (such as reset or interrupt line).
- Detecting SFP module existence, in low port count applications (such as MOD_ABS).

The 12 widget SDP/LED pins can be used as additional SDPs, for functions as described above or can be used as LEDs for low port count applications, up to three LEDs per port in 4-port configurations.

When a port has three dedicated LED pins, they are be configured as follows:

- One activity LED.
- One LED indicating the LINK is running at highest available speed (firmware only sets the highest Link speed in the LED control).
- One LED indicating the LINK is up but not at the highest speed available (firmware sets all speeds but the highest).

Another possible configuration is in a case of a break-out cable with QSFP+ cage. In this case there are only three LED pins for the entire cage that operates this way:

- One activity LED.
- One LED indicating that all LINKs in this cage are running at highest available speed (firmware configuration is TBD).
- One LED indicating at least one LINK in this cage is up (firmware sets all speeds but the highest).

The link topology netlist define how to use the I/O Widget SDP and LEDs. See Section 3.3.

3.5.1.1 E810 GPIO Pin Names

Table 3-88 summarize the GPIO pin names:

Table 3-88. E810 GPIO Pins

Pin Name	Source	Signal Name	Control Register	Usage
SDP0	I/O Widget	iow_gpio_o/i[0]	IOW/GPIO_CTL[0]	LED or SDP assigned via the link topology netlist.
SDP1	I/O Widget	iow_gpio_o/i[1]	IOW/GPIO_CTL[1]	
SDP2	I/O Widget	iow_gpio_o/i[2]	IOW/GPIO_CTL[2]	
SDP3	I/O Widget	iow_gpio_o/i[3]	IOW/GPIO_CTL[3]	
SDP4	I/O Widget	iow_gpio_o/i[4]	IOW/GPIO_CTL[4]	
SDP5	I/O Widget	iow_gpio_o/i[5]	IOW/GPIO_CTL[5]	
SDP6	I/O Widget	iow_gpio_o/i[6]	IOW/GPIO_CTL[6]	
SDP7	I/O Widget	iow_gpio_o/i[7]	IOW/GPIO_CTL[7]	
SDP8	I/O Widget	iow_gpio_o/i[8]	IOW/GPIO_CTL[8]	
SDP9	I/O Widget	iow_gpio_o/i[9]	IOW/GPIO_CTL[9]	
SDP10	I/O Widget	iow_gpio_o/i[10]	IOW/GPIO_CTL[10]	
SDP11	I/O Widget	iow_gpio_o/i[11]	IOW/GPIO_CTL[11]	
SDP12	I/O Widget	iow_gpio_o/i[12]	IOW/GPIO_CTL[12]	
SDP13	I/O Widget	iow_gpio_o/i[13]	IOW/GPIO_CTL[13]	
SDP14	I/O Widget	iow_gpio_o/i[14]	IOW/GPIO_CTL[14]	
SDP15	I/O Widget	iow_gpio_o/i[15]	IOW/GPIO_CTL[15]	
SDP16	I/O Widget	iow_gpio_o/i[16]	IOW/GPIO_CTL[16]	
SDP17	I/O Widget	iow_gpio_o/i[17]	IOW/GPIO_CTL[17]	
SDP18	I/O Widget	iow_gpio_o/i[18]	IOW/GPIO_CTL[18]	
SDP19	I/O Widget	iow_gpio_o/i[19]	IOW/GPIO_CTL[19]	
SDP20	Controller Core	gbe_o/i_gpio[0]	GLGEN_GPIO_CTL[0]	1588 timing support.
SDP21	Controller Core	gbe_o/i_gpio[1]	GLGEN_GPIO_CTL[1]	
SDP22	Controller Core	gbe_o/i_gpio[2]	GLGEN_GPIO_CTL[2]	
SDP23	Controller Core	gbe_o/i_gpio[3]	GLGEN_GPIO_CTL[3]	
CLK_OUT_p/n	Controller Core	gbe_o/i_gpio[5]	GLGEN_GPIO_CTL[5]	

Chapter 4 Initialization

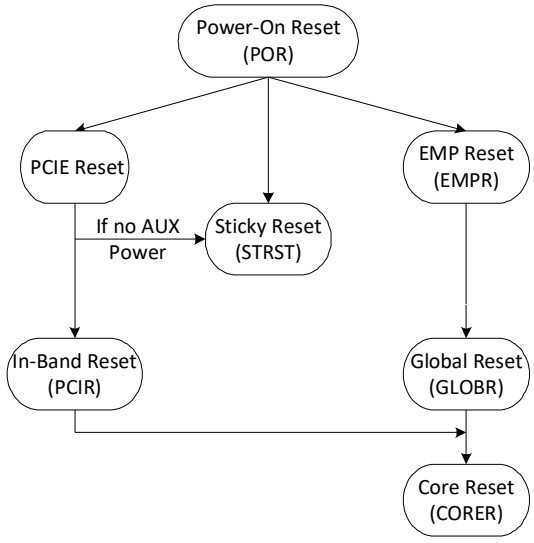
4.1 Reset Operation

The following sections lists the hardware and software reset sources that initialize the entire portions of the E810 and function-level resets. The reset sources are listed in Section 4.1.1 and the reset flows are detailed in Section 4.1.2.

4.1.1 Reset Sources

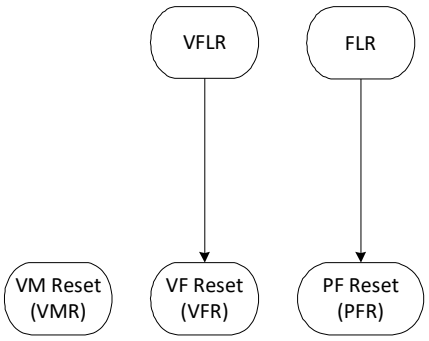
This section lists the reset sources supported by the E810, while the complete list of initialized logic is listed in Table 4-1.

A hierarchical reset tree is shown in the Figure 4-1. Any logic initialized by a specific reset is initialized also by any other reset source that is linked to it and located above it in the reset tree.



Reset Source	Cause List of the Reset Source
Power-On Reset (POR)	Power applied to the device.
Sticky Reset (STRST)	Internal reset that clears PCIe sticky registers following PCIe reset.
PCIE Reset	IOSF Primary/secondary reset input signal.
In-Band Reset (PCIR)	In-Band PCIe message signaling.
EMP Reset (EMPR)	EMP watchdog timer expiration or Force TCO command.
Global Reset (GLOBR)	Device driver setting the GLOBR bit in the GLGEN_RTRIG register.
Core Reset (CORER)	Device driver setting the CORER bit in the GLGEN_RTRIG register.

Figure 4-1. Hierarchical Hardware Reset Tree



Reset Source	Cause List of the Reset Source
PF Reset (PFR)	FLR assertion via the PCIe configuration space. D0 to D3 transition or Clearing the BME. Device driver setting the PFSWR bit in the PFGEN_CTRL register.
VM Reset (VMR)	Device driver setting the VMR bit in the VSIGEN_RTRIG register.
VF Reset (VFR)	VFLR assertion or setting the VFSWR bit in the GLGEN_VFRTRIG registe.r
PF Level reset (FLR)	Operating system sets the FLR bit in the PF PCIe configuration.
VF Level reset (VFLR)	Operating system sets the FLR bit in the VF PCIe configuration or clearing the VFE bit in the parent s PF PCIe configuration.

Figure 4-2. Function Virtual Resets

Hardware Resets:

- **Power-On Reset (POR)** — A full power-on flow is translated to sideband reset and global reset signals to the E810.
- **PCIe Reset (primary reset de-assertion)** — The primary reset signal is kept at the low level when the system is at power-down state and at system boot. PCIe reset triggers de-assertion of primary reset. If there is no AUX power, the PCI reset generates an internal STRST signal that clears PCIe sticky bits as listed in Table 4-1. De-assertion of primary reset also triggers internally a PCIR, which is detailed later in this section. Global reset is also de-asserted if link is not needed for APM and manageability is disabled.
- **Sticky Reset (STRST)** — Sticky reset is internal signal triggered by PCIe reset when the E810 is not powered by AUX power. This reset clears sticky registers in the PCIe interface (as defined by the PCIe specification). The sticky reset is also initiated by POR.
- **In-Band Reset (PCIR)** — PCIe supports in-band signaling for PCIe reset (called PCIR). Any cycles on the PCIe bus are gated instantly as well and packet transmission generated by software. The entire data path is initialized other than the EMP cluster. Although the EMP subsystem is not initialized, some packets of the EMP might be lost during a short window of about 1 µs.
- **Core Reset (CORER)** — CORER initializes the shared data path for all functions excluding the EMP subsystem, PCI interface, and MAC/PHY logic of all ports. Any further master cycles of all PFs and VFs are not initiated while some packets that were already fetched completely might still be sent out. Even though the EMP subsystem is not cleared, pass-through traffic might be inhibited during the initialization cycle that might take ~20 ms. Also, SMBus accesses are responded with NACK during the initialization cycle. This reset is not expected to be used other than as an escape mechanism in case the E810 hangs and the PFR did not resolve the problem. This reset is initiated by the PFs by setting the *CORER* bit in the GLGEN_RTRIG register. The EMP initiates this reset by setting a bit in an internal register. As seen in Figure 4-1, this reset is also set as part of EMPR reset or Global reset (higher level reset).
- **Global Reset (GLOBR)** — GLOBR is a superset CORER initializing any logic initialized by the CORER, plus the MAC/PHY logic of all ports (both internal PHY and external PHY if connected). This reset is not expected to be used other than escape mechanism in case CORER did not resolve the problem. This reset is initiated by the PFs by setting the GLOBR bit in the GLGEN_RTRIG register. The EMP initiates this reset by setting a bit in an internal register. Global reset is also initiated following a Force TCO command (if it is not disabled by the Force TCO Reset Disable bit in the NVM). As seen in Figure 4-1, this reset is also set as part of EMPR reset (higher level reset) and this reset also generates CORE reset.

- **EMP Reset (EMPR)** — EMPR initializes the resources and data path connected to the EMP including its firmware reload (excluding internal-SR). EMPR is triggered internally by the EMP watchdog timer expiration or by EMP setting an internal flag or due to Force TCO command or due to uncorrectable ECC error in one of the EMP memory shells. As seen in Figure 4-1, this reset generates CORE reset and global reset.

Function-Level Resets:

- **Function Level Reset (FLR)** — The E810 supports the standard FLR interface in the Device Control register of the PCIe capability structure within the PCI configuration space of the PFs. Setting the *FLR* bit initializes the PCI configuration of the PF (including the *VFE* flag in the SR-IOV Control/ Status register that disables all the VFs of the PF) and initiates an internal PFR described later in this section.
- **PF Reset (PFR)** — PFR initializes the resources and data path of the PF and its VFs with no impact on other PFs, VFs, or the EMP subsystem. Any further master cycles of the PF are not initiated while some packets that were already fetched completely might still be sent out. The PFR is generated by one of the following four causes:
  - D0 to D3hot transition, which is also known as ACPI reset.
  - FLR
  - PF software sets the *PFSWR* bit in the PFGEN_CTRL register.
  - De-assertion of the *Bus Master Enable* flag in the PCI configuration space.
- **VF Level Reset (VFLR)** — The E810 supports the standard VFLR interface in the Device Control register of the PCIe capability structure within the PCI configuration space of the VFs. Setting the *VFLR* bit initializes the PCI configuration of the VF and initiates an interrupt to the PF that completes the VFR reset described later in this section. Clearing the *VFE* flag in the PF configuration space also impacts all its VFs the same as a VFLR.
- **VF Reset (VFR)** — VFR initializes the resources and data path of the VF with no impact on other PFs, VFs, or the EMP subsystem. Any further master cycles of the VF are not initiated, while some packets that were already fetched completely might still be sent out. The VFR is generated by one of the following two causes:
  - VFLR or clearing the *VFE* bit of the parent PF. Note that after the VFE bit is cleared, the PF driver should follow the VFR flow for all the VFs of the PF, including those VFs that are not enabled.
  - PF software sets the VFSWR bit in the VPGEN_VFRTRIG register of its VF.
- **VM Reset (VMR)** — There are 768 VSIs. VMR is a mechanism to reset a VSI. VMR initializes the resources and data path of the VM with no impact on other PFs, VFs, VMs, or the EMP subsystem. Any further master cycles of the VM are not initiated, while some packets that were already fetched completely might still be sent out. The VMR is generated by the PF software setting the *VMSWR* bit in the VSIGEN_RTRIG register.

Table 4-1. Device Logic Affected by the Reset Sources

Reset Activation	POR	STRST / PCIR / PERST	EMPR	GLOBR	CORER	FPR / FLR	VMR	VFR/ VFLR
Load the NVM to the Shadow RAM in the hardware and clear the alternate structure	+							
Load the EMP and PE firmware from the NVM	Both+	PE	Both+	PE	PE			
Load device settings from NVM shadow and alternate structure (see details listed in Table 6-2 and the reset flow sections that follow)	Shad	Both	Both	Both	Both			
PF MAC Addresses (switch and WoL)[1]	+	+[1]	+	+	+	+		
MAC and PHY interface	+	[1]	+	+				
EMP subsystem including firmware reload	+		+					
Sticky PCIe context	+	[2]						
PCIe HWInit parameters	+	PERST only						
PCIe RO registers	+	+						
PCIe RW/RW1C registers	+	+				+[3]		VF by VFLR
Bus master disable[4]	+	+	+	+	+	PF	VM	VF
All CSRs (Refer to Section 13, "Programming Interface" for the reset source of each register.)								
Most of the PF and VF registers (PF registers are named "PFxxx", and VF registers named "VFxxx" and "VPxxx"). Refer to Section 13, "Programming Interface" for the reset source of each register.	+	+	+	+	+	PF and its VFs		VF only
Cache contexts (Quad hash filters, PE context) and FPMs settings (sector descriptors and cache entries)	+	+	+	+	+	PF and its VFs	VM	VF
Invalidate VF queue mapping tables (VPLAN_QTABLE)	+	+	+	+	+	VFs of the PF		VF
Invalidate VSI context (including the switch, VSILAN_QTABLE and all other VSI registers)	+	+	+	+	+	PF and its VFs	By the PF SW[5]	By the PF SW[5]
Load the PFs MAC Address to the switch and the WOL filters from the NVM (not all PFs must have a WOL filter)	+	+[6]	+	+	+	PF		
Tx and Rx data path + Tx-Scheduler	+	+	+	+	+	PF and its VFs	VM	VF
Tx and Rx packet buffers	+	+	+	+	+			
Tx and Rx queue disable	+	+	+	+	+	PF and its VFs	By the PF SW	VFs (Done by FW for Rx queues)
Admin queue disable (POR and EMP also clear the queue context memories.)	+	+	+	+	+	PF and its VFs		VF
Disable interrupts	+	+	+	+	+	PF and its VFs		VF
Interrupt cause control registers	+	+	+	+	+	By the PF SW	By the PF SW	By the PF SW

Table 4-1. Device Logic Affected by the Reset Sources [continued]

Reset Activation	POR	STRST / PCIR / PERST	EMPR	GLOBR	CORER	FPR / FLR	VMR	VFR/ VFLR
RSS key and table	+	+	+	+	+	PF		VF
Invalidate FD filters	+	+	+	+	+	PF	VM (FW clears all filters on VSI clear)	VF
Invalidate all internal caches: transmit and receive queue contexts; PE Quad Hash.	+	+	+	+	+			
Invalidate the FPM tables of the PF and its VFs (function private memory).	+	+	+	+	+	PF and its VFs		VF

1. PF MAC Addresses (switch and WoL) are cleared by hardware at POR and loaded from NVM by the firmware at any of the highlighted reset causes. Following PCIR, the switch MAC Addresses are loaded following the assertion of the PCIe reset or in-band reset, and the WoL MAC Addresses are loaded only following the de-assertion of the PCIe reset.The MAC and PHY are cleared only if link is not needed for APM and MNG is disabled. GLOBR if link is not needed for APM and MNG is disabled. If the WUC filter is inactive and no port is needed by firmware/MNG (PRTPM_GC.*EMP_LINK_ON* is clear), GLOBR is maintained low by hardware during PCIR de-assertion for power savings.
2. Sticky PCIe context is cleared on PERST if no AUX power as documented in Section 14.2.1).
3. For exception list of registers that are not cleared on PFR, see Section 14.2.1.
4. The E810 has several flags that control the Bus Master Enable (BME). BME flags on the PCI configuration space (for each PF and VF) and the VMRD flag in the VSIGEN_RSTAT registers for each VM that is not a VF. The BME flags of all PFs are cleared by all reset causes indicated by + symbol and a specific PF by FLR. The BME flags of all VFs are cleared by all reset causes indicated by + symbol and a specific VF by VFLR. The VMRD flags of all VSIs are set by all reset causes indicated by + symbol and a specific VSI by VMR. Note that as opposed to BMEs of the function that are cleared by the previous resets (disabling master accesses), the VMRD flags are set (enabling bus master accesses when the BME of their parent PF is set as well).
5. VSIs and its related switch context are cleared by admin command(s) initiated by the software.
6. Note that as opposed to any logic in the E810 that is initialized at the leading edge of PERST#, the WOL filters are initialized at the de-assertion of PERST# (entering the D0u state).

Table 4-2. NVM Section Loaded by Reset Source Covered by GLNVM_ULD Register

NVM Section	POR	PERST	PCIR	EMPR	GLOBR	CORER
POR Registers Auto-Load	+					
PCIe Analog Configuration	+					
PCIR Registers Auto-Load	+	+	+			
PCIe Transaction Layer (TL) Shared	+	+	+			
CORER Registers Auto-Load	+	+	+	+	+	+
GLOBR Registers Auto-Load	+			+	+	
PHY Analog Configuration	+					
EMPR Registers Auto-Load	+			+		

4.1.2 Hardware Reset Flows

This section describes the reset flows in the E810 and software interaction.

4.1.2.1 POR Flow

Power-up sequence described in this document starts at power-on reset towards the E810.

1. Power-on reset is de-asserted. Crystal clocks are stable and toggling, and memory repair process has completed.
2. IPs perform fuse polling. At that stage, the SPI controller is ready to accept messages from other IPs.
3. The E810 starts its boot process, checks the validity of the NVM, and loads the initial firmware code (mini-loader). The mini-loader code is authenticated by the E810.

   Note: PCI reset de-assertion occurs at least 100 ms after power-up flow is started. Since flow duration is less than 100 ms, it is guaranteed that firmware is ready for PCI reset de-assertion at the end of this stage.

   a. E810 firmware loads a small subset of configurations from the NVM into Shadow RAM (timing critical configurations or ones that might be later modified by software).
4. First load process. E810 firmware loads:
   a. HIP's PLL configuration to the HIP modules. HIP's auto-loaded data is pushed over SB-IOSF by the E810.
   b. CSR protected list.
   c. POR section from Shadow RAM.
5. E810 firmware loads and authenticates the full firmware code content.
6. Second load process:
   a. E810 firmware loads the full HIP configuration.

Figure 4-3 shows the stages through the power-up sequence. The numbers relate to the steps previously described.

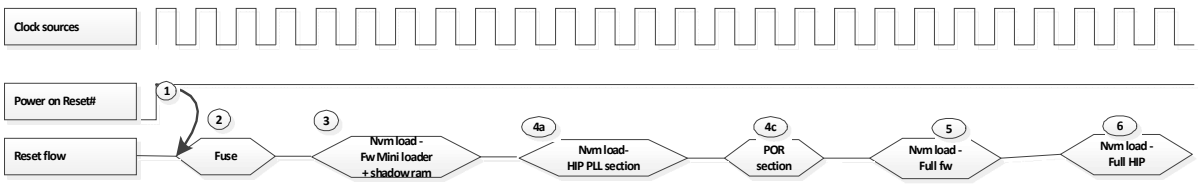


Figure 4-3. External Power-On Flow

Table 4-3 lists the timing of each of the steps.

Table 4-3. External Power-Up Sequence

Step		Duration (ms)[1]	Completion Time from Start (ms)[2]
1	Power-on reset.	0	40
2	Read fuse and straps information.	4	44
3	Load mini-loader from the NVM[3] + Load Shadow RAM from the NVM.	20	64
4	Initial configuration of hardware blocks (auto-load).		

1. The time it takes to complete the respective step (usually defines the maximum duration).
2. The time the respective step ends, counting from beginning of the power-up sequence. It usually defines the latest time this step might end.
3. All NVM loads assumes an NVM clock speed of 50 MHz and a quad SPI interface + authentication process done by firmware.

4.1.2.2 Primary Reset and In-Band PCI Reset Flow

The internal reset flow is shown in Figure 4-4 and described in this section.

Note: Core reset might be extended if none of the functions are enabled for WoL or Path-through.

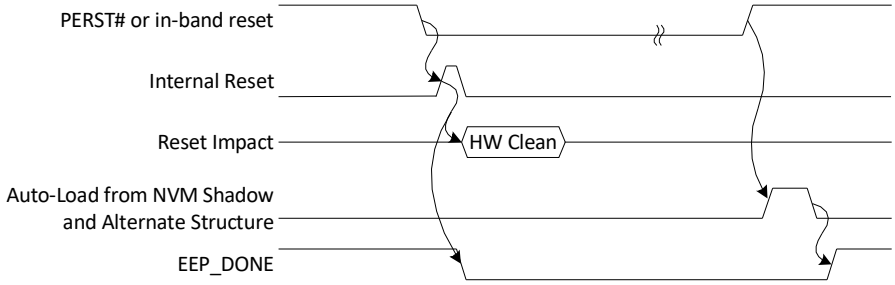

Figure 4-4. PCI Reset Flow

Hardware response:

1. Avoid any further master accesses on the PCIe bus and discard any completions for the PF.
2. Reset PCIe registers and core registers as listed in Table 4-1.
3. The following flags are cleared by the E810 when:
   - The *CONF_*_DONE* bits in GLNVM_ULD register are cleared.
4. The E810 loads the NVM section into hardware. After loading, the EMP might start responding to the Get Version Admin command, which is blocked until this stage.
   - When checking for hardware configuration to complete, software device driver should either wait for a response to Get Version Admin command, or poll on the *CONF_*_DONE* bits.

Following these steps, hardware is ready to accept operating system configuration cycles.

Note: EMP packets might be lost as well in a window frame of tens of milliseconds.

4.1.2.3 Core, Global, and EMP Reset Flows

The global resets can be initiated by the PF software or the EMP firmware. It is expected to be used as a mechanism to resolve potential hardware locks or synchronization lose, bringing the E810 to a known functional state. These global resets impact all PFs (and their VFs) as well as the EMP subsystem (EMP reset only). Therefore, graceful flow is enabled by hardware as shown in Figure 4-5 and described in the following sections. The software initiates the global resets by the GLGEN_RTRIG register. The EMP can access the same register or use an internal register.

As seen in the "Hierarchical Reset Tree" diagram (Figure 4-1):

- EMPR reset also triggers a global reset and a core reset.
- Global reset can be self asserted. When asserted, it also triggers a core reset.
- Core reset can be self-asserted.

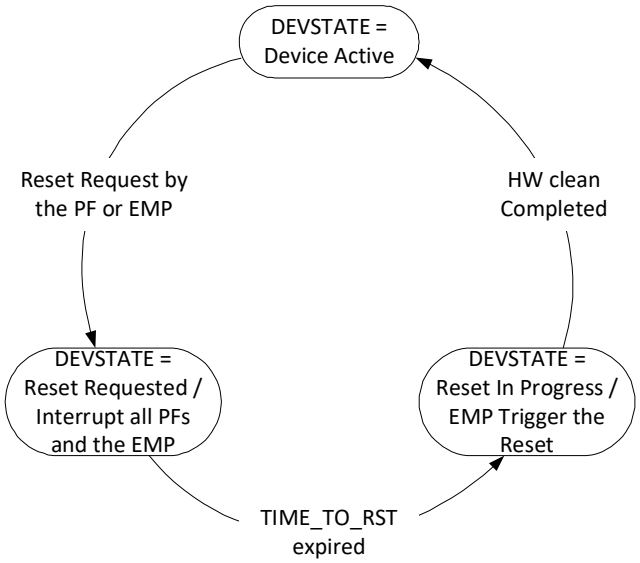

Figure 4-5. Global Reset Flow

4.1.2.3.1 Software and Firmware Interface

- **GLOBR/CORER** — Setting the *GLOBR* flag or *CORER* flag in the GLGEN_RTRIG register triggers a graceful global/core reset, respectively.
- **EMPFWR** — EMP firmware watchdog expiration or EMP setting internal EMP reset flag, triggers a graceful EMP reset (EMPR).
- **DEVSTATE** — Global device state exposed to all PFs in the GLGEN_RSTAT registers. The DEVSTATE can be at one of the following states: device active, reset requested, or reset in progress.
- **RESET_TYPE** — The RESET_TYPE reflects the last reset cause initiated to the E810. It changes its state once any of the following reset sources is triggered. The *RESET_TYPE* can be at one of the following states: POR, CORER, GLOBR, or EMPR.
- **RST_CNT** — The GLGEN_RSTAT reflects the following counters: CORERCNT, GLOBRCNT, and EMPRCNT. These fields are each 2-bit counters. They count the matched reset completion events since POR.

4.1.2.3.2 CORER Flow

The PF software or EMP firmware initiates a graceful core reset by setting the *CORER* flag in the GLGEN_RTRIG register and polling the E810 state in the GLGEN_RSTAT register.

Note: If a CORER occurs while internal Shadow RAM is inconsistent with Flash Shadow RAM content, an EMPR is triggered as part of the CORER flow.

Hardware/EMP firmware response:

1. Changes to the GLGEN_RSTAT register are as follows:
   a. Set *DEVSTATE* to reset requested.
   b. Set *RESET_TYPE* to CORER indicating the requested reset.
   c. Initiate a GRST interrupt to all PFs and EMP that the reset is about to be fired by hardware.
2. As a response to interrupt, EMP reads *TIME_TO_RST* by the GLGEN_RSTCTL.*GRSTDEL* value and start counting down. When timer expires, EMP triggers the reset via the GLGEN_IMRTRIG register. The *CONF_*_DONE* bits in GLNVM_ULD are cleared by the E810 when reset is asserted.
3. Clear the entire transmit and receive data path and core registers as listed in Table 4-1.
4. Avoid any further master accesses on the PCIe bus and discard any completions for the entire device, and abort any transmission in progress (including packets sent by the EMP).
5. Reset internal device logic excluding EMP cluster, PCI interface, and MAC/PHY cluster as listed in Table 4-1.
6. Once the reset flow is completed, update the GLGEN_RSTAT register as follows:
   a. Set *DEVSTATE* to device active.
   b. Increment the *CORERCNT* by one.
7. The E810 loads the NVM section into hardware. After loading, the EMP might start responding to the Get Version Admin command, which is blocked until this stage.

Following the GRST interrupt, all PFs poll the E810 state in the GLGEN_RSTAT register.

1. Keep polling the register as long as DEVSTATE is not equal to device active. The GLGEN_RSTAT register also indicates the number of the initiated global resets via the GLGEN_RTRIG register (CORER, GLOBR, EMPR). These counters might be needed in case a function initiated consecutive global reset before all other functions had the chance to realized that the previous reset was completed. It is a good practice to avoid too frequent global resets to avoid such cases.
2. Check the *RESET_TYPE* that indicates the reset that was initiated and follow the required initialization flow.

   Note: Also, the function that initiated the reset should check the *RESET_TYPE*, since it might reflect a stronger reset initiated by another function.
3. Check that the hardware completed to auto-load its settings from the NVM shadow and the alternate structure by polling the *CONF_*_DONE* flags in GLNVM_ULD register.

   Note: When checking for the EMP configuration to be done, software should either wait for a response to a Get Version Admin command or poll on the *CONF_*_DONE* bits.
4. The PFs proceeds with their software initialization flow.

4.1.2.3.3 GLOBR Flow

Global reset is initiated by the PFs or the EMP by setting the *GLOBR* flag in the GLGEN_RTRIG.

As seen in the "Hierarchical Reset Tree" diagram (Figure 4-1),global reset also triggers core reset.

The GLOBR flow is identical to the CORER flow with the following changes:

- GLOBR also initializes the MAC/PHY units.
- GLGEN_RSTAT.*RESET_TYPE* is set by the hardware to GLOBR (rather than CORER).
- Increment the *GLOBRCNT* by one (rather than *CORERCNT*).
- Loading the E810 setting from the NVM is listed by the GLOBR column in Table 4-2.

Note: If a GLOBR occurs while internal Shadow RAM is inconsistent with Flash Shadow RAM content, an EMPR is triggered as part of the CORER flow.

4.1.2.3.4 EMPR Flow

EMP reset is expected to be used by the EMP as a mechanism to resolve potential hardware locks or potential loss of synchronization between the firmware and hardware that are not expected to be resolved by CORER nor by GLOBR. The EMPR impacts also all PFs and their VFs. Therefore, the following graceful flow is recommended.

As seen in the "Hierarchical Reset Tree" diagram (Figure 4-1) EMPR reset also triggers and global reset and a core reset.

The EMP flow is identical to the CORER flow with the following changes:

- During normal operation, the EMPR can be initiated only by the EMP by setting an internal EMP reset flag.
- EMPR initializes also the MAC/PHY units as well as the EMP cluster.
- GLGEN_RSTAT.*RESET_TYPE* is set by hardware to EMPR (rather than CORER).
- Increment the *EMPRCNT* by one (rather than *CORERCNT*).
- Loading the E810 setting from the NVM is listed by the EMPR column in Table 4-2.

4.1.3 Function-Level Reset Flows

VF/VM/PF reset requests (VPGEN_VFRTRIG for VF reset, VSIGEN_RTRIG for VM reset, and PFGEN_CTRL.*PFSWR* for PF reset) are ignored in the following cases:

- CORER reset is asserted (also during pre-indication of CORER)
- Between CORER de-assertion and CORER NVM load completion (fleep_al_corer_done set)

Note: During a function-level reset, spurious malicious events might occur due to anti-spoof.

4.1.3.1 PFR Flow

PFR resets a specific PF. For SR-IOV, it also resets the VFs of this PF. The reset flow is shown in Figure 4-6. It is initiated by the PF driver (setting the *PFSWR* bit in the PFGEN_CTRL register) or operating system (setting the *FLR* flag in the Device Control register) or D0 to D3hot transition.

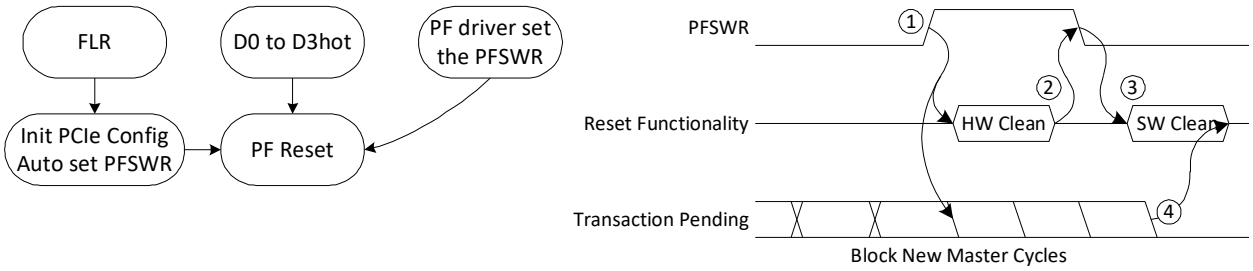

Figure 4-6. PFR Triggers

The PF hardware response to PFR is listed in Table 4-1.

The E810 hardware initiates two orthogonal flows as a response to FLR:

PCIe clean-up flow:

1. Emulate internal VFR to all its VFs (the hardware response to VFR is described in Section 4.1.3.3.3 with the exception that the VF's CSRs are not gated on read).
2. Avoid any further master accesses on the PCIe bus and discard any completions for the PF and its VFs.
   a. Once all pending requests of the PF are completed, the *Transaction Pending* bit in the Device Status register in the PCIe configuration space is cleared.
   b. Once all pending requests of each VF of the PF are completed, the *Transaction Pending* bit in the Device Status register the VF PCIe configuration space is cleared (per each VF).

Data path clean up flow:

1. Upon event, EMP does the next "pre hardware drain" clean ups:
   a. Cleans up switch population of the PF.
   b. Cleans up ACL population of the PF (as described in Section 7.9.2.10).
   c. Cleans up RSS population of the PF (as described in Section 7.10.11.2).
   d. Cleans and disables FD filters of the PF (as described in Section 7.10.12).
   e. Disables mailbox queues and sideband queues of the PF and its VFs in SR-IOV mode, or its VMs when working in PASID mode (as described in Section 9.5.3).
   f. Clears the enable bit of doorbell queues of the PF (doorbell queue context layout is described in Section 10.5.5.6).
   g. Halts all the initialized transmit queues using the following flow (firmware must not halt an uninitialized queue):
      1. Set count down register GL_TCVMLR_QCNTR to the number of disabled queues
      2. Per each halted Tx-Queue, EMP sends queue halt command using GL_TCVMLR_QCTL register. Queue IDs are described in the global space.
      3. Tracks the completion of the multiple Q halt commands using GL_TCVMLR_QCNTR register. The entire Q halt operation is completed when this register is zeroed. Firmware can load value to this register only when it is equal to zero. Must not initiate any Q halt flow before the previous one is completed.

2. Via the GL_XLR_MARKER_TRIG* registers, EMP indicates to hardware to send a drain marker that drains the Tx data path, Rx data path, and PE data path orthogonally.
   - The specific GL_XLR_MARKER_TRIG* registers are:
     — GL_XLR_MARKER_TRIG_VMLR
     — GL_XLR_MARKER_TRIG_TCVMLR
     — GL_XLR_MARKER_TRIG_RCU_PRS
     — GL_XLR_MARKER_TRIG_PE (should be written only if PW is enabled).
   - Draining the Tx and Rx data paths might take some time when the TC is paused by flow control. Hardware includes a timeout mechanism that prevents indefinite latency, as described in Section 8.2.4.4.1.
   - As the second part of the data path clean up flow (cache clean-up phase after main data path is drained), PE firmware, cleans and disables QH filters of the PF (as described in Section 7.10.12).

   PFGEN_PFRSTAT.*PFRD* indication is cleared when GL_XLR_MARKER_TRIG_VMLR is written.
3. When hardware drain flow ends, hardware sets the PFGEN_PFRSTAT.*PFRD* and issues an interrupt to EMP.
4. Upon interrupt (or firmware polling of *PFRD*), EMP sees that PFGEN_PFRSTAT.*PFRD* is set, then does the following "post hardware drain" clean-ups
   a. Firmware releases all resource of the PF and its VFs (for example, nodes in PSM and in PE scheduler, function profile, switch population).
5. Firmware resets (zeros all fields) the QINT_TXQCTL, QINT_RXQCTL, and GLINT_CEQCTL registers for the queues of the PF.
   a. Disable the receive queues of the PF using the fast queue disable flow per each queue.
   b. EMP polls that *Transactions Pending* flag in the PCI configuration space of the PF and of all its VFs until they are cleared.
6. After all the previous steps are complete, firmware clears the *PFSWR* bit in the PFGEN_CTRL register. As a response to *PFSWR* clearing, hardware releases bus master cycles for the PF and its VFs.
   - Before clearing the *PFSWR* bit in the PFGEN_CTRL, the firmware must clear *VFSWR* bit in the respective VPGEN_VFRTRIG register for all the PF's VF, and the *VMSWR* bit in the VSIGEN_VFRTRIG register for all the PF's VSIs.
   - Firmware should clear the *VFLRS* bit of the corresponding VFs in the GLGEN_VFLRSTAT register.

The PF software polls the *PFSWR* bit until it is cleared (indicating that hardware completed its reset flow). Additionally, software should also poll the *Transactions Pending* flag in the PCI configuration space of the PF (indicating that all outstanding requests of the PF were completed).

- Once the *Transactions Pending* flag is cleared, the PF software can release the pinned memory structures.
- Once the *PFSWR* bit is cleared as well, the PF software can proceeds to the following steps.

  Note: If the *PFSWR* bit is not cleared within ~100 ms, it can be assumed that the shared data path inhibits the PFR completion. In such a case, the software can initiate the CORER to overcome any possible lock.

As part of the initialization flow, the PF driver checks the pending transactions of its VFs (by setting the VF index and the offset of the VF Device Status register in the PF_PCI_CIAA register, and then polling the pending flag in the PF_PCI_CIAD register). As part of the software/hardware initialization flow, the PF software should check for potential race condition with another PF or EMP initiating a global reset (CORER, GLOBR. or EMPR):

1. Query the reset counters (*CORERCNT*, *GLOBRCNT*, and *EMPRCNT*) in the GLGEN_RSTAT register.
2. Interrupt enable flow.
3. Read the GLGEN_RSTAT register for the device state (*DEVSTATE*) and the reset counters (*CORERCNT*, *GLOBRCNT*, and *EMPRCNT*).
   - If *DEVSTATE* = "Reset requested" or "Reset in progress", go to the global reset flow.
   - If *DEVSTATE* = "Device active", if the updated values of the global reset counters equal to the value sampled at the beginning of this procedure, then "all good". Software can continue with the rest of the software/hardware initialization flow.
   - Else, go to the global reset flow.

The PF should also read the PFINT_OICR register in case there were "other cause" interrupts during reset.

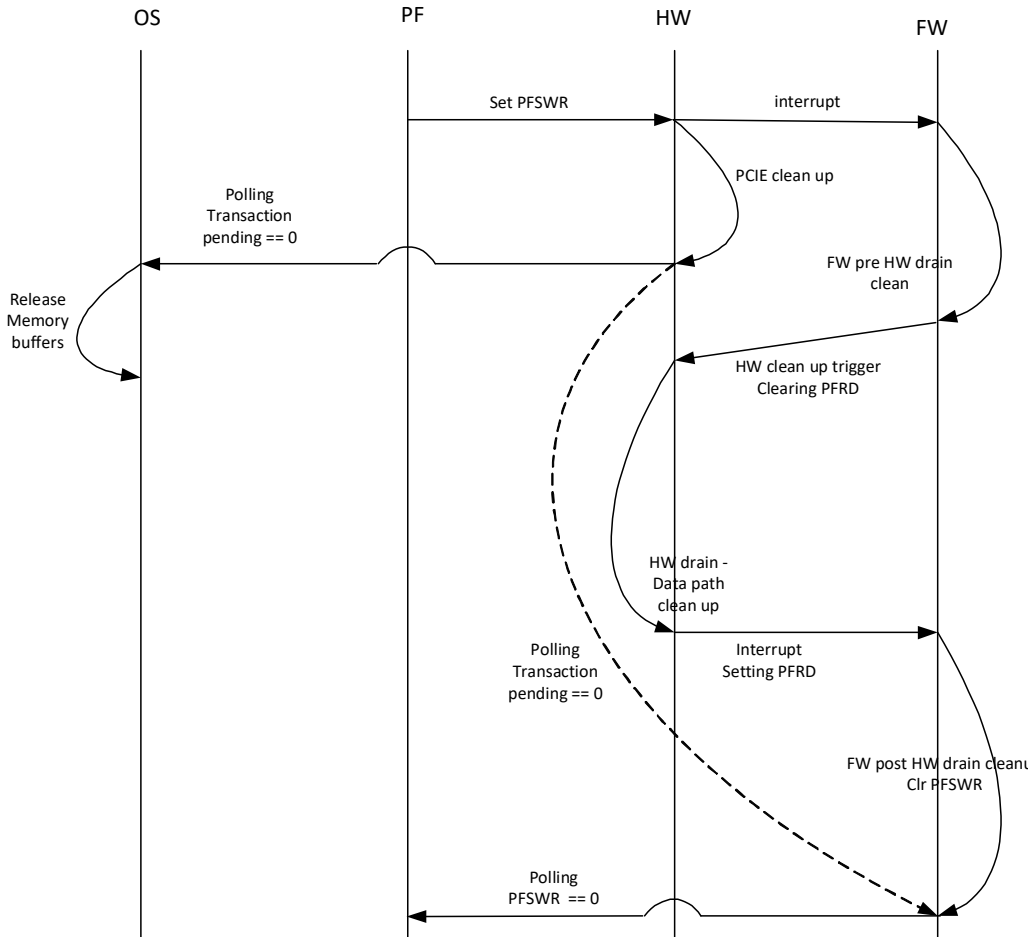

Figure 4-7. PFR Flow

4.1.3.2 FLR Flow

FLR resets a specific PF. In the case of SR-IOV, it also resets the VFs of this PF.

1. The following steps are optional:
   a. The operating system is expected to clear the *BME* bit in the Command register in the PCI configuration register of the PF.
   b. For SR-IOV, the operating system is expected to also clear the *BME* bit in the VF Command register in the PCI configuration register of all VFs of this PF.
   c. As a response, hardware avoids any new master cycles of the PF and its VFs (including MSI-X initiation).
   d. The operating system should poll the *Transaction Pending* bit in the Device Status register of the PF until it is cleared.
   e. For SR-IOV, the operating system should poll also the *Transaction Pending* bit in the VF Device Status register of all VFs of the PF until they are cleared.

   Note: All the previous steps are expected and recommended, but not enforced by the PCI specification.
2. The operating system sets the *FLR* bit in the Device Control register of the PF. The operating system is required by PCIe specification to wait 100 ms before it can assume that the FLR sequence is completed by hardware.
3. The PF hardware response as follows:
   a. Initialize the PCIe configuration space of the PF including clearing the *BME* bit of the PF and the *VFE* bit.
      - By clearing the *BME* bit, hardware avoids any further master accesses on the PCIe bus and discards any completions for the PF.
      - By clearing the *VFE* bit, all VFs of the PF avoid any further master accesses on the PCIe bus, discards any completions targeted for these VFs, and become hidden on the PCIe bus.
      - As part of the PCIe configuration initialization, the completion timeout is set to its hardware default.
      - Once all pending requests of the PF and its VFs are completed or completion timeout expires (whichever comes first), the T*ransaction Pending* bits in the PCIe configuration space are cleared.
   b. Auto-set the *PFSWR* bit in the PFGEN_CTRL register (triggering a PFR described in the section that follows).

Once the *Transaction Pending* bit in the PCIe configuration space of each VF is cleared, the operating system can release all VF memory structures and unload the VF driver (if required). Once the *Transaction Pending* bit in the PCIe configuration space of the PF is cleared, the operating system can release all PF memory structures and unload the PF driver (if required).

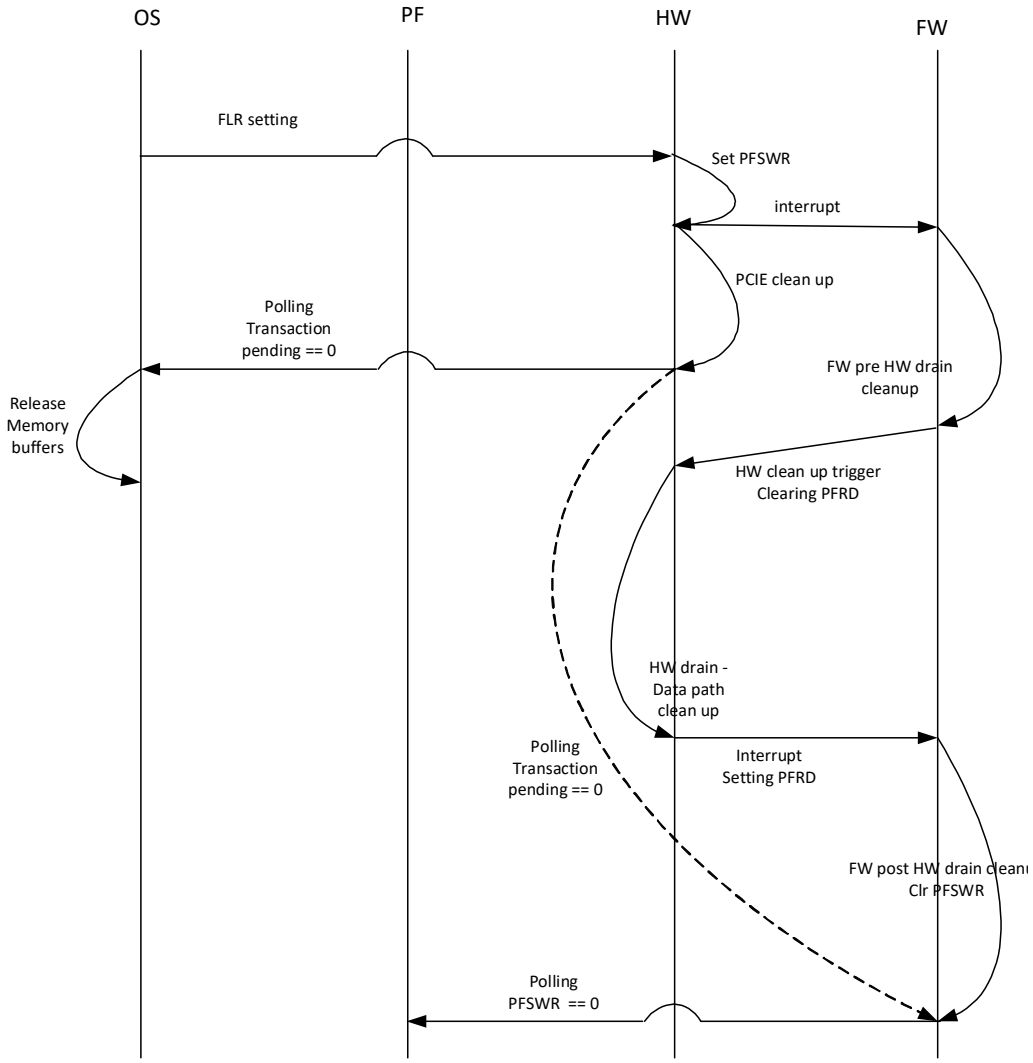

Figure 4-8. FLR Flow

4.1.3.3 VFR/VFLR Flows

The VF reset flow is shown in Figure 4-9 and detailed in the sections that follow.

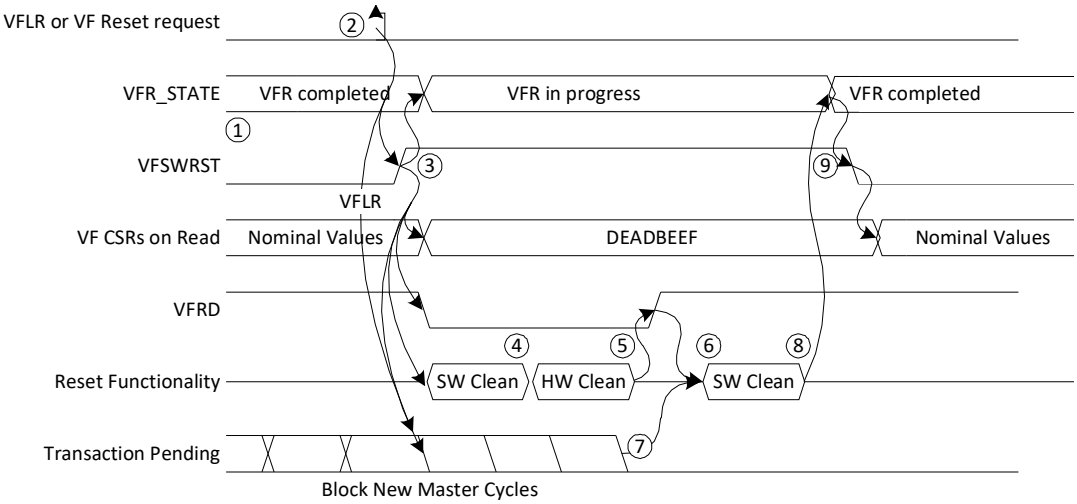

Figure 4-9. VF Reset (VFR) Flow

4.1.3.3.1 VF Reset Request by the VF Driver

The VF driver requests the VF reset from its parent PF as follows, and is shown in Figure 4-9. Also see Section 4.1.3.3.3, which describes the PF response to the VF reset request.

The *VFR_STATE* in the VFGEN_RSTAT register in this step is expected to be VFR completed.

Note: The VF software gets a control over its VF only after any prior VF reset flow is completed (step 1 in Figure 4-9).

1. The VF driver initiates a request to its parent PF to initiate a VF reset. The mechanism for sending this request is outside the scope of this document. It could be done using a VF-to-PF or any other software-based sideband channel (Step 2 in Figure 4-9).
2. The VF polls the *VFR_STATE* in the VFGEN_RSTAT register until it is set by the PF to VFR completed (Step 9 in Figure 4-9, and explained in Section 4.1.3.3.3).
3. The VF software proceeds activating the function.

At some point prior to requesting the PF for reset once again, VF must set *VFR_STATE* value to "reset in progress". When called, the PF software is called to initiate the VFR by the VF software. It sets the *VFSWR* bit in the VPGEN_VFRTRIG register of the VF (Step 3 in Figure 4-9) to initiate VFR (described in Section 4.1.3.3.3).

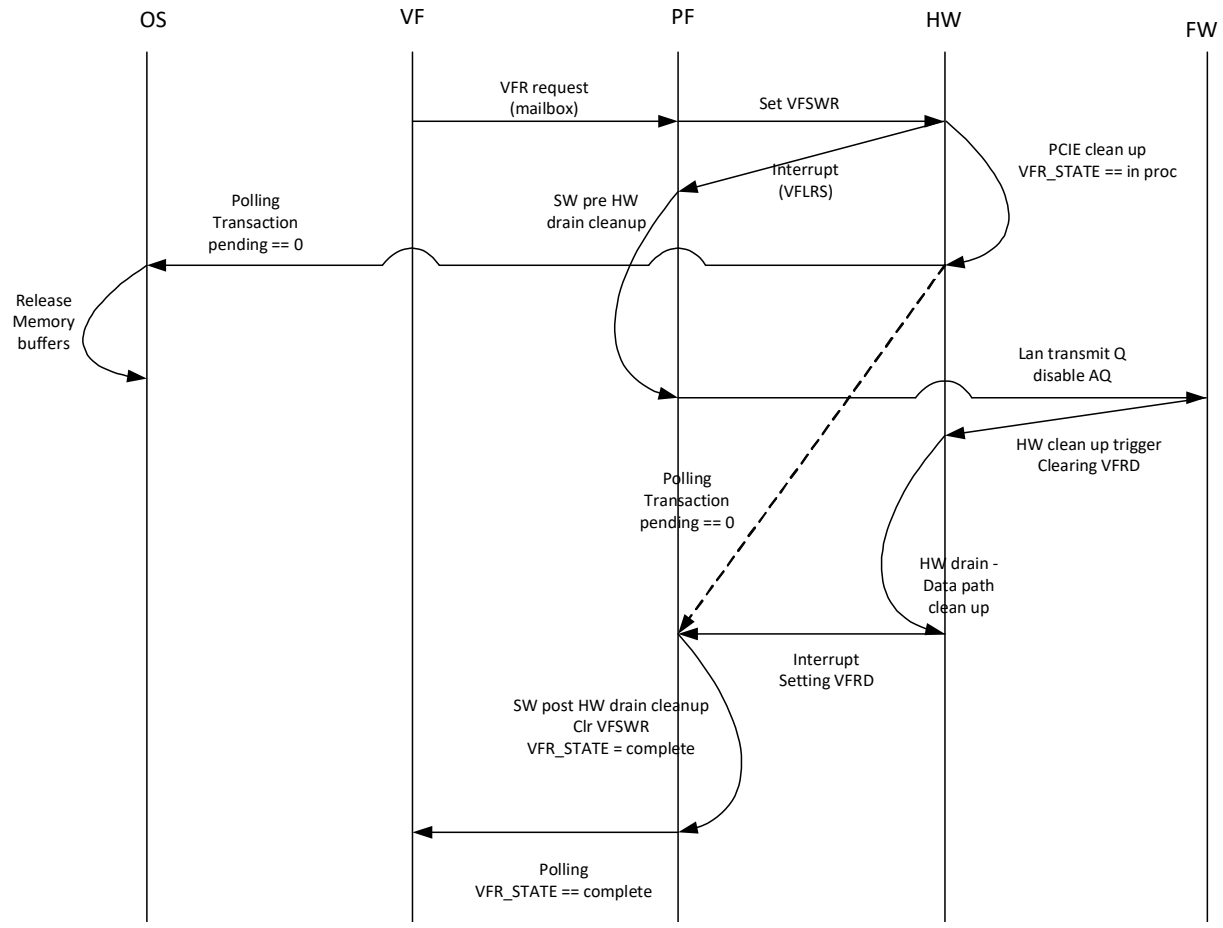

Figure 4-10. VFR Requested by VF Driver Flow

4.1.3.3.2 VF Reset Request by the Operating System (VFLR)

The VF reset initiation by the operating system is described as follows and shown in Figure 4-9.

1. The following steps are optional:
   a. Clear the *BME* bit in the VF Command register.
   b. As a response, hardware avoids any new master cycles of the VF (including MSI-X initiation). Old completions are trashed by hardware.
   c. The operating system polls the *Transaction Pending* bit in the VF Device Status register until it is cleared.
2. The operating system sets the *FLR* bit in the VF Device Control register (Step 2 in Figure 4-9).
3. The operating system is required by PCIe specification to wait 100 ms before it can assume that the VFLR sequence is completed by hardware.
4. If required, the operating system brings up a new VF (or the same VF). The VF software driver should poll the *VFR_STATE* in the VFGEN_RSTAT register until it equals to VFR completed (set by the PF software).

5. The VF software proceeds activating the function.

Hardware responses to VFLR are as follows:

1. Initialize the PCIe configuration space of the VF including the *Bus Master Enable* flag.
2. Set internally the *VFSWR* bit in the VPGEN_VFRTRIG register of the VF, which initiates a VFR (Step 3 in Figure 4-9, and explained in Section 4.1.3.3.3).

4.1.3.3.3 VF Reset Flow by the PF Software Driver

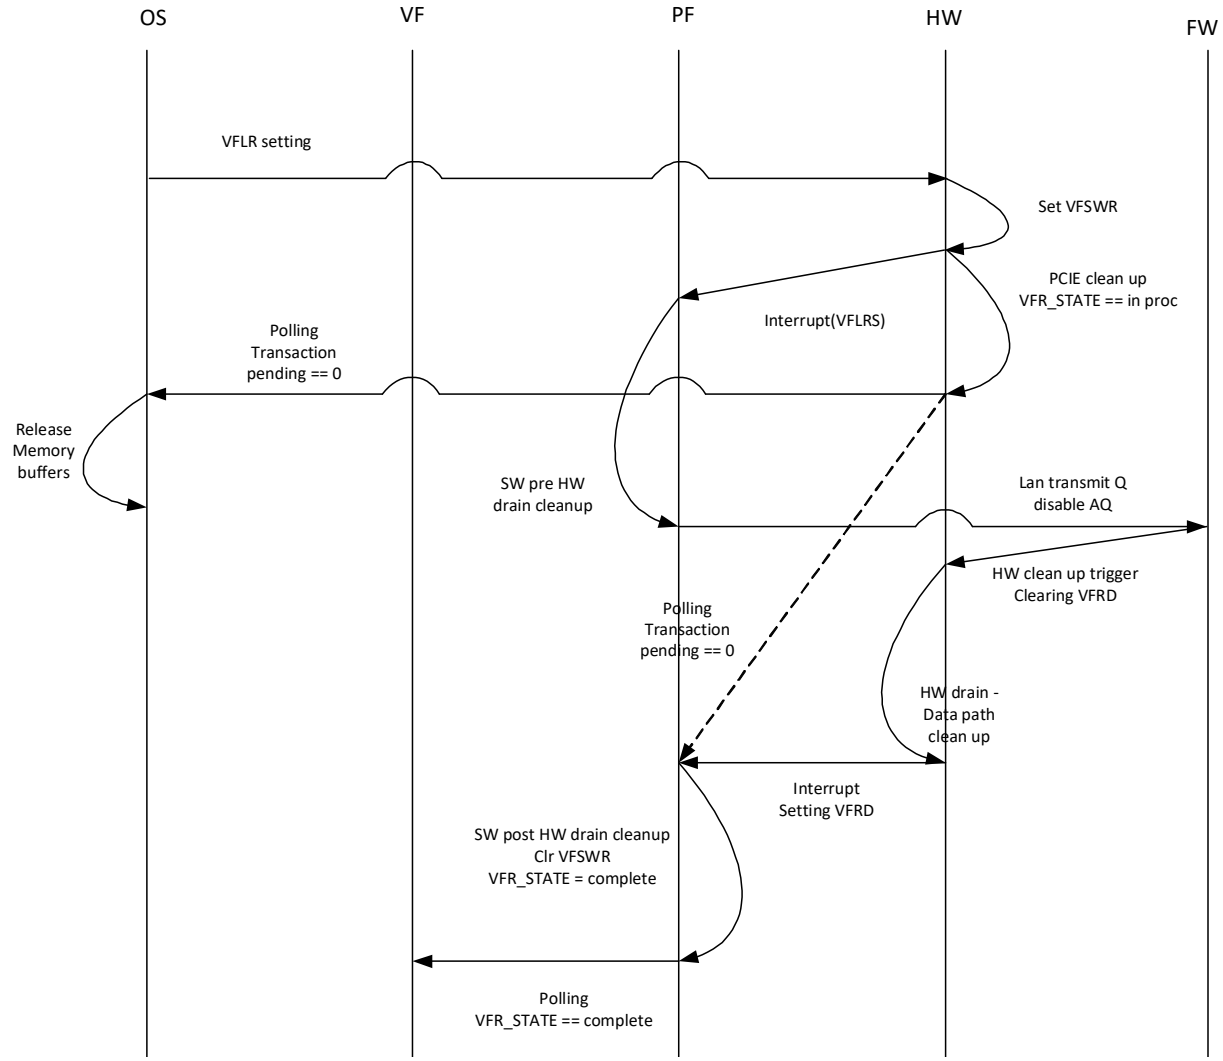

Figure 4-11. VFR Requested by OS

1. As a response to setting the *VFSWR*, hardware does the following:
   a. Reflects the *VFSWR* bit through *VFLRS* flags in the GLGEN_VFLRSTAT registers.
   b. Only in case of VFLR (OS initiated reset) an interrupt is issued to the parent PF. The PF response to the VFLR interrupt is described below.
   c. The hardware response to setting the *VFSWR* bit is listed in Table 4-1.

      Note: As part of the VF registers, the VFGEN_RSTAT register is cleared as well, reflecting VFR in progress state. Furthermore, hardware also gates read accesses to the CSRs of the VF returning DEADBEEF or DEADBEAF values and also gates any master accesses.

   d. The T*ransaction Pending* bit is cleared when there are no more pending completions. Once the *Transaction Pending* bit in the VF Device Status register is cleared, the operating system can release all VF memory structures and unload the VF driver (if required).
2. The PF software responds to the interrupt and queries the *VFLRS* flags in the GLGEN_VFLRSTAT registers to identify to which of its VFs a reset was issued (of the VFs that it owns). When set, PF software executes "pre hardware drain" clean-ups (Step 4 in Figure 4-9):
   a. PF software cleans up switch population of the VF.
   b. PF software cleans up ACL population of the VF (as described in Section 7.9.2.10).
   c. PF software cleans up RSS population of the VF (as described in Section 7.10.11.2).
   d. PF software cleans and disables FD and QH filters of the VF (as described in Section 7.10.12.1 and Section 7.10.12.2, respectively).
   e. PF software clears the enable bit of doorbell queues that are associated with the doorbell queues of the reset VF. Tx-Queues and Admin queues are automatically disabled by hardware
   f. When working in SR-IOV mode, PF software disables mailbox queues and sideband queues of the reset VF (as described in Section 9.5.3).
3. The PF software, via VM/VF Reset admin command, indicates firmware to initiate VF hardware drain (data path clean up) flow, it passes to firmware the Tx-Queue IDs of the VF (VM/VF Reset Admin queue command is described in Section 9.5.13.9). Queue IDs are described in the PF space. PF software must limit the amount of reset flows concurrently processed by hardware to maximum 4 for all its VFs and VMs (from GL_XLR_MARKER_TRIG* setting to data path clean in indication setting by hardware)
   a. EMP initiates and monitors the process of halting the Tx-Queues (as described in Section 9.5.13.9) via GL_XLR_MARKER_TRIG* registers, EMP indicates hardware to send a drain marker that drains the Tx data path, Rx data path, PE data path and logic orthogonally.
      - The specific GL_XLR_MARKER_TRIG* registers are:
        — GL_XLR_MARKER_TRIG_VMLR
        — GL_XLR_MARKER_TRIG_TCVMLR
        — GL_XLR_MARKER_TRIG_RCU_PRS
        — GL_XLR_MARKER_TRIG_PE (should be written only if PW is enabled)
   b. Draining the Tx and Rx data paths might take some time when the TC is paused by flow control. Hardware includes a timeout mechanism that prevents indefinite latency as described in Section 8.2.4.4.1.
   c. VPGEN_VFRSTAT.*VFRD* indication is cleared when GL_XLR_MARKER_TRIG_VMLR is written.

4. When hardware drain flow ends (reset flow is completed - Step 5 in Figure 4-9), hardware sets VPGEN_VFRSTAT.*VFRD* and issues an interrupt to parent PF.
5. Once the *VFRD* flag in the VPGEN_VFRSTAT register is found active, the PF software writes 1b to clear to the matched *FVLRS* bit in the GLGEN_VFLRSTAT registers for the VF under reset.

   Note: The GLGEN_VFLRSTAT registers are composed of 256 bits for the 256 VFs. All PFs have access to the bits of all VFs. However, it is expected that the PFs writes 1b to clear to those bits that match its VFs and only to those bits.)

6. After that PF software proceeds with the VF reset flow (Step 6 in Figure 4-9) and executes the "post hardware drain" clean-ups:
   a. Disable the receive queues of the VF following the fast queue disable flow per each queue as described in Section 10.4.3.1.2.

      Note: The hardware auto-disables the transmit queues of the VF.

   b. PF releases all resource of the VF (for example, nodes in PSM and in PE scheduler, function profile, switch population, and queue allocation as described in Section 10.2.1 and Section 10.2.2).
   c. PF resets (zeros all fields) the QINT_TXQCTL, QINT_RXQCTL, and GLINT_CEQCTL registers for the queues of the VF.
   d. Resets the VPINT_ALLOC, VPINT_ALLOC_PCI, and GLINT_VECT2FUNC registers of the VF (registers that define the vectors assignment to the VF).
7. The PF driver checks the pending transactions of its VF (by setting the VF index and the offset of the VF Device Status register in the PF_PCI_CIAA register and then polling the pending flag in the PF_PCI_CIAD register) (Step 7 in Figure 4-9).
8. The following steps in this bullet item are part of re-enabling the VF. It can be executed at this phase before notifying the VF that the reset flow is completed or at a later phase (depending on software implementation):
   a. Add the VSIs for the VF (including its Transmit and Receive queues and its scheduler).
   b. Add the MAC/VLAN filters for the VSI.
   c. Enable the VFLAN_QTABLE by setting the VPLAN_MAPENA and then program the VFLAN_QTABLE to the queues of the VF.
9. The PF software completes the flow by notifying the VF that the reset flow is completed. It sets the *VFR_STATE* field in the VFGEN_RSTAT register to VFR completed and clears the *VFSWR* bit in the VPGEN_VFRTRIG register (Step 8 in Figure 4-9).
10. Hardware response to cleared VFSWR flag:
    a. The VF CSRs are unlocked. As a result, the VF software can see the updated *VFR_STATE* in the VFGEN_RSTAT register that equals to VFR completed (Step 9 in Figure 4-9).
    b. Master cycles are not blocked anymore by the reset logic.
    c. The hardware is ready to be used by the VF.

4.1.3.4 VMR Flow

1. PF sets the *VMSWR* bit in the VSIGEN_RTRIG register of the VM.
2. PF initiates "pre hardware drain" clean-up flow.
   a. PF software cleans up switch population of the VM.
   b. PF software cleans up ACL population of the VM (as described in Section 7.9.2.10).
   c. PF software cleans up RSS population of the VM (as described in Section 7.10.11.2).
   d. PF software removes the QH and FD filters of the VM.
   e. PF software sends dummy doorbell for all the doorbell queues of the VM and waits for all dummy doorbells (generated at "pre hardware drain" flow) to be pulled from doorbell queues. Dummy doorbell is a regular doorbell description that has its *RS* and *Dummy* fields set to 1 (doorbell descriptor format is described at Section 10.5.5.6).
   f. When working in PASID mode, PF software disables mailbox queues of the reset VM.
   g. PF software removes the interrupt causes of the VM from the active linked list (as described in Section 9.1.3.1.2).
3. As a response to VMSWR bit setting, hardware does the following:
   a. The hardware response to setting the *VFSWR* bit is listed in Table 4-1.

      Note: As part of the VM registers, the VSIGEN_RSTAT register is cleared.

   b. The *Transaction Pending* bit is cleared when there are no more pending completions. Once the *Transaction Pending* bit in the VM Device Status register is cleared, the operating system can release all VM memory structures.
4. The PF software, via VM/VF Reset admin command, indicates firmware to initiate VM reset flow. It passes to firmware the VM Tx-Queues identifiers (VM/VF Reset Admin Queue command is described in Section 9.5.13.9). Queue IDs are relative to the PF space.
5. PF software must limit the amount of reset flows concurrently processed by hardware to maximum 4 for all its VFs and VMs (from GL_XLR_MARKER_TRIG* setting to data path clean in indication setting by hardware).
   a. EMP initiates and monitor the process of halting the Tx-Queues (as described in Section 9.5.13.9) via GL_XLR_MARKER_TRIG* registers, EMP indicates hardware to send a drain marker that drains the Tx data path, Rx data path, and PE data path and logic orthogonally.
      - The specific GL_XLR_MARKER_TRIG* registers are:
        — GL_XLR_MARKER_TRIG_VMLR
        — GL_XLR_MARKER_TRIG_TCVMLR
        — GL_XLR_MARKER_TRIG_RCU_PRS
        — GL_XLR_MARKER_TRIG_PE (should be written only if PW is enabled)
      - Draining the Tx and Rx data paths might take some time when the TC is paused by flow control. Hardware includes a timeout mechanism that prevents indefinite latency as described in Section 8.2.4.4.1.
      - VSIGEN_VFRSTAT.*VMRD* indication is cleared when GL_XLR_MARKER_TRIG_VMLR is written.
   b. When hardware drain flow ends (reset flow is completed - Step 5 in Figure 4-9), Figure 4-9 sets the VPGEN_VFRSTAT.*VFRD* and issues an interrupt to parent PF.

6. After that, PF software proceeds with the VF reset flow (step 6 in Figure 4-9) and executes the "post Figure 4-9 drain" clean-ups.
   a. Disables the receive queues of the VF following the fast queue disable flow per each queue.
   b. Sends a CQ drain marker for all the completion queue of the VMs. it waits for all completions to be pulled from completion queues. CQ drain marker is generated by writing GLCOMM_CQ_CTL with the CMD field set to *VM_reset_marker* value.
   c. PF releases all resource of the VM (For example, nodes in PSM and in PE scheduler, function profile, switch population). The PF driver checks the pending transactions of its VM and waits until it is cleared.
   d. PF resets (zeros all fields) in the QINT_TXQCTL, QINT_RXQCTL, and GLINT_CEQCTL registers for the queues of the VM.
7. The PF driver checks the pending transactions of its VM and waits until it is cleared.
8. The PF software clears the *VMSWR* bit in the VSIGEN_VFRTRIG register.
9. Hardware response to cleared *VMSWR* flag:
   a. Master cycles are not blocked anymore by the reset logic.
   b. The hardware is ready to be used by the VM.
10. After PF driver polls the VMR done indication in the VSIGEN_RSTAT register, it:
    a. Polls the *Transactions Pending* flag of the VM, verifying that there are no transaction pending of the VM as follows:
       - Set the VSI index in the PFPCI_VMINDEX and then poll the PFPCI_VMPEND register.
    b. Does not clear the interrupts settings that might be shared with the PF (or other VMs).
    c. Does not check pending transactions of the VM that does not exist.
    d. Completes the flow by clearing the VMSWR bit in the VSIGEN_RTRIG register.

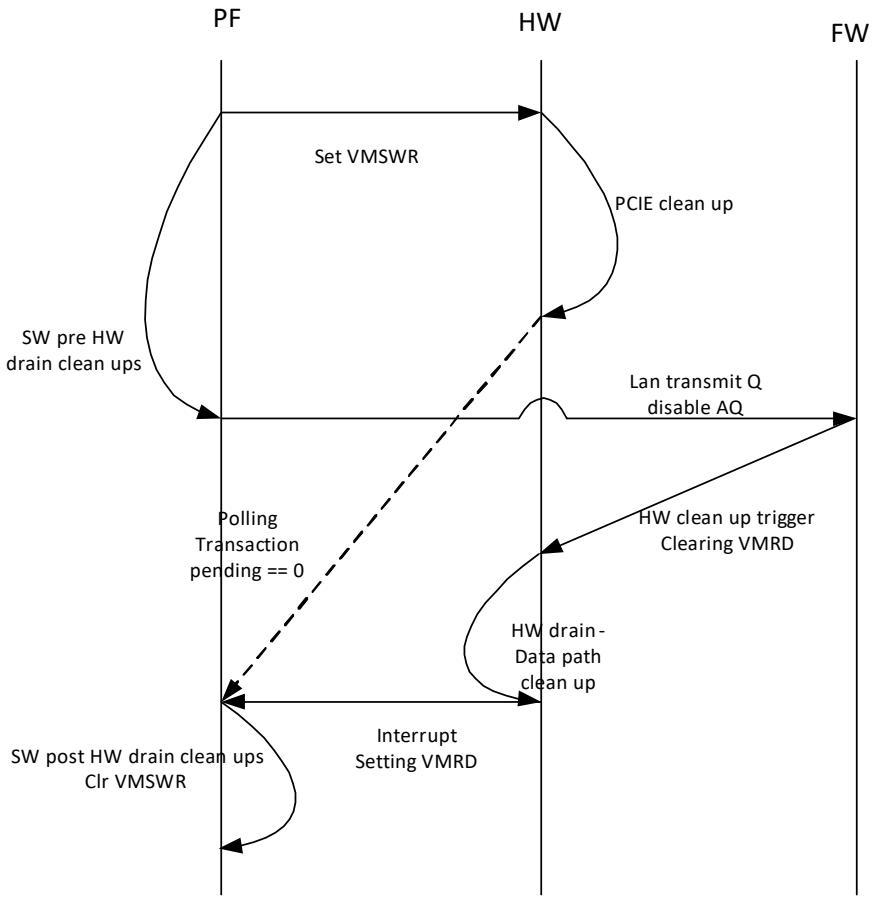

Figure 4-12. VMR Flow

Notes: Overall number of reset flows concurrently processed by hardware is limited to 40 (from GL_XLR_MARKER_TRIG* setting to data path clean in indication setting by hardware):

- Max 32 VF or VM reset flows - PF software limits the amount of reset flows concurrently processed by hardware to maximum 4 for all its VFs and VMs.
- Max 8 PF reset flows for 8 PFs.

4.2 Power-On and Reset

This section describes the flow of the E810 power-up. The initialization sequence for the E810 is broken down into phases: power on, BIOS initialization, and software device driver load.

- Power on (Section 4.1.2.1) is the first phase that includes all steps required to support pre-boot power management and manageability, satisfy the PCIe requirements for exiting cold reset, and prepare for the BIOS initialization phase. This stage also covers firmware initialization.
- BIOS initialization (Section 4.3) begins when Option ROM code is loaded by BIOS to provide boot services for PXE. Other Option ROM capabilities include configuration images for certain OEM environments, such as SMASH/CLP.
- The final phase of the E810 initialization is the software device driver load, where the operating system loads the various software device drivers and the E810 has been initialized for post-boot operation. See Section 4.4.

4.2.1 Auto-Load Shadow RAM

This phase of auto-load determines if a properly-configured Flash device is attached:

- If the attached Flash device is not properly configured, the default hardware settings are kept. The power-on flow continues without loading from the NVM.
  - The NVM is expected to be reprogrammed. See Section 3.4.4.2 for more details on how this is done.
- If the attached Flash device is properly configured, auto-load proceeds with its first stage. NVM modules loaded to the on-die Shadow RAM are read from the NVM.

Once the Shadow RAM is ready, an internal indication is set that the device enumeration may proceed. This indication is also set when the NVM is found blank.

4.2.1.1 Auto-Load into Device Units

The NVM configurations are loaded into the device units directly from the NVM or indirectly through Shadow RAM.

The loading process of the NVM modules that are specified in Table 4-2 are tracked and reported.

The following CSR fields track the progress of loading the NVM modules following power-on and the various resets:

- GLNVM_ULD.*_*DONE* bits (one per module) indicates the unit is ready to use.

Default hardware values:

• GLNVM_ULD.*_*DONE* = 0b

The flow during a power-on stage is as follows:

- If the NVM is found blank:
  - All GLNVM_ULD.*_*DONE* bits are set by the E810.
- If the NVM is found valid:
  - After process is done by EMP firmware, it sets the GLNVM_ULD.*_*DONE* bit to 1b.

4.2.1.2 Firmware Initialization

There are two sets of firmware loaded for the E810. The first is for the Embedded Management Processor (EMP). This firmware is first to load and is required for all E810 deployments. It is optionally followed by loading Protocol Engine firmware required for RDMA and UDA operation.

Once EMP firmware loads, the following E810 features are enabled:

- The external Ethernet link is active.
- Default internal switching components have been configured.
- Communication with the BMC is possible if supported by the E810 and the system (optional).
- OEM-specific manageability agents are active and responding to commands from the Ethernet fabric (optional).
- Admin queues for all enabled PCI functions are ready for commands - EMP responds to each function's Get Version AQ command to indicate that it is safe for software to start using the E810 for device driver initialization (see Section 9.5.3).
- HMC default profile has been configured.

Once EMP firmware is up and running, the E810 can be configured via its management interfaces, and certain device capabilities are then enabled or disabled (such as soft SKUing).

Protocol Engine firmware is responsible for processing configuration requests for RDMA and UDA functionality that is provided by the Protocol Engine. See Section 11.5.2 for more information on the specifics of the commands supported by Protocol Engine Firmware. Protocol Engine firmware load begins once the EMP firmware has finished loading and initialization and only after primary reset was de-asserted. When the Protocol Engine firmware is loaded and initialized, the GLPE_CPUSTATUS0-2 registers indicate that it is safe to start using Protocol Engine capabilities.

Protocol Engine firmware is loaded only when the protocol engine is enabled in the NVM.

4.2.1.3 MAC Address Initialization

The E810 supports a port MAC Address for each of its ports. These addresses are used by the internal switch for L2 filtering of packets, by the classification filters, for WoL purposes, and for link-level functionality, such as flow control frames and LLDP. The addresses are loaded from the NVM PRTPM_SAL and PRTPM_SAH registers.

Table 4-4 lists how each address can be set or read and where it is stored.

Table 4-4. MAC Address Information

MAC Address Type	Where Stored	How Reported	How Modified	Modified at Manufacturing?
LAN MAC Address - factory	NVM PF MAC Address section (TLV type = 0x10F) Loaded by firmware to: • Internal switch entries • PRTPM_SAL/H • PRTMAC_HSEC_CTL_TX_SA_PART1/2		N/A	Yes
LAN MAC Address – BIOS setting	Alternate RAM (Current LAN MAC Address (Low/High)) Loaded by firmware to: • Internal switch entries • PRTPM_SAL/H • PRTMAC_HSEC_CTL_TX_SA_PART1/2	Manage MAC Address read (LAN address valid) - if no LAA	Write Alternate AQ command: • Alternate LAN MAC Address (LS) • Alternate LAN MAC Address (MS) • NC-SI Set Address OEM command	No
WoL MAC Address	PRTPM_SAL/H	Manage MAC Address read (WoL address valid)	Manage MAC Address Write AQ command (update LAA and WoL address).	Yes
WoL MAC Address preserve on PFR	RAM	Manage MAC Address read (WoL_preserve_on_PFR)	Manage MAC Address Write AQ command (WoL_preserve_on_PFR). Set by software before D0->Dr/D3 transition. Cleared by software after returning to D0). 0 by default after POR/ EMPR.	No
LAA MAC Address	Local firmware variable	Manage MAC Address read (LAN address valid)	AQ command (update LAA address) ***Note:*** Changing the LAA only does not impact the address used to detect Magic Packets.	No
MNG MAC Address	MNG MAC Address NVM module	NVM Read command (module type = 0x110)	NVM Write command (module type = 0x110)	No
PCIe serial address	PCIe serial address NVM module	NVM Read command (module type = 0x133)	NVM Write command (module type = 0x133)	Yes

The following rules apply:

- The *PF_NUM* field in the PRTPM_SAH register is deducted from the PF issuing the command.
- The *AV* field in PRTPM_SAH is set by the EMP when writing a MAC Address.

The per-PF MAC Address used by the internal switch is managed via the Remove MAC/VLAN Pair and Add MAC/VLAN Pair commands.

4.2.1.3.1 Manage MAC Address Read Command (0x0107)

This command is used by the PF driver to read the per-PF station MAC Address. This is an indirect command.

Table 4-5. Manage MAC Address Read Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0107	Command opcode.
Datalen	4-5	0x0	0x18 (the response buffer size).
Return Value/VFID	6-7	0x0	Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16-17	Reserved	Reserved.
Port Number	18-19.0	Port Number	**Byte 18:** Logical Port Number This field specifies the logical port number, and is used when the physical function owns more than one port. A value of 0xFF means that a dump of all ports addresses is requested. A port number of 20 (logical port number of the E810) returns the local MAC Address of the E810. **Bit 19.0:** Logical Port Number is valid.
	19.1-19.7	Reserved	Reserved.
Reserved	20-23	0x0	Reserved.
Data Address High	24-27	Buffer Address	High bits of the return buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the return buffer address.

4.2.1.3.1.1 Manage MAC Address Read Response (0x0107)

A firmware acknowledge to the Manage MAC Address Read command. This is an indirect response.

Table 4-6. Manage MAC Address Read Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0107	Command opcode.
Datalen	4-5	0x0	0x18 (the response buffer size).
Return Value/VFID	6-7	Return Value	Return value. Firmware supplies in the *Return Value* field an indication on the completion of the Manage MAC Address Read command. 0x0 = No error. Others = Error detected in the command.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16.0-16.3	Reserved	Zeroed by the EMP.
	16.4	LAN Address Valid	This bit is set if any of the addresses reported in the buffer is of type LAN.
	16.5	SAN Address Valid	Reserved for the E810.
	16.6	Port Address Valid	Reserved for the E810.
	16.7	WoL Address Valid	This bit is set if any of the addresses reported in the buffer is of type WoL.
	17.0	MC_MAG_EN	If set, multicast Magic Packets generate a WoL event (if WoL is enabled for this function).
	17.1	WoL_preserve_on_PFR	Set to preserve WoL MAC on PFR (to be set by software before D0->Dr/D3 transition. Cleared by software after returning to D0 state). 0 by default after POR/EMPR. Relevant only if WOL MAC was set.
	17.2-17.7	Reserved	Reserved.
Reserved	18-23	0x0	Reserved.
Data Address High	24-27	Buffer Address	High bits of the return buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the return buffer address.

Note: All MAC Addresses are a byte stream in network order.

The buffer is as follows:

Address	Offset	Description
Reserved	0-1	Reserved.
PF LAN SA	2-7	Current device value of the PF LAN MAC Address. Validated by *LAN Address Valid* flag. This address is returned from LAA address if valid, otherwise from Alternate RAM if valid, otherwise from the NVM if valid.

4.2.1.3.2 Manage MAC Addresses Write Command (0x0108)

This command is used by the PF driver to write the per-PF station MAC Address. This is a direct command.

Table 4-7. Manage MAC Address Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0108	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7	0x0	Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16	Port Number	Port Number This field specifies the port number, and it is used when the physical function owns more than one port.
	17.0	MC_MAG_EN	Used to set the *MC_MAG_EN* bit.
	17.1	LAA_WOL_PRESERVE	LAA WoL preserve on PFR Relevant only if WOL MAC was set.
	17.2	Valid	Port number in byte 16 is valid.
	17.5-17.3	0x0	Reserved.
	17.7-17.6	Write Type	00b = Update LAA only. 01b = Update LAA and WOL address. All other values are reserved.
SAH	18-23	MAC Address	MAC Address as a byte stream in network order.
Reserved	24-31	Reserved	Reserved.

4.2.1.3.2.1 Manage MAC Address Write Response (0x0108)

A firmware acknowledge to the Manage MAC Address Write command. This is a direct response.

Table 4-8. Manage MAC Address Write Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0108	Command opcode.
Datalen	4-5	0x0	Must be 0x0. Value is ignored.
Return Value/VFID	6-7	Return value	Return value. Firmware supplies in the *Return Value* field an indication on the completion of the Manage MAC Address Write command. 0x0 = No error. Others = Error detected in the command.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16	Port Number	Port Number This field specifies the port number, and it is used when the physical function owns more than one port. Copied from command.
	17.0	MC_MAG_EN	Used to set the *MC_MAG_EN* bit.
	17.1	LAA_WOL_PRESERVE	LAA WoL preserve on PFR Relevant only if WOL MAC was set.
	17.2	Valid	Port number in byte 16 is valid.
	17.5-17.3	0x0	Reserved.
	17.7:17.6	Write Type	00b = Update LAA only. 01b = Update LAA and WOL address. All other values are reserved.
Reserved	18-31	Reserved	Reserved.

4.2.1.4 Power-On Device State

This section describes the specific setting of each of the E810's components required for pre-boot operation. It describes the information loaded from the NVM (per component) and the state attained by each.

- **Manageability** — System management functionality, if enabled, is fully operational by the end of the EMP firmware initialization sub-stage. Some configuration is loaded from the NVM during the power-on stage. Capabilities might include the following:
  - — Sideband interfaces
  - — Pass-through manageability (including packet filtering)
  - — Preparation for OS-to-BMC traffic
  - — Preparation for MCTP over PCIe operation

- **Internal MAC and PHY** — If either system management or APM WoL are enabled, enabled LAN ports are brought up by firmware once EMP firmware initialization completes. Otherwise, enabled LAN ports are brought up following PERST# de-assertion.
  - See Section 3.2 for more details.
- **Admin Queue (AQ)** — A queue (Tx and Rx pair) is activated per enabled PCI function. For example, an AQ is needed for BIOS to change the switch or scheduler configuration.
  - See Section 9.5.3 for more details.
- **Internal Switch** — The internal switch is configured from the NVM for basic switching capabilities to the EMP and the enabled PCI functions. First, the switch programmable logic is loaded, followed by configuration of a basic switch topology. The topology is for basic L2 functionality.
- **DCB** — The NVM loads the LLDP and DCBX setting into the E810. Once EMP firmware initializes and link is up, firmware engages in DCBX negotiation. Firmware then makes the appropriate changes in the E810's configuration based on the outcome of the DCBX protocol. At this stage, DCB capabilities (TCs, ETS, PFC) can be enabled.
- **Tx-Scheduler** — As the switch VSIs are enabled, firmware allocates Tx-Scheduler per each PF VSI based on the NVM configuration. Each queue is configured to default behavior. Firmware also generates the required handles to enable system software to update the configuration of each queue. If DCBX protocol runs, the outcome of the protocol exchange might translate into changes in scheduler configuration.
- **Host Memory Cache (HMC)** — NVM settings supply the initial HMC configuration using a simple set of rules that enable equal distribution of HMC resources to all PFs that are connected to external Ethernet ports.
- **Power Management** — Some power management capabilities are supported pre-boot or during BIOS initialization.
  - The E810 might be enabled for APM wake during power up. See Section 5.3.1 for more details on how APM Wake is configured.
  - EEE might be enabled once EMP firmware is initialized.
- **LAN** — LAN queues are available for network boot in the BIOS initialization phase. Some LAN configuration is loaded from the NVM during power on, including partitioning of the LAN queues among PFs.
- **Protocol Engine (PE)** — NVM setting can disable PE operation in the device. The Protocol Engine is not enabled during Power-On and BIOS Initialization stages. It is configured and initialized in the Driver Load phase.

4.3 BIOS Initialization

This section describes how BIOS code might update the E810's configuration and the capabilities for network boot. The following sections are provided:

- Section 4.3.2 describes how BIOS code might change the E810's configuration on each boot.
- Section 4.3.3 describes some aspects of supporting network boot.
- Section 4.3.4 describes the specific setting of each of the E810's components required for the BIOS initialization stage

4.3.1 Initial State

The state of the E810 when BIOS begins to access it is described in Section 4.3.4.

BIOS code must check that the EMP completed device initialization. This is done through the Get Version AQ command described in Section 9.5.13.1.

4.3.2 Non-Persistent Configuration

During power up, the E810 is factory-configured from the NVM. However, the factory configuration can be overridden in two possible ways:

- **Persistent Configuration** — System tools (such as software agents and SMCLP commands) can write into the NVM and change the factory defaults. It is also possible to add alternate values into the NVM so that the factory defaults are preserved and can be restored at a later time.
- **Non-Persistent Configuration** — An on-die Alternate RAM structure is provided to store configuration values that are not supposed to be maintained between cold resets. The information in this structure is retained during all resets other than a cold reset of the device. The specific fields are loaded by the device Firmware according to Table 4-9.

During a cold reset sequence, the alternate structure might be written by either an external system management agent (via the device management interfaces) or by BIOS level code (like SMASH/CLP commands).

4.3.2.1 Alternate RAM Structure

The alternate structure is 6 KB, partitioned into 32-bit entries. Accessing the structure is done by addressing 32-bit entries. An address is therefore 11 bits (1.5K DWords), where address 0x000 points to the beginning of the memory.

During a cold reset sequence, the alternate structure can be written by either an external system management agent (via the device management interfaces) or by BIOS level code (like SMASH/CLP commands).

The structure is partitioned as follows:

Section	Address (DW)	Size (DW)	Content
Per PF	0-511	512-64 per PF	8 per-PF sections, one per PF. These sections are described in Section 4.3.2.1.1 and can be accessed by each PF.
Reserved	512-1023		Reserved for more functions.
EMP	1024-1536	512	Reserved for EMP use, including error logging. Can be written and read only by the EMP. In debug mode, this section can be read by the PFs.

4.3.2.1.1 Per-PF Sections

Table 4-9. Per-PF Alt RAM Content

Scope	Address (DW)	Contents	Done Alternate Write Required[1]	NVM Dump Required[2]	Load Conditions
PF	0	Current LAN MAC Address (Low)	No	No	PFR, CORER
PF	1	Current LAN MAC Address (High)	No	No	PFR, CORER
PF	2-18	Reserved	N/A	N/A	Never
PF	19	RDMA	Yes	Yes	POR
PF	20-63	Reserved	N/A	N/A	Never

1. The "Done Alternate Write Required" column indicates whether the Done Alternate Write (Opcode: 0x0904) command needs to be issued to the device for the configuration to take place on the conditions specified by the "Load Conditions" column. If "Done Alternate Write" is not required, just writing the value into the Alternate RAM and meeting the load conditions is sufficient for the configuration to take place. If the "Done Alternate Write" command was required, but not sent, the configuration is not applied, even if the condition is met. Issuing the "Done Alternate Write" command when it is not explicitly required does not have any adverse effects on the operation of the device.
2. Some changes are persistent. To make sure the data is stored in NVM, the Shadow RAM must be written back to the Flash using the NVM Write Activate command (Section 3.4.10.8).

4.3.2.1.1.1 Current LAN MAC Address (Offset 0x0, 0x1)

Lower DWord:

Field	Bit(s)	Description
MAC Address	31:0	MAC Address Contains the LS 32-bit of the address.

Upper DWord:

Field	Bit(s)	Description
MAC Address	15:0	MAC Address Contains the MS 16-bit of the address.
Reserved	30:16	Reserved.
Valid	31	Valid Bit 0b = The MAC Address two DWords are invalid and should be skipped. 1b = The MAC Address two DWords are valid and should be processed.

Upper DWord:

Actions taken on a change in this entry:

- When valid, it overrides the MAC Address loaded from the NVM.

4.3.2.1.1.2 RDMA (Offset 0x19)

Field	Bit(s)	Description
Override Enable	0	Enable BIOS override of netlist configuration recommendation for topology of 4 ports and below.
RDMA Enable	1	Enable RDMA for topology of 4 ports and below.
Reserved	30:2	Reserved.
Valid	31	Valid bit 0b = DW is invalid and should be skipped. 1b = Entry is valid and should be processed.

4.3.2.2 AQ Commands

Table 4-10 lists the different AQ commands used to manage the alternate structure.

Table 4-10. List of AQ commands for the Alternate Structure

Command	Opcode	Description	Section Reference
Write Alternate - Direct	0x0900	Write up to two parameters into the alternate structure.	4.3.2.2.1
Write Alternate - Indirect	0x0901	Write a block of parameters into the alternate structure.	4.3.2.2.2
Read Alternate - Direct	0x0902	Read up to two parameters from the alternate structure.	4.3.2.2.3
Read Alternate - Indirect	0x0903	Read a block of parameters from the alternate structure.	4.3.2.2.4
Done Alternate Write	0x0904	Indication that all CLP strings (for the entire E810 in legacy BIOS mode, and per LAN Port in UEFI mode) have been sent to the E810.	4.3.2.2.5
Clear Port Alternate	0x0906	Clear content of Alternate RAM relevant to this port.	4.3.2.2.6

4.3.2.2.1 Write Alternate - Direct Command (0x0900)

The Write Alternate - Direct command writes to the alternate structure up to two parameters.

Table 4-11. Write Alternate - Direct Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0900	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
First Parameter Address	16-19		Accessing the alternate structure is done by addressing 32-bit entries.
First Parameter Data	20-23		
Second Parameter Address	24-27		Address should be within the range allocated to the function inside the alternate structure. Value of 0xFF..FF means only the first parameter is written. Accessing the alternate structure is done by addressing 32-bit entries.
Second Parameter Data	28-31		

The following completion is sent for the Write Alternate - Direct command:

Table 4-12. Completion for the Write Alternate - Direct Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0900	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7		Some comments on specific errors: 0x0 = No error. ENOMEM = Out of memory (access outside the alternate structure). EACCES = Permission denied (access to another PF's area).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved. Might contain the values sent in the original command.

4.3.2.2.2 Write Alternate - Indirect Command (0x0901)

The Write Alternate - Indirect command writes a block of parameters to the alternate structure. The command defines the number of DWords to be written and the starting address inside the alternate structure.

Table 4-13. Write Alternate - Indirect Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0901	Command opcode.
Datalen	4-5		Size of buffer accompanying the command (in bytes).
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alternate Structure Address	16-19		Lowest address to be written into the alternate structure. Accessing the alternate structure is done by addressing 32-bit entries.
Alternate Structure Length	20-23		Number of DWords to be written into the alternate structure.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

The following completion is sent for the Write Alternate - Indirect command:

Table 4-14. Completion for the Write Alternate - Indirect Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0901	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7		Some comments on specific errors: 0x0 = No error. ENOMEM = Out of memory (access outside the alternate structure). EACCES = Permission denied (access to another PF's area).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

4.3.2.2.3 Read Alternate - Direct Command (0x0902)

The Read Alternate - Direct command reads from the alternate structure up to two parameters. This command, and the next one, returns the values as stored in the Alternate RAM, which might not reflect the current hardware configuration.

Table 4-15. Read Alternate - Direct Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0902	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
First Parameter Address	16-19		Address should be within the range allocated to the function inside the alternate structure. Accessing the alternate structure is done by addressing 32-bit entries.
Reserved	20-23	0x0	Reserved.
Second Parameter Address	24-27		Address should be within the range allocated to the function inside the alternate structure. Value of 0xFF..FF means only the first parameter is read. Accessing the alternate structure is done by addressing 32-bit entries.
Reserved	28-31	0x0	Reserved.

The following completion is sent for the Read Alternate - Direct command:

Table 4-16. Completion for the Read Alternate - Direct Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0902	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7		Some comments on specific errors: 0x0 = No error. ENOMEM = Out of memory (access outside the alternate structure). EACCES = Permission denied (access outside of PF's area).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
First Parameter Address	16-19		Copied from the command.
First Parameter Data	20-23		Data read.
Second Parameter Address	24-27		Copied from command. Value of 0xFF..FF means only the first parameter is read.
Second Parameter Data	28-31		Data read.

4.3.2.2.4 Read Alternate - Indirect Command (0x0903)

The Read Alternate - Indirect command reads a block of parameters to the alternate structure. The command defines the number of DWords to be read and the starting address inside the alternate structure.

Table 4-17. Read Alternate - Indirect Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0903	Command opcode.
Datalen	4-5		Size of buffer accompanying the command (in bytes).
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alternate Structure Address	16-19		Lowest address to be read from the alternate structure. Accessing the alternate structure is done by addressing 32-bit entries.
Alternate Structure Length	20-23		Number of DWords to be read from the alternate structure.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

The following completion is sent for the Read Alternate - Indirect command:

Table 4-18. Completion for the Read Alternate - Indirect Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0903	Command opcode.
Datalen	4-5	0x0	Actual length of data returned by the command.
Return Value/VFID	6-7		Some comments on specific errors: 0x0 = No error. ENOMEM = Out of memory (access outside the alternate structure). EACCES = Permission denied (access to another PF's area).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alternate Structure Address	16-19		Lowest address read from the alternate structure.
Alternate Structure Length	20-23		Number of DWords read from the alternate structure.
Data Address High	24-27	Buffer Address	High bits of the buffer address.
Data Address Low	28-31	Buffer Address	Low bits of the buffer address.

4.3.2.2.5 Done Alternate Write Command (0x0904)

The Done Alternate Write command indicates to the E810 that the CLP strings have been sent to it:

- **Legacy BIOS mode** — Sent once per device after all CLP strings have been sent to the E810 (for all LAN ports). Following the command, firmware loads the contents of the alternate structure into the device functional units.
- **UEFI mode** — Sent once per each enabled LAN port. Once the command is received from all enabled ports, firmware loads the contents of the alternate structure into the E810's functional units.

After this command, the software should trigger a Shadow RAM dump using a dummy NVM update with *LAST* flag set (Bit 19.0 in Table 3-62).

Table 4-19. Done Alternate Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0904	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
BIOS Mode	16.0	See remarks	0b = Legacy BIOS 1b = UEFI
Reserved	16.1-31	0x0	Reserved.

The following completion is sent for the Done Alternate Write command:

Table 4-20. Completion for the Done Alternate Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0904	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7		ENOSPC - More than 128 VFs are requested.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16.0	0b	Reserved.
Return Flags	16.1		Reset Needed When set, indicates that software should do a global reset for the Alternate RAM content to take effect.
Reserved	16.1-31	0x0	Reserved.

4.3.2.2.6 Clear Port Alternate Write Command (0x0906)

The Clear Port Alternate command indicates to the E810 to clear the alternate sections of the PF. The port is inferred from the PF that sent the command.

Table 4-21. Clear Port Alternate Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0906	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	0x0	Reserved.

The following completion is sent for the Clear Port Alternate Write command:

Table 4-22. Completion for the Clear Port Alternate Write Command

Name	Byte.Bit	Value	Remarks
Flags	0-1		See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0906	Command opcode.
Datalen	4-5	0x0	N/A
Return Value/VFID	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	0x0	Reserved.

4.3.2.3 Example of a SMASH/CLP Flow - Legacy BIOS

The following pseudo code provides an example of how such a flow might be performed by legacy BIOS using SMASH/CLP commands. The following guidelines should be kept:

- If a certain PCI function is disabled via this mechanism, pre-boot software does not access any resource of that function (such as any CSR) once it sends the Done Alternate Write AQ command. The E810 confirms the command, resets, and disables the function.
- By the time the SMASH/CLP commands are executed and a function is disabled, there is no Tx/Rx activity in the E810 (since no queues have been initialized).
- All ports enabled in the NVM have the Option ROM enabled (such as the lowest PCI function per port has an Expansion ROM BAR).
- BIOS calls all CLP entry points for all functions before getting into the initialization phase.
- It is not guaranteed that a system reset is issued immediately following this sequence. For example, the configuration settings must take place even if such a reset is not issued.
- During the initialization phase, pre-boot software has to issue a global reset followed by a Start LLDP Agent AQ command to start the LLDP agent in firmware.

```
// Initial state:
// The device is configured from NVM.
// The following flow runs per each device.

BIOS does PCI enumeration and discovers functions with Option ROM enabled.

For each LAN Port with Option ROM enabled // sent to the lowest number PCI function on the port,
    BIOS loads the Option ROM into system RAM.
    Set First-Init to true // When Init is later called, it's the 1st call to Init.

    For each CLP string received by BIOS for a function within the port,

        If the Option ROM for the port supports SMCLP entry point,
            BIOS calls SMCLP entry point for port with CLP string.
            SMCLP section in Option ROM processes the CLP string.
            Option ROM keeps track of SMCLP status for the port.
        End-If

    End-For
End-For

For each LAN port with Option ROM enabled,
    BIOS calls INIT entry point for the port.
End-For

SMCLP Entry Point:

If CLP type is SET and action is “Return to default” // clear any pre-existing CLP configuration,
    Send the "Clear Port Alternate" admin command to invalidate all Alternate Memory parameters
    for the port and its PFs.
End-If

If CLP type is SET,
    Generate “Write Alternate - Direct” admin command(s) to the device.
End-If

If CLP type is EXIT // Apply any configuration changes from previous commands that have not
been applied,
    Send appropriate admin commands with default values for the PF parameters not specified by
    the CLP string that have a default behavior in this mode, different than the hardware
    default.
End-If

End SMPCLP Entry Point.

SMCLP INIT Entry point:

If First-Init is true // the flow below should only be executed on the 1st call to Init,

    If SMCLP status is false // means no CLP strings have been received for any functions for the
    device,
        // Option ROM INIT configures the device in a standard operating mode (i.e. not an OEM
        specific mode).
    End-If

    If SMCLP status is true // means at least one function had CLP strings,
        // This is the time to load the CLP parameters from the Alternate Structure into the
        device.
        Send "Done Alternate Write" command indicating end of CLP strings for the device.
    End-If

    // Global Reset should be done only once per device.

    If firmware required a reset in the "Done Alternate Write" response,
        Issue Global Reset of the device.
        Set First-Init to false.
    End-If

End-If
```

```
Continue with INIT code...

End SMCLP INIT Entry Point.
```

4.3.2.4 Example of a SMASH/CLP Flow - UEFI

The following pseudo code provides an example of how such a flow might be performed by the UEFI drivers using SMASH/CLP commands. The following guidelines should be kept:

- If a certain PCI function is disabled via this mechanism, pre-boot software does not access any resource of that function (such as any CSR) once it sends the Done Alternate Write AQ command for that function. The E810 confirm the command, resets, and disables the function.
- By the time the SMASH/CLP commands are executed and a function is disabled, there is no Tx/Rx activity in the E810 (since no queues have been initialized).
- A UEFI driver is executed for each enumerated LAN port. For example, any port enabled in the NVM and not disabled by strapping.
- It is not guaranteed that a system reset is issued immediately following this sequence. For example, the configuration settings must take place even if such a reset is not issued.

```
// Initial state:
// The device is configured from NVM.
// The following flow runs per each device.

BIOS does PCI enumeration and discovers PCI functions.

For each enabled LAN Port,
    BIOS calls driver START entry point.

    For each CLP string received by BIOS for a function within the port,
        SMCLP section processes the CLP string.
    End-For

    Driver sends a "Done Alternate Write" command indicating end of CLP strings for the port.

    If firmware required a reset in the "Done Alternate Write" response,
        Issue Global Reset of the device.
    End-If

End-For

SMCLP section in START:

If CLP type is SET and action is "Return to default" // clear any pre-existing CLP configuration,
    Send the "Clear Port Alternate" admin command to invalidate all Alternate Memory parameters
    for the port and its PFs.
End-If

If CLP type is SET.
    Generate "Write Alternate - Direct" admin command(s) to the device.
End-If

If CLP type is EXIT // Apply any configuration changes from previous commands that have not been
applied,
    Send appropriate admin commands with default values for the PF parameters not specified by
    the CLP strings that have a default behavior in this mode, different than the hardware
    default.
End-If

End SMPCLP section.
```

4.3.2.5 Processing the Alternate Structure

As a result of each Done Alternate Write AQ command, the EMP loads the relevant alternate structure parameters into the E810 according to the following sequence:

- EMP loads any required parameters from the alternate structure into the hardware.
- EMP ACKs the Done Alternate Write command.
- Global reset is performed:
  - Initiated by software.
  - Reset is done only once and not per each instance of the Done Alternate Write AQ command.
- Hardware is initialized, including loading of the relevant sections of the Alternate Structure into the Hardware.

4.3.3 Network Boot

Any functions can be a PXE or UEFI boot function (up to 8 such functions).

4.3.4 Device State

This section is limited to changes in the E810's state made in the BIOS initialization stage. For units not mentioned here, behavior is as described in Section 4.2.1.4.

4.3.4.1 Switch/Tx-Scheduler

Some parameters of the switch and Tx-Scheduler configuration might change by the contents of the alternate structure. Such changes take effect when the alternate structure is enabled.

4.3.4.2 LAN

Expansion ROM code might set LAN QPs for network boot. The sequence of setting a LAN QP is described in Table 10-31 and Section 10.4.3.6.1.

4.3.4.3 Interrupts

Interrupts must be set if used for Admin Queue or LAN queues operation. See Section 9.1.1.1 for the exact flow.

4.4 Driver Load

4.4.1 Introduction

4.4.1.1 Driver Load (non-Virtualized)

As described earlier in this section, by the time the device driver loads, the NVM configuration is already complete and PCIe configuration has taken place. During a device driver load, the following sequence of commands is typically issued to the E810 to initialize it for normal operation. The major initialization steps are:

1. Device driver probes the E810 for resource allocations.
2. Disable interrupts.
3. Initialize the Admin Queue (see Section 9.5.3).
4. Initialize HMC (see Section 9.3.4).
5. Initialize MAC/PHY.
6. Initialize power management - wake-up (see Section 5.3.5).
7. Initialize DCB, including Rx-PB.
8. Initialize the switch and Tx-Scheduler (see Section 7.8.12 and Section 8.3.4.1).
9. Initialize statistics by reading the counter's initial values to serve as a baseline.
10. Init Protocol Engine (see Section 11.5.1).
11. Initialize 1588.
12. Enable interrupts.

At this point, the E810 is ready to initialize VSIs and LAN/PE flows. These are done dynamically during operation:

- Initialize VSI.
- Initialize LAN QP, including its interrupts (see Section 10.4.3 and Section 10.5.5) or Init PE QP (see Section 11.5.1).
- Configure filters (see Section 7.10).

4.4.1.2 Driver Load (SR-IOV)

The E810 approach for virtualized device drivers is to depend heavily on the PF device driver for management of chip resources. The device driver models for newer virtualized operating systems are moving in a direction that requires such functionality. Figure 4-13 shows the high-level initialization flow for virtualized device drivers that use a VF in a guest operating system.

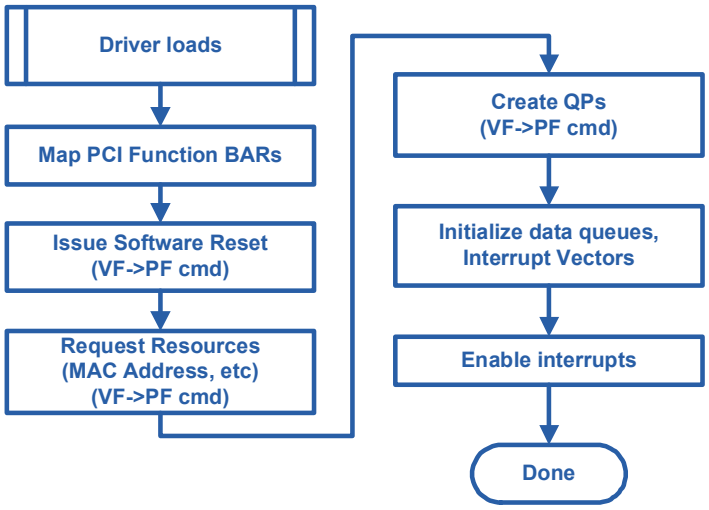

Figure 4-13. Virtualized Device Driver Initialization Flow

4.4.1.2.1 PF Initialization Details

In addition to the regular device driver initialization flow described in Section 4.4.1.1, the PF device driver should apply the following steps to enable support for VMs:

1. After the operating system enables virtual bridging, the PF device driver should create a VEB or a VEPA switching element using the following flow:
   a. Query the switch structure using the Get Switch Configuration command (Section 7.8.12.2.1) to get the initial VSI and initial switch ID associated with the port.
   b. Define mirroring rules using the Mirroring Rules commands (Section 7.8.12.7.1).
   c. Define storm control rules using the Set Storm Control Configuration command (Section 7.8.12.4.1).
   d. Activate malicious driver protection as described in Section 9.2.2.2.1.
2. When the VMM requests that a virtual port be created, the PF driver should:
   a. Create a set of VSIs according to the flow described in the paragraphs that follow. The exact flow depends on the VMM-to-PF API.
   b. Define the bandwidth allocated to the VSI and each of its TCs using the Scheduler Configuration commands (Section 8.3.4.3.6).
   c. If the virtual port is a VF, allow VF access to the network by clearing the associated bit in GL_VIRT_VFLRE register.

4.4.1.2.2 VF Initialization Details

This section describes the flow used to initialize a VF. It refers to various stages shown in Figure 4-13. Only stages involving the hardware are detailed.

4.4.1.2.2.1 Software Reset

A VF software reset can be asserted only by the PF using the VPGEN_VFRTRIG.*VFSWR* field. Following a VF software reset, the VF should request re-initialization of the queues from the PF.

Following the reset, the PF should preform the clean-up steps described in Section 4.1.3.3.

4.4.1.2.2.2 Request Resources and Create/Initialize Data Queues

On top of the resources statically allocated to a VF (interrupts, RSS table, and so on), a VF might have a set of VSIs. Each VSI contains objects such as:

- User priorities (transmit queue groups)
- Queue pairs
- Queuing filters

VSIs can be requested either for LAN or iWARP.

The resources should be requested in the following order (operations with the same stage number can be done in any order):

Step	Resource Requested	PF Action	Rules
1	VSI and UPs	Allocate VSIs according to allocation policies using the Add VSI AQ command (Section 7.8.12.3.1).	The PF should activate the security features in the VSI (anti spoof, port based VLAN) according to the VF settings.
2	Forwarding table entries (MAC and VLANs)	Add the requested filters using the Add Switch Rules command (Section 7.8.12.6.1).	
3	Data queue pairs	Create the requested queue contexts as described in Section 10.4.3 and Section 10.5.5.	
	Protocol Engine resources	The resources for the Protocol Engine are described in Section 11.1 and the PF flow is described in Section 11.5.1.	Before using any Protocol Engine related resources, the Host Memory Cache must be properly programmed. See section Section 9.3 for more details on the Host Memory Cache initialization. Virtual function HMC initialization must be performed by the PF driver on behalf of the VF driver.

4.5 Device/Port/Function Configuration

4.5.1 General

The E810 provides several mechanisms to configure which PCI functions and Ethernet ports are exposed.

The functions and ports can be hidden or exposed:

- Through NVM configuration.
- Based on power management policy.
- Through strapping pins.

4.5.1.1 Port-to-Function Mapping

The PFGEN_PORTNUM.*PORT_NUM* per-PF register field (loaded from the NVM) associates each PF with a port.

4.5.2 Disable Through Strapping Pins

For a LAN on Motherboard (LOM) design, it might be desirable for the system to provide BIOS setup capability for selectively enabling or disabling E810 PCI devices, PCI functions, or external Ethernet ports and the associated PCI function. It provides end users more control over system resource management and avoids conflicts with add-in NIC solutions. The E810 provides support for selectively enabling or disabling one or more LAN PCI device(s) in the system.

The E810 provides options to disable its external Ethernet ports and/or PCI functions:

- A strapping pin (DEV_DIS_N) is sampled on LAN_PWR_GOOD and PCIe resets to disable Ethernet ports. The specific port(s) to be disabled is determined from NVM. Additional NVM configuration is provided to determine which PCI functions are disabled at the same time. The expected usage is to disable the PCI functions associated with the disabled ports.
- A strapping pin (PCI_DIS_N) is sampled on LAN_PWR_GOOD and PCIe resets to disable PCI functions. The specific functions that are disabled are determined from the NVM.

Following are some guidelines on usage of these straps:

- During power up, the PCI_DIS_N and DEV_DIS_N pins are ignored until the NVM is read. From that point, the E810 might disable all PCI functions if either PCI_DIS_N or DEV_DIS_N is asserted.
- De-assertion of the PCI_DIS_N or DEV_DIS_N pins requires the system to issue a power-on reset/ LAN_PWR_GOOD/PE_RST_N/in-band reset to the E810 to re-enable any disabled PCI functions or external Ethernet ports.
- The PCI_DIS_N and DEV_DIS_N pins should maintain their state during system reset and system sleep states. It should also insure the proper default value on system power-up. For example, one could use a GPIO pin that defaults to 1b (enable) and is on system suspend power (such that it maintains its state in S0-S5 ACPI states).

4.5.3 Port and Device Disable

The following mechanisms are provided to enable and disable Ethernet ports:

- NVM configuration
  - Ports are enabled or disabled from the NVM. The PRTGEN_CNF.*PORT_DIS* per-port register bit (loaded from the NVM) disables external ports other than Port 0 (*PORT_DIS* for Port 0 is hard-wired to always enabled).
  - When cleared, the respective port is enabled.
  - The hardware default value is for Port 0 to be enabled and other ports to be disabled.
- Power management
  - If the Ethernet ports are not required in Dr state (such as if manageability is disabled and APME WoL is disabled as well), all ports are disabled during Dr state. See Section 5.1.3.4.
- Strapping (DEV_DIS_N)
  - When the DEV_DIS_N pin is asserted low, the PRTGEN_CNF.*ALLOW_PORT_DIS* per-port bits (loaded from the NVM) determine if the port is disabled.
  - The hardware default value for these bits is 0x0 (do not disable).
  - If a bit is set to 0b, DEV_DIS_N has no effect on the port.

Note: If a port is required for manageability purposes, it should not be disabled by the mechanisms previously described.

The result of the previous mechanisms is reflected in the PRTGEN_STATUS.*PORT_VALID* bit (per port), which denotes if the port is enabled. A bit is cleared (port disabled) if at least one of the previous mechanisms disables the port. The port is then powered down (including MAC, PCS, PHY).

If all ports are disabled, the E810 is put in a power-down, reset state. Specifically, the E810 does not respond to PCI configuration cycles, the PCIe link is in L3 state, and Ethernet ports are in power-down. All PCI functions must be disabled as well via the mechanisms previously described (such as the proper NVM configuration must be set to disable for PFs).

4.5.3.1 Dynamic Port Shutdown

Another related, per-port status bit is the PRTGEN_STATUS.*PORT_ACTIVE* indication. This is a dynamic state indicating that the port is temporarily inactive and is powered down. When the port is inactive, reactivating it does not require any reset, and the related PCIe function is still active.

A port is active (PRTGEN_STATUS.*PORT_ACTIVE* = 1b) based on the following rules:

- PRTGEN_STATUS.*PORT_VALID* = 1b, as previously described above AND the E810 is in D0 state (PMCSR.*PowerState* = D0).
  - If link is requested by manageability, the link is kept on. Specifically, hardware ignores disabling the link using the PRTGEN_CNF2.*ACTIVATE_PORT_LINK*.
  - Else,
    - In systems where the application needs to prevent any traffic on link before the device driver is loaded, the PRTGEN_CNF2.*ACTIVATE_PORT_LINK* is loaded from the NVM with the value of 0b (disable).

  - Once the device driver loads, it uses the Set Link and Restart AN with the command bit 2 set (Enable Link). Following this, the EMP enables the link by writing the value of 1b to the PRTGEN_CNF2.*ACTIVATE_PORT_LINK* and starts the link bring-up sequence.
  - If the device driver is about to be removed or disabled, then before going down the device driver might disable the link by the Set link and Restart AN with the command bit 2 cleared (Disable Link). Following this, firmware disables the link by writing the value of 0b to the PRTGEN_CNF2.*ACTIVATE_PORT_LINK*.

- PRTGEN_STATUS.*PORT_VALID* = 1b, as previously described, AND the E810 is in Dr state (PMCSR.*PowerState* = D3).
  - If port is enabled for wake-up. See the description in Section 5.3.
  - Else,
    - The link should be down as it is not required for EMP functionality.
    - BMC might enable manageability by sending the appropriate command (see Section 12.6.3.1). As a result, EMP transitions to pass-through manageability-on state, enables the respective port (if disabled), and starts the link bring-up sequence.
    - If the channel is disabled by the BMC (by sending the appropriate command - see Section 12.6.3.1), and EMP has no other needs for the LAN port in Dr state (like proxy), the EMP reverts to the value of *EMP_LINK_ON* bit in the NVM manageability module or is set to zero (in case of the Disable Channel command with the *ALD* bit set).

4.5.4 Function Disable

The following mechanisms are provided to enable and disable PCI functions.

- NVM configuration
  - PCI functions are enabled or disabled from the NVM. The PFPCI_FUNC.*FUNC_DIS* per-PF bit (loaded from the NVM) disables PCI functions (other than function 0. *FUNC_DIS* for function 0 is hard-wired to enabled).
  - When cleared, the respective function is enabled.
  - The hardware default value is for function 0 to be enabled and other functions to be disabled.
- Strapping through PCI_DIS_N
  - When the PCI_DIS_N pin is asserted low, the PFPCI_FUNC.*ALLOW_FUNC_DIS* per-PF register bit (loaded from the NVM) determines if the function is disabled.
  - If this bit is set to 0b, PCI_DIS_N has no effect on the PCI function.
  - The hardware default value is 0b (keep enabled).
- Strapping through DEV_DIS_N
  - When the DEV_DIS_N pin is asserted low, the PFPCI_FUNC.*DIS_FUNC_ON_PORT_DIS* per-PF bit (loaded from the NVM) determines if the function is disabled.
  - If this bit is set to 0b, DEV_DIS_N has no effect on the PCI function.
  - The hardware default value is 0 (do not disable).

- Soft SKU commands
  - The soft SKU commands are executed either before or after PERST# was de-asserted and in any case, before the first access by BIOS to the E810 (such as before the first PCIe configuration cycle to the E810).
  - When a LAN port is enabled or disabled via a Soft SKU command, the EMP identifies (through the PFGEN_PORTNUM registers) the PCI functions associated with the port.
  - EMP then updates the configuration of the functions enabled or disabled by writing to the PFPCI_FUNC.*FUNC_DIS* register bits.
  - PFPCI_FUNC.*FUNC_DIS* for function 0 is hard-wired to enabled, so is not affected by this mechanism.

The result of the previous mechanisms is reflected in the PFPCI_STATUS1.*FUNC_VALID* bit (per PF), which denotes if the function is enabled. A bit is cleared (function disabled) if at least one of the previous mechanisms disables the function.

When a function is disabled:

- It does not respond to PCI configuration cycles (unless specified otherwise). Effectively, the function becomes invisible to the system.
- The *PME_En* bit is cleared to avoid issuing PME.

The Ethernet ports associated with disabled PCI functions are still available for manageability purposes.

4.5.4.1 Dummy Function

When PCI function 0 is disabled, it does not disappear from the PCIe configuration space. Rather, the function presents itself as a dummy function. The Device ID and Class Code of this function change to other values (dummy function Device ID 0x10A6, Class Code 0xFF0000, with an option to load from the NVM) that claims 4 KB of memory. In addition, the function does not require any I/O space and does not require an interrupt line. All other PCI functions keep their respective locations.

4.5.5 Event Flow for Enable/Disable Ports and PCI Functions

This section describes the expected flow to disable or enable PCI functions or Ethernet ports. Following a power-on reset/LAN_PWR_GOOD/PE_RST_N/in-band reset, the DEV_DIS_N and PCI_DIS_N signals should be driven high (or left unconnected) for normal operation.

The following example assumes that PCI functions and/or Ethernet ports are being disabled during the BIOS initialization phase:

1. 1.Following a power-up sequence, the DEV_DIS_N and PCI_DIS_N signals are driven high.
2. The PCIe link is established following PE_RST_N.
3. BIOS goes through PCI bus enumeration.
4. BIOS recognizes that the PCI functions in the E810 should be disabled.
5. The BIOS drives the DEV_DIS_N or PCI_DIS_N signal to a low level.
6. The BIOS asserts PCIe reset, either in-band or via PE_RST_N.

7. As a result, the E810 samples the DEV_DIS_N and PCI_DIS_N signals and disables the PCI functions and/or external Ethernet ports.
8. BIOS might do device enumeration a second time (the disabled PCI functions are invisible or changed to dummy function).
9. Proceed with normal operation.
10. Re-enable could be done by driving the DEV_DIS_N and PCI_DIS_N signals high and re-issuing a power-on reset/LAN_PWR_GOOD/PE_RST_N/in-band reset.

4.5.5.1 Multi-Function Advertisement

If all but one of the PCI functions are disabled, the E810 is no longer a multi-function device. The E810 normally reports a 0x80 in the PCI configuration header field header type, indicating multi-function capability. However, if only a single LAN is enabled, the E810 reports a 0x0 in this field to signify single-function capability.

4.5.5.2 Legacy Interrupts Use

Each NVM PF configuration module specifies the interrupt line used for each PCI function. When more than one PCI function is enabled, the E810 uses the INTA# to INTD# interrupts for interrupt reporting. The specific interrupt pin used is reported in the *PCI Configuration Header Interrupt Pin* field associated with each PCI function.

However, if only one PCI function is enabled, the INTA# must be used for this PCI function, regardless of the NVM configuration. Under these circumstances, the *Interrupt Pin* field of the PCI header always reports a value of 0x1, indicating INTA# usage.

4.5.5.3 Power Reporting

When more than one PCI function is enabled, the PCI power management register block has the capability of reporting a common power value. The common power value is reflected in the *Data* field of the PCI Power Management registers. The value reported as common power is specified via the LAN Power Consumption NVM word (word 0x22), and is reflected in the *Data* field each time the *Data_Select* field has a value of 0x8 (0x8 = common power value select).

When only one PCI function is enabled, the E810 appears as a single-function device, the common power value, if selected, reports 0x0 (undefined value), as common power is undefined for a single-function device.

4.6 Shared Resource Management

The E810 is a device with multiple external Ethernet ports and that supports multiple PCI functions. Several on-chip resources are shared between device drivers that load the PCI functions exposed by the E810. Additionally, some resources for SR-IOV VFs are managed by the associated PFs. In general, the E810 minimizes the requirement for coordination between device drivers running on different PCI PFs through a combination of resource partitioning and programming interface assistance for remaining resources that are shared.

The E810 handles shared resources using a number of allocation mechanisms and/or access control mechanisms. Table 4-23 lists the supported mechanisms.

Table 4-23. Supported Mechanisms

Class	Description
Dedicated	This resource is associated with a particular E810 element and is always available without respect to any other configuration or setting. Examples of elements in this context could be a PCI function or external Ethernet port.
Administered	Administered resources can be re-assigned based on BMC, BIOS settings, or other OEM specific mechanisms. These resources can be changed with a PCI reset but do not change dynamically after the PCI reset.
Profiles	Resources that are allocated via profiles are typically divided up among different entities based on some combination of other input. A profile might dictate that a resource is divided among the active PCI functions in a particular manner. Another possible usage of a profile is to divide resources based on both the number of PCI functions and the number of external Ethernet ports. The division of resources that are allocated by profiles happens between the time that a PCI reset occurs and might be impacted by an initial device driver load, but resource allocation based on profiles require a PCI reset to change after the initial device driver load.
Pool	Resources that are allocated from pools are typically allocated in a fashion that guarantees no resource starvation to an individual consumer of a resource but enables flexible allocation of remaining resources to any consumer that requires additional resources beyond the minimum. Pools are used for resources that do not need to have a maximum number of resources allocated to all consumers at the same time and that the consumers are reasonably able to fail an allocation.
Service	Resources that are possibly allocated on a per-device or per-port basis but are accessed by a software service that has visibility to multiple device driver interfaces that do not need the E810 to provide an arbitration mechanism. In these cases each PCI function associated with a given resource provides equal access to the resource as other PCI functions associated with the resource. This enables the software service to have the flexibility to access such resources from any device driver instance that it finds available and to switch between device driver instances as the device drivers are stopped and started. Resources that need to accesses directly by a device driver without support from an overlaying software service cannot be handled in this fashion.
Arbitrated	Resources that are allocated on a per-device or per-port basis need an access control mechanism that enables multiple consumers of the resource to operate in an independent manner. The E810 does this by either providing a firmware interface to access the resource where firmware handles the requests one at a time or by other hardware based arbitration scheme.

4.6.1 Resource Profiles

The concept of resource profiles is used in order to make the E810's resource allocation mechanisms easier to understand. Resource profiles dictate how resources listed in Table 4-23 as profiles are distributed among PCI functions so that software drivers do not need to coordinate allocation of these resources.

A resource profile is made up of the set of equations that take input parameters from the system configuration and distributes each resource. Each resource has a different equation for distribution (see the Description column in Table 4-23). Also, the following tables list examples of the result calculations for a full set of resources. Since some of the resource distribution equations simply take the number of PCI functions as input, while others might need additional input (such as the number of external Ethernet ports or the software usage model that a device driver needs to implement), Table 4-24 lists which input parameters effect the allocation of each resource.

Table 4-24. Resource Profiles

Resource	# External Ethernet Ports	# PCI Physical Functions	PCI Function to External Ethernet Port Assignment	# PCI Virtual Functions	Driver Usage Model
LAN Queues	No	Yes	No	Yes	No
MSI-X Vectors	No	Yes	No	Yes	No
Multicast MAC Address Filters	No	Yes	No	No	No
Internal Switching Elements[1]	Yes	Yes	Yes	No	No
Protocol Engine Resources	No	Yes	No	Yes	Yes

1. Resource profiles only impact the default settings for internal switching elements. Run-time switch management software has the ability to override the default number of internal switching components and the internal switch topology.

Table 4-25 lists a few sample sets of typical input parameters that are used with the E810. The initial values of these resources are found in the NVM, but might be overridden by OEM-specific configuration mechanisms followed by a PCI reset.

Note: The device driver usage model can be changed and locked by the first device driver to load following a PCI reset. All other inputs are set at PCI reset.

Table 4-25. Resources per Configuration

Scenario Name	# External Ethernet Ports	# PCI Physical Functions	PCI Function to External Ethernet Port Assignment	# PCI Virtual Functions	Driver Usage Model
Single Port Default	1	1	PF0 -> Port 0	256	Default
Dual Port Default	2	2	PF0 -> Port 0 PF1 -> Port 1	256	Default
Quad Port Default[1]	4	4	PF0 -> Port 0 PF1 -> Port 2 PF2 -> Port 1 PF3 -> Port 3	256	Default
Octal Port Default[2]	8	8	PF0 -> Port 0 PF1 -> Port 1 PF2 -> Port 2 PF3 -> Port 3 PF4 -> Port 4 PF5 -> Port 5 PF6 -> Port 6 PF7 -> Port 7	256	Default
Single Port SR-IOV VF Primary	1	1	PF0 -> Port 0	256	SR-IOV PF Primary
Single Port SR-IOV Even Distribution	1	1	PF0 -> Port 0	256	SR-IOV Even Distribution

1. In this mode, the ports are ordered so that a single 100G port can be used in a 4x25G port configuration. See Table 3-22.
2. See Table 3-21.

Table 4-26 lists the resulting resource distribution for each of the input scenarios listed in Table 4-25. With the exception of the switch topology, none of the resource distribution can be changed after the initial device driver load without a PCI reset occurring. If the resource distribution changes while an active device driver is running, unpredictable results can occur. For example, repartitioning the Host Memory Cache segment descriptor table while a device driver is active causes the E810 to improperly interpret the host memory used for caching resource objects. The E810 provides various mechanisms (such as the HMC resource profile locking) to prevent software from unknowingly causing these types of reconfigurations.

Table 4-26. Resource Distribution

Resource	#LAN QPs Per PF	#LAN QPs Per VF	#MSI-X Vectors Per PF	#MSI-X Vectors Per VF	Default Internal Switch Topology	HMC and Protocol Engine Resources				
						No SR-IOV	SR-IOV Primary Distribution		SR-IOV Even Distribution[1]

Chapter 5 Power Management

This section defines how Power Management is implemented in the E810.

5.1 PCIe Power Management

5.1.1 Auxiliary Power Usage

Auxiliary power can be used for powering the E810 while the system is in low power state ($D3_{cold}$). The E810 uses the AUX_PWR pin as an indication that auxiliary power is available to it. The E810 uses this indication to advertise $D3_{cold}$ wake-up support in the PMC.*PME_Support* field and to set the *Aux Power Detected* bit in the PCIe capability structure Device Status Register. The AUX_PWR pin is strapped during Power-On Reset (POR). The E810 only uses the auxiliary power if one of the functions requiring it (as indicated below) are enabled (and, if auxiliary power is available). If the usage of auxiliary power is not enabled (that is, none of the functions requiring it are enabled), the E810 must be power-gated and does not consume auxiliary power in $D3_{cold}$.

If AUX power usage during $D3_{cold}$ is supported (as indicated below), all of the E810's sticky bits preserve their values and only get reset by the power-up reset (detection of power rising).

When AUX power is applied to the E810, the actual usage of AUX power during $D3_{cold}$ is controlled through the following factors:

- NVM loaded bits:
  - Manageability needed — Bit per port loaded from NVM, which indicates if the relevant port link should be established for EMP functionality. The E810 provides the proper clocking to establish the required port link/s at this state.
  - *APME* — Bit per function (loaded to PFPM_APM[PF]) indicates if the relevant PF associated to a port link should be established to enable APM WoL. The E810 provides the proper clocking to establish the required port link/s at this state.
- PCIe configuration bits:
  - *PME_En* — This bit in the PMCSR PCI config space is used to determine if the E810 is allowed to consume AUX power for WoL.
- EMP firmware decision:
  - The EMP firmware might prevent the device from being power-gated in Sx states, and thus consume auxiliary power. The E810 should be specifically configured by the EMP firmware to provide the proper clocking or to establish the required port link/s at this state.

The following pseudo code defines AUX Power usage where *APME* and *PME_En* bits refer to a logical OR over all the PFs attached to the port:

```
If (AUX_PWR = 1),
    If ((APME or EMP_LINK_ON or PME_En) = 1),
        AUX power is used to preserve link functionality.
    Else,
        Link functionality is not preserved during AUX power supply.
    End-IF
End-If
```

5.1.2 PCIe Link Power Management

The PCIe link state follows the power management state of the device. Since the E810 incorporates multiple PCI functions, the device power management state is defined as the power management state of the most awake function:

- If any function is in D0a state in ARI mode or either D0a or D0u in non-ARI mode, the PCIe link assumes the device is in D0 state.
- Else, If in ARI mode, at least one of the functions is in D3 state and the other functions are not in D0a state, or if in non-ARI mode all of the functions are in the D3 state, the PCIe link assumes the device is in D3 state.
- Else, the device is in Dr state (PE_RST_N is asserted to all functions).

The E810 supports all PCIe power management link states:

- L0 state is used in D0u and D0a states.
- The L0s state is used in D0a and D0u states each time link conditions apply.
- The L1 state is used in D0a and D0u states each time link conditions apply, as well as in the D3 state.
- The L2 state is used in the Dr state following a transition from a D3 state if PCI-PM PME is enabled.
- The L3 state is used in the Dr state following power up, on transition from D0a and also if PME is not enabled in other Dr transitions.

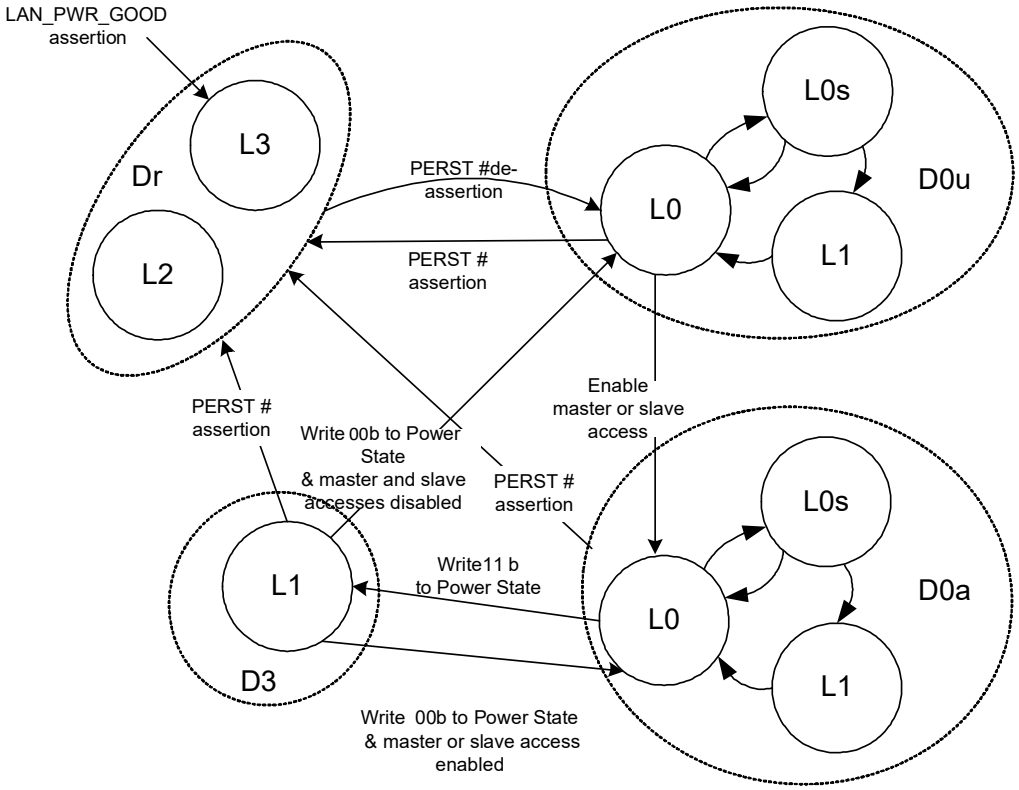

Figure 5-1. Link Power Management State Diagram

While in L0 state, the E810 transitions the transmit lane(s) into L0s state once the idle conditions are met for a period of time defined as follows.

- L0s configuration fields are:
  - L0s enable — The default value of the *Active State Link PM Control* field in the PCIe Link Control register is set to 00b (both L0s and L1 disabled). System software can later write a different value into the Link Control register.
  - L0s exit latency (as published in the *L0s Exit Latency* field of the Link Capabilities register) is loaded from/to the GLPCI_PMSUP.*L0S_EXIT_LAT* NVM/register field. Separate values are loaded when the E810 shares the same reference PCIe clock with its partner across the link, and when the E810 uses a different reference clock than its partner across the link. The E810 reports whether it uses the slot clock configuration through the *PCIe Slot Clock Configuration* bit loaded from/to the GLPCI_PMSUP.*SLOT_CLK* NVM/register bit.
  - L0s acceptable latency (as published in the *Endpoint L0s Acceptable Latency* field of the Device Capabilities register) is loaded from the GLPCI_PMSUP.*L0S_ACC_LAT* NVM/register field.

The E810 transitions the link into L0s state once the PCIe link has been idle for a period of time defined in the *l0s_idle_timer* field of PMIDLTMR register loaded from RO PCIe LCB module in NVM. The E810 then transitions the link into L1 state once the PCIe link has been in L0s state for a further period as defined in the *l1_idle_timer* register field of the same register.

The following NVM fields control L1 behavior:

- *L1 support* — Indicates support for ASPM L1 in the PCIe configuration space (loaded into the *Active State Link PM Support* field).
- *L1 exit latency* — Defines L1 active exit latency. The default value is loaded from/to the GLPCI_PMSUP.*L1_EXIT_LAT* NVM/register field.
- *L1 acceptable latency* — Defines L1 active acceptable exit latency. The default value is loaded from/to the GLPCI_PMSUP.*L1_ACC_LAT* NVM/register field.

5.1.3 Power States

The E810 supports the D0 and D3 architectural power states as described earlier. Internally, the E8100 supports the following power states:

- **D0u ($D0_{un\text{-}initialized}$)** — An architectural sub-state of D0.
- **D0a ($D0_{active}$)** — An architectural sub-state of D0.
- **D3** — Architecture state D3hot.
- **Dr** — Internal state that contains the architecture $D3_{cold}$ state. Dr state is entered when PE_RST_N is asserted, a PCIe in-band reset is received, or if the function is disabled.

Figure 5-2 shows the power states and transitions between them.

Note: PCI resets (cold/warm and hot) are reflected to the E8100 as primary bus reset (in case of cold/warm reset) or secondary bus reset (in case of a hot reset).

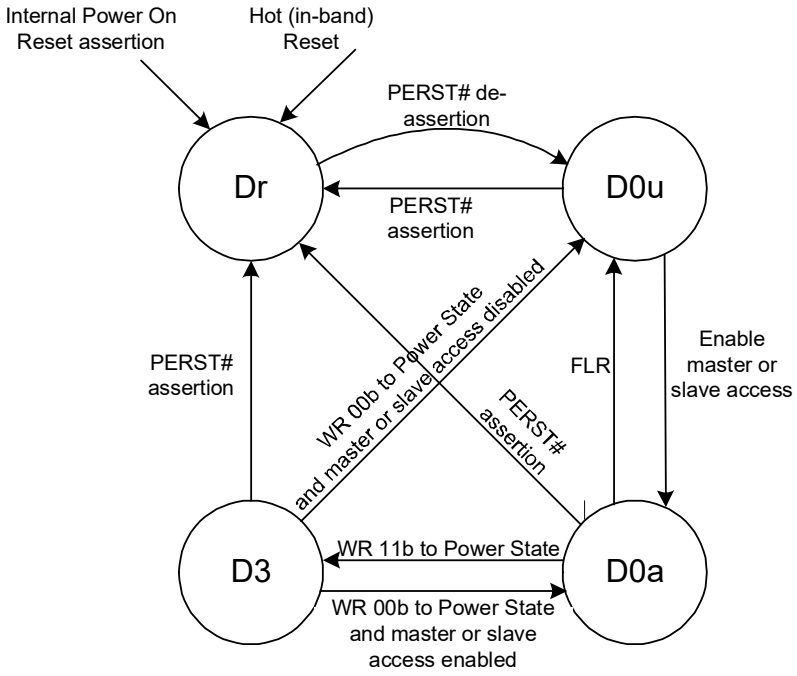

Figure 5-2. Power Management State Diagram

5.1.3.1 $D0_{uninitialized}$ (D0u) State

The D0u state is an architectural low-power state. In this state, the device is out of reset (conventional and FLR) but did not complete the enumeration and configuration stage.

5.1.3.1.1 Entry to a D0u State

D0u is reached from either the Dr state (on de-assertion of internal PE_RST_N and auto-load of hardware configuration done) or the D3hot state (by configuration software writing a value of 00b to the *Power State* field of the PCI PM registers while master and slave accesses are disabled). De-assertion of internal PE_RST_N causes the entire state of the E810 to be cleared except for bits defined as sticky in configuration space. PCIe configuration is loaded from the NVM, followed by establishment of the PCIe enumeration. Once this is done, configuration software can access the E810.

5.1.3.2 $D0_{active}$ (D0a) State

A E810 Function enters the $D0_{active}$ state whenever any single or combination of the function's *Memory Space Enable*, *I/O Space Enable*, or *Bus Master Enable* bits are enabled by system software in the PCI Command configuration register.

In this state, it can transmit and receive packets if properly configured by the software device driver.

The PHY is enabled (or re-enabled) by the software device driver to operate/auto-negotiate to full line speed/power if not already operating at full capability.

Notes:

- Wake behavior:
  - An APM wake event (PM_PME message) due to reception of a Magic Packet is not generated when the function is in $D0_{active}$ state.
  - Any APM wake up previously active remains active when moving from D3 to D0. That is, APM enable is loaded from NVM and is not reset by any reset but POR.
  - WAKE# pin is never toggled for an APM wake event when a function is in D0.
- If APM wake is required in D3, software driver should not disable APM wake-up via clearing the PFPM_APM.*APME* bit on entry into D0. Otherwise, APM wake following a system crash and entry into S3, S4, or S5 system power management state are not enabled. Following entry into D0, software device driver can activate the wake-up filters by writing to the Wake Up Filter Control (PFPM_WUFC) register.

5.1.3.2.1 Entry to a D0a State

D0a is entered from either the D0u state (by writing a 1b to the *Memory Access Enable* or the *I/O Access Enable* bit, or the *BME* bit of the PCI Command configuration register) or from the $D3_{hot}$ state (by configuration software writing a value of 00b to the *Power State* field of the PCI PM configuration registers while master or slave accesses is enabled). The receive and transmit flows of the appropriate LAN function are enabled.

5.1.3.3 D3 State (PCI-PM $D3_{hot}$)

The E810 functions can transition to D3 when the system writes a 11b to the *Power State* field of the Power Management Control/Status Register (PMCSR). Any wake-up filter settings that were enabled before entering this state are maintained. The E810 does not clear any bit in the PCIe configuration space of a function during the function's transition to D3 state. While in D3, the appropriate function of the E810 does not generate master cycles.

Configuration and message requests are the only TLPs accepted by a function in the $D3_{hot}$ state. All other received requests must be handled as unsupported requests, and all received completions are handled as unexpected completions. If an error caused by a received TLP (such as an unsupported request) is detected while in $D3_{hot}$ and reporting is enabled, the link must be returned to L0 if it is not already in L0, and an error message must be sent. See section 5.3.1.4.1 in the *PCIe Base Specification*.

5.1.3.3.1 Entry to D3 State

Transition to D3 state is through a configuration write to the *Power State* field of the PMCSR PCIe configuration register.

Prior to transition from D0 to the D3 state, the device driver disables scheduling of further tasks to the E810. It masks all interrupts, and it does not write to the Transmit Descriptor Tail register or to the Receive Descriptor Tail register.

If wake up capability is needed, system software should enable wake capability by setting to 1b the *PME_En* bit in the PMCSR PCIe configuration register of the PF. After Wake capability is enabled the software device driver should set up the required wake up functionality using the flow described in Section 5.3.5 prior to the D3 transition.

Notes:

- The PMCSR.*PME_En* bit setting can be overridden via the PFPM_APM.*APME* bit.
- If operation during D3*cold* is required, even when wake capability is not required (for example, for manageability operation), system should also set the *Auxiliary (AUX) Power PM Enable* bit in the PCIe Device Control register.

If all PCI functions are programmed into D3 state, the E810 attempts to brings its PCIe link into the L1 link state. As part of the transition into L1 state, the E810 suspends scheduling of new host TLPs, MCTP over PCIe VDMs is not suspended. The E810 waits for the completion of all previous TLPs it has sent. Any receive packets that have not been transferred into system memory are kept in the device (and discarded later on D3 exit). Any transmit packets that have not be sent can still be transmitted (assuming the Ethernet link is up).

In preparation for a possible transition to $D3_{cold}$ state, the device driver might disable up to all but one of its LAN ports (LAN disable) and/or transition the remaining link(s) to GbE speed (if supported by the network interface).

5.1.3.3.2 Exit from D3 State

A D3 state is followed by either a D0u state (in preparation for a D0a state) or by a transition to Dr state (PCI-PM $D3_{cold}$ state). To transition back to D0u, the system writes a 00b to the *Power State* field of the Power Management Control/Status Register (PMCSR). Transition to Dr state is through PE_RST_N assertion.

The *No_Soft_Reset* bit in the PCIe Power Management Control/Status (PMCSR) register in the E810 is always set to 1b to indicate that the E810 does not perform an internal reset on transition from $D3_{hot}$ to D0, so that transition does not disrupt the proper operation of other active functions. Software is not required to re-initialize the function's configuration space after a transition from $D3_{hot}$ to D0 (the function is in the D0 state).

The function is reset if the Link state had transition to the L2/L3 Ready state, on transition from $D3_{cold}$ to D0, if FLR is asserted, or if transition $D3_{hot}$ to D0 is caused by assertion of PCIe reset (PE_RST pin).

5.1.3.4 Dr State ($D3_{cold}$)

Transition to Dr state is initiated on system power-up. Dr state begins with the assertion of the internal power detection circuit (LAN_PWR_GOOD) and ends after the completion of the NVM auto-load.

Any wake-up settings that were enabled before entering this reset state are maintained.

The system can maintain PE_RST_N asserted for an arbitrary time. The de-assertion (rising edge) of PE_RST_N causes a transition to D0u state.

While in Dr state, the E810 can maintain functionality (for WoL or manageability) or can enter a Dr Disable state (if no WoL and no manageability) for minimal device power. The Dr Disable mode is described in Section 5.1.3.4.1.

5.1.3.4.1 Dr Disable Mode

The E810 enters a Dr disable mode on transition to $D3_{cold}$ state when it does not need to maintain any functionality. The conditions to enter either state are:

- The device (all PCI functions) is in Dr state.
- APM WOL is inactive for all PCI functions.
- Pass-through manageability is disabled.

Entry into Dr disable is usually done on assertion of PCIe PE_RST_N. It can also be possible to enter Dr disable mode by reading the NVM while already in Dr state. The usage model for this later case is on system power-up, assuming that manageability and wake up are not required. Once the device enters Dr state on power-up, the NVM is read. If the NVM contents determine that the conditions to enter Dr disable are met, the device then enters this mode (assuming that PCIe PE_RST_N is still asserted).

Exit from Dr disable is through de-assertion of PCIe PE_RST_N.

If Dr disable mode is entered from D3 state, the platform can remove the E810 power. If the platform removes the E810 power, it must remove all power rails from the device if it needs to use this capability. Exit from this state is through power-up cycle to the E810.

Note: The state of the TX_DIS (Optical module Tx disable connected to SDP pins) or any of the other SDP pins is undefined once power is removed from the device.

5.1.3.4.2 Entry to Dr State

Dr entry on platform power-up is as follows:

- Assertion of the internal power detection circuit (LAN_PWR_GOOD). Device power is kept to a minimum by keeping the network interfaces in low power.
- The NVM is then read and determines device configuration.
- If the *APM Enable* bit in the NVM is set, APM wake up is enabled (for each port independently).
- If the *MNG Enable* bit in the NVM word is set, pass-through manageability is enabled.
- Each of the LAN ports can be enabled if required for WoL or manageability. See Section 5.2 for exact condition to enable a port.
- The PCIe link is not enabled in Dr state following system power up (since PE_RST_N is asserted).

Entry to Dr state from D0a state is through assertion of the PE_RST_N signal. An ACPI transition to the G2/S5 state is reflected in a device transition from D0a to Dr state. The transition can be orderly (such as a user selected a shut down operating system option), in which case the device driver can intervene. Or, it can be an emergency transition (like power button override), in which case, the device driver is not notified.

Transition from D3 state to Dr state is done by assertion of PE_RST_N signal. Prior to that, the system initiates a transition of the PCIe link from L1 state to either the L2 or L3 state (assuming all functions were already in D3 state). The link enters L2 state if PCI-PM PME is enabled.

5.1.3.5 Protocol Engine Power Save Modes

Internally, the E810 supports two modes to reduce component power opportunistically by disabling the internal RDMA Protocol Engine (PE) via PE Clock Gating.

If the RDMA functionality is available, but not activated by software (for example, when PCIe reset is asserted), the E810 supports clock gating the PE block. Hardware determines whether RDMA is enabled if the GLHMC_PEHTEOBJSZ register is programmed to any non-zero value. GLHMC_PEHTEOBJSZ is reset by CORER. As with power gating, register accesses which would be decoded to the PE block are handled gracefully. Write transactions are silently discarded, and read accesses return deterministic values (0xDEADBEEF).

5.2 Network Interfaces Power Management

The E810 disables a network interface and transitions the interface into low-power state in the following cases:

- All LAN ports are in LAN disable mode as a result of the DEV_DIS_N pin.
- Low power state functionality as described in Section 5.1.1.

When the E810 is in low-power state, it asserts the respective TX_DIS pin (connected to an SDP pin) to enable powering down an external PHY or optical module as well.

5.2.1 Energy Efficient Ethernet (EEE)

Note: Energy Efficient Ethernet (EEE) is not currently supported in the E810. Some references may remain in this document in the event that it is enabled in the future.

5.2.2 Low Power Link Up (LPLU)

Auto-negotiation enables establishment of link speed at the Highest Common Denominator (HCD). When all PCIe functions belonging to a port are in Dx low power state, and the E810 is connected to an auxiliary power supply and main power is down, power saving might be more important than performance.

The E810 supports a mode where it auto-negotiates to the Lowest Common Denominator (LCD) link speed (that is, the lowest commonly-supported speed) in low power states. Initially, in this mode, the E810 attempts to negotiate to the lowest link rate. If the link partner does not support the lowest link rate, the E810 auto-negotiates to the lowest link rate advertised by the link partner.

5.2.2.1 LPLU-Related Link Speed Change

Figure 5-3 describes the flow for changing the link speed when entering/existing LPLU state.

The E810 attempts to lower the link to the lowest commonly-supported speed when entering to LPLU state. Entering LPLU state, and switching to a lower link speed is done by clearing the relevant bits in the auto-negotiation advertised capabilities in the (internal/external) PHY configuration (advertising only the lowest common speed), and triggering an auto-negotiation process. The device is expected to link at lower speed as higher speeds are not advertised as supported.

Similarly, exiting LPLU state and switching to a higher link speed is done by setting the relevant bits in the auto-negotiation advertised capabilities in the PHY configuration, and restarting auto-negotiation. The device is now expected to link at the highest common speed.

Note: Given the above, a temporary link loss (and a disruption to traffic) is expected when entering/exiting LPLU state.

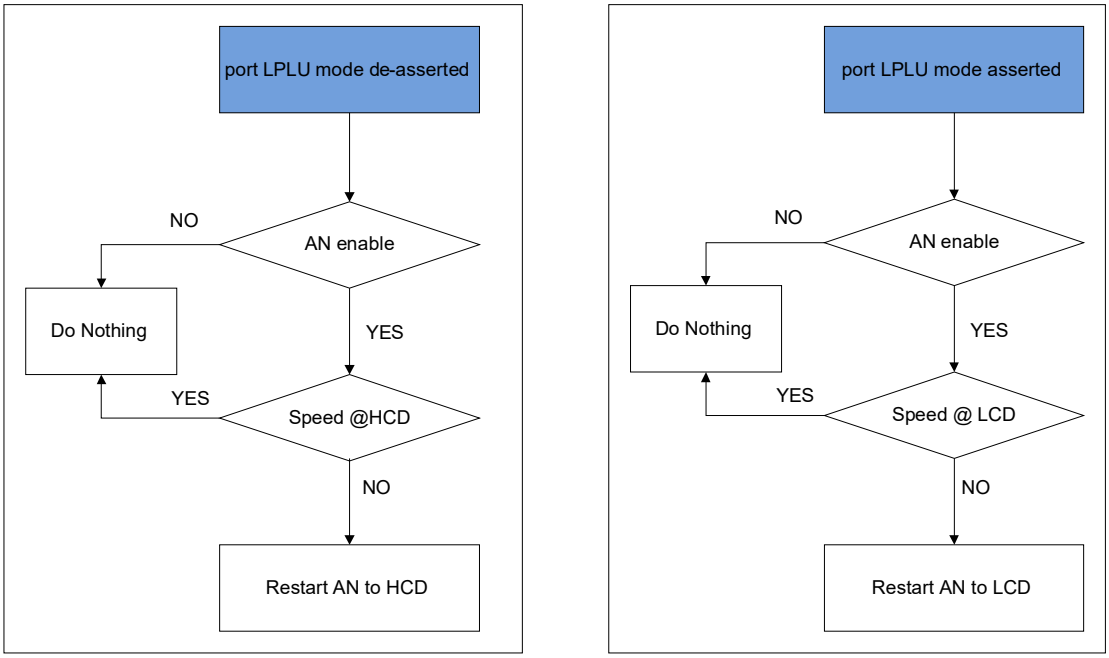

Figure 5-3. Link Speed Change on LPLU Assert/Clear

5.3 Wake-Up

The E810 supports wake up functionality in accordance with the APM and ACPI specifications. The following list provides a high-level view of the functionality supported in each specification, while the following sub-section provide more details and elaboration.

- Advanced Power Management (APM) wake-up (enabled via PFPM_APM.*APME*), which means support for wake from S5 (Soft Off) states using the well-known Magic Packet wake packet format.
- ACPI wake-up capabilities (enabled via PMCSR.PME_En):
  - Link State Change (*LNKC*) wake-up, which means the ability to wake up the host from S5 when a LAN link state goes up.
  - Magic Packet (*MAG*) wake-up, which means support for wake from S5 (Soft Off) states using the well-known Magic Packet wake packet format.
  - Firmware Reset (*FW_RST_WK*) wake-up, which means the ability to wake up the host from S5 when an EMPR event occurs.
  - Manageability (*MNG*) wake-up, which means the ability for the EMP to wake up the host from S5, on its own initiative. No usage model is actually defined for this option.

These wake-up mechanisms are basically controlled by the PF via the corresponding bit in the PFPM_WUFC and PFPM_WUS registers.

5.3.1 Advanced Power Management Wake-Up

This feature has existed in the 10/100 Mb/s NICs for several generations. System was activated from S3, S4, or S5 low power states on reception of a Magic Packet, which is a broadcast or unicast packet with an explicit data pattern. On reception of a Magic Packet, the E810 can wake up the system by also asserting the PCIe PE_WAKE_N signal and optionally via an in-band PM_PME message.

APM wake-up operation is controlled by the per-PF APM Control (PFPM_APM) register. At power-up, the E810 reads the *APM Enable* bit from the NVM into the APM Enable (PFPM_APM.*APME*) bit. This bit is used to enable WoL by overriding the *PME_En* bit. This bit controls enabling of the APM wake-up. Software enables or disables APM wake-up using the flows described in Section 5.3.5.1 and Section 5.3.5.2, respectively.

When APM wake-up is enabled, the E810 checks all incoming packets passing L2 filters (BCST, MCST, UCST) for Magic Packets. See Section 5.3.3.1.1 for a definition of Magic Packets. BCST and UCST (according to PFPM_SAL/H that are loaded from NVM and properly assigned by firmware to the PRTPM_SAL/H registers) Magic Packet filtering is enabled by default. To enable promiscuous MCST Magic Packets, WoL PRTPM_SAH.*MC_MAG_EN* must be set to 1b.

Once the E810 receives a matching Magic Packet, and the PFPM_APM.*APME* bit is set to 1b, it executes the ACPI flow described in Section 5.3.5.3.

Note: When the PFPM_APM.*APME* bit is set, a wake event is issued (PE_WAKE_N pin is asserted and a PM_PME PCIe message is issued), even if the PMCSR.*PME_En* bit in configuration space is cleared. To disable system wake-up when PMCSR.*PME_En* is cleared, software driver should clear the PFPM_APM.*APME* bit after power-up or PCIe reset.

5.3.2 ACPI Power Management Wake-Up

The E810 supports ACPI power management-based wake-up. It can generate system wake-up events from a number of sources:

- Detection of a change in network link (cable connected or disconnected).
- Firmware Reset (*FW_RST_WK*) wake-up, which means the ability to wake up the host from S5 when an EMPR event occurs.
- Magic Packet (*MAG*) wake-up, which means support for wake from S5 (Soft Off) states using the well-known Magic Packet wake packet format.
- Manageability (*MNG*) wake up, which means the ability for the EMP to wake up the host from S5, on its own initiative. No usage model is actually defined for this option.

Note: ACPI wake-up operation is controlled by the per-PF Wake Up Filter Control (PFPM_WUFC) register, and wake-up status is reported in the per PF Wake Up Status (PFPM_WUS) register. In the PCIe configuration space, the PMCSR register supports wake up. Software enables ACPI wake-up using the flow described in Section 5.3.5.

5.3.3 Wake-Up Filters

The E810 supports issuing wake-up indication to the Host on reception of non-errored packets when the device is in D3 low power state or in Dr with WoL enabled, using Magic Packet filters set from NVM.

Support of wake-up in Dr is only if the *AUX_PWR* bit is asserted.

5.3.3.1 Wake-Up Filter Types

Magic Packets are detected per-PF by the E810 as a possible wake-up.

5.3.3.1.1 Magic Packet

Magic Packets are defined in http://support.amd.com/TechDocs/20213.pdf as:

> "Once the LAN controller has been put into the Magic Packet mode, it scans all incoming frames addressed to the node for a specific data sequence. This sequence indicates to the controller that this is a Magic Packet frame. A Magic Packet frame must also meet the basic requirements for the LAN technology chosen, such as Source Address, Destination Address (which can be the receiving station's IEEE address or a Multicast address which includes the Broadcast address), and CRC. A Magic Packet must also be a valid non error L2 packet. The specific data sequence consists of 16 repetitions of the IEEE address of this node, with no breaks or interruptions. This sequence can be located anywhere within the packet, but must be preceded by a synchronization stream. The synchronization stream allows the scanning state machine to be much simpler. The synchronization stream is defined as 6 bytes of 0xFF. The device will also accept a Broadcast frame, as long as the 16 repetitions of the IEEE address match the address of the machine to be awakened."

The E810 expects the destination address to either:

- Be the broadcast address (FF.FF.FF.FF.FF.FF).
- Match the value of the port L2 Ethernet destination MAC Address (DA) set by firmware to the relevant filters PRTPM_SAL/H.

On power-up, the firmware loads the PRTPM_SAL/H addresses from NVM, each address entry contains:

- MAC Address for Magic Packet filtering.
- Address Valid (AV) indication.
- Promiscuous Multicast magic filtering enable (MC) indicating the L2 destination address can be any multicast address.
- The PF number (*PF_NUM*) to be reported if a Magic Packet matches this filter.

The firmware uses the PFGEN_PORTNUM registers to map the per PF MAC Address to the relevant ports.

The E810 searches for the contents of the port's Ethernet Destination MAC Address Receive Address as the embedded IEEE address. It considers any non-0xFF byte after a series of at least 6 0xFFs to be the start of the IEEE address for comparison purposes. For example, it catches the case of 7 0xFFs followed by the IEEE address). As soon as one of the first 96 bytes after a string of 0xFFs do not match, it continues to search for another set of at least 6 0xFFs followed by the 16 copies of the IEEE address later in the packet.

Note: This definition precludes the first byte of the destination address from being FF.

A Magic Packet's destination address must match the address filtering enabled in the configuration registers, with the exception that broadcast packets are considered to match even if broadcast packet reception is not enabled. If APM wake-up (wake-up by a Magic Packet) is enabled in the NVM, the E810 starts up with the Ethernet MAC Destination Address loaded from the NVM. This enables the E810 to accept packets with the matching IEEE address before the software device driver loads.

Table 5-1. Magic Packet Structure

Offset	# of Bytes	Field	Value	Action	Comment
0	6	Destination Address		Compare	MAC header – processed by main address filter.
6	6	Source Address		Skip	
12	T=(0/4/8)	Possible STag		Skip	
12 + T	S=(0/4)	Possible VLAN Tag		Skip	
12 + T + S	D=(0/8)	Possible Length + LLC/SNAP Header		Skip	
12 + T+ S + D	2	Type		Skip	
Any	6	Synchronizing Stream	FF*6+	Compare	
Any+6	96	16 copies of Node Address	A*16	Compare	Compared to relevant Station Addresses (PRTPM_SAH, PRTPM_SAL) registers.

5.3.4 Wake-Up and Virtualization

When operating in a virtualized environment, all wake-up capabilities are managed by a single entity (such as the VMM or an IOVM). In an IOV architecture, the physical (PF) driver controls wake-up and none of the Virtual Machines (VMs) has direct access to the wake-up registers. The wake-up registers are not replicated per VF.

5.3.5 Wake-Up Flows

5.3.5.1 Wake-Up Enable Flow

A WoL register set exists in each PF. Each set consists of the following wake-up filters and registers:

- PFPM_WUC — Wake Up Control Register.
- PFPM_WUS — Wake Up Status Register.

On power-up, values loaded from the NVM into the following per PF register define enablement of APM wake-up functionality:

- The NVM *APM Enable* bit is loaded to the PFPM_APM.*APME* register bit to enable detection of a Magic Packet destined to the PF.

Note: The *EN_APM_D0* bit also enables the wake functionality in ACPI mode while the device is in D0. Therefore, if any of the ACPI wake filters are enabled (See Section 5.3.2) and wake events in DO are not desired, *EN_APM_DO* must be cleared by the software. Similarly, if software wishes to enable wake events in D0, the *EN_APM_D0* bit must be set by the software in addition to enabling the relevant ACPI wake filters.

5.3.5.2 Wake-Up Disable Flow

Once the E810 wakes the system following transition to D0, the software driver can disable Wake-on-LAN directly by:

1. Clearing all the pending wake-up status bits in the Wake Up Status (PFPM_WUS) register.
2. Clearing the relevant bits in the PFPM_WUC register.

Note: This flow is not used by regular Intel drivers.

5.3.5.3 ACPI Wake-Up Flow

Once wake up is enabled, the E810 monitors the enabled wake functions. If at least one of the enabled wake events occurs, the E810 does the following:

- Sets the *PME_Status* bit in the PFPM_WUS and PCI PMCSR registers.
- Sets the proper bit, corresponding to the wake reason in PFPM_WUS:
  - *LINKC* for link status change.
  - *MAG* for Magic Packet reception.
  - *MNG* for general manageability wake-up.
  - *FW_RST_WK* for EMP reset event.
- If the *PME_En* bit in the PMCSR configuration register is set, asserts PE_WAKE_N and/or sends a PM_PME PCIe message.

Note: The PE_WAKE_N signal remains asserted, PM_PME Messages are periodically sent to the host, and the E810 ignores any subsequent ACPI wake-up packets and link change events for that function until the operating system either writes a 1b to the *PME_Status* bit of the PMCSR register or writes a 0b to the *PME_En* bit, or until de-assertion of PERST.

NOTE: ***This page intentionally left blank.***

Chapter 6 Non-Volatile Memory Map

6.1 NVM Organization

Note: All the offsets in this chapter are relative to the E810 Configuration region. This region is located in the flash at offset 4 KB as described in Section 3.4.2.1. So to obtain the actual offset in the flash, 0x800 should be added to the requested word address.

6.1.1 NVM Map High Level

Table 6-1. Flat NVM Map - High Level

Area	Section	Size (Words)	Description
Shadow RAM - Non-Preserved	Init Module	256	Pointers to other sections and legacy software word.
Shadow RAM - Preserved	PFA Area	12K	A set of TLV sections as described in section TBD containing all the information that should be preserved across updates.
Shadow RAM - Non-Preserved	Auto-Load Sections	Variable	Sections containing the auto-loaded registers at different resets.
	EMP Configuration Sections	Variable	Sections containing configurations of the EMP. Includes EMP SR settings, manageability sections and OEM sections.
Shadow Ram - Second Copy	SRb	32K	A second copy of the Shadow RAM for updates.
Flash	NVM Bank 1		Signed section containing the basic map from which all the other maps are generated via adaptive NVM. It also contains a copy of the Shadow RAM and extended mini-loader.
	NVM Bank 2		A second copy of the NVM Bank for updates.
	OROM Section		Signed section containing the Option ROM image.
	OROM Section - Second Copy		A second copy of the OROM section for updates.
	Extended TLVs - 1st Copy		Extension of the PFA module.
	Extended TLVs - 2nd Copy		
	Scratch Pad Area		Areas used for data not double banked.

6.1.2 NVM Header

Table 6-2 lists the format of the NVM Header section. It includes words with specific content and pointers to the first level of NVM modules.

- Items which are pointers to modules end with the pointer in there name.
  - The pointer to non-Shadow RAM modules that are part of NVM bank are relative to the beginning of the Flash, assuming 1st NVM bank is valid. In case the 2nd NVM bank is valid, there is a need to add NVM Bank Area Size to the pointer.
  - The pointer to Shadow RAM modules are relative to the beginning of the Shadow RAM.

- The "For Section [Auth] column indicates the following for modules pointed by pointers in the header:
  - Auth - The pointed module is authenticated.
  - Adaptive - Format of pointed module is Authenticated, but content can be changed by adaptive NVM flows.
  - RW - The module is read/write.

  A read-only item can be written only when in the blank Flash programming mode.
- The "CSR Format" column indicates whether the pointed module uses the formats described in Section 6.1.3.\
- The "Module is in Shadow RAM" column indicates whether the module is mapped into the basic banks mirrored into the internal Shadow RAM. If marked as No, the most significant bit of the pointer (Bit 15) must be set to 1b to indicate that the pointer value (in Bits 14:0) is expressed in 4 KB sector units. Otherwise, it is expressed in word units.

6.1.3 Structure of NVM Modules

An NVM module read by the EMP to configure hardware (as listed Table 6-2) is built according to one of the following structures:

- **Fixed Functionality Structure** — Each NVM word is allocated to one or more fixed fields, and the contents of the NVM word are loaded to fixed CSRs in the E810. In Table 6-2, these modules are referred to as CSR format = No modules.
- **Flexible Functionality Module** — The structure defines the device address or addresses into which the NVM words are loaded. Therefore, the module might be used for different purposes based on its contents. In Table 6-2, these modules are referred as CSR format = Yes modules.

The remainder of this section describes the structure of the contents of a flexible functionality module (excluding the module header described in Section 6.1.5). The general structure of the module is shown in Figure 6-1.

A CSR format module can be made of a mix of repeating Type 1, 2, 3 and 4 segments. Type 5 should be kept separate. Each segment is described by its own header (the shaded fields in Figure 6-1).

A sideband CSR format module includes a special Type F - subtype 0 segment, which includes the information needed to access the sideband module. The rest of the module can be made of a mix of repeating Type 1, 2, and 5 segments. This kind of module can only be loaded by firmware without any hardware acceleration. The Type F segment can repeat several times inside the module and is used to change access parameters to the sideband module. The sideband CSR format module is described in Section 6.1.3.6.

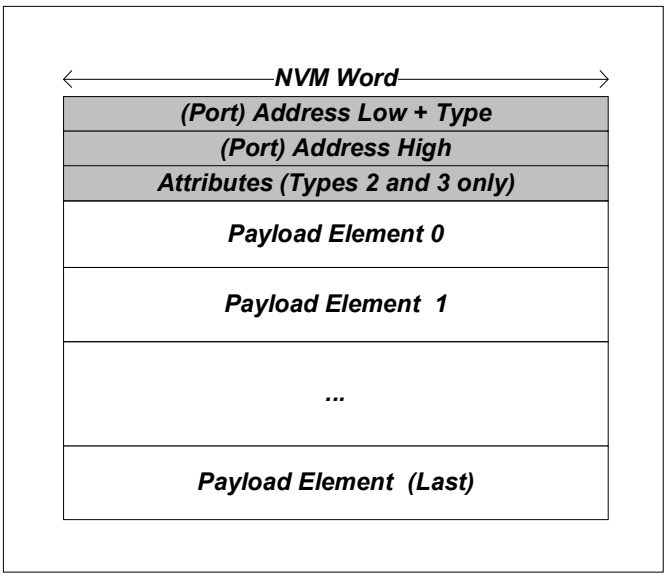

Figure 6-1. Structure of a Flexible Functionality Module

Following are descriptions of the fields in Figure 6-1:

- **(Port) Address** — A 28-bit value that defines the starting address to which data DWords are loaded. Serves as either a direct address to load into (Types 1 and 2), or as an indirect address referred to as a port address (Type 3 and 4). A port is made of a 32-bit address register followed by data registers of total size width. Address low is a 12-bit field mapped to Word[15:4].
- **Type** — A 4-bit command field mapped to Word[3:0] bits that defines the type of flexible module. Descriptions are as follows:
  - **Type 1 (0001b)** — Loads a single 32-bit data segment.
  - **Type 2 (0010b)** — Load a set of 32-bit data DWords into consecutive addresses.
  - **Type 3 (0011b)** — Loads a set of 32-bit data DWords through an address port.
  - **Type 4 (0100b)** — Loads, through an address port, a sequence of data blocks into arbitrary addresses.
  - **Type 5 (0101b)** - Loads a single 64-bit data segment.
  - **Type F (1111b)** - Used to define access parameters to sideband module.
- **Attributes** — A 16-bit optional word that defines attributes of the module:
  - **Width** — A 3-bit field mapped to Word[2:0] bits that describes the width (in 32-bit DWords) of a data element.
    - 000b = Data is 32-bits wide.
    - 001b = Data is 64-bits wide.
    - 010b = Data is 128-bits wide.
    - 011b = Data is 256-bits wide.
    - Else = Reserved.
  - **Skip** — A 2-bit field mapped to Word[4:3] bits that describes the number of address bytes to be skipped for getting the address of the next payload element (Type 2) or port register involved (Type 3 or 4).
    - 00b = Skip 4 bytes.
    - 01b = Skip 8 x 4 bytes = 32 bytes.
    - 10b = Skip 32 x 4 bytes = 128 bytes.
    - 11b = Skip 0 bytes.
  - **Length** — An 11-bit field mapped to Word[15:5] bits that contains the number of data elements, each of *Width* bits. Length of zero is illegal.
- **Payload Elements** — A sequence of address or data elements to be loaded into the E810. The structure of the *Payload* field varies with each type and is described in the sections that follow.

6.1.3.1 Type 1 Module

Used to specify a single 32-bit data segment.

- The *Address* field defines the address into which the 32-bit data is loaded. See Figure 6-2.

The common use of a Type 1 module is to concatenate a list of such structure to load a set of 32-bit values into various CSRs.

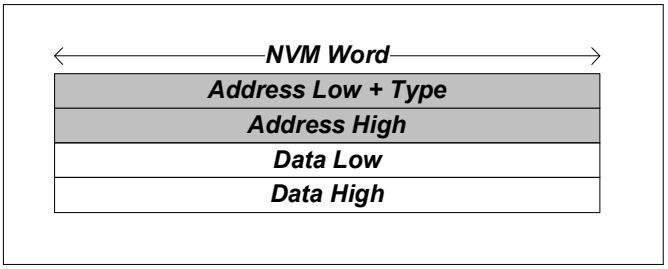

Figure 6-2. Structure of a Type 1 Module

6.1.3.2 Type 2 Module

Used to load a sequence of data into consecutive addresses, such as a memory array. See Figure 6-3.

- The *Address* field defines the first address to be loaded. Data is loaded as width-size elements into consecutive addresses.
- The *Attributes* field applies the following information:
  - *Width* = 000b
  - *Skip* = see previous description
  - *Length* = see previous description

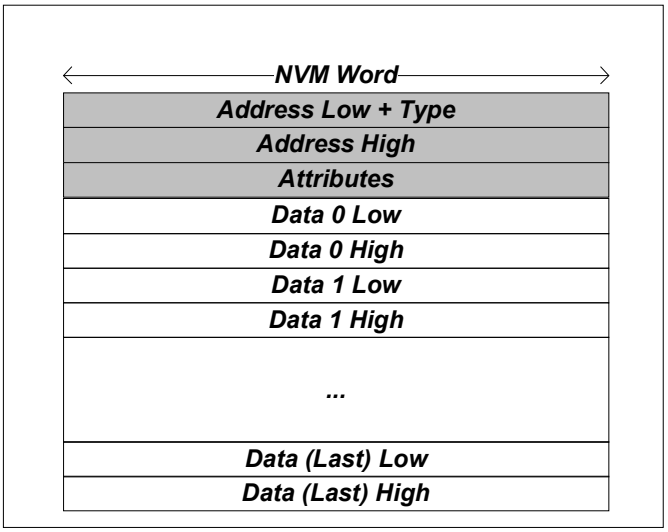

Figure 6-3. Structure of a Type 2 Module

6.1.3.3 Type 3 Module

Used to load a sequence of data through an address port.

Figure 6-4 shows the structure of a Type 3 module. The following fields have special values:

- The *Port Address* field defines the address of the port address register through which address/data is loaded. The Port Address register is followed by the Port Data registers.
- The *Attributes* field applies with the following fields:
  - *Width* — The size of a single data element written into the port during one port load cycle.
  - *Length* — Number of data elements written through the port.
  - *Skip* — Encodes the number of bytes between the addresses of the port registers involved.
- The *Indirect Address* field defines the first consecutive address to write to. It is written into the Port Address register for the first item and from then on the indirect address is increased (by the E810) with each write of a new data element from the list. Consecutive data elements are written into the port.
- The *Data Element* fields are made of length elements, each of the width DWords. Each port load cycle handles one data element

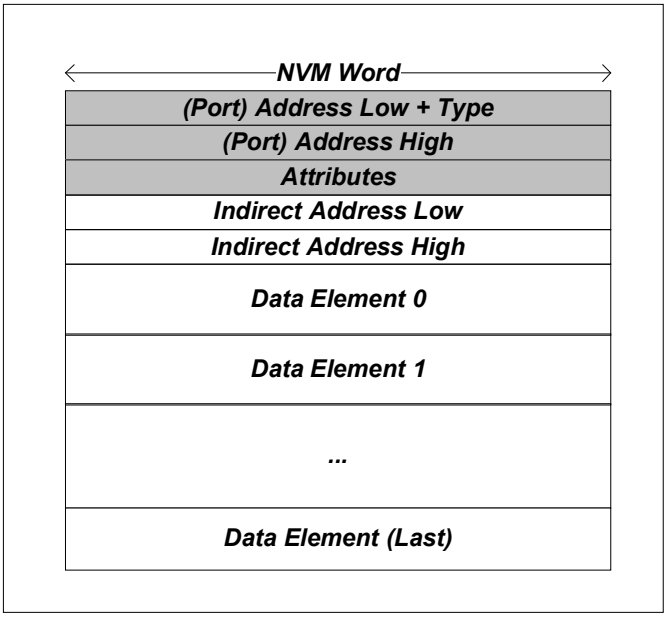

Figure 6-4. Structure of a Type 3 Module

The following figures describe two cases of using a Type 3 module:

- Figure 6-5 shows a case of loading 32-bit values into a Global (GL) port.
- Figure 6-6 shows a case of loading 64-bit values into a PRT port.

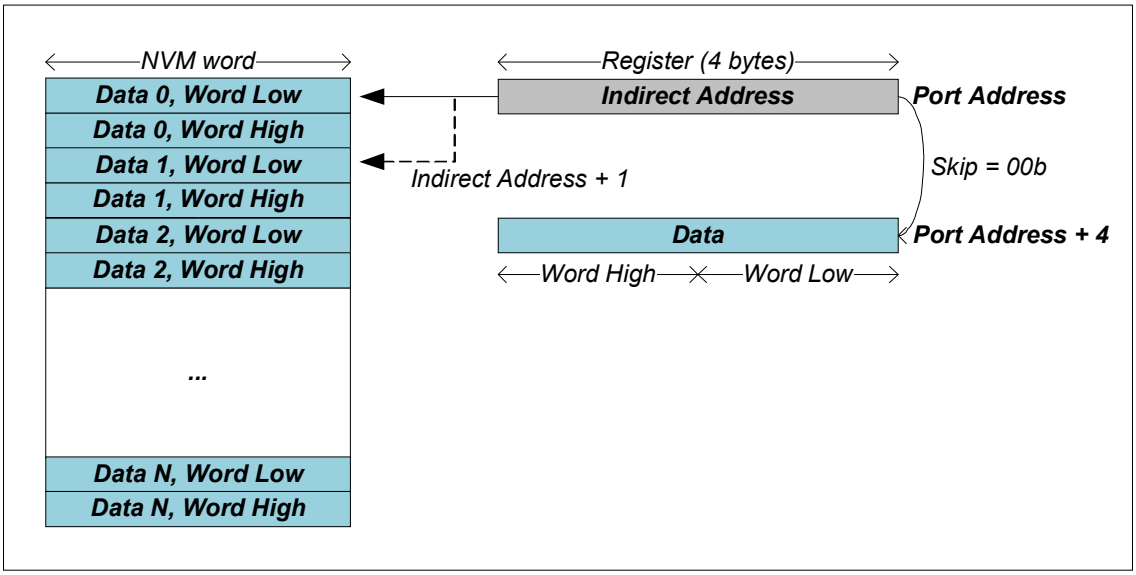

Figure 6-5. Access Through a Type 3 Module of 32-Bit Wide Data Elements

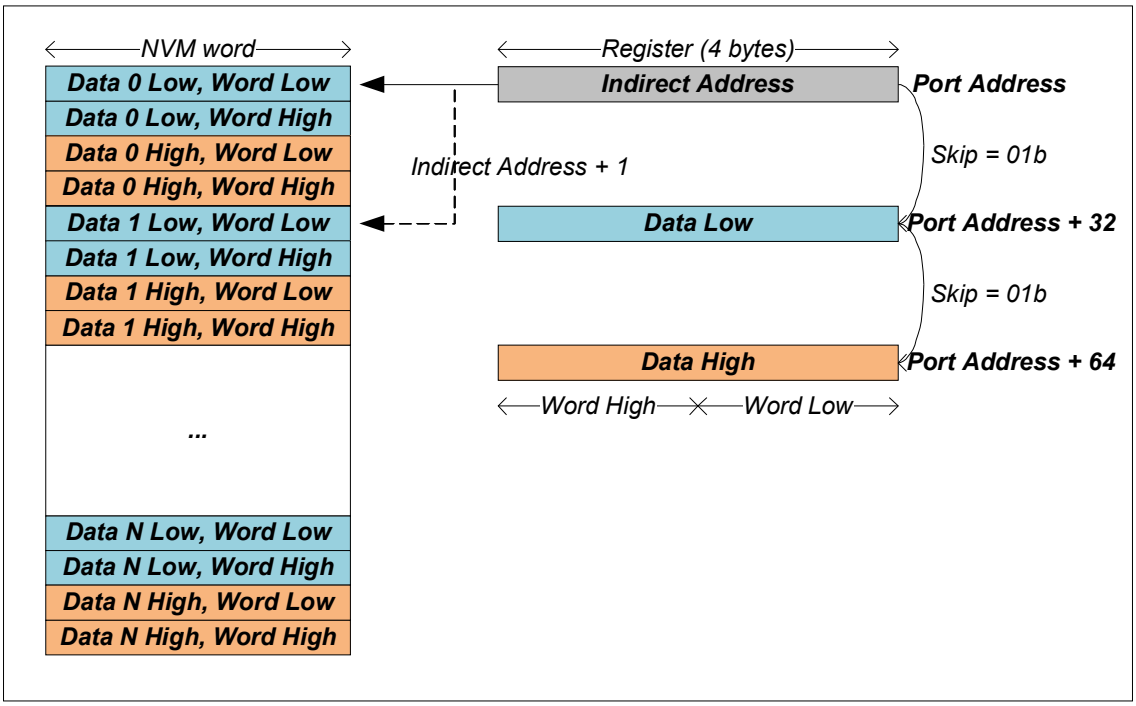

Figure 6-6. Access Through a Type 3 Module of 64-Bit Wide per-Port Data Elements

6.1.3.4 Type 4 Module

Used to load, through an address port, a sequence of scattered data elements at arbitrary addresses.

Figure 6-7 shows the structure of a Type 4 module. The following fields have special values:

- The *Port Address* field defines the address of the port address register through which address/data is loaded. The port address register is followed by the port data registers.
- The *Attributes* field applies with the following fields:
  - *Width* — The size of a single data element written into the port during one port load cycle.
  - *Length* — Number of data elements written through the port, not including the indirect address words (the words colored in gray in Figure 6-8 and Figure 6-9).
  - *Skip* — Encodes the number of bytes between the addresses of the port registers involved.
- The *Indirect Address* fields define the address that the following data element is written into. It is written into the Port Address register.
- The *Data Element* is written into the port data register. The sequence of writing (the *Indirect Address* and its *Data Element*) into the port is repeated per each data element (length times).

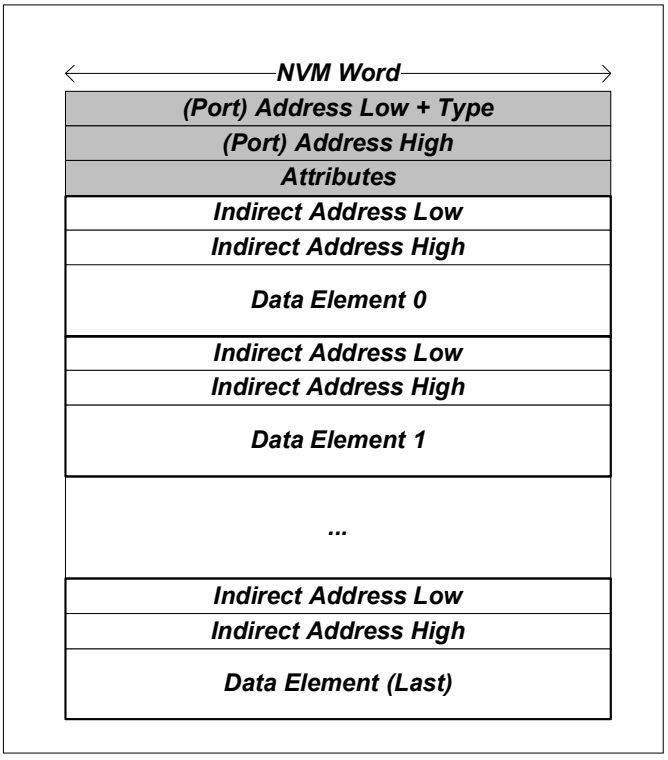

Figure 6-7. Structure of a Type 4 Module

The following figures show two cases of using a Type 4 module:

- Figure 6-8 shows a case of loading 32-bit values into a global (GL) port.
- Figure 6-9 shows a case of loading 64-bit values into a PRT port.

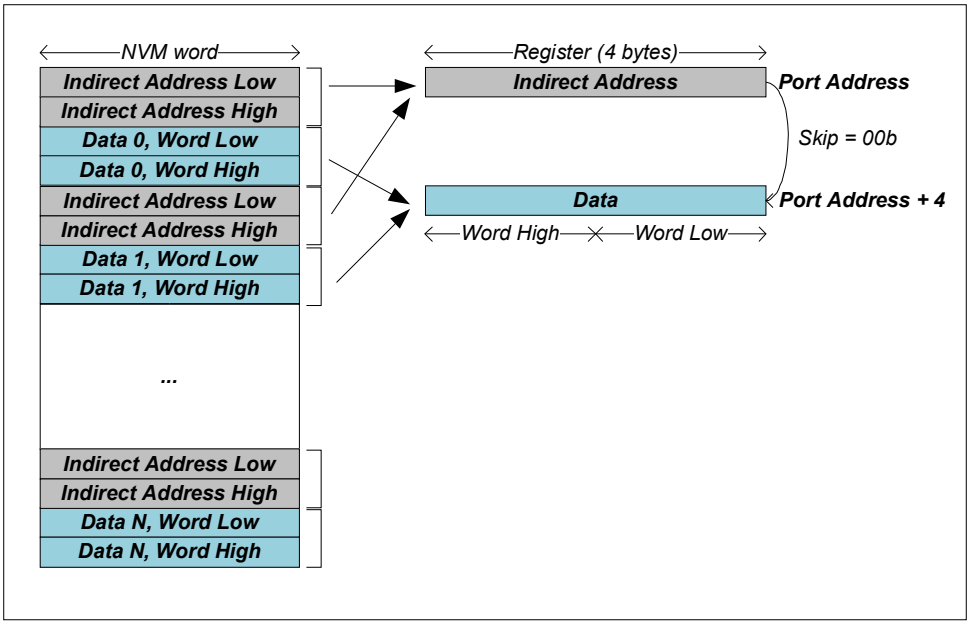

Figure 6-8. Access Through a Type 4 Module of 32-Bit Wide Data Elements

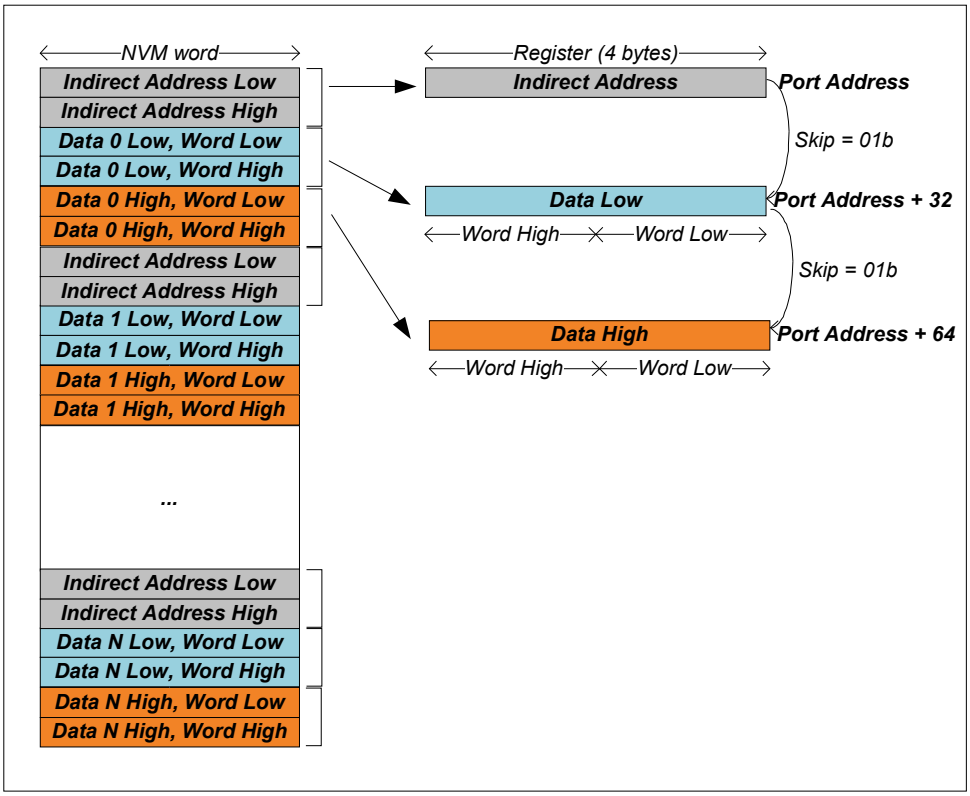

Figure 6-9. Access Through a Type 4 Module of 64-Bit Wide per-Port Data Elements

6.1.3.5 Type 5 Module

Used to load, a single 64-bit data segment addressed by 32-bit address. Firmware handles this module type without any hardware acceleration. It is intended for loading into external IPs.

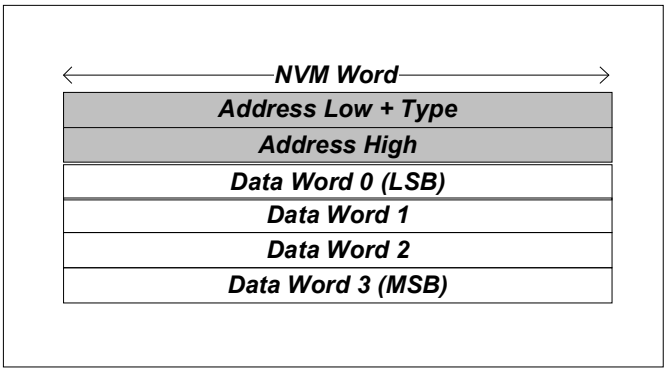

Figure 6-10. Structure of a Type 5 Module

6.1.3.6 Type F Module

This is a special type, which is not used to directly load a specific address, but it is used to indicate specific access conditions for the register in the auto-load module. Specifically, subtype 0 within Type F module indicates that this module is used to load sideband device. A Type F module should be followed by one or more Type 1,2 or 5 modules, which indicates the actual data to load. Figure 6-11 describes the format of Type F, subtype 0.

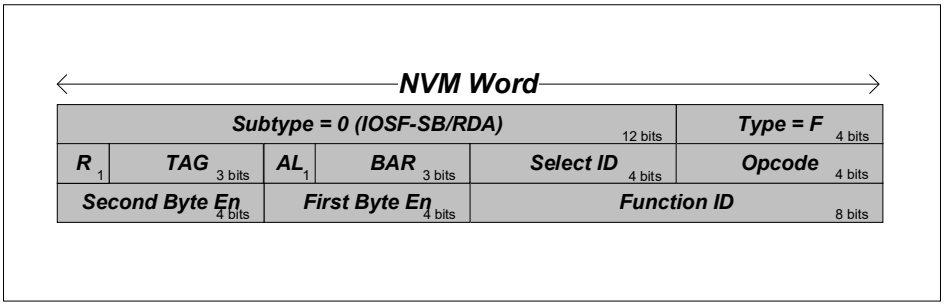

Figure 6-11. Structure of a Type F Module

Two additional 16-bits word are attached to Type F, subtype 0, with the following indications:

- **Opcode** — A 4-bit value that defines the sideband opcode that is used for loading the data in the following Type 1, 2, or 5 modules. Type 1 and 5 should typically use post or non-posted MWr or CRWr opcodes. Type 2 might use posted or non-posted MBWr opcode.
- **Select ID** - Indicates the sideband device to be loaded.
- **BAR** - Indicates BAR number of the sideband address (ignored - set to zero).

- **AL** — Address length flag. Indicates the length of the sideband address. For a 16-bit address, the 16 low significant bits are taken from the 28 bits of Type 1, 2, or 5 address. For a 48-bit address, the 28 bits of Type 1, 2, or 5 address are taken and padded with 20 bits of 0.
  - — 0 = 16-bit address
  - — 1 = 48-bit address
- **TAG** - Indicates TAG field of the sideband command (ignored - set to zero).
- **R** - Reserved. Set to 0.
- **Function ID** - Indicates the function ID of the sideband transaction (ignored - set to zero).
- **First Byte Enable** - Indicates the byte enable bits for the first 32 bits word written.
- **Second Byte Enable** - Indicates the byte enable bits for the second 32 bits word written.

Figure 6-12 illustrates the format of a Type F Auto-Load section.

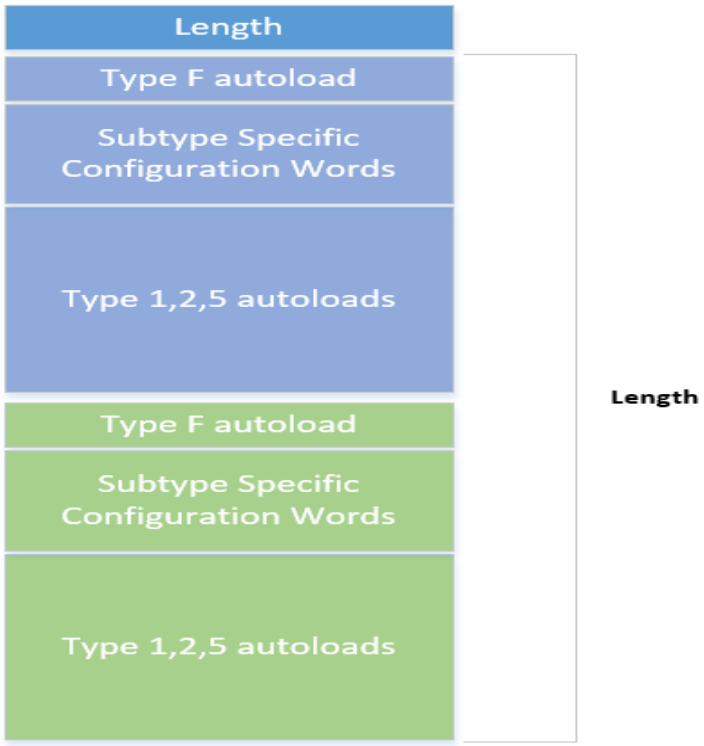

Figure 6-12. Type F Auto-Load Section

6.1.3.7 Format of the Hardware Modules in Flash

Some modules are not loaded directly from the Shadow RAM but read from Flash to the local RAM by firmware before loading to the hardware. Such modules could be too big to be copied to the local RAM as a single chunk. They could also be too big to be loaded with the hardware accelerator in a single run.

The module structure described shown in Figure 6-13 allows reading the module from NVM in chunks, which fit the allocated buffer in the local RAM and can be sent to the hardware accelerator. The chunk size is up to 4 KB. All length values are in 16-bit words not including the length itself. The firmware reads the module content chunk by chunk to the local RAM and runs the hardware accelerator for the loaded chunk.

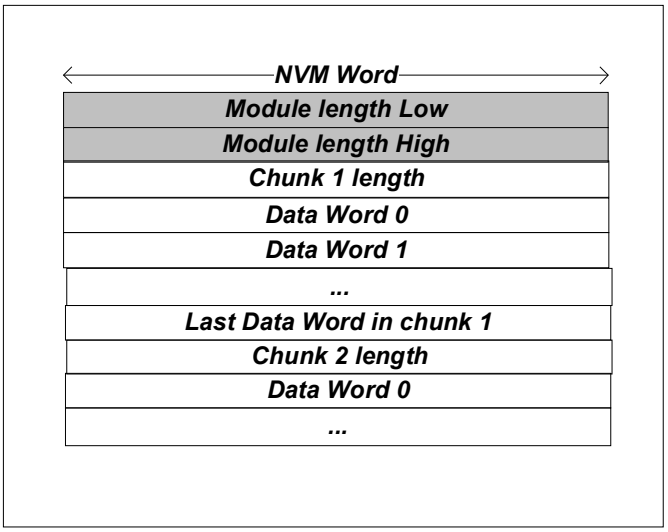

Figure 6-13. Format of Hardware Modules in Flash

6.1.3.8 Auto-Generated Pointers

Type 1 and Type 2 items are generated by the auto map generation tool from the project's register database. These items are automatically mapped into the Registers Auto-Load NVM modules according to their loading trigger (see Table 6-2) and with no possibility to perform manual changes.

EMP code and software tools cannot accommodate these variations in mapping offset. Hence, they need a fixed method for accessing some predefined Type 1/2 items. The Auto-Generated Pointers module is pointed to by NVM Word 0x07. It lists the mapping address in NVM of the pre-defined Type 1/2 items via a 2-word structure per item.

The word address in Shadow RAM of an item is given by the sum of the contents of its two associated words: pointer + offset. If the item is relative to an array of registers and/or to a register with a scope different than global, the offset is given for the first data word of the Type 1/2 array, for array instance [0] and scope instance [0].

In the Auto-Generated Pointers module, the location of the 2-word structures relative to an item is made invariant along the project's life. The alias name of the Type 1/2 register appears in the names of the two words in the structure.

See Auto-Generated Pointers module on the detailed NVM map for the list of auto-generated pointers (Section 6.3.60).

6.1.4 NVM Integrity Checks by Software

This section describes the NVM integrity fields inserted in the E810 NVM map to provide a basic detection of a faulty Flash part.

A software checksum is performed by the PF driver just after completion of its initialization sequence. It covers only PFA modules and the init section modules, which are mapped into Shadow RAM.

If the checks fails, another try is attempted, and if it fails again, the PF driver disables Tx/Rx operations with the E810.

Modules mapped outside the Shadow RAM are signed, except for the scratch pad areas. EMP is responsible for checking the signature of the modules at POR/EMPR.

6.1.4.1 Software Checksum

The Software Checksum section (*TLV Type* 0x3F in PFA) covers the PFA content (reserved words included).

The Software Checksum word in the TLV above is computed such that after adding all the covered words, including the Software Checksum word itself, the sum is 0xBABA.

Each time software tools are modifying one of these areas, EMP updates the *Software Checksum* field accordingly.

Each time EMP is updating the contents of one of these areas by its own initiative (not as part of an NVM Update AQ command) or for handling an MC command received over SMBus or NC-SI, it also updates the *Software Checksum* field accordingly.

The software device driver can check if the checksum is valid using the NVM Checksum Command (0x0706). See Section 3.4.10.7.

6.1.5 Header of NVM Modules

6.1.5.1 Header of All NVM Modules Mapped to Shadow RAM

Modules read by hardware do not contain pointers to sub-modules and they are not authenticated.

Table 6-3. NVM Header of Modules Mapped to Shadow RAM

Number of Words	Field or Segment Name	Description and Comments
1	Module Length	Length of the module contents expressed in words (*Module Length* field excluded). It must be set to N. Modules are size limited to the size of the Shadow RAM (64 KB).
N	Word 1	
	Word 2	
	...	
	Word N	

6.1.5.2 Header of Authenticated NVM Modules

This section concerns the following modules:

- NVM Bank (pointed by NVM word 0x42).
- Option ROM (pointed by NVM word 0x44).

For the NVM Bank, the first 330 words listed in Table 6-4 are mapped at the beginning of the module.

For the Option ROM, the first 330 words listed in Table 6-4 are mapped at the end of the area allocated to the module (at its trailer), though for the sake of the authentication, these words are mapped at the module's header, as listed in Table 6-4.

In Table 6-4, fields colored in cyan are protected by the authentication signature.

Table 6-4. Header of Authenticated NVM Modules

Number of Words	Field or Segment Name	Description and Comments
64	CSS Header	Refer to Section 3.4.9.2.
128	RSA Public Key	Refer to Section 3.4.9. This field is skipped due to SHA256 Hash computing.
2	RSA Exponent	Refer to Section 3.4.9. This field is skipped due to SHA256 Hash computing.
128	Encrypted SHA256 Hash	Refer to Section 3.4.9. This field is skipped due to SHA256 Hash computing.
1	E810 Blank NVM Device ID	A unique, Intel-provided Device ID that identifies the E810 controller among other Intel controllers. It must be set to 0x1590 in 25x25 mm package and 0x1598 in the 21x21 mm package.
2	Max Module Area	It is the maximum Flash area expressed in words that can be used by the module, starting from CSS header (included). It is set to 580K words (1160 KB) for an EMP and PE image modules and to 4K words (8 KB) for other authenticated modules.
2	Current Module Area	It is the Flash area expressed in words that is currently used by the module, starting from CSS header (included).
1	Module Format Version + CRC8	Bit 15 = CRC8 field is used. Set to 1b if a CRC8 is computed over the module, set to 0b otherwise. It is not used and must always be set to 0b. Bits 14:8 = Module format version. Set to 0x02 to use the currently-defined format. Bits 7:0 = CRC8 value.
1	Code Revision	Bits 15:8 = Major revision number. Bits 7:0 = Minor revision number.
1	Reserved Spare Word	Must be zeroed.
N		

6.1.5.3 Module TypeIDs

Each module has a TypeID. The TypeID uniquely identifies the module. The TypeID is used in admin commands to access the module. All modules can be read through the TypeID without knowing the exact location of the module in the NVM. PFA modules that allow direct update can be written using their TypeID.

Table 6-5 list the TypeIDs of all of the modules in the NVM.

Table 6-5. Module TypeID Table

Module TypeID	Section	In PFA	Read Only
0x00	Reserved (Has special meaning in admin commands)		N/A
0x03	GFID Module	No	N/A
0x06	RO PCIR Registers Auto-Load Module		RO
0x07	Auto Generated Pointers Module		RO
0x08	PCIR Registers Auto-Load Module		RO
0x09	EMP Global Module		RO
0x0A	Guarded Zone Module		RO
0x0B	EMP Image Module		RO
0x0C	PE Image Module		RO
0x0E	Manageability Module		RO
0x0F	EMP Settings Module		RO
0x16	PBA Block Module	Yes	RO after manufacturing
0x2F	VPD Module	Yes	RW via VPD access
0x38	POR Registers Auto-Load Module		RO?
0x3B	GLOBR Registers Auto-Load Module		RO
0x3C	CORER Registers Auto-Load Module		RO
0x3D	PHY Configuration Scripts Module		RO
0x3F	PFA Checksum Module	Yes	RO
0x40	Preserved Field Area Module	Yes	RO
0x42	1st NVM Bank Module		Writable through authenticated update
0x44	1st OROM Bank Module		Writable through authenticated update
0x46	1st TLV Extension Bank Module		RW
0x48	EMP SR Settings Module		RO
0x49	Feature Configuration Module	Yes	Writable via ANVM only
0x4A	PE CORER Registers Auto-Load Module		RO
0x4B	Link Topology Scratch Pad Area Module		RO
0x4D	Configuration Metadata Module		RO
0x4E	Immediate Values Module	Yes	Writable via ANVM only
0x4F	1588 Parameters Module	Yes	RW
0x50	FW Scratch Pad Area Module		RW
0x53	PE Settings Module		RO

Table 6-5. Module TypeID Table [continued]

Module TypeID	Section	In PFA	Read Only
0x54	PHY Core Post PLL Configuration Module		RO
0x56	External CORER Registers Auto-Load Module		RO
0x58	FW Switch Parameters Module		RO
0x5B	HLP Scratch Pad Area Module		
0x107	MNG Filters Module	Yes	RW
0x108	Pass-through Control Words Structure 0 Module	Yes	RW
0x109	Pass-through Control Words Structure 1 Module	Yes	RW
0x10A	Pass-through Control Words Structure 2 Module	Yes	RW
0x10B	Pass-through Control Words Structure 3 Module	Yes	RW
0x10C	Original EETrack ID Module	Yes	?
0x10F	PF MAC Addresses Module	Yes	RW
0x110	MNG MAC Addresses Module	Yes	RW
0x113	Early PCIR Auto-Load Module (512 bytes)	Yes	RO
0x114	Pass-Through Control Words Structure 4 Module	Yes	RW
0x115	Pass-Through Control Words Structure 5 Module	Yes	RW
0x116	Pass-Through Control Words Structure 6 Module	Yes	RW
0x117	Pass-Through Control Words Structure 7 Module	Yes	RW
0x118	Early POR Auto-Load Module (512 bytes)	Yes	RO
0x119	PSM Preserved Module	Yes	RW
0x11B	Link Topology Netlist Module	No	Updateable via Netlist update flow
0x11D	UART Debug Defaults Module	Yes	RW
0x120	Link Topology Module	Yes	RW
0x127	Component Image Set Version String	Yes	RW
0x128	OEM-Specific Modules	Yes	RW
0x129	LLDP Preserved	Yes	RW
0x130	MinSrev	Yes	RW (with limitations)
0x131	Redfish to the Endpoint (RDE) Parameters	Yes	RW
0x132	CIVD	Yes	RW (as part of NVM update)
0x133	PCIe Serial Number	Yes	RO after manufacturing
0x134	Link Default Override	Yes	RW
0x135	RDMA Control	Yes	RW
0x136	Redfish to the Endpoint (RDE) Parameters - Part II	Yes	RW
0x137	Default DCB Parameters	Yes	RW
0x138	Current DCB Parameters	Yes	RW
0x139	HII Port Disable by Function	Yes	RW
0xFFFF	Padding Module	Yes	RO

6.1.5.4 Preserved Fields Area Structure

The PFA is a structure built as a set of TLVs as follows:

- PFA Header
  - First word of PFA is the Length. Current value is 23 KB in Words (0x2F00).
- PFA Sub-Modules Format
  - The PFA Sub-Modules is in Type-Length-Data (TVL) Format.
  - Every *TLV Type* appears only once.
  - TLVs can come in any order, in Shadow RAM or in the Extension TLV area.
  - TLVs Format:
    - TypeID — 1 Word (taken from Table 6-5 only types that exists in PFA).
    - Length — 1 Word: Max area provisioned for the section.
    - Data — A variable number of words according to the *Length* field.

6.1.6 Adaptive NVM Structures

6.1.6.1 Metadata Structure

Metadata is a structure within the signed area that describes the different features, immediate fields and information on how to modify them.

The structure of the metadata is as follows:

Section Length (1W)	Super Feature Module Offset (1W)	Immediate Module Offset (1W)	Reserved (1W)
Features Fields Module			
Super-features Fields Module			
Immediate Fields Module			
Description Text Module			
CRC8 (1W)			

6.1.6.1.1 Feature Fields Module

The feature fields module contains the following sub-modules:

- Features Header Array
  - Contain a list of features, where each feature specifies number of options and fields.
  - Points to feature configuration pointer array and feature field description.
- Features Configuration Option Array
  - Contain a list of options, where each option points to a feature data array.
- Features Field Descriptor Array
  - Contain a list of fields, where each field is identified by its NVM address and mask.

- Features Data Array
  - — Contains a list of data per field.

Figure 6-14 describes the connection between the various feature tables.

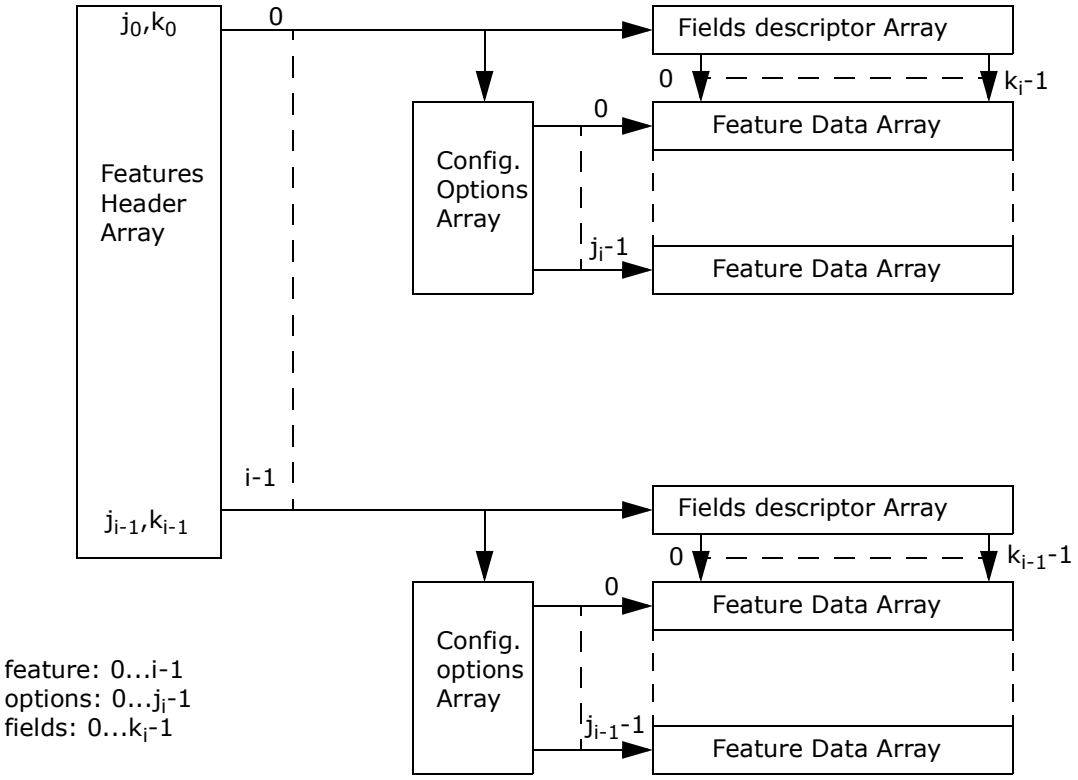

Figure 6-14. Feature Tables Diagram

6.1.6.1.1.1 Features Header Array

The features header array is built as follows:

Number of Features (1W)						
Feature ID (0) 1W	Pointer[1] to Description Text 1W	Feature (0) Flags 1W	Number of Options 1W	Number of Fields 1W	Pointer to Options Array 1W	Pointer to Fields Descriptor Array 1W
Feature ID (1) 1W	Pointer to Description Text 1W	Feature (1) Flags 1W	Number of Options 1W	Number of Fields 1W	Pointer to Options Array 1W	Pointer to Fields Descriptor Array 1W
...						
Feature ID (n) 1W	Pointer to Description Text 1W	Feature (n) Flags 1W	Number of Options 1W	Number of Fields 1W	Pointer to Options Array 1W	Pointer to Fields Descriptor Array 1W

1. The pointer is the word offset inside the metadata.

The feature flags are as follows:

Bit(s)	Content
15:4	Reserved
3	DWord
2	Hidden[1]
1	Reserved
0	OEM[2]

1. The hidden flag is set by default for features included in a super-feature.
2. Feature cannot be set by software as adaptive NVM feature. It is set during map generation per OEM.

6.1.6.1.1.2 Features Configuration Option Array

The features configuration option array is described as follows:

Option ID (0) 1W	Pointer[1] to Option Description Text 1W	Pointer in Features Data Array 1W
Option ID (1) 1W	Pointer to Option Description Text 1W	Pointer in Features Data Array 1W
...	...	...
Option ID (n) 1W	Pointer to Option Description Text 1W	Pointer in Features Data Array 1W

1. The pointer is the word offset inside the metadata.

6.1.6.1.1.3 Feature Field Descriptor Array – Case 1

- DWord flag = 0
- i = 0...Number of features -1
- j = 0...Number of fields -1

Field[0] (0) Address[1] 2W	Field[0] (0) Mask 1W	...	Field[0] (j) Address 2W	Field[0] (j) Mask 1W
Field[1] (0) Address 2W	Field[1] (0) Mask 1W	...	Field[1] (j) Address 2W	Field[1] (j) Mask 1W
Field[i] (0) Address 2W	Field[i] (0) Mask 1W	...	Field[i] (j) Address 2W	Field[i] (j) Mask 1W

1. The address is the absolute word address from the beginning of the NVM.

6.1.6.1.1.4 Feature Field Descriptor Array – Case 2 (Generic)

- DWord flag = 1
- i = 0...Number of features -1
- j = 0...Number of fields -1

Field[0] (0) Address[1] 2W	Field[0] (0) Mask LSB 1W	Field[0] (0) Mask MSB 1W	Reserved 2W	...	Field[0] (j) Address 2W	Field[0] (j) Mask LSB 1W	Field[0] (j) Mask MSB 1W	Reserved 2W
Field[1] (0) Address 2W	Field[1] (0) Mask LSB 1W	Field[1] (0) Mask MSB 1W	Reserved 2W	...	Field[1] (j) Address 2W	Field[1] (j) Mask LSB 1W	Field[1] (j) Mask MSB 1W	Reserved 2W
Field[i] (0) Address 2W	Field[i] (0) Mask LSB 1W	Field[i] (0) Mask MSB 1W	Reserved 2W	...	Field[i] (j) Address 2W	Field[i] (j) Mask LSB 1W	Field[i] (j) Mask MSB 1W	Reserved 2W

1. The address is the absolute word address from the beginning of the NVM.

6.1.6.1.1.5 Feature Field Descriptor Array – Case 2

- DWord flag = 1
  - — If field is a POR CSR:

    THEN the CSR address is attached.

    ELSE 0xFFFFFFFF to other fields of this feature.
- i = 0...Number of features -1
- j = 0...Number of fields -1

Field[0] (0) Address[1] 2W	Field[0] (0) Mask LSB 1W	Field[0] (0) Mask MSB 1W	Field[0] (0) CSR Address[2] LSB 1W	Field[0] (0) CSR Address MSB 1W	...	Field[0] (j) Address 2W	Field[0] (j) Mask LSB 1W	Field[0] (j) Mask MSB 1W	Field[0] (j) CSR Address LSB 1W	Field[0] (j) CSR Address MSB 1W
Field[1] (0) Address 2W	Field[1] (0) Mask LSB 1W	Field[1] (0) Mask MSB 1W	Field[1] (0) CSR Address LSB 1W	Field[1] (0) CSR Address MSB 1W	...	Field[1] (j) Address 2W	Field[1] (j) Mask LSB 1W	Field[1] (j) Mask MSB 1W	Field[1] (j) CSR Address LSB 1W	Field[1] (j) CSR Address MSB 1W
Field[i] (0) Address 2W	Field[i] (0) Mask LSB 1W	Field[i] (0) Mask MSB 1W	Field[i] (0) CSR Address LSB 1W	Field[i] (0) CSR Address MSB 1W	...	Field[i] (j) Address 2W	Field[i] (j) Mask LSB 1W	Field[i] (j) Mask MSB 1W	Field[i] (j) CSR Address LSB 1W	Field[i] (j) CSR Address MSB 1W

1. The address is the absolute word address from the beginning of the NVM.
2. The CSR address is added to enable E810 firmware patches (update CSR on next reset). The CSR address is the physical address of this CSR.

6.1.6.1.1.6 Feature Data Array

The fourth part of a featured fields module includes a 3D (ixjxk) feature data array.

Each data cell is by default 1W width.

If a DWord is set, it is 2W.

- i = 0...Number of features -1
- j = 0...Number of options -1
- k = 0...Number of fields -1

Note: Number of options and Number of fields are feature-dependent. See Section 6.1.6.1.1.1.

Feature(0)			
Data[0] (0)	Data[0] (1)	...	Data[0] (k)
Data[1] (0)	Data[1] (1)	...	Data[1] (k)
Data[j] (0)	Data[j] (1)	...	Data[j] (k)
Feature(1)			
Data[0] (0)	Data[0] (1)	...	Data[0] (k)
Data[1] (0)	Data[1] (1)	...	Data[1] (k)
Data[j] (0)	Data[j] (1)	...	Data[j] (k)
Feature(i)			
Data[0] (0)	Data[0] (1)	...	Data[0] (k)
Data[1] (0)	Data[1] (1)	...	Data[1] (k)
Data[j] (0)	Data[j] (1)	...	Data[j] (k)

6.1.6.1.2 Super-Feature Fields Module Structure

The super-feature fields module contains the following sub-modules:

- Super-Features Header Array
  - Contains a list of supper-features, where for each super-feature, the number of options and number of Feature Configuration IDs (FCIDs) is specified.
  - Points to Super-features Configuration Option Array.
- Super-Features Configuration Option Array
  - Contain a list of options, where each options points to a Super-Features Data Array.
- Super-Features Data Array
  - Contain a list of (Feature ID, Feature Configuration option number) pairs.

Figure 6-15 describes the connection between the various feature tables.

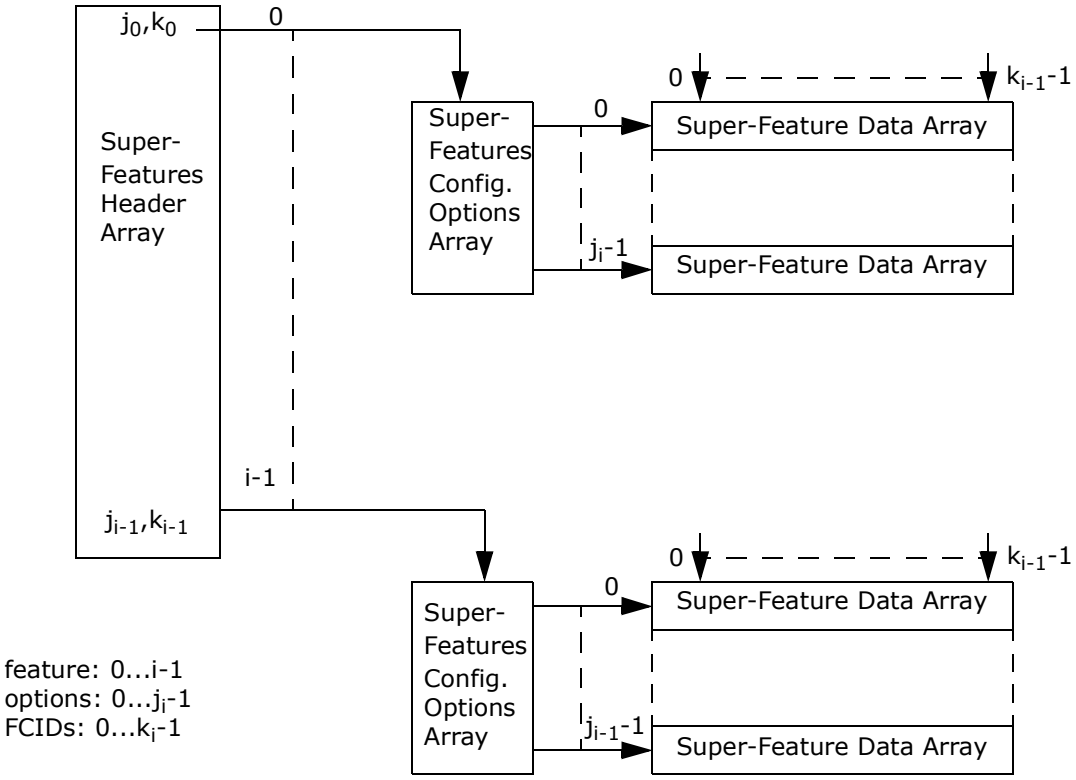

Figure 6-15. Super-Feature Tables Diagram

6.1.6.1.2.1 Super-Feature Header Array

Number of Super-Features (1W)					
Super-feature ID (0) 1W	Pointer[1] to Description Text 1W	Feature (0) Flags[2] 1W	Number of Options 1W	Number of selectable FCIDs 1W	Pointer to Options Array 1W
Super-feature ID (1) 1W	Pointer to Description Text 1W	Feature (1) Flags 1W	Number of Options 1W	Number of Selectable FCIDs 1W	Pointer to Options Array1W
...					
Super-feature ID (n) 1W	Pointer to Description Text 1W	Feature (n) Flags 1W	Number of Options 1W	Number of Selectable FCIDs 1W	Pointer to Options Array 1W

1. The pointer is the word offset inside the metadata.
2. Feature flags bit 0 is the OEM flag. Other bits are reserved in this DCR.

6.1.6.1.2.2 Super-Feature Configuration Option Array

Super-feature Option ID (0) 1W	Pointer[1] to Option Description Text 1W	Pointer in Super-Features Data Array 1W
Super-feature Option ID (1) 1W	Pointer to Option Description Text 1W	Pointer in Super-Features Data Array 1W
...	...	...
Super-feature Option ID (n) 1W	Pointer to Option Description Text 1W	Pointer in Super-Features Data Array 1W

1. The pointer is the word offset inside the metadata.

6.1.6.1.2.3 Super-Feature Data Array

3D (ixjxk) super-feature data array with a 2W data size.

- i = 0...Number of super-features -1
- j = 0...Number of options -1
- k = 0...Number of FCIDs -1

Super-Feature(0)			
Data[0] (0) 2W	Data[0] (1) 2W	...	Data[0] (k) 2W
Data[1] (0) 2W	Data[1] (1) 2W	...	Data[1] (k) 2W
Data[j] (0) 2W	Data[j] (1) 2W	...	Data[j] (k) 2W
Super-Feature(1)			
Data[0] (0) 2W	Data[0] (1) 2W	...	Data[0] (k) 2W
Data[1] (0) 2W	Data[1] (1) 2W	...	Data[1] (k) 2W
Data[j] (0) 2W	Data[j] (1) 2W	...	Data[j] (k) 2W
Super-Feature(i)			
Data[0] (0) 2W	Data[0] (1) 2W	...	Data[0] (k) 2W
Data[1] (0) 2W	Data[1] (1) 2W	...	Data[1] (k) 2W
Data[j] (0) 2W	Data[j] (1) 2W	...	Data[j] (k) 2W

6.1.6.1.3 Immediate Fields Module

The immediate ID allows to change predefined fields through management commands without knowing their location in the NVM. The location is written in the module specified as follows:

Number of Immediate Fields (1W)					
Immediate ID (0) 1W	Pointer[1] to Description Text 1W	Immediate Flags 1W	Mask 1W	Word Address[2] LSB 1W	Word Address MSB 1W
Immediate ID (1) 1W	Pointer to Description Text 1W	Immediate Flags 1W	Mask 1W	Word Address LSB 1W	Word Address MSB 1W
...					
Immediate ID (i)[3] 1W	Pointer to Description Text 1W	Immediate Flags (i)[3] 1W	Mask 1W	Word Address LSB 1W	Word Address MSB 1W

1. The pointer is the word offset inside the metadata.
2. Word address is the word offset inside the metadata.
3. i=0...Number of immediate fields-1.

The immediate fields module flags are as follows:

Bit(s)	Content
15:5	Reserved
4	Always preserved[1]
3	Pattern=0
2	Hidden
1	Reserved
0	OEM[2]

1. This flag indicates that this field is preserved in case of partial preservation.
2. 2.Feature cannot be set by software as adaptive NVM feature. It is set during map generation per OEM.

6.1.6.1.4 Description Text Module

Description (0) Length 1W	X words description in ASCII
Description (1) Length 1W	Y words description in ASCII
...	...
Description (n) Length 1W	Z words description in ASCII

6.1.6.2 Feature Configuration

This section contains the current configurations chosen for the specific image. It is stored in the PFA with a *TLV Type* of 0x49.

Section Length 1W	FCID (0) 2W	FCID (1) 2W	...	FCID (n) 2W

Section Length is in word units, excluding the section length itself.

FCID is the feature configuration ID and consists of these four bytes:

- Feature Major #
- Feature Minor #
- Configuration Major #
- Configuration Minor #

FCID also represents the order of features in the adaptive NVM tool.

Notes:

- Super-features have FCID = 0xFXXX (0xFFFF value is reserved).
- Super-feature FCIDs should precede subordinated features FCIDs (or feature FCIDs placeholders).
- The feature configuration section can be finished by an end-of-list string of 0xFFFF + padding zeros.

6.1.6.3 Immediate Field Values

This section contains the current configurations chosen for the specific image that are immediate fields. It is stored in the PFA and pointed from address 0x4E.

Section Length is in word units and excludes the section length itself.

Immediate ID has 1 Word – Major # (1B) and Minor # (1B).

The immediate ID number should be unique on a per-project step.

- n=0...Number of immediate fields-1.
- The immediate field configuration section can be finished by an end-of-list string of 0xFFFF + padding zeros.

Section Length 1W	Immediate Field ID (0) 2W	Data (0) 1W	...	Immediate Field ID (n) 1W	Data (n) 1W

6.2 PLDM Header

6.2.1 PLDM Header Section

This section is part of the PLDM package header. The PLDM header is not part of the NVM image.

Table 6-6. PLDM Header Section Summary Table

Word Address	Used By	Word Name	Section Reference

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageHeaderIdentifier	0xCB7D	

6.2.1.7 PackageHeaderIdentifier_6 (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageHeaderIdentifier	0x878C	

6.2.1.8 PackageHeaderIdentifier_7 (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageHeaderIdentifier	0xF018	

6.2.1.9 FormatRevision_HeaderSize_LSB (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:8	HeaderSize_LSB		
7:0	FormatRevision	0x01	

6.2.1.10 Headersize_MSB (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:8	RelelaseDateTimeUTC_offset_LSB	0x0	timestamp104 byte 0.
7:0	Headersize_MSB		

6.2.1.11 ReleaseDateTime_0 (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:8	RelelaseDateTimeMsec_0	0x0	timestamp104 byte 2.
7:0	RelelaseDateTimeUTC_offset_MSB_by	0x0	timestamp104 byte 1.

6.2.1.12 ReleaseDateTime_1 (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	RelelaseDateTimeMsec_1_2	0x0	timestamp104 byte 3:4.

6.2.1.13 ReleaseDateTime_2 (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ReleaseDateTimeMin	0x0	timestamp104 byte 6.
7:0	ReleaseDateTimeSec	0x0	timestamp104 byte 5.

6.2.1.14 ReleaseDateTime_3 (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ReleaseDateTimeDay	0x0	timestamp104 byte 8.
7:0	ReleaseDateTimeHour	0x0	timestamp104 byte 7.

6.2.1.15 ReleaseDateTime_4 (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ReleaseDateTimeYear_LSB	0x0	timestamp104 byte 10.
7:0	ReleaseDateTimeMonth	0x0	timestamp104 byte 9.

6.2.1.16 ReleaseDateTime_5 (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:12	ReleaseDateTime UTC Resolution	0x2	timestamp104 byte 12 [7:4]. Resolution is minutes.
11:8	ReleaseDateTime Resolution	0x7	timestamp104 byte 12 [3:0]. Resolution is minutes.
7:0	ReleaseDateTimeYear_MSB	0x0	timestamp104 byte 11.

6.2.1.17 ComponentBitmapBitLength (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentBitmapBitLength	0x8	

6.2.1.18 PackageVersionStringType_Length (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:8	PackageVersionStringLength	0x1F	Assuming a string length of 31. The last byte is part of the Firmware Device Identification Area.
7:0	PackageVersionStringType	0x1	

6.2.1.19 PackageVersionString- FW Component Prefix (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - FW Component Prefix	0x3A4E	"N:" in ASCII.

6.2.1.20 PackageVersionString - FW Component Version 0 (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - FW Component Version 0	0x3030	Firmware component version 0. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.21 PackageVersionString - FW Component Version 1 (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - FW Component Version 1	0x3030	Firmware component version 1. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.22 PackageVersionString - FW Component Version 2 (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - FW Component Version 2	0x3030	Firmware component version 2. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.23 PackageVersionString - FW Component Version 3 (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - FW Component Version 3	0x3030	Firmware component version 3. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.24 PackageVersionString - OROM Component Prefix (0x0017)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - OROM Component Prefix	0x3A4F	"O:" in ASCII.

6.2.1.25 PackageVersionString - OROM Component Version 0 (0x0018)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - OROM Component Version 0	0x3030	OROM component version 0. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.26 PackageVersionString - OROM Component Version 1 (0x0019)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - OROM Component Version 1	0x3030	OROM component version 1. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.27 PackageVersionString - OROM Component Version 2 (0x001A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - OROM Component Version 2	0x3030	OROM component version 2. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.28 PackageVersionString - OROM Component Version 3 (0x001B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - OROM Component Version 3	0x3030	OROM component version 3. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.29 PackageVersionString - Netlist Component Prefix (0x001C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - Netlist Component Prefix	0x3A54	“T:” in ASCII.

6.2.1.30 PackageVersionString - Netlist Component Version 0 (0x001D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - Netlist Component Version 0	0x3030	Netlist component version 0. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.31 PackageVersionString - Netlist Component Version 1 (0x001E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - Netlist Component Version 1	0x3030	Netlist component version 1. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.32 PackageVersionString - Netlist Component Version 2 (0x001F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - Netlist Component Version 2	0x3030	Netlist component version 2. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.33 PackageVersionString - Netlist Component Version 3 (0x0020)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageVersionString - Netlist Component Version 3	0x3030	Netlist component version 3. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.34 DeviceIDRecordCount and Last Byte of PackageVersionString (0x0021)

Bit(s)	Field Name	Default NVM Value	Description
15:8	DeviceIDRecordCount	0x1	
7:0	PackageVersionString Last Byte	0x0	

6.2.1.35 Recordlength (0x0022)

Bit(s)	Field Name	Default NVM Value	Description
15:0	RecordLength		Length in: 1 Byte unit First Section -> Word: PLDM Header -> Recordlength Last Section -> Word: PLDM Header -> FirmwareDevicePackageData - Additional TLVs The total length in bytes for this record. The length shall include the *RecordLength*, *DescriptorCount*, *DeviceUpdateOptionFlags*, *ComponentImageSetVersionStringType*, *ComponentSetVersionStringLength*, *FirmwareDevicePackageDataLength*, *ApplicableComponents*, *ComponentImageSetVersionString*, *RecordDescriptors*, and *FirmwareDevicePackageData* fields.

6.2.1.36 DescriptorCount and DeviceUpdateOptionFlags LSB (0x0023)

Bit(s)	Field Name	Default NVM Value	Description
15:9	DeviceUpdateOptionFlags LSB	0x0	Bits [31:24] reserved.
8	DeviceUpdateOptionFlags LSB - Continue Component Updates After Failure	0b	Bits [31:24] reserved.
7:0	DescriptorCount	0x1	The number of descriptors included within the *RecordDescriptors* field for this record.

6.2.1.37 DeviceUpdateOptionFlags - Middle (0x0024)

Bit(s)	Field Name	Default NVM Value	Description
15:0	DeviceUpdateOptionFlaDeviceUpdateOptionFlags - Middlegs -Middle	0x0	Bits [23:8] reserved.

6.2.1.38 DeviceUpdateOptionFlags - MSB and String Type (0x0025)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentImageSetVersionStringType	0x1	Valid values are: 0x0 = Unknown 0x1 = ASCII 0x2 = UTF-8 0x3 = UTF-16 0x4 = UTF-16LE 0x5 = UTF-16BE
7:0	DeviceUpdateOptionFlags - MSB	0x0	

6.2.1.39 ComponentImageSetVersionStringLength and FirmwareDevicePackageDataLength - LSB (0x0026)

Bit(s)	Field Name	Default NVM Value	Description
15:8	FirmwareDevicePackageDataLength - LSB		
7:0	ComponentImageSetVersionStringLength	0x20	

6.2.1.40 FirmwareDevicePackageDataLength - MSB and ApplicableComponents (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:11	Reserved ApplicableComponents	0x0	
10	FW Link topology ApplicableComponent	0b	0b = Non Applicable 1b = Applicable
9	OROM ApplicableComponent	1b	0b = Non Applicable 1b = Applicable
8	NVM ApplicableComponent	1b	0b = Non Applicable 1b = Applicable
7:0	FirmwareDevicePackageDataLength - MSB		

6.2.1.41 ComponentImageSetVersionString- FW Component Prefix (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Prefix	0x3A4E	"N:" in ASCII.

6.2.1.42 ComponentImageSetVersionString - FW Component Version 0 (0x0029)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 0	0x3030	Firmware component version 0. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.43 ComponentImageSetVersionString - FW Component Version 1 (0x002A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 1	0x3030	Firmware component version 1. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.44 ComponentImageSetVersionString - FW Component Version 2 (0x002B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 2	0x3030	Firmware component version 2. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.45 ComponentImageSetVersionString - FW Component Version 3 (0x002C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 3	0x3030	Firmware component version 3. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.2.1.46 ComponentImageSetVersionString - OROM Component Prefix (0x002D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Prefix	0x3A4F	"O:" in ASCII.

6.2.1.47 ComponentImageSetVersionString - OROM Component Version 0 (0x002E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 0	0x3030	OROM component version 0. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.48 ComponentImageSetVersionString - OROM Component Version 1 (0x002F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 1	0x3030	OROM component version 1. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.49 ComponentImageSetVersionString - OROM Component Version 2 (0x0030)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 2	0x3030	OROM component version 2. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.50 ComponentImageSetVersionString - OROM Component Version 3 (0x0031)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 3	0x3030	OROM component version 3. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.2.1.51 ComponentImageSetVersionString - Netlist Component Prefix (0x0032)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSet VersionString - Netlist Component Prefix	0x3A54	"T:" in ASCII.

6.2.1.52 ComponentImageSetVersionString - Netlist Component Version 0 (0x0033)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 0	0x3030	Netlist component version 0. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.53 ComponentImageSetVersionString - Netlist Component Version 1 (0x0034)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 1	0x3030	Netlist component version 1. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.54 ComponentImageSetVersionString - Netlist Component Version 2 (0x0035)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 2	0x3030	Netlist component version 2. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.55 ComponentImageSetVersionString - Netlist Component Version 3 (0x0036)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 3	0x3030	Netlist component version 3. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.2.1.56 ComponentImageSetVersionString - Null Padding (0x0037)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Null Padding	0x0	

6.2.1.57 InitialDescriptorType (0x0038)

Bit(s)	Field Name	Default NVM Value	Description
15:0	InitialDescriptorType	0x0	Indicates the type of the Initial descriptor. The initial descriptor for a device must be defined by one of the following (PCI Vendor ID, IANA Enterprise ID, UUID, PnP Vendor ID, or ACPI Vendor ID). Valid values are: 0x0 = PCI Vendor ID 0x1 = IANA Enterprise ID 0x2 = UUID 0x3 = PnP Vendor ID 0x4 = ACPI Vendor ID 0x100 = PCI Device ID 0x101 = PCI Subsystem Vendor ID 0x102 = PCI Subsystem ID 0x103 = PCI Revision ID 0x104 = PnP Product Identifier 0x105 = ACPI Product Identifier 0xFFFF = Vendor Defined

6.2.1.58 InitialDescriptorLength (0x0039)

Bit(s)	Field Name	Default NVM Value	Description
15:0	InitialDescriptorLength	0x2	Indicates the length, in bytes, of the *InitialDescriptorData* field.

6.2.1.59 InitialDescriptorData (0x003A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VendorID	0x8086	PCI Vendor ID assigned to the FD vendor.

6.2.1.60 AdditionalDescriptorType - DeviceID (0x003B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditionalDescriptorType	0x100	Indicates the type of the Initial descriptor. The initial descriptor for a device must be defined by one of the following (PCI Vendor ID, IANA Enterprise ID, UUID, PnP Vendor ID, or ACPI Vendor ID). Valid values are: 0x0 = PCI Vendor ID 0x1 = IANA Enterprise ID 0x2 = UUID 0x3 = PnP Vendor ID 0x4 = ACPI Vendor ID 0x100 = PCI Device ID 0x101 = PCI Subsystem Vendor ID 0x102 = PCI Subsystem ID 0x103 = PCI Revision ID 0x104 = PnP Product Identifier 0x105 = ACPI Product Identifier 0xFFFF = Vendor Defined

6.2.1.61 AdditionalDescriptorLength - DeviceID (0x003C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditionalDescriptorLength	0x2	Indicates the length, in bytes, of the *InitialDescriptorData* field.

6.2.1.62 AdditionalDescriptorData - Device ID (0x003D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	DeviceID	0x0	PCI Vendor ID assigned to the FD vendor.

6.2.1.63 AdditionalDescriptorType - SubVendorID (0x003E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditonialDescriptorType	0x101	Indicates the type of the Initial descriptor. The initial descriptor for a device must be defined by one of the following (PCI Vendor ID, IANA Enterprise ID, UUID, PnP Vendor ID, or ACPI Vendor ID). Valid values are: 0x0 = PCI Vendor ID 0x1 = IANA Enterprise ID 0x2 = UUID 0x3 = PnP Vendor ID 0x4 = ACPI Vendor ID 0x100 = PCI Device ID 0x101 = PCI Subsystem Vendor ID 0x102 = PCI Subsystem ID 0x103 = PCI Revision ID 0x104 = PnP Product Identifier 0x105 = ACPI Product Identifier 0xFFFF = Vendor Defined

6.2.1.64 AdditionalDescriptorLength - SubVendorID (0x003F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditonialDescriptorLength	0x2	Indicates the length, in bytes, of the *InitialDescriptorData* field.

6.2.1.65 AdditionalDescriptorIdentifierData - SubVendorID (0x0040)

Bit(s)	Field Name	Default NVM Value	Description
15:0	SubVendorID	0x8086	PCI Vendor ID assigned to the FD vendor.

6.2.1.66 AdditionalDescriptorType - SubSystemD (0x0041)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditonialDescriptorType	0x102	Indicates the type of the Initial descriptor. The initial descriptor for a device must be defined by one of the following (PCI Vendor ID, IANA Enterprise ID, UUID, PnP Vendor ID, or ACPI Vendor ID). Valid values are: 0x0 = PCI Vendor ID 0x1 = IANA Enterprise ID 0x2 = UUID 0x3 = PnP Vendor ID 0x4 = ACPI Vendor ID 0x100 = PCI Device ID 0x101 = PCI Subsystem Vendor ID 0x102 = PCI Subsystem ID 0x103 = PCI Revision ID 0x104 = PnP Product Identifier 0x105 = ACPI Product Identifier 0xFFFF = Vendor Defined

6.2.1.67 AdditionalDescriptorLength - SubSystemD (0x0042)

Bit(s)	Field Name	Default NVM Value	Description
15:0	AdditonialDescriptorLength	0x2	Indicates the length, in bytes, of the *InitialDescriptorData* field.

6.2.1.68 AdditionalDescriptorIdentifierData - SubSystemD (0x0043)

Bit(s)	Field Name	Default NVM Value	Description
15:0	SubSystemD	0x0	PCI Vendor ID assigned to the FD vendor.

6.2.1.69 FirmwareDevicePackageData - Header (0x0044)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x0	Reserved.
1	O-ROM Version to be Set in VPD	0x0	0b = Do not set O-ROM version in VPD. 1b = Set O-ROM version in VPD.
0	PFA Preserve	0x0	PFA Preserve (default mode). Should be set to zero

6.2.1.70 FirmwareDevicePackageData - GFID TLV Type (0x0045)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Type	0x0001	CURRENT_GFID

6.2.1.71 FirmwareDevicePackageData - GFID TLV Length (0x0046)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Length		

6.2.1.72 FirmwareDevicePackageData - GFID TLV Value - Current GFID IANA (0x0047)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value-IANA	0xB85C	

6.2.1.73 FirmwareDevicePackageData - GFID TLV Value - Current GFID DeviceID (0x0048)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value - device ID	0x1590	Valid values are: 0x1590 = E810 25x25 mm package (E810-CAM2/CAM1) 0x1598 = E810 21x21 mm package (E810-XXVAM2)

6.2.1.74 FirmwareDevicePackageData - GFID TLV Value - Current GFID Zeros[n] (0x0049 + 1*n, n=0...15)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value	0x0	

6.2.1.75 FirmwareDevicePackageData - GFID TLV Value - Original GFID IANA (0x0059)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value-IANA	0xB85C	

6.2.1.76 FirmwareDevicePackageData - GFID TLV Value - Original GFID DeviceID (0x005A)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value - Device ID	0x1590	Valid values are: 0x1590 = E810 25x25 mm package (E810-CAM2/CAM1) 0x1598 = E810 21x21 mm package (E810-XXVAM2)

6.2.1.77 FirmwareDevicePackageData - GFID TLV Value - Original GFID Zeros[n] (0x005B + 1*n, n=0...15)

An optional data field that can be provided within the firmware update package that the UA transfers to the FD during the firmware update process. The UA has no knowledge of what data is contained within this field, and simply passes the contents of this field when the FD requests it via the *GetPackageData* command response.

If the *FirmwareDevicePackageDataLength* field is set to 0x0000, this field contains no data and is zero bytes in length.

Bit(s)	Field Name	Default NVM Value	Description
15:0	TLV Value	0x0	

6.2.1.78 FirmwareDevicePackageData - Additional TLVs (0x006B)

Raw data module length: variable

TLVs needed for firmware update over PLDM.

6.2.1.79 ComponentImageCount (0x006C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageCount	0x3	

6.2.1.80 ComponentClassification (0x006D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentClassification	0xA	Valid values are: 0x0 = Unknown 0x1 = Other 0x2 = Driver 0x3 = Configuration Software 0x4 = Application Software 0x5 = Instrumentation 0x6 = Firmware/BIOS 0x7 = Diagnostic Software 0x8 = Operating System 0x9 = Middleware 0xA = Firmware 0xB = BIOS/FCode 0xC = Support/Service Pack 0xD = Software Bundle

6.2.1.81 ComponentIdentifier (0x006E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentIdentifier	0x6	Valid values are: 0x1 = TLV Extension 0x2 = Link Topology Scratch Pad Area 0x3 = Descriptor Block 0x5 = OROM 0x6 = NVM 0x8 = Topology Netlist

6.2.1.82 ComponentComparisonStamp LSB (0x006F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp Low	0x0	

6.2.1.83 ComponentComparisonStamp MSB (0x0070)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp High	0x0	

6.2.1.84 ComponentOptions (0x0071)

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x0	Reserved.
1	Use Component Comparison Stamp	1b	0b = Disabled 1b = Enabled
0	Force Update	1b	0b = Disabled 1b = Enabled

6.2.1.85 RequestedComponentActivationMethod (0x0072)

Bit(s)	Field Name	Default NVM Value	Description
15:6	Reserved		Reserved.
5	AC Power Cycle	0b	0b = Disabled 1b = Enabled
4	DC Power Cycle	0b	0b = Disabled 1b = Enabled
3	System Reboot	1b	0b = Disabled 1b = Enabled
2	Medium-Specific Reset	0b	0b = Disabled 1b = Enabled
1	Self-Contained	0b	0b = Disabled 1b = Enabled
0	Automatic	0b	0b = Disabled 1b = Enabled

6.2.1.86 ComponentLocationOffset LSB (0x0073)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.87 ComponentLocationOffset MSB (0x0074)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.88 ComponentSize LSB (0x0075)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize LSB	0x0	

6.2.1.89 ComponentSize MSB (0x0076)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize MSB	0x0	

6.2.1.90 ComponentVersionStringTypeAndLength (0x0077)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionStringLength	0x12	
7:0	ComponentVersionStringType	0x1	Valid values are: 0x0 = Unknown 0x1 = ASCII 0x2 = UTF-8 0x3 = UTF-16 0x4 = UTF-16LE 0x5 = UTF-16BE

6.2.1.91 ComponentVersionString- Dev Starter Major (0x0078)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Dev Starter Major	0x3030	

6.2.1.92 ComponentVersionString - Dev Starter Minor (0x0079)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Dev Starter Minor	0x3030	

6.2.1.93 ComponentVersionString - EETRACK-ID MSB (0x007A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - EETRACK-ID MSB	0x3030	MSB of EETRACK-ID. [17:0] bits of the EETRACK-ID (in ASCII).

6.2.1.94 ComponentVersionString - EETRACK-ID LSB (0x007B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - EETRACK-ID LSB	0x3030	

6.2.1.95 ComponentVersionString - Dot and Srev Byte 7 (0x007C)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Srev Byte7	0x30	MSB of 8-byte SREV version (in ASCII).
7:0	ComponentVersionString - Dot	0x2E	

6.2.1.96 ComponentVersionString - Srev Bytes 6-5 (0x007D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 6-5	0x3030	

6.2.1.97 ComponentVersionString - Srev Bytes 4-3 (0x007E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 4-3	0x3030	

6.2.1.98 ComponentVersionString - Srev Bytes 2-1 (0x007F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 2-1	0x3030	

6.2.1.99 ComponentVersionString - Srev Byte 0 and Null (0x0080)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Null	0x0	
7:0	ComponentVersionString - Srev LSB	0x30	LSB of 8-byte SREV version (in ASCII).

6.2.1.100 ComponentClassification (0x0081)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentClassification	0xA	Valid values are: 0x0 = Unknown 0x1 = Other 0x2 = Driver 0x3 = Configuration Software 0x4 = Application Software 0x5 = Instrumentation 0x6 = Firmware/BIOS 0x7 = Diagnostic Software 0x8 = Operating System 0x9 = Middleware 0xA = Firmware 0xB = BIOS/FCode 0xC = Support/Service Pack 0xD = Software Bundle

6.2.1.101 ComponentIdentifier (0x0082)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentIdentifier	0x5	Valid values are: 0x1 = TLV Extension 0x2 = Link Topology Scratch Pad Area 0x3 = Descriptor Block 0x5 = OROM 0x6 = NVM 0x8 = Topology Netlist

6.2.1.102 ComponentComparisonStamp LSB (0x0083)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp Low	0x0	

6.2.1.103 ComponentComparisonStamp MSB (0x0084)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp High	0x0	

6.2.1.104 ComponentOptions (0x0085)

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x0	Reserved.
1	Use Component Comparison Stamp	1b	0b = Disabled 1b = Enabled
0	Force Update	1b	0b = Disabled 1b = Enabled

6.2.1.105 RequestedComponentActivationMethod (0x0086)

Bit(s)	Field Name	Default NVM Value	Description
15:6	Reserved	0x0	Reserved.
5	AC Power Cycle	0b	0b = Disabled 1b = Enabled
4	DC Power Cycle	0b	0b = Disabled 1b = Enabled
3	System Reboot	0b	0b = Disabled 1b = Enabled
2	Medium-Specific Reset	0b	0b = Disabled 1b = Enabled
1	Self-Contained	0b	0b = Disabled 1b = Enabled
0	Automatic	0b	0b = Disabled 1b = Enabled

6.2.1.106 ComponentLocationOffset LSB (0x0087)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.107 ComponentLocationOffset MSB (0x0088)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.108 ComponentSize LSB (0x0089)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize LSB	0x0	

6.2.1.109 ComponentSize MSB (0x008A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize MSB	0x0	

6.2.1.110 ComponentVersionStringTypeAndLength (0x008B)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionStringLength	0x12	
7:0	ComponentVersionStringType	0x1	Valid values are: 0x0 = Unknown 0x1 = ASCII 0x2 = UTF-8 0x3 = UTF-16 0x4 = UTF-16LE 0x5 = UTF-16BE

6.2.1.111 ComponentVersionString- CIVD High MSB (0x008C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - CIVD High MSB	0x3030	

6.2.1.112 ComponentVersionString - CIVD High LSB (0x008D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - CIVD High LSB	0x3030	

6.2.1.113 ComponentVersionString - CIVD Low MSB (0x008E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - CIVD Low MSB	0x3030	

6.2.1.114 ComponentVersionString - CIVD Low LSB (0x008F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - CIVD Low LSB	0x3030	

6.2.1.115 ComponentVersionString - Dot and Srev Byte 7 (0x0090)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Srev Byte7	0x30	MSB of 8-byte SREV version (in ASCII).
7:0	ComponentVersionString - Dot	0x2E	

6.2.1.116 ComponentVersionString - Srev Bytes 6-5 (0x0091)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 6-5	0x3030	

6.2.1.117 ComponentVersionString - Srev Bytes 4-3 (0x0092)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 4-3	0x3030	

6.2.1.118 ComponentVersionString - Srev Bytes 2-1 (0x0093)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Srev Bytes 2-1	0x3030	

6.2.1.119 ComponentVersionString - Srev Byte 0 and Null (0x0094)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Null	0x0	
7:0	ComponentVersionString - Srev LSB	0x30	LSB of 8-byte SREV version (in ASCII).

6.2.1.120 ComponentClassification (0x0095)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentClassification	0xA	Valid values are: 0x0 = Unknown 0x1 = Other 0x2 = Driver 0x3 = Configuration Software 0x4 = Application Software 0x5 = Instrumentation 0x6 = Firmware/BIOS 0x7 = Diagnostic Software 0x8 = Operating System 0x9 = Middleware 0xA = Firmware 0xB = BIOS/FCode 0xC = Support/Service Pack 0xD = Software Bundle

6.2.1.121 ComponentIdentifier (0x0096)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentIdentifier	0x8	Valid values are: 0x1 = TLV Extension 0x2 = Link Topology Scratch Pad Area 0x3 = Descriptor Block 0x5 = OROM 0x6 = NVM 0x8 = Topology Netlist

6.2.1.122 ComponentComparisonStamp LSB (0x0097)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp Low	0x0	

6.2.1.123 ComponentComparisonStamp MSB (0x0098)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentComparisonStamp High	0x0	

6.2.1.124 ComponentOptions (0x0099)

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x0	Reserved.
1	Use Component Comparison Stamp	0b	0b = Disabled 1b = Enabled
0	Force Update	0b	0b = Disabled 1b = Enabled

6.2.1.125 RequestedComponentActivationMethod (0x009A)

Bit(s)	Field Name	Default NVM Value	Description
15:6	Reserved		Reserved.
5	AC Power Cycle	0b	0b = Disabled 1b = Enabled
4	DC Power Cycle	0b	0b = Disabled 1b = Enabled
3	System Reboot	1b	0b = Disabled 1b = Enabled
2	Medium-Specific Reset	0b	0b = Disabled 1b = Enabled
1	Self-Contained	0b	0b = Disabled 1b = Enabled
0	Automatic	0b	0b = Disabled 1b = Enabled

6.2.1.126 ComponentLocationOffset LSB (0x009B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.127 ComponentLocationOffset MSB (0x009C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentLocationOffset	0x0	

6.2.1.128 ComponentSize LSB (0x009D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize LSB	0x0	

6.2.1.129 ComponentSize MSB (0x009E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentSize MSB	0x0	

6.2.1.130 ComponentVersionStringTypeAndLength (0x009F)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionStringLength	0x2A	
7:0	ComponentVersionStringType	0x1	Valid values are: 0x0 = Unknown 0x1 = ASCII 0x2 = UTF-8 0x3 = UTF-16 0x4 = UTF-16LE 0x5 = UTF-16BE

6.2.1.131 ComponentVersionString- ReleaseVersion Major Bytes 7-6 (0x00A0)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Major Bytes 7-6	0x3030	

6.2.1.132 ComponentVersionString - ReleaseVersion Major Bytes 5-4 (0x00A1)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Major Bytes 5-4	0x3030	

6.2.1.133 ComponentVersionString - ReleaseVersion Major Bytes 3-2 (0x00A2)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Major Bytes 3-2	0x3030	

6.2.1.134 ComponentVersionString - ReleaseVersion Major Bytes 1-0 (0x00A3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Major Bytes 1-0	0x3030	

6.2.1.135 ComponentVersionString - Dot and ReleaseVersion Minor Byte 7 (0x00A4)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString -Dot and ReleaseVersion Minor Byte 7	0x30	
7:0	ComponentVersionString - Dot	0x2E	

6.2.1.136 ComponentVersionString - ReleaseVersion Minor Bytes 6-5 (0x00A5)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Minor Bytes 6-5	0x3030	

6.2.1.137 ComponentVersionString - ReleaseVersion Minor Bytes 4-3 (0x00A6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Minor Bytes 4-3	0x3030	

6.2.1.138 ComponentVersionString - ReleaseVersion Minor Bytes 2-1 (0x00A7)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Minor Bytes 2-1	0x3030	

6.2.1.139 ComponentVersionString - ReleaseVersion Minor Byte 0 and Dot (0x00A8)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Dot	0x2E	
7:0	ComponentVersionString -Dot and ReleaseVersion Minor Byte 0	0x30	

6.2.1.140 ComponentVersionString - ReleaseVersion Type Bytes 7-6 (0x00A9)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Type Bytes 7-6	0x3030	

6.2.1.141 ComponentVersionString - ReleaseVersion Type Bytes 5-4 (0x00AA)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Type Bytes 5-4	0x3030	

6.2.1.142 ComponentVersionString - ReleaseVersion Type Bytes 3-2 (0x00AB)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Type Bytes 3-2	0x3030	

6.2.1.143 ComponentVersionString - ReleaseVersion Type Bytes 0-1 (0x00AC)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - ReleaseVersion Type Bytes 0-1	0x3030	

6.2.1.144 ComponentVersionString - Dot and Customer Netlist IANA Byte 7 (0x00AD)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Customer Netlist IANA Byte 7	0x30	
7:0	ComponentVersionString - Dot	0x2E	

6.2.1.145 ComponentVersionString - Customer Netlist IANA Bytes 6-5 (0x00AE)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Customer Netlist IANA Byte 6-5	0x3030	

6.2.1.146 ComponentVersionString - Customer Netlist IANA Bytes 4-3 (0x00AF)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Customer Netlist IANA Byte 4-3	0x3030	

6.2.1.147 ComponentVersionString - Customer Netlist IANA Bytes 2-1 (0x00B0)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Customer Netlist IANA Byte 2-1	0x3030	

6.2.1.148 ComponentVersionString - Customer Netlist IANA Byte 0 and Dot (0x00B1)

Bit(s)	Field Name	Default NVM Value	Description
15:8	ComponentVersionString - Dot	0x2E	
7:0	ComponentVersionString - Customer Netlist IANA Byte 0	0x30	

6.2.1.149 ComponentVersionString - Customer Netlist Version Bytes 3-2 (0x00B2)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Customer Netlist Version Bytes 3-2	0x3030	

6.2.1.150 ComponentVersionString - Customer Netlist Version Bytes 1-0 (0x00B3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Customer Netlist Version Bytes 1-0	0x3030	

6.2.1.151 ComponentVersionString - Nulls (0x00B4)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentVersionString - Nulls	0x0	

6.2.1.152 PackageHeaderChecksum LSB (0x00B5)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageHeaderChecksum		CRC-32: Start Section -> Word: PLDM Header -> PackageHeaderIdentifier_0 End Section -> Word: PLDM Header -> ComponentVersionString

6.2.1.153 PackageHeaderChecksum MSB (0x00B6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PackageHeaderChecksum		

6.3 NVM Content

Caution: In the tables of this section, contents of the NVM Default Value column might not reflect the value programmed in the specific NVM image provided to the customer.

0x0062	Factory Settings Size	6.3.3.81
0x0063 + 1*n, n=0...156	Spare NVM Header Words	6.3.3.82

6.3.3.1 NVM Control Word 1 (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0x0	Reserved.
7:6	Bank Validity	01b	The *Bank Validity* (*Signature*) field indicates to the device that there is a valid NVM present. If it is not 01b, the other bits in this word are ignored, no further NVM read is performed, and the default values are used for the configuration space IDs. Valid values are: 00b = Value 0x0 01b = Shadow Ram Bank Valid 10b = Value 0x2 11b = Value 0x3
5	Valid NVM Bank Index	0b	First Bank is located at offset 128KB (pointed by 1st NVM bank pointer). Second Bank is located at 128K + NVM Bank Area Size * 4K. Valid values are: 0b = First Bank 1b = Second Bank
4	Valid TLV Extension Bank Index	0b	First Bank is located at offset 128KB (pointed by 1st NVM bank pointer). Second Bank is located at 128K + NVM Bank Area Size * 4K. Valid values are: 0b = First Bank 1b = Second Bank
3	Valid OROM Bank Index	0b	First Bank is located at offset 128KB (pointed by 1st NVM bank pointer). Second Bank is located at 128K + NVM Bank Area Size * 4K. Valid values are: 0b = First Bank 1b = Second Bank
2:0	Reserved	000b	Reserved.

6.3.3.2 Non-Persistent End Pointer (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units. Only the 4 KB sector unit is supported for this pointer.
14:0	Non-Persistent End Pointer	0x7FFF	Pointer to the end of the non-persistent Shadow RAM area

6.3.3.3 Last PFA Word Pointer (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units. Only the 4 KB sector unit is supported for this pointer.
14:0	Last PFA Word Pointer	0x0	Pointer to the end of the PFA excluding the PCI ALT module.

6.3.3.4 GFID Pointer (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	PCIR GFID Module Pointer	0x0	Points to GFID Module Section. For GFID Module inner structure, see Section 6.3.56.

6.3.3.5 Reserved (0x0004 - 0x0006)

6.3.3.6 Auto-Generated Pointers Pointer (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Auto-Generated Pointers Module Pointer	0x0	Points to Auto-Generated Pointers Module Section. For Auto-Generated Pointers Module inner structure, see Section 6.3.60.

6.3.3.7 Reserved (0x0008)

6.3.3.8 EMP Global Module Pointer (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	EMP Global Module Pointer	0x0	Points to EMP Global Module Section. For EMP Global Module inner structure, see Section 6.3.86.

6.3.3.9 Guarded Zone Pointer (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Guarded Zone Pointer	0x0	Points to Guarded Zone Section. For Guarded Zone inner structure, see Section 6.3.104.

6.3.3.10 EMP Image Pointer (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	EMP Image Pointer	0x7FFF	Points to EMP Image Section. For EMP Image inner structure, see Section 6.3.93.

6.3.3.11 Reserved (0x000C - 0x000D)

6.3.3.12 Manageability Module Pointer (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Manageabilty Configuration Module Pointer	0x0	Points to Manageability Module Header Section. For Manageability Module Header inner structure, see Section 6.3.57.

6.3.3.13 EMP Settings Module Pointer (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	EMP Module Pointer	0x0	Points to EMP Settings Module Header Section. For EMP Settings Module Header inner structure, see Section 6.3.87.

6.3.3.14 SW Compatibility Word 1 (0x0010)

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11	LOM	0b	Indicates whether the NVM attached to LAN silicon contains dedicated module for Option ROM. Used by Option ROM update applications. 0b = NIC (Attached flash contains module for Option ROM). 1b = LOM (Attached flash has no module for Option ROM).
10	Server	1b	Legacy – not currently used. 0b = Client 1b = Server
9	Reserved	0b	Reserved.

Bit(s)	Field Name	Default NVM Value	Description
8	OEM/Retail	0b	Legacy – not currently used. 0b = Retail 1b = OEM
7:0	Reserved	0x0	Reserved.

6.3.3.15 SW Compatibility Word 2 (0x0011)

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.16 SW Compatibility Word 3 (0x0012)

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.17 SW Compatibility Word 4 (0x0013)

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.18 SW Compatibility Word 5 (0x0014)

Five words in the NVM image are reserved for compatibility information. New bits within these fields are defined as the need arises for determining software compatibility between various hardware revisions.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.19 Reserved (0x0015 - 0x0017)

6.3.3.20 Software Reserved Word 1 - Dev Starter Version (0x0018)

Dev_Starter map version used to produce this image. This word must be filled manually. Used for upgrade/downgrade algorithm.

Bit(s)	Field Name	Default NVM Value	Description
15:12	Major	0x0	NVM major version - Customer set.
11:8	Decimal Point	0x0	Decimal point, used by automatic NVM reading tools. Must be always set to 0x0.
7:0	Minor	0x0	NVM minor version - Increased upon each release to customer.

6.3.3.21 Software Reserved Word 2 (0x0019)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0xFF	Reserved.
7	WoL Control Port 7	1b	Wake-on-LAN feature for Port 7. 0b = Supported and enabled. 1b = Disabled or not supported.
6	WoL Control Port 6	1b	Wake-on-LAN feature for Port 6. 0b = Supported and enabled. 1b = Disabled or not supported.
5	WoL Control Port 5	1b	Wake-on-LAN feature for Port 5. 0b = Supported and enabled. 1b = Disabled or not supported.
4	WoL Control Port 4	1b	Wake-on-LAN feature for Port 4. 0b = Supported and enabled. 1b = Disabled or not supported.
3	WoL Control Port 3	1b	Wake-on-LAN feature for Port 3. 0b = Supported and enabled. 1b = Disabled or not supported.
2	WoL Control Port 2	1b	Wake-on-LAN feature for Port 2. 0b = Supported and enabled. 1b = Disabled or not supported.
1	WoL Control Port 1	1b	Wake-on-LAN feature for Port 1. 0b = Supported and enabled. 1b = Disabled or not supported.
0	WoL Control Port 0	1b	Wake-on-LAN feature for Port 0. 0b = Supported and enabled. 1b = Disabled or not supported.

6.3.3.22 Software Reserved Word 3 (0x001A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.23 Software Reserved Word 4 - OEM Product Version Address Block Pointer (0x001B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	OEM Product Version Address Block Pointer	0x0	

6.3.3.24 Software Reserved Word 5 (0x001C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.25 Software Reserved Word 6 (0x001D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.26 Software Reserved Word 7 (0x001E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.27 Software Reserved Word 8 (0x001F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.28 Software Reserved Word 9 (0x0020)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.29 Software Reserved Word 10 (0x0021)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.30 Software Reserved Word 11 (0x0022)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.31 Software Reserved Word 12 (0x0023)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.32 Software Reserved Word 13 (0x0024)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.33 Software Reserved Word 14 (0x0025)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.34 Software Reserved Word 15 (0x0026)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.35 Software Reserved Word 16 (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.36 Software Reserved Word 17 (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.3.37 Software Reserved Word 18 - Map Version (0x0029)

Automatically generated by the tool.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Map Version		

6.3.3.38 Software Reserved Word 19 - NVM Image Version (0x002A)

Automatically generated by the tool.

Bit(s)	Field Name	Default NVM Value	Description
15:0	NVM Image Version		

6.3.3.39 Software Reserved Word 20 - NVM Structure Version (0x002B)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Major	0x0	NVM major version.
11:8	Decimal Point	0x0	Decimal point, used by automatic NVM reading tools. Must be always set to 0x0.
7:0	Minor	0x0	NVM Structure minor version.

6.3.3.40 Software Reserved Word 21 - FCoE Offload (0x002C)

This word is for Platform/NIC/LOM specific settings.

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x3FFF	Reserved.
1	FCoE Offload	1b	This bit indicates to software if the device supports FCoE Offload. 0b = FCoE Offload Enabled. 1b = FCoE Offload Disabled.
0	Reserved	1b	Reserved.

6.3.3.41 Software Reserved Word 22 - EETRACK ID 1 (0x002D)

This word is for the first word of the eTrack_ID number written by EEPROM Manager Tool.

Bit(s)	Field Name	Default NVM Value	Description
15:0	eTrack_ID Word 1	0xFFFF	EEPROM Manager Tool writes a unique 32-bit *eTrack_ID* number in two sequential NVM words. The *eTrack_ID* is written when EEPROM Manager Tool creates an image on the Intel network. The *eTrack_ID* DB tracks NVM images back to a specific SCM build.

6.3.3.42 Software Reserved Word 23 - EETRACK ID 2 (0x002E)

This word is for the second word of the eTrack_ID number written by EEPROM Manager Tool.

Bit(s)	Field Name	Default NVM Value	Description
15:0	eTrack_ID Word 2		

6.3.3.43 Reserved (0x002F - 0x0033)

6.3.3.44 Software Reserved Word 24 - Original EETRACK ID 1 (0x0034)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Original EETRACK ID 1	0x0	

6.3.3.45 Software Reserved Word 25 - Original EETRACK ID 2 (0x0035)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Original EETRACK ID 2	0x0	

6.3.3.46 Reserved (0x0036 - 0x003A)

6.3.3.47 GLOBR Registers Auto-Load Pointer (0x003B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	GLOBR Registers Auto-Load Module Pointer	0x7FFF	Points to GLOBR Registers Auto-Load Module Section. For GLOBR Registers Auto-Load Module inner structure, see Section 6.3.50.

6.3.3.48 CORER Registers Auto-Load Pointer (0x003C)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	CORER Registers Auto-Load Module Pointer	0x7FFF	Points to CORER Registers Auto-Load Module Section. For CORER Registers Auto-Load Module inner structure, see Section 6.3.49.

6.3.3.49 PHY Configuration Scripts (DNL) Pointer (0x003D)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	DNL Pointer	0x7FFF	Points to DL Scripts Section. For DL Scripts inner structure, see Section 6.3.88.

6.3.3.50 Reserved (0x003E - 0x003F)

6.3.3.51 Preserved Field Area Pointer (0x0040)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	PFA Pointer	0x7FFF	Points to PFA Header Section. For PFA Header inner structure, see Section 6.3.4.

6.3.3.52 HLP SR Module Pointer (0x0041)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	HLP Module Pointer	0x0	

6.3.3.53 1st NVM Bank Pointer (0x0042)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st NVM Bank Pointer	0x7FFF	

6.3.3.54 NVM Bank Area Size (0x0043)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	NVM Bank Area Size	0x41A	Size expressed in 4 KB sector units.

6.3.3.55 1st OROM Bank Pointer (0x0044)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st OROM Bank Pointer	0x0	Pointer to first OROM section (not swapped when section changes) ***Note:*** This value is fixed to 4224 KB - need to be manually changed if location of section changes. Points to OROM Section. For OROM inner structure, see Section 6.3.96.

6.3.3.56 OROM Bank Area Size (0x0045)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	OROM Bank Area Size	0x7D	Size expressed in 4 KB sector units.

6.3.3.57 1st TLV Extension Bank Pointer (0x0046)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st TLV Extension Bank Pointer	0x0	Pointer to first TLV extension section (not swapped when section changes) ***Note:*** This value is fixed to 4224 KB - need to be manually changed if location of section changes. Points to Link Topology Netlist Section. For Link Topology Netlist inner structure, see Section 6.3.98.

6.3.3.58 TLV Extension Bank Area Size (0x0047)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	TLV Extension Bank Area Size	0x7	Size expressed in 4 KB sector units.

6.3.3.59 EMP SR Settings Pointer (0x0048)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	EMP SR Settings Pointer	07FFF	Points to EMP SR Settings Module Header Section. For EMP SR Settings Module Header inner structure, see Section 6.3.53.

6.3.3.60 Reserved (0x0049)

6.3.3.61 PE CORER Registers Auto-Load Pointer (0x004A)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	PE CORER Config Pointer	07FFF	Points to PE CORER Registers Section. For PE CORER Registers inner structure, see Section 6.3.51.

6.3.3.62 Link Topology Scratch Pad Area Pointer (0x004B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Link Topology Scratch Pad Area Pointer	07FFF	Points to Link Topology Scratch Pad Area Section. For Link Topology Scratch Pad Area inner structure, see Section 6.3.100.

6.3.3.63 Link Topology Scratch Pad Area Size (0x004C)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	Link Topology Scratch Pad Area Size	0x5	Size expressed in 4 KB sector units.

6.3.3.64 Configuration Metadata Pointer (0x004D)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Configuration Metadata Pointer	07FFF	Points to Configuration Metadata Section. For Configuration Metadata inner structure, see Section 6.3.91.

6.3.3.65 Reserved (0x004E - 0x004F)

6.3.3.66 FW Scratch Pad Area Pointer (0x0050)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	FW Scratch Pad Area Pointer	07FFF	Points to FW Scratch Pad Area Section. For FW Scratch Pad Area inner structure, see Section 6.3.101.

6.3.3.67 FW Scratch Pad Area Size (0x0051)

Bit(s)	Field Name	Default NVM Value	Description
15:10	Reserved	0x0	Reserved.
9:0	FW Scratch Pad Area Size	0x40	Size expressed in 4 KB sector units.

6.3.3.68 Reserved (0x0052 - 0x0053)

6.3.3.69 Analog PHY Configuration Module Pointer (0x0054)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Internal PHY Configuration Module Pointer	07FFF	Points to Analog PHY Configuration Section. For Analog PHY Configuration inner structure, see Section 6.3.90.

6.3.3.70 Soft SKUs (0x0055)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0x0	Reserved.

6.3.3.71 Extended CORER Registers Auto-Load Pointer (0x0056)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Extended CORER Registers Auto-Load Module Pointer	07FFF	Points to Ext. CORER Registers Auto-Load Module Section. For Ext. CORER Registers Auto-Load Module inner structure, see Section 6.3.85.

6.3.3.72 Recovery Firmware Pointer (0x0057)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Recovery Firmware Pointer	0x0	Pointer to Recovery Firmware section.

6.3.3.73 Control Pipe Package Pointer (0x0058)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Control Pipe Package Pointer	07FFF	Points to Control Pipe Package Section. For Control Pipe Package inner structure, see Section 6.3.92.

6.3.3.74 Reserved (0x0059 - 0x005A)

6.3.3.75 DCB Rx Module Pointer (0x005B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	DCB Rx Module Pointer	07FFF	Points to DCB Rx Module Section. For DCB Rx Module inner structure, see Section 6.3.83.

6.3.3.76 DCB Tx Module Pointer (0x005C)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	DCB Tx Module Pointer	07FFF	Points to DCB Tx Module Section. For DCB Tx Module inner structure, see Section 6.3.84.

6.3.3.77 Whitelist Pointer (0x005D)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	White List Pointer	07FFF	Points to White list Section. For White list inner structure, see Section 6.3.89.

6.3.3.78 Sideband Auto-Load Pointer (0x005E)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	0b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Sideband Auto-Load Pointer	07FFF	Points to Sideband Bus Auto-Load Section. For Sideband Bus Auto-Load inner structure, see Section 6.3.52.

6.3.3.79 RDE Dictionaries Pointer (0x005F)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type	1b	Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	RDE Dictionaries Pointer	07FFF	Points to RDE Dictionaries Section. For RDE Dictionaries inner structure, see Section 6.3.94.

6.3.3.80 Reserved (0x0060 - 0061)

6.3.3.81 Factory Settings Size (0x0062)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	Factory Settings Size	0xD	Size expressed in 4 KB sector units.

6.3.3.82 Spare NVM Header Words[n] (0x0063 + 1*n, n=0...156)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0xFFFF	Reserved.

6.3.4 PFA Header Section

Preserved fields area header.

Table 6-10. PFA Header Section Summary Table

Word Offset	Description	Section Reference
0x0000	PFA Length	6.3.4.1

6.3.4.1 PFA Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFA Length	0x2F00	

6.3.5 PFA Features Module Section

Table 6-11. PFA Features Module Section Summary Table

Word Offset	Description	Section Reference
0x0101	Sub Module Type - Features	6.3.5.1

6.3.5.1 Sub Module Type - Features (0x0101)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x49	Valid values are: 0x49 = Feature Configuration

6.3.6 Feature Configuration Padding Module Section

Table 6-12. Feature Configuration Padding Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - Padding	6.3.6.1
0x0001	Length	6.3.6.2
0x0002	Padding	6.3.6.3

6.3.6.1 Sub Module Type - Padding (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0xFFFF	Valid values are: 0xFFFF = Padding Module

6.3.6.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Feature Configuration Padding Module -> Sub Module Type Padding Last Section -> Word: Feature Configuration Padding Module -> Padding

6.3.6.3 Padding (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	[New Field]		

6.3.7 PFA Immediate Values Module Section

Table 6-13. PFA Immediate Values Module Section Summary Table

Word Offset	Description	Section Reference
0x0901	Sub Module Type - Immediate	6.3.7.1

6.3.7.1 Sub Module Type - Immediate (0x0901)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x4E	Valid values are: 0x4E = Immediate Configuration

6.3.8 Immediate Fields Padding Module Section

Table 6-14. Immediate Fields Padding Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type Padding	6.3.8.1
0x0001	Length	6.3.8.2
0x0002	Padding	6.3.8.3

6.3.8.1 Sub Module Type Padding (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0xFFFF	Valid values are: 0xFFFF = Padding Module

6.3.8.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Immediate Fields Padding Module -> Sub Module Type Padding Last Section -> Word: Immediate Fields Padding Module -> Padding

6.3.8.3 Padding (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	[New Field]	0xFFFF	

6.3.9 PFA VPD Module Section

VPD area. Vital product data loaded by OEM. It contains RO and RW info about the NIC/LOM.

Table 6-15. PFA VPD Module Section Summary Table

Word Offset	Description	Section Reference
0x0F01	Sub Module Type - VPD	6.3.9.1
0x0F02	Length	6.3.9.2
0x0F03	VPD Data	6.3.9.3

6.3.9.1 Sub Module Type - VPD (0x0F01)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x2F	Valid values are: 0x2F = VPD Module

6.3.9.2 Length (0x0F02)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: PFA VPD Module -> Sub Module Type - VPD Last Section -> Word: PFA VPD Module -> VPD Data

6.3.9.3 VPD Data (0x0F03)

Raw data module length: 512 words

6.3.10 PFA MNG Filter Section

Table 6-16. PFA MNG Filter Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - MNG Filter	6.3.10.1
0x0001	Section Length	6.3.10.2
0x0002	Flexible Filter Data	6.3.10.3

6.3.10.1 Sub Module Type - MNG Filter (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x107	Valid values are: 0x107 = MNG Filters

6.3.10.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: PFA MNG Filter -> Section Length Last Section -> Word: PFA MNG Filter -> Flexible Filter Data

6.3.10.3 Flexible Filter Data (0x0002)

Raw data module length: variable

6.3.11 PFA PT Configuration 0 Section

Pass-through filters of Port 0 PFA section header.

Table 6-17. PFA PT Configuration 0 Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type PT Module 0	6.3.11.1

6.3.11.1 Sub Module Type PT Module 0 (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x108	Valid values are: 0x108 = Pass-Through Control Words Structure 0

6.3.11.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: PFA PT Configuration 0 -> Section Length Last Section -> Word: PFA PT Configuration 0 -> Manageability Special Modifiers MSB

6.3.11.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:8	IPv4 Address, Byte 1	0xFF	
7:0	IPv4 Address, Byte 0	0xFF	

6.3.11.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:8	IPv4 Address, Byte 3	0xFF	
7:0	IPv4 Address, Byte 4	0xFF	

6.3.11.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:0	LAN UDP Flexible Filter Port0	0xFFFF	

6.3.11.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:3	Reserved		Reserved.
2	Source Destination	0b	0b = Destination 1b = Source
1	Accept TCP	0b	If set, filter match if packet is TCP. 0b = Filter 1b = Accept
0	Accept UDP	0b	If set, filter match if packet is UDP. 0b = Filter 1b = Accept

6.3.11.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	VLAN Filter 0 Value	0xFFF	

6.3.11.8 LAN MANC Value LSB (0x0032)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0x0	Reserved.

6.3.11.9 LAN MANC Value MSB (0x0033)

Bit(s)	Field Name	Default NVM Value	Description
15:11	Reserved	0x0	Reserved.
10	NET_TYPE	0b	
9	FIXED_NET_TYPE	0b	
8	Reserved	0b	Reserved.
7	EN_XSUM_FILTER	0b	Should be used to set the RBCR.*EN_XSUM_FILTERn* bit, where *n* is the port number).
6:0	Reserved	0x0	Reserved.

6.3.11.10 Receive Enable 1 - LRXEN1 (0x0034)

Bit(s)	Field Name	Default NVM Value	Description
15:9	Receive Enable Byte 12	0x0	BMC SMBus slave address.
8	Reserved	0b	Reserved.
7	Enable BMC Dedicated	0b	When set, the BMC will receive traffic sent to the MAC Address defined in MMAH/MMAL[3]. The Firmware configures MDEF, MDEF_EXT (7) to dedicated MAC configured into MMAL/H (3) to implement this mode.
6	Reserved	1b	Reserved.
5:4	Notification Method	00b	This field is valid only in the section of port 0 and defines the notification method for all ports. Valid values are: 0x0 = SMBus Alert 0x1 = Asynchronous Notify 0x2 = Direct Receive 0x3 = Reserved
3	Enable ARP Response	0b	When set, the firmware offloads ARP handling sent to the IP Address defined in ARP Response IPv4 Address NVM words. The Firmware uses MDEF, MDEF_EXT (6) and MIPAF4[3] to implement this mode.
2	Enable Status Reporting	0b	
1	Enable Receive All	0b	
0	Enable Receive TCO	0b	

6.3.11.11 Receive Enable 2 - LRXEN2 (0x0035)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Receive Enable Byte 14	0x0	Alert value.
7:0	Receive Enable Byte 13	0x0	Interface data.

6.3.11.12 LAN MNGONLY LSB (0x0036)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0x0	Reserved.
7:0	Exclusive to MNG	0x0	

6.3.11.13 LAN MNGONLY MSB (0x0037)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Reserved	0x0	Reserved.

6.3.11.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MDEF0_L	0x0	

6.3.11.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MDEF0_M	0x0	

6.3.11.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MDEFEXT0_L	0x0	

6.3.11.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MDEFEXT0_M	0x0	

6.3.11.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	METF0_L	0x0	Loaded to 16 LS bits of METF[0] register.

6.3.11.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	METF0_M	0x0	Loaded to 16 MS bits of METF[0] register (reserved bits in the METF registers should be set in the NVM to the register default values).

6.3.11.20 ARP Response IPv4 Address LSB (0x005C)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	Firmware use.
7:0	Byte 0	0x0	Firmware use.

6.3.11.21 ARP Response IPv4 Address MSB (0x005D)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	Firmware use.
7:0	Byte 0	0x0	Firmware use.

6.3.11.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 0-1	0x0	

6.3.11.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 2-3	0x0	

6.3.11.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 4-5	0x0	

6.3.11.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 6-7	0x0	

6.3.11.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 8-9	0x0	

6.3.11.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 10-11	0x0	

6.3.11.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 12-13	0x0	

6.3.11.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	IPv6 Address Bytes 14-15	0x0	

6.3.11.30 Manageability Special Modifiers LSB (0x007E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MSFM_L	0x000F	

6.3.11.31 Manageability Special Modifiers MSB (0x007F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MSFM_M	0x0	

6.3.12 PFA PT Configuration 1 Section

Pass-through filters of Port 1 PFA section header.

Table 6-18. PFA PT Configuration 1 Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type PT Module 1	6.3.12.1

6.3.12.1 Sub Module Type PT Module 1 (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x109	Valid values are: 0x109 = Pass-Through Control Words Structure 1

6.3.12.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.12.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.12.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.12.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.12.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.12.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.12.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.12.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.12.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.12.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.12.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.12.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.12.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.12.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.12.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.12.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.12.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.12.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.12.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.12.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.12.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.12.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.12.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.12.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.12.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.12.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.12.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.12.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.12.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.12.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.13 PFA PT Configuration 2 Section

Pass-through filters of Port 2 PFA section header.

Table 6-19. PFA PT Configuration 2 Section Summary Table

Word Offset	Description	Section Reference

6.3.13.1 Sub Module Type PT Module 2 (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x10A	Valid values are: 0x10A = Pass-Through Control Words Structure 2

6.3.13.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.13.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.13.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.13.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.13.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.13.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.13.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.13.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.13.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.13.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.13.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.13.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.13.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.13.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.13.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.13.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.13.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.13.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.13.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.13.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.13.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.13.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.13.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.13.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.13.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.13.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.13.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.13.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.13.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.13.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.14 PFA PT Configuration 3 Section

Pass-through filters of Port 3 PFA section header.

Table 6-20. PFA PT Configuration 3 Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type PT Module 3	6.3.14.1

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x10B	Valid values are: 0x10B = Pass-Through Control Words Structure 3

6.3.14.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.14.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.14.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.14.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.14.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.14.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.14.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.14.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.14.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.14.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.14.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.14.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.14.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.14.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.14.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.14.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.14.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.14.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.14.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.14.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.14.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.14.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.14.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.14.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.14.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.14.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.14.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.14.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.14.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.14.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.15 PFA PT Configuration 4 Section

Pass-through filters of Port 4 PFA section header.

Table 6-21. PFA PT Configuration 4 Section Summary Table

Word Offset	Description	Section Reference

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x114	Valid values are: 0x114 = Pass-through Control Word Structure 4

6.3.15.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.15.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.15.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.15.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.15.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.15.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.15.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.15.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.15.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.15.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.15.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.15.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.15.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.15.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.15.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.15.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.15.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.15.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.15.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.15.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.15.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.15.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.15.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.15.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.15.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.15.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.15.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.15.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.15.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.15.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.16 PFA PT Configuration 5 Section

Pass-through filters of Port 5 PFA section header.

Table 6-22. PFA PT Configuration 5 Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type PT Module 5	6.3.16.1

15:0	Sub Module Type	0x115	Valid values are: 0x115 = Pass-through Control Word Structure 5

6.3.16.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.16.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.16.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.16.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.16.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.16.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.16.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.16.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.16.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.16.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.16.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.16.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.16.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.16.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.16.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.16.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.16.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.16.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.16.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.16.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.16.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.16.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.16.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.16.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.16.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.16.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.16.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.16.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.16.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.16.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.17 PFA PT Configuration 6 Section

Pass-through filters of Port 6 PFA section header.

Table 6-23. PFA PT Configuration 6 Section Summary Table

6.3.18.1 Sub Module Type PT Module 7 (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x117	Valid values are: 0x117 = Pass-through Control Word Structure 7

6.3.18.2 Section Length (0x0001)

The length of the section in words. Note that section length does not include a count for the section length word.

For inner structure, see Section 6.3.11.2.

6.3.18.3 LAN IPv4 Address (LSB) MIPAF0[n] (0x0002 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.3.

6.3.18.4 LAN IPv4 Address (MSB) MIPAF0[n] (0x0003 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.4.

6.3.18.5 LAN Flexible Filter Port[n] (0x000A + 2*n, n=0...15)

For inner structure, see Section 6.3.11.5.

6.3.18.6 LAN Flexible Filter Port - Modifiers[n] (0x000B + 2*n, n=0...15)

For inner structure, see Section 6.3.11.6.

6.3.18.7 LAN VLAN Filter[n] (0x002A + 1*n, n=0...7)

For inner structure, see Section 6.3.11.7.

6.3.18.8 LAN MANC Value LSB (0x0032)

For inner structure, see Section 6.3.11.8.

6.3.18.9 LAN MANC Value MSB (0x0033)

For inner structure, see Section 6.3.11.9.

6.3.18.10 Receive Enable 1 - LRXEN1 (0x0034)

For inner structure, see Section 6.3.11.10.

6.3.18.11 Receive Enable 2 - LRXEN2 (0x0035)

For inner structure, see Section 6.3.11.11.

6.3.18.12 LAN MNGONLY LSB (0x0036)

For inner structure, see Section 6.3.11.12.

6.3.18.13 LAN MNGONLY MSB (0x0037)

For inner structure, see Section 6.3.11.13.

6.3.18.14 Manageability Decision Filters LSB[n] (0x0038 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.14.

6.3.18.15 Manageability Decision Filters MSB[n] (0x0039 + 4*n, n=0...6)

For inner structure, see Section 6.3.11.15.

6.3.18.16 Manageability Extended Decision Filters LSB[n] (0x003A + 4*n, n=0...6)

For inner structure, see Section 6.3.11.16.

6.3.18.17 Manageability Extended Decision Filters MSB[n] (0x003B + 4*n, n=0...6)

For inner structure, see Section 6.3.11.17.

6.3.18.18 Manageability EtherType Filter (METF) LSB[n] (0x0054 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.18.

6.3.18.19 Manageability EtherType Filter (METF) MSB[n] (0x0055 + 2*n, n=0...3)

For inner structure, see Section 6.3.11.19.

6.3.18.20 ARP Response IPv4 Address LSB (0x005C)

For inner structure, see Section 6.3.11.20.

6.3.18.21 ARP Response IPv4 Address MSB (0x005D)

For inner structure, see Section 6.3.11.21.

6.3.18.22 IPv6 Address Bytes 0-1[n] (0x005E + 8*n, n=0...3)

For inner structure, see Section 6.3.11.22.

6.3.18.23 IPv6 Address Bytes 2-3[n] (0x005F + 8*n, n=0...3)

For inner structure, see Section 6.3.11.23.

6.3.18.24 IPv6 Address Bytes 4-5[n] (0x0060 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.24.

6.3.18.25 IPv6 Address Bytes 6-7[n] (0x0061 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.25.

6.3.18.26 IPv6 Address Bytes 8-9[n] (0x0062 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.26.

6.3.18.27 IPv6 Address Bytes 10-11[n] (0x0063 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.27.

6.3.18.28 IPv6 Address Bytes 12-13[n] (0x0064 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.28.

6.3.18.29 IPv6 Address Bytes 14-15[n] (0x0065 + 8*n, n=0...3)

For inner structure, see Section 6.3.11.29.

6.3.18.30 Manageability Special Modifiers LSB (0x007E)

For inner structure, see Section 6.3.11.30.

6.3.18.31 Manageability Special Modifiers MSB (0x007F)

For inner structure, see Section 6.3.11.31.

6.3.19 Original EETrack ID Section

Original EETrack ID PFA section.

Table 6-25. Original EETrack ID Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - Original EETrackID	6.3.19.1
0x0001	Length	6.3.19.2
0x0002	Original EETrackID MSB	6.3.19.3
0x0003	Original EETrackID LSB	6.3.19.4

6.3.19.1 Sub Module Type - Original EETrackID (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x10C	Valid values are: 0x10C = Original EETrack ID

6.3.19.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Original EETrack ID -> Sub Module Type - Original EETrackID Last Section -> Word: Original EETrack ID -> Original EETrackID LSB

6.3.19.3 Original EETrackID MSB (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	EETrackID - MSB	0x0	

6.3.19.4 Original EETrackID LSB (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	EETrackID - MLB	0x0	

6.3.20 IBA Capabilities Module Section

Table 6-26. IBA Capabilities Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - IBA Capabilities	6.3.20.1
0x0001	Length	6.3.20.2
0x0002	IBA Capabilities	6.3.20.3

6.3.20.1 Sub Module Type - IBA Capabilities (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x33	Valid values are: 0x33 = IBA Capabilities

6.3.20.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: IBA capabilities Module -> Sub Module Type - IBA Capabilities Last Section -> Word: IBA capabilities Module -> IBA Capabilities

6.3.20.3 IBA Capabilities (0x0002)

This word of the NVM is used to enumerate the boot technologies that have been programmed into the Flash. This is updated by Flash configuration tools and is not updated or read by IBA.

Bit(s)	Field Name	Default NVM Value	Description
15:14	Signature	01b	Signature Must be set to 01b to indicate that this word has been programmed by the agent or other configuration software.
13:6	Reserved	0x0	Reserved. Must be 0.
5	Reserved	0b	FCoE boot code is present if set to 1b. 0b = Not Present 1b = Present
4	iSCSI Boot	0b	iSCSI is present if set to 1b. 0b = Not Present 1b = Present
3	EFI EBD Driver	0b	EFI UNDI driver is present if set to 1b. 0b = Not Present 1b = Present
2	RPL	0b	RPL module is present if set to 1b. Reserved bit for devices. 0b = Not Present 1b = Present

Bit(s)	Field Name	Default NVM Value	Description
1	PXE/UNDI Driver	1b	PXE UNDI driver is present if set to 1b. 0b = Not Present 1b = Present
0	PXE Base Code	1b	PXE Base Code is present if set to 1b. 0b = Not Present 1b = Present

6.3.21 PXE Setup Options Module Section

Table 6-27. PXE Setup Options Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - PXE Setup	6.3.21.1
0x0001	Length	6.3.21.2
0x0002 + 1*n, n=0...7	Setup Options PCI Function	6.3.21.3

6.3.21.1 Sub Module Type - PXE Setup (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x30	Valid values are: 0x30 = PXE Setup Options

6.3.21.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: PXE Setup Options Module -> Sub Module Type - PXE Setup Last Section -> Word: PXE Setup Options Module -> Setup Options PCI Function

6.3.21.3 Setup Options PCI Function[n] (0x0002 + 1*n, n=0...7)

The main setup options for PF n are stored in this word. These options are those that can be changed by the user using the Control-S setup menu.

Bit(s)	Field Name	Default NVM Value	Description
15:13	Reserved	0x0	Reserved. Must be 0x0.
12:10	FSD	000b	Bits 12-10 control forcing speed and duplex during driver operation. 000b = Auto-negotiate 001b = 10 Mb/s half duplex 010b = 100 Mb/s half duplex 011b = Not valid (treated as 000b) 100b = 10 Mb/s full duplex 101b = 100 Mb/s full duplex 111b = 1000 Mb/s full duplex. Only applicable for copper-based adapters. Not applicable to 10 GbE. Default value is 000b.
9	Reserved	0b	Reserved to legacy OS Wakeup Support (for 82559-based adapters only), which is not supported in the E810.
8	DSM	1b	Display Setup Message If the bit is set to 1b, the Press Control-S message is displayed after the title message. Default value is 1b.
7:6	PT	0b	Prompt Time These bits control how long the Press Control-S setup prompt message is displayed, if enabled by DIM. 00b = 2 seconds (default) 01b = 3 seconds 10b = 5 seconds 11b = 0 seconds ***Note:*** The Ctrl-S message is not displayed if 0 seconds prompt time is selected.
5	iSCSI Boot Disabled	0b	When this bit is set and adapter port is neither iSCSI primary nor secondary, setup code must not be loaded. Otherwise iSCSI banner and Setup menu should be accessible as in current design. 0b = Enabled 1b = Disabled This bit must be changed at factory level and not be altered by any end-customer tools. For regular NIC and LOM design, this bit should be always cleared in the NVM image. Otherwise, iSCSI setup will not be accessible for the user.
4:3	DBS	00b	Default Boot Selection These bits select which device is the default boot device. These bits are only used if the agent detects that the BIOS does not support boot order selection or if the MODE field of word 31h is set to MODE_LEGACY. 00b = Network boot, then local boot (default) 01b = Local boot, then network boot 10b = Network boot only 11b = Local boot only
2:0	PS	000b	Protocol Select These bits select the active boot protocol. 000b = PXE (default value) 001b = RPL (only if RPL is in the Flash) 010b = iSCSI Boot primary port (only if iSCSI Boot is using this adapter) 011b = iSCSI Boot secondary port (only if iSCSI Boot is using this adapter). 100b = FCoE All other values are reserved. Only the default value of 000b should be initially programmed into the adapter. Other values should only be set by configuration utilities.

6.3.22 PXE Configuration Customization Options Module Section

Table 6-28. PXE Configuration Customization Options Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - PXE Configuration Customization Options	6.3.22.1
0x0001	Length	6.3.22.2
0x0002 + 1*n, n=0...7	Configuration Customization Options PCI Function	6.3.22.3

6.3.22.1 Sub Module Type - PXE Configuration Customization Options (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x31	Valid values are: 0x31 = PXE Configuration Customization Options

6.3.22.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: PXE Configuration Customization Options Module -> Sub Module Type - PXE Configuration Customization Options Last Section -> Word: PXE Configuration Customization Options Module -> Configuration Customization Options PCI Function

6.3.22.3 Configuration Customization Options PCI Function[n] (0x0002 + 1*n, n=0...7)

It contains settings that can be programmed by an OEM or network administrator to customize the operation of the software. These settings cannot be changed from within the Control-S setup menu. The lower byte contains settings that would typically be configured by a network administrator using an external utility; these settings generally control which setup menu options are changeable. The upper byte is generally settings that would be used by an OEM to control the operation of the agent in a LOM environment, although there is nothing in the agent to prevent their use on a NIC implementation. The default value for this word is 0x4000.

Bit(s)	Field Name	Default NVM Value	Description
15:14	Signature	01b	Signature Must be set to 01b to indicate that this word has been programmed by the agent or other configuration software.
13:12	Reserved	00b	Reserved. Must be 0b.

Bit(s)	Field Name	Default NVM Value	Description
11	Continuous Retry	0b	Selects Continuous Retry operation. If this bit is set, IBA does NOT transfer control back to the BIOS if it fails to boot due to a network error (such as failure to receive DHCP replies). Instead, it restarts the PXE boot process again. If this bit is set, the only way to cancel PXE boot is for the user to press ESC on the keyboard. Retry is not attempted due to hardware conditions such as an invalid NVM checksum or failing to establish link. 0b = Disable (default) 1b = Enable
10:8	Operating mode	000b	Selects the agent's boot order setup mode. This field changes the agent default behavior in order to make it compatible with systems that do not completely support the BBS and PnP Expansion ROM standards. Valid values and their meanings are: 000b = Normal behavior. The agent attempts to detect BBS and PnP Expansion ROM support as it normally does. 001b = Force legacy mode. The agent does not attempt to detect BBS or PnP Expansion ROM supports in the BIOS and assumes the BIOS is not compliant. The user can change the BIOS boot order in the Setup Menu. 010b = Force BBS mode. The agent assumes the BIOS is BBS compliant, even though it might not be detected as such by the agent's detection code. The user CANNOT change the BIOS boot order in the Setup Menu. 011b = Force PnP Int18 mode. The agent assumes the BIOS allows boot order setup for PnP Expansion ROMs and hooks interrupt 0x18 (to inform the BIOS that the agent is a bootable device) in addition to registering as a BBS IPL device. The user CANNOT change the BIOS boot order in the Setup Menu. 100b = Force PnP Int19 mode. The agent assumes the BIOS allows boot order setup for PnP Expansion ROMs and hook interrupt 0x19 (to inform the BIOS that the agent is a bootable device) in addition to registering as a BBS IPL device. The user CANNOT change the BIOS boot order in the Setup Menu. 101b = Reserved for future use. If specified, is treated as a value of 000b. 110b = Reserved for future use. If specified, is treated as a value of 000b. 111b = Reserved for future use. If specified, is treated as a value of 000b.
7:6	Reserved	00b	Reserved. Must be 00b
5	Disable Flash Update	0b	Disable Flash Update If this bit is set to 1b, the user is not allowed to update the flash image using PROSet. 0b = Enable Flash Update (default) 1b = Disable Flash Update
4	Disable Legacy OS Wakeup Menu	0b	Disable Legacy Wakeup Support If this bit is set to 1b, the user is not allowed to change the Legacy OS Wakeup Support menu option. 0b = Enable Legacy Wakeup Support (default) 1b = Disable Legacy Wakeup Support Default value is 0b.
3	Disable Boot Selection Menu	0b	Disable Boot Selection If this bit is set to 1b, the user is not allowed to change the boot order menu option. 0b = Enable (default) 1b = Disable
2	Disable Protocol Selection Menu	0b	Disable Protocol Select If set to 1b, the user is not allowed to change the boot protocol. 0b = Enable (default) 1b = Disable

Bit(s)	Field Name	Default NVM Value	Description
1	Disable Title Message Display	0b	Disable Title Message If this bit is set to 1b, the title message displaying the version of the Boot Agent is suppressed; the Control-S message is also suppressed. This is for OEMs who do not wish the boot agent to display any messages at system boot. 0b = Enable (default) 1b = Disable
0	Setup Menu	0b	Disable Setup Menu If this bit is set to 1b, the user is not allowed to invoke the setup menu by pressing Control-S. In this case, the NVM can only be changed via an external program. 0b = Enable (default) 1b = Disable

6.3.23 PXE Version Module Section

Table 6-29. PXE Version Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - PXE Version	6.3.23.1
0x0001	Length	6.3.23.2
0x0002	PXE Version	6.3.23.3

6.3.23.1 Sub Module Type - PXE Version (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x32	Valid values are: 0x32 = PXE version

6.3.23.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: PXE version Module -> Sub Module Type - PXE version Last Section -> Word: PXE version Module -> PXE Version

6.3.23.3 PXE Version (0x0002)

Word 0x32 of the NVM is used to store the version of the boot agent that is stored in the Flash image. When the Boot Agent loads, it can check this value to determine if any first-time configuration needs to be performed. The agent then updates this word with its version. Some diagnostic tools to report the version of the Boot Agent in the Flash also read this word.

Bit(s)	Field Name	Default NVM Value	Description
15:12	Major Version	0x0	PXE Boot Agent Major Version. Default value is 0.
11:8	Minor Version	0x0	PXE Boot Agent Minor Version. Default value is 0.
7:0	Build Number	0x0	PXE Boot Agent Build Number. Default value is 0.

6.3.24 VLAN Module Section

Table 6-30. VLAN Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - VLAN	6.3.24.1
0x0001	Length	6.3.24.2
0x0002	VLAN Block Signature	6.3.24.3
0x0003	Structure Version and Size	6.3.24.4
0x0004	Port 0 VLAN Tag	6.3.24.5
0x0005	Port 1 VLAN Tag	6.3.24.6
0x0006	Port 2 VLAN Tag	6.3.24.7
0x0007	Port 3 VLAN Tag	6.3.24.8
0x0008	Port 4 VLAN Tag	6.3.24.9
0x0009	Port 5 VLAN Tag	6.3.24.10
0x000A	Port 6 VLAN Tag	6.3.24.11
0x000B	Port 7 VLAN Tag	6.3.24.12

6.3.24.1 Sub Module Type - VLAN (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x37	Valid values are: 0x37 = VLAN Configuration

6.3.24.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: VLAN Module -> Sub Module Type - VLAN Last Section -> Word: VLAN Module -> Port 7 VLAN Tag

6.3.24.3 VLAN Block Signature (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VLAN Block Signature	0x4C56	'V'=0x56, 'L' = 0x4C

6.3.24.4 Structure Version and Size (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Structure Version and Size	0x0C	Total byte size of the configuration block. 0x06 = 1-port adapter 0x08 = 2-port adapter 0x0C = 4-port adapter (default)
7:0	Structure Version	0x01	The version of this structure. Should be set to 0x01.

6.3.24.5 Port 0 VLAN Tag (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:13	VLAN Priority	0x0	The value of VLAN priority (0-7).
12	Reserved	0b	This field is reserved and must be set to 0x0.
11:0	VLAN Tag ID	0x0	The value of VLAN ID (1-4095). 0 means no VLAN configured for port.

6.3.24.6 Port 1 VLAN Tag (0x0005)

For inner structure, see Section 6.3.24.5.

6.3.24.7 Port 2 VLAN Tag (0x0006)

For inner structure, see Section 6.3.24.5.

6.3.24.8 Port 3 VLAN Tag (0x0007)

For inner structure, see Section 6.3.24.5.

6.3.24.9 Port 4 VLAN Tag (0x0008)

For inner structure, see Section 6.3.24.5.

6.3.24.10 Port 5 VLAN Tag (0x0009)

For inner structure, see Section 6.3.24.5.

6.3.24.11 Port 6 VLAN Tag (0x000A)

For inner structure, see Section 6.3.24.5.

6.3.24.12 Port 7 VLAN Tag (0x000B)

For inner structure, see Section 6.3.24.5.

6.3.25 Boot Configuration Block Section

Table 6-31. Boot Configuration Block Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type	6.3.25.1
0x0001	Length	6.3.25.2
0x0002	Combo Image Version High	6.3.25.3
0x0003	Combo Image Version Low	6.3.25.4

6.3.25.1 Sub Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x132	Valid values are: 0x132 = CIVD

6.3.25.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Boot Configuration Block -> Sub Module Type Last Section -> Word: Boot Configuration Block -> Combo Image Version Low

6.3.25.3 Combo Image Version High (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Major	0x0	
7:0	Build	0x0	

6.3.25.4 Combo Image Version Low (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Build	0x0	
7:0	Patch	0x0	

6.3.26 PBA Header Section

Table 6-32. PBA Header Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - PBA	6.3.26.1
0x0001	Length	6.3.26.2

6.3.26.1 Sub Module Type - PBA (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x16	Valid values are: 0x16 = PBA block

6.3.26.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit First Section -> Word: PBA Block -> PBA Section Length Last Section -> Word: PBA Block -> Word5

6.3.27 PBA Block Section

The PBA block contains the complete PBA number, including the dash and the first digit of the 3-digit suffix.

Table 6-33. PBA Block Section Summary Table

Word Offset	Description	Section Reference
0x0000	PBA Section Length	6.3.27.1
0x0001	Word1	6.3.27.2
0x0002	Word2	6.3.27.3
0x0003	Word3	6.3.27.4
0x0004	Word4	6.3.27.5
0x0005	Word5	6.3.27.6

6.3.27.1 PBA Section Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PBA Section Length Field	0x6	Length in words of the PBA Block.

6.3.27.2 Word1 (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Word1 Field		PBA Number stored in hexadecimal ASCII values.

6.3.27.3 Word2 (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Word2 Field		PBA Number stored in hexadecimal ASCII values.

6.3.27.4 Word3 (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Word3 Field		PBA Number stored in hexadecimal ASCII values.

6.3.27.5 Word4 (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Word4 Field		PBA Number stored in hexadecimal ASCII values.

6.3.27.6 Word5 (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Word5 Field		PBA Number stored in hexadecimal ASCII values.

6.3.28 PCIR Registers PFA Auto-Load Module Section

Table 6-34. PCIR Registers PFA Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	PCIR Registers Auto-Load Type	6.3.28.1
0x0001	Module Length	6.3.28.2
0x0002 - 0x0014	NVM contents for PFINT_ALLOC_PCI	6.3.28.3
0x0015 - 0x0027	NVM contents for PFPCI_SUBSYSID	6.3.28.4
0x0028 - 0x003A	NVM contents for PF_VT_PFALLOC_HIF	6.3.28.5
0x003B - 0x004D	NVM contents for PFPCI_DEVID	6.3.28.6
0x004E - 0x0052	NVM contents for GLPCI_CAPCTRL	6.3.28.7
0x0053 - 0x0054	NVM contents for GLPCI_CAPSUP	6.3.28.8
0x0055 - 0x0056	NVM contents for GLPCI_LINKCAP	6.3.28.9
0x0057 - 0x005A	NVM contents for GLPCI_VENDORID	6.3.28.10
0x005B - 0x005E	NVM contents for GLPCI_SUBVENID	6.3.28.11
0x005F - 0x0071	NVM contents for PFPCI_CNF	6.3.28.12
0x0072 - 0x0075	Reserved	6.3.28.13
0x0075 - 0x0088	NVM contents for PF_VT_PFALLOC_PCIE	6.3.28.14

6.3.28.1 PCIR Registers Auto-Load Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x113	Valid values are: 0x113 = PCIR Registers Auto-load

6.3.28.2 Module Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 2 First Section -> Word: PCIR Registers PFA Auto-Load Module -> PCIR Registers Auto-Load Type Last Section -> Word: PCIR Registers PFA Auto-Load Module -> Starting Address Low at PF_VT_PFALLOC_PCIE, for PF[0]

6.3.28.3 PFINT_ALLOC_PCI (0x0002 - 0x0014)

6.3.28.3.1 Starting Address Low at PFINT_ALLOC_PCI (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFINT_ALLOC_PCI, for PF[0]	0x9D800	
3:0	Type	0x2	

6.3.28.3.2 Starting Address High at PFINT_ALLOC_PCI (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFINT_ALLOC_PCI, for PF[0]		

6.3.28.3.3 Attributes at PFINT_ALLOC_PCI (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.3.4 Data Low of PFINT_ALLOC_PCI[PF] (0x0005 + 2*PF, PF=0...7)

6.3.28.3.5 Data High of PFINT_ALLOC_PCI[PF] (0x0006 + 2*PF, PF=0...7)

6.3.28.4 PFPCI_SUBSYSID (0x0015 - 0x0027)

6.3.28.4.1 Starting Address Low at PFPCI_SUBSYSID (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPCI_SUBSYSID, for PF[0]	0x9D880	
3:0	Type	0x2	

6.3.28.4.2 Starting Address High at PFPCI_SUBSYSID (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPCI_SUBSYSID, for PF[0]		

6.3.28.4.3 Attributes at PFPCI_FUNC2[PF] (0x0017)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.4.4 Data Low of PFPCI_SUBSYSID[PF] (0x0018 + 2*PF, PF=0...7)

6.3.28.4.5 Data High of PFPCI_SUBSYSID[PF] (0x0019 + 2*PF, PF=0...7)

6.3.28.5 PF_VT_PFALLOC_HIF (0x0028 - 0x003A)

6.3.28.5.1 Starting Address Low at PF_VT_PFALLOC_HIF (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PF_VT_PFALLOC_HIF, for PF[0]	0x9DD80	
3:0	Type	0x2	

6.3.28.5.2 Starting Address High at PF_VT_PFALLOC_HIF (0x0029)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PF_VT_PFALLOC_HIF, for PF[0]		

6.3.28.5.3 Attributes at PF_VT_PFALLOC_HIF (0x002A)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.5.4 Data Low of PF_VT_PFALLOC_HIF[PF] (0x002B + 2*PF, PF=0...7)

6.3.28.5.5 Data High of PF_VT_PFALLOC_HIF[PF] (0x002C + 2*PF, PF=0...7)

6.3.28.6 PFPCI_DEVID (0x003B - 0x004D)

6.3.28.6.1 Starting Address Low at PFPCI_DEVID (0x003B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPCI_DEVID, for PF[0]	0x9DE00	
3:0	Type	0x2	

6.3.28.6.2 Starting Address High at PFPCI_DEVID (0x003C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPCI_DEVID, for PF[0]		

6.3.28.6.3 Attributes at PFPCI_DEVID (0x003D)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.6.4 Data Low of PFPCI_DEVID[PF] (0x003E + 2*PF, PF=0...7)

6.3.28.6.5 Data High of PFPCI_DEVID[PF] (0x003F + 2*PF, PF=0...7)

6.3.28.7 GLPCI_CAPCTRL (0x004E - 0x0052)

6.3.28.7.1 Starting Address Low at GLPCI_CAPCTRL (0x004E)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_CAPCTRL	0x9DE88	
3:0	Type	0X2	

6.3.28.7.2 Starting Address High at GLPCI_CAPCTRL (0x004F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_CAPCTRL		

6.3.28.7.3 Attributes at GLPCI_CAPCTRL (0x0050)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.7.4 Data Low of GLPCI_CAPCTRL (0x0051)

6.3.28.7.5 Data High of GLPCI_CAPCTRL (0x0052)

6.3.28.8 GLPCI_CAPSUP (0x0053 - 0x0054)

6.3.28.8.1 Data Low of GLPCI_CAPSUP (0x0053)

6.3.28.8.2 Data High of GLPCI_CAPSUP (0x0054)

6.3.28.9 GLPCI_LINKCAP (0x0055 - 0x0056)

6.3.28.9.1 Data Low of GLPCI_LINKCAP (0x0055)

6.3.28.9.2 Data High of GLPCI_LINKCAP (0x0056)

6.3.28.10 GLPCI_VENDORID (0x0057 - 0x005A)

6.3.28.10.1 Address Low at GLPCI_VENDORID (0x0057)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_VENDORID	0x9DEC8	
3:0	Type	0x1	

6.3.28.10.2 Address High at GLPCI_VENDORID (0x0058)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_VENDORID		

6.3.28.10.3 Data Low of GLPCI_VENDORID (0x0059)

6.3.28.10.4 Data High of GLPCI_VENDORID (0x005A)

6.3.28.11 GLPCI_SUBVENID (0x005B - 0x005E)

6.3.28.11.1 Address Low at GLPCI_SUBVENID (0x005B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_SUBVENID	0x9DEE8	
3:0	Type	0x1	

6.3.28.11.2 Address High at GLPCI_SUBVENID (0x005C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_SUBVENID		

6.3.28.11.3 Data Low of GLPCI_SUBVENID (0x005D)

6.3.28.11.4 Data High of GLPCI_SUBVENID (0x005E)

6.3.28.12 PFPCI_CNF (0x005F - 0x0071)

6.3.28.12.1 Starting Address Low at PFPCI_CNF (0x005F)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPCI_CNF, for PF[0]	0x9DF00	
3:0	Type	0x2	

6.3.28.12.2 Starting Address High at PFPCI_CNF (0x0060)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPCI_CNF, for PF[0]		

6.3.28.12.3 Attributes at PFPCI_CNF (0x0061)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.12.4 Data Low of PFPCI_CNF[PF] (0x0062 + 2*PF, PF=0...7)

6.3.28.12.5 Data High of PFPCI_CNF[PF] (0x0063 + 2*PF, PF=0...7)

6.3.28.13 Reserved (0x0072 - 0x0075)

6.3.28.14 PF_VT_PFALLOC_PCIE (0x0076 - 0x0088)

6.3.28.14.1 Starting Address Low at PF_VT_PFALLOC_PCIE (0x0076)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PF_VT_PFALLOC_PCIE, for PF[0]	0xBE080	
3:0	Type	0x2	

6.3.28.14.2 Starting Address High at PF_VT_PFALLOC_PCIE (0x0077)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PF_VT_PFALLOC_PCIE, for PF[0]		

6.3.28.14.3 Attributes at PF_VT_PFALLOC_PCIE (0x0078)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.28.14.4 Data Low of PF_VT_PFALLOC_PCIE[PF] (0x0079 + 2*PF, PF=0...7)

6.3.28.14.5 Data High of PF_VT_PFALLOC_PCIE[PF] (0x007A + 2*PF, PF=0...7)

6.3.29 POR Registers PFA Auto-Load Module Section

Register addresses and values loaded at Power-On Reset (POR).

Table 6-35. POR Registers PFA Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	POR Registers Auto-Load Type	6.3.29.1
0x0001	Module Length	6.3.29.2
0x0002 - 0x0012	NVM contents for GLGEN_GPIO_CTL	6.3.29.3
0x0013 - 0x0025	NVM contents for PFPCI_FUNC	6.3.29.4
0x0026 - 0x0038	NVM contents for PFPM_WUC	6.3.29.5
0x0039 - 0x003C	NVM contents for GLPCI_LBARCTRL	6.3.29.6
0x003D - 0x0040	NVM contents for GLPCI_CNF	6.3.29.7
0x0041 - 0x0044	NVM contents for GL_MNG_HWARB_CTRL	6.3.29.8
0x0045 - 0x0057	Reserved	6.3.29.9
0x0058 - 0x006A	NVM contents for PFPM_APM	6.3.29.10
0x006B - 0x007D	NVM contents for PRTGEN_CNF	6.3.29.11
0x007E - 0x008D	Reserved	6.3.29.12
0x008E - 0x009D	NVM contents for PRTGEN_CNF2	6.3.29.13
0x009E - 0x00A8	Reserved	6.3.29.14
0x00A9 - 0x00AC	NVM contents for GL_PWR_MODE_CTL	6.3.29.15

6.3.29.1 POR Registers Auto-Load Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x118	Valid values are: 0x118 =POR Registers Auto-load

6.3.29.2 Module Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 2 First Section -> Word: POR Registers PFA Auto-Load Module -> POR Registers Auto-Load Type Last Section -> Word: POR Registers PFA Auto-Load Module -> Address Low at GL_PWR_MODE_CTL

6.3.29.3 GLGEN_GPIO_CTL (0x0002 - 0x0012)

6.3.29.3.1 Starting Address Low at GLGEN_GPIO_CTL (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLGEN_GPIO_CTL	0x880C8	
3:0	Type	0x2	

6.3.29.3.2 Starting Address High at GLGEN_GPIO_CTL (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLGEN_GPIO_CTL		

6.3.29.3.3 Attributes at GLGEN_GPIO_CTL (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x7	
4:3	Skip	00b	
2:0	Width	000b	

6.3.29.3.4 Data Low of GLGEN_GPIO_CTL[n] (0x0005 + 2*n, n=0...6)

6.3.29.3.5 Data High of GLGEN_GPIO_CTL[n] (0x0006 + 2*n, n=0...6)

6.3.29.4 PFPCI_FUNC (0x0013 - 0x0025)

6.3.29.4.1 Starting Address Low at PFPCI_FUNC (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPCI_FUNC, for PF[0]	0x9D980	
3:0	Type	0x2	

6.3.29.4.2 Starting Address High at PFPCI_FUNC (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPCI_FUNC, for PF[0]		

6.3.29.4.3 Attributes at PFPCI_FUNC (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.29.4.4 Data Low of PFPCI_FUNC[PF] (0x0016 + 2*PF, PF=0...7)

6.3.29.4.5 Data High of PFPCI_FUNC[PF] (0x0017 + 2*PF, PF=0...7)

6.3.29.5 PFPM_WUC (0x0026 - 0x0038)

6.3.29.5.1 Starting Address Low at PFPM_WUC 0x0026)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPM_WUC, for PF[0]	0x9DC80	
3:0	Type	0x2	

6.3.29.5.2 Starting Address High at PFPM_WUC (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPM_WUC, for PF[0]		

6.3.29.5.3 Attributes at PFPM_WUC - 0x0028

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.29.5.4 Data Low of PFPM_WUC[PF] (0x0029 + 2*PF, PF=0...7)

6.3.29.5.5 Data High of PFPM_WUC[PF] (0x002A + 2*PF, PF=0...7)

6.3.29.6 GLPCI_LBARCTRL (0x0039 - 0x003C)

6.3.29.6.1 Address Low at GLPCI_LBARCTRL (0x0039)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_LBARCTRL	0x9DE74	
3:0	Type	0x1	

6.3.29.6.2 Address High at GLPCI_LBARCTRL (0x003A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_LBARCTRL		

6.3.29.6.3 Data Low of GLPCI_LBARCTRL (0x003B)

6.3.29.6.4 Data High of GLPCI_LBARCTRL (0x003C)

6.3.29.7 GLPCI_CNF (0x003D - 0x0040)

6.3.29.7.1 Address Low at GLPCI_CNF (0x003D)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_CNF	0x9DEA0	
3:0	Type	0x1	

6.3.29.7.2 Address High at GLPCI_CNF (0x003E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_CNF		

6.3.29.7.3 Data Low of GLPCI_CNF (0x003F)

6.3.29.7.4 Data High of GLPCI_CNF (0x0040)

6.3.29.8 GL_MNG_HWARB_CTRL (0x0041 - 0x0044)

6.3.29.8.1 Address Low at GL_MNG_HWARB_CTRL (0x0041)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_MNG_HWARB_CTRL	0xB6130	
3:0	Type	0x1	

6.3.29.8.2 Address High at GL_MNG_HWARB_CTRL (0x0042)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_MNG_HWARB_CTRL		

6.3.29.8.3 Data Low of GL_MNG_HWARB_CTRL (0x0043)

6.3.29.8.4 Data High of GL_MNG_HWARB_CTRL (0x0044)

6.3.29.9 Reserved (0x0045 - 0x0057)

6.3.29.10 PFPM_APM (0x0058 - 0x006A)

6.3.29.10.1 Starting Address Low at PFPM_APM (0x0058)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFPM_APM, for PF[0]	0xB8080	
3:0	Type	0x2	

6.3.29.10.2 Starting Address High at PFPM_APM (0x0059)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFPM_APM, for PF[0]		

6.3.29.10.3 Attributes at PFPM_APM (0x005A)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.29.10.4 Data Low of PFPM_APM[PF] (0x005B + 2*PF, PF=0...7)

6.3.29.10.5 Data High of PFPM_APM[PF] (0x005C + 2*PF, PF=0...7)

6.3.29.11 PRTGEN_CNF (0x006B - 0x007D)

6.3.29.11.1 Starting Address Low at PRTGEN_CNF (0x006B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PRTGEN_CNF, for PRT[0]	0xB8120	
3:0	Type	0x2	

6.3.29.11.2 Starting Address High at PRTGEN_CNF (0x006C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PRTGEN_CNF, for PRT[0]		

6.3.29.11.3 Attributes at PRTGEN_CNF (0x006D)

Bit(s)	Field Name	Default NVM Value	Description

4:3	Skip	00b	
2:0	Width	000b	

6.3.29.11.4 Data Low of PRTGEN_CNF[PRT] (0x006E + 2*PRT, PRT=0...7)

6.3.29.11.5 Data High of PRTGEN_CNF[PRT] (0x006F + 2*PRT, PRT=0...7)

6.3.29.12 Reserved (0x007E - 0x008D)

6.3.29.13 PRTGEN_CNF2 (0x008E - 0x009D)

6.3.29.13.1 Data Low of PRTGEN_CNF2[PRT] (0x008E + 2*PRT, PRT=0...7)

6.3.29.13.2 Data High of PRTGEN_CNF2[PRT] (0x008F + 2*PRT, PRT=0...7)

6.3.29.14 Reserved (0x009E - 0x00A8)

6.3.29.15 GL_PWR_MODE_CTL (0x00A9 - 0x00AC)

6.3.29.15.1 Address Low at GL_PWR_MODE_CTL (0x00A9)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_PWR_MODE_CTL	0xB820C	
3:0	Type	0x1	

6.3.29.15.2 Address High at GL_PWR_MODE_CTL (0x00AA)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_PWR_MODE_CTL		

6.3.29.15.3 Data Low of GL_PWR_MODE_CTL (0x00AB)

6.3.29.15.4 Data High of GL_PWR_MODE_CTL (0x00AC)

6.3.30 PSM Preserved Section

Tx-Scheduler parameters.

Table 6-36. PSM Preserved Section Summary Table

Word Offset	Description	Section Reference
0x0000	PSM Preserved Type	6.3.30.1
0x0001	PSM Preserved Length	6.3.30.2
0x0002	Logical Layer Config	6.3.30.3
0x0003 + 1*n, n=0...8	Logical Layer Structure	6.3.30.4
0x000C	Max_RDMA_Qsets	6.3.30.5
0x000D + 4*n, n=0...7	Logical L2/L3 CIR/EIR	6.3.30.6
0x000E + 4*n, n=0...7	Logical L4/L5 CIR/EIR	6.3.30.7
0x000F + 4*n, n=0...7	Logical L6/L7 CIR/EIR	6.3.30.8
0x0010 + 4*n, n=0...7	Logical L8/L9 CIR/EIR	6.3.30.9
0x002D + 1*n, n=0...7	Node Allocation per Layer	6.3.30.10

6.3.30.1 PSM Preserved Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x119	Valid values are: 0x119 = PSM preserved

6.3.30.2 PSM Preserved Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: PSM preserved -> PSM Preserved Type Last Section -> Word: PSM preserved -> Node Allocation per Layer Section length in words.

6.3.30.3 Logical Layer Config (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:14	Reserved	00b	Reserved.
13	L8_L9_SRL	0b	Selects if SRL is used in Physical L8 vs. Physical L9. 0b = L8 1b = L9
12	L6_L7_SRL	0b	Selects if SRL is used in Physical L6 vs. Physical L7. 0b = L6 1b = L7

Bit(s)	Field Name	Default NVM Value	Description
11	L4_L5_SRL	0b	Selects if SRL is used in Physical L4 vs. Physical L5. 0b = L4 1b = L5
10	L2_L3_SRL	0b	Selects if SRL is used in Physical L2 vs. Physical L3. 0b = L2 1b = L3
9	MFP	0b	0b = False 1b = True
8	DCB	1b	0b = False 1b = True
7:4	Number of Logical Layers	0x9	Including port, DCB, MFP and leaf layers.
3:0	Number of Physical Layers	0x9	Device dependent.

6.3.30.4 Logical Layer Structure[n] (0x0003 + 1*n, n=0...8)

Nine structures, one for each logical layer.

Bit(s)	Field Name	Default NVM Value	Description
15:13	Allocation Chunk Size	001b	Valid values are: 000b = N/A 001b = 2 011b = 4 111b = 8
12:0	Maximum Number of Nodes in the Logical Layer	0x8	2 - 4096 depends on the Layer ID and flattening setting based on Logical to Physical layer association.

6.3.30.5 Max_RDMA_Qsets (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:10	Reserved	0x0	Reserved.
9:0	Max_RDMA_Qsets_Index	0x1FF	Max index of RDMA QSets.

6.3.30.6 Logical L2/L3 CIR/EIR[n] (0x000D + 4*n, n=0...7)

Allocation to PF of dedicated L2/L3 Rate Limiter profiles.

Bit(s)	Field Name	Default NVM Value	Description
15:8	L3 CIR/EIR	0x1	L3 EIR/CIR RL profiles.
7:0	L2 CIR/EIR	0x1	L2 EIR/CIR RL profiles.

6.3.30.7 Logical L4/L5 CIR/EIR[n] (0x000E + 4*n, n=0...7)

Allocation to PF of dedicated L4/L5 Rate Limiter profiles.

Bit(s)	Field Name	Default NVM Value	Description
15:8	L5 CIR/EIR	0x2	L5 EIR/CIR RL profiles.
7:0	L4 CIR/EIR	0x1	L4 EIR/CIR RL profiles.

6.3.30.8 Logical L6/L7 CIR/EIR[n] (0x000F + 4*n, n=0...7)

Allocation to PF of dedicated L6/L7 Rate Limiter profiles.

Bit(s)	Field Name	Default NVM Value	Description
15:8	L7 CIR/EIR	0x8	L7 EIR/CIR RL profiles. ***Note:*** Max dedicated profiles is 255 out of 256.
7:0	L6 CIR/EIR	0x4	L6 EIR/CIR RL profiles.

6.3.30.9 Logical L8/L9 CIR/EIR[n] (0x0010 + 4*n, n=0...7)

Allocation to PF of dedicated L8/L9 Rate Limiter profiles.

Bit(s)	Field Name	Default NVM Value	Description
15:8	L9 CIR/EIR	0x20	L9 EIR/CIR RL profiles. ***Note:*** Max dedicated profiles is 255 out of 1024.
7:0	L8 CIR/EIR	0x10	L8 EIR/CIR RL profiles. ***Note:*** Max dedicated profiles is 255 out of 512.

6.3.30.10 Node Allocation per Layer[n] (0x002D + 1*n, n=0...7)

Allocation of nodes for each PF. Allocation is uniform to all PFs.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Node Allocation for Layer n	0x1	Number of nodes of Layer n allocated to each valid PF.

6.3.31 MinSrev Section

Table 6-37. MinSrev Section Summary Table

Word Offset	Description	Section Reference
0x0000	MinSrev Module Type	6.3.31.1
0x0001	Length	6.3.31.2
0x0002	Validity	6.3.31.3
0x0003	NVM MinSrev LSB	6.3.31.4
0x0004	NVM MinSrev MSB	6.3.31.5
0x0005	OROM MinSrev LSB	6.3.31.6
0x0006	OROM MinSrev MSB	6.3.31.7

6.3.31.1 MinSrev Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x130	Valid values are: 0x130 = MinSrev Module

6.3.31.2 Length (0x0001)

Length of section.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: MinSrev -> MinSrev Module Type Last Section -> Word: MinSrev -> OROM MinSrev MSB Section length in words

6.3.31.3 Validity (0x0002)

Validity of MinSrev words.

Bit(s)	Field Name	Default NVM Value	Description
15:2	Reserved	0x0	Reserved.
1	OROM	0b	OROM MinSrev valid.
0	NVM	0b	NVM MinSrev valid.

6.3.31.4 NVM MinSrev LSB (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MinSrev LSB	0x0	NVM MinSrev

6.3.31.5 NVM MinSrev MSB (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MinSrev MSB	0x0	NVM MinSrev

6.3.31.6 OROM MinSrev LSB (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MinSrev LSB	0x0	OROM MinSrev

6.3.31.7 OROM MinSrev MSB (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MinSrev MSB	0x0	OROM MinSrev

6.3.32 PF MAC Address Section

PF/Port MAC Address PFA section.

Table 6-38. PF MAC Address Section Summary Table

Word Offset	Description	Section Reference
0x0000	PCI Serial ID MAC Address Module Type	6.3.32.1
0x0001	Length	6.3.32.2
0x0002	GLPCI_SERL0	6.3.32.3
0x0003	GLPCI_SERL1	6.3.32.4
0x0004	GLPCI_SERH0	6.3.32.5
0x0005	GLPCI_SERH1	6.3.32.6
0x0006	PF MAC Address Module Type	6.3.32.7
0x0007	Section Header	6.3.32.8
0x0008 + 4*n, n=0...7	PFPM_SAL0	6.3.32.9
0x0009 + 4*n, n=0...7	PFPM_SAL1	6.3.32.10
0x000A + 4*n, n=0...7	PFPM_SAH0	6.3.32.11
0x000B + 4*n, n=0...7	PFPM_SAH1	6.3.32.12

6.3.32.1 PCI Serial ID MAC Address Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x133	Valid values are: 0x133 = PCI Serial id MAC Addresses Module

6.3.32.2 Length (0x0001)

Length of MAC Address section.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: PF MAC Address -> PCI Serial Id MAC Address Module Type Last Section -> Word: PF MAC Address -> PFPM_SAH1

6.3.32.3 GLPCI_SERL0 (0x0002)

This word is loaded by firmware to GLPCI_SERL 0:15

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAL0	0x0	See respective bits in the GLPCI_SERL register.

6.3.32.4 GLPCI_SERL1 (0x00023)

This word is loaded by firmware to GLPCI_SERL 16:31.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAL1	0x0	See respective bits in the GLPCI_SERL register.

6.3.32.5 GLPCI_SERH0 (0x0004)

This word is loaded by firmware to GLPCI_SERH 0:15.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAH0	0x0	See respective bits in the GLPCI_SERH register.

6.3.32.6 GLPCI_SERH1 (0x0005)

This word is loaded by firmware to GLPCI_SERH 16:31.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAH1	0x0	See respective bits in the GLPCI_SERH register.

6.3.32.7 PF MAC Address Module Type (0x0006)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x10F	Valid values are: 0x10F = PF MAC Addresses Module

6.3.32.8 Section Header (0x0007)

Length of MAC Address section.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: PF MAC Address -> PF MAC Address Module Type Last Section -> Word: PF MAC Address -> PFPM_SAH1 Section length in words.

6.3.32.9 PFPM_SAL0[n] (0x0008 + 4*n, n=0...7)

This word is loaded by firmware to the appropriate PRTPM_SAL register, bytes [1,0]. One MAC Address per enabled PF/port. This is a per-device, per-enabled-PF value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAL0	0x0	See respective bits in the PRTPM_SAL register.

6.3.32.10 PFPM_SAL1[n] (0x0009 + 4*n, n=0...7)

This register is loaded by firmware to the appropriate PRTPM_SAL register, bytes [3:2]. One MAC Address per enabled PF. This is a per-device, per-enabled-PF value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAL1	0x0	See respective bits in the PRTPM_SAL register.

6.3.32.11 PFPM_SAH0[n] (0x000A + 4*n, n=0...7)

This register is loaded by firmware to the appropriate PRTPM_SAH register, bytes [1,0]. One MAC Address per enabled PF/port. This is a per-device, per-enabled-PF value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAH0	0x0	See respective bits in the PRTPM_SAH register.

6.3.32.12 PFPM_SAH1[n] (0x000B + 4*n, n=0...7)

This register is loaded by firmware to the appropriate PRTPM_SAH register, bytes [3:2]. One MAC Address per enabled PF/port. This is a per-device, per-enabled-PF value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	PFPM_SAH1	0x0	See respective bits in the PRTPM_SAH register.

6.3.33 MNG MAC Address Section

Manageability MAC Address PFA section.

Table 6-39. MNG MAC Address Section Summary Table

Word Offset	Description	Section Reference
0x0000	MNG MAC Address Module Type	6.3.33.1
0x0001	Section Header - Length	6.3.33.2
0x0002 + 3*n, n=0...31	LAN Ethernet MAC Address (LSB) MMAL	6.3.33.3
0x0003 + 3*n, n=0...31	LAN Ethernet MAC Address (Mid) MMAL	6.3.33.4
0x0004 + 3*n, n=0...31	LAN Ethernet MAC Address (MSB) MMAH	6.3.33.5

6.3.33.1 MNG MAC Address Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x110	Valid values are: 0x110 = MNG MAC Addresses Module

6.3.33.2 Section Header - Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: MNG MAC Address -> MNG MAC Address Module Type Last Section -> Word: MNG MAC Address -> LAN Ethernet MAC Address (MSB) MMAH Section length in words.

6.3.33.3 LAN Ethernet MAC Address (LSB) MMAL[n] (0x0002 + 3*n, n=0...31)

This word is loaded by the firmware to the 16 LS bits of the MMAL[0-3] register of Port n. The index equals 4*Port#+ MAC#. It is used as the MAC Address when dedicated MAC Address mode is used in legacy SMBus. This is a per-device, per-port value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Ethernet MAC Address, Byte 1	0xFF	
7:0	Ethernet MAC Address, Byte 0	0xFF	

6.3.33.4 LAN Ethernet MAC Address (Mid) MMAL[n] (0x0003 + 3*n, n=0...31)

This word is loaded by the firmware to the 16 MS bits of the MMAL[0-3] register of Port n. The index equals 4*Port#+ MAC#. It is used as the MAC Address when dedicated MAC Address mode is used in legacy SMBus. This is a per-device, per-port value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Ethernet MAC Address, Byte 3	0xFF	
7:0	Ethernet MAC Address, Byte 2	0xFF	

6.3.33.5 LAN Ethernet MAC Address (MSB) MMAH[n] (0x0004 + 3*n, n=0...31)

This word is loaded by the firmware to the MMAH register of Port n. The index equals 4*Port#+ MAC#. It is used as the MAC Address when dedicated MAC Address mode is used in legacy SMBus. This is a per-device, per-port value allocated by manufacturing.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Ethernet MAC Address, Byte 5	0xFF	
7:0	Ethernet MAC Address, Byte 4	0xFF	

6.3.34 FW Logging Defaults Section

UART debug defaults.

Table 6-40. FW Logging Defaults Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type	6.3.34.1
0x0001	Section Length	6.3.34.2
0x0002	UART Control	6.3.34.3
0x0003	Module Logging Enable [n=0]	6.3.34.4
0x0004	Module Logging Enable [n=1]	6.3.34.5
0x0005	Module Logging Enable [n=2]	6.3.34.6
0x0006	Module Logging Enable [n=3]	6.3.34.7
0x0007	Module Logging Enable [n=4]	6.3.34.8
0x0008	Module Logging Enable [n=5]	6.3.34.9
0x0009	Module Logging Enable [n=6]	6.3.34.10
0x000A	Module Logging Enable [n=7]	6.3.34.11

6.3.34.1 Sub Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x11D	Valid values are: 0x11D = UART Debug

6.3.34.2 Section Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 2 First Section -> Word: FW Logging Defaults -> Sub Module Type Last Section -> Word: FW Logging Defaults -> Module Logging Enable [n=7] Section length in words.

6.3.34.3 UART Control (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	UART Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.4 Module Logging Enable [n=0] (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.5 Module Logging Enable [n=1] (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled

Bit(s)	Field Name	Default NVM Value	Description
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.6 Module Logging Enable [n=2] (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled

Bit(s)	Field Name	Default NVM Value	Description
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.7 Module Logging Enable [n=3] (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.8 Module Logging Enable [n=4] (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.9 Module Logging Enable [n=5] (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled

Bit(s)	Field Name	Default NVM Value	Description
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.10 Module Logging Enable [n=6] (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled

Bit(s)	Field Name	Default NVM Value	Description
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
1	Module 4n+0 Init Logging Enable	0b	0b = Disabled 1b = Enabled
0	Module 4n+0 Info Logging Enable	0b	0b = Disabled 1b = Enabled

6.3.34.11 Module Logging Enable [n=7] (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15	Module 4n+3 Error Logging Enable	0b	0b = Disabled 1b = Enabled
14	Module 4n+3 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
13	Module 4n+3 Init Logging Enable	0b	0b = Disabled 1b = Enabled
12	Module 4n+3 Info Logging Enable	0b	0b = Disabled 1b = Enabled
11	Module 4n+2 Error Logging Enable	0b	0b = Disabled 1b = Enabled
10	Module 4n+2 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
9	Module 4n+2 Init Logging Enable	0b	0b = Disabled 1b = Enabled
8	Module 4n+2 Info Logging Enable	0b	0b = Disabled 1b = Enabled
7	Module 4n+1 Error Logging Enable	0b	0b = Disabled 1b = Enabled
6	Module 4n+1 Flow Logging Enable	0b	0b = Disabled 1b = Enabled
5	Module 4n+1 Init Logging Enable	0b	0b = Disabled 1b = Enabled
4	Module 4n+1 Info Logging Enable	0b	0b = Disabled 1b = Enabled
3	Module 4n+0 Error Logging Enable	0b	0b = Disabled 1b = Enabled
2	Module 4n+0 Flow Logging Enable	0b	0b = Disabled 1b = Enabled

7:6	P11	00b	Port 11 same list as Port 8.
5:4	P10	00b	Port 10 same list as Port 8.
3:2	P9	00b	Port 9 same list as Port 8.

Bit(s)	Field Name	Default NVM Value	Description
1:0	P8	00b	Port 8. 00b = Disabled 01b = Reserved 10b = Timer 0 11b = Timer 1

6.3.35.6 1588 Functionality Enablement 16-19 (0x0005)

1588 functionality enablement per port.

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0x0	Reserved.
7:6	P19	00b	Port 19 same list as Port 16.
5:4	P18	00b	Port 18 same list as Port 16.
3:2	P17	00b	Port 17 same list as Port 16.
1:0	P16	00b	Port 16. 00b = Disabled 01b = Reserved 10b = Timer 0 11b = Timer 1

6.3.36 MD Link Topology Section

This is the Ethernet Link topology description of the motherboard. Link topology is described in Section 3.3.

Table 6-42. MD Link Topology Section Summary Table

Word Offset	Description	Section Reference
0x0000	FW MNG Link Topology Module Type	6.3.36.1
0x0001	FW MNG Link Topology Module Length	6.3.36.2
0x0002	Generic Info	6.3.36.3
0x0003	Netlist Version	6.3.36.4
0x0004 + 1*n, n=0...15	Pair PHY Type	6.3.36.5
0x0014	Port Bitmap 0	6.3.36.6
0x0015	Port Bitmap 1	6.3.36.7

6.3.36.1 FW MNG Link Topology Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x120	Valid values are: 0x120 = FW MNG Link Topology

6.3.36.2 FW MNG Link Topology Module Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: MD Link Topology -> FW MNG Link Topology Module Type Last Section -> Word: MD Link Topology -> Port Bitmap 1 Section length in words.

6.3.36.3 Generic Info (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Netlist Map Version	0x1	The version of the Netlist field definition.
7:1	Reserved	0x0	Reserved.

Bit(s)	Field Name	Default NVM Value	Description
0	Load Mode	1b	Netlist Loading Mode 0b = Normal Mode 1b = Resolution Mode Controls the steps taken at netlist load time. Valid only for the motherboard's netlist. There are two modes: • **Normal Mode** — The active Port Options are loaded. • **Resolution Mode** — The active Port Options of non-innermost PHY nodes is updated and then the active Port Options are loaded. The update is performed based on matching the active Port Option of the connected Innermost PHY. If the Port Option was forced, the active option is not updated.

6.3.36.4 Netlist Version (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Netlist Version	0x0	The version of the netlist.

6.3.36.5 Pair PHY Type[n] (0x0004 + 1*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:12	PHY 2*n+1 Reserved	0x0	
11:8	PHY 2*n+1 Active Option	0x0	The PHY active port option
7:4	PHY 2*n Reserved	0x0	
3:0	PHY 2*n Active Option	0x0	The PHY active port option.

6.3.36.6 Port Bitmap 0 (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Port Bitmap 0	0x0	

6.3.36.7 Port Bitmap 1 (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Reserved	0x0	Reserved.
3:0	Port Bitmap 1	0x0	

6.3.37 LLDP Preserved Section

Table 6-43. LLDP Preserved Section Summary Table

Word Offset	Description	Section Reference
0x0000	Type	6.3.37.1
0x0001	Length	6.3.37.2
0x0002	LLDP Admin Status 0	6.3.37.3
0x0003	LLDP Admin Status 1	6.3.37.4

6.3.37.1 Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x129	Valid values are: 0x129 = LLDP Preserved

6.3.37.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 2 First Section -> Word: LLDP Preserved -> Type Last Section -> Word: LLDP Preserved -> LLDP Admin Status 1 Section length in words.

6.3.37.3 LLDP Admin Status 0 (0x0002)

Defines status of LLDP agent. Each LAN port has independent status.

3: Both receive and transmit enabled.
2: LLDP is configured for transmits only.
1: LLDP is configured for receives only.
0: LLDP agent is disabled.

Bit(s)	Field Name	Default NVM Value	Description
15:12	Port 3	0xF	Defines status of LLDP agent. Applies to LAN Port 3.
11:8	Port 2	0xF	Defines status of LLDP agent. Applies to LAN Port 2.
7:4	Port 1	0xF	Defines status of LLDP agent. Applies to LAN Port 1.
3:0	Port 0	0xF	Defines status of LLDP agent. Applies to LAN Port 0.

6.3.37.4 LLDP Admin Status 1 (0x0003)

Defines status of LLDP agent. Each LAN port has independent status.

3: Both receive and transmit enabled.
2: LLDP is configured for transmits only.
1: LLDP is configured for receives only.
0: LLDP agent is disabled.

Bit(s)	Field Name	Default NVM Value	Description
15:12	Port 7	0xF	Defines status of LLDP agent. Applies to LAN Port 7.
11:8	Port 6	0xF	Defines status of LLDP agent. Applies to LAN Port 6.
7:4	Port 5	0xF	Defines status of LLDP agent. Applies to LAN Port 5.
3:0	Port 4	0xF	Defines status of LLDP agent. Applies to LAN Port 4.

6.3.38 RDE Module Section

LLDP Preserved.

Table 6-44. RDE Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Type	6.3.38.1
0x0001	Length	6.3.38.2
0x0002 + 1*n, n=0...31	AssetTag	6.3.38.3

6.3.38.1 Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x131	Valid values are: 0x131 = RDE Module

6.3.38.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: RDE Module -> Type Last Section -> Word: RDE Module -> AssetTag Section length in words.

6.3.38.3 AssetTag[n] (0x0002 + 1*n, n=0...31)

Defines status of LLDP agent. Each LAN port has independent status.

3: Both receive and transmit enabled.
2: LLDP is configured for transmits only.
1: LLDP is configured for receives only.
0: LLDP agent is disabled.

Bit(s)	Field Name	Default NVM Value	Description
15:0	AssetTag	0x0	Defines status of LLDP agent. Applies to LAN Port 0.

6.3.39 Identical Content as PLDM Header ComponentImageSetVersionString Section

Table 6-45. Identical Content as PLDM Header ComponentImageSetVersionString Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type	6.3.39.1
0x0001	Length	6.3.39.2
0x0002	ComponentImageSetVersionString- FW Component Prefix	6.3.39.3
0x0003	ComponentImageSetVersionString - FW Component Version 0	6.3.39.4
0x0004	ComponentImageSetVersionString - FW Component Version 1	6.3.39.5
0x0005	ComponentImageSetVersionString - FW Component Version 2	6.3.39.6
0x0006	ComponentImageSetVersionString - FW Component Version 3	6.3.39.7
0x0007	ComponentImageSetVersionString - OROM Component Prefix	6.3.39.8
0x0008	ComponentImageSetVersionString - OROM Component Version 0	6.3.39.9
0x0009	ComponentImageSetVersionString - OROM Component Version 1	6.3.39.10
0x000A	ComponentImageSetVersionString - OROM Component Version 2	6.3.39.11
0x000B	ComponentImageSetVersionString - OROM Component Version 3	6.3.39.12
0x000C	ComponentImageSetVersionString - Netlist Component Prefix	6.3.39.13
0x000D	ComponentImageSetVersionString - Netlist Component Version 0	6.3.39.14
0x000E	ComponentImageSetVersionString - Netlist Component Version 1	6.3.39.15
0x000F	ComponentImageSetVersionString - Netlist Component Version 2	6.3.39.16
0x0010	ComponentImageSetVersionString - Netlist Component Version 3	6.3.39.17
0x0011	ComponentImageSetVersionString - Null Padding	6.3.39.18

6.3.39.1 Sub Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x127	Valid values are: 0x127 = PLDM Component Image Set Version String

6.3.39.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Identical content as PLDM header ComponentImageSetVersionString -> Sub Module Type Last Section -> Word: Identical content as PLDM header ComponentImageSetVersionString -> ComponentImageSetVersionString - Null Padding

6.3.39.3 ComponentImageSetVersionString- FW Component Prefix (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Prefix	0x3A4E	"N:" in ASCII.

6.3.39.4 ComponentImageSetVersionString - FW Component Version 0 (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 0	0x3030	Firmware component version 0. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.3.39.5 ComponentImageSetVersionString - FW Component Version 1 (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 1	0x3030	Firmware component version 1. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.3.39.6 ComponentImageSetVersionString - FW Component Version 2 (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 2	0x3030	Firmware component version 2. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.3.39.7 ComponentImageSetVersionString - FW Component Version 3 (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - FW Component Version 3	0x3030	Firmware component version 3. ASCII presentation of firmware comparison stamp. Values are zero (in ASCII) padded.

6.3.39.8 ComponentImageSetVersionString - OROM Component Prefix (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Prefix	0x3A4F	"O:" in ASCII.

6.3.39.9 ComponentImageSetVersionString - OROM Component Version 0 (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 0	0x3030	OROM component version 0. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.3.39.10 ComponentImageSetVersionString - OROM Component Version 1 (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 1	0x3030	OROM component version 1. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.3.39.11 ComponentImageSetVersionString - OROM Component Version 2 (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 2	0x3030	OROM component version 2. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.3.39.12 ComponentImageSetVersionString - OROM Component Version 3 (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - OROM Component Version 3	0x3030	OROM component version 3. ASCII presentation of OROM comparison stamp. Values are zero (in ASCII) padded.

6.3.39.13 ComponentImageSetVersionString - Netlist Component Prefix (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSet VersionString - Netlist Component Prefix	0x3A54	"T:" in ASCII.

6.3.39.14 ComponentImageSetVersionString - Netlist Component Version 0 (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist component version 0	0x3030	Netlist component version 0. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.3.39.15 ComponentImageSetVersionString - Netlist Component Version 1 (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 1	0x3030	Netlist component version 1. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.3.39.16 ComponentImageSetVersionString - Netlist Component Version 2 (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 2	0x3030	Netlist component version 2. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.3.39.17 ComponentImageSetVersionString - Netlist Component Version 3 (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Netlist Component Version 3	0x3030	Netlist component version 3. ASCII presentation of Netlist comparison stamp. Values are zero (in ASCII) padded.

6.3.39.18 ComponentImageSetVersionString - Null Padding (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ComponentImageSetVersionString - Null Padding	0x0	

6.3.40 Software Checksum Module Section

The Software Checksum field covers the PFA portion of Shadow RAM contents (reserved words included). Its value is computed such that after adding all the covered words, including the software Checksum word itself, the sum is 0xBABA.

The checksum word is used to ensure that the base NVM image is a valid image. The initial value in the 16-bit summing register should be 0x0000 and the carry bit should be ignored after each addition.

This word is verified and recalculated by Firmware upon Checksum AQC.

Table 6-46. Software Checksum Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - Checksum	6.3.40.1
0x0001	Checksum Module Length	6.3.40.2
0x0002	Checksum	6.3.40.3

6.3.40.1 Sub Module Type - Checksum (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x3F	Valid values are: 0x3F = Checksum

6.3.40.2 Checksum Module Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Software Checksum Module -> Sub Module Type - Checksum Last Section -> Word: Software Checksum Module -> Checksum

6.3.40.3 Checksum (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Checksum		Checksum word. Calculated so that checksum over PFA is 0xBABA.

6.3.41 RDMA Control Section

Table 6-47. RDMA Control Section Summary Table

Word Offset	Description	Section Reference
0x0000	RDMA Control Module Type	6.3.41.1
0x0001	Length	6.3.41.2
0x0002	RDMA Control Settings	6.3.41.3

6.3.41.1 RDMA Control Module Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x135	Valid values are: 0x135 = RDMA Control Module

6.3.41.2 Length (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: RDMA Control -> RDMA Control Module Type Last Section -> Word: RDMA Control -> RDMA Control Settings

6.3.41.3 RDMA Control Settings (0x0002)

Bits	Field Name	Default NVM Value	Description
15:5	Reserved	0x0	Reserved.
4	High Port Count RDMA Control Override Value	0b	Enable or disable. 0b = Disabled 1b = Enabled
3	High Port Count RDMA Control Override Enable	0b	Enable/Disable alternative configuration request for 5 ports or higher. 0b = Disabled 1b = Enabled
2	Low Port Count RDMA Control Override Value	0b	Enable or disable. 0b = Disabled 1b = Enabled
1	Low port count RDMA Control Override Enable	0b	Enable/Disable alternative configuration request for 4 ports or lower. 0b = Disabled 1b = Enabled
0	RDMA Topology Setting	0b	Enable or disable. 0b = Disabled 1b = Enabled

6.3.42 Link Default Override Mask Section

Table 6-48. Link Default Override Mask Section Summary Table

Word Offset	Description	Section Reference
0x0000	Link Default Override Mask Type	6.3.42.1
0x0001	Length	6.3.42.2
0x0002 + 10*n, n=0...7	Port Options 0	6.3.42.3
0x0003 + 10*n, n=0...7	Port Options 1	6.3.42.4
0x0004 + 10*n, n=0...7	Port PHY Types 0	6.3.42.5
0x0005 + 10*n, n=0...7	Port PHY Types 1	6.3.42.6
0x0006 + 10*n, n=0...7	Port PHY Types 2	6.3.42.7
0x0007 + 10*n, n=0...7	Port PHY Types 3	6.3.42.8
0x0008 + 10*n, n=0...7	Port PHY Types 4	6.3.42.9
0x0009 + 10*n, n=0...7	Port PHY Types 5	6.3.42.10
0x000A + 10*n, n=0...7	Port PHY Types 6	6.3.42.11
0x000B + 10*n, n=0...7	Port PHY Types 7	6.3.42.12

6.3.42.1 Link Default Override Mask Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x134	Valid values are: 0x134 = Link Default Override Mask

6.3.42.2 Length (0x0001)

Length of section.

Bits	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Link Default Override Mask -> Link Default Override Mask Type Last Section -> Word: Link Default Override Mask -> Port PHY Types 7 Words

6.3.42.3 Port Options 0[n] (0x0002 + 10*n, n=0...7)

Port link options.

Bits	Field Name	Default NVM Value	Description
15	Auto FEC Enable	1b	When *Override Enable* bit is set, the *Auto FEC Enable* bit is taken from here and not from the topology netlist.
14	LESM Enable	1b	When *Override Enable* bit is set, the *LESM Enable* bit is taken from here and not from the topology netlist.
13:10	Reserved	0xF	Reserved.
9:8	PAUSE Ability	00b	When *Override Enable* bit is set, the *PAUSE Ability* bits are taken from here and not from the topology netlist.
7:6	Reserved	11b	Reserved.
5	EEE Enable Override	0b	When *Override Enable* bit is set, the EEE can be enabled or disabled according to this bit, assuming that the PHY_TYPE is supporting EEE. 0b = Disable 1b = Enable
4	Disable Automatic Link on Startup Override	0b	When *Override Enable* bit is set, the "Disable Automatic Link on Startup" feature is taken from here and not from the link topology. 0b = Automatic Link on Startup feature is enabled. 1b = Automatic Link on Startup feature is disabled.
3	Override Enable	0b	Enables the override ability from PFA for this port. When this bit is set for a specific port, the parameters of this port are taken from the PFA and not from the link topology structures. 0b = Disable 1b = Enable
2	Port Disable Behavior Mode	0b	Controls how to disable the port when requested. 0b = Disable only the host. 1b = Disables all usages.
1	EPCT ability to Change Lenient/Strict Enable	0b	EPCT ability to change Lenient/Strict mode.
0	Lenient/Strict Mode	0b	0b - Lenient 1b = Strict

6.3.42.4 Port Options 1[n] (0x0003 + 10*n, n=0...7)

Port PHY options.

Bits	Field Name	Default NVM Value	Description
15:8	Reserved	0xFF	Reserved.
7	FIRE_CODE_25_ABILITY	1b	Controls KR FEC ability advertisement for 25G KR1/CR1. 0b = EC Disabled 1b = FEC Enabled (advertised)
6	RS_528_ABILITY	1b	Controls RS FEC ability advertisement for 25G KR1/CR1. 0b = FEC Disabled 1b = FEC Enabled (advertised)
5	Reserved	0b	Reserved.
4	RS_544_REQUEST	0b	Controls RS FEC 544 capability request for 25G/50Glanes KR/KR-S/KR1/CR/CR-S/CR1.

Bits	Field Name	Default NVM Value	Description
3	FIRE_CODE_25_REQUEST	1b	Controls KR FEC capability request for 25G lanes KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC Disabled 1b = FEC Enabled (requested)
2	RS_528_REQUEST	1b	Controls RS FEC 528 capability request for 25G lanes KR/KR-S/KR1/CR/CR-S/CR1. 0b = FEC Disabled 1b = FEC Enabled (requested)
1	FIRE_CODE_10_REQUEST	0b	Controls FEC capability request for 10G KR and 40G KR4/CR4. 0b = FEC Disabled 1b = FEC Enabled (requested)
0	FIRE_CODE_10_ABILITY Enable	0b	Controls FEC capability advertisement for 10G KR and 40G KR4/CR4. 0b = FEC Disabled 1b = FEC Enabled (advertised)

6.3.42.5 Port PHY Types 0[n] (0x0004 + 10*n, n=0...7)

PHY types. 8 Words per port. 8 ports.

Bits	Field Name	Default NVM Value	Description
15	10GBASE-LR	1b	
14	10GBASE-SR	1b	
13	10G-SFI-DA	1b	
12	10GBASE-T	1b	
11	5GBASE-KR	1b	
10	5GBASE-T	1b	
9	2.5GBASE-KX	1b	
8	2.5GBASE-X	1b

6.3.43 RDE Ethernet MTU Section

Table 6-49. RDE Ethernet MTU Section Summary Table

Word Offset	Description	Section Reference
0x0000	RDE Ethernet MTU Type	6.3.43.1
0x0001	Length	6.3.43.2
0x0002 + 1*n, n=0...7	Ethernet MTU Size	6.3.43.3

6.3.43.1 RDE Ethernet MTU Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x136	Valid values are: 0x136 = RDE Ethernet MTU Type

6.3.43.2 Length (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: RDE Ethernet MTU -> RDE Ethernet MTU Type Last Section -> Word: RDE Ethernet MTU -> Ethernet MTU size

6.3.43.3 Ethernet MTU Size[n] (0x0002 + 1*n, n=0...7)

Bits	Field Name	Default NVM Value	Description
15:0	Ethernet MTU Size	0x5DC	

6.3.44 Default DCB Parameters Section

Table 6-50. Default DCB Parameters Section Summary Table

Word Offset	Description	Section Reference
0x0000	Default DCB Parameters Type	6.3.44.1
0x0001	Length	6.3.44.2
0x0002	Ports 0-3 Mode	6.3.44.3
0x0003	Ports 4-7 Mode	6.3.44.4

6.3.44.1 Default DCB Parameters Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x137	Valid values are: 0x137 = Default DCB Parameters Type

6.3.44.2 Length (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Default DCB Parameters -> Default DCB Parameters Type Last Section -> Word: Default DCB Parameters -> Ports 4-7 Mode

6.3.44.3 Ports 0-3 Mode (0x0002)

Bits	Field Name	Default NVM Value	Description
15:12	Port 3 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 3
11:8	Port 2 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 2
7:4	Port 1 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 1
3:0	Port 0 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 0

6.3.44.4 Ports 4-7 Mode (0x0003)

Bits	Field Name	Default NVM Value	Description
15:12	Port 7 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 7
11:8	Port 6 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 6
7:4	Port 5 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 5
3:0	Port 4 Mode	0x1	Default DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 4

6.3.45 Current DCB Parameters Section

Table 6-51. Current DCB Parameters Section Summary Table

Word Offset	Description	Section Reference
0x0000	Current DCB Parameters Type	6.3.45.1
0x0001	Length	6.3.45.2
0x0002	Ports 0-3 Mode	6.3.45.3
0x0003	Ports 4-7 Mode	6.3.45.4

6.3.45.1 Current DCB Parameters Type (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0x138	Valid values are: 0x138 = Current DCB Parameters Type

6.3.45.2 Length (0x0001)

Bits	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Current DCB Parameters -> Current DCB Parameters Type Last Section -> Word: Current DCB Parameters -> Ports 4-7 Mode

6.3.45.3 Ports 0-3 Mode (0x0002)

Bits	Field Name	Default NVM Value	Description
15:12	Port 3 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 3
11:8	Port 2 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 2
7:4	Port 1 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 1
3:0	Port 0 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 0

6.3.45.4 Ports 4-7 Mode (0x0003)

Bits	Field Name	Default NVM Value	Description
15:12	Port 7 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 7
11:8	Port 6 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 6
7:4	Port 5 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 5
3:0	Port 4 Mode	0xF	Current DCB Mode to apply default DCB settings after link up or not. Applies to LAN Port 4

6.3.46 Padding Module Section

Table 6-52. Padding Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Sub Module Type - Padding	6.3.46.1
0x0001	Length	6.3.46.2
0x0002	Padding	6.3.46.3

6.3.46.1 Sub Module Type - Padding (0x0000)

Bits	Field Name	Default NVM Value	Description
15:0	Sub Module Type	0xFFFF	Valid values are: 0xFFFF - Padding Module

6.3.46.2 Length (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: Padding module -> Sub Module Type - Padding Last Section -> Word: Padding module -> Padding

6.3.46.3 Padding (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	[New Field]	0xFFFF	

6.3.47 PCIR Type 1/2 Section

Table 6-53. PCIR Type 1/2 Section Summary Table

Word Offset	Description	Section Reference
0x0000 - 0x0003	NVM contents for GLPCI_PWRDATA	6.3.47.1
0x0004 - 0x0008	NVM contents for GLPCI_PMSUP	6.3.47.2
0x0009 - 0x000A	NVM contents for GLPCI_REVID	6.3.47.3
0x000B - 0x000E	Reserved	6.3.47.4

6.3.47.1 GLPCI_PWRDATA (0x0000 - 0x00003)

6.3.47.1.1 Address Low at GLPCI_PWRDATA (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_PWRDATA	0x9DE7C	
3:0	Type	0x1	

6.3.47.1.2 Address High at GLPCI_PWRDATA (0x000`)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_PWRDATA		

6.3.47.1.3 Data Low of GLPCI_PWRDATA (0x0002)

6.3.47.1.4 Data High of GLPCI_PWRDATA (0x0003)

6.3.47.2 GLPCI_PMSUP (0x0004 - 0x0008)

6.3.47.2.1 Starting Address Low at GLPCI_PMSUP (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLPCI_PMSUP	0x9DE94	
3:0	Type	0x2	

6.3.47.2.2 Starting Address High at GLPCI_PMSUP (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLPCI_PMSUP		

6.3.47.2.3 Attributes at GLPCI_PMSUP (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x2	
4:3	Skip	00b	
2:0	Width	000b	

6.3.47.2.4 Data Low of GLPCI_PMSUP (0x0007)

6.3.47.2.5 Data High of GLPCI_PMSUP (0x0008)

6.3.47.3 GLPCI_REVID (0x0009 - 0x000A)

6.3.47.3.1 Data Low of GLPCI_REVID (0x0009)

6.3.47.3.2 Data High of GLPCI_REVID (0x000A)

6.3.47.4 Reserved (0x000B - 0x000E)

6.3.48 POR Type 1/2 Section

Table 6-54. POR Type 1/2 Section Summary Table

Word Offset	Description	Section Reference
0x0000 - 0x0021	Reserved	6.3.48.1

6.3.48.1 Reserved (0x0000 - 0x0021)

6.3.49 CORER Registers Auto-Load Module Section

Default setup to registers and internal memories that load on CORER events.

Table 6-55. CORER Registers Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.49.1
0x0001 - 0x0013	NVM contents for PRT_TDPUL2TAGSEN	6.3.49.2

0x526B	ANA_MERGE Data	6.3.49.115

6.3.49.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: CORER Registers Auto-Load Module -> Module Length Last Section -> Word: CORER Registers Auto-Load Module -> ANA_MERGE Data

6.3.49.2 PRT_TDPUL2TAGSEN (0x0001 - 0x0013)

6.3.49.2.1 Starting Address Low at PRT_TDPUL2TAGSEN (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PRT_TDPUL2TAGSEN, for PRT[0]	0x40BA0	
3:0	Type	0x2	

6.3.49.2.2 Starting Address High at PRT_TDPUL2TAGSEN (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PRT_TDPUL2TAGSEN, for PRT[0]		

6.3.49.2.3 Attributes at PRT_TDPUL2TAGSEN (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.2.4 Data Low of PRT_TDPUL2TAGSEN[PRT] (0x0004 + 2*PRT, PRT=0...7)

6.3.49.2.5 Data High of PRT_TDPUL2TAGSEN[PRT] (0x0005 + 2*PRT, PRT=0...7)

6.3.49.3 GL_SWT_L2TAGTXIB (0x0014 - 0x0026)

6.3.49.3.1 Starting Address Low at GL_SWT_L2TAGTXIB (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_SWT_L2TAGTXIB	0x492E8	
3:0	Type		

6.3.49.3.2 Starting Address High at GL_SWT_L2TAGTXIB (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_SWT_L2TAGTXIB		

6.3.49.3.3 Attributes at GL_SWT_L2TAGTXIB (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.3.4 Data Low of GL_SWT_L2TAGTXIB[n] (0x0017 + 2*n, n=0...7)

6.3.49.3.5 Data High of GL_SWT_L2TAGTXIB[n] (0x0018 + 2*n, n=0...7)

6.3.49.4 GL_SWT_L2TAGRXEB (0x0027 - 0x0039)

6.3.49.4.1 Starting Address Low at GL_SWT_L2TAGRXEB (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_SWT_L2TAGRXEB	0x52000	
3:0	Type	0x2	

6.3.49.4.2 Starting Address High at GL_SWT_L2TAGRXEB (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_SWT_L2TAGRXEB		

6.3.49.4.3 Attributes at GL_SWT_L2TAGRXEB (0x0029)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.4.4 Data Low of GL_SWT_L2TAGRXEB[n] (0x002A + 2*n, n=0...7)

6.3.49.4.5 Data High of GL_SWT_L2TAGRXEB[n] (0x002B + 2*n, n=0...7)

6.3.49.5 GL_RDPU_CNTRL (0x003A - 0x003D)

6.3.49.5.1 Address Low at GL_RDPU_CNTRL (0x003A)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_RDPU_CNTRL	0x52054	
3:0	Type	0x1	

6.3.49.5.2 Address High at GL_RDPU_CNTRL (0x003B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_RDPU_CNTRL		

6.3.49.5.3 Reserved (0x003C - 0x003D)

6.3.49.6 PFLAN_DB_QALLOC (0x003E - 0x0050)

6.3.49.6.1 Starting Address Low at PFLAN_DB_QALLOC (0x003E)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFLAN_DB_QALLOC, for PF[0]	0x75680	
3:0	Type	0x2	

6.3.49.6.2 Starting Address High at PFLAN_DB_QALLOC (0x003F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFLAN_DB_QALLOC, for PF[0]		

6.3.49.6.3 Attributes at PFLAN_DB_QALLOC (0x0040)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.6.4 Data Low of PFLAN_DB_QALLOC[PF] (0x0041 + 2*PF, PF=0...7)

6.3.49.6.5 Data High of PFLAN_DB_QALLOC[PF] (0x0042 + 2*PF, PF=0...7)

6.3.49.7 PFLAN_CP_QALLOC (0x0051 - 0x0063)

6.3.49.7.1 Starting Address Low at PFLAN_CP_QALLOC (0x0051)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFLAN_CP_QALLOC, for PF[0]	0x75700	
3:0	Type	0x2	

6.3.49.7.2 Starting Address High at PFLAN_CP_QALLOC (0x0052)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFLAN_CP_QALLOC, for PF[0]		

6.3.49.7.3 Attributes at PFLAN_CP_QALLOC (0x0053)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.7.4 Data Low of PFLAN_CP_QALLOC[PF] (0x0054 + 2*PF, PF=0...7)

6.3.49.7.5 Data High of PFLAN_CP_QALLOC[PF] (0x0055 + 2*PF, PF=0...7)

6.3.49.8 GLDCB_GENC (0x0064 - 0x0067)

6.3.49.8.1 Address Low at GLDCB_GENC (0x0064)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_GENC	0x83044	
3:0	Type	0x1	

6.3.49.8.2 Address High at GLDCB_GENC (0x0065)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_GENC		

6.3.49.8.3 Data Low of GLDCB_GENC (0x0066)

6.3.49.8.4 Data High of GLDCB_GENC (0x0067)

6.3.49.9 Reserved (0x0068 - 0x018F)

6.3.49.10 GLTSYN_SYNC_DLAY (0x0190 - 0x0194)

6.3.49.10.1 Starting Address Low at GLTSYN_SYNC_DLAY (0x0190)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLTSYN_SYNC_DLAY	0x88818	
3:0	Type	0x2	

6.3.49.10.2 Starting Address High at GLTSYN_SYNC_DLAY (0x0191)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLTSYN_SYNC_DLAY		

6.3.49.10.3 Attributes at GLTSYN_SYNC_DLAY (0x0192)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x2	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.10.4 Data Low of GLTSYN_SYNC_DLAY (0x0193)

6.3.49.10.5 Data High of GLTSYN_SYNC_DLAY (0x0194)

6.3.49.11 GLTSYN_HH_DLAY (0x0195 - 0x0196)

6.3.49.11.1 Data Low of GLTSYN_HH_DLAY (0x0195)

6.3.49.11.2 Data High of GLTSYN_HH_DLAY (0x0196)

6.3.49.12 GLTPB_PACING_25G (0x0197 - 0x019B)

6.3.49.12.1 Starting Address Low at GLTPB_PACING_25G (0x0197)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLTPB_PACING_25G	0x994E0	
3:0	Type	0x2	

6.3.49.12.2 Starting Address High at GLTPB_PACING_25G (0x0198)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLTPB_PACING_25G		

6.3.49.12.3 Attributes at GLTPB_PACING_25G (0x0199)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.12.4 Data Low of GLTPB_PACING_25G (0x019A)

6.3.49.12.5 Data High of GLTPB_PACING_25G (0x019B)

6.3.49.13 GLTPB_PACING_10G (0x019C - 0x019D)

6.3.49.13.1 Data Low of GLTPB_PACING_10G (0x019C)

6.3.49.13.2 Data High of GLTPB_PACING_10G (0x019D)

6.3.49.14 GLTPB_PORT_PACING_SPEED (0x019E - 0x019F)

6.3.49.14.1 Data Low of GLTPB_PORT_PACING_SPEED (0x019E)

6.3.49.14.2 Data High of GLTPB_PORT_PACING_SPEED (0x019F)

6.3.49.15 Reserved (0x01A0 - 0x01A7)

6.3.49.16 GLRPB_DHW (0x01A8 - 0x01CA)

6.3.49.16.1 Starting Address Low at GLRPB_DHW (0x01A8)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLRPB_DHW	0xAC000	
3:0	Type	0x2	

6.3.49.16.2 Starting Address High at GLRPB_DHW (0x01A9)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLRPB_DHW		

6.3.49.16.3 Attributes at GLRPB_DHW (0x01AA)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x10

6.3.49.29.1 Data Low of GLDCB_TCUPM_WB_DIS (0x0336)

6.3.49.29.2 Data High of GLDCB_TCUPM_WB_DIS (0x0337)

6.3.49.30 GLHMC_PFPESDPART_FPMAT (0x0338 - 0x034A)

6.3.49.30.1 Starting Address Low at GLHMC_PFPESDPART_FPMAT (0x0338)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLHMC_PFPESDPART_FPMAT	0x100880	
3:0	Type	0x2	

6.3.49.30.2 Starting Address High at GLHMC_PFPESDPART_FPMAT (0x0339)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLHMC_PFPESDPART_FPMAT		

6.3.49.30.3 Attributes at GLHMC_PFPESDPART_FPMAT (0x033A)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.30.4 Data Low of GLHMC_PFPESDPART_FPMAT[n] (0x033B + 2*n, n=0...7)

6.3.49.30.5 Data High of GLHMC_PFPESDPART_FPMAT[n] (0x033C + 2*n, n=0...7)

6.3.49.31 GLHMC_VFSDPART_FPMAT (0x034B - 0x038D)

6.3.49.31.1 Starting Address Low at GLHMC_VFSDPART_FPMAT (0x034B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLHMC_VFSDPART_FPMAT	0x108800	
3:0	Type	0x2	

6.3.49.31.2 Starting Address High at GLHMC_VFSDPART_FPMAT (0x034C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLHMC_VFSDPART_FPMAT		

6.3.49.31.3 Attributes at GLHMC_VFSDPART_FPMAT (0x034D)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x20	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.31.4 Data Low of GLHMC_VFSDPART_FPMAT[n] (0x034E + 2*n, n=0...31)

6.3.49.31.5 Data High of GLHMC_VFSDPART_FPMAT[n] (0x034F + 2*n, n=0...31)

6.3.49.32 GLDCB_RETSTCC (0x038E - 0x03D0)

6.3.49.32.1 Starting Address Low at GLDCB_RETSTCC (0x038E)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_RETSTCC	0x122140	
3:0	Type	0x2	

6.3.49.32.2 Starting Address High at GLDCB_RETSTCC (0x038F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_RETSTCC		

6.3.49.32.3 Attributes at GLDCB_RETSTCC (0x0390)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x20	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.32.4 Data Low of GLDCB_RETSTCC[n] (0x0391 + 2*n, n=0...31)

6.3.49.32.5 Data High of GLDCB_RETSTCC[n] (0x0392 + 2*n, n=0...31)

6.3.49.33 PRTDCB_RPPMC (0x03D1 - 0x03E3)

6.3.49.33.1 Starting Address Low at PRTDCB_RPPMC (0x03D1)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PRTDCB_RPPMC, for PRT[0]	0x122240	
3:0	Type	0x2	

6.3.49.33.2 Starting Address High at PRTDCB_RPPMC (0x03D2)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PRTDCB_RPPMC, for PRT[0]		

6.3.49.33.3 Attributes at PRTDCB_RPPMC (0x03D3)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.33.4 Data Low of PRTDCB_RPPMC[PRT] (0x03D4 + 2*PRT, PRT=0)

6.3.49.33.5 Data High of PRTDCB_RPPMC[PRT] (0x03D5 + 2*PRT, PRT=0)

6.3.49.34 GLDCB_RSPMC (0x03E4 - 0x03E8)

6.3.49.34.1 Starting Address Low at GLDCB_RSPMC (0x03E4)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_RSPMC	0x1223C4	
3:0	Type	0x2	

6.3.49.34.2 Starting Address High at GLDCB_RSPMC (0x03E5)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_RSPMC		

6.3.49.34.3 Attributes at GLDCB_RSPMC (0x03E6)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x2	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.34.4 Data Low of GLDCB_RSPMC (0x03E7)

6.3.49.34.5 Data High of GLDCB_RSPMC (0x03E8)

6.3.49.35 GLDCB_RMPMC (0x03E9 - 0x03EA)

6.3.49.35.1 Data Low of GLDCB_RMPMC (0x03E9)

6.3.49.35.2 Data High of GLDCB_RMPMC (0x03EA)

6.3.49.36 Reserved (0x03EB - 0x03F1)

6.3.49.37 PFINT_TSYN_MSK (0x03F2 - 0x0404)

6.3.49.37.1 Starting Address Low at PFINT_TSYN_MSK (0x03F2)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFINT_TSYN_MSK, for PF[0]	0x16C980	
3:0	Type		

6.3.49.37.2 Starting Address High at PFINT_TSYN_MSK (0x03F3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFINT_TSYN_MSK, for PF[0]		

6.3.49.37.3 Attributes at PFINT_TSYN_MSK (0x03F4)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.37.4 Data Low of PFINT_TSYN_MSK[PF] (0x03F5 + 2*PF, PF=0...7)

6.3.49.37.5 Data High of PFINT_TSYN_MSK[PF] (0x03F6 + 2*PF, PF=0...7)

6.3.49.38 GLINT_CTL (0x0405 - 0x0408)

6.3.49.38.1 Address Low at GLINT_CTL (0x0405)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLINT_CTL	0x16CC54	
3:0	Type	0x1	

6.3.49.38.2 Address High at GLINT_CTL (0x0406)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLINT_CTL		

6.3.49.38.3 Data Low of GLINT_CTL (0x0407)

6.3.49.38.4 Data High of GLINT_CTL (0x0408)

6.3.49.39 PFGEN_PORTNUM (0x0409 - 0x041B)

6.3.49.39.1 Starting Address Low at PFGEN_PORTNUM (0x0409)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFGEN_PORTNUM, for PF[0]	0x1D2400	
3:0	Type	0x2	

6.3.49.39.2 Starting Address High at PFGEN_PORTNUM (0x040A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFGEN_PORTNUM, for PF[0]		

6.3.49.39.3 Attributes at PFGEN_PORTNUM (0x040B)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.39.4 Data Low of PFGEN_PORTNUM[PF] (0x040C + 2*PF, PF=0...7)

6.3.49.39.5 Data High of PFGEN_PORTNUM[PF] (0x040D + 2*PF, PF=0...7)

6.3.49.40 PF_VT_PFALLOC (0x041C - 0x042E)

6.3.49.40.1 Starting Address Low at PF_VT_PFALLOC (0x041C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PF_VT_PFALLOC, for PF[0]	0x1D2480	
3:0	Type	0x2	

6.3.49.40.2 Starting Address High at PF_VT_PFALLOC (0x041D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PF_VT_PFALLOC, for PF[0]		

6.3.49.40.3 Attributes at PF_VT_PFALLOC (0x041E)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.40.4 Data Low of PF_VT_PFALLOC[PF] (0x041F + 2*PF, PF=0...7)

6.3.49.40.5 Data High of PF_VT_PFALLOC[PF] (0x0420 + 2*PF, PF=0...7)

6.3.49.41 PFLAN_RX_QALLOC (0x042F - 0x0441)

6.3.49.41.1 Starting Address Low at PFLAN_RX_QALLOC (0x042F)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFLAN_RX_QALLOC, for PF[0]	0x1D2500	
3:0	Type	0x2	

6.3.49.41.2 Starting Address High at PFLAN_RX_QALLOC (0x0430)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFLAN_RX_QALLOC, for PF[0]		

6.3.49.41.3 Attributes at PFLAN_RX_QALLOC (0x0431)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.41.4 Data Low of PFLAN_RX_QALLOC[PF] (0x0432 + 2*PF, PF=0...7)

6.3.49.41.5 Data High of PFLAN_RX_QALLOC[PF] (0x0433 + 2*PF, PF=0...7)

6.3.49.42 PFLAN_TX_QALLOC (0x0442 - 0x0454)

6.3.49.42.1 Starting Address Low at PFLAN_TX_QALLOC (0x0442)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFLAN_TX_QALLOC, for PF[0]	0x1D2580	
3:0	Type	0x2	

6.3.49.42.2 Starting Address High at PFLAN_TX_QALLOC (0x0443)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFLAN_TX_QALLOC, for PF[0]		

6.3.49.42.3 Attributes at PFLAN_TX_QALLOC (0x0444)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.42.4 Data Low of PFLAN_TX_QALLOC[PF] (0x0445 + 2*PF, PF=0...7)

6.3.49.42.5 Data High of PFLAN_TX_QALLOC[PF] (0x0446 + 2*PF, PF=0...7)

6.3.49.43 PFINT_ALLOC (0x0455 - 0x0467)

6.3.49.43.1 Starting Address Low at PFINT_ALLOC (0x0455)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of PFINT_ALLOC, for PF[0]	0x1D2600	
3:0	Type	0x2	

6.3.49.43.2 Starting Address High at PFINT_ALLOC (0x0456)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of PFINT_ALLOC, for PF[0]		

6.3.49.43.3 Attributes at PFINT_ALLOC (0x0457)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.43.4 Data Low of PFINT_ALLOC[PF] (0x0458 + 2*PF, PF=0...7)

6.3.49.43.5 Data High of PFINT_ALLOC[PF] (0x0459 + 2*PF, PF=0...7)

6.3.49.44 GL_SWT_L2TAGCTRL (0x0468 - 0x047A)

6.3.49.44.1 Starting Address Low at GL_SWT_L2TAGCTRL (0x0468)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_SWT_L2TAGCTRL	0x1D2660	
3:0	Type	0x2	

6.3.49.44.2 Starting Address High at GL_SWT_L2TAGCTRL (0x0469)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_SWT_L2TAGCTRL		

6.3.49.44.3 Attributes at GL_SWT_L2TAGCTRL (0x046A)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.44.4 Data Low of GL_SWT_L2TAGCTRL[n] (0x046B + 2*n, n=0...7)

6.3.49.44.5 Data High of GL_SWT_L2TAGCTRL[n] (0x046C + 2*n, n=0...7)

6.3.49.45 GLDCB_PRS_RETSTCC (0x047B - 0x04BD)

6.3.49.45.1 Starting Address Low at GLDCB_PRS_RETSTCC (0x047B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_PRS_RETSTCC	0x2000B0	
3:0	Type	0x2	

6.3.49.45.2 Starting Address High at GLDCB_PRS_RETSTCC (0x047C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_PRS_RETSTCC		

6.3.49.45.3 Attributes at GLDCB_PRS_RETSTCC (0x047D)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x20	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.45.4 Data Low of GLDCB_PRS_RETSTCC[n] (0x047E + 2*n, n=0...31)

6.3.49.45.5 Data High of GLDCB_PRS_RETSTCC[n] (0x047F + 2*n, n=0...31)

6.3.49.46 GLDCB_PRS_RSPMC (0x04BE - 0x04C1)

6.3.49.46.1 Address Low at GLDCB_PRS_RSPMC (0x04BE)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_PRS_RSPMC	0x200160	
3:0	Type	0x1	

6.3.49.46.2 Address High at GLDCB_PRS_RSPMC (0x04BF)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_PRS_RSPMC		

6.3.49.46.3 Data Low of GLDCB_PRS_RSPMC (0x04C0)

6.3.49.46.4 Data High of GLDCB_PRS_RSPMC (0x04C1)

6.3.49.47 GLRPRS_PMCFG_DPS (0x04C2 - 0x04E4)

6.3.49.47.1 Starting Address Low at GLRPRS_PMCFG_DPS (0x04C2)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLRPRS_PMCFG_DPS	0x200308	
3:0	Type	0x2	

6.3.49.47.2 Starting Address High at GLRPRS_PMCFG_DPS (0x04C3)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLRPRS_PMCFG_DPS		

6.3.49.47.3 Attributes at GLRPRS_PMCFG_DPS (0x04C4)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x10	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.47.4 Data Low of GLRPRS_PMCFG_DPS[n] (0x04C5 + 2*n, n=0...15)

6.3.49.47.5 Data High of GLRPRS_PMCFG_DPS[n] (0x04C6 + 2*n, n=0...15)

6.3.49.48 GLRPRS_PMCFG_DHW (0x04E5 - 0x0507)

6.3.49.48.1 Starting Address Low at GLRPRS_PMCFG_DHW (0x04E5)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLRPRS_PMCFG_DHW	0x200388	
3:0	Type	0x2	

6.3.49.48.2 Starting Address High at GLRPRS_PMCFG_DHW (0x04E6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLRPRS_PMCFG_DHW		

6.3.49.48.3 Attributes at GLRPRS_PMCFG_DHW (0x04E7)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.48.4 Data Low of GLRPRS_PMCFG_DHW[n] (0x04E8 + 2*n, n=0...15)

6.3.49.48.5 Data High of GLRPRS_PMCFG_DHW[n] (0x04E9 + 2*n, n=0...15)

6.3.49.49 GLRPRS_PMCFG_DLW (0x0508 - 0x0527)

6.3.49.49.1 Data Low of GLRPRS_PMCFG_DLW[n] (0x0508 + 2*n, n=0...15)

6.3.49.49.2 Data High of GLRPRS_PMCFG_DLW[n] (0x0509 + 2*n, n=0...15)

6.3.49.50 GLRPRS_PMCFG_SPS (0x0528 - 0x0537)

6.3.49.50.1 Data Low of GLRPRS_PMCFG_SPS[n] (0x0528 + 2*n, n=0...7)

6.3.49.50.2 Data High of GLRPRS_PMCFG_SPS[n] (0x0529 + 2*n, n=0...7)

6.3.49.51 GLRPRS_PMCFG_SHW (0x0538 - 0x054A)

6.3.49.51.1 Starting Address Low at GLRPRS_PMCFG_SHW (0x0538)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLRPRS_PMCFG_SHW	0x200448	
3:0	Type	0x2	

6.3.49.51.2 Starting Address High at GLRPRS_PMCFG_SHW (0x0539)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLRPRS_PMCFG_SHW		

6.3.49.51.3 Attributes at GLRPRS_PMCFG_SHW (0x053A)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x10	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.51.4 Data Low of GLRPRS_PMCFG_SHW[n] (0x053B + 2*n, n=0...7)

6.3.49.51.5 Data High of GLRPRS_PMCFG_SHW[n] (0x053C + 2*n, n=0...7)

6.3.49.52 GLRPRS_PMCFG_SLW (0x054B - 0x055A)

6.3.49.52.1 Data Low of GLRPRS_PMCFG_SLW[n] (0x054B + 2*n, n=0...7)

6.3.49.52.2 Data High of GLRPRS_PMCFG_SLW[n] (0x054C + 2*n, n=0...7)

6.3.49.53 GLRPRS_PMCFG_TCHW (0x055B - 0x059D)

6.3.49.53.1 Starting Address Low at GLRPRS_PMCFG_TCHW (0x055B)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLRPRS_PMCFG_TCHW	0x200588	
3:0	Type	0x2	

6.3.49.53.2 Starting Address High at GLRPRS_PMCFG_TCHW (0x055C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLRPRS_PMCFG_TCHW		

6.3.49.53.3 Attributes at GLRPRS_PMCFG_TCHW (0x055D)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x40	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.53.4 Data Low of GLRPRS_PMCFG_TCHW[n] (0x055E + 2*n, n=0...31)

6.3.49.53.5 Data High of GLRPRS_PMCFG_TCHW[n] (0x055F + 2*n, n=0...31)

6.3.49.54 GLRPRS_PMCFG_TCLW (0x059E - 0x05DD)

6.3.49.54.1 Data Low of GLRPRS_PMCFG_TCLW[n] (0x059E + 2*n, n=0...31)

6.3.49.54.2 Data High of GLRPRS_PMCFG_TCLW[n] (0x059F + 2*n, n=0...31)

6.3.49.55 GL_SWT_LAT_SINGLE (0x05DE - 0x05E2)

6.3.49.55.1 Starting Address Low at GL_SWT_LAT_SINGLE (0x05DE)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_SWT_LAT_SINGLE	0x204000	
3:0	Type	0x2	

6.3.49.55.2 Starting Address High at GL_SWT_LAT_SINGLE (0x05DF)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_SWT_LAT_SINGLE		

6.3.49.55.3 Attributes at GL_SWT_LAT_SINGLE (0x05E0)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.55.4 Data Low of GL_SWT_LAT_SINGLE (0x05E1)

6.3.49.55.5 Data High of GL_SWT_LAT_SINGLE (0x05E2)

6.3.49.56 GL_SWT_LAT_DOUBLE (0x05E3 - 0x05E4)

6.3.49.56.1 Data Low of GL_SWT_LAT_DOUBLE (0x05E3)

6.3.49.56.2 Data High of GL_SWT_LAT_DOUBLE (0x05E4)

6.3.49.57 GL_SWT_LAT_QUAD (0x05E5 - 0x05E6)

6.3.49.57.1 Data Low of GL_SWT_LAT_QUAD (0x05E5)

6.3.49.57.2 Data High of GL_SWT_LAT_QUAD (0x05E6)

6.3.49.58 Reserved (0x05E7 - 0x06FF)

6.3.49.59 GLDCB_SWT_RETSTCC (0x0700 - 0x0742)

6.3.49.59.1 Starting Address Low at GLDCB_SWT_RETSTCC (0x0700)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLDCB_SWT_RETSTCC	0x20A040	
3:0	Type	0x2	

6.3.49.59.2 Starting Address High at GLDCB_SWT_RETSTCC (0x0701)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLDCB_SWT_RETSTCC		

6.3.49.59.3 Attributes at GLDCB_SWT_RETSTCC (0x0702)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x20	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.59.4 Data Low of GLDCB_SWT_RETSTCC[n] (0x0703 + 2*n, n=0...31)

6.3.49.59.5 Data High of GLDCB_SWT_RETSTCC[n] (0x0704 + 2*n, n=0...31)

6.3.49.60 GL_PSTEXT_FORCE_PID (0x0743 - 0x074B)

6.3.49.60.1 Starting Address Low at GL_PSTEXT_FORCE_PID (0x0743)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_PSTEXT_FORCE_PID	0x20E000	
3:0	Type	0x2	

6.3.49.60.2 Starting Address High at GL_PSTEXT_FORCE_PID (0x0744)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_PSTEXT_FORCE_PID		

6.3.49.60.3 Attributes at GL_PSTEXT_FORCE_PID (0x0745)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.60.4 Data Low of GL_PSTEXT_FORCE_PID[n] (0x0746 + 2*n, n=0...2)

6.3.49.60.5 Data High of GL_PSTEXT_FORCE_PID[n] (0x0747 + 2*n, n=0...2)

6.3.49.61 GL_PREEXT_FORCE_PID (0x074C - 0x0754)

6.3.49.61.1 Starting Address Low at GL_PREEXT_FORCE_PID (0x074C)

Bits	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_PREEXT_FORCE_PID	0x20F000	
3:0	Type	0x2	

6.3.49.61.2 Starting Address High at GL_PREEXT_FORCE_PID (0x074D)

Bits	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_PREEXT_FORCE_PID		

6.3.49.61.3 Attributes at GL_PREEXT_FORCE_PID (0x074E)

Bits	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.61.4 Data Low of GL_PREEXT_FORCE_PID[n] (0x074F + 2*n, n=0...2)

6.3.49.61.5 Data High of GL_PREEXT_FORCE_PID[n] (0x0750 +2*n, n=0...2)

6.3.49.62 GL_ACLEXT_FORCE_PID (0x0755 - 0x075D)

6.3.49.62.1 Starting Address Low at GL_ACLEXT_FORCE_PID (0x0755)

Bits	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_ACLEXT_FORCE_PID	0x210000	
3:0	Type	0x2	

6.3.49.62.2 Starting Address High at GL_ACLEXT_FORCE_PID (0x0756)

Bits	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_ACLEXT_FORCE_PID		

6.3.49.62.3 Attributes at GL_ACLEXT_FORCE_PID (0x0757)

Bits	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.62.4 Data Low of GL_ACLEXT_FORCE_PID[n] (0x0758 + 2*n, n=0...2)

6.3.49.62.5 Data High of GL_ACLEXT_FORCE_PID[n] (0x0759 + 2*n, n=0...2)

6.3.49.63 GL_SWT_SWIDFVIDX (0x075E - 0x0761)

6.3.49.63.1 Address Low at GL_SWT_SWIDFVIDX (0x075E)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_SWT_SWIDFVIDX	0x214114	
3:0	Type	0x1	

6.3.49.63.2 Address High at GL_SWT_SWIDFVIDX (0x075F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_SWT_SWIDFVIDX		

6.3.49.63.3 Data Low of GL_SWT_SWIDFVIDX (0x0760)

6.3.49.63.4 Data High of GL_SWT_SWIDFVIDX (0x0761)

6.3.49.64 GLLAN_RCTL_1 (0x0762 - 0x0765)

6.3.49.64.1 Address Low at GLLAN_RCTL_1 (0x0762)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLLAN_RCTL_1	0x2941FC	
3:0	Type	0x1	

6.3.49.64.2 Address High at GLLAN_RCTL_1 (0x0763)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLLAN_RCTL_1		

6.3.49.64.3 Data Low of GLLAN_RCTL_1 (0x0764)

6.3.49.64.4 Data High of GLLAN_RCTL_1 (0x0765)

6.3.49.65 GLLAN_PF_RECIPE (0x0766 - 0x0778)

6.3.49.65.1 Starting Address Low at GLLAN_PF_RECIPE (0x0766)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLLAN_PF_RECIPE	0x29420C	
3:0	Type	0x2	

6.3.49.65.2 Starting Address High at GLLAN_PF_RECIPE (0x0767)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLLAN_PF_RECIPE		

6.3.49.65.3 Attributes at GLLAN_PF_RECIPE (0x0768)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.65.4 Data Low of GLLAN_PF_RECIPE[n] (0x0769 + 2*n, n=0...7)

6.3.49.65.5 Data High of GLLAN_PF_RECIPE[n] (0x076A + 2*n, n=0...7)

6.3.49.66 VPDSI_TX_QTABLE_PQM (0x0779 - 0x09A8)

6.3.49.66.1 Starting Address Low at VPDSI_TX_QTABLE_PQM (0x0779)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of VPDSI_TX_QTABLE_PQM, for VP16[0]	0x2D2800	
3:0	Type	0x2	

6.3.49.66.2 Starting Address High at VPDSI_TX_QTABLE_PQM (0x077A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of VPDSI_TX_QTABLE_PQM, for VP16[0]		

6.3.49.66.3 Attributes at VPDSI_TX_QTABLE_PQM (0x077B)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x110	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.67 VPLAN_DSI_VF_MODE (0x097C - 0x099B)

6.3.49.67.1 Data Low of VPLAN_DSI_VF_MODE[VP16] (0x097C + 2*VP16, VP16=0...15)

6.3.49.67.2 Data High of VPLAN_DSI_VF_MODE[VP16] (0x097D + 2*VP16, VP16=0...15)

6.3.49.68 GLCOMM_QUANTA_PROF (0x099C - 0x09BE)

6.3.49.68.1 Starting Address Low at GLCOMM_QUANTA_PROF (0x099C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLCOMM_QUANTA_PROF	0x2D2D68	
3:0	Type	0x2	

6.3.49.68.2 Starting Address High at GLCOMM_QUANTA_PROF (0x099D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLCOMM_QUANTA_PROF		

6.3.49.68.3 Attributes at GLCOMM_QUANTA_PROF (0x099E)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x18	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.68.4 Data Low of GLCOMM_QUANTA_PROF[n] (0x099F + 2*n, n=0...15)

6.3.49.68.5 Data High of GLCOMM_QUANTA_PROF[n] (0x09A0+ 2*n, n=0...15)

6.3.49.69 GLCOMM_PKT_SHAPER_PROF (0x09BF - 0x09CE)

6.3.49.69.1 Data Low of GLCOMM_PKT_SHAPER_PROF[n] (0x09BF + 2*n, n=0...7)

6.3.49.69.2 Data High of GLCOMM_PKT_SHAPER_PROF[n] (0x09C0 + 2*n, n=0...7)

6.3.49.70 Reserved (0x09CF - 0x09DD)

6.3.49.71 GL_MDCK_CFG1_TX_PQM (0x09DE - 0x09E2)

6.3.49.71.1 Starting Address Low at GL_MDCK_CFG1_TX_PQM (0x09DE)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GL_MDCK_CFG1_TX_PQM	0x2D2DF4	
3:0	Type	0x2	

6.3.49.71.2 Starting Address High at GL_MDCK_CFG1_TX_PQM (0x09DF)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GL_MDCK_CFG1_TX_PQM		

6.3.49.71.3 Attributes at GL_MDCK_CFG1_TX_PQM (0x09E0)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.71.4 Data Low of GL_MDCK_CFG1_TX_PQM (0x09E1)

6.3.49.71.5 Data High of GL_MDCK_CFG1_TX_PQM (0x09E2)

6.3.49.72 Reserved (0x09E3 - 0x09E4)

6.3.49.73 GL_MDCK_EN_TX_PQM (0x09E5 - 0x09E6)

6.3.49.73.1 Data Low of GL_MDCK_EN_TX_PQM (0x09E5)

6.3.49.73.2 Data High of GL_MDCK_EN_TX_PQM (0x09E6)

6.3.49.74 Reserved (0x0E7 - 0x2A2B)

6.3.49.75 GLQF_FD_SIZE (0x2A2C - 0x2A2F)

6.3.49.75.1 Address Low at GLQF_FD_SIZE (0x2A2C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLQF_FD_SIZE	0x460010	
3:0	Type	0x1	

6.3.49.75.2 Address High at GLQF_FD_SIZE (0x2A2D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLQF_FD_SIZE		

6.3.49.75.3 Data Low of GLQF_FD_SIZE (0x2A2E)

6.3.49.75.4 Data High of GLQF_FD_SIZE (0x2A2F)

6.3.49.76 GLHMC_PFPESDPART (0x2A30 - 0x2A42)

6.3.49.76.1 Starting Address Low at GLHMC_PFPESDPART (0x2A30)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLHMC_PFPESDPART	0x520880	
3:0	Type	0x2	

6.3.49.76.2 Starting Address High at GLHMC_PFPESDPART (0x2A41)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLHMC_PFPESDPART		

6.3.49.76.3 Attributes at GLHMC_PFPESDPART (0x2A32)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x8	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.76.4 Data Low of GLHMC_PFPESDPART[n] (0x2A33 + 2*n, n=0...7)

6.3.49.76.5 Data High of GLHMC_PFPESDPART[n] (0x2A34 + 2*n, n=0...7)

6.3.49.77 Reserved (0x2A43 - 0x2A46)

6.3.49.78 GLHMC_VFSDPART (0x2A47 - 0x2A89)

6.3.49.78.1 Starting Address Low at GLHMC_VFSDPART (0x2A47)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLHMC_VFSDPART	0x528800	
3:0	Type	0x2	

6.3.49.78.2 Starting Address High at GLHMC_VFSDPART (0x2A48)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLHMC_VFSDPART		

6.3.49.78.3 Attributes at GLHMC_VFSDPART (0x2A49)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x20	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.78.4 Data Low of GLHMC_VFSDPART[n] (0x2A4A + 2*n, n=0...31)

6.3.49.78.5 Data High of GLHMC_VFSDPART[n] (0x2A4B + 2*n, n=0...31)

6.3.49.79 GLCOMM_MIN_MAX_PKT (0x2A8A - 0x2A8D)

6.3.49.79.1 Address Low at GLCOMM_MIN_MAX_PKT (0x2A8A)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLCOMM_MIN_MAX_PKT	0xFC064	
3:0	Type	0x1	

6.3.49.79.2 Address High at GLCOMM_MIN_MAX_PKT (0x2A8B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLCOMM_MIN_MAX_PKT		

6.3.49.79.3 Data Low of GLCOMM_MIN_MAX_PKT (0x2A8C)

6.3.49.79.4 Data High of GLCOMM_MIN_MAX_PKT (0x2A8D)

6.3.49.80 Reserved (0x2A8E - 0x2A8F)

6.3.49.81 DPU_IMEM Attributes (0x2A90)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x400	
4:3	Skip	00b	
2:0	Width	010b	

6.3.49.82 Reserved (0x2A91 - 0x2A92)

6.3.49.83 DPU_IMEM Data (0x2A93)

Raw data module length: 8192 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.49.84 Reserved (0x4A93 - 0x4A94)

6.3.49.85 DPU_RECIPE_ADDRESS Attributes (0x4A95)

Part of a Type 3 structure to load the DPU_RECIPE_ADDRESS.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x100	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.86 Reserved (0x4A96 - 0x4A97)

6.3.49.87 DPU_RECIPE_ADDRESS Data (0x4A98)

Raw data module length: 512 words.

Part of a Type 3 structure to load the DPU_RECIPE_ADDRESS.

6.3.49.88 Reserved (0x4C98 - 0x4C99)

6.3.49.89 DPU_RECIPE_CAM Attributes (0x4C9A)

Part of a Type 3 structure to load the DPU_RECIPE_CAM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x100	
4:3	Skip	00b	
2:0	Width	001b	

6.3.49.90 Reserved (0x4C9B - 0x4C9C)

6.3.49.91 DPU_RECIPE_CAM Data (0x4C9D)

Raw data module length: 1024 words.

Part of a Type 3 structure to load the DPU_RECIPE_CAM.

6.3.49.92 Reserved (0x509D - 0x509E)

6.3.49.93 DPU_RECIPE_MASK Attributes (0x509F)

Part of a Type 3 structure to load the DPU_RECIPE_MASK.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x008	
4:3	Skip	00b	
2:0	Width	001b	

6.3.49.94 Reserved (0x50A0 - 0x50A1)

6.3.49.95 DPU_RECIPE_MASK Data (0x509A2)

Raw data module length: 32 words.

Part of a Type 3 structure to load the DPU_RECIPE_MASK.

6.3.49.96 Reserved (0x50C2 - 0x50C3)

6.3.49.97 ANA_IMEM Attributes (0x50C4)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	001b	

6.3.49.98 Reserved (0x50C5 - 0x50C6)

6.3.49.99 ANA_IMEM Data (0x50C7)

Raw data module length: 160 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.49.100 Reserved (0x5167 - 0x5168)

6.3.49.101 ANA_NH Attributes (0x5169)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.102 Reserved (0x516A - 0x516B)

6.3.49.103 ANA_NH Data (0x516C)

Raw data module length: 80 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.49.104 Reserved (0x51BC - 0x51BD)

6.3.49.105 ANA_SKIP Attributes (0x51BE)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.106 Reserved (0x51BF - 0x51C0)

6.3.49.107 ANA_SKIP Data (0x51C1)

Raw data module length: 80 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.49.108 Reserved (0x5211 - 0x5212)

6.3.49.109 ANA_REPLACE Attributes (0x5213)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.110 Reserved (0x5214 - 0x5215)

6.3.49.111 ANA_REPLACE Data (0x5216)

Raw data module length: 80 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.49.112 Reserved (0x5266 - 0x5267)

6.3.49.113 ANA_MERGE Attributes (0x5268)

Part of a Type 3 structure to load the DPU_IMEM.

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x28	
4:3	Skip	00b	
2:0	Width	000b	

6.3.49.114 Reserved (0x5269 - 0x526A)

6.3.49.115 ANA_MERGE Data (0x526B)

Raw data module length: 80 words.

Part of a Type 3 structure to load the DPU_IMEM.

6.3.50 GLOBR Registers Auto-Load Module Section

Default setup to registers that load on GLOBR events.

Table 6-56. GLOBR Registers Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.50.1
0x0001 - 0x0004	NVM contents for GLGEN_MAC_LINK_TOPO	6.3.50.2
0x0005 - 0x0017	Reserved	6.3.50.3
0x0018 - 0x002A	NVM contents for PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE	6.3.50.4
0x002B - 0x003A	NVM contents for PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE	6.3.50.5
0x003B - 0x004A	NVM contents for PRTMAC_HSEC_CTL_RX_ENABLE_GCP	6.3.50.6
0x004B - 0x005D	NVM contents for PRTMAC_HSEC_CTL_RX_CHECK_UCAST_GCP	6.3.50.7
0x005E - 0x006D	NVM contents for PRTMAC_HSEC_CTL_RX_PAUSE_DA_UCAST_PART1	6.3.50.8
0x006E - 0x007D	NVM contents for PRTMAC_HSEC_CTL_RX_PAUSE_DA_UCAST_PART2	6.3.50.9
0x007E - 0x00E6	Reserved	6.3.50.10
0x00E7 - 0x00F9	NVM contents for PRTMAC_HSEC_CTL_RX_ENABLE_GPP	6.3.50.11
0x00FA - 0x010C	Reserved	6.3.50.12
0x010D - 0x011F	NVM contents for PRTMAC_HSEC_CTL_RX_ENABLE_PPP	6.3.50.13
0x0120 - 0x0132	Reserved	6.3.50.14
0x0133 - 0x0145	NVM contents for PRTMAC_HSEC_CTL_RX_FORWARD_CONTROL	6.3.50.15
0x0146 - 0x01D5	NVM contents for PRTMAC_HSEC_CTL_TX_PAUSE_QUANTA	6.3.50.16

4:3	Skip	00b	
2:0	Width	000b	

6.3.50.28 Data Low of PRTGEN_CNF2, for PRT[0] (0x03A1)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.29 Data High of PRTGEN_CNF2, for PRT[0] (0x03A2)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.30 Data Low of PRTGEN_CNF2, for PRT[1] (0x03A3)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.31 Data High of PRTGEN_CNF2, for PRT[1] (0x03A4)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.32 Data Low of PRTGEN_CNF2, for PRT[2] (0x03A5)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.33 Data High of PRTGEN_CNF2, for PRT[2] (0x03A6)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.34 Data Low of PRTGEN_CNF2, for PRT[3] (0x03A7)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.35 Data High of PRTGEN_CNF2, for PRT[3] (0x03A8)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.36 Data Low of PRTGEN_CNF2, for PRT[4] (0x03A9)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.37 Data High of PRTGEN_CNF2, for PRT[4] (0x03AA)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.38 Data Low of PRTGEN_CNF2, for PRT[5] (0x03AB)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.39 Data High of PRTGEN_CNF2, for PRT[5] (0x03AC)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.40 Data Low of PRTGEN_CNF2, for PRT[6] (0x03AD)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.41 Data High of PRTGEN_CNF2, for PRT[6] (0x03AE)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.50.42 Data Low of PRTGEN_CNF2, for PRT[7] (0x03AF)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	ACTIVATE_PORT_LINK	1b	When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability.

6.3.50.43 Data High of PRTGEN_CNF2, for PRT[7] (0x03B0)

This register contains configuration per Ethernet port loaded from NVM.

Bits	Field Name	Default NVM Value	Description
15:0	Reserved		Reserved.

6.3.51 PE CORER Registers Section

Default setup to registers and internal memories that load on CORER events for PE.

Table 6-57. PE CORER Registers Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.51.1
0x0001 - 0x0017	Reserved	6.3.51.2

6.3.51.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: PE CORER Registers -> Module Length Last Section -> Word: PE CORER Registers -> Reserved

6.3.51.2 Reserved (0x0001 - 0x0017)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Subtype	0x0	
3:0	Type	0xF	

6.3.52.3 CDF CFIO West - Type F Word 1 (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15	R	0b	
14:12	TAG	000b	
11	AL	0b	
10:8	BAR	000b	
7:4	Select ID	0x7	
3:0	Opcode	0x7	

6.3.52.4 CDF CFIO West - Type F Word 2 (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Second Byte En	0x0	
11:8	First Byte En	0x2	
7:0	Function ID	0x0	

6.3.52.5 GBE_SDP_TIMESYNC0 Address Low (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x800	
3:0	Type	0x1	

6.3.52.6 GBE_SDP_TIMESYNC0 Address High (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.7 GBE_SDP_TIMESYNC0 Data Low (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.8 GBE_SDP_TIMESYNC0 Data High (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.9 GBE_SDP_TIMESYNC1 Address Low (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x810	
3:0	Type	0x1	

6.3.52.10 GBE_SDP_TIMESYNC1 Address High (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.11 GBE_SDP_TIMESYNC1 Data Low (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.12 GBE_SDP_TIMESYNC1 Data High (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.13 GBE_SDP_TIMESYNC2 Address Low (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x820	
3:0	Type	0x1	

6.3.52.14 GBE_SDP_TIMESYNC2 Address High (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.15 GBE_SDP_TIMESYNC2 Data Low (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.16 GBE_SDP_TIMESYNC2 Data High (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.17 GBE_SDP_TIMESYNC3 Address Low (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x830	
3:0	Type	0x1	

6.3.52.18 GBE_SDP_TIMESYNC3 Address High (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.19 GBE_SDP_TIMESYNC3 Data Low (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.20 GBE_SDP_TIMESYNC3 Data High (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.21 GBE0_I2C_CLK Address Low (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x840	
3:0	Type	0x1	

6.3.52.22 GBE0_I2C_CLK Address High (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.23 GBE0_I2C_CLK Data Low (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.24 GBE0_I2C_CLK Data High (0x0017)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.25 GBE0_I2C_DATA Address Low (0x0018)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x850	
3:0	Type	0x1	

6.3.52.26 GBE0_I2C_DATA Address High (0x0019)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.27 GBE0_I2C_DATA Data Low (0x001A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.28 GBE0_I2C_DATA Data High (0x001B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.29 GBE1_I2C_CLK Address Low (0x001C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x860	
3:0	Type	0x1	

6.3.52.30 GBE1_I2C_CLK Address High (0x001D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.31 GBE1_I2C_CLK Data Low (0x001E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.32 GBE1_I2C_CLK Data High (0x001F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.33 GBE1_I2C_DATA Address Low (0x0020)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x870	
3:0	Type	0x1	

6.3.52.34 GBE1_I2C_DATA Address High (0x0021)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.35 GBE1_I2C_DATA Data Low (0x0022)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.36 GBE1_I2C_DATA Data High (0x0023)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.37 GBE2_I2C_CLK Address Low (0x0024)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x880	
3:0	Type	0x1	

6.3.52.38 GBE2_I2C_CLK Address High (0x0025)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.39 GBE2_I2C_CLK Data Low (0x0026)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.40 GBE2_I2C_CLK Data High (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.41 GBE2_I2C_DATA Address Low (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x890	
3:0	Type	0x1	

6.3.52.42 GBE2_I2C_DATA Address High (0x0029)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.43 GBE2_I2C_DATA Data Low (0x002A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.44 GBE2_I2C_DATA Data High (0x002B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.45 GBE3_I2C_CLK Address Low (0x002C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8A0	
3:0	Type	0x1	

6.3.52.46 GBE3_I2C_CLK Address High (0x002D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.47 GBE3_I2C_CLK Data Low (0x002E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.48 GBE3_I2C_CLK Data High (0x002F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.49 GBE3_I2C_DATA Address Low (0x0030)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8B0	
3:0	Type	0x1	

6.3.52.50 GBE3_I2C_DATA Address High (0x0031)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.51 GBE3_I2C_DATA Data Low (0x0032)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.52 GBE3_I2C_DATA Data High (0x0033)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.53 GBE0_LED0 Address Low (0x0034)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x0C8	
3:0	Type	0x1	

6.3.52.54 GBE0_LED0 Address High (0x0035)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.55 GBE0_LED0 Data Low (0x0036)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.56 GBE0_LED0 Data High (0x0037)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.57 GBE0_LED1 Address Low (0x0038)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8D0	
3:0	Type	0x1	

6.3.52.58 GBE0_LED1 Address High (0x0039)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.59 GBE0_LED1 Data Low (0x003A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.60 GBE0_LED1 Data High (0x003B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.61 GBE0_LED2 Address Low (0x003C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8E0	
3:0	Type	0x1	

6.3.52.62 GBE0_LED2 Address High (0x003D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.63 GBE0_LED2 Data Low (0x003E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.64 GBE0_LED2 Data High (0x003F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.65 GBE1_LED0 Address Low (0x0040)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8F0	
3:0	Type	0x1	

6.3.52.66 GBE1_LED0 Address High (0x0041)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.67 GBE1_LED0 Data Low (0x0042)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.68 GBE1_LED0 Data High (0x0043)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.69 GBE1_LED1 Address Low (0x0044)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x900	
3:0	Type	0x1	

6.3.52.70 GBE1_LED1 Address High (0x0045)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.71 GBE1_LED1 Data Low (0x0046)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.72 GBE1_LED1 Data High (0x0047)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.73 GBE1_LED2 Address Low (0x0048)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x910	
3:0	Type	0x1	

6.3.52.74 GBE1_LED2 Address High (0x0049)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.75 GBE1_LED2 Data Low (0x004A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.76 GBE1_LED2 Data High (0x004B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.77 GBE2_LED0 Address Low (0x004C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x920	
3:0	Type	0x1	

6.3.52.78 GBE2_LED0 Address High (0x004D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.79 GBE2_LED0 Data Low (0x004E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.80 GBE2_LED0 Data High (0x004F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.81 GBE2_LED1 Address Low (0x0050)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x930	
3:0	Type	0x1	

6.3.52.82 GBE2_LED1 Address High (0x0051)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.83 GBE2_LED1 Data Low (0x0052)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.84 GBE2_LED1 Data High (0x0053)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.85 GBE2_LED2 Address Low (0x0054)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x940	
3:0	Type	0x1	

6.3.52.86 GBE2_LED2 Address High (0x0055)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.87 GBE2_LED2 Data Low (0x0056)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.88 GBE2_LED2 Data High (0x0057)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.89 GBE3_LED0 Address Low (0x0058)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x950	
3:0	Type	0x1	

6.3.52.90 GBE3_LED0 Address High (0x0059)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.91 GBE3_LED0 Data Low (0x005A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.108 GBE_SMB_DATA Data High (0x006B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.109 GBE_SMB_ALRT_N Address Low (0x006C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xA30	
3:0	Type	0x1	

6.3.52.110 GBE_SMB_ALRT_N Address High (0x006D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.111 GBE_SMB_ALRT_N Data Low (0x006E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.112 GBE_SMB_ALRT_N Data High (0x006F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.113 UART1_RXD Address Low (0x0070)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xAE0	
3:0	Type	0x1	

6.3.52.114 UART1_RXD Address High (0x0071)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.115 UART1_RXD Data Low (0x0072)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.116 UART1_RXD Data High (0x0073)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.117 UART1_TXD Address Low (0x0074)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xAF0	
3:0	Type	0x1	

6.3.52.118 UART1_TXD Address High (0x0075)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.119 UART1_TXD Data Low (0x0076)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.120 UART1_TXD Data High (0x0077)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.121 CPU_GP_0 Address Low (0x0078)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xB00	
3:0	Type	0x1	

6.3.52.122 CPU_GP_0 Address High (0x0079)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.123 CPU_GP_0 Data Low (0x007A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.124 CPU_GP_0 Data High (0x007B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.125 GBE_MNG_I2C_CLK Address Low (0x007C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xC50	
3:0	Type	0x1	

6.3.52.126 GBE_MNG_I2C_CLK Address High (0x007D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.127 GBE_MNG_I2C_CLK Data Low (0x007E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.128 GBE_MNG_I2C_CLK Data High (0x007F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.129 GBE_MNG_I2C_DATA Address Low (0x0080)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0xC60	
3:0	Type	0x1	

6.3.52.130 GBE_MNG_I2C_DATA Address High (0x0081)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.131 GBE_MNG_I2C_DATA Data Low (0x0082)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.132 GBE_MNG_I2C_DATA Data High (0x0083)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.133 NCSI_RXD0 Address Low (0x0084)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x980	
3:0	Type	0x1	

6.3.52.134 NCSI_RXD0 Address High (0x0085)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.135 NCSI_RXD0 Data Low (0x0086)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.136 NCSI_RXD0 Data High (0x0087)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.137 NCSI_RXD1 Address Low (0x0088)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9A0	
3:0	Type	0x1	

6.3.52.138 NCSI_RXD1 Address High (0x0089)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.139 NCSI_RXD1 Data Low (0x008A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.140 NCSI_RXD1 Data High (0x008B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.141 NCSI_CRS_DV Address Low (0x008C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9B0	
3:0	Type	0x1	

6.3.52.142 NCSI_CRS_DV Address High (0x008D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.143 NCSI_CRS_DV Data Low (0x008E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.144 NCSI_CRS_DV Data High (0x008F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.145 NCSI_ARB_IN Address Low (0x0090)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9C0	
3:0	Type	0x1	

6.3.52.146 NCSI_ARB_IN Address High (0x0091)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.147 NCSI_ARB_IN Data Low (0x0092)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.148 NCSI_ARB_IN Data High (0x0093)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.149 NCSI_TX_EN Address Low (0x0094)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9D0	
3:0	Type	0x1	

6.3.52.150 NCSI_TX_EN Address High (0x0095)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.151 NCSI_TX_EN Data Low (0x0096)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.152 NCSI_TX_EN Data High (0x0097)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.153 NCSI_TXD0 Address Low (0x0098)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9E0	
3:0	Type	0x1	

6.3.52.154 NCSI_TXD0 Address High (0x0099)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.155 NCSI_TXD0 Data Low (0x009A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.156 NCSI_TXD0 Data High (0x009B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.157 NCSI_TXD1 Address Low (0x009C)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x9F0

15:0	Address High	0x0	

6.3.52.214 GPIO6 Data Low (0x00D5)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.215 GPIO6 Data High (0x00D6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.216 GPIO7 Address Low (0x00D7)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x880	
3:0	Type	0x1	

6.3.52.217 GPIO7 Address High (0x00D8)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.218 GPIO7 Data Low (0x00D9)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.219 GPIO7 Data High (0x00DA)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.220 GPIO8 Address Low (0x00DB)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x890	
3:0	Type	0x1	

6.3.52.221 GPIO8 Address High (0x00DC)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.222 GPIO8 Data Low (0x00DD)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.223 GPIO8 Data High (0x00DE)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.224 GPIO9 Address Low (0x00DF)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8A0	
3:0	Type	0x1	

6.3.52.225 GPIO9 Address High (0x00E0)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.226 GPIO9 Data Low (0x00E1)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.227 GPIO9 Data High (0x00E2)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.228 GPIO10 Address Low (0x00E3)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8B0	
3:0	Type	0x1	

6.3.52.229 GPIO10 Address High (0x00E4)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.230 GPIO10 Data Low (0x00E5)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.231 GPIO10 Data High (0x00E6)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.232 GPIO11 Address Low (0x00E7)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8C0	
3:0	Type	0x1	

6.3.52.233 GPIO11 Address High (0x00E8)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.234 GPIO11 Data Low (0x00E9)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.235 GPIO11 Data High (0x00EA)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.236 GPIO12 Address Low (0x00EB)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Address Low	0x8D0	
3:0	Type	0x1	

6.3.52.237 GPIO12 Address High (0x00EC)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Address High	0x0	

6.3.52.238 GPIO12 Data Low (0x00ED)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data Low	0x0700	Valid values are: 0x0700 = Function 1 0x0B00 = Function 2 0x0F00 = Function 3 0x1300 = Function 4

6.3.52.239 GPIO12 Data High (0x00EE)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Data High	0x0	

6.3.52.240 Manual Additions (0x00EF)

Raw data module length: variable

6.3.53 EMP SR Settings Module Header Section

This section contains the modes of operation of the EMP which are be stored in the Shadow RAM.

Table 6-59. EMP SR Settings Module Header Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Header	6.3.53.1
0x0001	SMBus Slave Addresses	6.3.53.2
0x0002	SMBus Slave Addresses 2	6.3.53.3
0x0003	SMBus Slave Addresses 3	6.3.53.4
0x0004	SMBus Slave Addresses 4	6.3.53.5
0x0005	OEM Capabilities	6.3.53.6
0x0006	OEM Technologies Enabled	6.3.53.7
0x0007	SR PF Allocations Pointer	6.3.53.8
0x0008	Max PF and VF per Port	6.3.53.9
0x0009	PF LAN Device ID	6.3.53.10
0x000A	PF SAN Device ID	6.3.53.11
0x000B	PF iSCSI Device ID	6.3.53.12
0x000C	PF RDMA Device ID	6.3.53.13
0x000D	VF LAN Device ID	6.3.53.14
0x000E	VF SAN Device ID	6.3.53.15
0x000F	VF iSCSI Device ID	6.3.53.16
0x0010	VF RDMA Device ID	6.3.53.17
0x0011	PF LAN Subsystem ID	6.3.53.18
0x0012	PF SAN Subsystem ID	6.3.53.19
0x0013	PF iSCSI Subsystem ID	6.3.53.20
0x0014	PF RDMA Subsystem ID	6.3.53.21
0x0015	VF LAN Subsystem ID	6.3.53.22
0x0016	VF SAN Subsystem ID	6.3.53.23
0x0017	VF iSCSI Subsystem ID	6.3.53.24
0x0018	VF RDMA Subsystem ID	6.3.53.25
0x0019 + 1*n, n=0...7	PFGEN_STATE	6.3.53.26
0x0021	Reserved	6.3.53.27
0x0022	Features Enable	6.3.53.28
0x0023	LLDP Configuration Pointer	6.3.53.29
0x0024	Allowed SB Targets	6.3.53.30
0x0025	Allow 64 Bits Transactions	6.3.53.31
0x0026	Allowed Opcodes	6.3.53.32

6.3.53.1 Section Header (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 1 First Section -> Word: EMP SR Settings Module Header -> Section Header Last Section -> Word: EMP SR Settings Module Header -> Allowed Opcodes Section length in words.

6.3.53.2 SMBus Slave Addresses (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:9	SMBus 1 Slave Address	0x4A	Dual address mode only.
8	Reserved	0b	Reserved.
7:1	SMBus 0 Slave Address	0x49	
0	Reserved	0b	Reserved.

6.3.53.3 SMBus Slave Addresses 2 (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:9	SMBus 3 Slave Address	0x4C	
8	Reserved	0b	Reserved.
7:1	SMBus 2 Slave Address	0x4B	
0	Reserved	0b	Reserved.

6.3.53.4 SMBus Slave Addresses 3 (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:9	SMBus 5 Slave Address	0x4E	Dual address mode only.
8	Reserved	0b	Reserved.
7:1	SMBus 4 Slave Address	0x4D	
0	Reserved	0b	Reserved.

6.3.53.5 SMBus Slave Addresses 4 (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:9	SMBus 7 Slave Address	0x50	
8	Reserved	0b	Reserved.
7:1	SMBus 6 Slave Address	0x4F	
0	Reserved	0b	Reserved.

6.3.53.6 OEM Capabilities (0x0005)

Defines the OEM technologies supported in this device.

Bit(s)	Field Name	Default NVM Value	Description
15:7	Reserved	0x0	Reserved.
6	OCBB over MCTP Capable	0b	HP OCBB over MCTP Capable enable. 0b = Disabled 1b = Capable
5	HP PLDM support Capable	0b	HP PLDM support Capable. 0b = Disabled 1b = Capable
4:0	Reserved	0x0	Reserved.

6.3.53.7 OEM Technologies Enabled (0x0006)

Defines the OEM technologies enabled in this device.

Bit(s)	Field Name	Default NVM Value	Description
15:14	Reserved	00b	Reserved.
13	Anti Rollback Feature Enable	0b	Anti Rollback feature enable. 0b = Disabled 1b = Enabled
12	OCBB over MCTP	0b	HP OCBB enable. 0b = Disabled 1b = Enabled
11	HP PLDM Support	0b	Enable PLDM support. 0b = Disabled 1b = Enabled
10:0	Reserved	0x0	Reserved.

6.3.53.8 SR PF Allocations Pointer (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF Allocations Pointer	0xFFFF	Points to SR PF Allocations Section. For SR PF Allocations inner structure, see Section 6.3.54.

6.3.53.9 Max PF and VF per Port (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Max VF per PF	0x80	Max number of VFs allocated to a PF.
7:3	Reserved	0x0	Reserved.
2:0	Max PF per Port	010b	Valid values are: 0x0 = 1 PF per Port 0x1 = 2 PFs per Port 0x2 = 4 PFs per Port 0x3 = 8 PFs per Port 0x4 = 16 PFs per Port

6.3.53.10 PF LAN Device ID (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF LAN Device ID	0x1888	

6.3.53.11 PF SAN Device ID (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF SAN Device ID	0x1888	

6.3.53.12 PF iSCSI Device ID (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF iSCSI Device ID	0x1888	

6.3.53.13 PF RDMA Device ID (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF RDMA Device ID	0x1888	

6.3.53.14 VF LAN Device ID (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF LAN Device ID	0x1889	

6.3.53.15 VF SAN Device ID (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF SAN Device ID	0x1889	

6.3.53.16 VF iSCSI Device ID (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF iSCSI Device ID	0x1889	

6.3.53.17 VF RDMA Device ID (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF RDMA Device ID	0x1889	

6.3.53.18 PF LAN Subsystem ID (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF LAN Subsystem ID	0x0	

6.3.53.19 PF SAN Subsystem ID (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF SAN Subsystem ID	0x0	

6.3.53.20 PF iSCSI Subsystem ID (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF iSCSI Subsystem ID	0x0	

6.3.53.21 PF RDMA Subsystem ID (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PF RDMA Subsystem ID	0x0	

6.3.53.22 VF LAN Subsystem ID (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF LAN Subsystem ID	0x0	

6.3.53.23 VF SAN Subsystem ID (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF SAN Subsystem ID	0x0	

6.3.53.24 VF iSCSI Subsystem ID (0x0017)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF iSCSI Subsystem ID	0x0	

6.3.53.25 VF RDMA Subsystem ID (0x0018)

Bit(s)	Field Name	Default NVM Value	Description
15:0	VF RDMA Subsystem ID	0x0	

6.3.53.26 PFGEN_STATE[n] (0x0019 + 1*n, n=0...7)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11	PFGEN_STATE[1 + 2*n].PFSCEN	0b	
10	PFGEN_STATE[1 + 2*n].PFLINKEN	1b	
9	PFGEN_STATE[1 + 2*n].PFFCEN	1b	
8	PFGEN_STATE[1 + 2*n].PFPEEN	0b	
7:4	Reserved	0x0	Reserved.
3	PFGEN_STATE[0 + 2*n].PFSCEN	0b	
2	PFGEN_STATE[0 + 2*n].PFLINKEN	1b	
1	PFGEN_STATE[0 + 2*n].PFFCEN	1b	
0	PFGEN_STATE[0 + 2*n].PFPEEN	0b	

6.3.53.27 Reserved (0x0021)

6.3.53.28 Features Enable (0x0022)

Describes support for various features.

Bit(s)	Field Name	Default NVM Value	Description
15	PHY 2 Autoload Enable	1b	PHY Auto-load Enable.
14	PHY 1 Autoload Enable	1b	PHY Auto-load Enable.
13	PHY 0 Autoload Enable	1b	PHY Auto-load Enable.
12	PXE Mode No-Drop Policy Supported	0b	The value indicates if the PXE Mode No-Drop policy is supported. 0b = No support. 1b = PXE Mode No-Drop is supported. This mode can be enabled by the Configure No-Drop Policy AQ command. ***Note:*** This field is preserved by Intel NVM Update Tool.
11:1	Reserved	0x0	Reserved.
0	Non-BTS Switch mode	0b	non-BTS mode. ***Note:*** This field is preserved by Intel NVM Update Tool.

6.3.53.29 LLDP Configuration Pointer (0x0023)

Bit(s)	Field Name	Default NVM Value	Description
15:0	LLDP Configuration Pointer	0xFFFF	Points to LLDP Configuration Section. For LLDP Configuration inner structure, see Section 6.3.55.

6.3.53.30 Allowed SB Targets (0x0024)

The list of allowed sideband targets.

Bits	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11	SPI	0b	
10	FC	0b	
9	DSA	0b	
8	LCB	1b	
7	PCIW	1b	
6	CAR	1b	
5	IO Widget	1b	
4:3	Reserved	00b	Reserved.
2	ETHW	1b	
1:0	Reserved	0b	Reserved.

6.3.53.31 Allow 64 Bits Transactions (0x0025)

Block/Allow 64 bits transactions.

Bits	Field Name	Default NVM Value	Description
15:1	Reserved		Reserved.
0	Allow 64 Bits Transactions	0b	

6.3.53.32 Allowed Opcodes (0x0026)

The list of allowed sideband opcodes.

Bits	Field Name	Default NVM Value	Description
15	Reserved	0b	Reserved.
14	IOWr - IO Register Write (Non Posted)	0b	
13	IOWr - IO Register Write (Posted)	0b	
12	IORd - IO Register Read (Non Posted)	0b	
11	CfgWr - Config Register Write (Non Posted)	1b	
10	CfgWr - Config Register Write (Posted)	0b	
9	CfgRd - Config Register Read (Non Posted)	1b	
8	CRRd - Read Private Control Register (Non Posted)	0b	
7	CRWr - Write Private Control Register (Non Posted)	0b	
6	CRWr - Write Private Control Register (Posted)	0b	
5	MBWr - Multiple Block Write (Non Posted)	0b	
4	MBWr - Multiple Block Write (Posted)	0b	
3	MBRd - Multiple Block Read (Non Posted)	0b	
2	MWr - Register Write (Non Posted)	0b	
1	MWr - Register Write (Posted)	1b	
0	Mrd - Register Read (Non Posted)	1b	

6.3.54 SR PF Allocations Section

This section contains the modes of operation of the EMP which are be stored in the Shadow RAM.

Table 6-60. SR PF Allocations Section Summary Table

Word Offset	Description	Section Reference
0x0000	Header	6.3.54.1
0x0001 + 2*n, n=0...7	PF Flags	6.3.54.2
0x0002 + 2*n, n=0...7	PF BW	6.3.54.3
0x0011 + 2*n, n=0...23	PF Allocations - Type	6.3.54.4
0x0012 + 2*n, n=0...23	PF Allocations - Value	6.3.54.5

6.3.54.1 Header (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Block Length		Length in: 2 Bytes unit - 1 First Section -> Word: SR PF Allocations -> Header Last Section -> Word: SR PF Allocations -> PF Allocations - Value Size of section.

6.3.54.2 PF Flags[n] (0x0001 + 2*n, n=0...7)

Bit(s)	Field Name	Default NVM Value	Description
15:1	Reserved	0x0	Reserved.
0	Load PF MAC Address	1b	Defines if the LAN MAC Address of the PF should be added to the filtering table. If this bit is set, only packets that passes the MAC and if needed, the STag are forwarded to the PF.

6.3.54.3 PF BW[n] (0x0002 + 2*n, n=0...7)

Bit(s)	Field Name	Default NVM Value	Description
15:8	PF Max BW	0x64	This field contains the Maximum Tx bandwidth allocation of the specified partition expressed in % of the Maximum physical port link speed. The % value ranges from 0 to 100.
7:0	PF Min BW	0x0	This field contains the Minimum Tx bandwidth allocation of the specified partition expressed in % of the Maximum physical port link speed. The % value ranges from 0 to 100.

6.3.54.4 PF Allocations - Type[n] (0x0011 + 2*n, n=0...23)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Type	0xFFFF	Type array.

6.3.54.5 PF Allocations - Value[n] (0x0012 + 2*n, n=0...23)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Value	0x0	Value array.

6.3.55 LLDP Configuration Section

Default settings to the embedded LLDP agent.

Table 6-61. LLDP Configuration Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.55.1
0x0001	LLDP Admin Status 0	6.3.55.2
0x0002	LLDP Admin Status 1	6.3.55.3
0x0003	msgFastTx	6.3.55.4
0x0004	msgTxInterval	6.3.55.5
0x0005	LLDP Tx Parameters	6.3.55.6
0x0006	LLDP Initialization Timers	6.3.55.7
0x0007	ENDLESS_XOFF_THRESH	6.3.55.8
0x0008	DCBX Mode 0	6.3.55.9
0x0009	DCBX Mode 1	6.3.55.10

6.3.55.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: LLDP Configuration -> Section Length Last Section -> Word: LLDP Configuration -> DCBX Mode 1

6.3.55.2 LLDP Admin Status 0 (0x0001)

Defines status of LLDP agent. Each LAN port has independent status.

0: LLDP agent is disabled.
1: LLDP is configured for receives only.
2: LLDP is configured for transmits only.
3: Both receive and transmit enabled (default).

Bit(s)	Field Name	Default NVM Value	Description
15:12	Port 3	0x3	Defines status of LLDP agent. Applies to LAN Port 3.
11:8	Port 2	0x3	Defines status of LLDP agent. Applies to LAN Port 2.
7:4	Port 1	0x3	Defines status of LLDP agent. Applies to LAN Port 1.
3:0	Port 0	0x3	Defines status of LLDP agent. Applies to LAN Port 0.

6.3.55.3 LLDP Admin Status 1 (0x0002)

Defines status of LLDP agent. Each LAN port has independent status.

0: LLDP agent is disabled.
1: LLDP is configured for receives only.
2: LLDP is configured for transmits only.
3: Both receive and transmit enabled (default).

Bit(s)	Field Name	Default NVM Value	Description
15:12	Port 7	0x3	Defines status of LLDP agent. Applies to LAN Port 7.
11:8	Port 6	0x3	Defines status of LLDP agent. Applies to LAN Port 6.
7:4	Port 5	0x3	Defines status of LLDP agent. Applies to LAN Port 5.
3:0	Port 4	0x3	Defines status of LLDP agent. Applies to LAN Port 4.

6.3.55.4 msgFastTx (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	msgFastTx	0x1	Time interval in timer ticks (Seconds) between PDU transmits during fast transmits period.

6.3.55.5 msgTxInterval (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	msgTxInterval	0x1E	Is the time in timer ticks (Seconds) between transmissions during normal transmission.

6.3.55.6 LLDP Tx Parameters (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:8	txCreditMax	0x5	Determines maximum number of LLDPDUs that can be sent per second.
7:0	msgTxHold	0x4	Is used as a multiplier of *msgTxInterval* to determine the txTTL that is carried in the LLDP frames.

6.3.55.7 LLDP Initialization Timers (0x0006)

Timers used by LLDP agent during initialization and when to reinitialize. All times are in seconds.

Bit(s)	Field Name	Default NVM Value	Description
15:8	reinitDelay	0x2	This parameter indicates the amount of delay, in seconds, from when adminStatus becomes disabled until re-initialization is attempted.
7:0	txFastInit	0x4	This variable is used as the initial value for the txFast variable. This value determines the number of LLDPDUs that are transmitted during a fast transmission period.

6.3.55.8 ENDLESS_XOFF_THRESH (0x0007)

Define a time limit the firmware waits for XOFF condition during PFR flow. The time is defined in 1msec units. A possible default setting is 10msec (DCR175 - PFR XOFF deadlock prevention).

Bit(s)	Field Name	Default NVM Value	Description
15:0	ENDLESS_XOFF_THRESH	0xA	Define a time limit the firmware waits for XOFF condition during PFR flow. The time is defined in 1 ms units. A possible default setting is 10 ms.

6.3.55.9 DCBX Mode 0 (0x0008)

Defines per-PORT DCBX mode. Please note that each port could be configured independently regardless of the other ports configurations.

0: No DCBX is supported.
1: IEEE DCBX only.
2: CEE DCBX only.
3: Auto-Select, starting in IEEE (default).

Bit(s)	Field Name	Default NVM Value	Description
15:12	DCBX Port[3]	0x3	Port[3] DCBX mode.
11:8	DCBX Port[2]	0x3	Port[2] DCBX mode.
7:4	DCBX Port[1]	0x3	Port[1] DCBX mode.
3:0	DCBX Port[0]	0x3	Port[0] DCBX mode.

6.3.55.10 DCBX Mode 1 (0x0009)

Defines per-PORT DCBX mode. Please note that each port could be configured independently regardless of the other ports configurations.

0: No DCBX is supported.
1: IEEE DCBX only.
2: CEE DCBX only.
3: Auto-Select, starting in IEEE (default).

Bit(s)	Field Name	Default NVM Value	Description
15:12	DCBX Port[7]	0x3	Port[7] DCBX mode.
11:8	DCBX Port[6]	0x3	Port[6] DCBX mode.
7:4	DCBX Port[5]	0x3	Port[5] DCBX mode.
3:0	DCBX Port[4]	0x3	Port[4] DCBX mode.

6.3.56 GFID Module Section

Table 6-62. GFID Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Length	6.3.56.1
0x0001 + 1*n, n=0...17	GFID	6.3.56.2
0x0013 + 1*n, n=0...17	Original GFID	6.3.56.3

6.3.56.1 Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 2 First Section -> Word: GFID Module -> Length Last Section -> Word: GFID Module -> Original GFID

6.3.56.2 GFID[n] (0x0001 + 1*n, n=0...17)

Bit(s)	Field Name	Default NVM Value	Description
15:0	GFID	0x0	

6.3.56.3 Original GFID[n] (0x0013 + 1*n, n=0...17)

Bits	Field Name	Default NVM Value	Description
15:0	Original GFID	0x0	

6.3.57 Manageability Module Header Section

This section contains parameters related to the manageability functionality, such as connection type and others, It also points to subsections configuring the filters and the sideband interfaces.

Table 6-63. Manageability Module Header Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.57.1
0x0001	Common Manageability Parameters	6.3.57.2
0x0002	Common Manageability Parameters 2	6.3.57.3
0x0003	PLDM Control Word	6.3.57.4
0x0004	RDE Control Word	6.3.57.5
0x0005	OCP NIC Parameters	6.3.57.6
0x0006	Reserved	6.3.57.7
0x0007	Sideband Configuration Pointer	6.3.57.8
0x0008	Reserved	6.3.57.9
0x0009	Traffic Types Parameters	6.3.57.10
0x000A	OEM Section Pointer	6.3.57.11

6.3.57.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: Manageability Module Header -> Section Length Last Section -> Word: Manageability Module Header -> OEM Section Pointer

6.3.57.2 Common Manageability Parameters (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:11	Reserved	0x0	Reserved.
10:8	Manageability Pass-Through Mode	010b	Valid values are: 000b = None 010b = Pass-through (PT) mode
7:5	Reserved	000b	Reserved.
4	Force TCO Reset Disable	1b	If cleared, allows the BMC to do a Global reset of the device using the Force TCO SMBus or NC-SI commands. 0b = Enable Force TCO reset. 1b = Disable Force TCO reset.
3	Reserved	0b	Reserved.
2	OS2BMC Capable	1b	0b = Disable 1b = Enable.

Bit(s)	Field Name	Default NVM Value	Description
1:0	Reserved	0b	Reserved.

6.3.57.3 Common Manageability Parameters 2 (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15	LAN7_FTCO_ISOL_DIS	1b	Allow isolation of port 7 per BMC request. 0b = Enabled 1b = Disabled
14	LAN6_FTCO_ISOL_DIS	1b	Allow isolation of port 6 per BMC request. 0b = Enabled 1b = Disabled
13	LAN5_FTCO_ISOL_DIS	1b	Allow isolation of port 5 per BMC request. 0b = Enabled 1b = Disabled
12	LAN4_FTCO_ISOL_DIS	1b	Allow isolation of port 4 per BMC request. 0b = Enabled 1b = Disabled
11	Multi-Drop NC-SI	1b	0b = Point-to-point 1b = Multi-drop
10	Reserved	0b	Reserved.
9	EMP_LINK_ON	0b	Copy of the PRTPM_GC.EMP_LINK_ON bit for EMP use. 0b = Disabled 1b = Enabled
8	Redfish Support for PLDM (Type 6)	1b	0b = Disabled 1b = Enabled
7	FW Update over PLDM Support	0b	Support for PLDM base is defined as bit 7 | bit 6 (FW update or monitoring and control support). 0b = Disabled 1b = Enabled
6	PLDM Monitoring and Control	0b	Support for PLDM base is defined as bit 7 | bit 6 (FW update or monitoring and control support). 0b = Disabled 1b = Enabled
5	OEM over MCTP Support	0b	0b = Disabled 1b = Enabled
4	NC-SI over MCTP Support	0b	0b = Disabled 1b = Enabled
3	LAN3_FTCO_ISOL_DIS	1b	Allow isolation of port 3 per BMC request. 0b = Enabled 1b = Disabled
2	LAN2_FTCO_ISOL_DIS	1b	Allow isolation of port 2 per BMC request. 0b = Enabled 1b = Disabled
1	LAN1_FTCO_ISOL_DIS	1b	Allow isolation of port 1 per BMC request. 0b = Enabled 1b = Disabled
0	LAN0_FTCO_ISOL_DIS	1b	Allow isolation of port 0 per BMC request. 0b = Enabled 1b = Disabled

6.3.57.4 PLDM Control Word (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0x0	
7	Expose Power Sensors	1b	
6	Expose Thermal Trip State Sensors	1b	
5	Expose Configuration and Configuration Change	1b	
4	Expose Presence State	1b	
3	Expose Health State	1b	
2	Expose Thermal Sensors	1b	
1	Expose Link Speed	1b	
0	Expose Link Status	1b	

6.3.57.5 RDE Control Word (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Reserved	0x0	Reserved for other schemas including OEM schema extensions.
3	EthernetInterface v1.4.0	1b	Ethernet Interface schema.
2	Reserved	0b	Reserved.
1	VLanNetworkInterface v1.1.1	1b	VLAN Network Interface schema.
0	ACD	1b	ACD collection.

6.3.57.6 OCP NIC Parameters (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:7	Reserved	0x0	
6	FAN_ON_AUX Valid	0b	
5	FAN_ON_AUX Value	0b	
4:0	FAN_ON_AUX SDP	0x0	Valid only if FAN_ON_AUX valid = 1.

6.3.57.7 Reserved (0x0006)

6.3.57.8 Sideband Configuration Pointer (0x0007)

This module is l28 bytes and must be mapped in the first valid 4 KB sector of the Flash.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Sideband Configuration Pointer	0xFFFF	Points to Sideband Configuration Structure Section. For Sideband Configuration Structure inner structure, see Section 6.3.58.

6.3.57.9 Reserved (0x0008)

6.3.57.10 Traffic Types Parameters (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:14	Port 7 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 3. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
13:12	Port 6 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 3. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
11:10	Port 5 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 2. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
9:8	Port 4 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 2. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
7:6	Port 3 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 1. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
5:4	Port 2 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 1. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic
3:2	Port 1 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 0. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic

Bit(s)	Field Name	Default NVM Value	Description
1:0	Port 0 Traffic Types	01b	Defines which type of traffic can flow to and from primary BMC connection on port 0. The traffic types defined by this field are enabled by the Manageability Mode field and the OS2BMC Capable bit in the Common Manageability Parameters 1 NVM word. 00b = Reserved 01b = Network to BMC traffic only 10b = OS2BMC traffic only 11b = Both Network to BMC traffic and OS2BMC traffic

6.3.57.11 OEM Section Pointer (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	OEM Section Pointer	0xFFFF	Points to OEM Section Section. For OEM Section inner structure, see Section 6.3.59.

6.3.58 Sideband Configuration Structure Section

This section describes the setting of the different pass-through interfaces (SMBus, NC-SI, and MCTP).

Table 6-64. Sideband Configuration Structure Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.58.1
0x0001	SMBus Maximum Fragment Size	6.3.58.2
0x0002	SMBus Notification Timeout and Flags	6.3.58.3
0x0003	NC-SI Configuration 1	6.3.58.4
0x0004	NC-SI Configuration 2	6.3.58.5
0x0005	NC-SI Flow Control XOFF	6.3.58.6
0x0006	NC-SI Flow Control XON	6.3.58.7
0x0007	NC-SI HW Arbitration Configuration	6.3.58.8
0x0008 - 0x000C	Reserved	6.3.58.9
0x000D	OEM IANA	6.3.58.10
0x000E	NC-SI over MCTP Message Types	6.3.58.11
0x000F	NC-SI over MCTP Configuration	6.3.58.12
0x0010	MCTP Rate Limiter Config 1	6.3.58.13
0x0011	MCTP Rate Limiter Config 2	6.3.58.14
0x0012	Port to MDEF Mapping 0	6.3.58.15
0x0013	Port to MDEF Mapping 1	6.3.58.16
0x0014	Port to MDEF Mapping 2	6.3.58.17

6.3.58.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: Sideband Configuration Structure -> Section Length Last Section -> Word: Sideband Configuration Structure -> Port to MDEF Mapping 2

6.3.58.2 SMBus Maximum Fragment Size (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Fragment Size	0x0020	SMBus Maximum Fragment Size (bytes). Supported range is between 32 and 240 bytes. ***Note:*** In MCTP mode, this value should be set to 0x45 (64 bytes payload + 5 bytes of MCTP header).

6.3.58.3 SMBus Notification Timeout and Flags (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:8	SMBus Notification Timeout (ms)	0xFF	
7:6	SMBus Connection Speed	00b	SMBus Connection Speed 00b = Standard SMBus connection 01b = 400 Kb/s fast I^2C. 10b = 1 Mb/s fast+ I^2C. 11b = Reserved.
5	SMBus Block Read Command	0b	SMBus Block Read Command 0b = Block read command is 0xC0. 1b = Block read command is 0xD0.
4	Reserved	0b	Reserved.
3	Enable Fairness Arbitration	1b	MCTP over SMBus feature 0b = Disable fairness arbitration. 1b = Enable fairness arbitration.
2	Disable SMBus ARP Functionality	0b	Disable SMBus ARP Functionality 0b = SMBus ARP Enabled. 1b = SMBus ARP Disabled.
1	SMBus ARP PEC	1b	SMBus ARP PEC 0b = Disable PEC Disable SMBus ARP PEC. 1b = Enable PEC Enable SMBus ARP PEC. Should be set in MCTP modes.
0	SMBus Transaction PEC	0b	SMBus Transactions PEC 0b = Disable PEC. If this bit is cleared, PEC is not added to master write or slave read transactions, a slave write transaction with PEC is dropped. 1b = Enable PEC. If this bit is set, PEC is added for master SMBus write transactions. a PEC is added to slave read transactions and can be received in slave write transaction. Should be set in MCTP modes.

6.3.58.4 NC-SI Configuration 1 (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15	NC-SI Channel to Port Mapping Table Valid	0b	0b = Table Invalid Use default algorithm described in Channel ID mapping section. 1b = Table Valid Use the mapping defined in this word.
14	Flow Control	0b	0b = NC-SI flow control disable. 1b = NC-SI flow control enable.
13:10	NC-SI Version	0x1	Supported NC-SI version. Valid values are: 0x0 = NC-SI 1.0.1 0x1 = NC-SI 1.1
9	NC-SI HW Arbitration Enable	0b	0b = Not supported 1b = Supported
8	Reserved		Reserved.
7:5	Package ID	000b	Meaningful only when bit 15 of NC-SI Configuration 2 word (offset 0x07) is cleared.
4:0	Reserved	0x0	Reserved. Must be zero.

6.3.58.5 NC-SI Configuration 2 (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:14	Read NC-SI Package ID from SDP	00b	Read NC-SI Package ID. 00b = PackageID from NVM Package ID is read from *NVM Package ID* field in the NC-SI Configuration 01b = PackageID from NVM and SDPs #0 and #1. The package ID is (NVM Package ID[2], SDP#1 value, SDP#0 value). 10b = PackageID from NVM and SDP#1. The package ID is (NVM Package ID[2], SDP#1 value, NVM Package ID[0]). 11b = Reserved
13:9	PackageID SDP 0	0x0	Defines the SDP#1 from which the NC-SI package ID[1] is taken.
8:4	PackageID SDP 1	0x0	Defines the SDP#0 from which the NC-SI package ID[0] is taken
3:0	Max XOFF Renewal	0x3	NC-SI Flow Control MAX XOFF Renewal (# of XOFF renewals allowed): 0x0 = Disabled. Unlimited number of XOFF frames can be sent. 0x1 = Up to 2 consecutive XOFFs frames can be sent by the device. 0x2 = Up to 3 consecutive XOFFs frames can be sent by the device. . . . 0xF = Up to 16 consecutive XOFFs frames can be sent by the device.

6.3.58.6 NC-SI Flow Control XOFF (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	XOFF Threshold	0x12C0	Tx buffer watermark for sending a XOFF NC-SI flow control packet in bytes. The XOFF Threshold value refers to the occupied space in the buffer. The value should be 16 bytes aligned. ***Notes:*** • Field relevant for NC-SI operation mode only. • To support a maximum packet size of 1.5 KB, the value programmed assuming a Tx buffer size of 8 KB value of field should be 0x12C0 (4,800 bytes).

6.3.58.7 NC-SI Flow Control XON (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	XON Threshold	0x1340	Tx buffer watermark for sending a XON NC-SI flow control packet in bytes. The XON Threshold value refers to the available space in the Tx buffer. The value should be 16 bytes aligned. ***Notes:*** • Field relevant for NC-SI operation mode only. • To support maximum packet size of 1.5 KB, the value programmed should be a positive value that equals: Buffer size - XOFF Threshold + 1536 bytes. Assuming a Tx Buffer size is 8 KB and the XOFF Threshold is 4800 bytes value of field should be 0x1340 (4,928 bytes).

6.3.58.8 NC-SI HW Arbitration Configuration (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	TOKEN Timeout	0xA000	NC-SI Hardware Arbitration TOKEN Timeout (in NC-SI REF_CLK cycles - 20 ns). Setting value to 0 disables the timeout mechanism.

6.3.58.9 Reserved (0x0008 - 0x000C)

6.3.58.10 OEM IANA (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	OEM IANA	0x0	Identifies the OEM targeted by this image. The set of commands accepted depends on the IANA value in this field. The regular Intel OEM commands are accepted only with IANA 0x157.

6.3.58.11 NC-SI over MCTP Message Types (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:8	NC-SI Control Message Type	0x2	Defines the MCTP message type used to identify NC-SI Control packets.
7:0	NC-SI Pass-Through Message Type	0x3	Defines the MCTP message type used to identify NC-SI pass-through packets.

6.3.58.12 NC-SI over MCTP Configuration (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:7	Reserved	0x0	Reserved.
6	Simplified MCTP	0b	If set, only SOM and EOM bits are used for the reassembly process. Relevant only in SMBus mode.
5	Disable ACLs	0b	If set, the ACLs on the PCIe VDMs are disabled.
4:0	Reserved	0x0	Reserved.

6.3.58.13 MCTP Rate Limiter Config 1 (0x0010)

MCTP rate limiter configuration for first channel.

Bit(s)	Field Name	Default NVM Value	Description
15:0	MCTP Rate	0x9C40	Defines the number of cycles between accesses of the MCTP send client to the memory arbiter. Current value assumes a clock of 312.5 MHz and a bus width of 128 bits. This value provides a bit rate of 1 Mb/s.

6.3.58.14 MCTP Rate Limiter Config 2 (0x0011)

MCTP rate limiter configuration for first channel.

Bit(s)	Field Name	Default NVM Value	Description
15	Decision Point	0b	Defines if, when credits are available, a full MCTP message is sent or a single VDM is sent. 0b = Per VDM 1b = Per Packet
14:0	MCTP Max Credits	0x5	Defines the maximum number of 16 bytes credit that can be accumulated. These credits include the VDM header line (one line for each 64 byte VDM).

6.3.58.15 Port to MDEF Mapping 0 (0x0012)

Defines the ports mapping to MDEF sets for sets 0-2.

Bit(s)	Field Name	Default NVM Value	Description
15	Reserved	0b	Reserved.
14:10	MDEF Set 2 Port	0x1F	If 0x1F the MDEF is not assigned to any port.
9:5	MDEF Set 1 Port	0x1F	If 0x1F the MDEF is not assigned to any port.
4:0	MDEF Set 0 Port	0x1F	If 0x1F the MDEF is not assigned to any port.

6.3.58.16 Port to MDEF Mapping 1 (0x0013)

Defines the ports mapping to MDEF sets for sets 3-5.

Bit(s)	Field Name	Default NVM Value	Description
15	Reserved	0b	Reserved.
14:10	MDEF Set 5 Port	0x1F	If 0x1F the MDEF is not assigned to any port.
9:5	MDEF Set 4 Port	0x1F	If 0x1F the MDEF is not assigned to any port.
4:0	MDEF Set 3 Port	0x1F	If 0x1F the MDEF is not assigned to any port.

6.3.58.17 Port to MDEF Mapping 2 (0x0014)

Defines the ports mapping to MDEF sets for sets 6-7.

Bit(s)	Field Name	Default NVM Value	Description
15:10	Reserved	0x0	Reserved.
9:5	MDEF Set 7 Port	0x1F	If 0x1F the MDEF is not assigned to any port.
4:0	MDEF Set 6 Port	0x1F	If 0x1F the MDEF is not assigned to any port.

6.3.59 OEM Section Section

This section is the header of the OEM-specific data identifying the OEM for which this data is defined.

Table 6-65. OEM Section Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.59.1
0x0001	OEM Header	6.3.59.2
0x0002	Reserved	6.3.59.3

6.3.59.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: OEM Section -> Section Length Last Section -> Word: OEM Section -> Reserved

6.3.59.2 OEM Header (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	OEM Identifier	0x02A2	Identify the OEM for which this section is defined. Should be equal to the OEM IANA value.

6.3.59.3 Reserved (0x0002)

6.3.60 Auto-Generated Pointers Module Section

Pointers to Type 1/2 words used by EMP and Software.

Table 6-66. Auto-Generated Pointers Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.60.1
0x0001	Pointer to PFPM_APM Section	6.3.60.2
0x0002	Pointer to PFPM_APM Offset	6.3.60.3
0x0003	Pointer to PRTPM_GC Section	6.3.60.4
0x0004	Pointer to PRTPM_GC Offset	6.3.60.5
0x0005	Pointer to GLPCI_CAPSUP Section	6.3.60.6
0x0006	Pointer to GLPCI_CAPSUP Offset	6.3.60.7
0x0007	Pointer to PRTDCB_FCCFG Section	6.3.60.8
0x0008	Pointer to PRTDCB_FCCFG Offset	6.3.60.9
0x0009	Pointer to PFGEN_PORTNUM Section	6.3.60.10
0x000A	Pointer to PFGEN_PORTNUM Offset	6.3.60.11
0x000B	Pointer to PFPCI_FUNC2 Section	6.3.60.12
0x000C	Pointer to PFPCI_FUNC2 Offset	6.3.60.13
0x000D	Pointer to PF_VT_PFALLOC_PCIE Section	6.3.60.14
0x000E	Pointer to PF_VT_PFALLOC_PCIE Offset	6.3.60.15
0x000F	Pointer to PF_VT_PFALLOC Section	6.3.60.16
0x0010	Pointer to PF_VT_PFALLOC Offset	6.3.60.17
0x0011	Pointer to GLPCI_REVID Section	6.3.60.18
0x0012	Pointer to GLPCI_REVID Offset	6.3.60.19
0x0013	Pointer to PFPCI_DEVID Section	6.3.60.20
0x0014	Pointer to PFPCI_DEVID Offset	6.3.60.21
0x0015	Pointer to GLPCI_SUBVENID Section	6.3.60.22

0x0020	Pointer to GLPCI_CAPCTRL Offset	6.3.60.33
0x0021	Pointer to PFGEN_PORTNUM_CAR Section	6.3.60.34

Table 6-66. Auto-Generated Pointers Module Section Summary Table [continued]

Word Offset	Description	Section Reference
0x0022	Pointer to PFGEN_PORTNUM_CAR Offset	6.3.60.35
0x0023	Pointer to GLFOC_CACHE_CTL Section	6.3.60.36
0x0024	Pointer to GLFOC_CACHE_CTL Offset	6.3.60.37
0x0025	Pointer to PRTGEN_CNF Section	6.3.60.38
0x0026	Pointer to PRTGEN_CNF Offset	6.3.60.39
0x0027	Pointer to PF_VT_PFALLOC_HIF Section	6.3.60.40
0x0028	Pointer to PF_VT_PFALLOC_HIF Offset	6.3.60.41
0x0029	Pointer to PRTMAC_HSECTL1 Section	6.3.60.42
0x002A	Pointer to PRTMAC_HSECTL1 Offset	6.3.60.43
0x002B	Pointer to PRT_TDPUL2TAGSEN Section	6.3.60.44
0x002C	Pointer to PRT_TDPUL2TAGSEN Offset	6.3.60.45
0x002D	Pointer to GLGEN_MAC_LINK_TOPO Section	6.3.60.46
0x002E	Pointer to GLGEN_MAC_LINK_TOPO Offset	6.3.60.47

6.3.60.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: Auto Generated Pointers Module -> Module Length Last Section -> Word: Auto Generated Pointers Module -> Pointer to GLGEN_MAC_LINK_TOPO Offset

6.3.60.2 Pointer to PFPM_APM Section (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPM_APM Section	0x0	

6.3.60.3 Pointer to Pfpm_apm Offset (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPM_APM Offset	0x59	

6.3.60.4 Pointer to PRTPM_GC Section (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PRTPM_GC Section		

6.3.60.5 Pointer to PRTPM_GC Offset (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRTPM_GC Offset	0x7C	

6.3.60.6 Pointer to GLPCI_CAPSUP Section (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_CAPSUP Section	0x0	

6.3.60.7 Pointer to GLPCI_CAPSUP Offset (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_CAPSUP Offset	0x51	

6.3.60.8 Pointer to PRTDCB_FCCFG Section (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRTDCB_FCCFG Section	0x0	

6.3.60.9 Pointer to PRTDCB_FCCFG Offset (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRTDCB_FCCFG Offset	0x35F	

6.3.60.10 Pointer to PFGEN_PORTNUM Section (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFGEN_PORTNUM Section	0x0	

6.3.60.11 Pointer to PFGEN_PORTNUM Offset (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFGEN_PORTNUM Offset	0x40B	

6.3.60.12 Pointer to PFPCI_FUNC2 Section (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFINT_ALLOC_PCI Section		

6.3.60.13 Pointer to PFPCI_FUNC2 Offset (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFINT_ALLOC_PCI Offset	0x3	

6.3.60.14 Pointer to PF_VT_PFALLOC_PCIE Section (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PF_VT_PFALLOC_PCIE Section		

6.3.60.15 Pointer to PF_VT_PFALLOC_PCIE Offset (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PF_VT_PFALLOC_PCIE Offset	0x77	

6.3.60.16 Pointer to PF_VT_PFALLOC Section (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PF_VT_PFALLOC Section		

6.3.60.17 Pointer to PF_VT_PFALLOC Offset (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PF_VT_PFALLOC Offset	0x41E	

6.3.60.18 Pointer to GLPCI_REVID Section (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_REVID Section	0x0	Points to PCIR Type 1/2 Section. For PCIR Type 1/2 inner structure, see Section 6.3.47.

6.3.60.19 Pointer to GLPCI_REVID Offset (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_REVID Offset	0x9	

6.3.60.20 Pointer to PFPCI_DEVID Section (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFPCI_DEVID Section		

6.3.60.21 Pointer to PFPCI_DEVID Offset (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPCI_DEVID Offset	0x3C	

6.3.60.22 Pointer to GLPCI_SUBVENID Section (0x0015)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to GLPCI_SUBVENID Section		

6.3.60.23 Pointer to GLPCI_SUBVENID Offset (0x0016)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_SUBVENID Offset	0x5B	

6.3.60.24 Pointer to PFPCI_SUBSYSID Section (0x017)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFPCI_SUBSYSID Section		

6.3.60.25 Pointer to PFPCI_SUBSYSID Offset (0x0018)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPCI_SUBSYSID Offset	0x16	

6.3.60.26 Pointer to GLPCI_VENDORID Section (0x0019)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to GLPCI_VENDORID Section		

6.3.60.27 Pointer to GLPCI_VENDORID Offset (0x001A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_VENDORID Offset	0x57	

6.3.60.28 Pointer to PFPCI_FUNC Section (0x001B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFPCI_FUNC Section		

6.3.60.29 Pointer to PFPCI_FUNC Offset (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPCI_FUNC Offset	0x14	

6.3.60.30 Pointer to PFPCI_CNF Section (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFPCI_CNF Section		

6.3.60.31 Pointer to PFPCI_CNF Offset (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFPCI_CNF Offset	0x60	

6.3.60.32 Pointer to GLPCI_CAPCTRL Section (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to GLPCI_CAPCTRL Section		

6.3.60.33 Pointer to GLPCI_CAPCTRL Offset (0x0020)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLPCI_CAPCTRL Offset	0x4F	

6.3.60.34 Pointer to PFGEN_PORTNUM_CAR Section (0x0021)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PFGEN_PORTNUM_CAR Section		

6.3.60.35 Pointer to PFGEN_PORTNUM_CAR Offset (0x0022)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PFGEN_PORTNUM_CAR Offset	0x46	

6.3.60.36 Pointer to GLFOC_CACHE_CTL Section (0x0023)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to GLFOC_CACHE_CTL Section		

6.3.60.37 Pointer to GLFOC_CACHE_CTL Offset (0x0024)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLFOC_CACHE_CTL Offset	0x1A5	

6.3.60.38 Pointer to PRTGEN_CNF Section (0x0025)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PRTGEN_CNF Section		

6.3.60.39 Pointer to PRTGEN_CNF Offset (0x0026)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRTGEN_CNF Offset	0x6C	

6.3.60.40 Pointer to PF_VT_PFALLOC_HIF Section (0x0027)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PF_VT_PFALLOC_HIF Section		

6.3.60.41 Pointer to PF_VT_PFALLOC_HIF Offset (0x0028)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PF_VT_PFALLOC_HIF Offset	0x29	

6.3.60.42 Pointer to PRTMAC_HSECTL1 Section (0x0029)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PRTMAC_HSECTL1 Section		

6.3.60.43 Pointer to PRTMAC_HSECTL1 Offset (0x002A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRTMAC_HSECTL1 Offset	0x2B2	

6.3.60.44 Pointer to PRT_TDPUL2TAGSEN Section (0x002B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to PRT_TDPUL2TAGSEN Section		

6.3.60.45 Pointer to PRT_TDPUL2TAGSEN Offset (0x002C)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to PRT_TDPUL2TAGSEN Offset	0x3	

6.3.60.46 Pointer to GLGEN_MAC_LINK_TOPO Section (0x002D)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Cloned Pointer to GLGEN_MAC_LINK_TOPO Section		

6.3.60.47 Pointer to GLGEN_MAC_LINK_TOPO Offset (0x002E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Pointer to GLGEN_MAC_LINK_TOPO Offset	0x2	

6.3.61 NVM Image CSS Header Section

6.3.69.1 Reserved (0x0000)

6.3.69.2 Analog PHY pre PLL Configuration Pointer (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Analog PLL Configuration Pointer	0x0	Points to Analog PHY pre PLL Configuration Section. For Analog PHY pre PLL Configuration inner structure, see Section 6.3.71.

6.3.69.3 CSR Protected List Pointer (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:0	CSR Protected List Pointer	0x0	Points to CSR Protected List Section. For CSR Protected List inner structure, see Section 6.3.72.

6.3.69.4 PCIe Analog Pointer (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PCIe Analog Pointer	0xFFF	Points to PCIe Analog Module Section. For PCIe Analog Module inner structure, see Section 6.3.73.

6.3.69.5 PCIR Fixed Auto-Load Pointer (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PCIR Fixed Autoload Pointer	0x0	Points to PCIR Registers Auto-Load Module Section. For PCIR Registers Auto-Load Module inner structure, see Section 6.3.74.

6.3.69.6 POR Fixed Auto-Load Pointer (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	POR Fixed Autoload Pointer	0x0	Points to POR Registers Auto-Load Module Section. For POR Registers Auto-Load Module inner structure, see Section 6.3.75.

6.3.69.7 PCIR PFA Auto-Load Whitelist Pointer (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PCIR PFA Autoload Whitelist Pointer	0x0	Points to POR PCIR_PFA Auto-Load Whitelist Module Section. For PCIR_PFA Auto-Load Whitelist Module inner structure, see Section 6.3.76.

6.3.69.8 POR PFA Auto-Load Whitelist Pointer (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:0	POR PFA Autoload Whitelist Pointer	0x0	Points to POR POR_PFA Auto-Load Whitelist Module Section. For POR_PFA Auto-Load Whitelist Module inner structure, see Section 6.3.77.

6.3.69.9 Reserved (0x0008)

6.3.69.10 1st NVM Bank Pointer (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st NVM Bank Pointer		

6.3.69.11 NVM Bank Area Size (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	NVM Bank Area Size		Size expressed in 4 KB sector units.

6.3.69.12 1st OROM Bank Pointer (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st OROM Bank Pointer		Pointer to first OROM section (not swapped when section changes).

6.3.69.13 OROM Bank Area Size (0x000C)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	OROM Bank Area Size		Size expressed in 4 KB sector units.

6.3.69.14 1st TLV Extension Bank Pointer (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	1st TLV Extension Bank Pointer		Pointer to first OROM section (not swapped when section changes).

6.3.69.15 TLV Extension Bank Area Size (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	TLV Extension Bank Area Size		Size expressed in 4 KB sector units.

6.3.69.16 Preserved Field Area Pointer (0x000F)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	PFA Pointer		

6.3.69.17 Recovery Firmware Pointer (0x0010)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units.
14:0	Recovery Firmware Pointer		Pointer to Recovery Firmware section.

6.3.69.18 Reserved (0x0011)

6.3.69.19 Factory Settings Size (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:12	Reserved	0x0	Reserved.
11:0	Factory Settings Size		Size expressed in 4 KB sector units.

6.3.69.20 Last PFA Word Pointer (0x0013)

Bit(s)	Field Name	Default NVM Value	Description
15	Pointer Type		Pointer Type: 0b = Word units. 1b = 4 KB sector units. Only the 4 KB sector unit is supported for this pointer.
14:0	Last PFA Word Pointer		Pointer to the end of the PFA excluding the PCI ALT module.

6.3.69.21 LVK Hashes Pointer (0x0014)

Bit(s)	Field Name	Default NVM Value	Description
15:0	LVK Hashes Pointer	0x0	Relative pointer to Low Value Keys Hashes. Points to LVK Hashes Section. For LVK Hashes inner structure See Section 6.3.78.

6.3.69.22 Reserved (0x0015)

6.3.70 ML Image Section

This module is the whole module that has been signed by CSS.

It is in the NVM map for EM tool needs only.

6.3.71 Analog PHY pre PLL Configuration Section

Includes static configurations of PHY Core registers for PLL lock.

Table 6-75. Analog PHY pre PLL Configuration Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.71.1
0x0001	Reg Write Indirect List	6.3.71.2

6.3.71.1 Section Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: Analog PHY pre PLL Configuration -> Section Length Last Section -> Word: Analog PHY pre PLL Configuration -> Reg Write Indirect List

6.3.71.2 Reg Write Indirect List (0x0001)

Raw data module length: variable

6.3.72 CSR Protected List Section

Defines the list of the protected CSRs and their default settings. These registers are made RO to the host as they contain settings that are critical for the host to Flash access when in blank Flash programming mode.

Table 6-76. CSR Protected List Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.72.1
0x0001 - 0x000C	Reserved	6.3.72.2
0x000D - 0x0010	NVM contents for GLGEN_STAT	6.3.72.3
0x0011 - 0x0014	NVM contents for GLNVM_ALTIMERS	6.3.72.4
0x0015 - 0x0018	Reserved	6.3.72.5
0x0019 - 0x0093	NVM contents for GLNVM_PROTCSR	6.3.72.6

6.3.72.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: CSR Protected List -> Module Length Last Section -> Word: CSR Protected List -> Starting Address Low at GLNVM_PROTCSR[0]

6.3.72.2 Reserved (0x0001 - 0x000C)

6.3.72.3 GLGEN_STAT (0x000D - 0x0010)

6.3.72.3.1 Address Low at GLGEN_STAT (0x000D)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLGEN_STAT	0xB612C	
3:0	Type	0x1	

6.3.72.3.2 Address High at GLGEN_STAT (0x000E)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLGEN_STAT		

6.3.72.3.3 Data Low of GLGEN_STAT (0x000F)

6.3.72.3.4 Data High of GLGEN_STAT (0x0010)

6.3.72.4 GLNVM_ALTIMERS (0x0011 - 0x0014)

6.3.72.4.1 Address Low at GLNVM_ALTIMERS (0x0011)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLNVM_ALTIMERS	0xB6140	
3:0	Type	0x1	

6.3.72.4.2 Address High at GLNVM_ALTIMERS (0x0012)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLNVM_ALTIMERS		

6.3.72.4.3 Data Low of GLNVM_ALTIMERS (0x0013)

6.3.72.4.4 Data High of GLNVM_ALTIMERS (0x0014)

6.3.72.5 Reserved (0x0015 - 0x0018)

6.3.72.6 GLNVM_PROTCSR (0x0019 - 0x0093)

6.3.72.6.1 Starting Address Low at GLNVM_PROTCSR (0x0019)

Bit(s)	Field Name	Default NVM Value	Description
15:4	Low Address Bits of GLNVM_PROTCSR	0xB6010	
3:0	Type	0x2	

6.3.72.6.2 Starting Address High at GLNVM_PROTCSR (0x001A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	High Address Bits of GLNVM_PROTCSR		

6.3.72.6.3 Attributes at GLNVM_PROTCSR (0x001B)

Bit(s)	Field Name	Default NVM Value	Description
15:5	Length	0x3C	
4:3	Skip	00b	
2:0	Width	000b	

6.3.72.6.4 Data Low of GLNVM_PROTCSR[n] (0x001C + 2*n, n=0...59)

6.3.72.6.5 Data High of GLNVM_PROTCSR[n] (0x001D + 2*n, n=0...59)

6.3.73 PCIe Analog Module Section

Contains read-only parameters that configure the PCIe Transaction layer.

Table 6-77. PCIe Analog Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.73.1
0x0001	PCIe Analog Data	6.3.73.2

6.3.73.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		

6.3.73.2 PCIe Analog Data (0x0001)

Raw data module length: variable

This word must be disabled at the image level.

6.3.74 PCIR Registers Auto-Load Module Section

Default setup to registers and internal memories that load on PCIR events.

Table 6-78. PCIR Registers Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.74.1
0x0001	PCIR Auto-Load Duplicate	6.3.74.2
0x0002 - 0x0005	Reserved	6.3.74.3

6.3.74.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: PCIR Registers Auto-load Module -> Module Length Last Section -> Word: POR Registers Auto-load Module -> Reserved

6.3.74.2 PCIR Auto-Load Duplicate (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PCIR Autoload Duplicate		

6.3.74.3 Reserved (0x0002 - 0x0005)

6.3.75 POR Registers Auto-Load Module Section

Default setup to registers that load on POR events.

Table 6-79. POR Registers Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.75.1
0x0001	POR Auto-Load Duplicate	6.3.75.2

6.3.75.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description

6.3.76.2 PCIR_PFA Auto-Load Duplicate (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PCIR_PFA Autoload Duplicate		

6.3.77 POR_PFA Auto-Load Whitelist Module Section

Default setup to registers and internal memories that load on POR events.

Table 6-81. POR_PFA Auto-Load Whitelist Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Module Length	6.3.77.1
0x0001	POR_PFA Auto-Load Duplicate	6.3.77.2

6.3.77.1 Module Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Module Length		Length in: 2 Bytes unit - 1 First Section -> Word: POR_PFA Auto-load Whitelist Module -> Module Length Last Section -> Word: POR_PFA Auto-load Whitelist Module -> POR_PFA Auto-Load Duplicate

6.3.77.2 POR_PFA Auto-Load Duplicate (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	POR_PFA Autoload Duplicate		

6.3.78 LVK Hashes Section

Hashes for Low Value Keys.

Table 6-82. LVK Hashes Section Summary Table

Word Offset	Description	Section Reference
0x0000	Length	6.3.78.1
0x0001 + 1*n, n=0...15	NVM Bank Key Hash	6.3.78.2
0x0011 + 1*n, n=0...15	OS Package Key Hash	6.3.78.3
0x0021 + 1*n, n=0...15	OROM Key Hash	6.3.78.4

6.3.78.1 Length (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Length		Length in: 2 Bytes unit - 1 First Section -> Word: LVK Hashes -> Length Last Section -> Word: LVK Hashes -> OROM Key Hash

6.3.78.2 NVM Bank Key Hash[n] (0x0001 + 1*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:0	NVM Bank Key Hash	0x0	Hash for NVM Bank and Recovery section key.

6.3.78.3 OS Package Key Hash[n] (0x0011 + 1*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:0	OS Package Key Hash	0x0	Hash for OS Package keys.

6.3.78.4 OROM Key Hash[n] (0x0021 + 1*n, n=0...15)

Bit(s)	Field Name	Default NVM Value	Description
15:0	OROM Key Hash	0x0	Hash for OROM key.

6.3.79 Recovery FW CSS Header Section

Table 6-83. Recovery FW CSS Header Section Summary Table

Word Offset	Description	Section Reference
0x21800	moduleTypeL	6.3.79.1

6.3.81.8 Reserved Spare Word (0x0007)

Bits	Field Name	Default NVM Value	Description
15:0	Reserved Spare Word	0x0	

6.3.82 Recovery FW Image Section

This module is the whole module which has been signed by CSS.

It is in the NVM map for EM tool needs only.

6.3.83 DCB Rx Module Section

6.3.84 DCB Tx Module Section

6.3.85 Ext. CORER Registers Auto-Load Module Section

Default setup to registers and internal memories that load on CORER events.

Table 6-86. Ext. CORER Registers Auto-Load Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	ModuleLenL	6.3.85.1
0x0001	ModuleLenH	6.3.85.2

6.3.85.1 ModuleLenL (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ModuleLenL	0x00000000	Length in: 2 Bytes unit - 2 First Section -> Word: Ext. CORER Registers Auto-load Module -> ModuleLenL Last Section -> Word: Ext. CORER Registers Auto-load Module -> ModuleLenH

6.3.85.2 ModuleLenH (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	ModuleLenH		

6.3.86 EMP Global Module Section

This section contains two sub-sections:

1. **Vendor-Specific Settings:** Settings for external PHY or Modules. This part has a proprietary format to enable advanced, vendor-specific, PHY setting. These settings are loaded into the external devices via the MDIO/I^2C interface.
2. **List of Qualified Modules:** Parameter list of up to 16 modules. Per module list holds OUI, Revision, and Version numbers.

Table 6-87. EMP Global Module Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.86.1
0x0001	Number of Qualified Modules	6.3.86.2
0x0002 + 12*n, n=0...15	Module OUI Bytes 0-1	6.3.86.3
0x0003 + 12*n, n=0...15	Module OUI Byte 2	6.3.86.4
0x0004 + 12*n, n=0...15	Vendor Part Number Bytes 0-1	6.3.86.5
0x0005 + 12*n, n=0...15	Vendor Part Number Bytes 2-3	6.3.86.6
0x0006 + 12*n, n=0...15	Vendor Part Number Bytes 4-5	6.3.86.7
0x0007 + 12*n, n=0...15	Vendor Part Number Bytes 6-7	6.3.86.8
0x0008 + 12*n, n=0...15	Vendor Part Number Bytes 8-9	6.3.86.9
0x0009 + 12*n, n=0...15	Vendor Part Number Bytes 10-11	6.3.86.10
0x000A + 12*n, n=0...15	Vendor Part Number Bytes 12-13	6.3.86.11
0x000B + 12*n, n=0...15	Vendor Part Number Bytes 14-15	6.3.86.12
0x000C + 12*n, n=0...15	Module Revision Number Bytes 0-1	6.3.86.13
0x000D + 12*n, n=0...15	Module Revision Number Bytes 2-3	6.3.86.14

6.3.86.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: EMP Global Module -> Section Length Last Section -> Word: EMP Global Module -> Module Revision Number Bytes 2-3

6.3.86.2 Number of Qualified Modules (0x0001)

Number of valid entries, 0 through 15, in the qualified modules' list.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Number of Qualified Modules	0x10	

6.3.86.3 Module OUI Bytes 0-1[n] (0x0002 + 12*n, n=0...15)

OUI of qualified external modules.

- SFP Vendor OUI is located at offsets [39:37].
- QSFP Vendor OUI is located at offsets [167:165].

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.4 Module OUI Byte 2[n] (0x0003 + 12*n, n=0...15)

OUI of qualified external modules.

- SFP Vendor OUI is located at offsets [39:37].
- QSFP Vendor OUI is located at offsets [167:165].

Bit(s)	Field Name	Default NVM Value	Description
15:8	Reserved	0x0	Reserved.
7:0	Byte 2	0x0	

6.3.86.5 Vendor Part Number Bytes 0-1[n] (0x0004 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.6 Vendor Part Number Bytes 2-3[n] (0x0005 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.7 Vendor Part Number Bytes 4-5[n] (0x0006 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.8 Vendor Part Number Bytes 6-7[n] (0x0007 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.9 Vendor Part Number Bytes 8-9[n] (0x0008 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.10 Vendor Part Number Bytes 10-11[n] (0x0009 + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.11 Vendor Part Number Bytes 12-13[n] (0x000A + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.12 Vendor Part Number Bytes 14-15[n] (0x000B + 12*n, n=0...15)

Vendor Part Number of qualified external modules.

- SFP+: Addr A0h Bytes 55:40
- QSFP+: Addr 183:168 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.13 Module Revision Number Bytes 0-1[n] (0x000C + 12*n, n=0...15)

Revision Number of qualified external modules.

- SFP+: Addr A0h Bytes 59:56
- QSFP+: Addr 185:184 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.86.14 Module Revision Number Bytes 2-3[n] (0x000D + 12*n, n=0...15)

Revision Number of qualified external modules.

- SFP+: Addr A0h Bytes 59:56
- QSFP+: Addr 185:184 page 0

Bit(s)	Field Name	Default NVM Value	Description
15:8	Byte 1	0x0	
7:0	Byte 0	0x0	

6.3.87 EMP Settings Module Header Section

This section contains the modes of operation of the EMP.

Table 6-88. EMP Settings Module Header Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length	6.3.87.1
0x0001	Common Firmware Parameters	6.3.87.2
0x0002	FW Misc	6.3.87.3
0x0003	EEE Variables	6.3.87.4
0x0004	Maximal Wear-Out Value	6.3.87.5
0x0005	Initial Wear-Out Value	6.3.87.6
0x0006	Staggering Delay	6.3.87.7
0x0007	PXE PFC Timer Value	6.3.87.8
0x0008	PXE GPC High Threshold Value	6.3.87.9
0x0009	PXE GPC Low Threshold Value	6.3.87.10
0x000A	Internal Thermal Sensor Maximum Secured Value	6.3.87.11
0x000B	Internal Thermal Sensor Minimum Secured Value	6.3.87.12
0x000C	MAX_LL_AQ_CREDITS	6.3.87.13

6.3.87.1 Section Length (0x0000)

The length of the section in words. Note that section length does not include a count for the section length word.

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length		Length in: 2 Bytes unit - 1 First Section -> Word: EMP Settings Module Header -> Section Length Last Section -> Word: EMP Settings Module Header -> MAX_LL_AQ_CREDITS

6.3.87.2 Common Firmware Parameters (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:10	Reserved	0x5	Reserved.
9	PF Reset on Queue Overflow	0b	0b = Disabled (default) 1b = Enabled
8:0	Reserved	0x3	Reserved.

6.3.87.3 FW Misc (0x0002)

Bit(s)	Field Name	Default NVM Value	Description
15:1	FW Reserved	0x0	Reserved.
0	VEB Statistics Disable	0x0	0b = VEB Statistics are enable (default). 1b = VEB Statistics are disabled.

6.3.87.4 EEE Variables (0x0003)

Bit(s)	Field Name	Default NVM Value	Description
15:8	receiveTW	0xE	Value determines the time (expressed in microseconds) that the receiving link partner is requesting the transmitting link partner to wait before starting the transmission data following the LPI. This value is platform dependent and depends on the OEM platform.
7:0	transmitTW	0xE	Value determines the time (expressed in microseconds) that the transmitting link partner waits before it starts transmitting data after leaving the Low Power Idle (LPI) mode. This value is platform dependent and depends on the OEM platform.

6.3.87.5 Maximal Wear-Out Value (0x0004)

Bit(s)	Field Name	Default NVM Value	Description
15:0	MAX	0x1400	Maximal wear out credit value.

6.3.87.6 Initial Wear-Out Value (0x0005)

Bit(s)	Field Name	Default NVM Value	Description
15:0	INITIAL	0x800	Initial wear out credit value.

6.3.87.7 Staggering Delay (0x0006)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Delay	0x0	Port staggering delay in µs.

6.3.87.8 PXE PFC Timer Value (0x0007)

Bit(s)	Field Name	Default NVM Value	Description
15:14	Reserved	0x0	Reserved.
13:0	PXE PFC Timer	0x4	The value [in ms] to be set as the PFC timer in PCE mode.

6.3.87.9 PXE GPC High Threshold Value (0x0008)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PXE GPC High Threshold	0x0080	High threshold [in quanta of 32B] of GPC to be used in the RPB monitoring flow.

6.3.87.10 PXE GPC Low Threshold Value (0x0009)

Bit(s)	Field Name	Default NVM Value	Description
15:0	PXE GPC Low Threshold Value	0x0010	Low threshold [in quanta of 32B] of GPC to be used in the RPB monitoring flow.

6.3.87.11 Internal Thermal Sensor Maximum Secured Value (0x000A)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Internal Thermal Sensor Maximum Secured Value	0x73	0-255 Recommended 0-115 degrees.

6.3.87.12 Internal Thermal Sensor Minimum Secured Value (0x000B)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Internal Thermal Sensor Minimum Secured Value	0c60	0-255 Recommended 90-100 degrees.

6.3.87.13 MAX_LL_AQ_CREDITS (0x000C)

Bits	Field Name	Default NVM Value	Description
15:0	MAX_LL_AQ_CREDITS	0x8	

6.3.88 DL Scripts Section

6.3.89 Whitelist Section

6.3.90 Analog PHY Configuration Section

Includes static configurations of SerDes PHY registers for link establishment.

Table 6-89. Analog PHY Configuration Section Summary Table

Word Offset	Description	Section Reference
0x0000	Section Length Low	6.3.90.1
0x0001	Section Length High	6.3.90.2
0x0002	Reg Write Indirect List	6.3.90.3
0x0003	Reg Write Indirect List	6.3.90.4

6.3.90.1 Section Length Low (0x0000)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length Low		Length in: 2 Bytes unit - 2 First Section -> Word: Analog PHY Configuration -> Section Length Low Last Section -> Word: Analog PHY Configuration -> Reg Write Indirect List

6.3.90.2 Section Length High (0x0001)

Bit(s)	Field Name	Default NVM Value	Description
15:0	Section Length High		

6.3.90.3 Reg Write Indirect List (0x0002)

Raw data module length: variable

6.3.90.4 Reg Write Indirect List (0x0003)

Raw data module length: variable

6.3.91 Configuration Metadata Section

NVM adaptive configuration metadata.

Table 6-90. Configuration Metadata Section Summary Table

Word Offset	Description	Section Reference

6.3.92 Control Pipe Package Section

This module contains the package used to configure the control pipe. This package is encoded as a set of Download Package Command (Opcode: 0x0C40) buffers.

Table 6-91. Control Pipe Package Section Summary Table

Word Offset	Description	Section Reference
0x0000	ModuleLenL	6.3.92.1

Chapter 7 Packet Processing

7.1 Introduction

The E810 provides a programmable packet processing engine with extensive support for advanced applications ranging from Enterprise LAN to SDN/NFV, Cloud, Comms, and Wireless.

Key features include:

- FlexiPipe virtualized pipeline with profile-based processing stages.
- OpenFlow-enabled Flow-Tables structure with metadata propagation between pipeline stages.
- P4-ready parsing and classification flows.
- Multiple binary and ternary (like ACL) classification stages.
- RDMA Flow Table expansions to host DRAM.
- SDN-enabled architecture.
  - Generic L1 to L5+ protocol handling.
  - Protocol-agnostic SDN parsing, classification, and packet forwarding and modification, including standard L2 and/or L3+ packet switching.
  - N-Tuple lookup key classification.
  - M-Tuple action execution.
- Deep header processing up to 504 bytes.
  - Supports tunneled overlay encapsulations and large IPv6 extension headers.
- Fully software-programmable FlexiParser.
  - Supports user-defined proprietary packet formats.
  - Programmable parse graph, enforcing user-defined parsing policy.
  - Programmable PTYPEs (Packet Types).
- Cloud-enabled generic overlays including GRE, NVGRE, VXLAN, VXLAN-GPE, Geneve.
- MPLS-enabled processing.
  - Outer MPLS and inner-MPLS (e.g., MPLSoGRE, MPLSoUDP).
- Service chaining forwarding including NSH (Network Service Header) processing.

The advanced packet processing engine enables high-performance acceleration by hardware-offloading of software functions, especially in a VMM/Hypervisor environments with SR-IOV paths.

7.2 FlexiPipe Processing Pipeline

The E810 FlexiPipe pipeline serves as the backbone of the packet processing engine. The OpenFlow-enabled pipeline is fully SDN/NFV-enabled, providing multiple programmable lookup stages (Flow Tables) augmented with programmable FlexiParser and packet modifier.

The generic FlexiPipe pipeline architecture enables support for diverse processing requirements. The pipeline provides multiple protocol-agnostic processing stages that can be re-purposed according to the target application. For example, a generic classification stage in the pipe can set a Destination VSI/ Destination Q in one application, whereas in another application the same generic classification stage can set an opaque metadata associated with the packet. Each of these classifications can be performed using different lookup keys over different protocols.

7.2.1 Rx and Tx Pipeline Structure

The E810 pipeline shares sections of the pipe between Rx and Tx flows. Shared components are designed to process packets at the combined rates of Rx and Tx.

The pipeline provides a loopback forwarding path between Tx and Rx for packets that are destined to functions residing on the same host. Such packets are first processed in the Tx section of the pipeline, stored in the Tx Packet Buffer, copied to Rx Packet Buffer, and then processed in the Rx section of the pipeline.

The Rx processing pipeline contains the following stages for LAN traffic:

1. Rx Packet Buffer
2. Rx FlexiParser (Section 7.7)
3. Switch (Binary Classifier) — Default function: VEB switch, multi-cast and mirror replicate (Section 7.8)
4. ACL (Ternary Classifier) — Default function: ACL (Section 7.9)
5. Classifications filters (Section 7.10)
   - FD (Binary Classifier) — Default function: Flow Director (Q steering)
   - QH (Binary Classifier) — Default function: RDMA flow steering
   - Hash — Default function: RSS
6. Flex Descriptor Builder (Section 7.6)
7. Packet Modifier

A detailed view of the FlexiPipe Rx processing pipeline is illustrated in Figure 7-1.

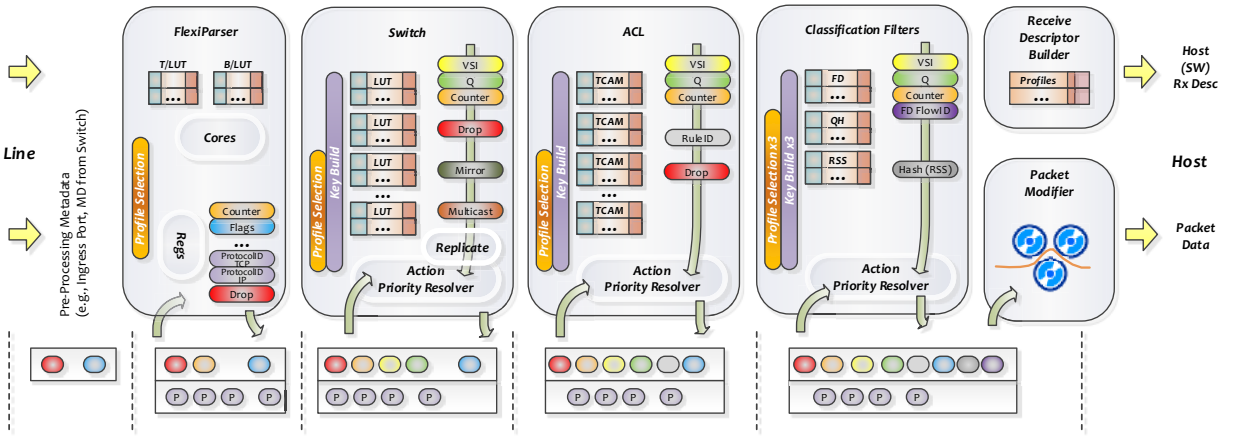

Figure 7-1. Rx Processing Pipeline (Showing Post-Receive Packet Buffer Section)

The FlexiPipe Tx processing pipeline contains the following stages:

1. Tx WFQ Scheduler (Section 8.3)
2. LSO/TSO Segmentation Offload (Section 10.5.8.4)
3. Packet Modifier
4. Tx FlexiParser (Section 7.7)
5. Switch (Binary Classifier) - Default function: Packet steering to LAN (Line) / LB (Loopback to host) (Section 7.8)
6. ACL (Ternary Classifier) - Default function: ACL (Section 7.9)
7. Tx Packet Buffer

A detailed view of the FlexiPipe Tx processing pipeline is illustrated in Figure 7-2.

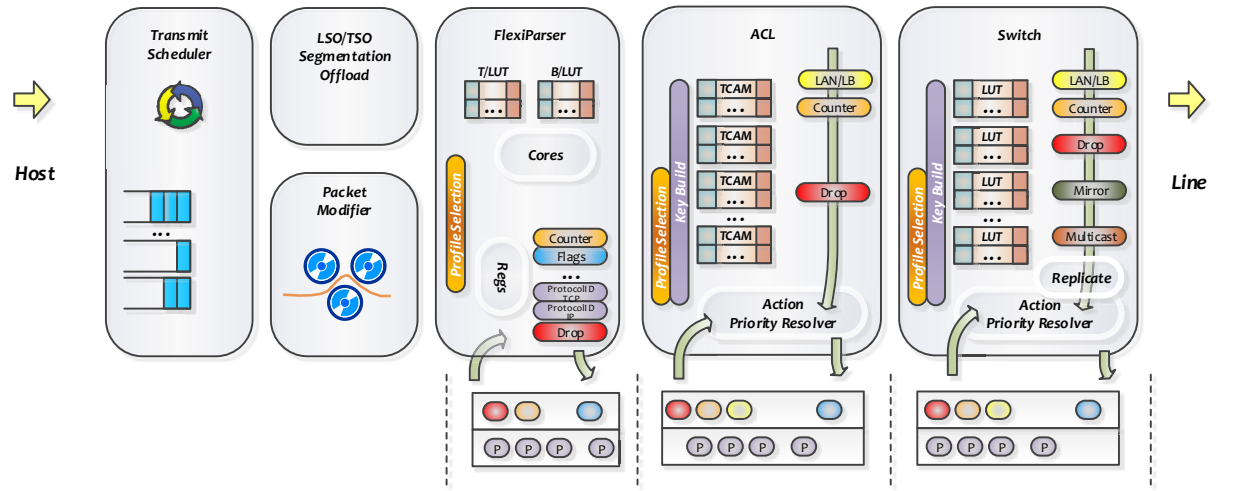

Figure 7-2. Tx Processing Pipeline (Showing Pre-Transmit Packet Buffer Section)

Further descriptions of the pipeline stages appear in subsequent sections of this document.

7.2.2 Pipeline Virtualization

The E810 FlexiPipe provides a unique feature of Pipeline Virtualization that logically partitions the single physical pipeline instance into functionally-independent logical pipeline instances. Each behaves like a standalone pipeline available for programming, as illustrated in Figure 7-3.

In Figure 7-3, the physical pipeline is virtualized and partitioned into two logical pipeline instances: orange and green. Each of the logical pipeline instances can be programmed independently and provide different functionality.

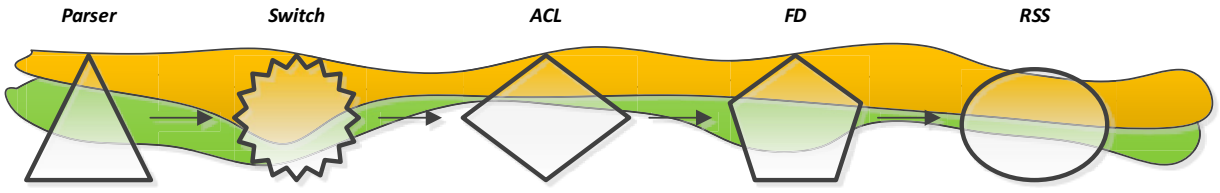

Figure 7-3. Pipeline Virtualization

7.3 Priority Resolver

The E810 pipeline provides a generic action-agnostic metadata generation at each pipeline stage. Consequently, multiple pipeline stages are allowed to generate the same MDID types, possibly creating conflicts.

For example, multiple pipeline stages might attempt to set the <Destination Q> of the packet: the switch, the ACL, and the FD (Flow Director). Similarly, multiple pipeline stages might attempt to set the <DestinationVSI>.

To guarantee consistent behavior, the pipeline provides a metadata Priority Resolver at each pipeline stage, resolving possible conflicts per each MDID type. The Priority Resolver selects the highest priority metadata value per each MDID metadata type, based on the input metadata to the pipeline stage and the metadata generated by the pipeline stage itself (the core). When priorities are equal, the later pipeline stage wins (for example, if switch selects <DestinationVSI>=A Priority=3, and ACL selects <DestinationVSI>=B Priority=3, the ACL wins because it is a later stage in the pipe).

The metadata Priority Resolver is illustrated in Figure 7-4.

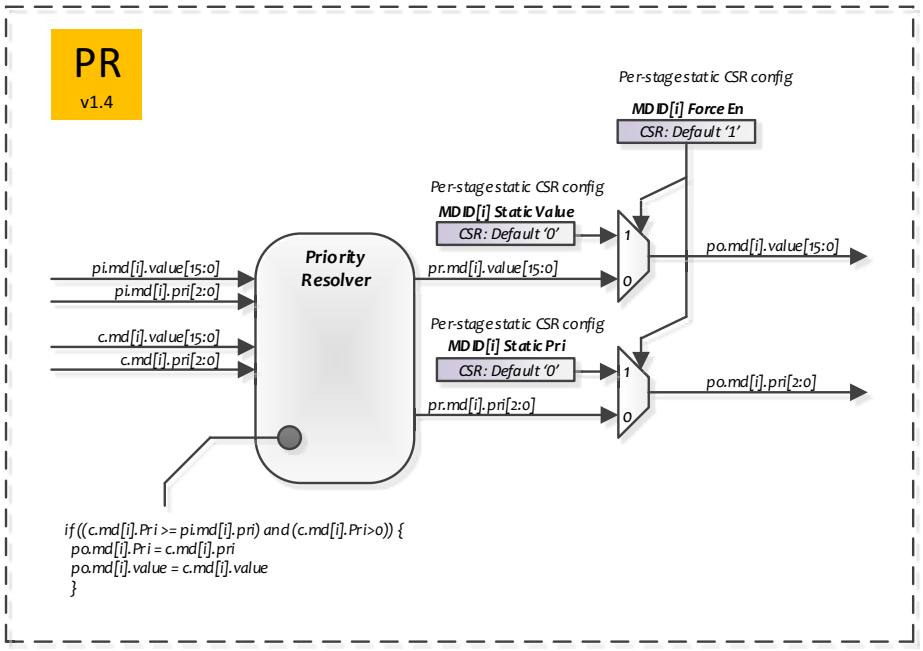

Figure 7-4. Metadata Priority Resolver

MDID metadata types that have priority association are carried in the pipeline alongside with their priority association and provided to the next pipeline stage for further processing.

7.3.1 MDID Override

The Priority Resolver in each pipeline stage provides an MDID Override feature for setting the MDID outputs of the pipe stage from CSRs. For each RW MDID metadata, the following CSRs are provided:

- <MDID[i] Force Enable> — When set, MDID override is enabled for MDID type i.
- <MDID[i] Static Value> — When MDID override is enabled for MDID type i, the metadata value is taken from CSR.
- <MDID[i] Static Priority> — When MDID override is enabled for MDID type i, the metadata priority is taken from CSR.

The metadata override feature enables functional bypassing of pipeline stages, complete or partial bypass, depending on the target use case. It also facilitates the silicon bring-up process by placing the pipeline into a simple static configuration where all traffic is directed to known destinations (VSI, Q, and so on) determined by CSRs.

7.3.2 Programming the Priority Resolver

As detailed in earlier sections, the E810 FlexiPipe implements priority resolution mechanisms for several of its actions.

These mechanisms are placed in each of the four stages of the Routing Control Unit (RCU): the parser, the switch, the ACL, and the Rx filters.

7.4 FlexActions

When a pipe stage generates FlexActions, they are mapped into the MDID metadata infrastructure of the pipeline. A generic FlexAction structure is made of xM[1] FlexAction Tuples that define the actions generated and the mapping of these actions into the pipeline metadata.

Note: Some legacy blocks in the E810 pipeline provide a hybrid FlexAction implementation, where some actions are statically mapped (for example, VSI selection in the legacy portion of the E810 switch), while the block also provides a FlexAction structure for generating all the other actions and metadata supported by the pipeline (like the flex portion of the E810 switch). More details are provided in further sections of this document that refer to the corresponding pipeline stages.

An example for the generic structure of a FlexAction is illustrated in Figure 7-5.

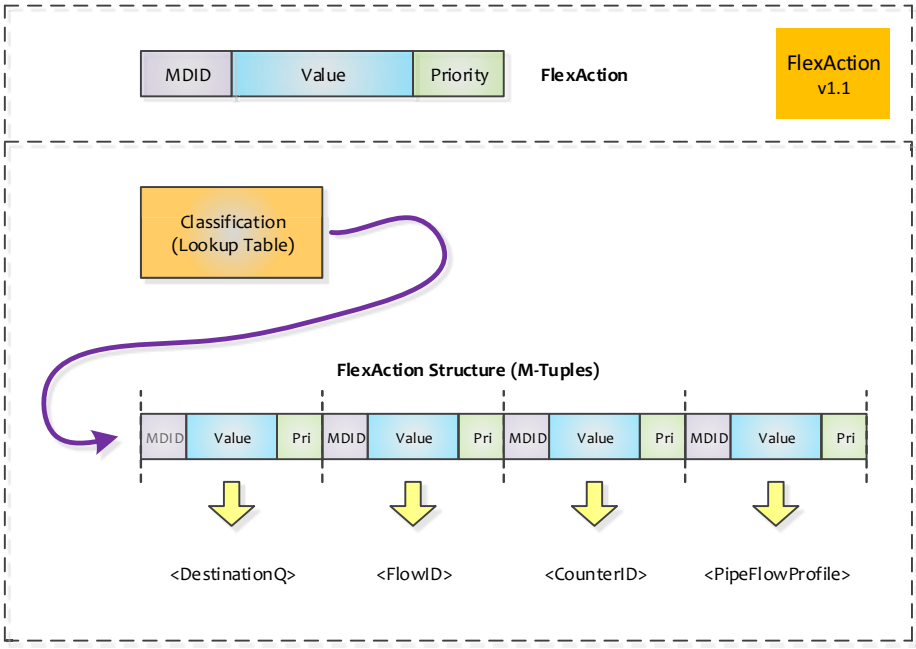

Figure 7-5. FlexAction Structure

The FlexAction structure is made of xN FlexAction Tuples, each carrying the following fields:

- <MDID> — The MDID type to be assigned, such as <DestinationQ>.
- <Value> — The value to associate with the MDID, such as the <DestinationQ> number.
- <Priority> — The priority to associate with the Action Tuple, for resolving conflicts with other sources in the pipe that can generate the same MDID type.

Note: <Priority>=0 indicates that the MDID is invalid and its <Value> should be disregarded.

1. xM is an implementation parameter selected independently per each pipeline function that generates actions. It denotes the number of FlexActions generated simultaneously, e.g., as a result of a classification lookup hit. In the example in Figure 7-5, M=4 and the FlexActions generated are <DestinationQ>, <FlowID>, <CounterID>, and a user-defined <PipeFlowProfile>.

7.5 Extractor

The E810 pipeline provides a generic extraction logic instantiated at pipeline stages that require extraction from the packet header, namely:

- Switch
- ACL
- Rx filters: FD (Flow Director), HASH, RDMA/QH (Quad Hash)

The Extractor's logic uses the Profile ID, generated by the Profile Builder, and the metadata supplied by previous stages in the pipeline to extract fields to be used in each stage.

Each extractor contains a configuration per Profile ID, which determines which fields from the packet header or its metadata are used for packets that hit that Profile ID. The extractor output, which contains the set of fields selected for the packet, is referred as the *Fields Vector*.

The extractor offsets are expressed in byte resolution while the extraction itself is done in word resolution. For each word in the Fields Vector, the configuration must specify a source word that can be from either the packet's header (up to 504B first bytes) or the packet metadata. Furthermore, a source offset in the packet's header is expressed as a relative offset to a protocol offset, using the protocol IDs offset (Section A.4), thus leveraging the capabilities of the programmable parser.

Note: Any configuration that causes the extractor to cross the header length boundaries (either by crossing the maximal supported header size or by crossing the packet length) is illegal, but an extraction can cross boundaries of internal protocols and can also refer to parts of the payload that are within the extracted header.

7.5.1 Programming the Extraction Logic

In general, the extraction logic must be programmed after the relevant profile builder is configured and the Profile ID is allocated. This section describes the configuration method used to program the extraction sequence for a previously allocated Profile ID. When an incoming packet is associated with that Profile ID, the extractor logic must use this configuration to extract fields from the packet's header and metadata to create a fields vector that are used in the given stage.

Important: The E810 pipeline supports extraction from packet headers of up to 504 byes (that is, only from the 504 bytes trailing the start-of-frame delimiter) or the length of the packet (the lowest of both). Any extractor configuration that relates to an offset beyond the maximal packet size or beyond the maximal supported header size is invalid and can cause unexpected hardware behavior.

The extractor CSRs are listed in Table 7-1. Each CSR mentioned in Table 7-1 is instantiated in three pipeline stages (Switch, ACL, and Rx filters), though some might be valid only in specific stages. Therefore, the three rightmost columns in the table specify which of the CSRs is valid in each stage and its functionality in the relevant stage.

Furthermore, each extractor in each stage supports a different output width, based on the needs of that stage. Table 7-2 specifies the output size of each extractor in each stage.

Important: Attempting to configure an extractor to output more words than it supports is forbidden and can cause unexpected hardware behavior.

Table 7-1. Extractor CSRs

CSR	Description	Switch	ACL	Rx Filters
PRFLM_DATA_0	Each CSR is used to configure protID (see Section A.4)/offset of extraction word N (See Table 7-2 for applicable FV sizes in each stage) for FV of sub-extractor #i (i=[0..2]) of this extractor. If the specified protocol ID is smaller than 255, the source is taken from packet using the protocol ID's offset plus the offset in the protocol (in bytes). If the specified offset is equal to 255, the source is taken from the packet's metadata according to the following rules: • Offset 0-30: The word is extracted from the pipe status bus. The source word byte offset is the value specified in this field. • Offset 32-62: The word is extracted from the packet status bus. The source word byte offset is the value specified in this field minus 32 (for example, a value of 32 extracts a word from byte offset 0 in the packet status bus). ***Note:*** The byte offset values mentioned above should not be confused with the MDID. ***Note:*** Offset values 31 and 63 are invalid, as word boundary crosses the relevant status bus width.	Main switch	ACL	Hash
PRFLM_DATA_1		MNG	Invalid	FD
PRFLM_DATA_2		Invalid	Invalid	Quad-Hash
PRFLM_CTRL[0]	When the CSRs is written, it determines the profileID within sub-extractor #i (i=0..2) for which the FV extractions determined in PRFLM_data_i are configured. This CSR is to be written only after all relevant PRFLM_data_i have the correct value. This CSR is also used to read the relevant content into the relevant PRFLM_data_i array. RD/WR is controlled by a field in this CSR.	Main switch	ACL	Hash
PRFLM_CTRL[1]		MNG	Invalid	FD
PRFLM_CTRL[2]		Invalid	Invalid	Quad-Hash

Table 7-2. Extractor Output Width per Stage

Stage	Extractor Instance	Output Width (Words)
Switch	Main switch	48
	Manageability	32
ACL	ACL	32
Rx Filters	Hash	24
	Quad-hash	32 (24 + 8 for fixed fields)
	Flow-director	24

7.5.1.1 Programming Flow

When programming an extraction sequence for a Profile ID #n, the programming entity follows the flow below:

1. For each of the words in the fields vector, define the location of the source word that will be placed in the fields vector:
   a. Set PRFLM_DATA_i.*PROT* to the protocol ID whose offset in the packet's header will be used as a base offset for the source word.
   b. Set PRFLM_DATA_i.*OFF* to the byte offset relative to the protocol ID offset. This field's value is added to the protocol offset to generate the final offset of the source word.

Note: When the PRFLM_DATA_i.*PROT* field is set to 255, the source word is taken from the packet's metadata and not from the packet's header. In this case, the value of the PRFLM_DATA_i.*OFF* field determines the source in the packet's metadata as described in Table 7-1.

2. Once the sources for all words in the fields vector were configured, complete the programming:
   a. Set PRFLM_CTRL[i].*PRFL_IDX* to the Profile ID for which the extraction sequence is being programmed.
   b. Set PRFLM_CTRL[i].*WR_REQ*.
3. Pull for the value of PRFLM_CTRL[i].WR_REQ. Once it is cleared, the programming is completed.

7.5.1.2 Querying Flow

The extractor logic supports reading back an extraction sequence for a given Profile ID. This flow can be useful for implementing a read-modify-write mechanism allowing a partial change in configuration.

1. Trigger the read of the configuration:
   a. Set PRFLM_CTRL[i].*PRFL_IDX* to the Profile ID for which the extraction sequence is being read.
   b. Set PRFLM_CTRL[i].*RD_REQ*.
2. Pull for the value of PRFLM_CTRL[i].*RD_REQ*. Once it is cleared, the read is completed.
3. The values are available in the PRFLM_DATA_i array.

7.6 Receive Descriptor Builder

7.6.1 Overview

The E810 provides new programmable receive descriptor formats on top of the legacy (backward compatible) receive descriptor formats. The new Flex Descriptor feature virtualizes the hardware/ software interface on the receive path, allowing software entities to program customized receive descriptors for specific use cases and applications. The feature allows each PF/VF/VM to customize its own Flex Descriptor structure with different fields and flags, exposing to software pre-processing results of interest such as <FlowID>, <ACLRuleID>, offsets to protocol headers or other opaque metadata that generated by the E810.

The Receive Descriptor Builder stage in the E810 pipeline provides the programming infrastructure and the composition logic of the Flex Descriptors.

The generic structure of the receive Flex Descriptor is illustrated in Figure 7-6.

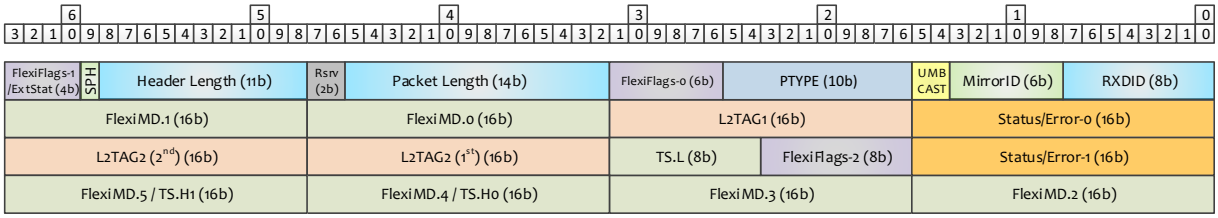

Figure 7-6. Receive Flex Descriptor

Note: Figure 7-6 shows the structure of the 32-byte receive Flex Descriptor. The shorter 16-byte receive Flex Descriptor uses the first 16 bytes of this structure, while the last 16-byte chunk of the structure is omitted.

The E810 provides 63 x Descriptor Builder Profiles for programming different descriptor formats, including the 16-byte and 32-byte legacy descriptor formats. The *RXDID* field in the Flex Descriptor structure identifies the profile and hence the descriptor format delivered to software, in particular the contents of fields and flags.

Note: *RXDID*=7 is reserved and should not be used (in legacy descriptors, *MIRR*=7 means "mirror packet", and that is the only way to distinguish it from Flex Descriptors).

The Descriptor Builder Profile selected for each packet is derived from two sources:

- **Pipeline Actions** — Based on rules programmed into the pipeline (for example, if the packet matches a rule in the ACL, the action of that rule might request a descriptor profile that exposes the <ACLRuleID> via the Receive Flex Descriptor).
- **Queue Context** — Based on the Destination Q of the packet (for example, packets sent to specific destination queue can have the same descriptor format, like the 16-byte legacy format).

The profile request is an MDID metadata/action carried in the pipeline. Conflicting actions from multiple sources that request different profiles for the same packet are resolved through the standard MDID priority resolution scheme described in Section 7.3.

7.6.2 Legacy Descriptor Format

The E810 preserves the legacy (backward compatible) descriptor format (see Section 10.4.2).

The legacy formats are available for selection as Descriptor Builder Profiles #0 (16-byte) and #1 (32-byte):

- **Descriptor Builder Profiles #0** — Generates the legacy 16-byte descriptor format, identified by *RXDID*=0 in the descriptor structure delivered to software.
- **Descriptor Builder Profiles #1** — Generates the legacy 32-byte descriptor format, identified by *RXDID*=1 in the descriptor structure delivered to software.

Note: *RXDID*=7 is reserved and should not be used (in legacy descriptors, *MIRR*=7 means "mirror packet", and that is the only way to distinguish it from flex descriptors).

The legacy descriptor can be used in applications where it is required to preserve backward compatibility at the driver level. For example, using the legacy X710/XXV710/XL710 VF driver in VFs running over the E810.

The structure of the 32-byte legacy (backward compatible) descriptor is illustrated in Figure 7-7.

The first two QW (Quad Words = 16B) are identical to the 16B legacy descriptor format.

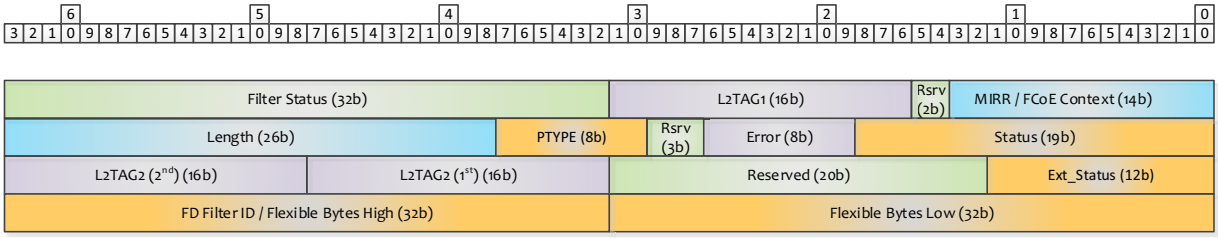

Figure 7-7. Receive Descriptor (32-Byte) - Legacy Format

7.6.2.1 PTYPE Translation

The legacy (backward compatible) descriptor uses an 8-bit PTYPE, whereas the E810 pipeline provides an advanced 10-bit PTYPE. The E810 provides a PTYPE Translation Table for matching the 10-bit E810 PTYPEs to the legacy 8-bit PTYPEs.

Note: The PTYPE Translation Table also provides the legacy 8-bit PTYPE to the Receive Data Processing Unit (RDPU) for the purpose of checksum generation.

The factory parsing program loaded from NVM provides the default 10-bit PTYPEs and their translations to legacy 8-bit PTYPEs. Further information is found in Appendix A.

7.6.3 Flex Descriptor Format

The Flex Descriptor includes permanent infrastructure fields that appear in all Flex Descriptor formats and user-defined fields that can be programmed differently by different Descriptor Builder Profiles:

- Permanent infrastructure fields:
  - RXDID
  - MirrorID
  - UMBCAST
  - PTYPE
  - Packet Length
  - Header Length
  - SPH
  - Status/Error field(s)
  - L2TAG fields
- User-defined fields:
  - FlexiFlags (user-selectable indications)
  - FlexiMD (user-selectable Metadata) and TS (Timestamp)

Detailed structure of the Flex Descriptor is illustrated in Figure 7-8.

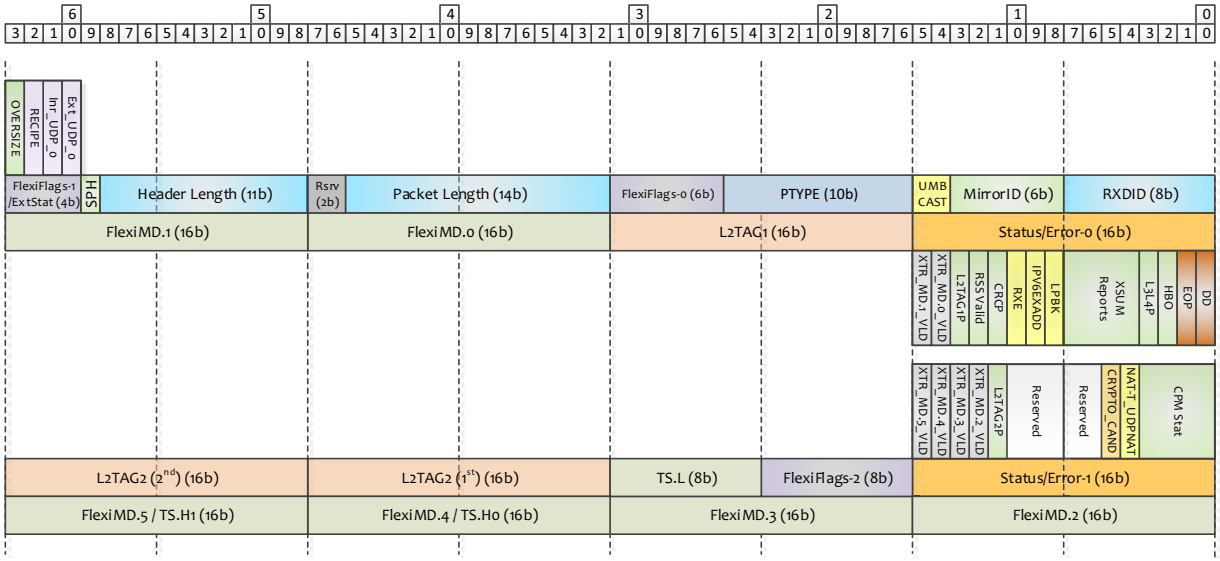

Figure 7-8. Receive Flex Descriptor (with Flags)

Table 7-3. Receive Flex Descriptor Fields

Word	Field Mnemonic	Width (bits)	Description
16-byte/32-byte Receive Flex Descriptors			
0	RXDID	8	**Descriptor Builder ProfileID** — Denoted the number of profile entry selected for this descriptor. Profiles #0 - Generates the legacy 16B descriptor format, identified by *RXDID*=0. Profiles #1 - Generates the legacy 32B descriptor format, identified by *RXDID*=1.
	MirrorID	6	**Mirror ID** — Identical to the field definition in the legacy descriptor format.
	UMBCAST	2	**UMBCAST** — Identical to the field definition in the legacy descriptor format.
1	PTYPE	10	**Packet Type** — Enumerates the packet type according to the packet types programmed into the device. The Flex Descriptor *PTYPE* is a 10-bit field. It can carry different packet type encoding than the legacy 8-bit *PTYPE* field in legacy descriptors.
	FlexiFlags.0	6	**Flexible Flags Section 0** — Up to 6 x user-selectable flags per *RXDID ProfileID*.
2	Packet Length	14	**Packet Length** — Identical to the field definition in the legacy descriptor format.
	Reserved	2	Reserved.
3	Header Length	11	**Header Length** — Identical to the field definition in the legacy descriptor format.
	SPH	1	**SPH** — Identical to the field definition in the legacy descriptor format.
	FlexiFlags.1/ExtStats	4	**Flexible Flags Section 1/Extended Status** — Up to 4 x user-selectable flags per *RXDID ProfileID*. This field can also carry additional status information: Ext_UDP_0, Int_UDP_0, RECIPE, OVERSIZE.
4	Status/Error.0	16	**Status/Error Section 0** — Status and error indications.
5	L2TAG1	16	**L2TAG1** — Identical to the field definition in the legacy descriptor format.
6	FlexiMD.0	16	**Flexible Metadata Container #0** — Generic 16-bit container for conveying metadata/ actions from the E810 pipeline to the host.
7	FlexiMD.1	16	**Flexible Metadata Container #1** — Generic 16-bit container for conveying metadata/ actions from the E810 pipeline to the host.

Table 7-3. Receive Flex Descriptor Fields [continued]

Word	Field Mnemonic	Width (bits)	Description
32-byte Receive Flex Descriptors Only			
8	Status/Error.1	16	**Status/Error Section 1** — Additional status and error indications.
9	FlexiFlags.2	8	**Flexible Flags Section 2** — Up to 8 x user-selectable flags per *RXDID ProfileID*.
	TS.L	8	**TimeStamp Word Low** — Lower word of the TimeStamp value.
10	L2TAG2 (1st)	16	**L2TAG2 (1st)** — Identical to the field definition in the legacy descriptor format.
11	L2TAG2 (2nd)	16	**L2TAG2 (2nd)** — Identical to the field definition in the legacy descriptor format.
12	FlexiMD.2	16	**Flexible Metadata Container #2** — Generic 16-bit container for conveying metadata/ actions from the E810 pipeline to the host.
13	FlexiMD.3	16	**Flexible Metadata Container #3** — Generic 16-bit container for conveying metadata/ actions from the E810 pipeline to the host.
14	FlexiMD.4/TS.H0	16	**Flexible Metadata Container #4/TimeStamp Word High #0** — Generic 16-bit container for conveying metadata/actions from the E810 pipeline to the host / Higher word #0 of the timestamp value.
15	FlexiMD.5/TS.H1	16	**Flexible Metadata Container #5/TimeStamp Word High #1** — Generic 16-bit container for conveying metadata/actions from the E810 pipeline to the host / Higher word #0 of the timestamp value.

7.6.3.1 Status/Error.0 Field

Table 7-4 details the contents of the *Status/Error.0* field.

Table 7-4. Status/Error.0 Field (16b)

Bit	Field Mnemonic	Width (Bits)	Description
0	DD	1	**Descriptor Done** — Identical to the filed definition in the legacy descriptor format.
1	EOP	1	**End Of Packet** — Identical to the filed definition in the legacy descriptor format.
2	HBO	1	**Header Buffer Overflow** — Identical to the filed definition in the legacy descriptor format.
3	L3L4P	1	**L3 and L4 Integrity Check** — Identical to the field definition in the legacy descriptor format.
7:4	XSUM Reports	4	**Checksum Reports** — Checksum error indications: bit 4 = IPE — IP checksum error indication (for tunneled packets it is the most inner IP header indication). bit 5 = L4E — L4 integrity error indication (most inner L4 header in case of UDP tunneling). bit 6 = EIPE — External (most outer) IP header (only relevant for tunneled packets). bit 7 = EUDPE — External (most outer) UDP checksum error (only relevant for tunneled packets).
8	LPBK	1	**Loopback** — Identical to the field definition in the legacy descriptor format.
9	IPV6EXADD	1	**IPv6 with Destination Options Header or Routing Header** — Identical to the field definition in the legacy descriptor format.
10	RXE	1	**Receive MAC Errors** — Identical to the field definition in the legacy descriptor format.
11	CRCP	1	**Ethernet CRC Present** — Identical to the field definition in the legacy descriptor format.
12	RSS/HASH Valid	1	**RSS/HASH Valid** — Indicates that the RSS/HASH result is valid. Qualifies RSS/HASH metadata in *FlexiMD* fields.

Table 7-4. Status/Error.0 Field (16b) [continued]

Bit	Field Mnemonic	Width (Bits)	Description
13	L2TAG1P	1	**L2 Tag 1 Presence** — Identical to the field definition in the legacy descriptor format.
14	XTR_MD.0_VLD	1	**Extract MD.0 Valid** — Indicates that extracted data from the packet is valid in MD.0. Extraction is performed according to the *ProfileID* entry in *RXDID*.
15	XTR_MD.1_VLD	1	**Extract MD.1 Valid** — Indicates that extracted data from the packet is valid in MD.1. Extraction is performed according to the *ProfileID* entry in *RXDID*.

7.6.3.2 Status/Error.1 Field

Table 7-5 details the contents of the *Status/Error.1* field.

Table 7-5. Status/Error.1 Field (16b)

Bit	Field Mnemonic	Width (Bits)	Description
0-3	Reserved	4	Reserved.
4	NAT-T/UDP-NAT	1	**NAT-T / UDP-NAT** — The packet is a UDP tunneled packet (including UDP-NAT-ESP).
10:5	Reserved	6	Reserved.
11	L2TAG2P	1	**L2 Tag 2 Presence** — Identical to the field definition in the legacy descriptor format.
12	XTR_MD.2_VLD	1	**Extract MD.2 Valid** — Indicates that extracted data from the packet is valid in MD.2. Extraction is performed according to the *ProfileID* entry in *RXDID*.
13	XTR_MD.3_VLD	1	**Extract MD.3 Valid** — Indicates that extracted data from the packet is valid in MD.3. Extraction is performed according to the *ProfileID* entry in *RXDID*.
14	XTR_MD.4_VLD	1	**Extract MD.4 Valid** — Indicates that extracted data from the packet is valid in MD.4. Extraction is performed according to the *ProfileID* entry in *RXDID*.
15	XTR_MD.5_VLD	1	**Extract MD.5 Valid** — Indicates that extracted data from the packet is valid in MD.5. Extraction is performed according to the *ProfileID* entry in *RXDID*.

7.6.3.3 ExtStat Field (FlexiFlags.1 Status Overlay)

Table 7-6 details the contents of the *ExtStat* field.

Table 7-6. ExtStat Field (4b) (When Enabled by ProfileID in FlexiFlags.1)

Bit	Field Mnemonic	Width (Bits)	Description
0	Ext_UDP_0	1	**Outer UDP Checksum Equals 0** — Identical to the field definition in the legacy descriptor format.
1	Int_UDP_0	1	**Inner UDP Checksum Equals 0** — Identical to the field definition in the legacy descriptor format.
2	RECIPE	1	**RDPU Recipe Error** — Identical to the field definition in the legacy descriptor format.
3	OVERSIZE	1	**Oversize Packet Error** — Identical to the field definition in the legacy descriptor format.

7.6.4 RXDID Descriptor Builder Profiles

For each packet, the format of the receive descriptor and particularly the contents that go into fields of the descriptor, is determined by the RXDID Descriptor Builder profile selected for the packet.

The E810 provides 63 x Descriptor Builder Profiles for programming different descriptor formats, including the 16-byte and 32-byte legacy descriptor formats that are preassigned:

- **Descriptor Builder Profiles #0** — Generates the legacy 16-byte descriptor format, identified by *RXDID*=0 in the descriptor structure delivered to software.
- **Descriptor Builder Profiles #1** — Generates the legacy 32-byte descriptor format, identified by *RXDID*=1 in the descriptor structure delivered to software.

Note: *RXDID*=7 is reserved and should not be used (in legacy descriptors, *MIRR*=7 means "mirror packet", and that's the only way to distinguish it from flex descriptors).

The Descriptor Builder Profile selected for each packet is derived either from a pipeline action that sets the *RXDID* MDID and its priority, or from the Flex Queue Context that defines an *RXDID* and priority per each queue. Conflicts are resolved through the standard MDID priority resolution scheme described in Section 7.3.

The *RXDID* field in the Flex Descriptor structure identifies the profile. Hence, the descriptor format delivered to software, in particular the contents of fields and flags.

The definition of a new Flex Descriptor format is as follows:

- Allocation of a new Descriptor Builder Profile entry.
- Programming the Descriptor Builder Profile entry:
  - FlexiMD contents (up to 6 x FlexiMD in 32-byte Flex Descriptors). Each MDID can provide one of the following:
    - MDID metadata from the pipeline (for example, opaque metadata from classification results).
    - Extracted fields from the packet (either header or payload up to the parsing depth of 504 bytes. See Section 7.6.7).
    - Pointers to locations of interest in the packet (for example, offset to the outer IPv4 header. Section 7.6.8).
  - FlexiFlags contents (up to 18 x FlexiFlags in 32-byte Flex Descriptors).

7.6.4.1 Programming RXDID Receive Descriptor Profiles

The Receive Descriptor Builder provides 64 x *RXDID* profile entries. The first two entries are preassigned for the legacy descriptor formats.

The configuration of a profile entry is done as follows:

For FlexiMD (n=0..5):

- GLFLXP_RXDID_MD[n].*ProtID_MDID*:
  - This field holds either a ProtocolID value or an MDID value. It's decoding is based on *RXDID_opcode* field.
    - ProtID (ProtocolID): For reporting its offset or for extracting packet bytes from this offset.
    - MDID: For reporting the MDID metadata contents.

- GLFLXP_RXDID_MD[n].*extraction_offset*:
  - Relevant only if *ProtID_MDID* field is a protID.
  - Used as offset within ProtID to extract bytes from the packet.
  - Its usage is based on *RXDID_opcode* field.
- GLFLXP_RXDID_MD[n].*RXDID_opcode*:
  - The opcode selects the type of report that goes into FlexiMD[n] in the Flex Descriptor:
    - 00b = "Fixed Value": Report the value from protID_MDID field itself (for debug purposes).
    - 01b = "Metadata Offset": Report the selected MD word from the internal FlexiPipe buses.
    - 10b = "Extraction Offset": Extract 16 bits (2 bytes) from offset location (ProtocolID offset + byte offset) in the packet.
    - 11b = "Protocol Offset": Report the offset to the selected ProtocolID.

For FlexiFlags.0 (6 bits) / FlexiFlags.1 (4 bits) / FlexiFlags.2 (8 bits) (n=0..17, total 18 bits):

- General:
  - The Receive Flex Descriptor includes 3 x FlexiFlags fields providing a total of 18 flags:
    - flexiflags0[5:0]
    - flexiflags1[3:0]
    - flexiflags2[7:0]
  - Note that the fields *flexiflag_4n*+2/*flexiflag_4n*+3 are invalid in last index as there are only 18 flags, not 20.
- GLFLXP_RXDID_FLAG [n].*flexiflag_4n/4n+1/4n+2/4n+3*:
  - Determines the flag index to be reported in flexiflag[4n/4n+1/4n+2/4n+3] from the FLG64 64 x flags available in the pipeline.

FlexiFlags.1 provides additional indications from RDPU that can override the regular flag selections:

- GLFLXP_RXDID_FLAGS1_OVERRIDE.flags1_override:
  - If Bit 0 is set, EXT_UDP_0 indication from RDPU replaces the value of flexiflags1[0].
  - If Bit 1 is set, INT_UDP_0 indication from RDPU replaces the value of flexiflags1[1].
  - If Bit 2 is set, RECIPE_ERROR indication from RDPU replaces the value of flexiflags1[2].
  - If Bit 3 is set, OVERSIZE indication from RDPU replaces the value of flexiflags1[3].

  Note: Further description of these indications from RDPU can be found in the legacy descriptors chapter section.

A special case is the support for legacy descriptors. For those, the configuration convention is:

- *RXDID* entry#0 is used for legacy 16-byte descriptors, and RXDID entry#1 is used for legacy 32-byte descriptors.
- Accordingly, the setting for the CSRs for entries 0 and 1 are:
  - GLFLXP_RXDID_MD.*protID_MDID*[0]=56 (HASH Low)
  - GLFLXP_RXDID_MD.*protID_MDID*[1]=57 (HASH High)
  - GLFLXP_RXDID_MD.*protID_MDID*[4]=5 (FDID Low)

— GLFLXP_RXDID_MD.*protID_MDID*[5]=6 (FDID High)

— GLFLXP_RXDID_MD[0].*RXDID_opcode*=01b (signaling MDID)

— GLFLXP_RXDID_MD[1].*RXDID_opcode*=01b (signaling MDID)

— GLFLXP_RXDID_MD[4].*RXDID_opcode*=01b (signaling MDID)

— GLFLXP_RXDID_MD[5].*RXDID_opcode*=01b (signaling MDID)

— All other fields are don't care for entries 0 and 1.

7.6.5 Receive Flex Queue Context

The E810 Flex Descriptor enhances the queue context with additional fields on top of the legacy queue context, as illustrated in Figure 7-9.

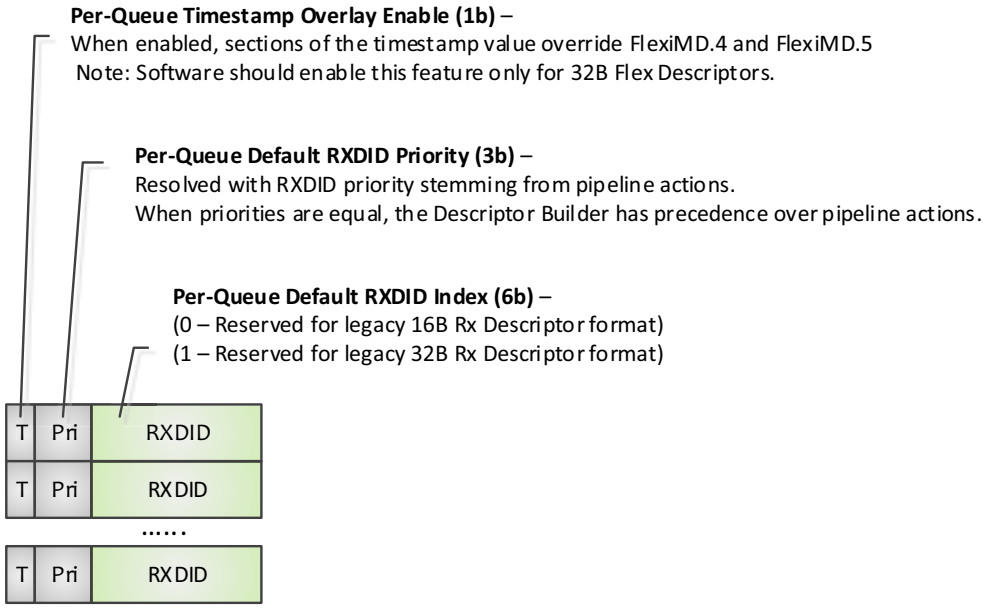

Figure 7-9. Receive Flex Queue Context

7.6.5.1 Programming the Receive Queue Context for Flex Descriptors

Programming of the additional Flex Queue Context is done via the QRX_FLEX_CNTXT CSRs, as follows:

- QRXFLXP_CNTXT.*RXDID_idx* — Determines the default *RXDID_idx* for this Q.
- QRXFLXP_CNTXT.*RXDID_prio* — Determines the default priority for the default *RXDID_idx* for this Q. This value is compared against RXDID priority from the RCU pipe. If this one is equal or higher, it wins, and the *RXDID_idx* for this pkt is determined by QRX_FLXP_CNTXT.*RXDID_idx*. Otherwise, it is determined by the value from the RCU pipe.
- QRXFLXP_CNTXT.*TS* — Determines whether timestamp reporting per Rx packet is enabled for this Q. If enabled, the *TS.H1*/*TS.H0*/*TS.L* fields in the Rx-Descriptor contains the timestamp for this packet. Bit 0 of the *TS.L* field is the "valid" bit for this timestamp.

7.6.6 Timestamp Overlay

The E810 provides a Timestamp Overlay feature for conveying timestamp information from receive ports to the host. The feature is enabled per destination Q via the Flex Queue Context structure, as described in Section 7.6.5.

The 40-bit timestamp value generated by the receive port is populated into fields in the 32-byte Receive Flex Descriptor as illustrated in Figure 7-10. Description of the Receive Flex Descriptor fields in provided in Section 7.6.3.

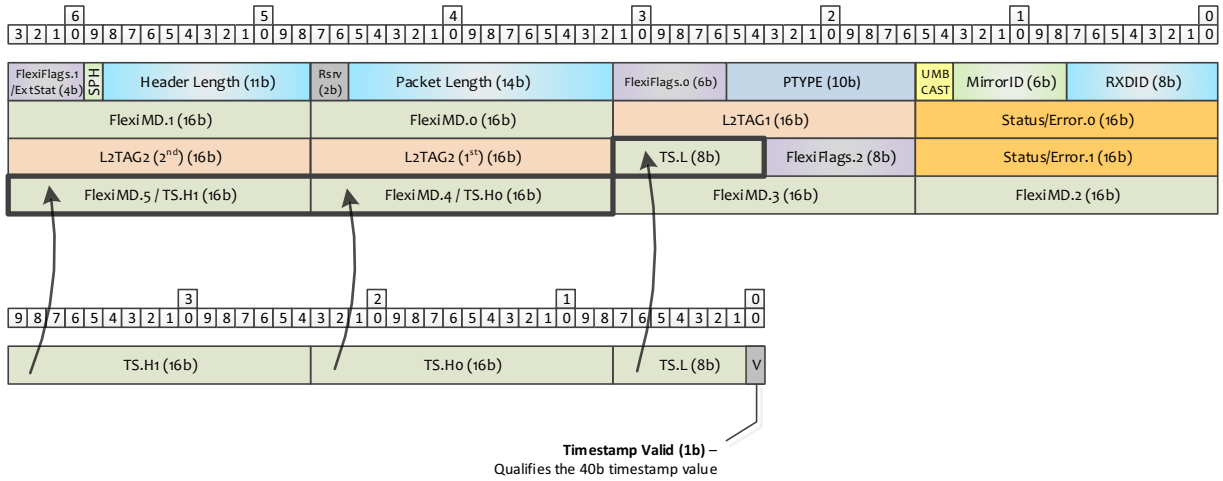

Figure 7-10. Timestamp Overlay in 32-Byte Receive Flex Descriptor

Note: The Timestamp Overlay feature is available only in 32-byte Flex Descriptors. The user should program the RXDID Profile for that queue accordingly, so that 32-byte Flex Descriptors are generated for packets arriving at that queue. The user should also enable the Timestamp Overlay feature in the Flex Queue Context as described in Section 7.6.5.

Note: The LSb (Bit 0) of the *TS.L* field is the timestamp valid bit, qualifying the timestamp value.

When the QRX_FLXP_CNTXT.*TS* bit in the Flex Queue Context is set, the E810 overlays the 40-bit timestamp value into these fields of the 32-byte Flex Descriptor:

- • TS.H1 (16 bits) — Replacing FlexiMD.5
- • TS.H0 (16 bits) — Replacing FlexiMD.4
- • TS.L (8 bits) — LSb (Bit 0) is the timestamp valid bit

The corresponding FlexiMD.5 and FlexiMD.4 metadata selected by the RXDID Profile for that packet are overwritten and replaced with sections of the timestamp value.

Note: When TimeStamp Overlay is enabled for particular queue in the Flex Queue Context, all 32-byte Flex Descriptors associated with packets arriving at that queue contain the timestamp overlay fields, regardless of whether the timestamp value is valid. When a queue is programmed to receive timestamps, software should evaluate the LSb (Bit 0) of *TS.L* of the 32-byte Flex Descriptor to infer whether a timestamp is valid for that packet.

7.6.7 Field Extraction into the Flex Descriptor

The E810 provides programmable field extractions from the packet into the Receive Flex Descriptor. Fields can be extracted either from the packet header or from the payload, up to the maximum parsing depth (504 bytes). Packet fields are extracted into the FlexiMD containers of the Receive Flex Descriptor. The number of field extractions provided depends on the size of the Receive Flex Descriptor:

- 16-byte Receive Flex Descriptors provide up to 2 x FlexiMD fields that can be used for field extractions.
- 32-byte Receive Flex Descriptors provide up to 6 x FlexiMD fields that can be used for field extractions.

Extraction width is always 16 bits. Software can opt to use smaller parts of the extraction (for example, when a smaller 8-bit is required.

Note: Any extraction of fields to the receive descriptor is done before any modification potentially done on the packet (for example, VLAN stripping) with the exception of CRC. Requesting the extraction of the CRC field to the receive descriptor is not allowed.

Each field extraction is defined by the following parameters in the RXDID Profile structure as described in Section 7.6.4:

- ProtocolID — Offset position generated by the parser.
- Offset — Relative byte offset from the ProtocolID position.

For example, to extract the destination port of a UDP packet, the user should program the extraction to use the ProtocolID of UDP with Offset=2 (bytes), as illustrated in Figure 7-11.

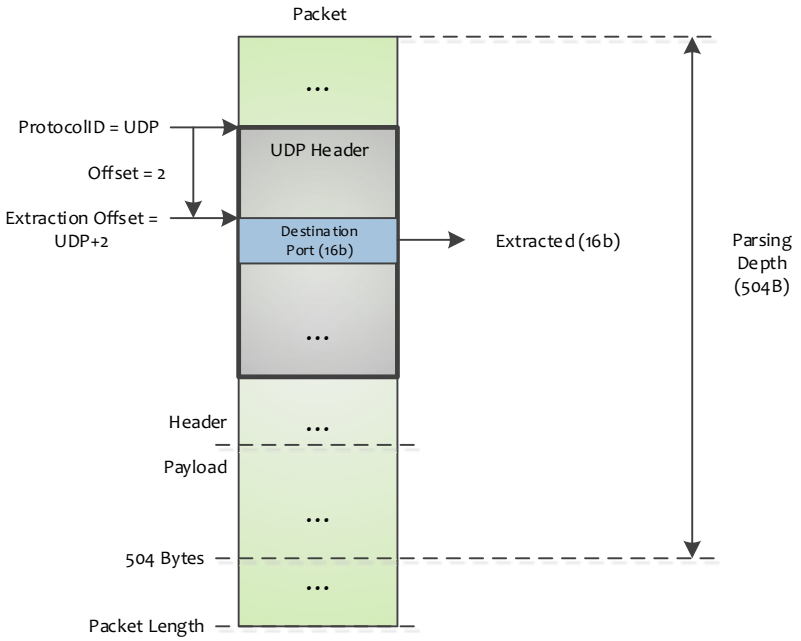

Figure 7-11. Field Extraction into the Flex Descriptor - Example

Note: Figure 7-11 illustrates a particular example in which the packet length is larger than 504 bytes. The packet header in this example is shorter than 504, allowing extraction from the payload.

The E810 indicates successful extraction per FlexiMD container by setting the corresponding XTR_MD.*#_VLD* bit in the Status/Error fields as described in Section 7.6.3.1 and Section 7.6.3.2. When the particular FlexiMD is programmed to contain an extraction result, but the XTR_MD.*#_VLD* bit is clear, software should disregard the value in the FlexiMD field.

The Receive Descriptor Builder validates for each extraction that the requested extraction offset is within packet boundaries. In case the extraction offset exceeds the packet boundary (that is, since the extraction works in word resolution, the byte offset is >{packet size - 2}), the Receive Descriptor Builder:

- Places the value 0xFFFF into the corresponding FlexiMD container.
- Clears the corresponding XTR_MD.*#_VLD* bit in the Status/Error field.
- Sets the Malicious Event exception flag.

Note: When using 16-byte descriptors, setting an out-of-bound extraction offset in FlexMD[5:2] (which is only relevant for 32-byte descriptors) also sets the malicious exception flag. Therefore, even when using 16-byte descriptors, the extraction offsets programmed for FlexMD[5:2] should contain valid offsets (though not used).

7.6.8 Pointers to Location of Interest

The FlexiMD metadata containers in the Flex Descriptor can be programmed to convey pointers to locations of interest in the packet, such as offsets to packet headers. Programming of the feature is done via the GLFLXP_RXDID_MD[n].*RXDID_opcode* CSR as described in Section 7.6.4.1.

For example, to provide the host with the IPv4 offset and the TCP offset of the packet, the RXDID profile entry is programmed to assign 2 x FlexiMD containers, as illustrated in Figure 7-12.

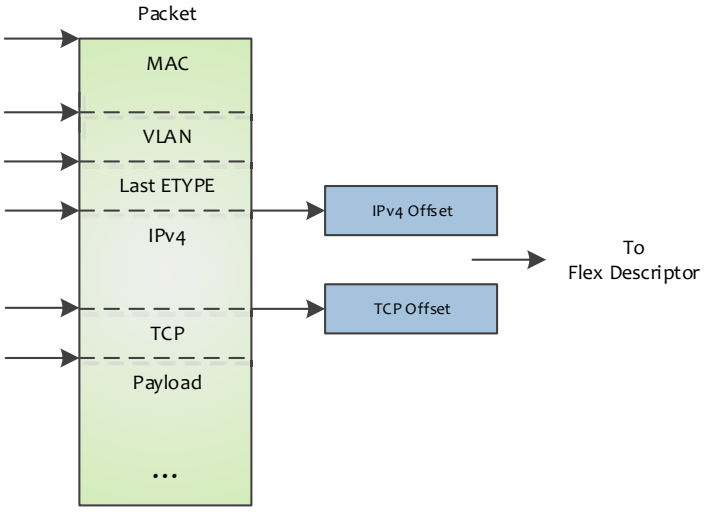

Figure 7-12. Field Extraction into the Flex Descriptor - Example

Note: Any offset report generated by the Parser can be placed into the Flex Descriptor. Offset reports normally point to protocol headers, however the Parser can be programmed to report offsets of any other location of interest such as TLV headers, option fields, and so on.

7.7 Programmable Parser

7.7.1 Introduction

The E810 provides a software programmable Parser (Analyzer) capable of supporting a wide range of well-known and proprietary protocols. The Parser examines the traffic that enters the pipeline, retrieves search parameters from the packet and from associated packet context, and then generates additional context based on certain packet attributes. This context is further used by other packet processing modules in the pipeline to associate the packet with a flow, software hints, and so on.

The factory parsing program loaded into the Parser from NVM supports a large set of frame formats that are common in various networking applications. These formats are provided by the E810 out of the box, not requiring any additional installation or programming.

A detailed description of the Factory Parsing Program appears in Appendix A.

These native formats include various protocols such as:

- L2: VLAN
- L2.5: MPLS
- L3: IPv4, IPv6
- L4: TCP, UDP, ICMP
- Overlay Network Formats: VXLAN, NGE, GRE
- Service chaining: NSH

7.7.1.1 Parsing Policy - Parse Graph

A parse graph is a representation of permitted protocol sequences in the network. The parse graph is composed of nodes and arcs. Each node represents a state, normally a protocol header. It is associated with a {NodeID} identifier. An arc represents traversal between nodes, normally between protocol headers. It originates from a source {NodeID} to a target {NodeID}.

Figure 7-13 illustrates a simple parse graph.

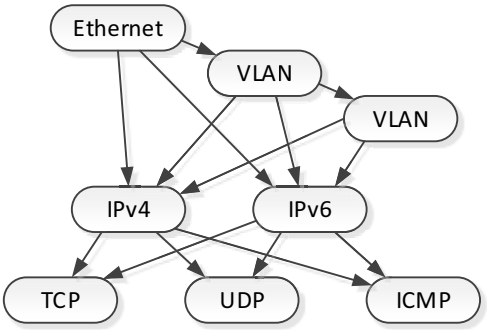

Figure 7-13. Simple Parse Graph

The simple parse is made from eight nodes and 14 arcs. The nodes in this parse graph correspond to protocols (Ethernet MAC header, VLANs, IPv4, IPv6, TCP, UDP, ICMP). Traversal conditions between nodes can be unconditional (that is, always take, or conditional (for example based on a protocol identifier in the protocol header such as the protocol field in an IPv4 header).

An example of an advanced parse graph scenario is illustrated in Figure 7-14.

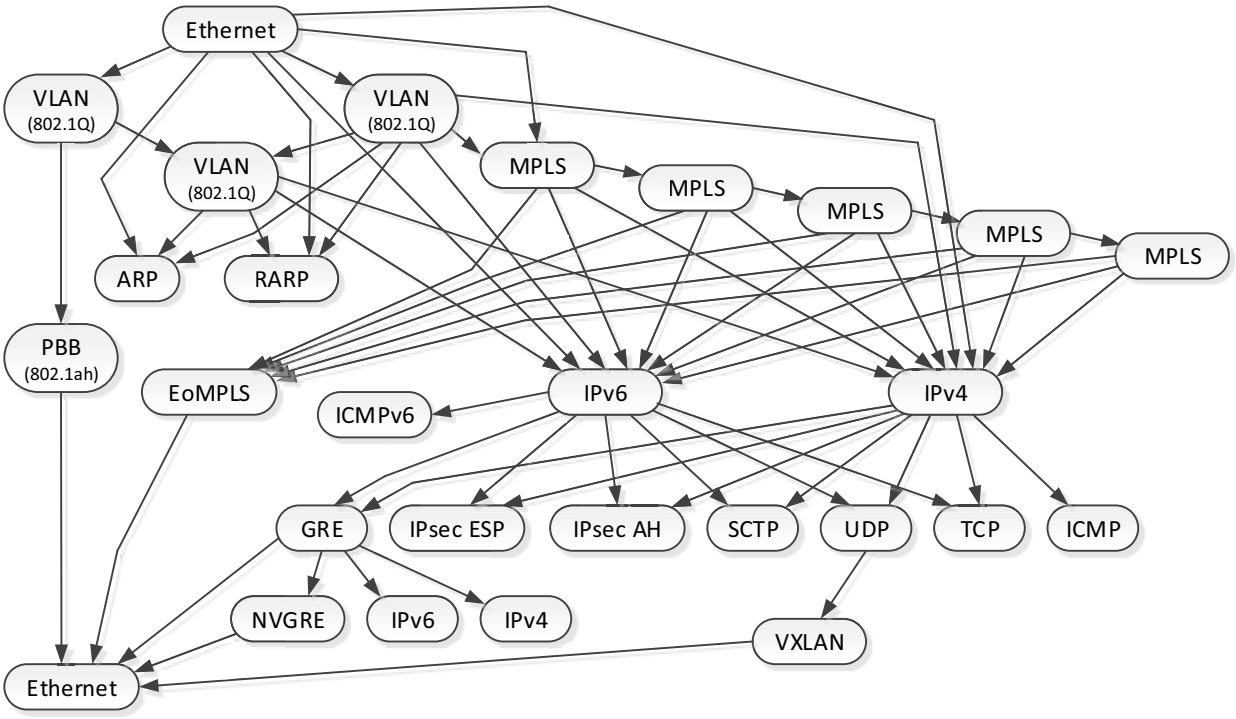

Figure 7-14. Advanced Parse Graph

7.7.1.2 Parsing Depth

The E810 Parser processes packet headers included in the first 504 bytes of the packet. The extensive depth covers complex encapsulation scenarios found in Cloud, Overlay-Networks, and Comms applications.

Note: Though the parsing depth is 504 bytes, the parser has an additional "protocol parsing depth" limitation allowing it to process up to 16 protocols (as specified in the parse graph) including the payload as the last protocol ID (the "payload" protocol ID is always be reported as the last protocol).

7.7.1.3 Parsing Profiles

The FlexiParser provides 16 x Parsing Profiles that determine the parsing execution flow.

A Parsing Profile determines:

- Initial PC (Program Counter) — Where the parsing program begins execution.
- Initial HO (Header Offset) — The offset location in the packet from where parsing starts.
- Initial NodeID — The root node of the parse graph selected.
- Register load — CPU General Purpose Registers (GPRs) loaded with pipeline metadata.

The structure of the profile table is shown in Table 7-7.

Table 7-7. Parser Profile Table

Field	Width	Description
TSR	8	Initial value for the TSR register.
HO	9	Initial value for the HO register.
NPC	8	Initial value for the NPC register.
NID	11	Initial value for the NID register.
Control domain	3	Control domain identifier. Used for marker PTYPE TCAM look up operation.
GPR_A_ctrl	1	General purpose register A Control: 0b = Copies constant value to the GPR. 1b = Copies a certain field from interface to GPR_A_ID: GPR_A_ID = MDID_A[MDID_A_start + MDID_A_len -1 : MDID_A_start] MDID_A_target_GPR = GPR_A_DATA
GPR_A_DATA	16	General purpose register A Data: Bits 0:4 = MDID_A Bits 5:8 = MDID_A_start Bits 9:12 = MDID_A_len Bits 13:16 = Reserved
GPR_A_ID	4	General purpose register A ID.
GPR_B_ctrl	1	General purpose register B Control.
GPR_B_DATA	16	General purpose register B Data.
GPR_B_ID	4	General purpose register B ID.
GPR_C_ctrl	1	General purpose register C Control.
GPR_C_DATA	16	General purpose register C Data.
GPR_C_ID	4	General purpose register C ID.
GPR_D_ctrl	1	General purpose register D Control.
GPR_D_DATA	16	General purpose register D Data.
GPR_D_ID	4	General purpose register D ID.
Flags initial value	64	Initial values for flags register.

7.7.1.4 PTYPE Generation

The FlexiParser generates a 10-bit PTYPE (Packet Type) that can be derived from:

- **Terminating NodeID** — When parsing stops at a NodeID that has an attribute of a terminating NodeID, the PTYPE is taken from the terminating NodeID PTYPE table.
- **Marker Sets** — When parsing stops at a NodeID that does not have an attribute of a terminating NodeID, the PTYPE is derived from the Marker Set Rules Table.

7.7.1.5 Programming Flow

The following sections describe the programming flows of the Parser.

7.7.1.5.1 Initialization

Following a device core reset the factory parsing program is loaded from NVM. A detailed description of the Factory Parsing Program appears in Appendix A. The parsing program includes complete configuration of the Parser, ready to run, including:

- Program code (iMEM)
- Protocol templates (TCAM)
- ProtocolIDs
- Parse Graph (PG)
- PTYPEs
- Well-Known/Public CDs (CD0+) and Profiles
- Misc tables/regs (e.g., ALU translation tables)

The parsing program carries a version number that the driver can query via a firmware AQC.

The factory parsing program loaded from NVM is initially unlocked and managed by firmware as a shared resource ownership using existing firmware infrastructure. A PF driver can obtain a lock on pipeline programming to update it via an ACQ.

The sequence is as follows:

1. Parsing image loaded from NVM.
2. First PF driver obtains lock on pipeline programming via ACQ.
3. PF driver queries version of parsing program via ACQ.
4. PF driver can choose to update the parsing program.
5. Firmware keeps timeout to release lock if PF driver fails/crashes.
6. When update is completed, the parsing program is available with updated version number.
7. PF driver continues programming the rest of the pipeline until done.
8. PF driver releases lock (the firmware provides a timeout fall-back procedure).
9. Firmware prevents further updates until next core reset or after the last PF driver goes down.
10. All PF drivers use the same parsing program.

Note: Manageability traffic is disabled during the update of the parsing program.

7.7.1.5.2 Configuration Access to Parser Resources

The Parser exposes indirect interface for reading and writing tables or execute table lookups using the following set of registers:

- GLGEN_ANA_CFG_CTRL
- GLGEN_ANA_CFG_RDDATA[0..15]
- GLGEN_ANA_CFG_WRDATA

7.7.1.5.2.1 Write Sequence

1. Before writing a line, firmware writes the GLGEN_ANA_CFG_CTRL register to point to the target line in the target table.
2. Firmware writes the GLGEN_ANA_CFG_WRDATA register multiple times until a complete line is accumulated.
3. The Parser accumulates the 32-bit CSR writes into a wide data line. When it detects that a full line is accumulated, it writes it to target line in memory.
4. In case firmware continues writing the WR_DATA (without writing the CTRL register first), the Parser continues to write the next line in the same memory.

7.7.1.5.2.2 Read Sequence

1. Firmware writes the GLGEN_ANA_CFG_CTRL register to point to the target line in the target table.
2. Firmware reads the relevant data directly from GLGEN_ANA_CFG_RDDATA[0..16] registers.
3. Before reading the next line, firmware must set the GLGEN_ANA_CFG_CTRL register again.

7.7.1.5.3 In-Service Programmability

The Parser provides in-service programming of the following resources:

- Add/Remove of PG arc
- Add/Remove of TCAM entry
- Add/Remove/Change of Profile

Note: It is assumed that the associated PG nodes and iMEM instructions are already configured in the Parser database.

7.7.1.5.3.1 Add/Remove of PG Arc

The flow of adding/removing of PG is as follows:

1. Firmware writes the PGkey to GLGEN_ANA_CFG_LU_KEY.
2. Firmware initiates PG lookup via GLGEN_ANA_CFG_CTRL.
3. The Parser hardware returns:
   - The CAM hit result, the CAM bank number (when not in spill buffer), and the CAM line index in GLGEN_ANA_CFG_SPLBUF_LU_RESULT and GLGEN_ANA_CFG_HTBL_LU_RESULT.
   - TCAM unit 0 capacity - GLGEN_ANA_CFG_RDDATA 0.

- TCAM unit 1 capacity - GLGEN_ANA_CFG_RDDATA 1.
- TCAM unit 0 bin vector - GLGEN_ANA_CFG_RDDATA 2.
- TCAM unit 1 bin vector - GLGEN_ANA_CFG_RDDATA 3.
- TCAM unit 0 HASH value - GLGEN_ANA_CFG_RDDATA 4.
- TCAM unit 1 HASH value - GLGEN_ANA_CFG_RDDATA 5.
- Spill buffer capacity vector - GLGEN_ANA_CFG_RDDATA 7/8.

4. Firmware initiates or resets the PG action memory using memory write sequence.
5. Firmware initiates or resets the PG key using memory write sequence.

7.7.1.5.3.2 Add/Remove of TCAM Entry

The flow of adding/removing of TCAM entry is as follows:

1. Firmware writes an action to a well-known address in the TCAM action memory using the memory write sequence.
2. Firmware writes a key to a well-known address in the TCAM key using the memory write sequence.

7.7.1.5.3.3 Entry Change in Profile Table

Table content change happens only for a Profile that its packets are drained from pipe.

Before changing content:

1. Firmware routes the modified profile N to a stable default profile by writing the default Profile ID to index N in the P2P table.
2. Firmware waits 10 μs. During this time period it is guaranteed that:
   - Packets processed in pipe before the change are drained towards the reorder logic.
   - New packets enter the pipe with the default profile.
3. Firmware does table changes for the reset profile using memory write sequence.
4. Firmware enables the modified profile by writing “N” to the index N in the P2P table.

7.8 Switch (Binary Classifier)

7.8.1 Features

Table 7-8. Binary Classifier Features

Description
Logical Switching Tables • Supports up to 64 different switching lookups/recipes (all actions included). • Supports up to 10 concurrent switching lookups per specific packet type @ 90 Mpps. • Each lookup can contain up to five 16-bit tuples. Lookups can be chained to create longer recipes. • Support up to 32K lookup entries. The actual number depends on the length of the recipe and the utilization of the hash.
Built in recipes loaded from NVM to implement basic NIC functionality • Supports simple L2 switching including VEB and VEPA modes. • Supports default VSI per VEB (using default, direction recipe). • Supports flooding action per VSI. • Anti spoofing.
Sample use cases to be supported • Multi Channel VEPA (STag based). • Tenant Forwarding (NVGRE, Geneve, and so on). • Q-in-Q forwarding. • Private VLAN. • Local VLAN. • Floating VEB.
Support for multiple switch instances • Allow classification of traffic to different switch instances based on source or tag in packet. • Tag can be up to four words long from anywhere in header. • Support up to 64 tag based switch IDs.
Allows Tx-Descriptor from trusted driver to define the destination of a packet. Allows the following options: • Send To LAN only. • Do not send to LAN. Let switch define the destination within loopback. • Send to a specific VSI
Actions - support multiple type of actions per recipe • Forwarding - to VSI, VSI list, queue group within a VSI, or queue within a VSI. • Pruning. • Statistics. • Support up to 8K basic actions that can be chained in up to four actions. • Multiple forwarding actions can be prioritized or merged.
Support for different switching Profiles • Applicable recipes can be selected according to source of packet, packet type, and other packet parameters. • Support bypass of classifier for selected packet profiles. • Allow trusted software to fix destination of packet.
Egress Rules - support additional actions on egress copy of a packet • Egress mirroring. • Source pruning. • Limit decrypted traffic to function owning the SA.
Support up to 768 VSIs. • Allow replication to multiple VSIs.

Table 7-8. Binary Classifier Features [continued]

Description
Statistics • Per VSI statistics. • Up to 32 per VEB statistics block. • Up to 128 per VLAN/UP statistics block.
Mirroring • Ingress mirroring (according to packet source). • Egress Mirroring (according to packet destination). • VLAN/VEB mirroring. • Event based mirroring. • Mirroring destination to local VSI only.
Storm Control • Per port broadcast and multicast storm control.
Programming API • Allow Software to add or remove switching recipes on the fly. • Allow Software to classify traffic to profiles on the fly.
Manageability forwarding. • Supports forwarding of packets to the BMC or the internal EMP based on the MDEF filters described in Section 12.4.

7.8.2 Binary Classifier (Switch) Block Diagram

Figure 7-15 describes the switch blocks:

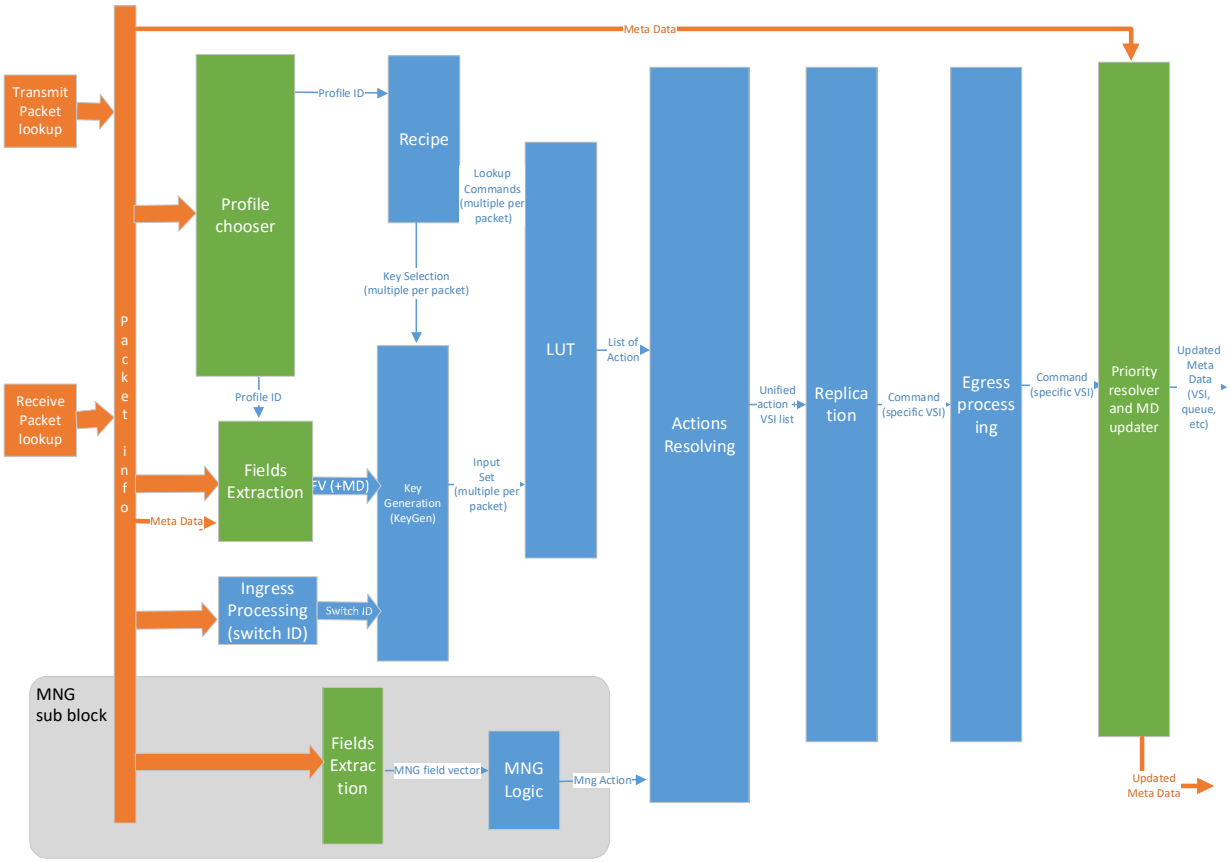

Figure 7-15. Switch Block Diagram

A packet entering the E810 switch goes through the following steps, depicted Figure 7-15:

1. **Profile Selection** — A Profile ID is selected based on metadata of the packet (typically, the packet type and the source of the packet). The Profile ID later defines the set of recipes and the input set that is relevant for each packet.
2. **Switch ID Generation** — The header and metadata of the packet are used to define a switch ID for the packet. The switch ID associates a packet with a specific switch instance. The switch ID is used in subsequent steps to identify lookup entries that are relevant to this packet.
3. **Field Extraction** — Based on the Profile ID, a set of fields from the header are extracted and organized as a "field vector". The extracted fields should be all the fields relevant for the different recipes lookups.
4. **Lookups**:
    a. Recipes selection — Based on the Profile ID, a set of lookups to apply to the packet's field vector are selected.

b. For each recipe, the Key Generator (KeyGen) selects from the packet's field vector the parts of the header needed to create this lookup and presents the results to the Lookup Table (LUT).

c. The LUT is a binary CAM containing the various lookup values and actions. The output of this stage is a set of actions to apply to the packet.

5. **MNG Sub-Block (Manageability Lookup)** — In parallel to the host forwarding lookup, filters specific to traffic that need to be forwarded to the BMC via sideband are applied to implement NC-SI and other pass-through forwarding rules. This stage can add an additional action to the set previously defined. This block has its own profile selection unit.
6. **Action Resolving** — After all the actions are created, unified actions are created. The output is a list of VSIs that should receive the packet and other actions such as statistic actions and others.
7. **Replication** — For each VSI in the resulting VSI list, a command to replicate the packet is created.
8. **Egress Processing** — For each copy of the packet, egress rules are applied. Applied actions can be egress mirroring.
9. **Priority Resolver and Metadata Updater** — The resulting commands are forwarded to the next stages of the pipe. As part of this the decision of the switching blocks are merged into the global metadata bus.

7.8.3 Control Domain and Profile Selection

The profile selection block is described in Section 7.2.2. The usage of this block in the switch context is to select a profile based on the packet type and based on the source of the packet. Selection based on the packet type is used to reduce the lookups to the ones relevant to this packet type. Selection based on the packet source is used to assign different recipes for different networks.

There are up to 256 profiles in the binary classifier, and 512 rules in the TCAM to select them.

A profile is be selected according to the following parameters. Some of them are used as part of the current implementation and some are reserved for future expansions:

- Packet Source:
  - — Transmit - VSI Number
  - — Receive - Physical port# or logical port ID
- Packet Source Type:
  - — Receive - from LAN
  - — Loopback - from Host
  - — Loopback - from EMP/BMC
  - — Transmit - query

  Note: The packet source type and packet source are used to create the first input of the control domain selection, thus allowing selection of a control domain according to the VSI that sent the packet or according to the port on which the packet was received.
- Packet Type — This field allows different profiles for different packet type groups, thus allowing reduction of the number of recipes that can be applied to a single packet, and improving the performance of the switch.

- Flags:
  - Bypass switch command, bad packets, SWPE — Fields that allow a bypass of the switch for packets that do not require a switch decision via the lookup tables.
  - Software command — This field is be used to prevent regular traffic from matching a profile, while allowing software commands to still match the profile (for example, to delete recipes).
- Other optional fields not currently used, but that can impact the profile:
  - TC
  - Other fields can be defined later by software.

7.8.4 Ingress Pre-Processing

7.8.4.1 Field Extractor

The Fields Extractor is a standard block that extracts a local Field Vector (FV) from the packet info. The list of fields that are extracted is based on the selected Profile ID.

The configuration of this block should be that all the fields used by any of the recipe selected by this Profile ID are represented in the generated field vector.

See Section 7.5 for programming of the extraction vector and encoding of the Protocols.

The resulting vector can be up to 48 words for the main switch and 32 words for the manageability decision. See Section 7.8.7 for details of the manageability filtering Fields Extractor.

The default vector is defined in Section 7.8.11.3.2.

7.8.4.2 Switch ID Creation

The ingress switch ID is an identifier of the virtual VEB to which the packet belongs, and it is used as an input to the LUT.

The switch ID is based on the source of the packet (VSI, port or logical port).

The input to this block is the metadata bus and the field vector. The relevant information taken from these buses is the packet source:

- For Transmit - VSI Number
- For Receive - Physical port# or logical port ID

The following data is defined in the block:

- A per-VSI switch ID — Used to identify the switch ID of a packet based on the VSI that sent the packet. This is part of the VSI context and is stored in the VSI_SWITCHID array (*SWTCHID*[7:0] field).
- A per logical/physical port switch ID — Used to identify the default switch ID of packets. Stored in the GL_VP_SWITCHID array (*SWITCHID*[7:0] field).
  - The selection between physical or logical port is done according to the GL_SWT_SWIDFVIDX.*PORT_TYPE* field (0b = Physical, 1b = Logical).

The switch ID is created according to the following logic:

```
if (packet is Tx (loopback or query)) { switch ID = VSI Switch ID}
else if (packet is rx) { switch ID = logical port/physical port Switch ID}
```

The output of the Block is switch ID[7:0] and it is added as part of the Field vector.

Per switch ID, a GLSWID_STAT_BLOCK register defines if one of 32 VEB statistic block is associated with this switch ID. The GLSWID_STAT_BLOCK.*VEBID* field defines the stat block ID to which the switch ID is associated. A switch ID cannot be associated with any switch block (GLSWID_STAT_BLOCK.*VEBID_VALID* = 0).

The switch ID extracted as described above should be part of the Field Vector described in Section 7.8.4.1 to enable differentiation between lookup entries of different VEBs.

7.8.5 Switching Engine

7.8.5.1 Switching Recipes and Key Generation (KeyGen)

The switch recipe block is a set of 64 lines that describes the lookups to do on the field vector. Each recipe can be based on multiple lookups and multiple recipes can be applied to a single packet. The set of recipes to apply on a given packet is defined according to the Profile ID using a per Profile ID bitmap defining which lookups to apply.

In addition, another table maps the dependencies between recipes. For each recipe, there is a bitmap of all the recipe entries that are part of the decision tree of this recipe.

Each lookup line can be defined as a root of a recipe or a line that creates an intermediate lookup used for another calculation. A root line can also serve as an intermediate lookup of another root line. Only root lines points to an action.

The intermediary results are stored back into the field vector and so can be used as part of the input set of subsequent lookups.

Lines that are used as intermediate steps of a recipe should be stored before the root of this recipe. See Figure 7-16 for the multiple lookup recipe diagram.

Per profile, up to 32 lookup lines can be selected, and 24 of them can be recipe roots.

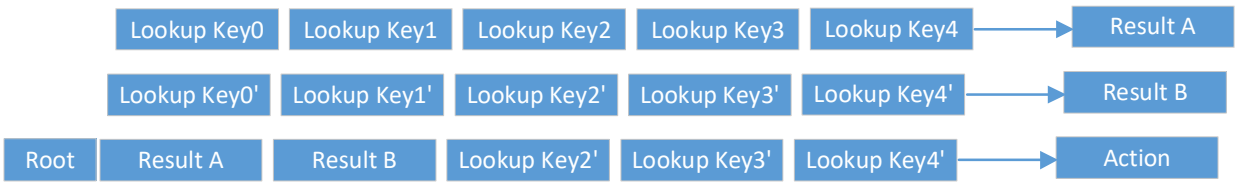

Figure 7-16. Multiple Lookup Recipe

Once a lookup line is chosen, the list of lookup words are used by the KeyGen block to build the part of the lookup key extracted from the packet header or the metadata. The generated key, the mask bits, and the RID are then looked up against the Lookup table.

The lookup lines are applied in the order they appear in the table. Hence, entries in the recipe table should be in order so that lines used as an intermediate lookup creates intermediary results before a line that uses the lookup result is run.

Each lookup line contains the following information:

Table 7-9. Recipe Content

Field	Byte Range	Width	LSB	MSB	Sub-Field Description
RID	Byte 0	6	0	5	Recipe ID (RID)[1].
		1	6	6	Reserved (for recipe expansion).
		1	7	7	isroot — Defines if this lookup line is a root of a recipe.
Lookup Index 0	Byte 1	6	8	13	First word to be compared to data from the Field Vector or the metadata. The value is an offset within the extracted Field vector. Unused fields should be masked in the *Mask* field.
		1	14	14	Reserved.
		1	15	15	Ignore Valid — If set, the field match even if the field is not valid. Should be set for VLAN entries where a value of zero with valid bit clear indicates an untagged packet that should be treated as VLAN = 0.
Lookup Index 1	Byte 2	6	16	21	Second word index in Field Vector.
		1	22	22	Reserved.
		1	23	23	Ignore Valid — If set, the field match even if the field is not valid.
Lookup Index 2	Byte 3	6	24	29	Third word index in Field Vector.
		1	30	30	Reserved.
		1	31	31	Ignore Valid — If set, the field match even if the field is not valid.
Lookup Index 3	Byte 4	6	32	37	Fourth word index in Field Vector.
		1	38	38	Reserved.
		1	39	39	Ignore Valid — If set, the field match even if the field is not valid.
Lookup Index 4	Byte 5	6	40	45	Fifth word index in Field Vector.
		1	46	46	Reserved.
		1	47	47	Ignore Valid — If set, the field match even if the field is not valid.
Mask	Bytes 6-15	16	48	63	Bit-mask of word 0 of the LU key. 1 means the bit is compared.
		16	64	79	Bit-mask of word 1 of the LU key.
		16	80	95	Bit-mask of word 2 of the LU key.
		16	96	111	Bit-mask of word 3 of the LU key.
		16	112	127	Bit-mask of word 4 of the LU key.
Result Index	Byte 16	6	128	133	Word index in which LU result will be placed.
		1	134	134	Reserved.
		1	135	135	Result Enable — LU yields result that should be stored in Field Vector.
Reserved	Bytes 17-19	24	136	159	Reserved.

Table 7-9. Recipe Content [continued]

Field	Byte Range	Width	LSB	MSB	Sub-Field Description
Action Control	Bytes 20-23	8	160	167	A bitmap of the join priorities of forwarding actions associated to this recipe. Relevant only for roots. The join priority defines which priorities are joined by this recipe. See Section 7.8.6.1 for details.
		4	168	171	The priority of forwarding actions associated to this recipe. Relevant only for roots.
		4	172	175	Reserved.
		1	176	176	Need_pass_l2 — If set, for the action of this recipe to be relevant, a recipe with *allow_pass_L2* bit set should match[2].
		1	177	177	Allow_pass_l2 — If set, allows recipes with *need_pass_L2* bit set to pass[3].
		1	178	178	Inverse Action — This bit is used to allow forwarding lookups to be used as anti-spoof (Tx) and source pruning (Rx) actions. See Section 7.8.5.1.1 for details.
		1	179	179	Reserved.
		2	180	181	Prune Index — Defines the enable bits to use it the VSI context to qualify a pruning action associated with this recipe. The VSI_SRCSWCTRL.*PRUNEENABLE*[3:0] and VSI_RXSWCTRL.*PRUNEENABLE*[3:0] are used to enable the pruning in Tx and Rx respectively.
		10	182	191	Reserved.
Default Action	Bytes 24-27	19	192	210	Default action according to the format described in Table 7-12. The default action can be a pointer to a large action or a single action.
		12	211	222	Reserved.
		1	223	223	Default Action valid.

1. For normal recipes, the RID should be equal to the index of the recipe. If *Inverse Action* flag is set, the RID might differ from the recipe index. In this case, lookup entries should not be populated with this recipe index. For non-root recipes, the RID must be zero.
2. This bit requires another recipe lookup with *Allow_pass_l2* set to match.
3. This bit identities this filter as an L2 filter, qualifying filters with *Need_pass_l2* set.

7.8.5.1.1 Inverse Action

The operation of anti-spoof of transmit packets is based on checking the SA or the {SA, VLAN} pair used to send the packet. If this SA or {SA, VLAN} pair where used as DA or {DA, VLAN} it would have to allow the VSI to receive the packet, then it can use them as SA or the SA, VLAN pair.

Similarly the operation of source pruning in receive can be based either on the source VSI as described in Section 7.8.6.5 or on the identification the SA or {SA, VLAN} pair as belonging to a VSI by identifying that if his SA or {SA, VLAN} pair where used as DA or {DA, VLAN} it would have allow the VSI to receive the packet.

This means that in the same MAC Address or MAC/VLAN pair could be used both to forward to a VSI or for anti-spoof or source pruning actions. To save the need for two entries for each of the MAC Address or MAC/VLAN pair in the lookup table, the inverse action mechanism is provided.

If inverse action bit in recipe (Bit 178) is set, any forwarding action to a single VSI or to a queue in the recipe is replaced with comparison of the source VSI of the packet with the VSI or the VSI matching the queue in the action for Tx traffic, and is replaced with a prune (AND NOT) for receive traffic. There is no support for inverse action when the forwarding action points to a list.

This is applied only if the action is a VSI forwarding action to a single VSI or a ToQueue action, either in a regular or large action.

If set, the action is enabled for Tx traffic using the VSI_SRCSWCTRL.*MACAS* bit and for Rx traffic using the VSI_RXSWCTRL.*MACVSIPRUNEENABLE* bit.

When setting this bit, the RID of the inverse action recipe should be equal to the RID of the matching forwarding recipe.

7.8.5.1.2 Sample Recipes

Table 7-10 provide a few examples of recipes (a letter in one of the words indicates usage of intermediary lookups, according to the result field in the intermediary line). Lines 0-10 are the basic recipes loaded from NVM.

Note: The layout of the recipes can be different if needed to optimize lookups. For example, if a part of a lookup is common to multiple lookups (for example, {switch ID, tenant ID, Key}), it might be worthwhile to have it a single lookup entry shared by multiple recipes.

Table 7-10. Sample Recipes

Recipe Index (RID)	Recipe	Priority (Joint Priority)[1]	Is Root	Word0	Word1	Word2	Word3	Word4	Result[2]
0	EtherType, Direction	4	Y	switch ID	EtherType	Direction	-	-	E
1	DA	2	Y	switch ID	MAC0	MAC1	MAC2	-	B
2	DA, VLAN	2	Y	switch ID	MAC0	MAC1	MAC2	VLAN	-
3	Packet Type, Direction (promiscuous)	1 (1,2,3)[3]	Y	switch ID	Packet Type	Direction[4]	-	-	-
4	VLAN[5]	N/A[6]	Y	switch ID	VLAN		-	-	-
5	Default, Direction	0	Y	switch ID	Direction	-	-	-	-
1	SA (inverse action)	N/A[7]	Y[8]	switch ID	SMAC0	SMAC1	SMAC2	-	-
2	SA, VLAN (inverse action)	N/A	Y[9]	switch ID	SMAC0	SMAC1	SMAC2	VLAN	-
8	EtherType, MAC, Direction	4	Y	switch ID	MAC0	MAC1	MAC2	E	-
9	Promiscuous, VLAN, Packet Type, Direction	1 (1,2,3)[3]	Y	switch ID	Packet Type	VLAN	Direction	-	-
10	Logical Port	0	Y	switch ID	Logical Port				
11	Inner MAC, Tunnel Type	3	Y	switch ID	IMAC0	IMAC1	IMAC2	Tunnel Type	A
12	Inner MAC, Inner VLAN, Tunnel Type	3	Y	A	iVLAN	-	-	-	-
13	Inner MAC, Inner VLAN, Tenant ID, Tunnel Type	3	Y	A	iVLAN	Key0	Key1	-	-
14	Inner MAC, Tenant ID, Tunnel Type	3	Y	A	-	Key0	Key1	-	-
15	Outer MAC, Tenant ID, Inner MAC, Tunnel Type	3	Y	B	A	Key0	Key1	-	-
16		N/A	N	D-IP-0	D-IP-1	D-IP-2	D-IP-3	D-IP-4	C
17	Application Dest IPv6	3	Y	switch ID	D-IP-5	D-IP-6	D-IP-7	C	-
18		N/A	N	S-IP-0	S-IP-1	S-IP-2	S-IP-3	S-IP-4	G
20	Application Dest IPv4	3	Y	switch ID	D-IP-0	D-IP-1	-	-	D

Table 7-10. Sample Recipes [continued]

Recipe Index (RID)	Recipe	Priority (Joint Priority)[1]	Is Root	Word0	Word1	Word2	Word3	Word4	Result[2]
21	Application Source IPv6, Inner MAC	3	Y	S-IP-5	S-IP-6	S-IP-7	A	G	-
22	Application Source IPv4, Inner MAC	3	Y	S-IP-0	S-IP-1	A	-	-	-
24	Application Dest IPv4, Application Source IPv4	3	Y	S-IP-0	S-IP-1	D	-	-	-
25	TCP/UDP Port	3	Y	switch ID	DPort	-	-	-	-
26	STag	1	Y	switch ID	STag	-	-	-	-
27	iVLAN	3	Y	switch ID	iVLAN				

1. If a joint priority is not provided, it is equal to the regular priority.
2. The letters in the Result column indicate indexes in the field vectors that are updated by a match of this recipe, and are used as inputs in subsequent recipes.
3. Assuming promiscuous additive to other filters.
4. For rules where a direction is used, it is defined by the type of rule added (T_LOOKUP_TX (packet sent by the driver) or T_LOOKUP_RX (packet received by the driver)).
5. Should allocate a Prune Index to this rule (assume Prune Index = 0 for the examples and for the NVM default package).
6. Assumption is that VLAN filter is used for pruning.
7. No priority for inverse actions.
8. Use same RID as DA table. Used for anti-spoof/source pruning.
9. Use same RID as DA, VLAN table. Used for anti-spoof/source pruning.

7.8.5.2 Lookup Table

The lookup table is a Binary-CAM with 32K entries accessed using the Key generated in the KeyGen. The masked lookup key is searched in the table. If a match is found, the result is provided to the action resolving block that registers an action to do on the packet (if this is a root lookup) and to the KeyGen that can update the Field Vector (if intermediate or root lookup). If a match is not found, a default action per recipe can be used.

The format of each entry in the lookup table is as follows:

Table 7-11. Field Lookup Entry Format

Field		Width	LSB	MSB
Action		19	0	18
Ref. Count		16	19	34
Pointer		16	35	50
Filter Key	FV Word 0	16	51	66
	FV Word 1	16	67	82
	FV Word 2	16	83	98
	FV Word 3	16	99	114
	FV Word 4	16	115	130
	RID	6	131	136
	Reserved	9	137	145
	IsRoot	1	146	146

7.8.5.3 Actions

There are three types of actions supported:

- Single action per lookup (Section 7.8.5.3.1).
- List of actions per lookup divided to three sections of single, double, and quad lists (Section 7.8.5.3.2).
- Default Action, if the lookup does not result in a match (Section 7.8.5.3.3).

Figure 7-17 shows the different types of actions:

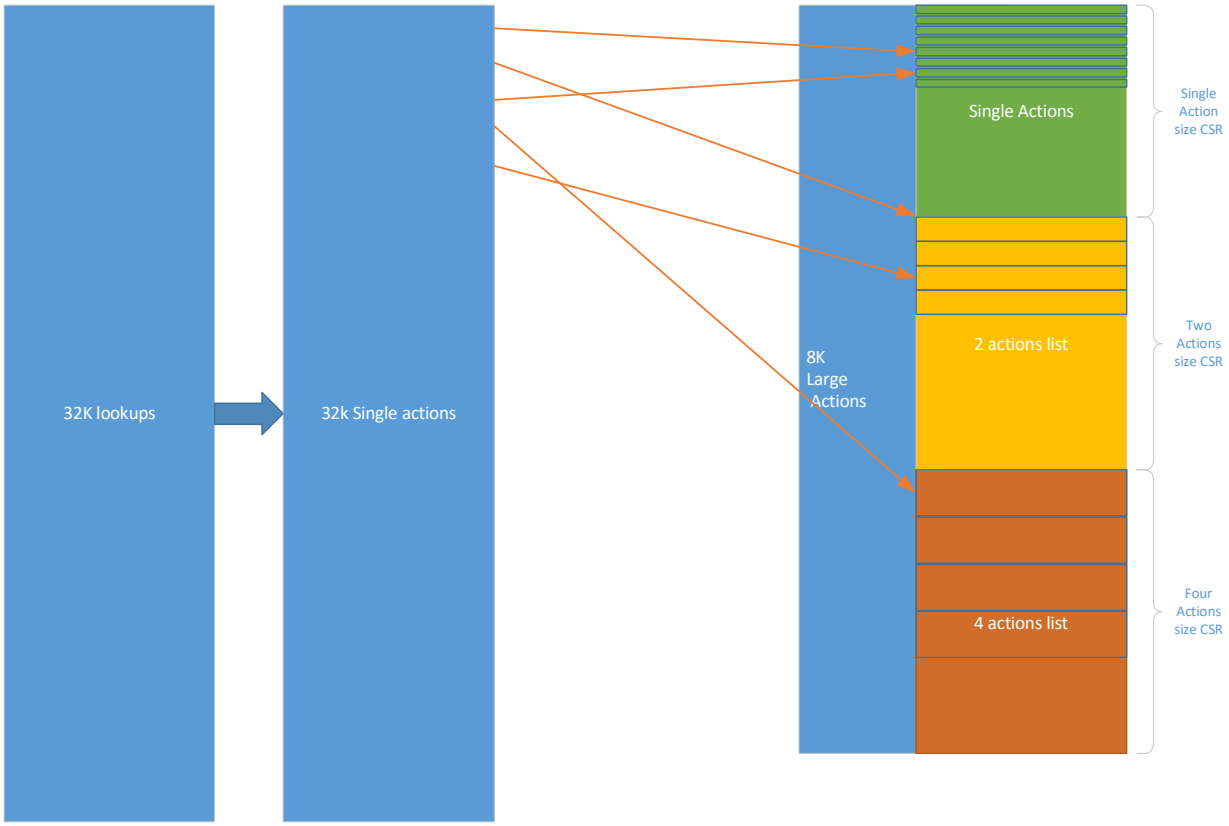

Figure 7-17. Single Actions and Large Actions

7.8.5.3.1 Single Action

For each of the 32K lookups, a single action can be applied if the lookup matches.

The following actions can be requested by a lookup entry:

- Forwarding actions (see Section 7.8.5.3.5)
- Pruning action (see Section 7.8.5.3.7)
  - — Prune the existing forwarding list to include only VSIs matching a VSI or VSI list (AND operation). This action can be applied to ingress traffic, egress traffic or both.

Note: The usage model is to allow a single VLAN entry to point to different lists for ingress and egress traffic.

— Prune the forwarding list not to include a VSI list (AND NOT operation).

- Statistic actions (see Section 7.8.5.3.9)

If a large action is needed, the single action can be replaced with a pointer to a list of actions described below.

Note: All actions are additive, apart from forwarding actions to a VSI or a queue, which are defined by priorities.

The format of the single action is described in Table 7-12.

Table 7-12. Single Actions Format

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
00b (VSI Forwarding)		LB EN[1]	LAN EN[2]	VSI/VSI_list										List	Reserved		Valid[3]	Drop[4]
01b (To Queue)		LB EN	LAN EN	Q Index[5]											Q Region Size			Q_PRI[6]
10b (Prune)		LB EN[7]	LAN EN	VSI_list										List = 1[8]	Egr[9]	Ing[10]	Prune T[11]	0b
10b (Pointer)		LB EN[7]	LAN EN[12]	Pointer to a large action. Points to the first action in the large action in the 8K range.													hasFWD[13]	1b
11b (Other Actions)		Reserved		Mirror VSI										Reserved			00b (Mirror)	
		Reserved															10b/11b (Reserved)	
		Reserved		Statistics Counter Index							Reserved						11b (Stat Count)	

1. Allows packet to be looped back.
2. Might prevent packet from being sent to the network.
3. The *Valid* bit should be set by the software device driver in all forwarding actions. Adding an entry with *Valid* = 0 is allowed if *allow_pass_L2* is set in the recipe, and only a hit in the table is needed with no real action.
4. If *Drop* is set, VSI/VSI_list is ignored.
5. The queue index is an absolute queue number in the 0-2K range and should be used as such in the lookup programming commands.
6. Defines queue priority.
7. *LB EN* should not be set for prune actions or for large actions not including a forwarding action.
8. Must be set. Direct pruning is only available according to a VSI list.
9. Apply pruning to egress traffic (traffic received by VSIs).
10. Apply pruning to ingress traffic (traffic sent by a VSI).
11. AND prune (0) or AND NOT prune (1).
12. *LAN EN* is relevant only if large action includes prune or forwarding actions.
13. Should be set if the large action includes a forwarding command.

7.8.5.3.2 Large Actions

To allow multiple actions to be activated from a single lookup, on top of the 32K per lookup actions, a table with 8K entries is provided. Each entry represents a single action, and up to four actions can be chained into an action list. If the original action points to one of these action lists, all the combined actions are applied.

These 8K are divided to three programmable sections:

- A section of single actions (to allow usage of new actions not available directly).
- A section of two actions lists.

- A section of four actions lists.

Each lookup can point to any section depending of the number of requested action. The size of each section is programmable from NVM or from software device driver at init time (before any extended action is programmed) via the following registers:

Table 7-13. Large Actions Table Allocation

Table Part	Register	Note
Single Action	GL_SWT_LAT_SINGLE.*BASE*[10:0]	Encoded as base/4
	GL_SWT_LAT_SINGLE.*SIZE*[10:0]	Encoded as size/4
Double Actions	GL_SWT_LAT_DOUBLE.*BASE*[10:0]	Encoded as base/4
	GL_SWT_LAT_DOUBLE.*SIZE*[10:0]	Encoded as size/4
Quad Actions	GL_SWT_LAT_QUAD.*BASE*[10:0]	Encoded as base/4
	GL_SWT_LAT_QUAD.*SIZE*[10:0]	Encoded as size/4

The allocation is common to all ports.

Note: As there is a single such table, usage of large actions might degrade performance, if applicable for a large part of the traffic and used multiple times on the same packet.

Any of the actions included in the list can implement one of the actions defined above. In addition, the following actions are available only as part of large actions:

- Generic Action to update metadata (see Section 7.8.5.3.8).
- Increase counter — Used to support event counters.

The format of each action in an action list is described in Table 7-14.

Table 7-14. Large Actions Entries

0:2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19:21	22:24
000b (VSI Forwarding)	VSI/VSI_list										List	Reserved		Valid[1]	Reserved			
001b (To Queue)	Q Index[2]											Q Region Size			Q_PRI[3]	Reserved		
010b (Pruning)	VSI_list										List = 1[4]	Egr[5]	Ing[6]	Prune[7]	Reserved			
011b (Mirroring)	Mirror VSI										Reserved							
101b (Generic Action)	Generic Value																Generic Offset	Generic Priority
110b	Spare																	
010b (Statistics)	Statistics Counter Index							Reserved										

1. The *Valid* bit should be set by the software device driver in any forwarding action.
2. Queue index is the absolute queue number (0-2047) and should be used as such in the lookup programming commands.
3. Defines queue priority.
4. Must be set. Direct pruning is only available according to a VSI list.
5. Apply pruning to egress traffic.
6. Apply pruning to ingress traffic.
7. AND prune or AND NOT prune.

7.8.5.3.3 Default Actions

Each entry in the recipe table associated with an RID (isroot = 1) can define a default action to take if a lookup was done but no match was found. For example a VLAN lookup default action might be to prune all VSIs that are doing VLAN filtering (not in ignore VLAN mode). For a MAC lookup, the default action might be null. The default action layout is described as part of the recipe in Table 7-9.

7.8.5.3.4 Valid = 0 Action

A recipe can use as sub-entries other root entries. In this case, the entry can match as part of the large lookup, but not induce a match of an actual filter. For example, a MAC/VLAN filter can use a MAC filter as a sub-recipe, but a match of the MAC should not be considered as an action. To indicate this, the hardware sets, for root entries added only as part of another recipe with a *Valid* = 0 bit. This entry is ignored as part of the rules resolution. The only exception is for recipes for which the *allow_pass_L2* is set. In this case, an action with *Valid* = 0 is considered as a match.

Caution: If it is important to differentiate between an entry added as a part of a larger lookup and an entry added to allow L2 filtering. The recipe used with *allow_pass_L2* set should not be used as part of other recipes.

7.8.5.3.5 Forwarding Actions

The following forwarding actions are available:

- **Forward to a VSI** — Using VSI forwarding action with *LIST* bit cleared.
- **Forward to a list of VSIs** — Using VSI forwarding action with *LIST* bit set.
- **Forward to a queue group within a VSI** — Using ToQueue action with non zero Qregion. The region base equals "Queue Index" and the region size equals 2^(Qregion). The priority used is defined by the *Q_PRI* bit.
- **Forward to a queue within a VSI** — Using ToQueue action with zero Qregion.

  Note: The forwarding actions to a queue do not include the VSI as part of the command and uses the absolute queue. The forwarding action to a queue group uses the absolute queue number of the first queue in the queue group. The VSI number is extracted from the queue number using a queue to VSI table described in Section 7.8.8.3.
- **Do not forward to the LAN** — Using the *LANEN* field. If *LANEN* bit is cleared in any of the matched lookup with a forwarding or pruning action, the packet is not sent to the LAN. This action is relevant only for transmit packets.

  Note: This action is forced if *LANENABLE* field in the source VSI context is cleared. This means that if *LANENABLE* is cleared, the packet is not sent to the LAN independent of the programmed actions.
- **Allow loopback** — Using the *LBEN* field. If *LBEN* bit is set in any of the matched lookup with a forwarding action, the packet is loopback.

  Note: This action is gated by the *ALLOWLOOPBACK* field in the source VSI context. This means that if ALLOWLOOPBACK is cleared, the packet is not sent to the loopback path independent of the programmed actions.
- **Drop packet**

  See below for details on how multiple forwarding actions are applied.

7.8.5.3.5.1 Forwarding Actions Priorities

Each recipe contains two priority values used by forwarding actions:

- **Priority** — A number between 0-7 (represented in the recipe as a one hot bitmap).
- **Join Priority** — An 8-bit bitmap.

The following algorithm is used to define which forwarding actions are retained to create the ultimate forwarding action:

```
For all the matching recipes resulting in a "forwarding" and "to queue" actions {
    find maximum value of Priority --> max_priority
}
For all the matching recipes resulting in a "forwarding" and "to queue" actions {
    If (join_priority[max_priority] == 1) {
    // note that the bit of the max priority should be set in the join priority vector
        Add VSI/VSI list/Queue to resulting VSI list
    }
}
```

7.8.5.3.6 Event-Based Mirroring Action

This action allows event-based mirroring of the traffic for which the action is enabled to a mirror VSI. Event based mirroring is independent of the forwarding priorities and the mirror VSI is always added even if the packet is dropped.

Event mirroring action can cause a loopback, even if loopback is not enabled for the ingress VSI.

Port-based mirroring is also available and is described in Section 7.8.5.4.1.

Note: The mirror VSI should be used only to receive mirror traffic (either event-based or port-based).

7.8.5.3.7 Prune Action

The prune action acts on the VSI list created by the forwarding action. It can either:

- Remove VSI listed in a VSI list from the forwarding list (AND NOT prune - PruneT = 1)
- Remove VSI not listed in a VSI list from the forwarding list (AND prune - PruneT = 0)

Each pruning action is enabled for Rx/loopback or Tx traffic using the Egress (Rx) pruning enables and Ingress (Tx) pruning enables fields in the Add VSI command. The enable index to use is set in the *Prune Index* field in the recipe pointing to this action.

This action is additive and not dependent on the priority of the recipe. Multiple prune actions can be applied.

In addition to these actions, there can be anti-spoofing rules and source pruning rules that also generate an implicit pruning. These rules are implemented in the default configuration using recipes with an inverse action bit set as described in Section 7.8.5.1.1.

7.8.5.3.8 Generic Value Action

This action allows setting of metadata forwarded to the next stages of the pipe. The Generic Offset, Generic Value, and Generic Priority define the location, the content, and the priority of the data in the metadata bus.

The encoding of the generic offset is as follows:

Table 7-15. Generic Offset Encoding

Value	Field	Priority Field	Notes
0x0	genericMD_word_0	genericMD_word_0_prio	
0x1	genericMD_word_1	genericMD_word_1_prio	
0x2	genericMD_word_2	genericMD_word_2_prio	
0x3	genericMD_word_3	genericMD_word_3_prio	
0x4	genericMD_word_4	genericMD_word_4_prio	
0x5	flowID_word_0	flowID_prio	The priority is common to these two fields. If both are set through actions, the priority is taken from the flowID_word_0 action.
0x6	flowID_word_1		
0x7	RX_descr_structure_prof_idx	RX_descr_structure_prof_idx_prio	Only first six bits of the word are set.

7.8.5.3.9 Statistics Actions

Statistics gathering can be done at four different levels:

- At the switch ID level:
  - Per switch ID packets are counted that matched a switch ID, but were dropped.
  - If the switch ID is part of a VEB. There are 32 VEB statistic blocks. In this case, statistics are gathered at the VEB level and at the VEB/UP level.
- At the VSI level, if packet is forwarded to a VSI (egress) or sent by a VSI (ingress).
- At the port level if packet is forwarded to a port (egress) or received from a port (ingress).
- Gather event statistics (usually VEB/VLAN) in statistic block N out of 128 available blocks. These counters are activated using the "statistics" action.

Note: See Section 7.8.6.1.1 for limitations on multiple event counting per packet.

Unless noted otherwise, dropped packets are not counted in the statistic counters.

7.8.5.3.9.1 Statistics Registers

The following registers are available for statistics gathered by the binary classifier:

- 256 per switch ID registers to count drops — GLSWID_RUPP[255:0].
- 32 instances of VEB, VEB/UP statistics described in Section 9.6.5.2.
- 128 instances of block statistics also described in Section 9.6.5.2.

All these counters are accessible to all the PF drivers and are read only registers that wrap around after reaching their maximum value.

7.8.5.3.9.2 Association of VEB Statistic Block to a VEB

The following flow can be used to associate a VEB statistic block to a VEB.

1. When creating a VEB, decide if a counter is needed.
2. If yes, allocate a VEB counter by using the Allocate Resources (0x0208) command with a resource type of VEB statistic counter (0x0) and get a counter ID.
3. For each VSI added/updated to this VEB, in the Add VSI command (0x0210) set *VEB_CNT_VAL* = 1 and *VEB_CNT_ID* to the associated counter ID.

7.8.5.3.10 VSI Bitmaps

Three types of actions can point to list of VSIs:

- Forward to a list of VSIs
- Prune (AND)
- Prune (AND NOT)

The E810 provides two set of 1024 per-VSI bitmaps that allows setting all the VSIs that are to be included in the action. The first set can be pointed by forwarding actions. The second set can be pointed by the two types of pruning actions.

The 1024 VSI bitmaps used for pruning actions are divided to four banks of 256 entries each. To achieve the nominal performance, pruning actions applied to a single packet should be divided between the four banks, so that in each bank there are up to two pruning lists.

7.8.5.4 Post Processing Actions

In addition to the actions generated by the lookup table, a few actions are generated by dedicated logic:

- Transmit Packets received with a non-zero *SWTCH* field from a VSI where the VSI_SRCSWCTRL.*ALLOWDESTOVERRIDE* bit is set in their descriptor are forwarded according to this flag:
  - If *SWTCH* = 01b, the packet is sent to the LAN.
  - If *SWTCH* = 10b, the LAN is removed from the list of destinations.
  - If *SWTCH* = 11b, the packet is sent to the VSI specified in the *TARGET_VSI* field in the descriptor. In this case, the switch cannot set a specific queue destination within the VSI.

    Note: If the VSI_SRCSWCTRL.*ALLOWDESTOVERRIDE* bit is not set, and a non-zero value is set, the packet is dropped. In this case, the GL_OVERRIDEC.*OVERRIDE_ATTEMPTC* field is increased, and the GL_OVERRIDEC.*LAST_VSI* field is set with the value of the source VSI.

    If *SWTCH* = 01b or 11b, the switch is bypassed and no action is applied to this packet (for example, event counters, generic actions, prune, MAC source pruning).

    If *SWTCH* not equal zero, the ingress prune rules do not apply.

    Note: When *SWTCH* = 11b, the switch does not check that the packet is sent to a VSI within the same PF. Use with care.
- SWPE — A packet received with this bit set, the packet is sent back to the source VSI.

- Store Bad Packets — If PRT_SBPVSI.*SBP* is set, packets received with MAC errors as defined in Section 3.2.1.8 are forwarded to queue 0 of the VSI defined in the Bad Frames VSI (PRT_SBPVSI.*BAD_FRAMES_VSI*).
- Default action for transmit packets — A transmit packet is sent by default to the LAN, unless a "do not forward to LAN" action is set.

7.8.5.4.1 Port-Based Mirroring

The E810 supports 64 port-based mirror rules that can be a combination of the following four types. These types are implemented using dedicated hardware and not through the regular actions:

- **Mirror ingress traffic from host** — Mirror packets sent from a specific VSI.
- **Mirror egress traffic to host** — Mirror packets sent to a specific VSI.
- **Mirror ingress traffic from LAN** — Mirror packets received from a specific LAN port. This includes packets with L2 errors.
- **Mirror egress traffic to LAN** — Mirror packets sent to a specific LAN port.

Each ingress or egress VSI/Port can be mirrored by one rule only.

Per mirror rule, a mirror VSI is defined that specifies where packets are mirrored. There is no support for mirroring to an external port.

To differentiate packets received according to the different rules, the matched rule is indicated in the Mirror Rule ID (MIRR) field in the receive descriptor.

In addition to these rules, specific traffic can be mirrored by assigning a mirror action to a specific lookup. In this case, the mirrored packet is not identified with a Mirror Rule ID (MIRR) in the receive descriptor. Event based mirroring is described in Section 7.8.5.3.6.

Note: The mirror VSI should be used only to receive mirror traffic (either event-based or port-based).

Packets that are dropped by the switch can still be mirrored due to ingress mirror rules. In this case, the packet is counted as dropped in the GLSWID_RUPP counters and is not counted in the regular switch counters.

7.8.6 Egress Post Processing Actions

7.8.6.1 Actions Merging and Priorities

As described above, each recipe can provide one or more actions. Each recipe is associated with a priority and a join priority bitmap applied to forwarding actions only.

The following rules describe the resulting actions in decreasing order of priority:

- If drop action exists, drop packet.
- If any filter matched a non-default action (including a non-valid action) and has the Pass L2 filter in its recipe, the packet is assumed to pass L2 filter. If pass L2 filter is false, the subsequent forwarding actions merging step should take into account only actions not requiring L2 filtering. Otherwise, all actions are considered.

- Forwarding actions merging:
  - From all recipes with forwarding actions, devise the highest priority (H-P) available.
  - Find forwarding actions with H-P bit set in join priority bitmap in recipe and merge VSI destination list of all these actions. Following is an example of this algorithm:

Recipe	Priority	Join Priority	Forwarding Action
1	4	00010000	VSI_1
2	3	00011000	VSI_2
3	2	00001100	VSI_3
4	2	00011100	VSI_4
Result	H-P (4)		VSI_1, VSI_2, VSI_4

  - If two of the selected actions points to the same VSI, but one of them defines a queue, the packet is sent to this queue.
  - If no "allow loopback" action found and packet is Tx, remove from list all local VSIs.
  - If "do not forward to LAN" action found and packet is Tx, remove "LAN" from list.
  - If the manageability filters indicate the packet as exclusive to the BMC (MNGONLY), modify the list to include only the BMC VSI (including removal of forwarding to LAN for OS2BMC traffic).
- Pruning actions:
  - All pruning actions should be applied after the forwarding list is ready.

    Note: Currently there are two pruning actions applied on the list: Egress/Ingress VLAN (AND), and Source MAC Address (AND NOT). Additional actions (source VSI pruning) are applied per egress replica. See Section 7.8.6.5 for details.
  - Add ingress mirroring rules.

    Note: Egress mirroring rules are applied at a later stage, when packets are replicated.
- Statistic actions are always applied if they exist.

7.8.6.1.1 Actions Limitations

For a single packet lookup the following limitations applies:

- At most, 16 actions can be generated. The combined VSI forwarding actions counts as a single action.
- Per egress VSI, a single destination Queue can be specified. If more than one is specified, the result is unexpected.
- For a all replications, up to two destination queues for different VSIs can be specified. If there are more than two actions defining a queue, then the first two "to queue" actions from the recipes with the highest RIDs are retained, and all other are translated to simple VSI forwarding actions.
- Per profile, up to 32 lookup lines can be selected and 24 of them can be recipe roots.
- If more than one hit action points to the same counter for the same packet, it is counted only once. The counter with the higher recipe index is counted. If the same wide action has several statistic actions, the last action is chosen.

7.8.6.2 Bypassing Actions

The following flags in metadata result in a bypass of the actions described above:

- If the *Switch_directives*[1:0] field (from descriptor) is set to 01b (to LAN), Tx packet is sent to LAN only (not relevant for receive packets).
- If the *Switch_directives*[1:0] field (from descriptor) is set to 11b (specific VSI), Tx packet is sent to the VSI set in the *target_vsi* only (not relevant for packets received from LAN).
- If *SWPE* bit is set, the packet is sent back to the source VSI.
- If *l2_mac_err* bit is set and pass bad frame is allowed for the receive port (PRT_SBPVSI.*SBP*), the packet is sent to Bad Frames VSI (PRT_SBPVSI.*BAD_FRAMES_VSI*).
- If *pkt_is_marker* bit is set, no action is taken.
- If *hit_mirror* bit is set, the packet is looped back only for mirroring, so other lookups should not be applied.
- If *target_vsi_is_mng* bit is set, the packet is looped back only for forwarding to manageability through MDEF filters, so other lookups should not be applied.
- If storm control is active, and packet should be dropped (broadcast/multicast), apply storm control actions and drop the packet. See Section 7.8.6.3 for details.

7.8.6.3 Storm Control

As there is no separate path for multicast and broadcast packets, too many replicated packets might cause congestions in the data path. To avoid such scenarios, broadcast and multicast storm control rate limiters are added. The rate controllers define windows and the maximal allowed number of multicast or broadcast bytes/packets per window. Once the threshold is crossed, different types of policies can be applied.

7.8.6.3.1 Storm Control Functionality

Note: Most of the parameters in this section refer to the Set Storm Control Configuration admin command described is Section 7.8.12.4.1.

The time interval over which Broadcast Storm Control is performed is controlled by three factors:

- PRT_SWT_SCBI register (loaded from NVM)
- Port speed
- INTERVAL value (see Section 7.8.12.4.1)

The first two factors determine the Unit time interval as described in Table 7-16. The interval is automatically chosen internal to hardware based on port speed. The third factor (*Interval* field) determines how many of such unit intervals are considered for one Storm Control Interval (SCI).

Table 7-16. Storm Control Basic Interval by Speed

Port Speed	MIN Time Arrival	MAX Time Arrival	Default Time Interval (1 Mbit)
100 Gb/s	1 µs	1 ms	10 µs
50 Gb/s	2 µs	2 ms	20 µs
25 Gb/s	4 µs	4 ms	40 µs
10 Gb/s	10 µs	10 ms	100 µs
1 Gb/s	100 µs	100 ms	1 ms
100 Mb/s	1 ms	1 second	10 ms

The number of 64-byte chunk of broadcast or multicast packets that are allowed in a given SCI is determined by the Set Storm Control admin command.

In each SCI, the E810 counts the number of relevant 64-byte chunks received. The count is done per-port and separately for broadcast and multicast packets. This includes packets received from the network and loopback packets sent by local VSI. Once one of the counters crosses the threshold defined in the admin command, a storm event is detected.

Note: Every time a threshold is updated, the relevant counter is zeroed.

The E810 supports two modes of reactions to storm events:

- Block all multicast or broadcast packets from the moment the threshold is crossed until the end of the interval. The block is removed at the end of the interval until the threshold is crossed again. This mode is set by setting the *MDICW* (for multicast) and *BDICW* (for broadcasts) bits in the PRT_SWT_SCCRL register. This mode is used as a rate limiter.
- Block all multicast or broadcast packets from the moment the threshold is crossed until a full interval without threshold crossing is registered. This mode is set by asserting *MDICW* and *MDIPW* (for multicast) and *BDICW* and *BDIPW* (for broadcasts) bits in the PRT_SWT_SCCRL register. This mode is used for storm blocking.

Any change in the storm control state (block or pass of multicast or broadcast packets) is indicated to the PF associated with this port via the PFINT_OICR.*STORM_DETECT* interrupt cause. The current state is reflected in the PRT_SCSTS register.

The number of dropped packets due to storm control events is reflected in the GLPRT_STDC[7..0] registers.

7.8.6.3.2 Storm Control Programming

The following admin commands described are used to program the storm control elements:

- Set Storm Control Configuration (see Section 7.8.12.4.1)
- Get Storm Control Configuration (see Section 7.8.12.4.2)

7.8.6.4 Packets Replication

If the combination of actions yields a list of destination VSIs, the packet is replicated to each VSI.

The replicated packets cannot be sent contiguously. If traffic from other traffic classes exists, each copy of the packet is sent when the round-robin arbiter reaches the traffic class queue. See Section 8.2.1 for a full description of the receive path QoS scheme.

7.8.6.5 Post-Replication Actions

- **Egress Mirroring** — If an egress mirror rule applies to the destination VSI, the mirroring port should be added to the destination list of the packet. Egress mirroring is programmed through the VSI_SWT_MIREG CSRs (see Section 7.8.5.4.1 for details).

  Note: A packet can be replicated multiple times to the same VSI if additional replications are added as part of port based mirroring actions, or if the VSI is modified in subsequent blocks in the pipe.

- **Source Pruning** — If the destination VSI of this replica is the same as the source VSI, and VSI_RXSWCTRL.*MACVSIPRUNEENABLE* is set for this VSI, this replica is dropped.

7.8.7 Manageability Filtering

The manageability filters are described in Section 12.4.

The manageability sub-block has its own field extractor.

The manageability traffic is directed to one of eight MDEF sets according to the port or virtual port number.

The GL_SWT_PRT2MDEF registers define the mapping from port to MDEF set. The selection between port and virtual port is done according to GL_SWT_SWIDFVIDX.*PORT_TYPE* field.

The field extractor for all the profiles is pre-programmed from NVM and should include extraction of the following fields which are part of the input set needed for manageability filtering:

- Destination MAC Address
- Destination IP Address (including ARP target IP)
- Destination and Source TCP/UDP port
- EtherType
- ICMP (or IP protocol)
- ICMPv6 types
  - 0x86 (134d) — Router Advertisement.
  - 0x87 (135d) — Neighbor Solicitation.
  - 0x88 (136d) — Neighbor Advertisement.
  - 0x89 (137d) — Redirect.

• Flex filter match (in metadata)

The result of the manageability filters is a forwarding decision for the traffic of the BMC. The used VSI is defined in the per decision filter, per MDEF set PRT_MNG_MDEFVSI registers. In case of multiple matches, the VSI assigned to the MDEF with the highest index is used.

7.8.7.1 Manageability Configuration

The field vector used for manageability filtering is described in Table 7-17 and is configured using the regular field extractor logic programming flow.

Table 7-17. Default Field Vector for Manageability Filtering

Filter	Words	Notes
Destination MAC Address	0-2	Single/outer
Outer VLAN	3	2nd in case of double VLAN
EtherType	4	Outer
ARP	5	Operation field
	6-7	TPA
Neighbor Discovery and MLD	8	Type field of ICMPv6
RMCP/Flexible Port - Dest	9	TCP destination port
	10	UDP destination port
ICMP	11	Protocol field of single/outer IPv4
IP Address	12-13	Single/outer IPv4
	14-21	Single/outer IPv6
Flexible - SRC	22	TCP Source port
	23	UDP Source Port
Non Valid Packets — If any of these word's valid bit is set, the packet is not a candidate for MDEF lookup. Currently includes outer IPv4 and IPv6.	24	Inner IPv4 - LSB
	25	Inner IPv6 - LSB
	26-31	Reserved

In addition, a set of masks is applied to the 64-bit flag bus to define if a packet is candidate to the MDEF filters. These masks filters packets like GRE or MPLS, which are not relevant for manageability traffic.

7.8.8 Virtual Station Interfaces

Virtual Station Interfaces (VSIs) are the connections from the switch to entities interfacing with the host. It can be either the entire queue set of a PCIe function, or part of the queues of a function.

There can be up to 768 VSIs in the E810. All the VSIs are equivalent.

At init time, each physical function is assigned a VSI.

Other VSIs can be assigned to the physical function or to Virtual functions and can be used for the following purposes:

- VMDq2
- VMDq1
- Control ports
- iWARP traffic
- Mirroring

In addition, EMP VSIs can also be defined. The EMP VSIs are used for:

- Pass-through traffic
- Control ports

Each VSI has an Egress and Ingress context as described in Section 7.8.8.1 and Section 7.8.8.2, respectively. In addition, a queue context mapping queues to VSIs is also available.

Note: Additional VSI contexts are part of the ACL and Filtering blocks.

7.8.8.1 Egress VSI Context

A per-VSI table containing the context of the VSI with the following parameters looked up with the destination VSI (VSI_RXSWCTRL and VSI_VSI2F registers):

- VSI_VSI2F.*VFVMNUMBER*, VSI_VSI2F.*PFNUMBER*, VSI_VSI2F.*FUNCTIONTYPE* — PF/VF to which the VSI belongs.
- VSI_VSI2F.*BUFFERNUMBER* — The buffer in the manageability block to which traffic is sent if *FUNCTIONTYPE* = EMP.
- VSI_RXSWCTRL.*MACVSIPRUNEENABLE* — Defines if the VSI can receive packets with its own MAC Address. If set, such packets are dropped. Enabling recipes where the *inverse_action* is set for Rx packets.
- VSI_RXSWCTRL.*SRCPRUNEENABLE* — Defines if a VSI can receive packets it sent.
- VSI_RXSWCTRL.*PRUNEENABLE*[3:0] — Enables prune actions for Rx traffic. According to the *prune_index* in recipe
- VSI_VSI2F.*VSI_ENABLE* - VSI Enable.

7.8.8.2 Ingress VSI Context

A per-VSI table containing the context of the VSI with the following parameters looked up with the source VSI (VSI_SRCSWCTRL registers):

- *ALLOWDESTOVERRIDE* — Defines if a source VSI is allowed to bypass the switch using the *SWTCH* flag in Tx-Descriptor.
- *ALLOWLOOPBACK* — Defines if packets sent from a VSI can be looped back.
- *LANENABLE* — Defines if packets sent from a VSI can be sent to the LAN.
- *PRUNEENABLE*[3:0] — Enables prune actions for Tx traffic. According to the *prune_index* in recipe.
- *MACAS* — Allows MAC anti-spoof for this VSI. Enabling recipes where the *inverse_action* is set for Tx packets. If set, a packet is sent only if at least one recipe with inverse action provides an indication of a matching VSI to the source VSI.

7.8.8.3 Queue Context

A 2K-entries table mapping absolute queue numbers to VSIs and relative queue numbers.

All tables are filled by the Add VSI command.

7.8.9 Classifier Performance

The classifier is able to classify up to 171 Mpps Rx/Tx packets assuming up to 10 lookups per packet. The classification includes a forwarding decision and two ingress pruning decisions. Other actions, like statistics or storm control, should not impact the performance of the classifier. Replication or mirroring of a packet causes a reduction of the number of packets handled per second.

The classifier supports up to 500 VM configurations per second (includes VSI and filters configurations) in run time, and up to 5000 filter configurations at init time, to allow bring-up of a complex topology in a short time. This assumes bundling multiple filters configurations within a single Add Switch Rules command (Section 7.8.12.6.1).

There is no requirement on the profile configuration performance.

7.8.10 Resource Allocation

The following resources, including Switch, Flow Director, RSS, and per-pipe stage profile configuration resources, are managed by the firmware:

Table 7-18. Resource Types

Resource ID	Resource Type	Allocation Type	Notes	Pre-Allocatable in NVM
0x0	VEB Statistic Counter	Specific entries	Up to 32 VEB counter blocks.	
0x1	Event Statistic Counter	Specific entries	Up to 128 events (for example, VEB/VLAN) counter blocks.	
0x2	Mirror rule	Specific entries	Up to 64 mirror rules.	
0x3	VSI List - Replication	Specific entries	Up to 1K lists.	
0x4	VSI List - Prune	Specific entries	Up to 1K lists	
0x5	Recipe	Specific entries	Up to 64 recipes. At init time, all recipes are shared. The default recipes are shared and available for all the functions. If a global package is loaded, all the recipes are replaced by the recipes of the package, and are shared and available for all the functions.	
0x6	Switch Profiles	Specific entries	Up to 256 profiles.	
0x7	SWID	Specific entries	Up to 256 switch IDs.	
0x8	VSI	Specific entries	Up to 768 VSIs.	Yes
0x9	FLU Entry	Quantity only	Up to 32K FLU entries. The allocation and de-allocation assumes each filter uses new entries, so the actual usage can be lower than what is reflected by this command.	Yes
0xA	Wide Table 1	Specific entries	Total 8K wide actions. See Table 7-13 for the distribution.	
0xB	Wide Table 2	Specific entries		
0xC	Wide Table 4	Specific entries		
0xD-0x1F	Reserved for future switch resources	N/A		
0x20	Global RSS Hash	Specific entries	Up to 16 RSS hash tables.	
0x21	Flow Director Counter Block	Specific 256 counters blocks	One of 32 blocks (total 8K counters).	

Table 7-18. Resource Types [continued]

Resource ID	Resource Type	Allocation Type	Notes	Pre-Allocatable in NVM
0x22	Flow Director Guaranteed Entries (for software-based filters)	Quantity only	The total number of available Flow Director guaranteed entries is GLQF_FD_SIZE.*FD_GSIZE*. To increase this resource, use the Allocate Resources AQ command. To decrease this resource, use the Free Resources AQ command. Using the Get Allocated Resource Descriptors AQ command for this resource is not relevant and returns an empty buffer.	
0x23	Flow Director Shared Entries (for ATR filters)	Quantity only	The total number of available Flow Director guaranteed entries is GLQF_FD_SIZE.*FD_BSIZE*, but there can be over-subscription between PFs. To increase this resource, used the Allocate Resources AQ command. To decrease this resource, use the Free Resources AQ command. Using the Get Allocated Resource Descriptors AQ command for this resource is not relevant and returns an empty buffer.	
0x24-0x2F	Reserved for future filtering resources	N/A		
0x30	Flexible Descriptors Programming	Specific entries	Up to 64. Shared by default. These resources are not cleared by PFR. ***Note:*** Resources #0, #1, and #7 are pre-allocated, and never allocated to a specific PF. See Section 7.6.4.	
0x31-0x3F	Reserved for filter resources	N/A		
0x40-0x47	Reserved for Parser Profile Builder	N/A		
0x48	Switch Field Vector Table	Specific entries		
0x49	Switch Profile ID TCAM Entries	Specific entries		
0x4A-0x4F	Reserved for Switch Profile Builder	N/A		
0x50	ACL Field Vector Table	Specific entries		
0x51	ACL Profile ID TCAM Entries	Specific entries		
0x52-0x57	Reserved for ACL Profile Builder	N/A		
0x58	Flow Director Field Vector Table	Specific entries		
0x59	Flow Director ID TCAM Table Entries	Specific entries		
0x5A-0x5F	Reserved for Flow Director Profile Builder	N/A		
0x60	Hash Field Vector Table	Specific entries		
0x61	Hash Profile ID TCAM Entries	Specific entries		
0x62-0x67	Reserved for Hash Profile Builder	N/A		
0x68	Quad Hash Field Vector Table	Specific entries		

Table 7-18. Resource Types [continued]

Resource ID	Resource Type	Allocation Type	Notes	Pre-Allocatable in NVM
0x69	Quad Hash Profile ID TCAM Entries	Specific entries		
0x6A-0x6F	Reserved for Quad Hash Profile Builder			
0x70-0x7F	Reserved			

The following principles are defined to support these resources management:

- Every resource could be Persistent (unmanaged) or Dedicated (exclusive). Profile builder resources can be also Shared.
- Dedicated resource rules:
  - — One resource / one owner.
  - — Dedicated resource allocation/de-allocation (explicitly by the owning driver).
  - — If a device driver attempts to reference/modify a dedicated resource owned by another function's driver, it gets an error (shared resource could be referenced/modified by any device driver).
  - — During PFR, firmware clears all the dedicated resources owned by the function.

  Note: Profile Builder resources are defined as Dedicated using the Download Package AQ command. Their ownership is kept across a PFR. However, for Profile ID TCAM, the resource's hardware information is cleared during PFR.
- Persistent resources rules:
  - — Not owned by any function driver.
  - — Allocation/de-allocation (explicitly by any driver).
  - — Any modification possible.
  - — PFR has no impact. Cleared by CORER.

  Note: Profile Builder resources can be deallocated only using the Download Package AQ command sequence.
- Shared resources rules (relevant only to Profile Builder resources):
  - — Set ownership as "shared" is done using Download Package AQ command.
  - — Can be owned by any function driver using Allocate Resource AQ command (and freed using the Free Resource AQ command).
  - — Modification is possible using the Update Package AQ command.
  - — PFR clears PF usage of resource. For Profile ID TCAM, the resource's hardware information is cleared when no PF is using the resource.
- If the software device driver attempts to reference/modify unallocated resource, it gets an error.

The commands used to manage the resources are described in Section 7.8.12.2.

Profile builder ownership is defined in Table 7-192.

7.8.10.1 Initial Resource Allocations

Resources can be pre-allocated from NVM to a PF, or can be dynamically assigned using the commands in Section 7.8.12.2. The allocation in NVM is done through the SR PF Allocations NVM section. This section allows for the allocation of up to two resources per PF, by setting the "PF allocations -Type" and "PF allocations -Value" words with {resource type, number of resources allocated} pairs.

Regardless, for each PF, a VSI and an FLU entry are allocated per function (PF or VF) associated with this PF. If a different allocation of VSI or FLU entries is specified in NVM, the maximum value between these two is taken to guarantee minimal allocation per PF/VF.

7.8.11 Binary Classifier Configuration

7.8.11.1 Overview

The configuration of the binary classifier can be done in three modes:

- Basic configuration loaded from NVM. This is a basic configuration that provides a basic L2 switching configuration. This configuration can never be removed.
- Public configurations loaded by driver that can be used by other drivers on the device. For example, a driver loading a set of filters to match the encapsulation used in the network (NVGRE, Geneve, and so on), that can be used by other drivers connected to the same network. Such a configuration can be removed only if no driver is registered to use it.
- A private configuration loaded by a driver and not exposed to other drivers. The driver is free to remove this type of configuration independently.

7.8.11.2 Parameters Summary

Table 7-19 summarize the parameters configurable in the switch and the way to configure them.

Table 7-19. Configurable Parameters

Parameter	Config Source	Mechanism	Rate	Section Reference
Profile Selection Parameters	NVM	CSRs	Once	7.8.11.3.1 through 7.8.11.3.3
Initial Recipes and Default Profile	NVM	CSRs	Once	
Initial Population (Basic L2 Filtering)	Firmware	See lookup population.	N/A	
New Control Domain - Add/Remove	Software via firmware	CSRs	500/s	
New Profile - Add/ Remove	Software via firmware	CSRs	1000/s. Up to 5000/s combined population requests	
New Set of Recipe - Add/remove	Software via firmware	CSRs	1000/s	
(Dis)Association of Traffic to Profile	Software via firmware	CSRs	N/A	

Table 7-19. Configurable Parameters [continued]

Parameter	Config Source	Mechanism	Rate	Section Reference
Add/remove VSI	Software via firmware	CSRs		
Lookup Population	Software via firmware (using packet header) Each population request in a different AQ command.	Command FIFO (lookup and action). CSRs (VSI bitmaps and large actions).		
Lookup Removal	Software via firmware (using index)	Command FIFO (lookup and action) CSRs (VSI bitmaps and large actions)		
FLR/PFR, VFR	Firmware	Hardware iterators to get lookup. Lookup removal as above.		

7.8.11.3 NVM Loaded POR

7.8.11.3.1 Default Profiles

Four profiles are defined from NVM:

- **Bypass profile (0x0)** — This profile is used for packets that are not impacted by the switch block.
- **Default profile (0x1)** — Includes all traffic not included in any other profiles.
- **Control Packets profile (0x2)** — Includes LLDP packets and flow control packets (PTYPEs = 6, 278).
- **Hardware handled packets (0x3)** — This profile is used for packets for which there is no lookup and special hardware is used to implement the decision.

Note: All the flags that are part of the bypass and hardware handled profiles have dedicated hardware to handle them. The inclusion in these profiles is to save the need for regular recipe lookup.

7.8.11.3.2 Default Field Vector

The default field vector is generated for the Default Profile (1) and Control Packets Profile (2), and contains the following data:

Table 7-20. Default Field Vector

Offset (Words)	Content	Notes
0	Switch ID	Mandatory in all extractions.
1	MAC DA 0	
2	MAC DA 1	
3	MAC DA 2	
4	MAC SA 0	
5	MAC SA 1	
6	MAC SA 2	
7	Outer VLAN	Not used by basic filters. Equals zero if not present.

Table 7-20. Default Field Vector [continued]

Offset (Words)	Content	Notes
8	VLAN	Equals zero if not present
9	EtherType	

For the Bypass Profile (0) and Hardware-Based Profile (3), the extracted vector is empty.

7.8.11.3.3 Default Recipes

The first 11 filters defined in Table 7-10 are loaded from NVM.

7.8.11.4 Resets

The entire switch configuration is cleared and reloaded from NVM upon a CORER or higher reset.

At a PFR or FLR reset, all the entries populated by the PF, all the recipes and profiles private to this PF, and all the VSI context for VSIs allocated to this PF are cleared.

At a VFR or VMR, there is no modification of the switch configuration.

7.8.12 Software Programming Model

The programming of the different switching elements is done using admin commands. Commands to configure a switching element can be received only from the control port of the element.

7.8.12.1 Switch Configuration Admin Commands Summary

The set of commands is based on X710/XXV710/XL710 switch commands with adaptations to the new programming paradigm of the E810.

Table 7-21 summarize the different commands used to configure the binary classifier.

Table 7-21. Switch Configuration Admin Commands (0x02xx)

Command	Opcode	Description	Section Reference
Common Commands The commands common to the entire receive control pipe are described in Section 7.11.			
Generic Commands/Resource Management (0x020x)			
Get Switch Configuration	0x0200		7.8.12.2.1
Set Port Parameters	0x0203		7.8.12.2.2
Get Resource Allocation	0x0204		7.8.12.2.3
Allocate Resources	0x0208		7.8.12.2.4
Free Resources	0x0209		7.8.12.2.5
Get Allocated Resources Descriptor	0x020A		7.8.12.2.6
Other commands in this section supported in previous products are obsolete in the E810.			

Table 7-21. Switch Configuration Admin Commands (0x02xx) [continued]

Command	Opcode	Description	Section Reference
VSI Commands (0x021x)			
Add VSI	0x0210		7.8.12.3.1
Update VSI	0x0211		7.8.12.3.2
Get VSI Parameters	0x0212		7.8.12.3.3
Free VSI	0x0213		7.8.12.3.4
Port Virtualizer Control (0x022x) All the commands in this section supported in previous products are obsolete in the E810.			
VEB/Port Aggregator Control (0x023x) While these commands are no longer supported in the E810, the functionality of the VEB configuration is replaced by the SWID configuration, also knows as the Switch ID provided in the Get Switch Config and Add/Update VSI commands.			
Switch Connectivity Configuration (0x024x) All the commands in this section supported in previous products are obsolete in the E810.			
Forwarding Table Configuration (0x025x) All the commands in this section supported in previous products are obsolete in the E810.			
Storm Control Commands (0x028x)			
Set Storm Control Configuration	0x0280		7.8.12.4.1
Get Storm Control Configuration	0x0281		7.8.12.4.2
Binary Classifier Configuration (0x029x) See Section 7.11 for profiles configuration			
Add Recipe	0x0290		7.8.12.5.1
Set Recipes-to-Profile Association	0x0291		7.8.12.5.2
Get Recipe	0x0292		7.8.12.5.3
Get Recipes-to-Profile Association	0x0293		7.8.12.5.4
Binary Classifier Population (0x02Ax)			
Add Switch Rules	0x02A0		7.8.12.6.1
Update Switch Rules	0x02A1		7.8.12.6.2
Remove Switch Rules	0x02A2		7.8.12.6.3
Get Switch Rules	0x02A3		7.8.12.6.4
Clear PF Configuration	0x02A4		7.8.12.6.5
Mirroring Configuration (0x026x)			
Add Mirror Rule	0x0260		7.8.12.7.1
Delete Mirror Rule	0x0261		7.8.12.7.2

7.8.12.2 Generic Commands (0x020x)

7.8.12.2.1 Get Switch Configuration (0x0200)

After receiving this command, firmware returns a list of currently allocated and used resources (VSIs and SWIDs), so a topology tree could be built.

Table 7-22. Get Switch Configuration Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0200	Command opcode.
Datalen	4-5	(2-2048)	Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16-17		Reserved.
First Descriptor	18-19	0x0	If not zero, start the report from the requested descriptor.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-23. Get Switch Configuration Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0200	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Flags	16-17		Copy of request flags.
New Element	18-19		If not zero, indicates that not all the configuration was returned and a new command should be sent with this value in the *First Descriptor* field.
Number of Elements	20-21		Number of elements in response buffer.
Reserved	22-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-24. Get Switch Configuration Response Buffer

Offset (Bytes)	Description
0 -5	Port/VSI Element 1 (see Table 7-25).
…	
6*(n-1):6*n-1	VSI Element #n.

Table 7-25. Get Switch Configuration – Port/VSI Element

Offset (Bytes)	Description
0-1	**Bits 9:0:** VSI number/Port Number **Bits 13:10:** Reserved **Bits 15:14:** 00b = Physical Port 01b = Virtual Port 10b = VSI 11b = Reserved
2-3	SWID VSI/port belongs to
4-5	**Bits 14:0:** PF/VF number, VSI belongs to. **Bit 15:** VF indication bit

7.8.12.2.2 Set Port Parameters (0x0203)

This command is used to define the default parameters of a physical port.

Table 7-26. Set Port Parameters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0203	Command opcode.
Datalen	4-5	0x0	Length of buffer
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16-17	Bitfield	**Bit 0:** Save Bad Packets If set, packets with errors are forwarded to the bad frames VSI. **Bit 2:** Enable Double VLAN If set, this port expects double VLAN packets. ***Note:*** After setting this bit, the software device driver should associate the port to a double VLAN profile in the parser. All other bits are Reserved.
Bad Frames VSI	18-19		Defines the VSI to which bad frames are forwarded. **Bit 15:** Valid VSI - ignored in this field **Bits 14:10:** Reserved **Bits 9:0:** Number of the VSI ***Note:*** Relevant only if Command Flags.Save Bad Packets is set.

Table 7-26. Set Port Parameters Command [continued]

Name	Byte.Bit	Value	Remarks
Port Switch ID	20-21		**Bit 15:** Valid Switch ID **Bits 14:8:** Reserved **Bits 7:0:** Switch ID ***Note:*** If a switch ID is already allocated to the port, it is replaced by the new one.
Reserved	22-31	0x0	Reserved.

Table 7-27. Set Port Parameters Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0203	Command opcode.
Datalen	4-5	0x0	Length of buffer
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following response might be returned by this command: ENOENT = Index is invalid for one of the chosen resources. EACCES = PF does not own one of the chosen resources.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Command Flags	16-17	Bitfield	
Bad Frames VSI	18-19		
Default Switch ID	20-21		Returns the Switch ID assigned to the port.
Reserved	22-31	0x0	Reserved.

7.8.12.2.3 Get Resource Allocation (0x0204)

This command returns the number of resources allocated to a function from each type of resource. For all the subsequent resource management commands, the encoding of the resource type is described in Table 7-18.

Table 7-28. Get Resource Allocation Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0204	Command opcode.
Datalen	4-5		Length of response buffer. Should be enough to store response.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-29. Get Resource Allocation Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0204	Command opcode.
Datalen	4-5		Length of response buffer. Should be number of resource returned x resource entry size.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Entries	16-17		Number of entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-30. Get Resource Allocation Response Buffer Entry

Offset (Bytes)	Description
0-1	**Bits 6:0:** Resource type - see above for encoding. **Bits 15:7:** Reserved
2-3	Total Capacity — Total number of resources from this type available to all functions (fixed according to hardware capabilities).
4-5	Allocated Function — Number of resources from this type allocated to this function (for most resources but hash based, this means actual entries are owned by the function).
6-7	Allocated Shared — Number of resources from this type allocated as shared.
8-9	Total Free — Total number of resources from this type still unallocated and not reserved by any function.

7.8.12.2.4 Allocate Resource (0x0208)

Table 7-31. Allocate Resource Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0208	Command opcode.
Datalen	4-5	(6-4096)	Length of command/response buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Entries	16-17		Number of resource entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

In response, firmware fills buffer (See Table 7-33) with corresponding resource descriptors.

Table 7-32. Allocate Resource Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0208	Command opcode.
Datalen	4-5	(6-4096)	Length of command/response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Codes returned by firmware: OK = Success EINVAL = One of the requested parameters is invalid. ENOSPC = Allocation failed, all resources until the problematic resource (including) contain the number of resources currently available for allocation.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Entries	16-17		Number of resource entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-33. Allocate Resource Command Buffer Entry

Offset (Bytes)	Description
0-1	**Bits 6:0:** Resource type (see Table 7-18 for encoding) **Bit 7:** Shared 0b = Allocate Dedicated 1b = Allocate Shared **Bits 11:8:** VSI prune list hint A bitmap that provides a hint to the firmware from which of the four banks to allocate the VSI prune lists. VSI prune list hint is a suggestion for allocation in one of the list banks, starting from the lowest bank. If the suggestion is failed due to lack of resources than there will be a try to allocate in different bank. **Bit 12:** If this bit is set, firmware scans from the bottom (last) entry (relevant only if Bit 13 is enabled, otherwise index is given in Bytes 2-3). **Bit 13:** If this bit is set, the index values (Bytes 2-3) are be ignored in command and firmware returns in response new allocated indexes. ***Note:*** Bits 12,13 are relevant only for Profile builder Resource Allocation and reserved otherwise. **Bits 15:14:** Reserved
2-3	Number of resource descriptors to allocate. Must not be zero or larger than max available number of this resource. ***Note:*** For Profile Builder Resource Allocation, if Bit 13 in Bytes 0-1 is enabled, these bytes contain an indication of which index to begin the search if it is non-zero (it is assumed that index zero is the top of the list). For example, if the PF driver owned Profile ID TCAM entry X, it might want to start scanning for new elements at X, to ensure that the new entry was higher, that is, closer to the first entry in the table.
4-...	Placeholder for resource descriptors. Two bytes/descriptor, except FLU entries (0x9) and FD filters (0x22 and 0x23): Number of resource descriptors to allocate x 2. In case of ENOSPC, first descriptor contains number of resources currently available for allocation, and no resources within this request are allocated. Two bytes for FLU and FD filters: Ignored on success, number of resources currently available for allocation on ENOSPC. The resource descriptors returned are the indexes in the resource's table. ***Note:*** When adding Profile Builder resources, firmware checks that the resource is defined as shared (inside downloaded package) and adds PF's usage of the shared resource.

Figure 7-18 describes the relationship between the different resources reported.

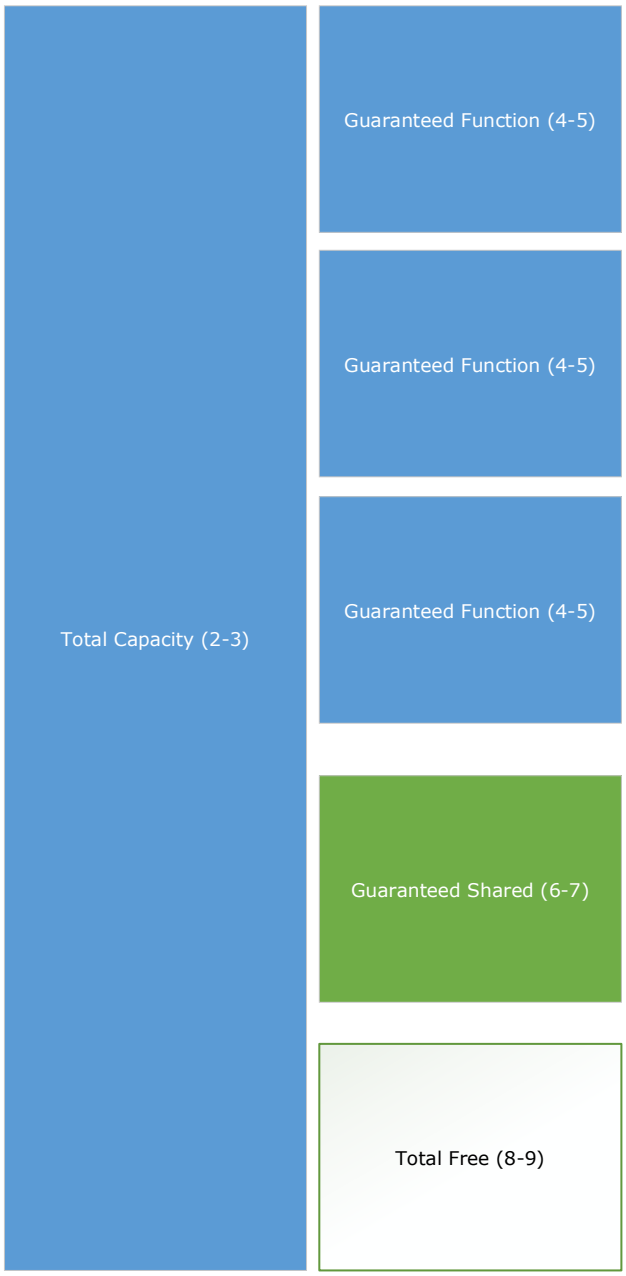

Figure 7-18. Resources Reported

7.8.12.2.5 Free Resource (0x0209)

Table 7-34. Free Resource Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0209	Command opcode.
Datalen	4-5	(6-4096)	Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Entries	16-17		Number of resource entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-35. Free Resource Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0209	Command opcode.
Datalen	4-5	(6-4096)	Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Codes, returned by firmware: OK = Success EINVAL = Some resources could not be freed, details inside buffer. EBUSY = Trying to release a resource which is in use.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Entries	16-17		Number of resource entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-36. Free Resource Command Buffer Entry

Offset (Bytes)	Description
0-1	**Bits 6:0:** Resource type (see Table 7-18 for encoding) **Bits 15:7:** Reserved
2-3	Number of resource descriptors to free. Must not be zero or larger than number of this resource allocated to this function.
4-...	Resource descriptors. Two bytes/descriptor, except FLU. In case of EINVAL, every descriptor firmware failed to released is overwritten as follows: Bit 15 is set, the rest of the bits - extended firmware diagnostic codes (like access denied, resource still referenced, and so on). Two bytes for FLU. Ignored on success, number of resources, currently possible to free on EINVAL. The resource descriptors are the indexes in the resource's table. ***Note:*** When releasing Profile Builder resources, firmware checks that the resource is defined as shared (inside downloaded package) and removes PF's usage of the shared resource. When releasing Profile ID TCAM resources, firmware clears the resource data inside hardware tables in case no PF uses the resource.

7.8.12.2.6 Get Allocated Resource Descriptors (0x020A)

This command is used to get the list of the actual resources allocated to the PF of a given resource type. This command is N/A for FD filters (0x22 and 0x23) resource types. If used for these resources, an empty buffer is returned. For FLU entries (0x9), only root lookup entries actually used are returned.

Table 7-37. Get Allocated Resource Descriptors Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x020A	Command opcode.
Datalen	4-5	(2-2048)	Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Resource	16-17		**Bits 6:0:** Resource Type See Table 7-18 for encoding. **Bit 7:** Shared 0b = Get Dedicated 1b = Get Shared **Bits 15:8:** Reserved
First Descriptor	18-19		If not zero, start the report from the requested descriptor.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-38. Get Allocated Resource Descriptors Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x020A	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. EINVAL = One of the requested parameters is invalid.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Resource	16-17		**Bits 6:0:** Resource Type See Table 7-18 for encoding. **Bit 7:** Shared 0b = Get Dedicated 1b = Get Shared **Bits 15:8:** Reserved
Next Descriptor	18-19		If not zero, indicates that not all the configuration was returned and a new command should be sent with this value in the *First Descriptor* field.
Number of Descriptors	20-21		Number of descriptors in buffer.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-39. Get Allocated Resources Response Buffer

Offset (Bytes)	Description
0-...	Resource descriptors. Two bytes/descriptor. The resource descriptors returned are the indexes in the resource's table.

7.8.12.3 VSI Commands (0x021x)

7.8.12.3.1 Add VSI (0x0210)

This command is used to add a new VSI.

When an Add VSI command is received, the internal firmware checks if all the requested resources are available and allocate them to the VSI.

Table 7-40 describes the structure of the command buffer for the Add VSI command.

Table 7-40. Add VSI Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0210	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7	0x0	Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI	16-17	0x0	**Bit 17.7:** VSI is valid **Bits 17.6-17.2:** Reserved **Bits 17.1-16.7:** VSI Number If VSI is valid, the VSI should be from resources allocated to this PF. Otherwise, a free VSI is allocated from the shared pool.
Reserved (Connection Type)	18	0x0	Reserved.
Reserved	19	0x0	Reserved.
VF Function Number	20		Defines the VF function to which this VSI connects. Valid only if Function Type is VF. Should be ignored if VSI type is not VF. ***Note:*** The VF number here is the absolute VF number (0-255) and not the number relative to the PF first VF.
Reserved	21		Reserved.
Command Flags	22-23		**Bits 1:0:** VSI type: 00b = VF 01b = VMDq2 (a.k.a. VM) 10b = PF 11b = EMP/MNG **Bits 15:2:** Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-41. Add VSI Command Buffer

Category	Byte.Bit	Field	Description
Valid Sections	0-1		Defines which sections are valid in the command. **Bit 0:** Switching section is valid. **Bit 1:** Security section is valid **Bit 2:** VLAN handling section is valid. **Bit 3:** Outer tag section is valid. **Bit 4:** Ingress UP translation section is valid. **Bit 5:** Egress UP translation section is valid. **Bit 6:** Rx-Queue Mapping section is valid. If set, modified queues must be disabled. **Bit 7:** Queuing option section is valid. **Bit 8:** Outer UP mapping section is valid. **Bit 9:** Reserved. **Bit 10:** ACL section valid. **Bit 11:** Flow Director section valid. **Bit 12:** PASID section valid. **Bits 13:15:** Reserved. ***Note:*** Relevant only for Update VSI command. In Add VSI command, all the sections are assumed to be valid.
Switching	2	Switch ID	Defines the switch ID to which this VSI belongs.
	3.0-3.3	Reserved (Switch ID MSB)	Reserved.
	3.4	Reserved (Is not STag	Reserved.
	3.5	Allow Loopback	If set, traffic from this VSI can be loopback.
	3.6	Allow Local Loopback	If cleared, inverse actions are applied to Rx traffic to this VSI (used in default image for MAC source pruning).
	3.7	Apply Source VSI Pruning	If set, traffic sent from a VSI can be forwarded to the same VSI. ***Note:*** It is recommended to always set this bit, unless there is an explicit need to receive back traffic sent by the VSI.
	4.0-4.3	Egress (Rx) Pruning Enables	Defines which pruning modes are enabled for egress traffic Setting Bit 0 enables VLAN pruning.
	4.4	LAN Enable	If set, traffic from this VSI can be sent to LAN.
	4.5-4.7	Reserved	Reserved.
	5.0-5.4	VEB Statistic Block ID	Defines which VEB statistic block this VSI is associated to.
	5.5	VEB Statistic Block ID Valid	If set, the *VEB Statistic Block ID* field is valid. 0b = When this bit is cleared, this association is removed. 1b = When this bit is set (in Add VSI or Update VSI command), the switch ID associated with this VSI is assigned a VEB statistic block defined by *VEB Statistic Block ID* field. Must be set for any Add/Update VSI of VSIs associated with a VEB statistic block.
	5.6-5.7	Reserved	Reserved for future switching parameters. Must be zero.

Table 7-41. Add VSI Command Buffer [continued]

Category	Byte.Bit	Field	Description
Security	6.0	Allow Destination Override	Allow the VSI to override the switching decision and fix the destination of a transmit packet. This bit should be set only for trusted VSIs. ***Note:*** If this bit is set, the *Enable MAC Anti-Spoof* bit and the VLAN anti-spoofing (*Ingress Pruning Ena*bles[0]) should not be set.
	6.1	Reserved (Enable VLAN Anti-Spoof)	Reserved.
	6.2	Enable MAC Anti-Spoof	If set, inverse actions are applied to Tx traffic to this VSI (used in default image for MAC anti-spoof).
	6.3	Reserved	Reserved.
	6.4-6.7	Ingress (Tx) Pruning Enables	Defines which pruning modes are enabled for ingress traffic Setting Bit 0 enables VLAN anti-spoofing.
	7	Reserved	Reserved for future security parameters. Must be zero.
VLAN Handling	8-9	PVID + Default UP (16 bits)	VLAN ID to use in port-based VLAN insertion. This field is relevant only if the *Insert PVID* field is set.
	10-11	Reserved	Reserved.
	12.0-12.1	VLAN Driver Insertion Mode	This field defines if the driver is allowed/should add a VLAN tag to the packets it sends. If the *Insert PVID* field is set, this field should be set to 01b. 00b = Reserved. 01b = Admit untagged/Priority tagged only - allow only packets without VLAN or with VLAN tag = 0. 10b = Admit.1Q tagged only - Allow only packets with VLAN. 11b = Allow all packets.
	12.2	Insert PVID	Port-based VLAN insertion. This bit controls the port based insertion of VLANs. Should be set for VFs/ VMDq2 VSIs according to the VMM request. If this field is set, the *PVID + Default UP* field should be set to the port-based VLAN.
	12.3-12.4	VLAN and UP Expose Mode (Rx)	This field defines how received VLAN are handled. For non-VF VSIs, 00b or 11b should be used. For VF VSIs, the mode should be set according to the VLAN awareness of the VM and the offload requested. 00b = Show VLAN, DEI and UP in descriptor (legacy behavior). 01b = Hide VLAN, show UP and DEI (VLAN ID = 0). 10b = Hide VLAN, DEI and UP. 11b = Do nothing (leave VLAN in packet).
	12.5-12.7	Reserved	Reserved for future port VLAN parameters. Must be zero.
Ingress UP Translation	16-19	Ingress UP Translation Table	Defines the UP translation table for received packets according to the following list: **Bits 16.0-16.2:** UP set if received UP is 0. **Bits 16.3-16.5:** UP set if received UP is 1. **Bits 16.6-17.0:** UP set if received UP is 2. **Bits 17.1-17.3:** UP set if received UP is 3. **Bits 17.4-17.6:** UP set if received UP is 4. **Bits 17.7-18.1:** UP set if received UP is 5. **Bits 18.2-18:4:** UP set if received UP is 6. **Bits 18.5-18.7:** UP set if received UP is 7. **Byte 19:** Reserved. This map is used to translate the 802.1P user priority bits received in the packet to the user priority exposed to the host. Relevant only if the UP is exposed to the host (*VLAN and UP Expose Mode* not equal 10b).

Table 7-41. Add VSI Command Buffer [continued]

Category	Byte.Bit	Field	Description
Egress UP Translation	20-23	Egress UP Translation Table	Defines the UP translation table for transmit packets according to the following list: **Bits 20.0-20.2:** UP set if sent UP is 0. **Bits 20.3-20.5:** UP set if sent UP is 1. **Bits 20.6-21.0:** UP set if sent UP is 2. **Bits 21.1-21.3:** UP set if sent UP is 3. **Bits 21.4-21.6:** UP set if sent UP is 4. **Bits 21.7-22.1:** UP set if sent UP is 5. **Bits 22.2-22.4:** UP set if sent UP is 6. **Bits 22.5-22.7:** UP set if sent UP is 7. **Byte 23:** Reserved. This map is used to translate the 802.1P user priority bits sent by the host to the user priority sent to the network. ***Note:*** The resulting user priority is further translated using the per TC translation table.
Outer Tags Handling	24-25	Outer Tag	The outer tag (STag/Outer VLAN) to be inserted in transmit packets. This field is relevant only if *STag Insert Enable* field is set. This field is 16 bits and should also include the default PCP priority bits to insert in the STag.
	26.0-26.1	Outer Tag Extract Tag	This field defines how received outer tags (STag/Outer VLAN) are handled. 00b = Do nothing. 01b = Extract tag and do not insert in descriptor. 10b = Extract tag from packet and expose in descriptor. 11b = Reserved.
	26.2-26.3	Outer Tag Type	Defines the type of outer tag expected. 00b = No outer tag. 01b = 0x88A8 STag. 10b = 0x8100 VLAN. 11b = 0x9100 VLAN.
	26.4	Outer Tag Insert Enable	This bit controls the port based insertion of outer tag (STag/Outer VLAN). When this bit is set, the *Accept Tag from Host* bit should be cleared.
	26.5	Reserved	Reserved.
	26.6	Accept Tag from Host	When this bit is set, the *Outer Tag Insert Enable* bit should be cleared ***Note:*** When this bit is cleared, the device prevents insertion of the tag through the descriptor.
	26.7-27.7	Reserved	Reserved for future port outer tag parameters. Must be zero.

Table 7-41. Add VSI Command Buffer [continued]

Category	Byte.Bit	Field	Description
Rx-Queue Mapping	28.0	Mapping Method	Selects between contiguous range of queues for this VSI vs. scattered range: 0b = The VSI is assigned a contiguous range of PF Rx-Queues. 1b = The VSI is assigned a scattered range of PF Rx-Queues.
	28.1-29.7	Reserved	Reserved. Must be zero.
	30-61	Rx-Queue Mapping	If *Mapping Method* = 0 (contiguous): **Bits 30.0-31.2:** The first queue allocated for this VSI in the PF space. **Bits 31.7-31.3:** Reserved **Bytes 33-32:** Number of queues allocated to this VSI. Used to define the number of queues associated with this VSI **Bytes 61-34:** Reserved If *Mapping Method* = 1 (scattered): For each of the queues in the VSI, defines the actual queue in the PF according to the following encoding: For queue 'n' of the VSI offsets 30+2n - 31+2n are used the define the mapping to PF queues. For example for queue 0: • **Bits 30.0-31.2:** The PF queue matching allocated to queue 'n' of the VSI. For non allocated queue, a value of 0x7FF should be set. • **Bits 31.3-31.7:** Reserved. The same mapping is used for the next queues. In this method, up to 16 queues can be assigned. ***Note:*** For VSIs assigned to VFs for which VPLAN_RX_QBASE.*VFQTABLE_ENA* is set, only the scattered method can be used. ***Note:*** The first queue (in both modes) is the default queue of the VSI to which packets not queued by any filter are sent.
	62-77	Number and Offset of Rx-Queue per TCs	Fixes the number of queue pairs assigned to the VSI for each traffic class and the offset of these queues. **Bits 62.0-63.2:** Queue offset for TC0. **Bits 63.3-63.6:** Number of queues allocated to TC0. The actual number is 2^n. The allowed number of queues is: 1, 2, 4, 8, 16, 32, 64, 128. **Bit 63.7:** Reserved. ***Note:*** If no queues needs to be associated to a TC, the queue offset should be set to 0 and the number of queues to 0 (1 queue). This way, traffic associated with this TC is sent to the default queue. The following addresses are used with the same format for the next TCs: **Bytes 64-65:** TC1 **Bytes 66-67:** TC2 **Bytes 68-69:** TC3 **Bytes 70-71:** TC4 **Bytes 72-73:** TC5 **Bytes 74-75:** TC6 **Bytes 76-77:** TC7

Table 7-41. Add VSI Command Buffer [continued]

Category	Byte.Bit	Field	Description
Queuing Options	78.1-78.0	RSS LUT Selection	RSS LUT used. 00b = VSI LUT 01b = Reserved 10b = PF LUT 11b = Global LUT (one of 16 Global LUTs)
	78.5-78.2	RSS Global LUT	If *RSS LUT Selection* = 11b (Global LUT), selects the LUT assigned to this VF.
	78.7-78.6	Hash Scheme	Hash scheme. 00b = Toeplitz Hash 01b = Symmetric Toeplitz 10b = Simple XOR 11b = Reserved
	79.4-79.0	TC Override Option	TC override option.
	79.6-79.5	Reserved	Reserved.
	79.7	Profile Override TC	Profile override TC.
	80.0	Enable PE Filtering	Enable PE filtering.
	80.1-83.7	Reserved	Reserved for future queuing parameters. Must be zero.
Outer UP Mapping	84-87	Egress Inner UP to Outer Translation Table	Defines the UP translation table for transmit packets from inner to outer UP according to the following list: **Bits 84.0-84.2:** Outer UP set if inner UP is 0. **Bits 84.3-84.5:** Outer UP set if inner UP is 1. **Bits 84.6-85.0:** Outer UP set if inner UP is 2. **Bits 85.1-85.3:** Outer UP set if inner UP is 3. **Bits 85.4-85.6:** Outer UP set if inner UP is 4. **Bits 85.7-86.1:** Outer UP set if inner UP is 5. **Bits 86.2-86.4:** Outer UP set if inner UP is 6. **Bits 86.5-86.7:** Outer UP set if inner UP is 7. **Byte 87:** Reserved. This map is used to translate the 802.1P user priority bits on the inner UP to outer UP. To get a fixed outer UP, all the values should be set to the requested outer UP.
ACL	88.0-88.3	Rx Profile Miss Default Action	Selects one of four predefined actions to be applied in case a receive packet does not match any ACL profile.
	88.4-88.7	Rx Table Miss Default Action	Selects one of four predefined actions to be applied in case a receive packet does not match any ACL table entry.
	89.0-89.3	Tx Profile Miss Default Action	Selects one of four predefined actions to be applied in case a transmit packet does not match any ACL profile.
	89.4-89.7	Tx Table Miss Default Action	Selects one of four predefined actions to be applied in case a transmit packet does not match any ACL table entry.

Table 7-41. Add VSI Command Buffer [continued]

Category	Byte.Bit	Field	Description
Flow Director	90.0	Flow Director Enable	Enable Flow Director filtering.
	90.1	Tx Auto-Evict Enable	Enables eviction of ATR filters if a FIN/RST packet is sent.
	90.2	Reserved	Reserved.
	90.3	Flow Director Programming Enable	Enable Flow Director programming.
	90.4-91.7	Reserved	Reserved.
	92-93	Max Dedicated	Max Number of allocated Flow Director filters to a VSI.
	94-95	Max Shared	Max number of shared Flow Director filters any VSI can program. ***Note:*** If both dedicated and shared values are zero, the VSI cannot program filters.
	96.0-97.2	Default Queue	This field defines the receive queue index within the VSI of the default FD. Permitted values are in the range of the queues of the VSI.
	97.3	Reserved	Reserved.
	97.6-97.4	Default Queue Group	The *ToQueue* parameter associate a target queue or a queue group to the FD filter: 0 = The default filter assign a target queue defined by the QINDX 1...7 = The default filter assign a region of queues. The region base equals to QINDX and the region size equals to 2^(ToQueue).
	97.7	Reserved	Reserved.
	98.0-99.2	Reporting Queue	This field defines the receive queue index of the programming VSI on which the FD filter completion status is reported when the *COMP_Queue* flag in the programming descriptor is set.
	99.3	Reserved	Reserved.
	99.6-99.4	Default Priority	The priority of the default QINDX action.
	99.7	Default Drop	When set, a packet that miss the FD filters is dropped.
PASID Section	102.3-100.0	PASID ID	PASID for this VSI.
	103.6-102.4	Reserved	Reserved.
	103.7	PASID ID Valid	PASID ID is valid.
Reserved	104-127	Reserved	Reserved.

Table 7-42 describes the Add VSI response.

Table 7-42. Add VSI Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0210	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOSPC = If there are not enough resources to assign a VSI (in case of VSI number invalid) or part of the requested resources. EINVAL = The VSI is already enabled ENOENT = Index is invalid for one of the VSI resource parameters. EACCES = PF does not own one of the VSI resource parameters.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI	16-17		Returns the assigned VSI number. If VSI is provided in command, the same value is returned. **Bit 17.7:** VSI is valid (always valid) **Bits 17.6-17.2:** Reserved **Bits 17.1-16.7:** VSI Number
Extended Status	18-19		If this value is not zero and there is no error code, the command succeeded but with warnings.
VSIs Allocated from Guaranteed	20-21		Number of VSIs that were either allocated using the Allocate Resource command, or allocated and enabled using the Add VSI command, both from the VSIs pre-allocated in NVM.
Total VSIs Un-Allocated	22-23		Total number of VSIs still unallocated and not reserved by any function.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.3.2 Update VSI (0x0211)

This command is used to update the parameters of an existing VSI. A function can update only a VSI it controls. Only sections defined as valid in Bytes 0-1 of the buffer are updated.

Table 7-43. Update VSI Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0211	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI Number	16-17		**Bit 17.7:** VSI is valid (should always be set) **Bits 17.6-17.2:** Reserved **Bits 17.1-16.7:** VSI Number
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

The command buffer and the completion buffer used to update a VSI is the same as the command buffer of the Add VSI command (Table 7-41). Specific limitations are listed in the table.

All the filters set before the VSI type updates are kept, and the software device driver should guarantee they are compliant with the new VSI parameters.

Table 7-44. Update VSI Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0210	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If the VSI is not owned by this PF or PF does not own one of the VSI resource parameters. EINVAL = The VSI was not enabled. ENOSPC = There are not enough resources to allocate new resources requested. ENOENT = Index is invalid for one of the VSI resource parameters.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI Number	16-17	0x0	Copied from command.
Reserved	18-19		Reserved.
VSIs Allocated from Guaranteed	20-21		Number of VSIs that were either allocated using the Allocate Resource command, or allocated and enabled using the Add VSI command, both from the VSIs pre-allocated in NVM.
Total VSIs Un-Allocated	22-23		Total number of VSIs still unallocated and not reserved by any function.

Table 7-44. Update VSI Response [continued]

Name	Byte.Bit	Value	Remarks
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.3.3 Get VSI Parameters (0x0212)

This command is used to get the parameters of an existing VSI. A function can query only a VSI it controls.

Table 7-45. Get VSI Parameters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0212	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI Number	16-17		**Bit 17.7:** VSI is valid (should always be set) **Bits 17.6-17.2:** Reserved **Bits 17.1-16.7:** VSI Number
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-46. Get VSI Parameters Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0212	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: ENOENT = If the SEID do not point to a valid VSI. EACCES = If the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI Number	16-17		VSI Number (copied from command).
VF Function Number	18		Defines the VF function to which this VSI connects. Valid only if Function Type is VF. Should be ignored if VSI type is not VF. ***Note:*** The VF number here is the absolute VF number (0-255) and not the number relative to the PF first VF.

Table 7-46. Get VSI Parameters Response [continued]

Name	Byte.Bit	Value	Remarks
Status Flags	19		**Bits 1:0:** VSI type 00b = VF 01b = VMDq2 (a.k.a. VM) 10b = PF 11b = EMP/MNG **Bit 7:2:** Reserved.
VSIs Allocated from Guaranteed	20-21		Number of VSIs that were either allocated using the Allocate Resource command, or allocated and enabled using the Add VSI command, both from the VSIs pre-allocated in NVM.
Total VSIs Un-Allocated	22-23		Total number of VSIs still unallocated and not reserved by any function.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-47 describes the response buffer received when querying a VSI.

Table 7-47. Get VSI Parameters Response Buffer

Byte.Bit	Description
0-95	Same parameters as described in Table 7-41.
96-127	Reserved.

7.8.12.3.4 Free VSI (0x0213)

This command is used to remove a VSI. A function can remove only a VSI it owns. The driver should make sure that every queue in a VSI is disabled before a VSI is removed and that no rules pointing to this VSI exists.

As part of this command, the firmware should clear all the Flow Director filters assigned to this VSI by applying the flow of the Clear FD Table AQ command (0x0B06) described in Section 7.10.12.1 and clear the RSS key of the VSI as if the Set RSS Key (0x0B02) command was received with an all-zero key.

Table 7-48. Free VSI Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0213	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI	16-17	VSI	The VSI to remove **Bit 17.7:** VSI is valid (should always be set) **Bits 17.6-17.2:** Reserved **Bits 17.1-16.7:** VSI Number
Command Flags	18-19		**Bits 19.7-18.1:** Reserved **Bit 18.0:** Keep VSI Allocation If set, the VSI stays part of the PF allocated resources. Otherwise, it is returned to the shared pool.
Reserved	20-31		Reserved. Must be zero.

Table 7-49. Free VSI Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0213	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If the element is not owned by this PF. ENOENT = VSI number is invalid.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-19		Reserved.
VSIs Allocated from Guaranteed	20-21		Number of VSIs that were either allocated using the Allocate Resource command, or allocated and enabled using the Add VSI, both from the VSIs pre-allocated in NVM.
Total VSIs Un-Allocated	22-23		Total number of VSIs still unallocated and not reserved by any function.
Reserved	24-31		Reserved.

7.8.12.4 Storm Control Commands (0x028x)

7.8.12.4.1 Set Storm Control Configuration (0x0280)

This command is used to configure the Storm Control Mechanism of the port.

This command can be applied only by the function that controls the physical port.

Table 7-50. Set Storm Control Configuration Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0280	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by device driver.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Broadcast Threshold	16-19	0x0	**Bits 18:0:** Traffic Upper Threshold Size Represents the upper threshold for broadcast storm control. **Bits 31:19:** Reserved
Multicast Threshold	20-23	0x0	**Bits 18:0:** Traffic Upper Threshold Size Represents the upper threshold for multicast storm control. **Bits 31:19:** Reserved
Storm Control Control	24-27	0x0	**Bit 0:** MDIPW Drop multicast packets (excluding flow control and manageability packets) if multicast threshold is exceeded in previous window. **Bit 1:** MDICW Drop multicast packets (excluding flow control and manageability packets) if multicast threshold is exceeded in current window. **Bit 2:** BDIPW Drop broadcast packets (excluding flow control and manageability packets) if broadcast threshold is exceeded in previous window. **Bit 3:** BDICW Drop broadcast packets (excluding flow control and manageability packets) if broadcast threshold is exceeded in current window. **Bits 7:4:** Reserved **Bits 27:8:** INTERVAL - BSC/MSC Time-interval-specification The interval size for applying Ingress Broadcast or Multicast Storm Control. Interrupt decisions are made at the end of each interval (and most flags are also set at interval end). **Bits 31:28:** Reserved
Reserved	28-31		Reserved.

Table 7-51. Set Storm Control Configuration Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0280	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/VFID	6-7		Return value. There is no specific error code for this command.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

7.8.12.4.2 Get Storm Control Configuration (0x0281)

This command is used to query the configuration of the storm control mechanism. Note that the current status of the storm control is received via the SCSTS register.

Table 7-52. Get Storm Control Configuration Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0281	Command opcode.
Datalen	4-5	0x0	Reserved
Return Value/VFID	6-7	0x0	Must be zero.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

Table 7-53. Get Storm Control Configuration Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0281	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/VFID	6-7		Return value. There is no specific error code for this command.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Broadcast Threshold	16-19	0x0	**Bits 18:0:** Traffic Upper Threshold Size Represents the upper threshold for broadcast storm control. **Bits 31:19:** Reserved
Multicast Threshold	20-23	0x0	**Bits 18:0:** Traffic Upper Threshold Size Represents the upper threshold for multicast storm control. **Bits 31:19:** Reserved

Table 7-53. Get Storm Control Configuration Response [continued]

Name	Byte.Bit	Value	Remarks
Storm Control Control	24-27	0x0	**Bit 0:** MDIPW Drop multicast packets **Bit 1:** MDICW Drop multicast packets **Bit 2:** BDIPW Drop broadcast packets **Bit 3:** BDICW Drop broadcast packets **Bit 4:** BIDU BSC Includes Destination Unresolved packets: **Bits 7:5:** Reserved **Bits 27:8:** Interval - BSC/MSC Time-interval-specification The interval size for applying Ingress Broadcast or Multicast Storm Control. **Bits 31:28:** Reserved
Reserved	28-31		Reserved.

7.8.12.5 Switch Recipes Configuration (0x029x)

7.8.12.5.1 Add Recipe (x0x290)

This command adds a recipe to the 64-entry recipe table. The recipe can include multiple entries to create a composite rule. After the recipe is added, it should be associated with packet profiles using the Set Recipes to Profile Association command.

If the recipe exists, it is updated. It is the responsibility of software not to change recipes pointing to populated rules, unless the change is to add a result to the recipe to be able to use it as a sub-recipe.

Table 7-54. Add Recipe Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0290	Command opcode.
Datalen	4-5	Buffer Length	(Number of recipe +1) * 32
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Sub-Recipes	16-17		Number of sub-recipe entries in buffer.
Reserved	18-23	0x0	Reserved. Must be zero.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

The buffer in the command is as follows:

Table 7-55. Add Recipe Buffer[1]

Byte	Description
0 + n *64	Recipe index.
1 + n *64 - 3 + n *64	For command: Reserved. For response: 0: Recipe was updated. 23:1: Reserved.
4 + n *64 - 11+ n *64	Bitmap of the recipe indexes associated with this recipe A recipe can make use of already programmed entries that might not be part of the recipes described in this command.
12+ n *64 - 15+ n *64	Reserved.
16 + n *64 - 43 + n *64	Content of recipe as described in Table 7-9.
44 + n *64 - 63 + n *64	Reserved.

1. Repeated n times, based on the number of programmed recipe entries.

Table 7-56. Add Recipe Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0290	Command opcode.
Datalen	4-5	Buffer Size	
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOENT = Bad resource index.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Sub-Recipes	16-17		Number of sub-recipe entries in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.5.2 Set Recipes-to-Profile Association (0x0291)

This command is use to associate recipes with packet profiles.

Table 7-57. Set Recipes-to-Profile Association Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0291	Command opcode.
Datalen	4-5	Buffer Length	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16-17		The profile to associate recipes to.
Reserved	18-23	0x0	Reserved. Must be zero.
Recipe Association	24-31		Bitmap of the recipe indexes associated with this profile. The bitmap should include both root and non-root recipe associated with the profile.

Table 7-58. Set Recipes-to-Profile Association Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0291	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOENT = Bad resource index. ERANGE = A root recipe is added to the association list without its dependent recipes.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

7.8.12.5.3 Get Recipe (0x0292)

This command returns a recipe and all the associated entries.

Table 7-59. Get Recipe Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0292	Command opcode.
Datalen	4-5	Buffer Length	Should be 4 KB.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Rules	16-17		Reserved in command. Filled in response.
Recipe Root Number	18-19		Index of the root recipe to return (0-63). All the child recipes of this root recipe are also returned. A value of 0xFFFF means to start from the very first root and return all the active recipes with their children. ***Note:*** The recipes returned are either allocated to the PF or persistent.
Reserved	20-23	0x0	Reserved. Must be zero.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-60. Get Recipe Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0292	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: ENOENT = Bad resource index.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Rules	16-17		Reserved in command. Filled in response according to the number of rules associated with the requested root ID.
Recipe Number	18-19		Index of root recipe requested.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

The buffer in the response is as follows:

Table 7-61. Get Recipe Response Buffer[1]

Byte.Bit	Description
0 + n *64	Recipe Index (the recipes are ordered numerically). The Root recipe is the last one in the list
1 + n *64 - 3 + n *64	Reserved.
4 + n *64 - 11+ n *64	Bitmap of the recipe indexes associated with this recipe (all the recipe that participates in the creation of the requested recipe). These recipe should appear earlier in the buffer.
12+ n *64 - 15+ n *64	Reserved.
16 + n *64 - 43 + n *64	Content of recipe as described in Table 7-9.
44 + n *64 - 63 + n *64	Reserved.

1. The list is repeated *Number of Rules* times.

7.8.12.5.4 Get Recipes-to-Profile Association (0x0293)

This command is use to read the recipes associated with a packet profile.

Table 7-62. Get Recipes-to-Profile Association Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0293	Command opcode.
Datalen	4-5	Buffer Length	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16-17		The profile to read the association of.
Reserved	18-31	0x0	Reserved. Must be zero.

Table 7-63. Get Recipes-to-Profile Association Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0293	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = if one of the resources is not owned by this PF. ENOENT = Bad resource index.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16-17		The profile to read the association of.
Reserved	18-23	0x0	Reserved.
Recipe Association	24-31		Bitmap of the recipe indexes associated with this profile.

7.8.12.6 Switch Rules Population Commands (0x02Ax)

7.8.12.6.1 Add Switch Rules (0x02A0)

This command is used to populate the switch. It can be used to program a combination of lookup rules + actions, large actions or VSI lists.

A single buffer can include multiple commands from different types. The commands are applied in order, so if a rule points to a large action or a VSI list, the list and the large action should be programmed before the lookup + action.

If a rule already exists and needs to be updated, the Update Switch Rules command should be used.

Table 7-64. Add Switch Rules Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x02A0	Command opcode.
Datalen	4-5	Buffer Length	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Rules	16-17		Number of rules in buffer.
Reserved	18-23	0x0	Reserved. Must be zero.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Table 7-65. Add Switch Rules Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x02A0	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOSPC = If one of the filters cannot be allocated. EINVAL = Invalid parameters or rule already exists. ENOENT = Bad resource index. ***Note:*** If an ENOSPC error is returned, check the return buffer for the exact list of filters not allocated. Other errors indicates that the entire command was not executed.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

The content of the return buffer is the same as the input buffer. The *Status* field and the LUT index are updated as part of the response. The first filter allocation that fails due to lack of resources stops the command.

7.8.12.6.1.1 Add Switch Rules Buffer Format

The buffer contains a “Number of Rules” structures with the following format:

```
struct
{
#define T_LOOKUP_RX         0x0 // Used to add a rule for traffic from network.
#define T_LOOKUP_TX         0x1 // Used to add a rule for traffic from VSI.
#define T_LARGE_ACTION      0x2 // Used to define content of large action.
#define T_VSI_LIST_SET      0x3 // Used to set VSIs in a multicast VSI list.
#define T_VSI_LIST_CLEAR    0x4 // Used to clear VSIs from a multicast VSI list or to
                                // clear the entire list.
#define T_PRUNE_LIST_SET    0x5 // Used to set VSIs in a prune VSI list.
#define T_PRUNE_LIST_CLEAR 0x6 // Used to clear VSIs from a prune VSI listor to clear
                                // the entire list.

    __le16 Type;     // One of #defines above.
    __le16 Status;   // Return status. For Add/Update indicates the resource was
                     // successufully allocated/updated. For Get, always succeed for
                     // entries in range. A status of zero means a success. A non
                     // zero status reflects one of the errors listed in Table 7-65
                     // for return value.

    union
    {
        struct
        {
            __le16 RID;        // Recipe ID.
            __le16 Source;     // Source VSI for LOOKUP_TX and source port for
                               // LOOKUP_RX. This field is used by the hardware to
                               // derive the switch ID (based on source of packet).
                               // Reserved for Get command.
            __le32 Action;     // Action as defined in Table 7-12.
            __le16 Index;      // LUT index. Return value for Add, parameter for
                               // Get/Update.
            __le16 HeaderLen; // Header length (in bytes) for add command. Should be
                               // zero for remove and update command. Should be 24 for
                               //  query. Should be aligned to four bytes.
            u8 HeaderData[0]; // Header data, array of HeaderLen for add and update
                               // commands. For query, contains the content of the
                               // FLU. Should be null for remove command.
        } LOOKUP; // LOOKUP_TX and LOOKUP_RX

        struct
        {
            __le16 Index;      // Index in Large action table.
            __le16 Size;       // 0/1/2/4 - 0 is used for free commands.
            __le32 Action[0]; // Array of Size of actions as defined in Table 7-14.
        } LARGE_ACTION;

        struct
        {
            __le16 Index;         // Index of VSI/Prune list.
            __le16 NumberOfVSIs; // Should be zero to clear the entire list.
```

```
            __le16 VSI[0];       // Array of NumberOfVSIs VSI numbers.
        } VSI_LIST; // Used for VSI_LIST_SET, VSI_LIST_CLEAR, PRUNE_LIST_SET and
                    // PRUNE_LIST_CLEAR.

        struct
        {
            __le16 Index;       // Index of VSI/Prune list.
            __le8 VSI_lIST[96]  // Bitmap of VSI list.
        } VSI_LIST_QUERY; //Used for queries of VSI_LIST_SET/CLEAR

    u8 Padding[0]; //Array of padding bytes
    } Data;
} PopulationEntry;
```

Note: The option to clear an entire VSI list by using an empty VSI_LIST and a PRUNE_LIST_CLEAR action is available only as part of a Remove Switch Rules command.

The buffer header should be a valid packet header.

7.8.12.6.1.2 Population Example

The following is an example of a population request to implement a rule that upon reception of a multicast packet with DA = DA1, it forwards it to VSI1 and VSI3 and mirrors it to VSI12. It is assumed that all the resources are already allocated.

The buffer consists of 3 rules:

- Populate a VSI list with VSI1 and VSI3.
- Create a large action with two actions:
  - Forward to VSI list.
  - Mirror to VSI.
- Create a lookup rule with the packet header and with an action pointing to the larger action mentioned in the previous step.

Assume that VSI List VLn and Large Action LAk are the resources the software device driver chooses to use for this rule and assume RID = 0 is the MAC forwarding recipe used.

To create this, the following buffer is created:

```
struct
{
    __le16 Type = T_VSI_LIST_SET;
    __le16 Status; // filled in response
        struct
        {
            __le16 Index = n;          //VLn
            __le16 NumberOfVSIs = 2;
            __le16 VSI[0] = {1,3};     // VSI1 and VSI3
        } VSI_LIST;
} Entry_1;

struct
{
    __le16 Type = T_LARGE_ACTION;
    __le16 Status; // filled in response
    struct
```

```
        struct
        {
            __le16 Index = k; // LAk
            __le16 Size = 2;  // 2 actions in large action
            __le32 Action[0] = {VSI List forward action(000), Mirror action(011),...}
        } LARGE_ACTION;
    } Data;
} Entry_2;

struct
{
    __le16 Type = T_LOOKUP_TX;
    __le16 Status; // filled in response
    struct
        struct
        {
            __le16 RID = 0 ; //MAC Forwarding
            __le16 Source = 1; // VSI1 is one of the VSIs in the VEB
            __le32 Action = {Pointer Action};
            __le16 Index; // filled in response
            __le16 HeaderLen = 14; //Header length of an L2 packet
        u8 HeaderData[0] = {DA1,Dummy SA, any EtherType }; // Do not use an EtherType
                                                          // of IP if IP header not
                                                          // provided.
        } LOOKUP;
   } Data;
} Entry_3;
```

7.8.12.6.2 Update Switch Rules (0x02A1)

Table 7-66. Update Switch Rules Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x02A1	Command opcode.
Datalen	4-5		Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Filters	16-17		Number of filters in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Data buffer format is described in Section 7.8.12.6.1.1. For update commands, the lookup rules should be accessed by index.

Note: For Large Action and VSI list updates, the Add Switch Rules command and this command can be used interchangeably.

Table 7-67. Update Switch Rules Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x02A1	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOENT = If the lookup rule does not exists.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.6.3 Remove Switch Rules (0x02A2)

Table 7-68. Remove Switch Rules Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x02A2	Command opcode.
Datalen	4-5		Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Filters	16-17		Number of filters in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Data buffer format is described in Section 7.8.12.6.1.1. For remove commands, the lookup rules should be accessed by index.

Table 7-69. Remove Switch Rules Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x02A2	Command opcode.
Datalen	4-5	0x0	Reserved
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOENT = If the lookup rule does not exists.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.6.4 Get Switch Rules (0x02A3)

Table 7-70. Get Switch Rules Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x02A3	Command opcode.
Datalen	4-5		Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Filters	16-17		Number of filters in buffer.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

Data buffer format is described in Section 7.8.12.6.1.1. For Get command, the lookup rules should be accessed by index. In the case of Get command there is no difference between T_VSI_LIST_CLEAR and T_VSI_LIST_SET types, and no difference between T_PRUNE_LIST_CLEAR and T_PRUNE_LIST_SET types. For large actions, the buffer size should be set according to the expected size of the action.

Table 7-71. Get Switch Rules Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x02A3	Command opcode.
Datalen	4-5		Length of command buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: EACCES = If one of the resources is not owned by this PF. ENOENT = If the lookup rule does not exists.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.6.5 Clear PF Configuration (0x02A4)

This command clears all the configuration of the PF, including all VSIs and all Flow Director filters allocated to this PF.

The command does not release resources allocated to the function and the switch ID allocation of the port.

The following resources are removed (but not deallocated) as part of the command:

- Port Configuration
- Switch Rules
- Mirror Rules
- VSI lists
- VSIs
- VEB Counters
- FD Filters

Resource management, Recipes (and Recipe to Profile associations), PE filters are not cleared by this command.

The original topology (VSI + port MAC filter) is not initiated after this command and should be built by the software device driver.

Table 7-72. Clear PF Configuration Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x02A4	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

Table 7-73. Clear PF Configuration Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x02A4	Command opcode.
Datalen	4-5		Length of return buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

7.8.12.7 Mirroring Commands (Opcode 0x026x)

The mirroring behavior is described in Section 7.8.5.4.1.

7.8.12.7.1 Add/Update Mirror Rule (0x0260)

This command is used to add a port mirror rule. Rules can be added for any ingress or egress port, virtual (VSI) or physical (Ethernet port). Lookup based mirroring (a.k.a. VLAN mirroring), is programmed via the regular Add Switch Rules command (Section 7.8.12.6.1).

Table 7-74. Add/Update Mirror Rule Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0260	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to 2 * *Number of Mirrored Entries*.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Rule ID	16-17		**Byte 17:** Reserved **Bit 16.7:** Rule ID Valid **Bit 16.6:** Reserved **Bits 16.5-16.0:** Rule ID If *Rule ID Valid* is set, the requested *Rule ID* is used. If the rule is already in use, the new mirroring rules are added to this rule. The rule should be owned by the PF requesting the it. If *Rule ID Valid* is cleared, a new *Rule ID* is assigned from the shared pool of rules.
Rule Type	18-19		**Bits 2:0:** Rule Type 000b = Reserved. 001b = Virtual port ingress mirroring. All traffic sent from the VSIs in the buffer 010b = Virtual port egress mirroring. All traffic received by the VSIs in the buffer 011b = Reserved (VLAN mirroring in previous products). 100b = Reserved (All ingress traffic in previous products). 101b = Reserved (All egress traffic n previous products). 110b = Physical Port ingress mirroring. All traffic received by this LAN port. 111b = Physical Port egress mirroring. All traffic sent by this LAN port. **Bits 15:3**: Reserved. ***Note:*** If the *Rule Type* is 110b or 111b (ingress/egress port mirroring), there is no associated buffer. The flags in bytes 0-1 should be set accordingly and *Number of Mirrored Entries* should be zero.
Number of Mirrored Entries	20-21		Defines the number of VSIs that should be mirrored. The values are in the command buffer.
Destination VSI	22-23		Defines the VSI to which the packets matching the mirror rule will be mirrored. **Bits 15:10:** Reserved **Bits 9:0:** VSI Number
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

The Command Buffer is built as *Number of Mirrored Entries* entries of two bytes each containing a single VSI/VLAN, depending on the rule requested as described in Table 7-75.

Table 7-75. Add/Update Mirror Rule Command Buffer

Byte.Bit	Description
1.7	Action 0b = Remove VSI from mirror rule. 1b = Add VSI to mirror rule.
1.6-1.2	Reserved.
1.1-1.0	Mirrored VSI.

Table 7-76 describes the Add/Update Mirror rule response (with no buffer).

Table 7-76. Add/Update Mirror Rule Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0260	Command opcode.
Datalen	4-5	0x0	No return buffer.
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOENT = If the mirrored or mirroring VSI do not point to a valid VSI. ENOSPC = If there are not enough resources to assign an mirror rule. EACCES = If the *Rule ID* is not owned by this PF. EEXIST = VSI is already mirrored by another rule. ***Note:*** If an error is returned, the entire command was not executed.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Rule ID	16-17		**Byte 17:** Reserved **Bit 16.7:** Rule ID valid (always set) **Bit 16.6:** Reserved **Bits 16.5-16.0:** Rule ID Defines the *Rule ID* that is returned in the receive descriptor. This number is assigned by the firmware and should be used as a handle when requesting deletion of an existing rule. If the *Rule ID Valid* flag was set in the command, the returned *Rule ID* is the same as the requested one.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	Address of Buffer
Data Address Low	28-31	Buffer Address	

7.8.12.7.2 Delete Mirror Rule (0x0261)

This command is used to delete an existing mirror rule.

Table 7-77. Delete Mirror Rule Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0261	Command opcode.
Datalen	4-5	0x0	
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Rule ID	16-17		**Byte 17:** Reserved **Bit 16.7:** Rule ID valid (always set) **Bit 16.6:** Reserved **Bits 16.5-16.0:** Rule ID Defines the Rule ID to delete.
Reserved	18-19		Reserved.
Command Flags	20-21		**Bits 21.7-20.1:** Reserved **Bit 20.0:** Keep m Allocation If set, the VSI stays part of the PF allocated resources. Otherwise, it is returned to the shared pool.
Reserved	22-31	Buffer Address	Reserved.

Table 7-78 describes the Delete Mirror rule response (with no buffer)

Note: When a mirror rule is shared (VSIs of multiple PFs are mirrored through the same rule), this command should not be used. Instead, each PF should remove its VSIs using the Update Mirror rule command and this command should be used only by the last PF to remove the rule itself.

Table 7-78. Delete Mirror Rule Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0261	Command opcode.
Datalen	4-5	0x0	
Return Value/VFID	6-7		Return value. The following error values can be returned: EINVAL = If the Rule ID does not exist. ENOENT = If the Rule ID is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31	Buffer Address	Reserved.

7.8.12.8 Default Configuration at Init Time

On each function, a single VSI is initiated with a distinct switch ID. This VSI is set in VLAN promiscuous mode with loopback disabled and source pruning enable.

On each VSI, a single filter is added to allow reception of the default MAC Address of the port.

7.9 ACL (Ternary Classifier)

7.9.1 Overview

7.9.1.1 General

The Packet Processor pipeline in the E810 provides a programmable Ternary Classifier stage for implementing functions such as ACL (Access Control List), IP LPM (Longest Prefix Match), and so on. The Ternary Classifier is SDN/NFV-enabled, supporting a wide range of network protocols, both standard-based and proprietary. The architecture is fully programmable, protocol-agnostic and action-agnostic, capable of adapting to future protocol headers and use cases.

Since the architecture of the Ternary Classifier is protocol-agnostic and action-agnostic, it can be programmed to serve as a switch extension and thus provide packet forwarding based on programmable rules, augmenting the capabilities of the switch.

The ACL's block logical location in the E810 data-path is illustrated in Figure 7-19.

On the receive side, the ACL is located on an internal egress port of the switch. This means that it can base its decisions on the switch switching decision (destination information). The ACL block gets the packet's header as received by the switch. Any potential transposition (for example, VLAN stripping) occurs in the data path following the packet processing by the ACL block.

On the transmit side, the ACL is location on an internal ingress port of the switch. This means that the ACL block can base its decisions based on the source information. The ACL block gets packet header in its final transmitted form. Any potential transposition (for example, VLAN insertion) occurs in the data path prior to the packet processing by the ACL block.

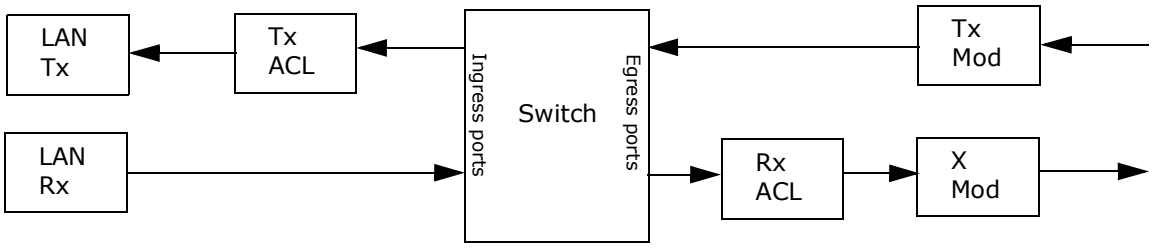

Figure 7-19. ACL Logical Location in the Data Path

7.9.1.2 Features

- Provides ACL lookup tables:
  - Table contain association between ACL entries and actions.
  - ACL match is done using up to 16 TCAM blocks.
  - Each TCAM block has 512 entries of 40 bits.
  - TCAM cascading.
- Hit result of consecutive range of TCAM block indexes can be used to create an ACL table with wider rules (multiple of 40 bits).
  - TCAM stacking.
- Multiple TCAM blocks, with consecutive index range, can be stacked to create a table with more than 512 rules (cascaded table can be stacked as well).
- 128 lookup profiles:
  - Standard FlexiPipe method of profile selection.
  - One profile is used for by pass (profile number 1).
  - Eight range checkers per profile:
    - Range checker works on a word (16-bit value).
    - Range checker apply a mask on the value and checks if it is between a start value and an end value.
  - Profile controls the extractions:
    - Extraction of a field vector (FV) built from 32 words.
    - Build of three arrays from the FV:
      - 32-byte array with also contain the Profile ID and the eight range checks result (pass/fail per each checker).
      - 32-word array.
      - 16 double word array.

      Profiles selects a scenario.
- 64 Scenario
  - Controls generation of key per TCAM block.
  - Controls mask of entries per TCAM block in 64 entries granularity (bit per 64 entries).
  - Controls TCAM block arrangement.
  - Controls action memories to TCAM block association.
- Action memories:
  - 20 action memories with 512 pair of actions each.
  - Multiple action memories CAN be associated with single TCAM block.
  - Key action types.
    - Generic MDID 0-4

    - flowID_word_0/1
    - RX_descr_structure_prof_idx
    - pkt_drop
    - Target/destination VSI
    - Destination Q
    - Count packet (MDID 56)
    - Count bytes (MDID 57)
    - Count packet and bytes (MDID 58)
    - NOP (MDID 55)
  - Counter banks:
  - Four counter banks of 512 40 bit wide counters.
  - Lookup results of a scenario can update one counter in each bank.
- Programming model
  - CSRs
  - Indirect programming access to allow multiple atomic updates.
    - TCAM entry update.
    - Action memory update.
    - Scenario configuration per TCAM block update.
    - Scenario configuration per action memory update.
    - General profile concurrent configuration update.
    - Range checkers profile concurrent configuration update.
  - Dynamic updates.
    - New profiles and scenarios can be added/removed/updated.
    - Actions can be updated/added/removed.

7.9.1.3 Basic Operation and Terms

A ternary classifier is a unique filtering mechanism able to compare a given dataset (referred hereafter as a "key") to a set (referred hereafter as a "table") of multiple entries (referred hereafter as "table entries") at the same time being able to ignore bits in the compare process. This means that a compare operation for each bit in the table entry has three match conditions:

- Match if '0'
- Match if '1'
- Match always (Don't care)

A match in a table entry is achieved only if there is a match on all of the bits of that table entry.

In case of a multiple hit to different table entries, a priority mechanism is used to determine the highest priority-matched entry. The priority mechanism implemented in the E810's ACL block, which selects the lowest hit entry's index in the table. For example, if entries 3, 7, and 11 are hit, the result is entry 3.

Employing the priority mechanism essentially means that a specific key search in a specific entry can yield multiple hits, but only a single result (referred hereafter as a "result entry").

The ternary match and priority mechanisms are implemented using a TCAM block. Multiple TCAM blocks in parallel are used to extend the functionality of a single TCAM block by:

- Extending the number of entries.
- Producing wider entries.
- Doing a match on multiple tables in parallel.

7.9.1.4 Table Configuration Options

7.9.1.4.1 General

The ACL block supports a flexible arrangement of its TCAM blocks to support tables with various key widths and entry amounts. This section depicts the various tools implemented in the ACL block that can be used to manifest tables in different sizes.

The TCAM blocks arrangement is a scenario based configuration (see Section 7.9.1.8), which means that the ACL block can support up to 64 independent TCAM block configurations.

7.9.1.4.2 Table Sizing Support

Since the TCAM blocks used in the design are 40 bits wide, supporting a table with a wider key requires cascading several TCAM blocks (see Section 7.9.1.4.2.1). Each TCAM block cascaded to the other increases the supported key width of the table by 40 bits.

Similarly, since the TCAM blocks used in the design support a total of 512 entries, supporting a table with a larger amount of entries requires stacking several TCAM blocks.

As the E810 implementation uses 16 TCAM blocks, and given the description above, the maximal supported key width for an ACL table in the E810 is 640 bits (16 cascaded TCAM blocks yielding 512 entries), and the maximal supported entry amount for an ACL table in the E810 is 8,192 (16 stacked TCAM blocks and using 40-bit entries).

7.9.1.4.2.1 TCAM Cascade

A TCAM cascade is used to support tables with a key width wider than 40 bits. The TCAM cascade mechanism operates by running several TCAM blocks lookup in parallel and returning a hit in a given entry only if the same entry was hit in all the cascaded TCAM blocks (that is, perform a logic AND operation).

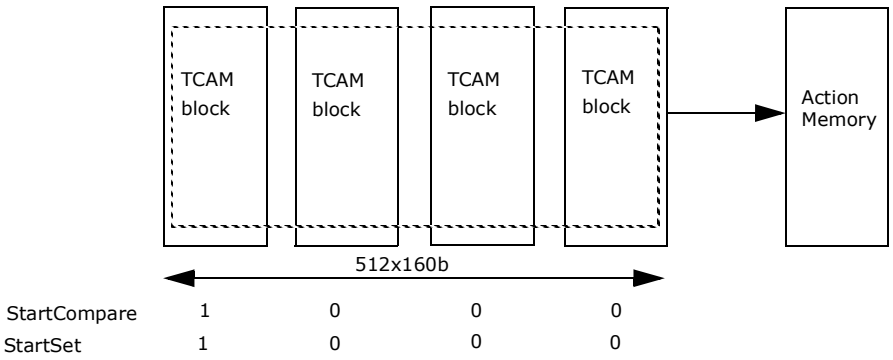

Figure 7-20. TCAM Cascading Example

The ACL block requires cascaded TCAM blocks to be adjacent (i.e., to have consecutive indexes). For example, a table supporting an 80-bit wide key can be implemented using TCAM blocks index 1 and 2, but not using TCAM block 1 and 3.

When cascaded, the hit vector, representing the hit indications for an entire TCAM, is propagated to the next TCAM. The result of that next TCAM block is the logical AND of the previous TCAM block's hit vector and its own local hit vector. That result can also be used in the next TCAM block and so forth to support wider keys.

The basic mechanism that controls TCAM cascading is that each TCAM block can either use its local hit vector or the result of a logical AND between the previous TCAM hit vector and its local hit vector. This setting is controlled by the StartCompare configuration, which is part of the scenario configuration per TCAM (see Section 7.9.2.5.1). When setting StartCompare for a given TCAM block, it uses its local hit vector. When clearing StartCompare for a given TCAM block, it uses the result of a logical AND between the previous TCAM hit vector and its local hit vector.

Given this explanation, the StartCompare setting is set for independent TCAM blocks and for the first TCAM block in a TCAM cascade.

The unified result entry is reflected in the output of the last TCAM block in the cascade. Therefore, when using a cascade, the action memories (see Section 7.9.1.5.3) are associated with the last memory in the cascade.

Figure 7-21 illustrates an example of cascading two TCAM blocks to manifest a table with an 80-bit key. Using the configuration illustrated in the figure, a hit indication in the last TCAM (TCAM *n+1* in the figure) is only possible if the same entry is hit in both the last TCAM and the previous TCAM (TCAM *n* in the figure) because the StartCompare input for TCAM *n+1* is cleared. The first TCAM, however, ignores the previous TCAM block (TCAM *n-1* in the figure) hit indications, since it's StartCompare input is set.

Note: As highlighted in the figure, the first TCAM block's (TCAM *n* in the figure) priority logic is unused. and instead, the last TCAM block's (TCAM *n+1* in the figure) priority logic output reflects the cascade hit indication and hit index. Therefore, in the case described in this example, the action memories associated with the table implemented using this cascade is associated with TCAM *n+1*.

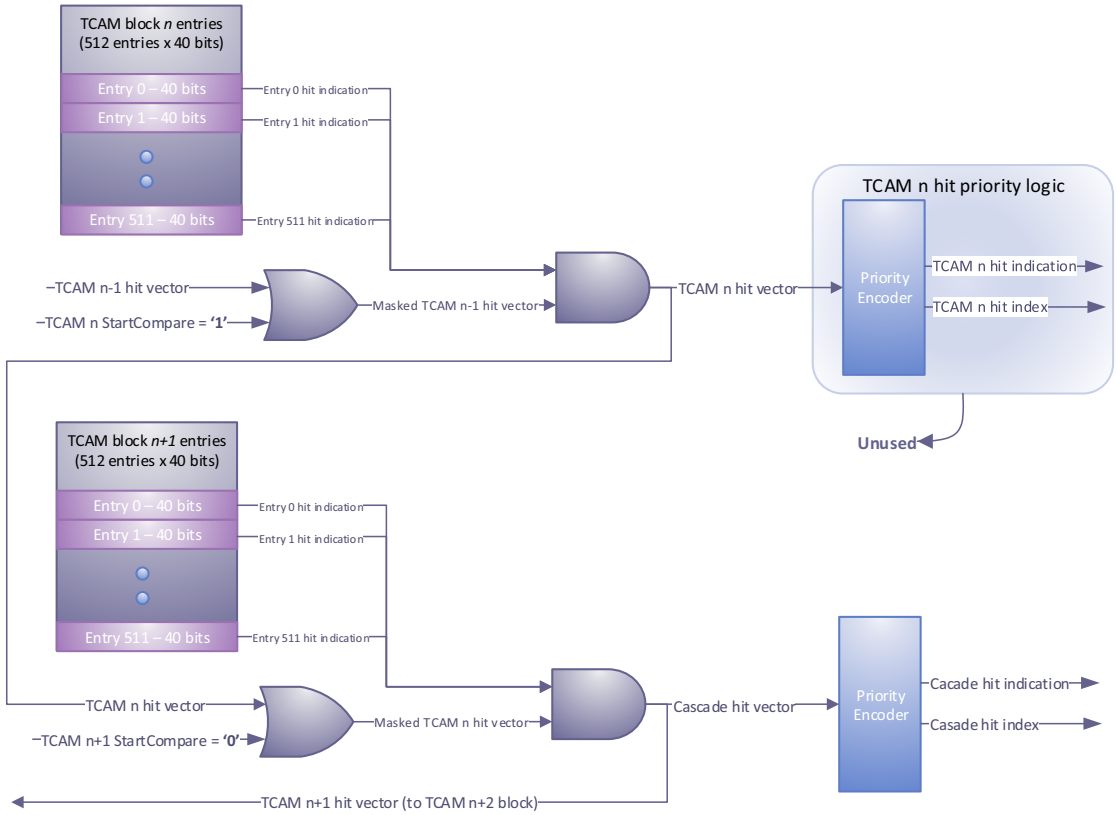

Figure 7-21. TCAM Cascade Example

7.9.1.4.2.2 TCAM Stacking

TCAM stacking is used to support tables with a key amount higher than 512. The TCAM stacking mechanism operates by running several TCAM blocks lookup in parallel and returning a unified result entry that represents the highest indexed entry hit in the highest indexed TCAM block in the stack. Figure 7-22 shows and example of two cascaded tables 1024x80b table and a 1024x40b table.

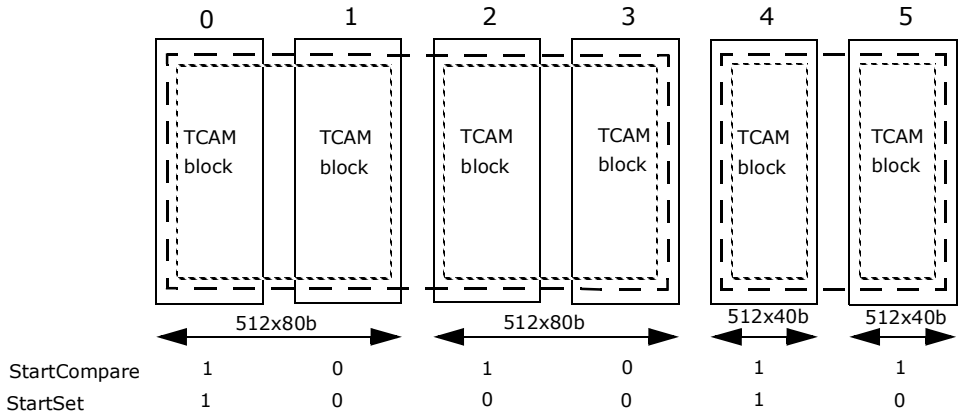

Figure 7-22. Cascaded TCAM Example

The ACL block requires stacked TCAM blocks to be adjacent one to another (that is, to have consecutive indexes). For example, a table supporting an 40-bit wide key and 1,024 entries can be implemented using TCAM blocks index 1 and 2, but not using TCAM block 1 and 3.

When stacked, the hit vector, representing the hit indications for an entire TCAM, disables the hit of the next TCAM. As such, only the first hit of the cascaded TCAM provides the result of the entire table.

Note: TCAM stacking and TCAM cascading can be used jointly to form. For example, a table with 1,024 entries and a key of 80 bits.

This setting is controlled by the StartSet configuration, which is part of the scenario configuration per TCAM (see Section 7.9.2.5.1). The action memory are associated with every TCAM that completes a table entry.

7.9.1.4.3 Concurrent Table Support

Concurrent tables are tables that are searched in parallel for the same input. An example of concurrent tables is a MAC Address table and an IPv4 Address table which can be searched concurrently for the same input. Figure 7-23 shows a concurrent TCAM example. The two tables can be searched concurrently since they occupies different TCAMs

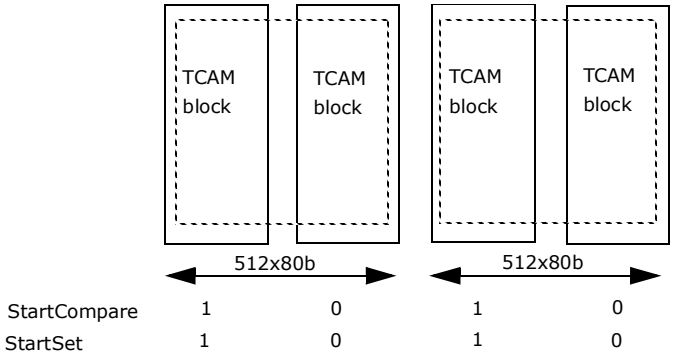

Figure 7-23. Concurrent Tables Example

The ACL block in the E810 supports multiple concurrent tables. This is done by using several TCAM blocks in parallel for implementing different tables that are searched in parallel for each input. Each table supports its own key structure configuration.

The amount of concurrent tables supported by the design is equal to the amount of TCAM blocks in the design (that is, support a case where each TCAM block is used to implement a single table).

Note: Concurrent tables usage is not related to TCAM cascading (see Section 7.9.1.4.2.1) or TCAM stacking (see Section 7.9.1.4.2.2). This means that some of the concurrent tables can use a stacked or cascaded TCAM configuration.

7.9.1.4.4 Non-Concurrent Table Support

The ACL block in the E810 supports multiple non-concurrent tables (or, tables that are not working concurrently). An example of non-concurrent tables is an inner IPv6 Address table and an inner IPv4 Address table that are naturally never searched concurrently. Figure 7-24 shows an example of non-concurrent tables. Because the two tables consume the same TCAM block they cannot be searched concurrently. In fact they are going to be define in a different scenarios.

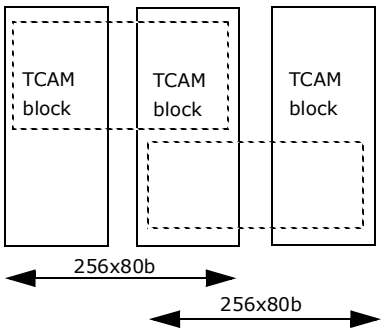

Figure 7-24. Non-Concurrent Tables Example

Supporting multiple non-concurrent tables is used to optimize the use of TCAM blocks when tables are not using the full amount of entries supported by a TCAM block used to implement it.

The ACL block in the E810 supports multiple non-concurrent tables by allowing the same TCAM block to store multiple tables while masking the hits in the irrelevant tables on a per-input basis. Entry masking is possible in 64-entries resolution.

Note: Though the example given above is implying using the packet type as a mean to select the relevant (or masking the irrelevant tables) per input, this feature can use other information (like the function ID) for selecting the active tables to allow different functionality (like function isolation).

7.9.1.5 Actions

7.9.1.5.1 General

If a table yielded a hit, the result entry points to a specific set of actions associated with the entry. The ACL block supports at least two actions per entry and up to 20,480 actions in total for all entries. Example actions might be: count bytes, count packets, drop, and change VSI.

The action format supported by the ACL block is the format supported by the flexible pipeline architecture and includes an action priority, action value and action metadata ID (MDID).

The ACL block supports up to 8 actions per a single output.

7.9.1.5.2 Aggregation and Prioritization

As mentioned in Section 7.9.1.3, the ACL block supports multiple concurrent tables working simultaneously. Potential multiple tables hit results in multiple actions being aggregated to a single set of actions.

A single set of ACL actions may include only a single action per action type (or, metadata ID). When two or more table hits result in the same action type, a priority mechanism uses the action priority, which is part of the action definition associated with each action, to determine which is used in the output. When two or more table hits result in the same action type with the same priority, the action from the highest index action memory is used in the output.

Note: Any combination of table hit that results in an action set of more that eight unique actions, corresponding to the ACL block limit mentioned in Section 7.9.1.5.1, is considered as an invalid programming and might result in unexpected behavior.

Similar to the aggregation and prioritization mechanism in the ACL block, the ACL block's actions are aggregated with and prioritized against the pipeline's actions. When a result action in the ACL block has the same type of a pipeline action, the highest priority action prevails. When two priorities of the same action type are equal, the ACL action prevails unless the priority is set to 0.

7.9.1.5.3 Action Memories

The actions are stored in arrays referred to as action memories. The ACL block in the E810 includes 20 action memories, where each memory has 512 entries containing up to two actions per entry.

Any action memory can be associated with any of the TCAM blocks so that a hit in a specific entry of the TCAM block points to the same entry in the associated action memory. This allows the action memories to support flexible table sizing as mentioned in Section 7.9.1.4.2. Several action memories can also be associated with the same TCAM block, allowing the support for more than two actions per table hit.

Figure 7-25 shows and example of action memory-to-TCAM block association. A single action memory can be associated with only on TCAM block per scenario.

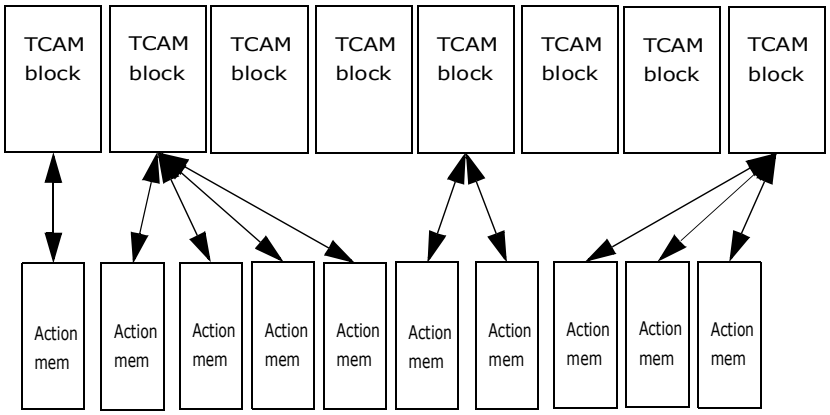

Figure 7-25. Action Memory-to-TCAM Association Example

7.9.1.5.4 Default Action

There are three special cases that involve associating an action with an incoming command when there is no valid action as a result of the ACL operation:

- Profile miss — An incoming command that did not select any profile (see Section 7.9.2.2) and was thus associated with by pass profile.
- Tables miss — An incoming command that did not match any entry in the ACL (that is, missed all tables it searched through).

3. Table hit without any valid action.

When any of these cases occurs, the output actions is defined by the default action mechanism. The default action mechanism allows associating each VSI with four independent default action sets. An independent action set can be selected for profile miss and table miss and for Rx and Tx traffic (see Section 7.9.2.8).

Each default action set contains up to four predefined actions. An example for a default action set might be: drop the packet, count packets, and set a special tag that is reflected in the Rx-Descriptor for software.

Note: It is not expected that there are two actions in the default set with the same MDID and different priority. However, if this happens, only one of them is selected, disregarding the other.

Note: A hit where all the action associated with it has priority 0 results the invocation of the default actions. To avoid that, the NOP action with non-0 priority value is used. Then, the hit causes no action.

7.9.1.5.5 VSI Reassignment

One of the actions supported by the ACL block is to change the destination VSI (applicable only for Rx packets). When this action is selected and based on its priority compared to previous set VSI actions, it causes the destination VSI associated with the packet to change.

When a VSI change occurs, the ACL block also updates the function context based on the new VSI value, according to the value in the applicable VSI_VSI2F CSR.

The following cases causes the ACL block to mark the packet to be dropped following a VSI reassignment:

- The newly assigned VSI is disabled (i.e., VSI_VSI2F[VSI].*ENABLE* is clear).
- The packet was an encrypted packet that went through in-line decryption. The newly assigned VSI is different than the original VSI, and GL_SWT_FUNCFILT.*FUNCFILT* is asserted.

7.9.1.6 Counters

7.9.1.6.1 General

The count action is a fundamental feature of the ACL block. One or more count actions can either be associated with an entry hit by programming it to the relevant entry in the action memory (see Section 7.9.1.5.3), or be associated with a default action for a table/profile miss (see Section 7.9.1.5.4).

Note: Counters are an action associated with an entry(ies). Therefore, counters are agnostic to the traffic type or properties, and can count, for example, Tx/Rx traffic in the same counter.

Note: In case VSI reassignment has occurred, the VSI used for checking the enablement for counting is the "new VSI" as defined in Section 7.9.1.5.5.

7.9.1.6.2 Counting Drops

Count actions might be part of an action set that includes a drop command (that is, one or more tables hit resulted in both count and drop actions).

Note: Counter always counts. This allows the ability to count the number of dropped packets.

7.9.1.6.3 Counter Banks

The ACL block in the E810 supports 2048, 40-bit wide, counters arranged in four banks/arrays, and is able to support up to four counter updates for the same search.

Each counter bank/array contains 512 counters according to the following distribution:

- Bank 0 contains counter indexes 0-511.
- Bank 1 contains counter indexes 512-1023.

- Bank 2 contains counter indexes 1024-1535.
- Bank 3 contains counter indexes 1536-2047.

Note: The update of more than a single counter in the same bank is forbidden and can yield unexpected behavior.

7.9.1.6.4 Counters Read and Reset

The ACL counters are accessible via the following CSRs, where "bank offset" is the offset of the counter withing the bank:

- Bank 0 counters are accessible via GLSTAT_ACL_CNT_0_L/H[bank offset].
- Bank 1 counters are accessible via GLSTAT_ACL_CNT_1_L/H[bank offset].
- Bank 2 counters are accessible via GLSTAT_ACL_CNT_2_L/H[bank offset].
- Bank 3 counters are accessible via GLSTAT_ACL_CNT_3_L/H[bank offset].

Since the counters are wider than a single 32-bit CSR access, the ACL block counters supports a 64-bit CSR access. A 64-bit access causes the hardware to latch the entire value of the counter and allows reading it using 2two consecutive 32-bit transactions without needing to check for wrap-around terms.

The counters are also accessible for write transaction. Any write transaction to a counter causes its value to be reset.

7.9.1.6.5 Supported Count Actions

The ACL block supports three different action commands/MDIDs (see Section 7.9.1.5.1) for manipulating counters:

- **Count packets (MDID 56)** — When this action is used, the counter referenced by the action's value field is incremented by one. The counter ID used in this command can be in the full range of counter indexes (0-2047) under the restriction on updates in the same bank (see Section 7.9.1.6.3).
- **Count bytes (MDID 57)** — When this action is used, the counter referenced by the action's value field is incremented by the amount of bytes contained in the packet (the packet length). The counter ID used in this command can be in the full range of counter indexes (0-2047) under the restriction on updates in the same bank (see Section 7.9.1.6.3).
- **Count packets and bytes (MDID 58)** — When this action is used, the action's value field references a counter dual and updates two counters in two separate banks. The counter referenced in the action's value field is incremented by the one (that is, serves as a packet counter), while the counter indexed (index in the command +1024) is incremented by the amount of bytes contained in the packet (in other words, serves as a byte counter). The counter ID used in this command can be in half the range of counter indexes (0-1023) under the restriction on updates in the same bank (see Section 7.9.1.6.3).

Given that the ACL block only allows a single action of each type (see Section 7.9.1.5.2) and the restriction on same bank counter updates (see Section 7.9.1.6.3), the amount of valid combinations of counter manipulation actions for a single search is limited and is summarized in Table 7-79.

Table 7-79. Counter Actions Possible Combinations

Counter Updates	Bank 0 (Index 0-511)	Bank 1 (Index 512-1023)	Bank 2 (Index 1023-1535)	Bank 3 (Index 1536-2047)
0	None	None	None	None
1	Count bytes or packets	None	None	None
1	None	Count bytes or packets	None	None
1	None	None	Count bytes or packets	None
1	None	None	None	Count bytes or packets
2	Count bytes	Count packets	None	None
2	Count packets	Count bytes	None	None
2	Count bytes	None	Count packets	None
2	Count packets	None	Count bytes	None
2	Count bytes	None	None	Count packets
2	Count packets	None	None	Count bytes
2	None	Count bytes	Count packets	None
2	None	Count packets	Count bytes	None
2	None	Count bytes	None	Count packets
2	None	Count packets	None	Count bytes
2	None	None	Count bytes	Count packets
2	None	None	Count packets	Count bytes
2	Count bytes and packets	None	None	None
2	None	Count bytes and packets	None	None
3	Count bytes and packets	Count bytes or packets	None	None
3	Count bytes or packets	Count bytes and packets	None	None
3	Count bytes and packets	None	None	Count bytes or packets
3	None	Count bytes and packets	Count bytes or packets	None
4	Count bytes and packets	Count bytes	None	Count packets
4	Count bytes and packets	Count packets	None	Count bytes
4	Count bytes	Count bytes and packets	Count packets	None
4	Count packets	Count bytes and packets	Count bytes	None

Note: When an action set contains two actions of the same type (for example, two “count bytes” actions), the hardware uses the priority mechanism to prioritize and yields a single action of each type, thus such programming is allowed (see Section 7.9.1.5.2). However, the hardware does not implement a mechanism to resolve multiple counter updates in the same counter bank.

7.9.1.7 Key Selection

7.9.1.7.1 General

The key used for each input depends on multiple factors including the packet type, the function, and the matched fields. It is therefore done in three separate levels:

1. Global level, selection base creation (see Section 7.9.1.7.2).
2. TCAM block level selection (see Section 7.9.1.7.3).

Each level is controlled by a different configuration. The three-level approach allows both flexible usage and optimized utilization of the TCAM blocks which are a relatively limited resource.

7.9.1.7.2 Selection Base

Figure 7-26 shows the generation of the selection base.

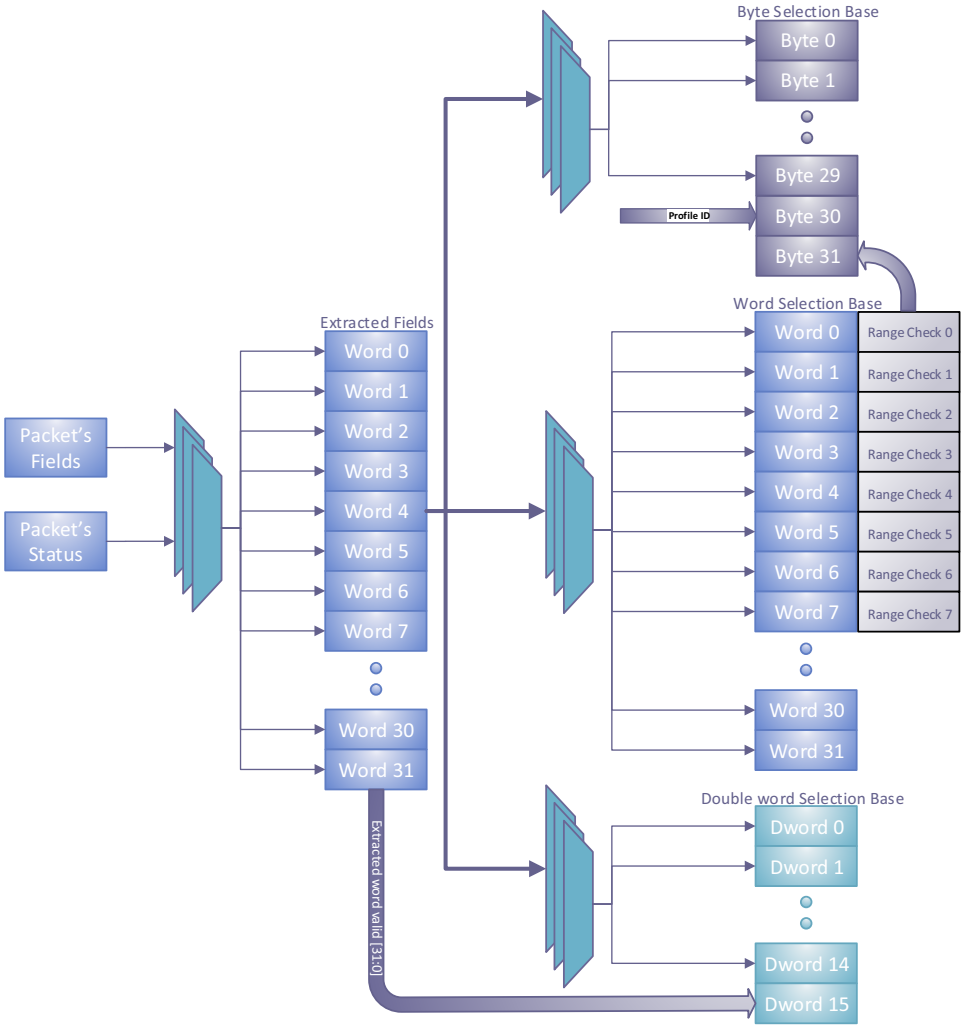

Figure 7-26. Selection Base Generation

7.9.1.7.2.1 Selection Base Vectors

The creation of the selection base involves the selection of the packet's properties and header fields that are available for all the TCAM blocks.

This stage is implemented using two sub-stages:

1. The extractor creates an extracted fields vector containing up to 32 words from the packet's header fields and status.
2. The key generation block selects fields from the extracted fields vector and generates the selection base.

Both extractor and key generation block configuration source is associated with a profile (see Section 7.9.2.2).

The selection base is comprised of the selection base vectors accumulating to 160 bytes (see Figure 7-26):

1. **Byte selection base** — A 32-byte vector containing byte-sized fields (32 fields supported). Selection of bytes from this vector for a match is done in byte resolution.
2. **Word selection base** — A 64-byte vector containing word-sized fields (32 fields supported). Selection of bytes from this vector for a match is done in word resolution.
3. **Double-word selection base** — A 64-byte vector containing double-word-sized fields (16 fields supported). Selection of bytes from this vector for a match is done in double-word resolution.

7.9.1.7.2.2 Range Checkers

A range checker is a mechanism that allows checking if a specific field, representing a natural number, is within range of two given natural numbers (that is, defining the boundaries).

The range checker output is positive if the field associated with it is within range (is higher than or equal to the low boundary and is lower than or equal to the high boundary), and is negative if it is out of the given range (is lower than the low boundary or is higher than the high boundary).

The ACL block in the E810 supports eight word-sized range checkers working concurrently. Each of the eight range checkers is associated with a specific word in the word selection base (see Figure 7-26). Also, each of the words mapped to a range checker includes a bit-level masking mechanism, which allows checking ranges for a sub-field in each word.

Note: Masking of words mapped to the range checkers is done between the word in the word selection base and the associated range checker, and is employed only for range checking purposes. This means that if a table selects one of these words as part of its key, it gets the unmasked version of the word.

The range checkers output is mapped to the byte selection base (see Section 7.9.1.7.2) and can be used for matching.

The range checkers boundaries are a profile dependent configuration (see Section 7.9.2.6), and thus the ACL block can virtually support 1,024 range checkers (eight range checkers per profile).

Note: Logical combination of several checkers for forming a single match is possible. For example, by requiring several range checkers positive/negative output in the relevant table entry a logical AND can be created between range checkers.

7.9.1.7.2.3 Fixed Fields and Restrictions

The selection of fields to each selection base vector is part of the profile specific programming (see Section 7.9.2.2) and is (in general) flexible, meaning that any field can be selected to any location in the selection base. There are, however, several fixed fields located in the selection base, which impose restrictions that apply for selection of fields to the selection base.

Byte selection base fixed fields:

- Byte index 31 contains the range checkers output (see Section 7.9.1.7.2.2). Each bit index *n* in this byte corresponds to a range checker index *n* output.
- Byte index 30 contains the selected Profile ID.

Word selection base restrictions:

- Word indexes 0-7 are the only words that can be used for range check (see Section 7.9.1.7.2.2). Each word index *n* is associated with range checker index *n* input.

Note: It is emphasized that the restriction mentioned above, only relates to the ability of selecting a source for the range checkers. This does not impose any restriction on the ability of selecting a word from the extracted fields to these words in the word selection base.

Double-word selection base fixed fields:

- Double-word index 15 contains the extracted fields vector valid indication per word (a total of 32 valid indication bits). Each word *n* of the extracted fields vector valid indication is associated with bit *n* in double-word 15.

7.9.1.7.3 TCAM Key Byte Selection

The TCAM key byte selection occur in each TCAM level. As mentioned in Section 7.9.1.4.2, the ACL block in the E810 includes 16 TCAM blocks, each supporting a 40-bit wide key. Each TCAM block supports selecting each of the five bytes of the key used for a match out of the three fields vectors constituting the selection base (see Section 7.9.1.7.2).

The configuration of the TCAM byte selection is associated with a scenario (see Section 7.9.1.8) and depends on the structure of the selection base, the tables being used (that is, the fields being matched) and the specific table configuration used to implement the tables (see Section 7.9.1.4). The same factors are taken into account when programming the contents of each TCAM block.

The TCAM byte selection available options are defined in Table 7-80, where each byte is selected independently.

Table 7-80. TCAM Byte Selection Options

Byte Index	Bit Indexes	Byte Fields	Word Fields	Double Word Fields
4	[39:32]	Any byte (32 options)	Not available	Not available
3	[31:24]	Any byte (32 options)	Bits 15:8 of any word (32 options)	Bits 31:24 of any double word (16 options)
2	[23:16]	Any byte (32 options)	Bits 7:0 of any word (32 options)	Bits 23:16 of any double word (16 options)
1	[15: 8]	Any byte (32 options)	Bits 15:8 of any word (32 options)	Bits 15:8 of any double word (16 options)
0	[7: 0]	Any byte (32 options)	Bits 7:0 of any word (32 options)	Bits 7:0 of any double word (16 options)

7.9.1.8 The Scenario Mechanism

A scenario is a set of configuration including:

- TCAM blocks configuration (cascading or stacking) for supporting flexible table sizing (see Section 7.9.1.4.2).
- TCAM blocks enablement for supporting concurrent table support (see Section 7.9.1.4.3).
- TCAM blocks specific entries enablement for supporting non-concurrent table support (see Section 7.9.1.4.4).
- Key selection configuration for each TCAM block (see Section 7.9.1.7.3).
- Association of action memories to TCAM blocks and enablement of each action memory (see Section 7.9.1.5.3).

The ACL block in the E810 supports 64 independent scenario sets. The selection of which scenario set to use for a given input is based on the profile selected (see Section 7.9.2.6) and the PF.

7.9.2 ACL Programming

7.9.2.1 General

This section depicts the relevant flows and methods for programming the ACL block.

7.9.2.2 Configuration Sources

There are three types of configuration origins in the ACL block (see Figure 7-27):

- **Global Configuration** — A block-wide configuration that is not dependent on the incoming command.
- **Profile-Based Configuration** — Settings are loaded according to the selected Profile ID. Each of these settings has a unique value for each Profile ID.
- **Scenario-Based Configuration** — Settings are loaded according to the selected scenario. Each of these settings has a unique value for each scenario.

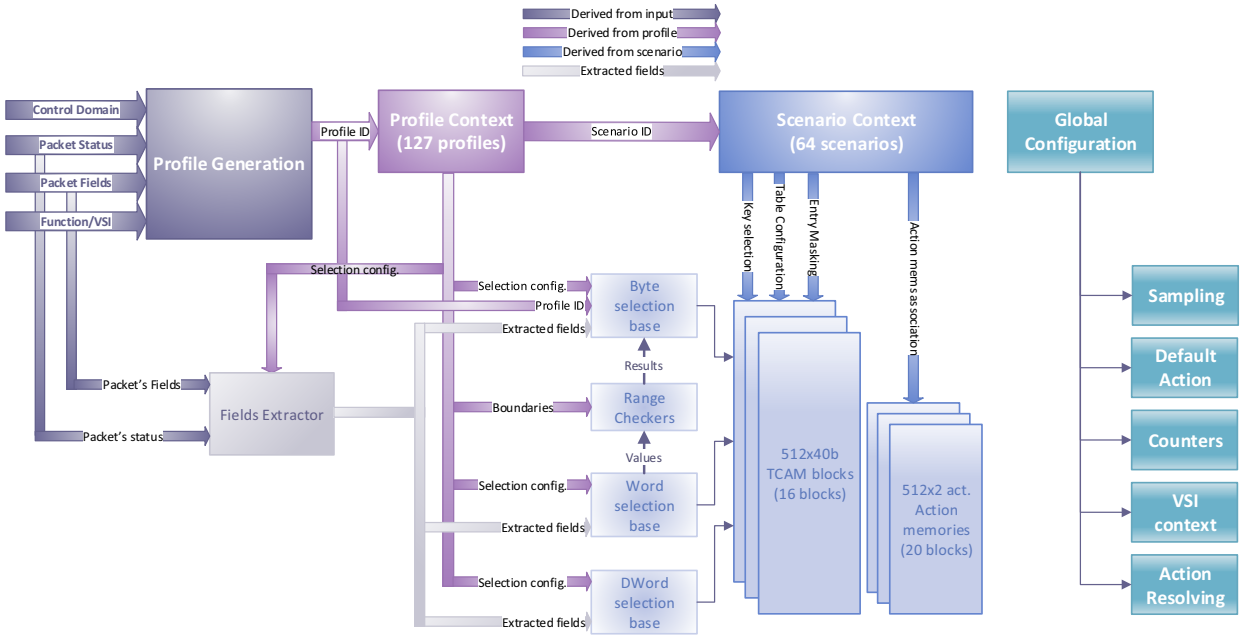

Figure 7-27. Configuration Sources[1]

1. Number of profiles is 127 to signify that one profile is the bypass one.

7.9.2.3 TCAM Entry Configuration

As described in Section 7.9.1.4, a TCAM block is 40 bits wide and can be used to implement a table or part of a table. No matter which of part of the table the TCAM block is implementing, its entry is configured using the same basic principals.

The programming of the TCAM blocks' entries is done using the indirect access mechanism. Each TCAM block entry programming is comprised of writing two values:

- **The key** — A 40-bit wide value that is matched against an incoming key/key part. This value is programmed using the GL_ACL_TCAM_KEY_L/H CSRs.
- **The key invert** - A 40-bit wide 1's compliment value of the key used to define a "don't care" or a mask operation (see Section 7.9.1.3). This value is programmed using the GL_ACL_TCAM_KEY_INV_L/H CSRs.

The functionality per entry bit derived from the different combinations of key and key invert programming is explained in Table 7-81.

Table 7-81. Key and Key Invert Programming Effect

Key Value	Key Invert Value	Functionality
1	1	Don't care (bit always matches)
1	0	Entry bit holds a '0' value.
0	1	Entry bit holds a '1' value.
0	0	Bit never matches (invalidate entry)

7.9.2.4 Action Memory Entry Configuration

As described in Section 7.9.1.5.3, the ACL block includes 20 action memories, each containing 512 entries of two actions.

The programming of action memories entries is done using the indirect access mechanism. The two actions associated with each entry is programmed using the GL_ACL_ACTMEM_CFG array.

- The GL_ACL_ACTMEM_CFG[action index].*PRIORITY* field is programmed with the action's priority to be used for the action prioritization mechanism (see Section 7.9.1.5.2).
- The GL_ACL_ACTMEM_CFG[action index].*MDID* field is programmed with the action's metadata identifier.
- The GL_ACL_ACTMEM_CFG[action index].*VALUE* field is programmed with the action's value (the meaning of the value depends on the action type).

7.9.2.5 Scenario-Dependent Configuration

As described in Section 7.9.1.8, the ACL block supports a total of 64 scenarios.

The programming of the scenario dependent configuration is done using the indirect access mechanism.

The configuration associated with each scenario is divided to two configuration sets (see Figure 7-28):

- Scenario Configuration per TCAM block (see Section 7.9.2.5.1).
- Action memories association to TCAM blocks (see Section 7.9.2.5.2).

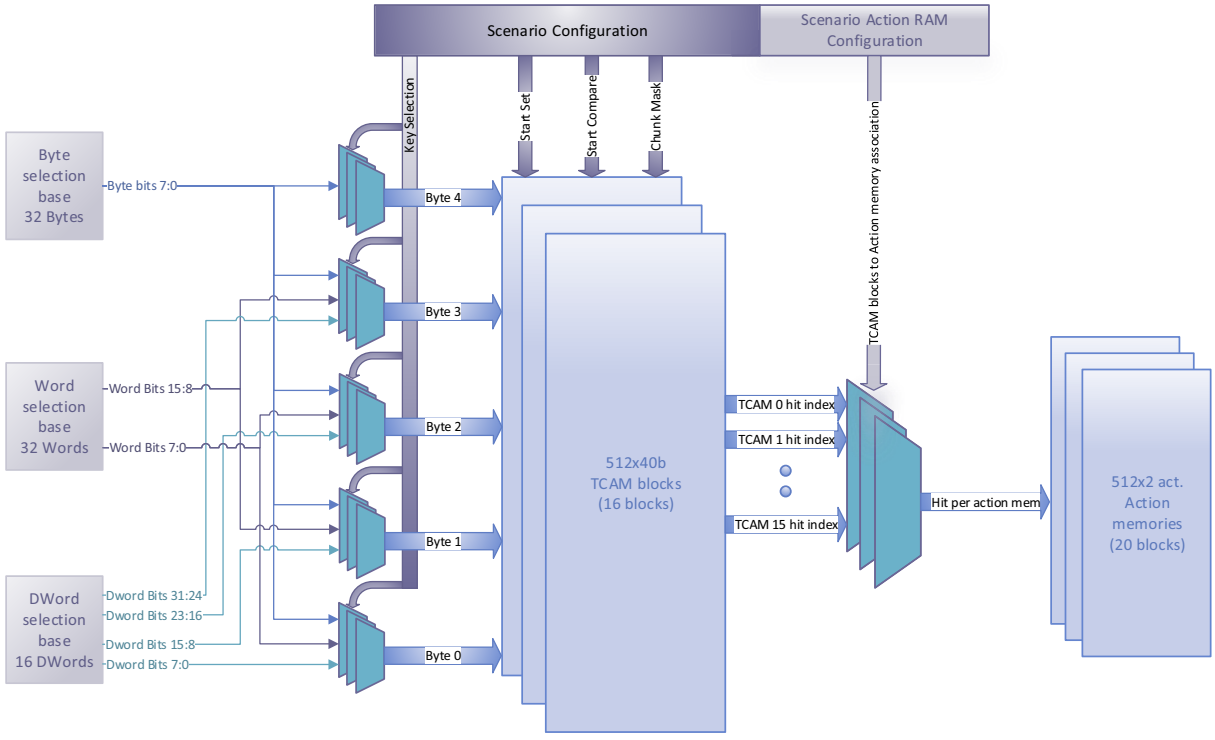

Figure 7-28. Scenario-Dependent Configuration

7.9.2.5.1 Scenario Configuration per TCAM

Scenario Configuration per TCAM block includes:

- Key selection for each of the 5-byte key for each TCAM (see Section 7.9.1.7.3):
  - Byte 0 selection is programmed in GL_ACL_SCENARIO_CFG_L[TCAM index].*SELECT0*.
  - Byte 1 selection is programmed in GL_ACL_SCENARIO_CFG_L[TCAM index].*SELECT1*.
  - Byte 2 selection is programmed in GL_ACL_SCENARIO_CFG_L[TCAM index].*SELECT2*.
  - Byte 3 selection is programmed in GL_ACL_SCENARIO_CFG_L[TCAM index].*SELECT3*.
  - Byte 4 selection is programmed in GL_ACL_SCENARIO_CFG_H[TCAM index].*SELECT4*.
  - See CSR fields description for more information about the selection value.

  Note: Refer to Table 7-80 for the selection options.
- Entry masking in 64-entries resolution for each TCAM (see Section 7.9.1.4):
  - The masking is programmed in GL_ACL_SCENARIO_CFG_H[TCAM index].*CHUNKMASK*.
  - Each bit masks 64 entries (that is, bit 0 masks entries 0-63, bit 1 masks entries 64-127, and so on).

  Note: When an entire TCAM is masked (CHUNKMASK for a specific TCAM is set to 0x00), the TCAM block is power gated.
- TCAM blocks configuration for implementing flexible table sizes (see Section 7.9.1.4.2):
  - The StartCompare setting is programmed in GL_ACL_SCENARIO_CFG_H[TCAM index].*START_COMPARE*.
  - The StartSet setting is programmed in GL_ACL_SCENARIO_CFG_H[TCAM index].*START_SET*.

7.9.2.5.2 Action Memories-to-TCAM Association

The mapping of action memories to TCAMs is programmed using the indirect access mechanism.

Each memory can be associated to a single TCAM block, thus making it possible to support a topology in which the same TCAM block is associated with several action memories (to support more than two actions per hit) or be completely disabled (allowing it to be power-gated). When using TCAM cascade (see Section 7.9.1.4.2.1), the action memory(ies) associated with the cascade is associated with the last TCAM block in the cascade.

The TCAM block index associated with the action memory is programmed in GL_ACL_SCENARIO_ACT_CFG[action memory index].*ACTMEM_SEL*.

Action memory enable/disable status is programmed in GL_ACL_SCENARIO_ACT_CFG[action memory index].*ACTMEM_EN*.

7.9.2.6 General Profile-Dependent Configuration

Any incoming command passes through the profile selection stage as the initial stage in the ACL. The selection of the profile is similar to all blocks in the packet processing pipeline and depends on the packet's properties and associated function.

The profile selection result is the Profile ID which loads a specific profile dependent configuration which is unique per profile. The profile dependent configuration in the ACL block includes (see Figure 7-27):

- **Fields extractor selection** (see Section 7.5).
- **Byte selectionbase select** — Selection for each of the bytes in the byte selection base programmed in GL_ACL_PROFILE_BWSB_SEL[byte index].*BSB_SRC_OFF*.
- **Word selectionbase select** — Selection for each of the words in the words selection base programmed in GL_ACL_PROFILE_BWSB_SEL[word index].*WSB_SRC_OFF*.
- **Double-word selection base select** — Selection for each of the double-words in the double-words fields vector programmed in GL_ACL_PROFILE_DWSB_SEL[DWord index].*DWORD_SEL_OFF*.

Scenario selection per PF programmed in GL_ACL_PROFILE_PF_CFG[PF index].*SCEN_SEL*.
Profile-dependent configuration access is done using the indirect access mechanism.

Note: As mentioned in Section 7.9.1.5.4, profile index 0 is a special profile index reserved for input commands that are not associated with any profile and are thus not performing any search in the ACL. Attempting to program a profile dependent configuration for profile index 0 is treated by the hardware as an error.

Note: As mentioned in Section 7.9.1.7.2.3, bytes indexes 30 and 31 in the byte selection base are occupied by fixed fields and thus the value of GL_ACL_PROFILE_BWSB_SEL[30].*BSB_SRC_OFF* and GL_ACL_PROFILE_BWSB_SEL[31].*BSB_SRC_OFF* is ignored by hardware.

7.9.2.7 Range Checkers Profile-Dependent Configuration

As mentioned in Section 7.9.1.7.2.2, the range checkers configuration is a profile-dependent configuration. The range checkers profile dependent configuration in the ACL block includes (see Figure 7-27):

- Range checkers boundaries for each of the range checkers programmed in GL_ACL_PROFILE_RC_CFG[range checker index].
- Range checkers fields mask for each of the range checkers programmed in GL_ACL_PROFILE_RCF_MASK[range checker index].

The range checkers profile dependent configuration access is done using the indirect access mechanism.

7.9.2.8 Default Action Programming

As described in Section 7.9.1.5.4, the ACL block allows each VSI to be associated with two sets of actions (out of possible four) that are used as the action set in case of a profile miss or a table miss.

The action sets are configured in the GL_ACL_DEFAULT_ACT array in which every array member defines a single action (out of possible four) in a single set (out of possible four).

- GL_ACL_DEFAULT_ACT[set index*4action index].*PRIORITY* is used to program the action's priority.
- GL_ACL_DEFAULT_ACT[set index*4+action index].*MDID* is used to program the action's Metadata ID.
- GL_ACL_DEFAULT_ACT[set index*4+action index].*VALUE* is used to program the action's value.

For an Rx input, the selection of default action set is programmed for a destination VSI (as determined by a previous block such as the switch) in VSI_ACL_DEF_SEL[VSI index].*RX_PROFILE_MISS_SEL* for profile miss, and in VSI_ACL_DEF_SEL[VSI index].*RX_TABLES_MISS_SEL* for tables miss.

For a Tx input, the selection of default action set is programmed for a source VSI in VSI_ACL_DEF_SEL[VSI index].*RX_PROFILE_MISS_SEL* for profile miss, and in VSI_ACL_DEF_SEL[VSI index].*RX_TABLES_MISS_SEL* for tables miss.

Note: If one or more of the default actions involves counter manipulation, all the rules and restrictions related to counter manipulation is followed (see Section 7.9.1.6).

7.9.2.9 VSI Count Programming

Count enablement per VSI (see Section 7.9.1.6.1) is programmed in VSI_ACL_CNT_EN[VSI].*COUNT_EN*.

Note: In case of a VSI reassignment, the VSI referred to with respect to VSI count enablement is be the new VSI.

7.9.2.10 Reset and Initialization

7.9.2.10.1 Reset Sources

The ACL block's main reset source is the device's core reset (CORER) or any higher level reset source that triggers a core reset. When CORER is asserted, the hardware clears:

- Profile association and profile dependent configuration (see Section 7.9.2.6).
- Scenario configuration per TCAM (see Section 7.9.2.5.1).
- Action memories to TCAM association (see Section 7.9.2.5.2).
- Counters (see Section 7.9.1.6).
- Default action configuration (see Section 7.9.2.8).

Hardware does not handle function resets. It is up to the firmware or software to handle these resets.

When a PF is being reset, firmware releases the resources allocated to it (see Section 7.9.3.2), which makes the resources available and guarantees that no incoming command searches the reseted PF tables. It is emphasized that the firmware is not required to invalidate the table entries contents.

Note: When a graceful PF reset occurs (that is, the software driver unloads), the software driver is expected to release its resources in a graceful manner (see Section 7.9.3.2) by issuing a command to the firmware to release all its resources (see Section 7.9.3.4.2.9).

When a VF is being reset, software (the relevant PF driver) clears (invalidate) the entries associated with the VF being reset.

7.9.2.10.2 Initialization

7.9.2.10.2.1 Initial State and Reset Values

With the exception of the default action sets (see Section 7.9.1.5.4) that are expected to be loaded by either NVM or firmware, the ACL block has no pre-configured content following a hardware reset event (see Section 7.9.2.10.1). This means that there will not be any profiles allocated or associated with any traffic type and hence no scenarios are allocated nor tables populated. All incoming traffic is expected to hit the default "no profile hit" profile (programmed in GL_ACLEXT_DFLT_L2PRFL_ACL).

The only applicable flow at this state is the default action flow related to profile miss (see Section 7.9.1.5.4). This flow is only relevant once VSIs are added to the system and thus, when adding a VSI to the system, the default action set selection for that VSI must be programmed (see Section 7.9.2.8) as part of the process.

7.9.2.10.2.2 Allocated Resources Initialization

No assumption is made on the initial content of allocated resources (see Section 7.9.3.2). Whenever a resource is allocated, the software driver that received the resource allocation completely initializes/ programs the resource.

Specifically, no assumption is made regarding the contents of the allocated table entries (see Section 7.9.3.2.1) and software is expected to invalidate all allocated entries prior to enabling the table entries in the scenario.

As mentioned in Section 7.9.2.10.2.1, when a PF reset occurs, the EMP firmware releases the relevant function's allocated resources but does not clear/invalidate the contents.

7.9.3 ACL Operation and Management

7.9.3.1 General

This section depicts the concepts and flows related to the operation and management of the ACL block.

7.9.3.2 Resource Allocation

The ACL block's resources are shared by the system's functions. To allow efficient use of the ACL block's resources, the EMP firmware is used for managing the ACL block resources allocation.

When a PF driver wishes to populate any of the resources in the list below, it requests an allocation from EMP firmware using the relevant AQ command. Similarly, when a PF driver wishes to release an allocated resource it requests the EMP firmware to deallocate the relevant resources and allow other PFs to use it.

Note: When a PF is reset, the EMP firmware releases its resources without requiring the PF to issue the relevant AQ command/s.

The ACL block resources allocated by the EMP firmware are:

- TCAM blocks and entries
- Action memories
- Profiles
- Scenarios
- Counters

7.9.3.2.1 Tables and Actions Allocation and Programming

The driver is able to request a table allocation and a set of corresponding action memory entries in the ACL block using the allocate_acl_table AQ command (see Section 7.9.3.4.2.1). The EMP firmware allocates TCAM blocks and entries according to the rules and restrictions described in Section 7.9.1.4.

When allocating a new table, the software indicates whether the table is an non-concurrent table (see Section 7.9.1.4.4), which can be allocated in any TCAM block unrelated to other allocated tables, or a concurrent table (see Section 7.9.1.4.3), and then the software can specify up to 12 previously allocated tables which cannot share a TCAM block with the new table.

The allocated tables is rounded to 64x40-bit units. For example, when the driver requests to allocate a table of 120 entries of 60 bits, it allocates a 128x80-bit table (that is, two blocks of 64 entries in two adjacent TCAM blocks).

In addition, the EMP firmware allocates action memories according to the amount of actions requested in the command. Action memories are allocated according to the guidelines described in Section 7.9.1.5.3.

Note: Action pairs can allocated and added to the allocated table in a later stage using the allocate_acl_actionpair command (see Section 7.9.3.4.2.3). The minimal allocated action pairs (a set of two actions) per table is 1.

Similarly, the driver is able to request releasing a table allocated to it using the deallocate_acl_table AQ command (see Section 7.9.3.4.2.2). Following this command, the EMP firmware is allowed to allocate the TCAM blocks and entries in addition to the action memories associated with the released table to other drivers usage.

Note: An action pair that was allocated and added to an allocated table using the allocate_acl_actionpair command (see Section 7.9.3.4.2.3) can be deallocated using the deallocate_acl_actionpair command (see Section 7.9.3.4.2.4) without deallocating the entire table resources.

Table entry programming is done using the program_acl_entry command (see Section 7.9.3.4.3.5) and querying an entry is done using the query_acl_entry command (see Section 7.9.3.4.4.4). When programming or querying a table entry, the EMP firmware follows the guidelines described in Section 7.9.2.3.

Action pairs can be programmed using the program_acl_actionpair command (see Section 7.9.3.4.3.2) and querying an action pair is done using the query_acl_actionpair command (see Section 7.9.3.4.3.5). When programming or querying an action pairs, the EMP firmware follows the guidelines described in Section 7.9.2.4.

7.9.3.2.2 Profile Allocation and ACL-Related Configuration

Profile allocation and deallocation in the ACL block is similar to the methods defined in other blocks (for example, the switch or post-switch) defined in Section 7.8.10, "Resource Allocation", and are beyond the scope of this discussion.

When a profile is requested by the driver, the EMP firmware allocates a free Profile ID and associates the profile with the requesting PF. It then allows the PF to program the general and range checkers profile-dependent configuration for the allocated Profile ID (see Section 7.9.2.6 and Section 7.9.2.7).

General profile-dependent configuration is done using the program_acl_profile_extraction command (see Section 7.9.3.4.3.3) and querying a general profile dependent configuration is done using the query_acl_profile command (see Section 7.9.3.4.4.1). When programming or querying a general profile-dependent configuration, the EMP firmware follows the guidelines described in Section 7.9.2.6.

Range checkers profile-dependent configuration is done using the program_acl_profile_ranges command (see Section 7.9.3.4.3.4) and querying a range checker profile dependent configuration is done using query_acl_profile_ranges command (see Section 7.9.3.4.4.2). When programming or querying a range checkers profile dependent configuration, the EMP firmware follows the guidelines described in Section 7.9.2.7.

7.9.3.2.3 Scenario Allocation and Programming

The driver is able to request a scenario allocation in the ACL block using the allocate_acl_scenario AQ command (see Section 7.9.3.4.2.5). When allocating a scenario, the software is able to program it with an initial programming.

The EMP firmware allocates a free scenario for the software and programs it with the initial programming requested in the command. Updating the configuration is possible using the update_acl_scenario command (see Section 7.9.3.4.3.1) and querying an allocated scenario configuration is done using the query_acl_scenario command (see Section 7.9.3.4.2.6).

When configuring/updating/querying a scenario, the EMP firmware follows the guidelines described in Section 7.9.2.5.

Similarly, the driver can request to deallocate a scenario allocated for it using the deallocate_acl_scenario command (see Section 7.9.3.4.2.6).

7.9.3.2.4 Counters Allocation

The driver is able to request an allocation of a block of counters using the allocate_acl_counters command (see Section 7.9.3.4.2.7). The counters allocated are of the same type (see more information about counter types in Section 7.9.1.6).

Similarly, the driver can request to deallocate a group of counters previously allocated for it using the deallocate_acl_counters command (see Section 7.9.3.4.2.8).

Note: The driver is not required to deallocate an entire block of counters allocated for it using the allocate_acl_command and can elect to deallocate only part of the counters allocated for it.

When allocating counters, the EMP firmware attempts to allocate a contiguous block of counters according to the driver's request. If the allocation fails, the driver might be able to allocate the same amount of counter in a non-contiguous block by invoking several allocation requests for smaller amounts of counters.

Note: The driver is responsible on maintaining the VSI related counters configuration (Section 7.9.2.9).

7.9.3.3 Software Flows

7.9.3.3.1 Initialization

As mentioned in Section 7.9.2.10.2, the ACL block default state is uninitialized. This means that even if software does not wish to use the ACL block, it has to define the default set of actions that is applied for each added VSI (see Section 7.9.1.5.4 and Section 7.9.2.8).

The configuration of the default action set used by the VSI for a profile miss and table miss is done using the Add VSI and Update VSI commands (see Table 7-41 for buffer format).

As there is no default configuration associated with the ACL block, all traffic that misses the profiles lookup, should be associated with profile 0 and be applied with the default action set associated with the VSI.

7.9.3.3.2 General Table Allocation Flow

As a prerequisite, before allocating and populating a table (and for each allocated table), software needs to determine the following items:

- Which header fields is available for lookup and range checking.
- What is the fields location in the selection base (byte/words/double words).
- The desired key structure that is used for lookup.

When the software wishes to allocate and populate a table in the ACL block, it executes the following flow:

1. Request a table allocation using the allocate_acl_table command (see Section 7.9.3.4.2.1). The table can be either concurrent or non-concurrent (see Section 7.9.3.2.1). The table width corresponds to the determined key width and the table depth corresponds to the expected amount of entries that is populated.

   Note: If the amount of action pairs associated with the table is known at this stage, software specifies it in the command. Otherwise, software specifies 1 (the minimal value) as the requested amount of action pairs to be associated with the table.

2. Initialize the resources allocated in Step 1:
   a. Invalidate all allocated TCAM entries by setting all key and key invert bits to each entry using the program_acl_entry command (see Section 7.9.3.4.3.5).
   b. Invalidate all allocated action pairs by clearing the action entries using the program_acl_actionpair command (see Section 7.9.3.4.3.2).
3. Allocate a scenario using the allocate_acl_scenario command (see Section 7.9.3.4.2.5) or alternatively, use a previously-allocated scenario and configure it to use the resources allocated in Step 1:
   a. Configure which TCAM blocks and entries are masked for this scenario.

      Note: Any TCAM block and entries that were not allocated for the driver must be masked.

   b. Configure the configuration of TCAM blocks (for example. cascaded, stacked).
   c. Configure the selection of key bytes into each of the TCAM blocks from the selection base vectors.
   d. Configure the association of action memories to TCAM blocks.
4. If no relevant profile was previously allocated, allocate a profile and configure the extracted fields vector.
5. Configure the ACL profile dependent configuration for the profile allocated/used in Step 4:
   a. Program the byte, word, and double-word selection bases composition by configuring the relevant selections.
   b. Program the scenario ID allocated in Step 3 to be associated with this profile.
6. Associate the ACL profile allocated/used in Step 4 with the relevant traffic/VSI.

   Note: At this stage, the table is allocated and a lookup is being performed for each relevant incoming packet. The software can start adding entries to the table (see Section 7.9.3.3.4) or action pairs to it (see Section 7.9.3.3.3).

7.9.3.3.3 Action Pair Allocation Flow

A prerequisite for allocating an action pair is to allocate a table using the table allocation flow (see Section 7.9.3.3.2).

When software wants to add another action pair to an existing table, it executes the following flow:

1. Request an action pair allocation using the allocate_acl_actionpair command (see Section 7.9.3.4.2.3).
2. Initialize the resources allocated in Step 1:
   a. Invalidate all allocated action pairs by clearing the action entries using the program_acl_actionpair command (see Section 7.9.3.4.3.2).
3. Update the relevant scenario using the update_acl_scenario command (see Section 7.9.3.4.3.1):
   a. Configure the association of allocated action memories to TCAM blocks.

   Note: At this stage. the action pair is allocated and is associated with the relevant tables. The software can start adding actions to it by invoking the program_acl_actionpair command (see Section 7.9.3.4.3.2).

7.9.3.3.4 Table Entries Addition Flow

A prerequisite for adding an entry to a table is to allocate a table using the table allocation flow (see Section 7.9.3.3.2).

When software wants to add an entry to a table, it executes the following flow:

1. Optionally, if used by the entry, configure the range checkers that is used in the profiles enabling this table using the program_acl_profile_ranges command (see Section 7.9.3.4.3.4).
2. Optionally, if used by the entry, allocate counter(s) for the entry using the allocate_acl_counters command (see Section 7.9.3.4.2.7).
3. Program the action pairs associated with the table (either by the action pair allocation flow or the table allocation flow) using the program_acl_actionpair command (see Section 7.9.3.4.3.4).
4. Program the entry key and key invert to the relevant entry using the program_acl_entry command (see Section 7.9.3.4.3.5) for all TCAM blocks forming the table.

   Note: At this stage, the entry is programmed in the table and any packet hitting it invokes the actions associated with it.

7.9.3.3.5 Table Entries Removal Flow

When software wants to remove an entry from a table, it executes the following flow:

1. Invalidate the relevant entry by setting all bits in the key and key invert using the program_acl_entry command (see Section 7.9.3.4.3.5) for all TCAM blocks forming the table.

   Note: At this stage, no packet hits the entry.
2. Optionally, if counter(s) were used by the entry and are no longer required, deallocate the counter(s) used by the entry using the deallocate_acl_counters command (see Section 7.9.3.4.2.8).
3. Optionally, if additional action pairs were added to the table using the allocate_acl_actionpair command (see Section 7.9.3.4.2.3) and are no longer required, deallocate the additional action pairs by using the deallocate_acl_actionpair command (see Section 7.9.3.4.2.4).

Note: At this stage, the entry is removed and all its private resources free.

7.9.3.3.6 Table Removal Flow

When software wants to remove an entire table, it executes the following flow:

1. If there are active scenarios that are enabling the table, mask the relevant TCAM entries/slices in all the scenarios that are enabling the table by using the update_acl_scenario command (see Section 7.9.3.4.3.1).

   Note: At this stage, no packet performs a lookup in the table.

2. Optionally, if counter(s) were used by the table and are no longer required, deallocate the counter(s) used by the table using the deallocate_acl_counters command (see Section 7.9.3.4.2.8).

3. Deallocate the table using the deallocate_acl_table command (see Section 7.9.3.4.2.2).

   Note: At this stage, the table is removed and all its private resources freed.

7.9.3.3.7 Scenario Removal Flow

Important: An active profile (a profile associated with active traffic) must point to a valid scenario. Therefore, the profile must be either disabled (for example, by preventing the relevant PF from selecting it), removed, or routed to a different valid scenario prior to removing the scenario.

When software wants to remove a scenario, it executes the following flow:

1. Prevent all profiles selecting the scenario from selecting the scenario by either:

   a. Preventing the PFs selecting the scenario from selecting the relevant profiles (unsubscribe the relevant VSIs from the profiles).

   b. Remove the profiles.

   c. Change the scenario pointed by the profiles to a different valid scenario by using the program_acl_profile_extraction command (see Section 7.9.3.4.3.3).

2. Deallocate the scenario by using the deallocate_acl_scenario command (see Section 7.9.3.4.2.6).

   Note: At this stage, the scenario is free.

7.9.3.4 ACL Block Admin Queue Commands

7.9.3.4.1 General

This section describes the Admin Queue commands related to the ACL operation and management. The Admin Queue operation is described in Section 9.5, and the general Admin Queue command format is described in Section 9.5.5.

The ACL block's Admin Queue commands are divided into three main groups:

- **Resource allocation commands** — These commands are used for resource allocation/ deallocation and, in some cases, initial programming or configuration of the resources.
- **Programming/update commands** — These commands are used for allocated resources programming or updating.

- **Query commands** — These commands are used for querying the allocated resources programming/status for reprogramming or debug.

The ACL block Admin Queue commands are summarized in Table 7-82.

Table 7-82. Admin Queue Commands Summary

Resource	Allocation/Deallocation	Programming	Querying
Tables	• allocate_acl_table Command (Section 7.9.3.4.2.1) • deallocate_acl_table Command (Section 7.9.3.4.2.2)	• program_acl_entry Command (Section 7.9.3.4.3.5)	• query_acl_entry Command (Section 7.9.3.4.4.4)
Actions	• allocate_acl_actionpair Command (Section 7.9.3.4.2.3) • deallocate_acl_actionpair Command (Section 7.9.3.4.2.4) ***Note:*** Action pairs are also allocated/deallocated as part of the table allocation.	• program_acl_actionpair Command (Section 7.9.3.4.3.2)	• query_acl_actionpair Command (Section 7.9.3.4.4.5)
Scenarios	• allocate_acl_scenario Command (Section 7.9.3.4.2.5) • deallocate_acl_scenario Command (Section 7.9.3.4.2.6)	• update_acl_scenario Command (Section 7.9.3.4.3.1) ***Note:*** The initial scenario configuration is done on allocation.	• query_acl_scenario Command (Section 7.9.3.4.4.3)
Profiles	• Profile allocation, Section 7.9.3.4.2.10, "Generic Allocate Resource Command" • Profile deallocation, Section 7.9.3.4.2.11, "Generic Free Resource Command"	• program_acl_profile_extraction Command (Section 7.9.3.4.3.3)	• query_acl_profile Command (Section 7.9.3.4.4.1)
Counters	• allocate_acl_counters Command (Section 7.9.3.4.2.7) • deallocate_acl_counters Command (Section 7.9.3.4.2.8)	Not applicable.	• query_acl_counter Command (Section 7.9.3.4.4.6)
Range Checkers	Allocated with the profile.	• program_acl_profile_ranges Command (Section 7.9.3.4.3.4)	• query_acl_profile_ranges Command (Section 7.9.3.4.4.2)
CDIDs and TCAM entries	See Section 7.9.3.4.2.10 and Section 7.9.3.4.2.11.	See Section 7.8.10.	See Section 7.8.10 and Section 7.9.3.4.4.7.
All except profiles CDIDs and TCAM entries	• deallocate_acl_resources Command (Section 7.9.3.4.2.9)	Not applicable.	Not applicable.

7.9.3.4.2 Resource Allocation Commands

7.9.3.4.2.1 allocate_acl_table Command (0x0C10)

The allocate_acl_table command is used by software to allocate a virtual table and its associated action entries in the ACL block.

Table 7-83. allocate_acl_table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C10	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TableWidth	16-17		Requested table width in bits. Minimum width is TCAP entry which is 40 bits.
TableDepth	18-19		Requested table depth.
Action Pairs for Entry	20		Amount of action pairs per table entry. The minimal valid value for this field is 1 (a single pair of actions).
TableType	21		Table type. This field is set to 0x0 for a non-concurrent table (see Section 7.9.1.4.4) allocation. For a concurrent table (see Section 7.9.1.4.3) allocation, this field specifies the amount of concurrent tables whose Alloc IDs are specified in the *Concurrent AllocIDs* field (up to 15 concurrent tables). Thus, the new allocated table is concurrent with the table IDs specified in Alloc IDs. ***Note:*** The EMP firmware blocks commands with an out-of-bound value in this field.
Reserved	22-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

Table 7-84 specifies the format of the indirect buffer:

Table 7-84. allocate_acl_table Buffer Format

Name	Bytes.Bits	Comments
Dependent AllocIDs	0-29	Dependent tables AllocIDs. Each word in this 15-word array specifies a dependent table Alloc ID (up to 15 Alloc IDs can be specified) according to the amount specified in the *TableType* field. All unused words are set to 0xFFFF.

The EMP firmware responds with a completion command (described in Table 7-85) containing an allocation status and, if allocation succeeded, the allocated resources IDs.

Table 7-85. Completion for allocate_acl_table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C10	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TableWidth	16-17		Requested table width.
TableDepth	18-19		Requested table depth.
Action Pairs for Entry	20		Amount of action pairs per table entry. The minimal valid value for this field is 1 (a single pair of actions).
TableType	21		Table type. This field is set to 0x0 for a non-concurrent table (see Section 7.9.1.4.4) allocation. For a concurrent table (see Section 7.9.1.4.3) allocation, this field specifies the amount of concurrent tables whose Alloc IDs are specified in the *Concurrent AllocIDs* field (up to 15 concurrent tables). Thus, the new allocated table is concurrent with the table IDs specified in Alloc IDs. ***Note:*** The EMP firmware blocks commands with an out-of-bound value in this field.
Reserved	22-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

Table 7-86 specify the format of the indirect buffer.

Table 7-86. Completion for allocate_acl_table Buffer Format

Name	Bytes.Bits	Comments
Alloc_ID	0-1	If *Alloc_ID* is below 0x1000, allocation failed due to unavailable resources. Otherwise, successful allocation, this field is used by firmware to identify the table allocation.
First_TCAM	2	Index of the first allocated TCAM block. This field is set to 0xFF for a failed allocation.
Last_TCAM	3	Index of the last allocated TCAM block. This index is set to the value of *First_TCAM* for a single TCAM block allocation. This field is set to 0xFF for a failed allocation.
First_Entry	4-5	Index of the first allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Last_Entry	6-7	Index of the last allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Action memory 0	8	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 1	9	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 2	10	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 3	11	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 4	12	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.

Table 7-86. Completion for allocate_acl_table Buffer Format [continued]

Name	Bytes.Bits	Comments
Action memory 5	13	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 6	14	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 7	15	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 8	16	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 9	17	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 10	18	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 11	19	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 12	20	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 13	21	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 14	22	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 15	23	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 16	24	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 17	25	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 18	26	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 19	27	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.

7.9.3.4.2.2 deallocate_acl_table Command (0x0C11)

The deallocate_acl_table command is used by software to release a table allocation.

Table 7-87. deallocate_acl_table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C11	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being released. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_table command for this table.
Reserved	18-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

The EMP firmware responds with a completion command (described in Table 7-88) containing a release status and, if deallocation succeeded, the deallocated resources IDs.

Table 7-88. Completion for deallocate_acl_table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C11	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being released. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_table command for this table.
Reserved	18-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

Table 7-89. Completion for deallocate_acl_table Buffer Format

Name	Bytes.Bits	Comments
Alloc_ID (result)	0-1	If *Alloc_ID* is below 0x1000, deallocation failed due to unavailable resources. Otherwise, successful deallocation.
First_TCAM	2	Index of the first released TCAM block. This field is set to 0xFF for a failed deallocation.
Last_TCAM	3	Index of the last released TCAM block. This index is set to the value of *First_TCAM* for a single TCAM block allocation. This field is set to 0xFF for a failed deallocation.
First_Entry	4-5	Index of the first deallocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed deallocation.
Last_Entry	6-7	Index of the last deallocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed deallocation.
Action memory 0	8	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 1	9	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 2	10	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 3	11	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 4	12	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 5	13	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 6	14	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 7	15	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 8	16	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 9	17	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 10	18	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 11	19	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 12	20	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 13	21	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 14	22	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 15	23	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 16	24	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 17	25	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 18	26	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 19	27	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.

7.9.3.4.2.3 allocate_acl_actionpair Command (0x0C12)

The allocate_acl_actionpair command is used by software to allocate an additional array of action pairs to an existing table allocated using the allocate_acl_table command (see Section 7.9.3.4.2.1).

Table 7-90. allocate_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C12	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being associated with the allocated action pair. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_actionpair command for that table.
Reserved	18-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

The EMP firmware responds with the allocate_acl_actionpair completion (described in Table 7-91).

Table 7-91. Completion for allocate_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C12	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being associated with the allocated action pair. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_actionpair command for that table.
Reserved	18-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

Table 7-92. Completion for allocate_acl_actionpair Structure Format

Name	Bytes.Bits	Comments
Alloc_ID (result)	0-1	If *Alloc_ID* is below 0x1000, allocation failed due to unavailable resources. Otherwise, successful allocation.
Reserved	2-3	Reserved.
First_Entry	4-5	Index of the first allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Last_Entry	6-7	Index of the last allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Action memory 0	8	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 1	9	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 2	10	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 3	11	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 4	12	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 5	13	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 6	14	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 7	15	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 8	16	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 9	17	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 10	18	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 11	19	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 12	20	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 13	21	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 14	22	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 15	23	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 16	24	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 17	25	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 18	26	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.
Action memory 19	27	Specify the order of the memory in the allocation starting from 0. If the memory is not allocated, its order is 0xFF.

7.9.3.4.2.4 deallocate_acl_actionpair Command (0x0C13)

The deallocate_acl_actionpair command is used by software to release an allocation of an action pair array associated with an existing table using the allocate_acl_actionpair command (see Section 7.9.3.4.2.3).

Note: The deallocate_acl_actionpair command cannot be used to release an action pair array allocated using the allocate_acl_table.

Table 7-93. deallocate_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C13	Command opcode.
Datalen	4-5	32	Indirect data length in bytes, with space for completion.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being associated with the allocated action pair. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_actionpair command for that table.
Reserved	18-23		Reserved.
Data Address High	24-27		Indirect data pointer high.
Data Address Low	28-31		Indirect data pointer low.

Table 7-94. deallocate_acl_actionpair Structure Format

Name	Bytes.Bits	Comments
Reserved	0-3	Reserved.
First_Entry	4-5	Index of the first allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Last_Entry	6-7	Index of the last allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Action memory 0	8	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 1	9	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 2	10	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 3	11	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 4	12	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 5	13	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 6	14	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 7	15	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.

Table 7-94. deallocate_acl_actionpair Structure Format [continued]

Name	Bytes.Bits	Comments
Action memory 8	16	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 9	17	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 10	18	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 11	19	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 12	20	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 13	21	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 14	22	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 15	23	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 16	24	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 17	25	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 18	26	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 19	27	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.

The EMP firmware responds with the deallocate_acl_actionpair completion (described in Table 7-95).

Table 7-95. Completion for deallocate_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C13	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Alloc_ID	16-17		Allocation ID of the table being associated with the allocated action pair. This is the *Alloc_ID* field supplied in the completion of the allocate_acl_actionpair command for that table.
Reserved	18-31		Reserved.

Table 7-96. Completion for deallocate_acl_actionpair Structure Format

Name	Bytes.Bits	Comments
Alloc_ID (result)	0-1	If alloc ID is below 0x1000, deallocation failed due to unavailable resources. Otherwise, successful deallocation, deallocated *Alloc_ID*.
Reserved	2-3	Reserved.
First_Entry	4-5	Index of the first allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Last_Entry	6-7	Index of the last allocated entry (in both TCAMs and action memories). This field is set to 0xFFFF for a failed allocation.
Action memory 0	8	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 1	9	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 2	10	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 3	11	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 4	12	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 5	13	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 6	14	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 7	15	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 8	16	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 9	17	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 10	18	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 11	19	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 12	20	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 13	21	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 14	22	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 15	23	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 16	24	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 17	25	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 18	26	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.
Action memory 19	27	Specify the order of the memory in the deallocation starting from 0. If the memory is not deallocated, its order is 0xFF.

7.9.3.4.2.5 allocate_acl_scenario Command (0x0C14)

The allocate_acl_scenario command is used by software to allocate a scenario in the ACL block and configure it. If software only wants to change a configuration of an existing scenario, it uses the update_acl_scenario command (see Section 7.9.3.4.3.1).

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-97. allocate_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C14	Command opcode.
Datalen	4-5	84	Usable length of additional buffer (132 bytes).
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-98.

Table 7-98. allocate_acl_scenario Buffer Format

Name	Bytes.Bits	Comments
TCAM 0 Select0	0.0-0.6	Byte 0 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT0* description for more details on applicable values.
Reserved	0.7	Reserved.
TCAM 0 Select1	1.0-1.6	Byte 1 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT1* description for more details on applicable values.
Reserved	1.7	Reserved.
TCAM 0 Select2	2.0-2.6	Byte 2 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT2* description for more details on applicable values.
Reserved	2.7	Reserved.
TCAM 0 Select3	3.0-3.6	Byte 3 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT3* description for more details on applicable values.
Reserved	3.7	Reserved.
TCAM 0 Select4	4.0-4.4	Byte 4 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_H.*SELECT4* description for more details on applicable values.
Reserved	4.5-4.7	Reserved.

Table 7-98. allocate_acl_scenario Buffer Format [continued]

Name	Bytes.Bits	Comments
TCAM 0 Chunk Mask	5	TCAM block entry masking. See GL_ACL_SCENARIO_CFG_H.*CHUNKMASK* description for more details on applicable values. This value is set to 0x0 for an unused TCAM. ***Note:*** The EMP firmware blocks attempts of a PF to enable entries/TCAM blocks which where not allocated to it using the allocate_acl_table command (see Section 7.9.3.4.2.1).
TCAM 0 StartCompare	6.0	TCAM block StartCompare setting (see Section 7.9.2.5.1 for additional details). This value is set to 0x1 for an unused TCAM.
TCAM 0 StartSet	6.1	TCAM block StartSet setting (see Section 7.9.2.5.1 for additional details). This value is set to 0x0 for an unused TCAM.
Reserved	6.2-6.7	Reserved.
TCAM 1 configuration	7-13	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 2 configuration	14-20	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 3 configuration	21-27	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 4 configuration	28-34	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 5 configuration	35-41	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 6 configuration	42-48	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 7 configuration	49-55	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 8 configuration	56-62	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 9 configuration	63-69	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 10 configuration	70-76	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 11 configuration	77-83	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 12 configuration	84-90	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 13 configuration	91-97	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 14 configuration	98-104	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 15 configuration	105-111	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
Action memory 0 TCAM association	112.0-112.6	Action memory association to a TCAM block (see Section 7.9.2.5.2 for more details) for this scenario. This field is set to 0x0 for a disabled action memory. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.

Table 7-98. allocate_acl_scenario Buffer Format [continued]

Name	Bytes.Bits	Comments
Action memory 0 enable	112.7	Action memory enable for this scenario see Section 7.9.2.5.2 for more details). ***Note:*** The EMP firmware blocks attempts of a PF to use an action memory no associated to it using the allocate_acl_table command (see Section 7.9.3.4.2.1) or the allocate_acl_actionpair command (see Section 7.9.3.4.2.3).
Action memory 1 configuration	113	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 2 configuration	114	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 3 configuration	115	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 4 configuration	116	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 5 configuration	117	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 6 configuration	118	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 7 configuration	119	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 8 configuration	120	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 9 configuration	121	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 10 configuration	122	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 11 configuration	123	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 12 configuration	124	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 13 configuration	125	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 14 configuration	126	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 15 configuration	127	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 16 configuration	128	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 17 configuration	129	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 18 configuration	130	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 19 configuration	131	Action memory configuration including the same structure defined in byte 112 for action memory 0.

The EMP firmware responds with a completion command (described in Table 7-99) containing an allocation status and, if allocation succeeded, the allocated scenario ID.

Table 7-99. Completion for allocate_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C14	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario_ID	16-17		If the value of this field is less than 0x1000, the allocation failed. Otherwise, for a successful allocation, this field holds the allocated scenario ID where the low eight bits of the ID specify the scenario index.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address copied from the command.
Data Address Low	28-31	Buffer Address	Low bits of buffer address copied from the command.

7.9.3.4.2.6 deallocate_acl_scenario Command (0x0C15)

The deallocate_acl_scenario command is used by software to release a scenario allocation.

Table 7-100. deallocate_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C15	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario_ID	16-17		Scenario ID of the scenario being released. This is the *Scenario_ID* field supplied in the completion of the allocate_acl_scenario command for this scenario.
Reserved	18-31		Reserved.

The EMP firmware responds with a completion command (described in Table 7-101) containing a release status and, if deallocation succeeded, the deallocated scenario ID.

Table 7-101. Completion for deallocate_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C15	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

7.9.3.4.2.7 allocate_acl_counters Command (0x0C16)

The allocate_acl_counters command is used by software to allocate a contiguous block of counters to be used in the actions related to its entries.

Note: After several occurrences of counter allocation and deallocation, the counters might get fragmented, which affects the ability of EMP firmware ability to allocate a large contiguous block of counters. In case software was unable to get it's initial request, it might want to repeat the allocation request with a smaller amount request.

Table 7-102. allocate_acl_counters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C16	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Counter Amount	16		Amount of contiguous counters requested. ***Note:*** The minimal valid value for this field is 1. The maximal valid value is 255. If the software requires more counters, it issues an additional allocate_acl_counters command.
Counters Type	17		0x0 = Byte or Packet counters 0x1 = Byte/Packet counter duals 0x2-0xFF = Reserved
Counter Bank	18		Requested counter bank allocation. The valid values for Byte or Packet counters are 0-3. The valid values for Byte/Packet counter duals are 0-1. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.
Reserved	19-31		Reserved.

The EMP firmware responds with a completion command (described in Table 7-103) containing an allocation status and, if allocation succeeded, the allocated counter IDs.

Table 7-103. Completion for allocate_acl_counters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C16	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Counter Amount	16		Amount of contiguous counters requested. ***Note:*** The minimal valid value for this field is 1. The maximal valid value is 255. If the software requires more counters, it issues an additional allocate_acl_counters command.
Counters Type	17		0x0 = Byte or Packet counters 0x1 = Byte/Packet counter duals 0x2-0xFF = Reserved
Counter Bank	18		Requested counter bank allocation. The valid values for Byte or Packet counters are 0-3. The valid values for Byte/Packet counter duals are 0-1. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.
Reserved	19		Reserved.
First_Counter	20-21		First allocated counter index. For unsuccessful allocation, this value is set to 0xFFFF.
Last_Counter	22-23		Last allocated counter index. For unsuccessful allocation, this value is set to 0xFFFF.
Reserved	24-31		Reserved.

7.9.3.4.2.8 deallocate_acl_counters Command (0x0C17)

The deallocate_acl_counters command is used by software to release a contiguous block of counters to be used in the actions related to its entries.

When using the deallocate_acl_counters command, software is not obligated to release a full counter block it allocated using the allocate_acl_counters command. It can choose to release all of it or a part of it. Since counters are a limited resource, software is encouraged to release counters it does not use.

Table 7-104. deallocate_acl_counters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C17	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
First_Counter	16-17		First released counter index.

Table 7-104. deallocate_acl_counters Command [continued]

Name	Byte.Bit	Value	Remarks
Last_Counter	18-19		Last released counter index.
Counters Type	20		0x0 = Byte or Packet counters 0x1 = Byte/Packet counter duals 0x2-0xFF = Reserved
Counter Bank	21		Requested counter bank allocation. The valid values for Byte or Packet counters are 0-3. The valid values for Byte/Packet counter duals are 0-1. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.
Reserved	22-31		Reserved.

The EMP firmware responds with a completion command (described in Table 7-105).

Table 7-105. Completion for deallocate_acl_counters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C17	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
First_Counter	16-17		First released counter index.
Last_Counter	18-19		Last released counter index.
Counters Type	20		0x0 = Byte or Packet counters 0x1 = Byte/Packet counter duals 0x2-0xFF = Reserved
Counter Bank	21		Requested counter bank allocation. The valid values for Byte or Packet counters are 0-3. The valid values for Byte/Packet counter duals are 0-1. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.
Reserved	22-31		Reserved.

7.9.3.4.2.9 deallocate_acl_resources Command (0x0C1A)

The deallocate_acl_resources command is used by software to release all the resources allocated for it using a single command.

Table 7-106. deallocate_acl_resources Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C1A	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

In response, the EMP firmware responds with a completion command (described in Table 7-107) containing a release status.

Table 7-107. Completion for deallocate_acl_resources Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C1A	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-31		Reserved.

7.9.3.4.2.10 Generic Allocate Resource Command

The command is fully described in Section 7.8.12.2.4, "Allocate Resource (0x0208)". This command can allocate the following resources:

- ACL profile builder CDID
- ACL profile builder TCAM table entries
- ACL profile builder Profile ID

A list of resource descriptors is supplied as a response to this admin command. For the ACL, each descriptor of two bytes specifies the number of the resource.

7.9.3.4.2.11 Generic Free Resource Command

The command is fully described in Section 7.8.12.2.5, "Free Resource (0x0209)". This command can deallocate the following resources:

- ACL profile builder CDID
- ACL profile builder TCAM table entries
- ACL profile builder Profile ID

A list of resource descriptors is supplied as a to this admin command. For the ACL, each descriptor of two bytes specifies the number of the resource.

7.9.3.4.3 Programming/Update Commands

7.9.3.4.3.1 update_acl_scenario Command (0x0C1B)

The update_acl_scenario command is used to update the context of a scenario previously allocated using the allocate_acl_scenario command (see Section 7.9.3.4.2.3).

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-108. update_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C1B	Command opcode.
Datalen	4-5	0x84	Usable length of additional buffer (132 bytes).
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario_ID	16-17		Updated scenario ID. ***Note:*** The firmware blocks attempts by software to update configuration for a scenario not allocated to it.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-109.

Table 7-109. update_acl_scenario Buffer Format

Name	Bytes.Bits	Comments
TCAM 0 Select0	0.0-0.6	Byte 0 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT0* description for more details on applicable values. This value is set to 0x0 for an unused TCAM.
Reserved	0.7	Reserved.

Table 7-109. update_acl_scenario Buffer Format [continued]

Name	Bytes.Bits	Comments
TCAM 0 Select1	1.0-1.6	Byte 1 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT1* description for more details on applicable values. This value is set to 0x0 for an unused TCAM.
Reserved	1.7	Reserved.
TCAM 0 Select2	2.0-2.6	Byte 2 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT2* description for more details on applicable values. This value is set to 0x0 for an unused TCAM.
Reserved	2.7	Reserved.
TCAM 0 Select3	3.0-3.6	Byte 3 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_L.*SELECT3* description for more details on applicable values. This value is set to 0x0 for an unused TCAM.
Reserved	3.7	Reserved.
TCAM 0 Select4	4.0-4.4	Byte 4 selection for the TCAM key. See GL_ACL_SCENARIO_CFG_H.*SELECT4* description for more details on applicable values. This value is set to 0x0 for an unused TCAM.
Reserved	4.5-4.7	Reserved.
TCAM 0 Chunk Mask	5	TCAM block entry masking. See GL_ACL_SCENARIO_CFG_H.*CHUNKMASK* description for more details on applicable values. This value is set to 0x0 for an unused TCAM. ***Note:*** The EMP firmware blocks attempts of a PF to enable entries/TCAM blocks which where not allocated to it using the allocate_acl_table command (see Section 7.9.3.4.2.1).
TCAM 0 StartCompare	6.0	TCAM block StartCompare setting (see Section 7.9.2.5.1 for additional details). This value is set to 0x1 for an unused TCAM.
TCAM 0 StartSet	6.1	TCAM block StartSet setting (see Section 7.9.2.5.1 for additional details). This value is set to 0x0 for an unused TCAM.
Reserved	6.2-6.7	Reserved.
TCAM 1 configuration	7-13	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 2 configuration	14-20	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 3 configuration	21-27	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 4 configuration	28-34	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 5 configuration	35-41	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 6 configuration	42-48	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 7 configuration	49-55	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 8 configuration	56-62	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.

Table 7-109. update_acl_scenario Buffer Format [continued]

Name	Bytes.Bits	Comments
TCAM 9 configuration	63-69	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 10 configuration	70-76	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 11 configuration	77-83	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 12 configuration	84-90	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 13 configuration	91-97	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 14 configuration	98-104	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
TCAM 15 configuration	105-111	TCAM configuration including the same structure defined in bytes 0-6 for TCAM 0.
Action memory 0 TCAM association	112.0-112.6	Action memory association to a TCAM block (see Section 7.9.2.5.2 for more details) for this scenario. This field is set to 0x0 for a disabled action memory. ***Note:*** The EMP firmware blocks attempts of a PF to program an out-of-bound value in this field.
Action memory 0 enable	112.7	Action memory enable for this scenario (see Section 7.9.2.5.2 for more details). The EMP firmware blocks attempts of a PF to use an action memory no associated to it using the allocate_acl_table command (see Section 7.9.3.4.2.1) or the allocate_acl_actionpair command (see Section 7.9.3.4.2.3).
Action memory 1 configuration	113	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 2 configuration	114	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 3 configuration	115	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 4 configuration	116	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 5 configuration	117	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 6 configuration	118	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 7 configuration	119	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 8 configuration	120	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 9 configuration	121	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 10 configuration	122	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 11 configuration	123	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 12 configuration	124	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 13 configuration	125	Action memory configuration including the same structure defined in byte 112 for action memory 0.

Table 7-109. update_acl_scenario Buffer Format [continued]

Name	Bytes.Bits	Comments
Action memory 14 configuration	126	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 15 configuration	127	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 16 configuration	128	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 17 configuration	129	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 18 configuration	130	Action memory configuration including the same structure defined in byte 112 for action memory 0.
Action memory 19 configuration	131	Action memory configuration including the same structure defined in byte 112 for action memory 0.

The EMP firmware responds with a completion command (described in Table 7-110).

Table 7-110. Completion for update_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C1B	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario_ID	16-17		If failed value smaller than 0x1000, unsuccessful update. Otherwise, successful update, this field holds the updated scenario ID.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address copied from the command.
Data Address Low	28-31	Buffer Address	Low bits of buffer address copied from the command.

7.9.3.4.3.2 program_acl_actionpair Command (0x0C1C)

The program_acl_actionpair command is used by software to program and/or update action entries.

Table 7-111. program_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C1C	Command opcode.
Datalen	4-5	0x8	Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
action_mem_index	16		Action memory index to program/update. ***Note:*** The firmware blocks attempts by software to update an action memory not allocated to it.
Reserved	17		Reserved.
action_entry_index	18-19		The entry index in the action memory to be programmed/updated. ***Note:*** The firmware blocks attempts by software to update an entry not allocated to it.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-112.

Table 7-112. program_acl_actionpair Buffer Format

Name	Bytes.Bits	Comments
Action0_Priority	0	Action priority. Applicable values are between 0 to 7.
Action0_MDID	1	Action metadata identifier. This field is set to 0x0 for a NOP action.
Action0_value	2-3	Action value.
Action1_Priority	4	Action priority. Applicable values are between 0 to 7.
Action1_MDID	5	Action metadata identifier. This field is set to 0x0 for a NOP action.
Action1_value	6-7	Action value.

The EMP firmware responds with a completion command described in Table 7-113.

Table 7-113. Completion for program_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C1C	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.

Table 7-113. Completion for program_acl_actionpair Command [continued]

Name	Byte.Bit	Value	Remarks
action_mem_index	16		Action memory index to program/update. ***Note:*** The firmware blocks attempts by software to update an action memory not allocated to it.
Reserved	17		Reserved.
action_entry_index	18-19		The entry index in the action memory to be programmed/updated. ***Note:*** The firmware blocks attempts by software to update an entry not allocated to it.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address copied from the command.
Data Address Low	28-31	Buffer Address	Low bits of buffer address copied from the command.

7.9.3.4.3.3 program_acl_profile_extraction Command (0x0C1D)

The program_acl_profile_extraction command is used by software to program or update the profile-dependent configuration (see Section 7.9.2.6) for a profile allocated to it.

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-114. program_acl_profile_extraction Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C1D	Command opcode.
Datalen	4-5	0x4C	Usable length of additional buffer (76 bytes).
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Programmed/updated Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-115.

Table 7-115. program_acl_profile_extraction Buffer Format

Name	Bytes.Bits	Comments
Byte selection base-select for byte 0	0.0-0.5	Byte selection for the byte selection base from the extracted fields (expressed as a byte offset in the extracted fields). Applicable values are 0-63.
Reserved	0.6-0.7	Reserved.
Byte selection base-select for byte 1	1	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 2	2	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 3	3	Byte selection using the same structure defined in byte 0 for byte 0.

Table 7-115. program_acl_profile_extraction Buffer Format [continued]

Name	Bytes.Bits	Comments
Byte selection base-select for byte 4	4	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 5	5	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 6	6	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 7	7	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 8	8	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 9	9	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 10	10	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 11	11	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 12	12	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 13	13	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 14	14	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 15	15	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 16	16	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 17	17	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 18	18	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 19	19	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 20	20	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 21	21	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 22	22	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 23	23	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 24	24	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 25	25	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 26	26	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 27	27	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 28	28	Byte selection using the same structure defined in byte 0 for byte 0.
Byte selection base-select for byte 29	29	Byte selection using the same structure defined in byte 0 for byte 0.
Word selection base-select for word 0	30.0-30.4	Word selection for the word selection base from the extracted fields (expressed as a word offset in the extracted fields). Applicable values are 0-31.
Reserved	30.5-30.7	Reserved.
Word selection base-select for word 1	31	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 2	32	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 3	33	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 4	34	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 5	35	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 6	36	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 7	37	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 8	38	Word selection using the same structure defined in byte 30 for word 0.

Table 7-115. program_acl_profile_extraction Buffer Format [continued]

Name	Bytes.Bits	Comments
Word selection base-select for word 9	39	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 10	40	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 11	41	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 12	42	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 13	43	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 14	44	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 15	45	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 16	46	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 17	47	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 18	48	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 19	49	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 20	50	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 21	51	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 22	52	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 23	53	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 24	54	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 25	55	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 26	56	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 27	57	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 28	58	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 29	59	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 30	60	Word selection using the same structure defined in byte 30 for word 0.
Word selection base-select for word 31	61	Word selection using the same structure defined in byte 30 for word 0.
Double word selection base-select for double-word 0	62.0-62.3	Double word selection for the double-word selection base from the extracted fields (expressed as a double-word offset in the extracted fields). Applicable values are 0-15.
Reserved	62.4-62.7	Reserved.
Double word selection base-select for double-word 1	63	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 2	64	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 3	65	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 4	66	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 5	67	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 6	68	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 7	69	Double word selection using the same structure defined in byte 60 for double-word 0.

Table 7-115. program_acl_profile_extraction Buffer Format [continued]

Name	Bytes.Bits	Comments
Double word selection base-select for double-word 8	70	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 9	71	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 10	72	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 11	73	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 12	74	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 13	75	Double word selection using the same structure defined in byte 60 for double-word 0.
Double word selection base-select for double-word 14	76	Double word selection using the same structure defined in byte 60 for double-word 0.
PF0 scenario	77	PF0 scenario number
PF1 scenario	78	PF1 scenario number
PF2 scenario	79	PF2 scenario number
PF3 scenario	80	PF3 scenario number
PF4 scenario	81	PF4 scenario number
PF5 scenario	82	PF5 scenario number
PF6 scenario	83	PF6 scenario number
PF7 scenario	84	PF7 scenario number

The EMP firmware responds with the completion command described in Table 7-116.

Table 7-116. Completion for program_acl_profile_extraction Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C1D	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Programmed/updated Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

7.9.3.4.3.4 program_acl_profile_ranges Command (0x0C1E)

The program_acl_profile_ranges command is used by software to program or update the range checkers profile dependent configuration (see Section 7.9.2.7) for a profile allocated to it.

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-117. program_acl_profile_ranges Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C1E	Command opcode.
Datalen	4-5	0x30	Usable length of additional buffer (48 bytes).
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Programmed/updated Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-118.

Table 7-118. program_acl_profile_ranges Buffer Format

Name	Bytes.Bits	Comments
Range checker 0 low boundary	0-1	Range checker low boundary. The range checker output is negative when the value related to this range checker is lower than the low boundary.
Range checker 0 high boundary	2-3	Range checker high boundary. The range checker output is negative when the value related to this range checker is higher than the high boundary.
Range checker 0 mask	4-5	Range checker bit-mask. A value of '0' in a bit clears the relevant bit input to the range checker.
Range checker 1 configuration	6-11	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 2 configuration	12-17	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 3 configuration	18-23	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 4 configuration	24-29	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 5 configuration	30-35	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 6 configuration	36-41	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.
Range checker 7 configuration	42-47	Range checker configuration using the same format specified in bytes 0-5 for range checker 0.

The EMP firmware responds with the completion command described in Table 7-119.

Table 7-119. Completion for program_acl_profile_ranges Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C1E	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Programmed/updated Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

7.9.3.4.3.5 program_acl_entry Command (0x0C20)

The program_acl_entry command is used by software to program or update an entry in a TCAM block allocated to it using the allocate_acl_table command (see Section 7.9.3.4.2.1).

Table 7-120. program_acl_entry Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C20	Command opcode.
Datalen	4-5	0x8	
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TCAM Index	16		Updated TCAM block index. ***Note:*** The firmware blocks attempts by software to update a TCAM block not allocated to it.
Reserved	17		Reserved.
Entry Index	18-19		Updated entry index. ***Note:*** The firmware blocks attempts by software to update an entry not allocated to it.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

Table 7-121. program_acl_entry Buffer Format

Name	Bytes.Bits	Comments
Entry key	0-4	Entry key (40 bits). See Section 7.9.2.3 for more details.
Reserved	5-7	Reserved.
Entry key invert	8-12	Entry key invert (40 bits). See Section 7.9.2.3 for more details.
Reserved	13-15	Reserved.

The EMP firmware responds with the completion described in Table 7-122.

Table 7-122. Completion for program_acl_entry Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C20	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TCAM Index	16		Updated TCAM block index.
Reserved	17		Reserved.
Entry Index	18-19		Updated entry index.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

7.9.3.4.4 Query Commands

7.9.3.4.4.1 query_acl_profile Command (0x0C21)

The query_acl_profile command is used by software to query a profile dependent configuration (see Section 7.9.2.6) for a profile allocated for it.

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-123. query_acl_profile Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C21	Command opcode.
Datalen	4-5	0x4C	Usable length of additional buffer (76 bytes)
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Queried Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The EMP firmware responds with a completion described in Table 7-124.

Table 7-124. Completion for query_acl_profile Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C21	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Programmed/updated Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the completion has the format described in Table 7-115.

7.9.3.4.4.2 query_acl_profile_ranges Command (0x0C22)

The query_acl_profile_ranges command is used by software to query the range checkers profile dependent configuration (see Section 7.9.2.7) for a profile allocated to it.

Due to the large data structure required for scenario configuration, the AQ command is an indirect command.

Table 7-125. query_acl_profile_ranges Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C22	Command opcode.
Datalen	4-5	0x30	Usable length of additional buffer (48 bytes)
Return Value/VFID	6-7		Return value/VF ID for command or event. Only sent by firmware or PF driver. See Section 9.5.9.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Queried Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the command has the format described in Table 7-118.

The EMP firmware responds with the completion command described in Table 7-126.

Table 7-126. Completion for query_acl_profile_ranges Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C22	Command opcode.
Datalen	4-5		Reserved.
Return Value/VFID	6-7		Return value/VF ID for command or event. Only sent by firmware or PF driver. See Section 9.5.9.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Profile ID	16		Queried Profile ID.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the completion has the format described in Table 7-118.

7.9.3.4.4.3 query_acl_scenario Command (0x0C23)

The query_acl_scenario command is used by software to query the scenario dependent configuration for a scenario associated with it.

Due to the large data structure required for scenario configuration, the AQ command is an indirect command. The buffer associated with the command has the format described in Table 7-98.

Table 7-127. query_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C23	Command opcode.
Datalen	4-5	0x0	Usable length of additional buffer (132 bytes)
Return Value/VFID	6-7		Return value/VF ID for command or event. Only sent by firmware or PF driver. See Section 9.5.9.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario ID	16-17		Updated scenario ID. ***Note:*** The firmware blocks attempts by software to query configuration for a scenario not allocated to it.
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The EMP firmware responds with a completion command (described in Table 7-128).

Table 7-128. Completion for query_acl_scenario Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C23	Command opcode.
Datalen	4-5		Reserved.
Return Value/VFID	6-7		Return value/VF ID for command or event. Only sent by firmware or PF driver. See Section 9.5.9.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Scenario ID	16-17		
Reserved	18-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address copied from the command.
Data Address Low	28-31	Buffer Address	Low bits of buffer address copied from the command.

The buffer associated with the completion has the format described in Table 7-109.

7.9.3.4.4.4 query_acl_entry Command (0x0C24)

The query_acl_entry command is used by software to query an ACL entry contents.

Table 7-129. query_acl_entry Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C24	Command opcode.
Datalen	4-5	0x0	Reserved. 8 bytes for result.
Return Value/VFID	6-7		Return value/VF ID for command or event. Only sent by firmware or PF driver. See Section 9.5.9.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TCAM Index	16		Updated TCAM block index. ***Note:*** The firmware blocks attempts by software to query a TCAM block not allocated to it.

Entry Index	18-19		Updated entry index.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the completion has the format described in Table 7-121.

7.9.3.4.4.5 query_acl_actionpair Command (0x0C25)

The query_acl_actionpair command is used by software to query an action pair allocated to it.

Table 7-131. query_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C25	Command opcode.
Datalen	4-5	0x0	Reserved. 8 bytes for result.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
action_mem_index	16		Action memory index to program/update. ***Note:*** The firmware blocks attempts by software to query an action memory not allocated to it.
Reserved	17		Reserved.
action_entry_index	18-19		The entry index in the action memory to be programmed/ updated. ***Note:*** The firmware blocks attempts by software to query an entry not allocated to it.
Reserved	20-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The EMP firmware responds with a completion described in Table 7-132.

Table 7-132. Completion for query_acl_actionpair Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C25	Command opcode.
Datalen	4-5	0x8	
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
action_mem_index	16		Action memory index to program/update.
Reserved	17-23		Reserved.
Data Address High	24-27	Buffer Address	High bits of buffer address.
Data Address Low	28-31	Buffer Address	Low bits of buffer address.

The buffer associated with the completion has the format described in Table 7-112.

7.9.3.4.4.6 query_acl_counter Command (0x0C27)

The query_acl_counter command is used by software to query the value of a counter allocated to it.

Table 7-133. query_acl_counter Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0C27	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Zeroed. Used for return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Counter Index	16-17		Queried counter index. This field is the relative counter index within the queried counter bank.
Counter Back	18		Queried counter bank.
Reserved	19-31		Reserved.

The EMP firmware responds with a completion command (described in Table 7-134).

Table 7-134. Completion for query_acl_counter Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0C27	Command opcode.
Reserved	4-5		Reserved.
Return Value	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Counter Index	16-17		Queried counter index. This field is the relative counter index within the queried counter bank.
Counter Back	18		Queried counter bank.
Counter Value/Packet Counter Value	19-23		This field holds the counter value.
Reserved	24-31		Reserved.

7.9.3.4.4.7 Generic Get Resource Allocation Command

The command is fully described in Section 7.8.12.2.3, "Get Resource Allocation (0x0204)". This command retrieve the allocation information for the following resources:

- ACL profile builder CDID
- ACL profile builder TCAM table entries
- ACL profile builder Profile ID

A list of resource descriptors is supplied as a response to this admin command. For the ACL, each descriptor of two bytes specify the number of the resource.

7.9.4 ACL Configuration Example

7.9.4.1 Requested Scenario

- Create a table with 64 entries.
- Create scenario to partition the table.
- create a key to access the flow entry (IPv4 5 topple).
- Create a flow entry to allow all packets with source IP 10.0.10.10 with a port range from 1000 to 50000.

7.9.4.2 Configuration Flow

7.9.4.2.1 Assumptions

GL_ACL_DEFAULT_ACT array is pre-programmed in such a way that:

- The first set of four actions are filled with non-valid actions so it does not do anything (set 0).
- The second set of four actions are filled with valid pkt_drop actions (MDID 0x8).

Profile section mechanism is pre-configured (using packages) in such a way that:

- PTYPE is transformed to PTG (PTYPE group) using XTL1 table.
  - The extractor is programmed to extract the relevant fields for every PTYPE.
  - For this example it is assumed that whenever IPv4 exists in the packets, the first two words extracted are the IPv4 source address, where its bytes are noted as SIP[0], SIP[1], SIP[2], and SIP[3].
- VSI is transformed to VSIG (VSI group) using XTL2 table.
  - Default VSIG of uninitialized VSI is 0, which causes the ACL to be by passed.

In this example, the profile that the VSI uses is noted as ACL_ProfileID.

Table 7-135 specify the configuration flow. For general table allocation see Section 7.9.3.3.2.

Table 7-135. ACL Example Command Table

Command	Input	Output	Comment
In add VSI command	Rx profile miss default action =1 Rx table miss default action =1 Tx profile miss default action =0 Tx table miss default action =0		This is set so that the default VSI behavior is to allow the Tx packet and to not allow Rx packet with table miss or profile miss.
Table Allocation			
allocate_acl_table command	TableWidth=40 (5 bytes) TableDepth=64 (entries) Action Pairs Per Entry=1 TableType =0	Alloc_ID First_TCAM Action memory 0 First Entry Last Entry	Allocate a single table of 64 entries of width five bytes (four bytes for the IP Address and one byte for range check results). The table spans over 1 TCAM. Last_Entry is First_Entry + 63. It is expected that First entry is 64 entries aligned.

Table 7-135. ACL Example Command Table [continued]

Command	Input	Output	Comment
Resource initialization			
For j=First_Entry to Last_Entry do program_acl_entry	TCAM index=First TCAM Entry index=j Entry key=0x0000000000 Entry key=0x0000000000		Make all entries of the table as never match.
for i=First_Entry to Last_Entry do program_acl_actionpair	action_mem_index=Action memory 0 action_entry_index=i Action0_Priority=0 Action1_Priority=0		Clear action memory making all action invalid.
Allocate ACL scenario			
allocate_acl_scenario	for i=0 to 15 {TCAM i Chunk Mask =0 TCAM i StartCompare=1 TCAM i StartSet=0} j=First_TCAM TCAM j Chunk Mask= 1 <<(First+Entry/64) TCAM j Startset=1 TCAM j Select0=0 (IPv4 SIP[0]) TCAM j Select1=1 (IPv4 SIP[1]) TCAM j Select2=2 (IPv4 SIP[2]) TCAM j Select3=3 (IPv4 SIP[3]) TCAM j Select4=31 (range check) for k=0 to 19 Action memory k enable=0 m=Action memory 0 Action memory m enable=1 Action memory m TCAM association=First_TCAM	Scenario_ID	Program everything into the scenario. Byte 31 looks at the range result byte.
Program/update selection base and scenario into profile			
query_acl_profile_extraction	Profile ID=ACL_ProfileID		It is assumed that the profile is already configured such that: Byte selection base-select for byte 0 =IPv4 SIP[0] Byte selection base-select for byte 1 =IPv4 SIP[1] for byte 2 =IPv4 SIP[2] for byte 3 =IPv4 SIP[3] So the first four bytes extract the source IP.
program_acl_profile_extraction	Profile ID=ACL_ProfileID i=PF number associated with the VSI PFi_scenario=Scenario_ID		Associate the scenario to the Profile for the PF of the VSI.
query_acl_profile_ranges	Profile ID=ACL_ProfileID	for i=0 to 7 { Range checker i low boundary Range checker i high boundary Range checker i mask}	According to the mask if the next available range is found. Available range is identified by mask==0. The next available range is noted by N.

Table 7-135. ACL Example Command Table [continued]

Command	Input	Output	Comment
program_acl_profile_ranges	Profile ID=ACL_ProfileID Range checker N low boundary=1000 Range checker N high boundary=50000 Range checker N mask=0xffff		Only for range checker N the parameters change.
upload section Command	Section Type Number=0x17 (XLT2 table for ACL)		Get current XLT2 table.
upload section Command	Number=0x17 (XLT2 table for ACL) Update the VSIG in XLT2 data buffer		Program VSIG for that VSI to use the profile.
Add rule to table (can be done while packets are being received)			
program_acl_actionpair	action_mem_index =Action memory 0 action_entry_index=First Entry Action0_Priority=0x7 Action0_MDID=55 (nop) Action1_Priority=0		The NOP allows the packet by doing no change. Because of the NOP, the default action is not applied.
program_acl_entry	TCAM index=First TCAM Entry index=First Entry m=1<<N; Entry key=~0x0A000A0A00|~m Entry key invert=0x0A000A0AFF		The four high bytes are pre-configured to identify 10.0.10.10. The least significant byte is programed to identify the bit set of the bit indicated by 1<<N.

7.10 Receive Classification Filters

7.10.1 Introduction

This section describes the receive classification filters that direct inbound packets to a processing engine or cluster out of the LAN engine and RDMA engine (also named as Protocol Engine or PE). The filters also define a specific queue or a context within the selected engine. All the filters described in this section relate to filtering within a specific VSI that is defined by the switch filters or ACL filters.

The classification filters and other header processing units in the device inspect the first 504 bytes of the received packets.

7.10.1.1 Association with a Packet Engine

The general rule is that a frame is tested to be PE type or LAN. Filtering to the PE is subject to a set of rules defined in the subsections of Section 7.10.9, "Protocol Engine (PE) Filters": APBVT L4 port table and PE Quad-hash filter (described in detail in Section 7.10.9.1).

7.10.1.2 Receive Classification Filters Priority and Usage

Received traffic goes through a set of filters that determine the destination of each received frame. The receive classification filters operate on frames received from the network as well as frames forwarded by the internal switch from a local port (VSI). If a frame is replicated by the internal switch, each replica goes independently through the filters.

The classification filters operate in the following priority ordering (illustrated in the Figure 7-29):

- The PE filters (described in Section 7.10.9.1) direct packets to the PE at strict highest priority.
- The ACL filters (described in Section 7.10.6), the L2 switch filters (described in Section 7.10.5) and the Flow Director filter (described in Section 7.10.8) compete on queue selection according to its programmed priority (any priority setting equals to 1 or higher). These filters can optionally define a region of queues (on the same priority of queue selection) that operate together with the hash filter.
- At lowest priority, the hash filter define a region of queues and the specific queue within the region (as described in Section 7.10.7).
- Packets that do not hit any of the above filters are posted to the default queue zero of the VSI.

Note: In nominal operation, the following filters are expected to be mutually exclusive. Meaning, the same packet is not expected to match more than one of them: PE Quad hash filter, L2 Switch filter that assigns a queue, and FD filter.

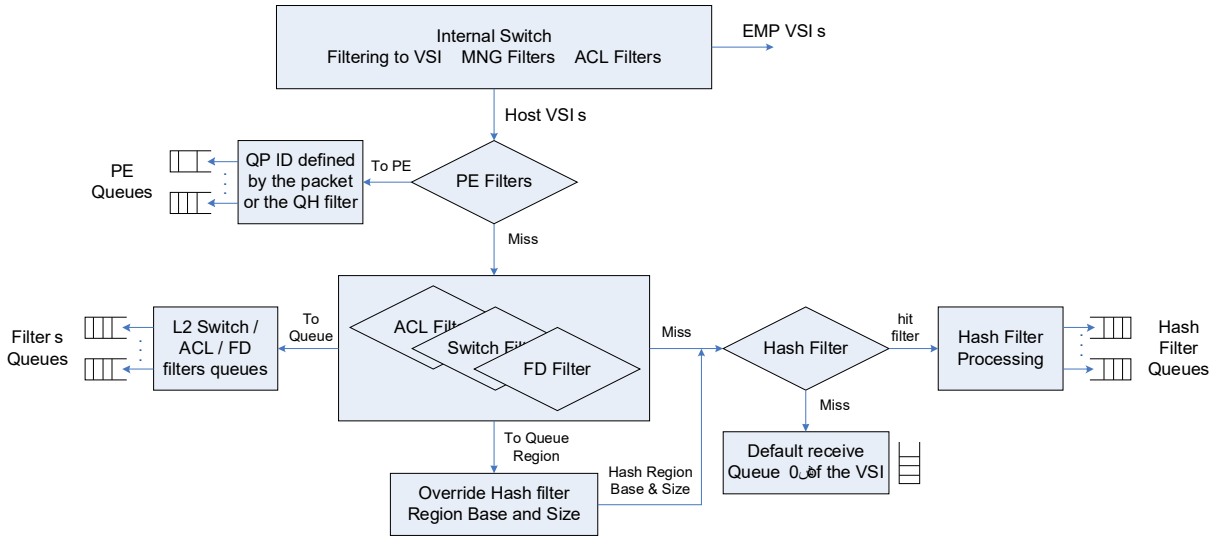

Figure 7-29. Receive Classification Filters - Top Level

Table 7-136 below shows typical use cases of the classification filters and its programming option per function.

Table 7-136. Classification Filters per PF/VF

VSI	L2 Switch Filters	ACL Filters	PE Quad Hash	Flow Director	Hash
Main Usage	VMDq1 / Control Ports / L2 Protocols	Policer	RDMA	Flex Filters[1]	Load Balance
Programming exposed to the PF	Yes	Yes	Yes[2]	Yes	Yes[3]
Programming exposed to the VF	No	No	Yes[2]	Yes[1]	No[3]

1. There are two main usages for Flow Director filters: Software driver controlled filters for Automatic Target Routing (ATR), and user/OS controlled filters. FD programming is exposed to VSIs of the PFs and the VFs as enabled by the parent PF.
2. The hardware supports RDMA offload for all PFs and up to 32 VFs (enabled by its parent PFs). Software should enable the filter only to VSIs of the PFs and the enabled VFs. Note that the software enables the VSIs, while the PE programs the specific filters.
3. Hash filters are allocated per VSI for the PFs and the VFs. Programming is enabled by the hardware for both PFs and VFs, but as a product it is exposed by the driver only for the PFs.

Table 7-137 shows the filters actions enabled per-filter type:

Table 7-137. Filter Actions by Filter Type

Action	L2 Switch Filters and ACLs	ACL Filters	PE Quad Hash	Flow Director
Target Engine: LAN, PE	LAN	PE	LAN	LAN
Receive Queue index / Context ID	Queue index within the VSI or setting a queue region for the Hash filter	QPN (QP ID)	Queue index within the VSI or setting a queue region for the Hash filter	Queue index within the region of queues within the VSI
Accept / Reject	Yes		Yes	
Increment Statistic Counter	Yes		Yes	
Flow ID	Flow ID	Report QPN (QP Index) to the PE	Report FDID in the Rx-Descriptor	Report Hash Signature in the Rx-Descriptor
Report selected bytes from the receive packet	Yes		Yes	
Flexible Actions	Yes	No	Yes	No

7.10.1.3 Resource Allocation

Some of the filter's resources can be allocated in a flexible manner between the functions, and the VSIs. allocation to the PFs are configured during run time by the Allocate Resource admin command (see Section 7.8.12.2.4).

Table 7-138 lists those parameters that are allocated using this admin command. The Flow Director table can be further allocated to VSIs by the Add VSI or Update VSI admin commands (Section 7.8.12.3.1 and Section 7.8.12.3.2, respectively).

Table 7-138. Resource ID and Types Used by the "Get Resource Allocation" Command

Resource ID	Resource Type	Allocation Type
0x20	Global RSS hash	A Global RSS LUT
0x21	Flow director Counters	Any number of counters
0x22	Guaranteed Flow director entries	Any number of filter entries
0x23	Best Effort Flow director entries	Any number of filter entries

7.10.1.4 Filter's Candidacy Rules

The Table 7-139 below list the candidacy rules for matching a filter. Complete description of the filters in the following sections.

Table 7-139. Filter's Candidacy Rules

Rule	Relevancy	Mechanism
The filter is enabled for the function	PE filters	Setting options (PFQF_PE_ENA, VPQF_PE_ENA)
The filter is enabled for the PF	FD filter	Setting options (PFQF_FD_ENA)
The filter is enabled per VSI	FD and PE filters	VSI Setting options
The filter is enabled per TC	QH filter	PF Setting options (PFQF_PE_TC_CTL)
The filter is enabled per VSI group	All filters	Packet profile selection logic

Table 7-139. Filter's Candidacy Rules [continued]

Rule	Relevancy	Mechanism
The packet's profile is enabled for the filter	All filters	Packet profile selection logic
Matched packet's VSI and packet profile	FD and QH filters	Hard -coded
Exact match of the packet's fields	FD and PE filters[1]	Matched fields are defined by the input set per packet profile.
Packet must match the APBVT	PE filters	Setting option per packet profile (GLQF_PE_CTL2)
Enable filter programming by Tx packets	FD filter	VSI Setting options
Enable filter removal by Tx FIN/RST packets	FD filter	VSI Setting option plus enabled per filter
Rx LPBK packets and Rx from the network	All filters	Both are enabled for the filters - hard-coded.

1. FD and QH filters must match complete pattern. PE filters that bypass the QH filter just match the packet profile. Hash filters that match the packet profile always pass this criteria

7.10.1.5 Filter's Candidacy Exceptions

Received packets with exception status are handled according to the rules listed below in Table 7-140.

Table 7-140. Packets Exceptions Handling[1]

Exception	Handling	Mechanism
L2 error.	Not candidate for any classification filters.	Handled by profile selection (l2_mac_error).
L3, L4 integrity error.	The packet is processed by the Hash and FD filters, but is not candidate for the PE filters.	Handled by profile selection (L3/L4 XSUM done/pass).
MPA CRC or RoCE iCRC integrity error.	Relevant only for the PE filters. Packet is posted in all cases to the PE with a hint on the CRC integrity check.	N/A
The packet includes IPv4 options or IPv6 extension headers.	Not candidate for the PE filters.	Handled by profile selection (L3/L4 XSUM not done).
The packet includes ESP extension header.	Not candidate for the PE filters.	Handled by profile selection (L3/L4 XSUM not done | pkt_is_esp). Dedicated hardware (no setting option).
The packet includes MPLS header(s).	Not candidate for the PE filters.	Handled by profile selection (outer_mpls_present_0x8847 and outer_mpls_present_0x8848).
The packet is fragmented.	Not candidate for the PE filters.	Handled by profile selection (L3/L4 XSUM not done).
Any tunneled packets.	Not candidate for the PE filters.	Handled by profile selection (L3/L4 XSUM not done).
"Drop" indication by previous units (like parser, switch, and ACL filters).	Not candidate for any classification filters.	Handled by profile selection (pkt_is_drop).
Packets indicated as DSI.	Not candidate for any classification filters.	Handled by profile selection (pkt_is_DSI).
Pre-Parser no checksum offload.	Not candidate for the PE filters.	Handled by profile selection (pprs_no_offload).
Parser Abort indication.	Not candidate for any classification filters.	Handled by profile selection (abort).
Malicious detect.	Not candidate for any classification filters.	Handled by profile selection (abort).

1. See additional candidacy criteria per filters in the following sections of the PE, Hash and FD filters

7.10.1.6 Configuration and Filter Programming Rates

Table 7-141. Performance Summary Table

Parameter	Configuration Source	Mechanism	Rate
Initial Control Domain	NVM	CSRs	Once
Profile selection parameters	NVM	CSRs	Once
Control Domain and profiles for the PE filters	NVM	CSRs	Once
Add / Remove Control Domain and profiles for the FD or RSS filters	Software via firmware	CSRs	10/Sec
PE QH Filter population	PE to hardware	Internal PE to hardware config path	Shared 0.5 M/s restriction
PE QH Filter removal	PE to hardware	Internal PE to hardware config path	
FD Filter Population	Software Application[1]	Tx packet descriptor + packet (sum of the two)	
	Software driver for ATR		
FD Filter Removal	Software[1]	Tx packet descriptor + packet	
	Auto Filter Removal by Tx or Rx traffic	Tx or Rx packet with SYN/FIN	
RSS table and Key	Software	CSR	10/sec

1. For performance considerations, FD filter population and removal by software application is expected to be made by dummy packets. Meaning, an extra 1 Mpps for population and removal.

7.10.1.7 Receive Queue Index

As indicated in the previous section, one of the filter's actions is the packet classification to LAN queues. The LAN queue indexes defined by the classification filters are within the VSI space (the VSI inherited by the switch or ACL filters). Assuming a classification filters defines a queue index 'n', then:

- VSI that is defined by the VSILAN_QTABLE (VSILAN_QBASE.*VSIQTABLE_ENA* = 1b). The queue index in the PF space equals:
  - VSILAN_QTABLE[vsi_idx, n/2].*QINDEX_0* for even 'n'
  - VSILAN_QTABLE[vsi_idx, (n-1)/2].*QINDEX_1* for odd 'n'

  Where 'n' is the VSI Queue (values in [0..15]).
- VSI that is defined by the VSILAN_QBASE (VSILAN_QBASE.*VSIQTABLE_ENA* = 0b. The queue index in the PF space equals to VSILAN_QBASE.*VSIBASE* + 'n'.
- VF queues: The mapping of the above queue indexes to relative indexes in the VF space is not a direct mapping. The mapping is defined by the queue indexes in the PF space that are programmed in the VSILAN_QTABLE and the VPLAN_QTABLE registers. For example, assuming a VF with four queues in a single VSI with the following settings:
  - VPLAN_QTABLE[0:3] = A,B,C,D (where A...D are the queue indexes in the PF space)
  - VSILAN_QTABLE[0].*QINDEX_0* = C
  - VSILAN_QTABLE[0].*QINDEX_1* = D
  - VSILAN_QTABLE[1].*QINDEX_0* = A
  - VSILAN_QTABLE[1].*QINDEX_1* = B

Then receiving a packet to queue '0' of the VSI is mapped to queue C in the PF space, which is queue index 2 in the VF space.

Note: VF queues accessed by software can be mapped as scattered queues (in the PF space) by the VPLAN_QTABLE registers or as contiguous queues (in the PF space) by the VPLAN_QBASE register.

The hash filter is a little bit more complex, as the queue index is a relative index within a specific range of queues of a VSI. See Section 7.10.7, "Hash Filter". This range of queues is also referred as "region" of queues.

Following are some exception rules for the receive queue index:

- If a frame does not match any of the classification filters below (with a queue action), the frame is directed to the default queue (queue zero of the VSI).
- The receive queue index that defines an "invalid" queue causes dropping of the packets. Such packets are counted by the GLV_RDPC counter of the VSI. The following cases are considered as "invalid" queue:
  - A VSI that is defined by VSILAN_QTABLE is limited to 16 queues (which is the size of this table). Therefore, a queue index that equals or is larger than 16 is considered "invalid".
  - The queues in a VSI that is defined by VSILAN_QTABLE are enabled by the *QINDEX_0* and *QINDEX_1* parameters. A queue index that points to a VSILAN_QTABLE entry with a value of 0x7FF is considered "invalid".
  - A VSI that is defined by VSILAN_QBASE.*VSIBASE* is limited only by the PF queue space. A queue index that exceeds the PF space is considered "invalid".

7.10.1.8 Initialization

This section lists all registers associated with the classification filters directly or indirectly and its required initialization.

Note: This section does not provide a complete description of the registers.

This description is given in the following sections as well as in the Section 13, "Programming Interface". The initialization sequence should be executed according to the following order (described in the subsections below):

1. Function Private Memory Allocation
2. Queue Allocation
3. Profiles Allocation
4. Static Classification Filters Registers
5. Dynamic Classification Filters Registers

Note: It is expected that all EMP VSIs are not enabled to any of the classification filters. Specifically the *PE_ENA* and the *FD_ENA* flags in the Add VSI commands are expected to be cleared. In addition, the EMP VSIs should be associated with VSI Groups that are not enabled for any of the classification filters.

7.10.1.8.1 Function Private Memory Allocation

The PE Quad hash filters are stored in the Function Private Memory (FPM), while part of them are fetched to the on-chip cache. The FPM allocation registers are described in Section 9.4.2, "Function Private Memory Space Configuration". These registers should be initialized per PF prior to any settings of the LAN queues and before enabling these filters.

7.10.1.8.2 Queue Allocation

LAN queues should be allocated to the functions before packets are directed to these queues. If this rule is not kept, packets directed to these queues are dropped.

PE quad hash filters, as well as TCP port filters, should be programmed before matched packets are expected. Received packets with non-matched filters are directed to the LAN queues of the function.

7.10.1.8.3 Profile Allocation

The association between packets and filters type is made through profiles. The profiles are a standard method of selecting and action based on source and type of the functions.

7.10.1.8.4 Static Classification Filters Registers

Table 7-142 describes static classification registers:

Table 7-142. Static Classification Filters Registers Initialization

CSR	Installation Comment
QH (PE) Registers	
GLQF_PEMASK_SEL	Global Classification Filter - PE Mask Select is loaded from the NVM
GLQF_PEINSET	Global Classification Filter - PE Input Set is loaded from the NVM
GLQF_PEMASK	Global Classification Filter - PE Mask is loaded from the NVM
GLQF_PE_CTL2	Global Classification Filter - PE Control 2 is loaded from the NVM
GLQF_PE_CTL	Global Classification Filter Control
GLQF_PE_OSR_STS	Global PE Classification Filter outstanding request counter
GLQF_APBVT	Global Classification Filter Accelerated Port Bit Vector
GLQF_PE_OSR_LIM	QH FLU - PCIe/FOC Outstanding Request limits
VSIQF_PE_CTL1	VSI Classification Filter - PE Control 1 (programmed by add VSI)
PFQF_PE_CTL2	PF Classification Filter - PE Control
PFQF_PE_TC_CTL	PF Classification Filter - QH TC Enable
PFQF_PE_CTL1	PF Classification Filter - PE Control
PFQF_PE_ST_CTL	PF Control register for the Statistic counter

VSIQF_HKEY	VSI Classification Filter - Hash Key: programmed by Set RSS LUT command

7.10.2 Block Diagram

A top-level block diagram of the classification filters is illustrated in Figure 7-30 and described below.

Each of the filters: FD filter, QH filter, and Hash filter has its own dedicated logic.

- **Profile Chooser** and **Field Extractor** — The building blocks of the Fields Extractor logic are similar to those ones used by the switch filters and the ACL filters. The extractor logic extracts a local Field Vector (FV) from the packet headers based on the packet profile (Profile ID) per filter. The Profile ID is a function of the packet structure (packet type and flags) that is configured per filter per VSI group and per control domain that are defined per VSI.
- **Field Vector (FV) and Input Set** — Input set is a set of fields from the packet that are used for the packet classification. The input set is taken from the FV while some of the fields might be partially masked and some of the fields might be swapped or XORed. See details in Section 7.10.4.
- **Filter Lookup** — In this stage the lookup is performed either by an exact match or hash distribution (RSS). This associates the packet with a set of actions.
- **Filter Action** and **Priority Resolver** — Filter action can be classification to engine (LAN/PE), selecting a target queue, pass/reject the packet and other actions listed in Table 7-137. The action is defined by the filter with highest priority defined by the priority resolver. The default setting of the priority resolver is illustrated in Figure 7-29.

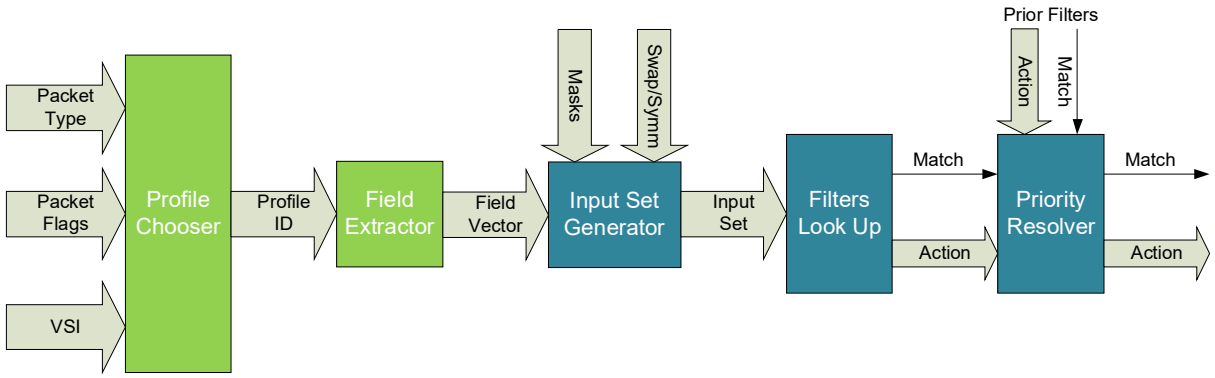

Figure 7-30. Classification Filters Block Diagram

7.10.3 Profile Chooser

- **Control Domain (CDID)** and **VSI Group (VSIG)** — The VSIs are mapped to control domains and VSI groups that are used by the extractor logic. Then the CDIS and VSIG maps the Packet Type Groups (PTGs) and the packet flags (FLGs) to packet profiles.
- **Packet Types** and **Flags** — Some combinations of the packet headers are defined by unique identification called "packet types". A portion of these packet types are defined by a smaller set of PTGs. The PTG tables map the packet types per filter per, per control domain and per VSI to a small set of 64 PTGs. On top of the PTG, there is some portion of the FLGs that are used for the classification task. A set of 16 FLGs are selected from the global set of flags per filter and per control domain.

Figure 7-31 shows the default profile chooser diagram.

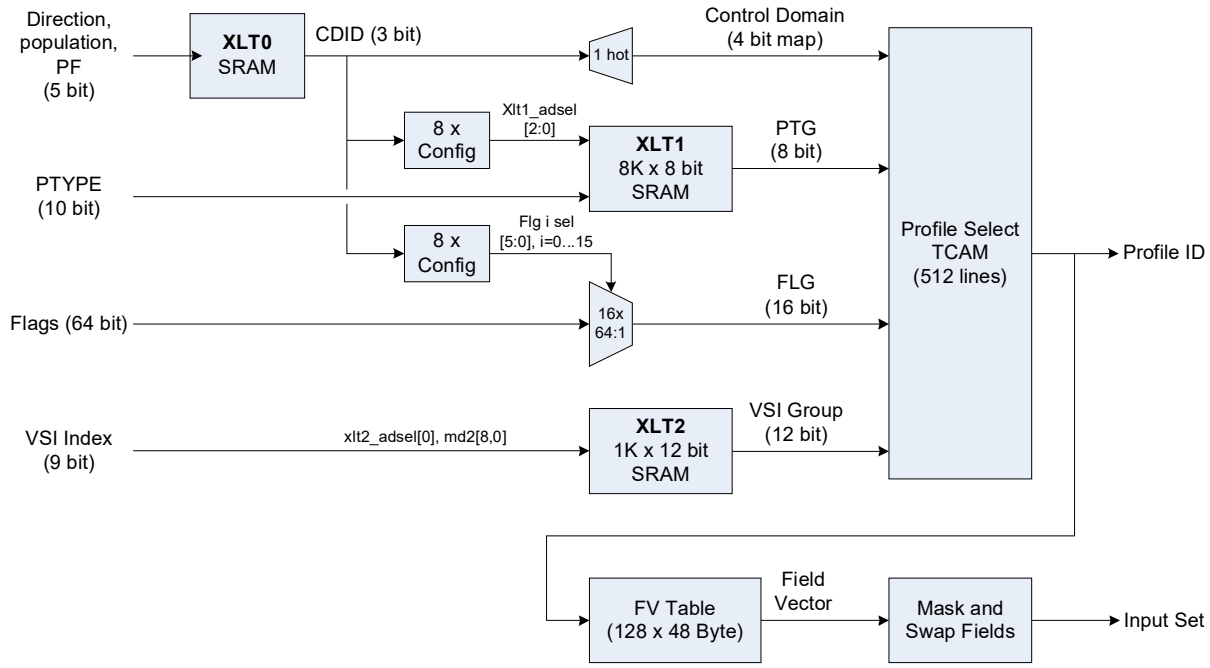

Figure 7-31. Profile Chooser - Packet Types to Profile ID and Input Set Flow

7.10.3.1 Settings for the Classification Filters

See default setting of the packet Profile IDs and the field vectors for the FD, Hash, and PE in Section 7.10.13, "Default Extractor Configuration".

7.10.4 Input Sets Generator

The input set is cleared to zero's for every packet (before the fields are posted to it from the field vector). The hardware supports any mapping between the field vector to the input set. Yet, in most cases (default setting), the input set equals exactly to the field vector. Cases in which the input set differs from the field vectors relates to swapped fields, masked fields, and asymmetric input sets. Bit fields that are masked, are replaced by zeros in the input set.

7.10.4.1 Generating PE Input Set from the Field Vector

Unique parameters of the FV to input set extraction of the PE filter are:

- The FV is mapped to the Input Set vector by the GLQF_PEINSET registers. Default settings of these registers (loaded from the NVM) map all valid words in the FV to the Input Set vector at the same word offsets. The GLQF_PEINSET is a two-dimensional array: 32 profiles x 24 words offsets per profile.
- Masking option. The mask registers are used to mask bit fields per words in the FV. There is a global set of 16 x mask registers for the PE filter. A mask register can mask out any selected bits in a FV word. Multiple mask registers can be selected for a packet profile. Multiple profiles can share the same registers. The mask options are defined by the following registers:
  - 16 x GLQF_PEMASK registers — Each register defines the byte index in the input set that should be masked and the 16-bit masking.
  - 32 x GLQF_PEMASK_SEL registers — Register 'n' in the array is associated with packet profile 'n'. It defines the GLQF_PEMASK registers that should be used for profile 'n'.

  Note: By default setting (loaded from the NVM), none of the words in the input set are masked.

7.10.4.2 Generating FD Input Set from the Field Vector

Unique parameters of the FV to input set extraction of the FD filter are:

- The FV is mapped to the Input Set vector by the GLQF_FDINSET registers. Default settings of these registers (loaded from the NVM) map all valid words in the FV to the Input Set vector at the same word offsets. The GLQF_FDINSET is a two-dimensional array: 128 profiles x 24 words offsets per profile.
- The swap option is defined by the GLQF_FDSWAP registers. The swap functionality is meaningful only at FD programming time with the GLQF_FDINSET registers. If the *SWAP* flag in the programming descriptor is set, the input set is defined by the GLQF_FDSWAP registers. Otherwise, it is defined by the GLQF_FDINSET registers.
- Masking option. The mask registers are used to mask bit fields per words in the input set. There is a global set of 32 x mask registers for the FD filter. A mask register can mask out any selected bits in an input set word. Multiple mask registers can be selected for a packet profile. Multiple profiles can share the same registers. The mask options are defined by the following registers:
  - 32 x GLQF_FDMASK registers — Each register defines the byte index in the input set that should be masked and the 16-bit masking.
  - 128 x GLQF_FDMASK_SEL — Register 'n' in the array is associated with packet profile 'n'. It defines the GLQF_FDMASK registers that should be used for profile 'n'.

  Note: By default setting (loaded from the NVM), none of the words in the input set are masked.

7.10.4.3 Generating Hash Input Set from the Field Vector

Unique parameters of the FV to input set extraction of the Hash filter are:

- The FV is mapped to the Input Set vector by the GLQF_HINSET registers. Default settings of these registers (loaded from the NVM) map all valid words in the FV to the Input Set vector at the same word offsets. The GLQF_HINSET is a two-dimensional array: 128 profiles x 24 words offsets per profile.

- Symmetric hash is defined by the GLQF_HSYMM registers. Symmetric hash is enabled for a VSI (by the Hash Scheme field in the Add VSI AQC). The symmetric hash registers structure is identical to the GLQF_HINSET registers with one difference: the *Valid* flag in the GLQF_HINSET registers is replaced by a *SYMM_ENA* flag in the GLQF_HSYMM registers. For each word with active *SYMM_ENA* flag, the input set is defined by a XOR function of the words defined by the matched GLQF_HSYMM and GLQF_HINSET registers.
- Masking option. The mask registers are used to mask bit fields per words in the input set. There is a global set of 32 x mask registers for the Hash filter. A mask register can mask out any selected bits in an input set word. The masking operation is executed after any possible symmetric action described above. Multiple mask registers can be selected for a packet profile. Multiple profiles can share the same registers. The mask options are defined by the following registers:
- 32 x GLQF_HMASK registers — Each register defines the byte index in the input set that should be masked and the 16-bit masking.
- 128 x GLQF_HMASK_SEL — Register 'n' in the array is associated with packet profile 'n'. It defines the GLQF_HMASK registers that should be used for profile 'n'.

Note: By default setting (loaded from the NVM), none of the words in the input set are masked.

7.10.5 Switch Filters

The switch filters are enabled only for packets that are not rejected for filtering by exception rules that are listed in Section 7.10.1.5. For queue-related programming in the switch, see Section 7.8.12.3.1.

7.10.6 ACL Filters

The ACL filters are enabled only for packets that are not rejected for filtering by exception rules that are listed in Section 7.10.1.5.

Some of the ACL filters can be programmed to define a target queue or a target region of queues for the hash filter. Section 7.9.3.4.3.2 for details.

7.10.7 Hash Filter

The hash filter is a mechanism to statistically distribute received packets into several receive queues. Software allocates the queues among the different processors, therefore sharing the load of packet processing among several processors. One of the most common use cases of hash filters is the RSS hash defined by Microsoft and used widely by other operating systems as well. Other generic hash functions are used by embedded systems as well. The hash filter directs the received packets to queue index within a "region" of queues of the VSI, as illustrated in the Figure 7-32. Listed below are some terms relating the hash filter.

Hash Filter Candidate Rules

The receive packet is not rejected for the filter by the exception rules listed in Section 7.10.1.5. The Hash filter is enabled per VSI group as shown in Section 7.10.13.1 (the VSI is associated to a VSI group (VSIG) that is enabled for the Hash filter by profile selection mechanism).

The hash filter priority selecting a queue is hard-coded as the lowest priority between ACL filter, PE filter, L2 Switch filter, and FD filter.

Queue Index

The queue index within the VSI is defined by the sum of the Region base and the output of the hash lookup table (modulo the region size).

Queue Region

A region of queues is defined by two parameters: Region base and Region Size. The region of queues can be defined by one of the following options in priority order:

1. **Switch filters** with *ToQueue* parameters greater than zero. In this case the region base is the "Queue Number" parameter and the region size is equal to 2^(ToQueue). Priority is defined by the *ToQueue_PRIO* of the switch filter. If the packet does not match the RSS filter, the packet is directed to queue zero of the VSI.
2. **ACL filters** with *ToQueue* parameters greater than zero - same functionality as the switch filter. In this case, the region base is the "Queue Number" parameter and the region size is equal to 2^(ToQueue), (same as the switch filters). Priority is defined by the *ToQueue_PRIO* of the FD filter.
3. **FD filter** with *ToQueue* parameter greater than zero - same functionality as the switch filter. In this case, the region base is the "Queue Number" parameter and the region size is equal to 2^(ToQueue), (same as the switch filters). Priority is defined by the *ToQueue_PRIO* of the FD filter.
4. The **packet's profile** is indicated as "Override TC" by one of 32 global GLQF_PROF2TC tables. These tables are enabled for VSIs by the TC override option and *Profile Override TC* fields in the Add VSI admin command. In this case, the region base and size are defined by the TC region described below. Priority is lower than the above filters switch and FD filters, and higher than the TC of the packet.
5. The **TC of the packet** defines the queue region. The region base and size are defined by the number and offset of Rx-Queues per TCs parameters in the Add VSI admin command. Priority is lowest of all the above options.

Hash LUT

The queue index in the region is defined by a hash value on the input set of the packet. The LS bits of the hash value selects an entry in the hash LUT. Then the LS bits of the programmed value in the LUT is the queue index within the region. The number of bits used to select the entry in the LUT match the LUT size. The number of LS bits taken from the LUT are defined by the region size. The E810 supports three sizes of Hash LUTs. Any of these LUT options is selected per VSI according to the RSS LUT selection field in the Add VSI command.

- 8 LUTs (one table per PF) that support 256 queues per region. These tables are 2K entries and support a reduces size of 512 entries and a reduced size of 128 entries as well (controlled by the *HSIZE* field in the PFQF_HLUT_SIZE registers).
- 16 global LUTs of 512 entries that support 64 queues per region. These tables support a reduces size of 128 entries (controlled by the *HSIZE* field in the matched GLQF_HLUT_SIZE registers). Selecting the Global LUTs, a specific table is selected by the RSS global LUT parameter in the Add VSI command.
- Per VSI LUT with 64 entries that support 16 queues per region.

Hash Key

See Section 7.10.10.1, "Microsoft Toeplitz-Based Hash".

Hash Function

The hash is calculated on the input set words. Masked bits within the input set are replaced by zeros for the hash calculation (as indicated in Section 7.10.4). The Hash signature is used to select a queue index as explained above. It can also be reported in the receive descriptor as detailed in Section 7.6.3.

The E810 supports one of the following 32-bit hash schemes selected per-VSI by the *Hash Scheme* field in the Add VSI command

- **Toeplitz Hash** — The hash key for the VSI is defined by the VSIQF_HKEY registers (detailed in Section 7.10.10).
- Symmetric Toeplitz Hash — The hash key is defined as above by the VSIQF_HKEY registers. Symmetric hash provides the same signature for packets in both Tx and Rx direction. It is done by a XOR function between "source" and "destination" tuples (see description of the GLQF_HSYMM registers in Section 7.10.4.3 and Section 7.10.10).
- **XOR Hash** — Simple XOR function between the DWords of the input set. Furthermore, 16-bit XOR function is made if the required XOR output is 16 bits or less and further 8-bit XOR is made if the required XOR output is 8 bits or less.
- **Jenkin's Hash** — This options is provided only for small input sets up to four bytes long (detailed in Section 7.10.10).

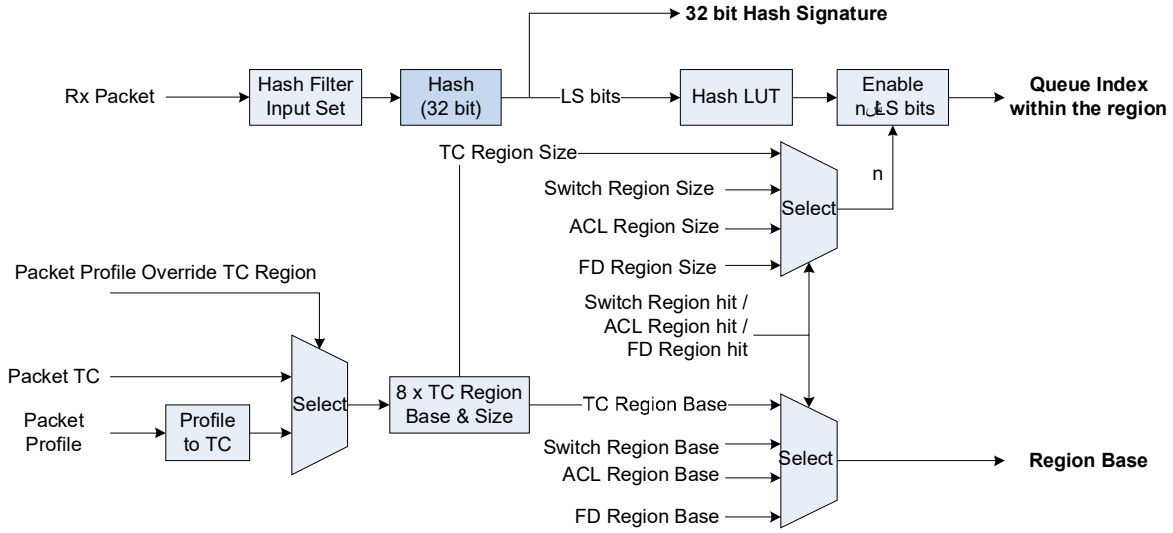

Figure 7-32. Hash Filter Block Diagram

7.10.8 Flow Director (FD) Filter

The Flow Director (FD) filter is aimed to match specific flow or flows with "some" action. The FD filter is based on "exact" match of the selected tuples named as "input set" for filtering purposes. The FD filter is composed of the following components.

FD Filter Candidacy Rules

The FD filtering is enabled by the following parameters:

- The receive packet is not rejected for the filter by the exception rules listed in Section 7.10.1.5.

- The FD filter is enabled for the parent PF by the *FD_ENA* flag in the PFQF_FD_ENA register.
- The FD filter is enabled for the VSI by the *FD_ENA* flag in the Add VSI admin command.
- The FD filter is enabled per VSI group as shown in Section 7.10.13.1 (the VSI is associated to a VSI group that is enabled for the FD filter by the *VSIG_FD* parameter in the Add VSI admin command).
- Filtering is also qualified per packet for matched profile before a search in FD table is triggered.

FD Filter Match Criteria

Packet matches a filter entry if the following packet's parameters match the filter context:

- Input Set fields.
- Packet's VSI and Packet profile.

Filter Action

The filter actions are defined by specific fields in the FD programing descriptor and are listed here (see Section 10.5.3.3 for FD programming descriptor structure):

- Pass/Reject the packet is defined by the *DROP* flag.
- Destination queue or region of queues for the hash filter and its priority are defined by the *QINDEX*, *ToQueue* and *ToQueue_PRIO* parameters in the FD programming descriptor. See Figure 7-32 for details on region of queues action.
- Statistic counters (see Section 7.10.8.1 for more details). Packet and byte counters are enabled by the *STAT_CNT* and *STAT_ENA*. The *STAT_ENA* field could be set to one of the following: No stat counter:
  - Packet counter
  - Both packet and byte counters
- Report the FD filter ID (FDID) and its priority in the Rx-Descriptor are defined by the *FDID_VAL*, *FDID_MDID*, and *FDID_PRIO* parameters in the FD programming descriptor.
- Post selected fields from the packet or metadata of the packet to the Rx-Descriptor. The selected fields that should be posted are defined by the *DESC_PROF* and *DESC_PROF_PRIO* parameters in the FD programming descriptor. For more details on the Rx-Descriptor profiles, see Section 7.6.4.

Default Filter Action

Packets that are subjected to look up in the FD table but do no match any entry are handled according the default FD action.

Note: In case of any default action other than drop, the relevant Rx-Descriptor reflects no hit occurred in the FD table.

The default is defined by the following parameters in the Add VSI admin command:

- Pass/Reject the packet is defined by the *Default Drop* flag.
- Destination queue or region of queues parameters with a priority option as defined for packets that hit the FD table:
  - Default Queue
  - Default queue group
  - Default Priority.

- If the *Default Drop* flag is cleared and the *Default Priority* equals to zero, packets that miss the FD table are handled by the next classification filter(s) according to its priority order, as shown in Figure 7-29.

FD Programming Enable

FD filters programming is enabled by the following parameters:

- Programming is enabled for the parent PF by the *FD_ENA* flag in the PFQF_FD_ENA register.
- Programming is further enabled for the programming VSI by the Flow Director programming enable flag in the Add VSI command.
- Programming is further enabled for the VSI defined by the *FD_VSI* field in the programming descriptor for the best effort space or guaranteed space in the table by the *Max Dedicated* and *Max Shared* parameters in the Add VSI command. Best effort and guaranteed spaces are described in this section.
- All conditions for the packet match the FD filter criteria including enable for the VSI group, matched profile, and no errors.
- Programming request that failed the above conditions is ignored silently.

Programming

FD filter programming is done through packets that pass through the FD. The packet causes an FD Filter programming when it is associated with a "Flow Director Programming Descriptor" described in Section 10.5.3.3 followed by packet structure that contains the filter fields.

- The descriptors used for programming (in order) are:
  - Optional Context Descriptor
  - Optional IPsec context descriptor
  - FD filter programming descriptor
  - Tx Data descriptor

  Note: Programming of the FD table cannot occur if the programming packet (described above), is dropped by any of the pipeline mechanisms.
- Programming can be selected to be on the Guaranteed space or Best Effort space according to the *FD_SPACE* field in the FD programming descriptor. It can be one of the following options:
  - Guaranteed
  - Best Effort
  - Prefer-Guaranteed
  - Prefer-Best Effort
- Programming completion status can be reported back (by the "Programming Status" Descriptor described in Section 10.4.2.2.3). It is enabled by the *COMP_REP* field in the programming descriptor that can be one of the following options:
  - No completion status
  - Completion status on failed programing
  - Completion status at all cases.

- The receive queue for the completion status is selected by the *COMP_QUEUE* flag in the FD programming descriptor. It selects between queue zero of the programming VSI or *Reporting Queue* field in the Add VSI admin command.
- *ToQueue* field in the FD programming descriptor. If there are no descriptors in the target receive queue the completion indication is dropped and counted as a dropped packet by the GLV_RDPC counter of the VSI.
- The packet that is used to program the filter can be a single packet or a TSO and it can be transmitted or not depending on the *Dummy* flag in the transmit data descriptor.
- Reprogramming an existing filter updates its parameters.
- The "source" and "destination" fields in the transmitted packets of the filter programming are usually presented in a reversed order with respect to the expected received packets. It can be adjusted by the device.

Filter Removal

Filters are removed in one of the following options:

- **Remove a single filter** by the software using the FD filter programming sequence (as above).
- **Auto-evict a single filter** by the hardware following a transmission or reception of TCP packet with *FIN* or *RST* flags. Packets that are candidates for auto-eviction are enabled per-profile by the GLQF_FDEVICTENA. The TCP flags that matters for auto-eviction are defined by the GLQF_FDEVICTFLAG register. Filters are enabled for auto-evict by the *EVICT_ENA* flag in the filter programming descriptor. The auto-eviction is also qualified per VSI by the appropriate VSIQF_FD_CTL1.*EVICT_ENA* bit and per profile by the appropriate GLQF_FDEVICTENA.
- **PF Reset** — Auto-evict all filters of the PF following a PF reset.
- **VF Reset** — As part of the VF reset flow the parent PF software is expected to initiate a request to remove all the filters of all the VSIs of the VF.
- **VM Reset** — As part of the VM reset flow the parent PF software is expected to initiate a request to remove all the filters for the VM VSI.
- **Software initiated request to remove all filters of the PF(VSI of the PF) or a VSI** — It is done by initiating the Clear FD Table admin command. Removing the filters of a PF removes the filters of all VSIs of the PF. This action can be done during nominal operation without impacting the functionality of other entities.

VSI Rules - Summary

Table 7-144 summarizes the VSI's FD actions and validity rules:

Table 7-144. VSI Rules - Summary

Action/Validity Check	The VSI by which the Action/Validity is Checked / Configuration Completion
Enable for programming	*CFG_ENA* for the source VSI and FD_ENA for the parent PF.
Programming Budget	Guaranteed and Best Effort spaces for the VSI defined by the *FD_VSI* field in the FD programming descriptor.
Enable for Filtering	*FLT_ENA* for the destination VSI + *FD_ENA* for the parent PF.
VSI in the FD filter context	Equals to the *FD_VSI* field in the FD programming descriptor.
Tx ATR filter removal	The source VSI from which the packet is sent is compared against the VSI in the filter context.
Rx ATR filter removal	The destination VSI is compared against the VSI in the filter context.
Configuration Completion	Completion is reported to the same VSI that initiated the configuration/removal command.

FD Table Size and Space

The FD table is stored in the device and can hold up to 16K filters. There are two spaces in the FD table: Guaranteed space and Best Effort space.

- **Global Setting** — These spaces are defined for the whole device by the GLQF_FD_SIZE.*FD_GSIZE* and GLQF_FD_SIZE.*FD_BSIZE* registers. Each space can be defined up to 16K filters as long as the sum of the two does not exceed the table size (of 16K filters).
- **Per PF Setting** — Each PF can be allocated a guaranteed space and best effort space by the PFQF_FD_SIZE.*FD_GSIZE* and PFQF_FD_SIZE.*FD_BSIZE* registers. Each space can be defined up to 16K filters as long as the sum of the Guaranteed spaces of all the PFs do not exceed the global guaranteed space and as long as the best effort of each PF does not exceed the global best effort space.
- **Per VSI Setting** — Each VSI can be allocated a guaranteed space and best effort space by the VSIQF_FD_SIZE.*FD_GSIZE* and VSIQF_FD_SIZE.*FD_BSIZE* registers. Each space can be defined up to 16K minus 1 filters as long as the sum of the Guaranteed spaces of all the VSIs of a PF do not exceed guaranteed space of its parent PF, and as long as the best effort of each VSI does not exceed its parent PF's best effort space.

At programming, the software can chose the space on which the filter is counted. If there is no space on the selected space, the programming request is rejected.

The software can track the number of programmed filters.

- **Per PF** — By PFQF_FD_CNT.FD_GCNT and PFQF_FD_CNT.FD_BCNT counters.
- **Per VSI** — By VSIQF_FD_CNT.FD_GCNT and VSIQF_FD_CNT.FD_BCNT counters.
- **Globally** — By the GLQF_FD_CNT.FD_GCNT and GLQF_FD_CNT.FD_BCNT counters.

FD Filter Context

Each filter entry is consisted of 64 bytes with the following parameters:

- **Parameters extracted from the packet** — Input Set (48 bytes) and the Matched packet profile.
- **Parameters from the programming descriptor** — Target Queue and control, Filter ID and control; Packet's VSI, Statistic Counter, Receive Descriptor Profile and control, and Other control flags.
- **Self table management parameters** — Linked list pointers.
- **Self storage managed parameters** — PF/VF/VSI identification, *Valid* flag, and *Dirty* flag.

FD Filter Match Criteria

Packet matches a filter entry if the following packet's parameters match the filter context:

- Input Set fields
- Packet's VSI
- Packet profile

Hash and Buckets

The FD table is organized in buckets. Buckets are sets of filters addressed by a hash function on the input set (Toeplitz hash using a global key defined by the GLQF_HKEY registers). Multiple filters might share the same hash. In such case the hardware checks for perfect match between these filters one entry at a time. The number of searches is compared against the FDLONG parameter in the GLQF_FD_CTL register.

7.10.8.1 Statistic Counters

There are 8K statistic counters that can be used by the FD filters. These counters are organized in two banks of 4K counters each. The statistic counters are allocated in blocks of 256 counters to the PFs by the Allocate Resource admin command (resource type = Flow Director counter block). An FD filter can assign no counters; a single counter (counting bytes of packets) or count both (bytes and packets). Assigning a single counter, software can select any counter out of the two banks. Assigning two counters, software defines a single counter index in the two banks for these counters. In this case, the packets are counted in bank zero and the bytes are counted in bank one.

7.10.8.2 Performance

7.10.8.2.1 Programming and Removal Performance Targets

The FD filter is expected to be used by two main usage models. Filters programming initiated by software application (above the driver). And filters programmed and owned by the driver (usually for ATR functionality).

Expected filter programming rate initiated by software application is in the range of up to 0.5M filters per second. Same rate of removing filters. Targeting Si performance for programming and removing filters at double rate of the above.

Expected filter programming by the driver is in the order of once every 20 packets. Expected auto-removal by FIN/RST is in the order of 1M filters per second.

Notes: The hardware does not provision the rate of programming nor the rate of transmit FIN/RST packets that are candidates for auto-removal of filters from the table. It is the responsibility of software to follow the above programming and auto-removal performance. Exceeding these rates, might impact transmission and reception rates. Therefore, the PF driver should enable direct programming and auto filter removal only for trusted VSIs. The PF driver could add and remove FD filters for non-trusted VSIs that are not enabled for direct programming (non-trusted VFs).

The interface by which these VFs request FD filter programming and remove FD filters is outside the scope of this document.

7.10.9 Protocol Engine (PE) Filters

The PE filters direct received packets to the Protocol Engine. It is mainly (but not limited) to iWARP and RoCEv2 traffic. The PE filter is composed of an APBVT filter and a Quad Hash (QH) filter described below.

Accelerated Port Bit Vector Table - APBVT

The L4 destination port number is compared against an internal Accelerated Port Bit Vector Table (GLQF_APBVT registers). The E810 includes a 64K x 1-bit vector for the whole device (all eight LAN ports). An active bit in the table means that the port number is enabled by one (or more) functions. Programming the table is done by the PE interface, as described in Section 11.5.3.18.

For the sake of the APBVT functionality, the destination L4 port number is posted by the extractor logic to word zero in the Field Vector.

Quad Hash Filter - QH

The QH Filter checks for perfect match between selected fields in the packet (called input set) and pre-programmed values in the filter table. The E810 stores some of the QH filters in an internal cache (holding up to 1K filters) while the other filters are kept in host memory (FPM). The maximum number of PE contexts for the device is 256K. These contexts can be allocated in a flexible manner between the functions with a maximum limit per function of 256K minus 1.

Filter Candidate Rules

Packets are forwarded to the PE if they meet the following conditions:

- The receive packet is not rejected for the filter by the exception rules listed in Section 7.10.1.5.
- Receive to a PF — The PE is enabled for the PF by the *PE_ENA* flag in the PFQF_PE_ENA register.
- Receive to a VF — The PE is enabled for the VF and its parent PF by the *PE_ENA* flags in the matched VP/PFQF_PECTL registers.
- Receive to a VSI — The PE is enabled for the VSI by the *PE_ENA* flags in the matched VSIQF_PE_CTL1 register (should be set by add VSI).
- The packet profile is enabled for the VSI group as shown in Table 7-160 (the VSI is associated to a VSI group for the PE by the *VSIG_PE* parameter in the Add VSI admin command). The add VSI admin command PE enable sets *PE_FLTENA* bit in the corresponding VSIQF_PE_CTRL1 CSR.
- The packet's TC is enabled by the PFQF_PE_TC_CTL registers (programmed by the PF driver).
- The packet hits the APBVT table (if required by the *APBVT_ENA* flag in the GLQF_PE_CTL2 register of the matched packet profile). By default, iWARP packets are candidate for the APBVT. If the packet is candidate for the APBVT, hitting the filter is a prerequisite condition for lookup in the QH filter.
- The packet hits the QH filter (if required by the *TO_QH* field in the GLQF_PE_CTL2 register of the matched packet profile). By default setting:
  - iWARP packets must match the QH filter as a criteria for PE hit.
  - Non-unicast RoCEv2 packets are subjected to QH filter check but they are forwarded to the PE regardless of hit or miss.

7.10.9.1 PE Quad Hash Filter (QH filter)

The Quad Hash Filter (QH filter) is aimed to match specific flows with the protocol engine. The E810 maintains some of the Quad Hash filter in internal cache, while the other filters are stored in host memory (FPM). The number of quad hash filters per function is a function of the number of flows supported by that function. The Quad Hash Filter is composed of the following components:

QH Filter Candidate Rules

See Section 7.10.9, "Protocol Engine (PE) Filters".

QH Filter Match Criteria

A packet matches a filter entry if the following packet's parameters match the filter context:

- Input Set fields
- Packet's VSI
- Packet profile

Filter Action

The filter provides a hit/miss indication. In the case of hit, the matched quad hash filter index (QPN) is reported to the PE together with the packet. In case of a miss, the destination queue pair from the packet is reported to the PE with the packet.

Filter Programming

A QH filter is added or removed by the PE (using direct internal interface to the filter logic). As part of the filter parameters, the PE provides the identification fields, the packet's profile, and the QPN.

Note: A filter should be programmed by the PE only if the PF or VF are enabled for the PE and the packet profile is enabled for the VSI group.

Filter Removal

Filters are removed in one of the following options:

- Remove a single filter by the PE using its programming interface.
- PF Reset — Auto-evict all filters of the PF and its VFs following a PF reset. After the reset is completed, or before the PE QH filter is re-enabled, the software driver must clear all the filter entries in the Hash space in the FPM (the Hash space is indicated by PEHSIZE in the Figure 7-33). Only then it can set the *PE_ENA* flag in the PF/VPQF_PE_ENA register.
- VF Reset initiated by the software driver — Auto-evict all filters of the VFs following a VF reset. After the reset is completed, or before the PE QH filter is re-enabled, the parent PF software driver must clear all the filter entries in the Hash space in the FPM (the Hash space is indicated by PEHSIZE in Figure 7-33). Only then it can set the *PE_ENA* flag in the VPQF_PE_ENA register.
- Explicit request by the PE to remove all filters of the function (PF or VF) from the cache. The PE driver initiates a request to clear all filters of a function through the CSR fabric.

QH Table Size

The E810 supports up to 256K Quad Hash contexts for the whole device. These filters are fetched to internal cache that can hold up to 1K filters. The number of supported QH filters is limited by the *PEDSIZE* parameters in the PFQF_PE_CTL register for the PF and VPQF_PE_CTL registers for the VFs. Programming request for a QH filter above these limits is rejected.

QH Filter Context

Each filter entry is consisted of 64 bytes.

Storage in Host Memory

The filters are backed up in the function's private memory (FPM) in buckets as described in Figure 7-33. Filters are stored in the "hash space" at address defined by the hash value that is calculated on the input set (the hash function is Toeplitz using a global key defined by the GLQF_HKEY registers). If this location is occupied (hash collision), the filter is stored in a free location in the "collision space".

The filter in the "hash space" points to all the other filters in the "collision space" that share the same hash. It is organized in a linked list structure. The number of supported buckets (hash space) and the number of supported filters (collision space) are defined per function by the *PEHSIZE* and *PEDSIZE* parameters in the PFQF_PE_CTL and VPQF_PE_CTL registers. Software should clear the hash space in the FPM before filters are programmed. The QH filters of the PF and its VFs are stored in the FPM of the PF.

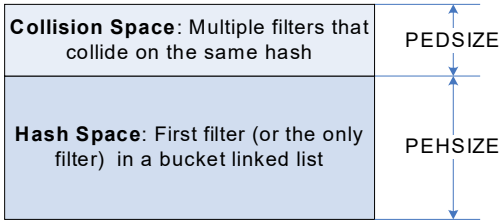

Figure 7-33. Buckets and Collided Filter Entries Space

The actual number of Hash Table entries for the PF is programmed using the PFQF_PE_CTL1 and PFQF_PE_CTL2. Per VF it is programmed through the VPQF_PE_CTL1 and VPQF_PE_CTL2 registers.

7.10.9.1.1 Performance

7.10.9.1.1.1 Programming and Removal Performance Targets

Expected filter programming and removal rate equals to 0.5M filters per second.

7.10.9.1.1.2 Buckets Length Impact on Filter Search Performance

The E810 is able to sustain its maximum packet rate when the matched QH filters are stored in the cache. In the case of miss, the E810 fetches the filters from the FPM (host memory). Host memory latency for fetching the filtering depends on the bucket length. The E810 reports the number of buckets for the function in the PF/VPQF_PECNT_0.*BUCKETCNT*. It also reports the number of programmed filters by the function in the PF/VPQF_PECNT_1 registers. The ratio between these two numbers provides an indication for the QH table distribution and hence for possible long buckets.

On top of it the PE QH table counts each packet positioning in its bucket at reception time. Received packets at a position shorter or equal than GLQF_PE_CTL.*PELONG* are counted by PFQF_PE_CLSN0.*HITSBCNT*, while packets at position longer than *PELONG* are counted by the PFQF_PE_CLSN1.*HITLBCNT*. When GLQF_PE_CTL.*PELONG* equals 0, the functionality is disabled and all packets are counted by PFQF_PE_CLSN1. The counting is qualified by PFQF_PE_ST_CTL CSR.

The *PELONG* threshold applies to all PE packets, including iWARP and RoCEv2. However, for RoCEv2 packet, where there is no QH lookup, the "position in bucket" is always considered as shorter than or equal to GLQF_PE_CTL.*PELONG*.

Received packets that match PE filters at position longer than GLQF_PE_CTL.*PELONG* are reported by the *PELONGB* flag in the receive descriptor. Thus, software can use these parameters as a criteria for the QH table performance. It then could decide to remove some filters that possibly hit performance or flush the whole table.

7.10.10 Hash Functions

The E810 supports several hash functions to be used by the various filters:

- Bucket number of the FD filter and the PE quad hash filter use the Toeplitz scheme with a shared global key defined by the GLQF_HKEY registers.
- The hash filter uses one of the following schemes selected per VSI by the *Hash Scheme* field in the Add VSI command.

— **Toeplitz Hash** — The hash key for the VSI is defined by the VSIQF_HKEY registers (detailed in Section 7.10.10.1).

— **Symmetric Toeplitz Hash** — The hash key is defined as above by the VSIQF_HKEY registers. Symmetric hash is calculated by XOR function between "source" and "destination" tuples providing the same hash signature for Tx and Rx packets of the same "flows" (detailed in Section 7.10.10.2).

— **XOR Hash** — Simple XOR hash function between the DWords of the input set. The input set is padded with zeros if not whole number of DWords. If the hash function is used as an address to a lookup table smaller or equal then 64K entries, a 16-bit hash is used by XOR function of the 16 MS bits and 16 LS bits of the 32-bit hash. If the hash function is used as an address to a lookup table smaller or equal than 256 entries, an 8-bit hash is used by a XOR function of the four bytes of the 32-bit hash.

— **Jenkin's Hash** — This options is provided only for small input sets up to four bytes long (detailed in Section 7.10.11).

The following notations are used to describe the hash functions:

- Ordering is big endian in both bytes and bits. For example, the IP Address 161.142.100.80 translates into 0xA18E6450.
- A "**^**" denotes bit-wise XOR operation of same-width vectors.
- **@x-y** denotes bytes x through y (inclusive) of the incoming packet, where Byte 0 is the first byte of the IP header. In other words, all byte-offsets are considered as offsets into a packet where the framing layer header has been stripped out. Therefore, the source IPv4 Address is referred to as @12-15, while the destination IPv4 Address is referred to as @16-19.
- **@x-y, @v-w** denotes concatenation of bytes x-y, followed by bytes v-w, preserving the order in which they occurred in the packet.

7.10.10.1 Microsoft Toeplitz-Based Hash

The hash uses a random secret key of 416 bits (52 bytes). The key is defined per VSI by the VSIQF_HKEY registers. The algorithm works by examining each bit of the hash input from left to right. Our nomenclature defines left and right for a byte-array as follows:

Given an array K with k bytes, our nomenclature assumes that the array is laid out as follows:

K[0] K[1] K[2] … K[k-1]

Where:

- K[0] is the left-most byte, and the MSB of K[0] is the left-most bit.
- K[k-1] is the right-most byte, and the LSB of K[k-1] is the right-most bit.

```
ComputeHash(input[], N)
    For input[] of length N bytes (8N bits) and a random secret key K of 416 bits
        Result = 0;
    For each bit b in input[] {
        if (b == 1) then Result ^= (left-most 32 bits of K);
            shift K left 1 bit position; // Cyclic shift while the right-most bit of
                                         // K gets the leftmost bit of K
}
return Result;
```

7.10.10.1.1 Pseudo-Code Examples

The following four pseudo-code examples are intended to help clarify exactly how the hash is performed in four cases: IPv4 with and without ability to parse the L4 header, and IPv6 with and without a L4 header.

Table 7-145. Examples of Input Fields for the Hash Function

Packet Type	Hash Input	Hash Result
IPv4 with TCP or UDP	SourceAddress, DestinationAddress, SourcePort, DestinationPort: Input[12] = @12-15, @16-19, @20-21, @22-23	Result = ComputeHash(Input, 12)
IPv4 without L4	SourceAddress, DestinationAddress: Input[12] = @12-15, @16-19	Result = ComputeHash(Input, 8)
IPv6 with TCP or UDP	SourceAddress, DestinationAddress, SourcePort, DestinationPort: Input[12] = @8-23, @24-39, @40-41, @42-43	Result = ComputeHash(Input, 36)
IPv6 without L4	SourceAddress, DestinationAddress: Input[12] = @8-23, @24-39	Result = ComputeHash(Input, 32)

7.10.10.1.2 RSS Verification Suite

This section provides a verification suite used to validate that the hash function is computed according to MSFT nomenclature.

Assume that the random key byte-stream is:

```
0x6d, 0x5a, 0x56, 0xda, 0x25, 0x5b, 0x0e, 0xc2,
0x41, 0x67, 0x25, 0x3d, 0x43, 0xa3, 0x8f, 0xb0,
0xd0, 0xca, 0x2b, 0xcb, 0xae, 0x7b, 0x30, 0xb4,
0x77, 0xcb, 0x2d, 0xa3, 0x80, 0x30, 0xf2, 0x0c,
0x6a, 0x42, 0xb7, 0x3b, 0xbe, 0xac, 0x01, 0xfa,
0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00,
0x00, 0x00, 0x00, 0x00
```

Table 7-146. IPv4

Destination Address/Port	Source Address/Port	IPv4 Only	IPv4 with TCP
161.142.100.80 / 1766	66.9.149.187 / 2794	0x323E8FC2	0x51CCC178
65.69.140.83 / 4739	199.92.111.2 / 14230	0xD718262A	0xC626B0EA
12.22.207.184 / 38024	24.19.198.95 / 12898	0xD2D0A5DE	0x5C2B394A
209.142.163.6 / 2217	38.27.205.30 / 48228	0x82989176	0xAFC7327F
202.188.127.2 / 1303	153.39.163.191 / 44251	0x5D1809C5	0x10E828A2

The IPv6 Address tuples are only for verification purposes, and might not make sense as a tuple.

Table 7-147. IPv6

Destination Address/Port	Source Address/Port	IPv4 Only	IPv4 with TCP
3FFE:2501:200:3:1 / 1766	3FFE:2501:200:1FFF:7 / 2794	0x2CC18CD5	0x40207D3D
FF02:1 / 4739	3FFE:501:8:260:97FF:FE40:EFAB / 14230	0x0F0C461C	0xDDE51BBF
FE80:200:F8FF:FE21:67CF / 38024	3FFE:1900:4545:3:200:F8FF:FE21:67CF / 44251	0x4B61E985	0x02D1FEEF

7.10.10.2 Symmetric Hash

A symmetric hash provides the same value if its respective source and destination fields are swapped. For example, suppose that the hash is done on the frame source and destination IP Addresses. A symmetric hash guarantees that: **hash(src IP, dst IP)** = **hash(dst IP, src IP)**.

The motivation behind symmetric hash is to route frames of a specific "flow" between two nodes to the same receive queue independent of the transmission direction (Tx or Rx).

The symmetric hash is useful for matched pairs of tuples like:

- IP Addresses
- L4 port numbers
- MAC Addresses

Symmetric hash is defined per packet profile by its GLQF_HSYMM registers. For each word with active *SYMM* flag in the GLQF_HSYMM registers, the input set is defined by a XOR function of the words defined by the matched GLQF_HSYMM and GLQF_HINSET registers.

7.10.10.2.1 Symmetric Hash Example for IPv4 with TCP

Non Symmetric input vector is:

```
Input[12] = @12-15, @16-19, @20-21, @22-23
```

Symmetric input vector is:

```
Input[12] = @12-15 ^ @16-19, @12-15 ^ @16-19, @20-21 ^ @22-23, @20-21 ^ @22-23.
```

7.10.11 Receive Filters Admin Commands

7.10.11.1 Set RSS Key (0x0B02)

This command is used to set the RSS Key of a VSI. It can be used by a PF or a VF for VSIs assigned to it. A PF can set the RSS key on behalf of its VFs.

Table 7-148. Set RSS Key Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0B02	Command opcode.
Datalen	4-5	0x34	Length of buffer. Should be equal to 0x34 (hash key size).
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI#	16-17	0x0	**Bit 15:** Valid VSI# Must always be set. Ignored by firmware. **Bits 14:10:** Reserved **Bits 9:0:** VSI Number
Reserved	18-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the RSS key to set:

Offset	Content
0x0 - 0x27	Standard RSS Key
0x28 - 0x33	Extended hash key. Must be zero for regular RSS.

Table 7-149. Set RSS Key Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0B02	Command opcode.
Datalen	4-5	0x0	No return buffer.
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOENT = If not a valid VSI. EACCES = If the VSI is not owned by this PF/VF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

7.10.11.2 Set RSS LUT (0x0B03)

This command is used to set the RSS LUT of a VSI or RSS LUT of the PF or one of the global RSS LUT. This command can be initiated only by the PF. A VF can request its parent PF to configure an RSS LUT for its use via software interface or by the Mailbox AQ. It can be used by a PF or a VF for VSIs assigned to it. A PF can set the RSS LUT on behalf of its VFs.

Table 7-150. Set RSS LUT Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0B03	Command opcode.
Datalen	4-5	64/128/512	Length of buffer. Should be equal to 0x
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI#	16-17		**Bit 15:** Valid VSI# Is set if *Table Type* = VSI. Otherwise, ignored by firmware. **Bits 14:10:** Reserved **Bits 9:0:** VSI Number
Command Flags	18-19		**Bits 0:1:** Table Type 00b = VSI 01b = PF 10b = Global LUT 11b = Reserved **Bits 2:3**: LUT Size For VSI LUT this field is reserved and must be set to 00b. For PF LUT: 00b = 128 01b = 512 10b = 2K 11b = Reserved For Global LUT: 00b = 128 01b = 512 All other values are reserved. **Bits 4:7:** Global LUT Index Relevant only for *Table Type* equals to "Global LUT". Otherwise it must be 0. **Bits 15:8:** Reserved
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the LUT to set:

Offset	Content
0x0 - LUT Size	LUT content. Must match the format of the VSIQF_HLUT or PFQF_HLUT registers or GLQF_HLUT registers. For VSI LUT - 64 bytes For PF LUT or Global LUT it is according to the LUT size.

Upon reception of this command, the firmware:

1. Checks if the VSI or the Global LUT belongs to the function that sent the command.
2. Writes the VSIQF_HLUT or PFQF_HLUT registers or GLQF_HLUT registers from the command buffer according to the *Table Type* flag. When a PF table is written, the software might choose to write only the first 128 entries.

Table 7-151. Set RSS LUT Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0B03	Command opcode.
Datalen	4-5		No return buffer.
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOENT = If not a valid VSI. EACCES = If the VSI or the global LUT is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

7.10.11.3 Get RSS Key (0x0B04)

This command is used to get the RSS Key of a VSI. It can be used by a PF or a VF for VSIs assigned to it. A PF can query the RSS key of its VFs.

Table 7-152. Get RSS Key Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0B04	Command opcode.
Datalen	4-5	0x34	Length of buffer. Should be equal to 0x34 (has key size) or more.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
VSI#	16-17		**Bit 15:** Valid VSI# Must always be set. Ignored by firmware. **Bits 14:10:** Reserved **Bits 9:0:** VSI Number
Reserved	18-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Upon reception of this command, the firmware:

1. Checks if the VSI belongs to the function that sent the command using the VSI_VSI2F[VSI] register.
2. Reads the VSIQF_HKEY[VSI] registers and fill the response buffer.

Table 7-153. Get RSS Key Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0B04	Command opcode.
Datalen	4-5	0x0	0x34
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOENT = If not a valid VSI. EACCES = If the VSI is not owned by this PF/VF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The response buffer of this command contains the RSS key currently set:

Offset	Content
0x0 - 0x27	Standard RSS Key
0x28 - 0x33	Extended hash key. Must be zero for regular RSS.

7.10.11.4 Get RSS LUT (0x0B05)

This command is used to get the RSS LUT of a VSI or RSS LUT of the PF or one of the global RSS LUT. This command can be initiated only by the PF. A VF can request its parent PF to configure an RSS LUT for its use via software interface or by the Mailbox AQ. It can be used by a PF or a VF for VSIs assigned to it. A PF can query the RSS LUT of its VFs.

Table 7-154. Get RSS LUT Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0B05	Command opcode.
Datalen	4-5	64/512	Length of buffer. Should be equal to 512 or more for a PF table, or 64 or more for a VSI table.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.

Table 7-154. Get RSS LUT Command [continued]

Name	Byte.Bit	Value	Remarks
VSI#	16-17		**Bit 15:** Valid VSI# Is set if *Table Type* = VSI. Otherwise, ignored by firmware. **Bits 14:10:** Reserved **Bits 9:0:** VSI Number
Command Flags	18-19		**Bits 0:1:** Table Type 00b = VSI 01b = PF 10b = Global LUT 11b = Reserved **Bits 2:3**: Reserved Must be set to zero. **Bits 4:7:** Global LUT Index Relevant only for *Table Type* equals to "Global LUT". Otherwise it must be 0. **Bits 15:8:** Reserved
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Upon reception of this command, the firmware:

1. Checks if the VSI or the Global LUT belongs to the function that sent the command.
2. Reads the VSIQF_HLUT or PFQF_HLUT registers and fill the response buffer according to the *Table Type* flag. When a PF table is read, the entire 512 entries are read.

Table 7-155. Get RSS LUT Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0B05	Command opcode.
Datalen	4-5	0x0	0x2
Return Value/VFID	6-7		Return value. The following error values can be returned: ENOENT = If not a valid VSI. EACCES = If the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The response buffer contains the LUT currently set:

Offset	Content
0x0 - LUT Size	LUT content as read from f the VSIQF_HLUT or PFQF_HLUT registers or GLQF_HLUT registers. For VSI LUT - 64 bytes For PF LUT or Global LUT it is according to the LUT size.

7.10.12 Filter Clearing Commands and Flows

7.10.12.1 Clear FD Table (0x0B06)

This command is used to clear the FD filters associated with a given PF or a specific VSI. Upon reception of this command, the firmware must execute the flow described in Section 7.10.12.1.1.

Note: As part of a PF reset processing, the same flow is executed by the firmware for the PF being reset, without the need for software to send an AQC.

Table 7-156. Clear FD Table Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0B06	Command opcode.
Reserved	4-5		Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Clear_type	16		Clear Type 0x0 = Reserved 0x1 = VSI 0x2 = PF 0x3-0xFF = Reserved
Reserved	17		Reserved.
VSI_index	18-19		VSI Index This field is not applicable and should be set to 0x0 if function type is PF. ***Note:*** Inapplicable MSBs should always be set to 0x0.
Reserved	20-31	0x0	Reserved.

Table 7-157. Clear FD Table Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0B06	Command opcode.
Reserved	4-5		Reserved.
Return Value/VFID	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Clear_type	16		Clear Type 0x0 = Reserved 0x1 = VSI 0x2 = PF 0x3-0xFF = Reserved
Reserved	17		Reserved.

Table 7-157. Clear FD Table Response [continued]

Name	Byte.Bit	Value	Remarks
VSI_index	18-19		VSI Index This field is not applicable and should be set to 0x0 if function type is PF. ***Note:*** Inapplicable MSBs should always be set to 0x0.
Reserved	20-31	0x0	Reserved.

7.10.12.1.1 FD Table Clearing Flow

This section describes the flow, executed by the EMP firmware, for clearing the FD filters associated with a given function. The flow can be either initiated by the EMP firmware, for PF reset events, or by software using the relevant AQC.

Clearing the FD table is composed of the following main steps:

1. Block new inputs (searches and configuration) associated with the entity being cleared.
2. Wait for any ongoing/"in-flight" operations associated with the entity being cleared complete.
3. Clear/remove the table entries associated with the cleared entity.
4. Fix the filter counters so they correspond to the new filter amounts.

7.10.12.1.1.1 Clearing the FD Filter Flow

1. Set the following CSR fields:
   - GLQF_FDPIPE_CLR.*DIS_CFG*
   - GLQF_FDPIPE_CLR.*DIS_FLT*
   - GLQF_FDPIPE_CLR.*FD_BUSY*
   - GLQF_FDPIPE_CLR.*VM_VF_TYPE* to the *Clear_type* operand value.
   - GLQF_FDPIPE_CLR.*PF_NUM* to the PF index.
   - GLQF_FDPIPE_CLR.*VM_VF_NUM* to the *VSI_index* operand value.

   Note: As a response to the CSR write, the hardware blocks new search requests and new configuration requests for the cleared entity (PF or VSI). It does so by clearing the following flags:

   For PF entity, it clears the PFQF_FD_ENA.*FD_ENA* flag.

   For VSI entity, it clears the *FLT_ENA*, *CFG_ENA*, and *EVICT_ENA* flags in the VSIQF_FD_CTL1 register.

   Once there are no pending searches and configuration requests in the pipe, the *FD_BUSY* flag is cleared. This flow is implemented by initiating a "mini marker" in the post (from extractor input till end of FLU). Following a marker done indication, the *FD_BUSY* flag is cleared.
2. The EMP firmware pulls the status of GLQF_FDPIPE_CLR.*FD_BUSY* flag until it is cleared by the hardware.

   Note: At this stage, no additional inputs associated with the cleared entity are allowed to enter the pipe and there are no ongoing operations associated with the cleared entity.

3. The EMP firmware sets the following CSR fields:
   - GLQF_FDTABLE_CLR.*FD_CLEAR*
   - GLQF_FDTABLE_CLR.*FD_BUSY*
   - GLQF_FDTABLE_CLR.*VM_VF_TYPE* to the *Clear_type* operand value.
   - GLQF_FDTABLE_CLR.*VM_VF_NUM* to the *VSI_index* operand value.

   Note: As a response to the CSR write, the hardware invalidates all the filters of the requested entity and clears the GLQF_FDTABLE_CLR.*FD_BUSY* flag.
4. The EMP firmware pulls the status of GLQF_FDTABLE_CLR.*FD_BUSY* flag until it is cleared by the hardware.

   Note: At this stage, the filter entries associated with the cleared entity are cleared/invalidated.
5. In case of a VSI entity clear:
   a. The EMP firmware records the value of the following fields:
      - VSIQF_FD_CNT[VSI_index].*FD_GCNT*
      - VSIQF_FD_CNT[VSI_index].*FD_BCNT*

   b. The EMP firmware clears VSIQF_FD_CNT[VSI_index].*FD_GCNT* and VSIQF_FD_CNT[VSI_index].*FD_BCNT* by writing zero to the relevant fields.

   c. The EMP firmware writes the values, recorded instep a above, to PFQF_FD_SUBTRACT[PF_index].*FD_GCNT* and PFQF_FD_SUBTRACT[PF_index].*FD_BCNT*.
6. This operation subtract the filter count of the removed VSI from the PFQF_FD_CNT and GLQF_FD_CNT registers.

   Note: For PF reset case, all the counters associated with the reseted PF's VSIs are zeroed by software as part of the driver initialization. Therefor they do not need to be addressed as part of the clear flow.

   In case the filters associated with a PF are being cleared not as part of a PF reset event (that is, the clearing is initiated by the software), the software can follow the steps specified above for fixing the counters' values. If software does not decrement the counters, the counters' values will not correspond to the actual amount of filters stored in the FD storage.
7. The EMP firmware clears the GLQF_FDPIPE_CLR.*DIS_CFG* and GLQF_FDPIPE_CLR.*DIS_FLT* bits, and reports the completion of the clear flow to software.

   Note: At this stage, the PF/VSI is still not enabled yet, as hardware cleared *FD_ENA*(PF) or *FLT_ENA*/*CFG_ENA*/*EVICT_ENA* (VSI) as described at the note in Step 1.
8. The software can re-enable the FD for the VSI/PF by setting the applicable flags:
   - For PF entity, it sets the PFQF_FD_ENA.*FD_ENA* flag.
   - For VSI entity, it sets the *FLT_ENA*, *CFG_ENA*, and *EVICT_ENA* flags in the VSIQF_FD_CTL1 register.

7.10.12.2 QH Table Clearing

7.10.12.2.1 QH Table Clearing Flow

This section describes the flow for clearing the PE QH table for a specific PF/VF.

Note: This flow is not expected to be executed by software, and clearing of the QH filters is done solely by the PE firmware in functional environment. The option for software to clear the QH filters, mentioned in this section is therefore for debug purposes only.

Note: Removing the filters from the FPM is the responsibility of software.

The same flow can also be processed by the PE firmware as part of an internal table removal process. In this case, the instance index #0 for CSRs that appear in this flow should be replaced by instance index #1.

1. The software/firmware sets the following CSR fields:
   - GLQF_PEPIPE_CLR[0].*DIS_FLT*
   - GLQF_PEPIPE_CLR[0].*PE_BUSY*
   - GLQF_PEPIPE_CLR[0].*PF_VF_TYPE* to the *Clear_type* operand value.
   - GLQF_PEPIPE_CLR[0].*PF_VF_NUM* to the *VF_index* operand value.

   Note: As a response to the CSR write, the hardware blocks new search requests and new configuration requests for the entity being cleared by clearing the *PE_ENA* flag in the relevant PF/VPQF_PE_ENA registers.

   Once there are no pending searches and pending configuration requests, the hardware clears the GLQF_PEPIPE_CLR[0].*PE_BUSY* flag. This flow is implemented by initiating a "mini marker" in the post (from extractor input till end of FLU). Following a marker done indication, the *PE_BUSY* flag is cleared.
2. The software/firmware polls the status of GLQF_PEPIPE_CLR[0].*PE_BUSY* flag until it is cleared.

   Note: At this stage, no additional inputs associated with the cleared entity are allowed to enter the pipe and there are no ongoing operations associated with the cleared entity.
3. The software/firmware sets the following CSR fields:
   - GLQF_PETABLE_CLR[0].*PE_CLEAR*
   - GLQF_PETABLE_CLR[0].*PE_BUSY*
   - GLQF_PETABLE_CLR[0].*PF_VF_TYPE* to the *Clear_type* operand value.
   - GLQF_PETABLE_CLR[0].*PF_VF_NUM* to the *VF_index* operand value.

   Note: As a response to the CSR write, the hardware clears the table pointers associated with the cleared function and then clear the GLQF_PETABLE_CLR[0].*PE_BUSY* flag.
4. The software/firmware polls the status of GLQF_PETABLE_CLR[0].*PE_BUSY* flag until it is cleared.

   Note: At this stage, the logical tables holding the QH filters for the cleared function are cleared.
5. The software/firmware clears the filter counters associated to the function being cleared:
   a. For a VF Clear, clear following fields:
      - VPQF_PECNT1[VF_index].*FLTCNT*
      - VPQF_PECNT0[VF_index].*BUCKETCNT*

- VPQF_PE_FLHD[VF_index].*FLHD*

Note: Since VF counter values are not accumulated in the associated PF counter, there is no need to touch the PF counter in that case.

b. For a PF Clear, clear the following associated fields:

- PFQF_PECNT1[PF_index].*FLTCNT*
- PFQF_PECNT0[PF_index].*BUCKETCNT*
- PFQF_PE_FLHD[PF_index].*FLHD*

6. The software/firmware clears the GLQF_PEPIPE_CLR[0].*DIS_FLT* bit.
7. Software steps to re-enable the filter:
   a. Clear the filter entries in the Hash space in the FPM (the Hash space is indicated by PEHSIZE in the Figure 7-33).
   b. Set the PF/VPQF_PE_ENA.*PE_ENA* flags that were cleared in the clear process.

   This step is similar to any PF/VF initialization flow.

7.10.13 Default Extractor Configuration

This section describe the default configuration of the packet profile tables as well as the field vector extraction tables in the NVM.

Note: The device is programmed to the NVM default when the driver does not load any package. Therefore, the configuration described in this section is provided as sample configuration, while the driver might load different configuration package during initialization.

7.10.13.1 Profiles, Field Vector, and Input Sets

Table 7-158 through Table 7-160 show the default setting of the field vector and input set for the FD filter and Hash filter selected by control domain zero. And also the default setting of the PE quad hash filter.

Table 7-158. Default Hash filter Field Vector Configuration

Profile ID	Description	Hash Filter Field Vector	Possible Symmetric Fields
Miss the Filter - Combination of packet types and flags that do no match any profile results with a default profile index.			
0	No Match	None	None
1	Reserved for Bypass the filter	None	None
IPv4 Packets			
2	NonF IPv4, TCP **and** VSIG[2]=0	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
3	NonF IPv4, UDP-(incl. RoCEv2) **and** VSIG[2]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
4	NonF IPv4, Payload/Other **or** Fragmented IPv4 **or** VSIG[2]=1	IP-S, IP-D	IP-S, IP-D
IPv4 Tunneled Packets (fields are inner header fields)			
5	NonF IPv4, TCP **and** VSIG[2]=0	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
6	NonF IPv4, UDP-(incl. RoCEv2) **and** VSIG[2]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D

Table 7-158. Default Hash filter Field Vector Configuration [continued]

Profile ID	Description	Hash Filter Field Vector	Possible Symmetric Fields
7	NonF IPv4, Payload/Other **or** Fragmented IPv4 **or** VSIG[2]=1	IP-S, IP-D	IP-S, IP-D
IPv6 Packets			
8	NonF IPv6, TCP **and** VSIG[1]=0	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
9	NonF IPv6, UDP-(incl. RoCEv2) **and** VSIG[1]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
10	NonF IPv6, Payload/Other **or** Fragmented IPv6 **or** VSIG[1]=1	IP-S, IP-D	IP-S, IP-D
IPv6 Tunneled Packets (fields are inner header fields)			
11	NonF IPv6, TCP and VSIG[1]=0	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
12	NonF IPv6, UDP-(incl. RoCEv2) **and** VSIG[1]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
13	NonF IPv6, Payload/Other **or** Fragmented IPv6 **or** VSIG[1]=1	IP-S, IP-D	IP-S, IP-D

Notes:

- All PTGs above are derivatives of tunneled and non-tunneled packet types. For tunneled packets, it is expected that the OAM flag is inactive. Active OAM will yield "no Match" PTG.
- By default, settings the profiles for the packet types depends on the VSIG(XLT2), as follows:
  - VSIG 0x00 — The filter is not enabled (all packet types Miss).
  - VSIG bit 1 = 1 — IPv6 packets use IP tuples only for hash.
  - VSIG bit 2 = 1 — IPv4 packets use IP tuples only for hash.

  Although the different VSIGs are supported in the NVM, the NVM generate only the VSIG=0x80 case.
- In the hash filters, all fields must be "left shift" in the Input set to comply with Toeplitz RSS hash.

Table 7-159. Default FD Filters Profiles and Key Structure (Loaded from NVM)

Profile ID	PTG(XLT1) and PFLAG_G	FD Filter Key	Possible Swapped Field (FD Filter)
Miss the Filter - Combination of packet types and flags that do no match any profile results with a default profile index.			
0	No Match	None	None
1	Reserved for Bypass the filter	None	None
IPv4 Packets			
2	NonF IPv4, TCP, SYN No ACK **and** VSIG[2]=0 **and** VSIG[3]=0	IP-D, TCP-D	IP-S, IP-D, TCP-S, TCP-D
3	NonF IPv4, TCP **and** VSIG[2] = 0 **or** (NonF IPv4, TCP, SYN **and** VSIG[3]=1)	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
4	NonF IPv4, UDP-(incl. RoCEv2) **and** VSIG[2]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
5	NonF IPv4, ESP **and** VSIG[2]=0 **and** VSIG[0]=0	IP-S, IP-D, SPI	IP-S, IP-D
6	NonF IPv4, SCTP **and** VSIG[2]=0	IP-S, IP-D, SCTP-S, SCTP-D, SCTP-VTag	IP-S, IP-D, SCTP-S, SCTP-D
7	NonF IPv4, Payload/Other **or** VSIG[2]=1 **or** (NonF IPv4, ESP **and** VSIG[0]=1)	IP-S, IP-D	IP-S, IP-D
8	Fragmented IPv4	IP-S, IP-D	IP-S, IP-D
IPv4 Tunneled Packets (fields are inner fields)			
9	NonF IPv4, TCP, SYN No ACK **and** VSIG[2]=0 **and** VSIG[3]=0	IP-D, TCP-D	IP-S, IP-D, TCP-S, TCP-D
10	NonF IPv4, TCP **and** VSIG[2]=0 **or** (NonF IPv4, TCP, SYN **and** VSIG[3]=1)	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D

Table 7-159. Default FD Filters Profiles and Key Structure (Loaded from NVM) [continued]

Profile ID	PTG(XLT1) and PFLAG_G	FD Filter Key	Possible Swapped Field (FD Filter)
11	NonF IPv4, UDP-(incl. RoCEv2) **and** VSIG[2]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
12	NonF IPv4, ESP **and** VSIG[2]=0 **and** VSIG[0]=0	IP-S, IP-D, SPI	IP-S, IP-D
13	NonF IPv4, SCTP **and** VSIG[2]=0	IP-S, IP-D, SCTP-S, SCTP-D, SCTP-VTag	IP-S, IP-D, SCTP-S, SCTP-D

16	NonF IPv6, TCP, SYN No ACK **and** VSIG[1] 0 **and** VSIG[3]=0	IP-D, TCP-D	IP-S, IP-D, TCP-S, TCP-D
17	NonF IPv6, TCP **and** VSIG[1]=0 **or** (NonF IPv6, TCP, SYN **and** VSIG[3]=1)	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
18	NonF IPv6, UDP-(incl. RoCEv2) **and** VSIG[1]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
19	NonF IPv6, ESP **and** VSIG[1]=0 **and** VSIG[0]=0	IP-S, IP-D, SPI	IP-S, IP-D
20	NonF IPv6, SCTP **and** VSIG[1]=0	IP-S, IP-D, SCTP-S, SCTP-D, SCTP-VTag	IP-S, IP-D, SCTP-S, SCTP-D
21	NonF IPv6, Payload/Others **or** VSIG[1]=1 **or** (NonF IPv6, ESP **and** VSIG[0]=1)	IP-S, IP-D	IP-S, IP-D
22	Fragmented IPv6	IP-S, IP-D	IP-S, IP-D
IPv6 Tunneled Packets (fields are inner fields)			
23	NonF IPv6, TCP, SYN No ACK **and** VSIG[1]=0 **and** VSIG[3]=0	IP-D, TCP-D	IP-S, IP-D, TCP-S, TCP-D
24	NonF IPv6, TCP **and** VSIG[1]=0 **or** (NonF IPv6, TCP, SYN **and** VSIG[3]=1)	IP-S, IP-D, TCP-S, TCP-D	IP-S, IP-D, TCP-S, TCP-D
25	NonF IPv6, UDP-(incl. RoCEv2) **and** VSIG[1]=0	IP-S, IP-D, UDP-S, UDP-D	IP-S, IP-D, UDP-S, UDP-D
26	NonF IPv6, ESP **and** VSIG[1]=0 **and** VSIG[0]=0	IP-S, IP-D, SPI	IP-S, IP-D
27	NonF IPv6, SCTP **and** VSIG[1]=0	IP-S, IP-D, SCTP-S, SCTP-D, SCTP-VTag	IP-S, IP-D, SCTP-S, SCTP-D
28	NonF IPv6, Payload/Others **or** VSIG[1]=1 **or** (NonF IPv6, ESP **and** VSIG[0]=1)	IP-S, IP-D	IP-S, IP-D
29	Fragmented IPv6	IP-S, IP-D	IP-S, IP-D
GTP Tunneling			
30	IPv4, GTP-C, TEID	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D
31	IPv4, GTP-C, No TEID	IP-S, IP-D, UDP-S,UDP-D	IP-S, IP-D, UDP-S, UDP-D
32	IPv4, GTP-U, service = 0xFF	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D
33	IPv4, GTP-U, service != 0xFF	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D
34	IPv6, GTP-C, TEID	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D
35	IPv6, GTP-C, No TEID	IP-S, IP-D, UDP-S,UDP-D	IP-S, IP-D, UDP-S, UDP-D
36	IPv6, GTP-U, service = 0xFF	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D
37	IPv6, GTP-U, service != 0xFF	IP-S, IP-D, UDP-S,UDP-D, TEID	IP-S, IP-D, UDP-S, UDP-D

Table 7-159. Default FD Filters Profiles and Key Structure (Loaded from NVM) [continued]

Profile ID	PTG(XLT1) and PFLAG_G	FD Filter Key	Possible Swapped Field (FD Filter)
L2 Packet Types			
38	NSH	Service path header and Index	
39	ARP	TPA	SPA, TPA
40	Other L2 packets	L2 EtherType	

Notes:

- All PTGs above are derivatives of tunneled and non-tunneled packet types. For tunneled packets, it is expected that the OAM flag is inactive. Active OAM will yield "no Match" PTG.
- By default, settings the profiles for the packet types depends on the VSIG(XLT2), as follows:
  - VSIG 0x00 — The filter is not enabled (all packet types Miss).
  - VSIG bit 0 = 1 — Mapping of the packet types other than ESP is according to this table. ESP packets are mapped to IP, Other.
  - VSIG bit 1 = 1 — Use only IP tuples for all IPv6 packets.
  - VSIG bit 2 = 1 — Use only IP tuples for all IPv4 packets.
  - VSIG bit 3 = 1 — Treat TCP/SYN (with/without ACK) packets as TCP packets.

  Although the different VSIGs are supported in the NVM. The NVM generate only the VSIG=0x80 case.
- In the FD filters this is a possible setting but not mandatory for all fields to be "left shifted" in the Input set. In those fields that the mask option is used, it is recommended to locate them in the same location in the Input set for all packet profiles. This way, the mask registers utilization is optimized.

Table 7-160. Default PE Filter Profiles and Input Sets (Loaded from NVM)

Profile ID	PTG and PFLAG_G	PE Filter FV and Input Set	Additional Match Criteria
Miss the Filter - Combination of packet types and flags that do no match any profile results with a default profile index.			
0	No Match	None	None
1	Reserved for Bypass the filter	None	None
TCP iWARP Packets			
2	NonF IPv4, TCP, SYN No ACK (Unicast)	D-MAC+VLAN, IP-D, TCP-D	Packet must match the APBVT to be a candidate for the QH filter. Then, it should match the QH filter to be a candidate for the PE.
3	NonF IPv4, TCP (Unicast)	D-MAC+VLAN, IP-S, IP-D, TCP-S, TCP-D	
4	NonF IPv6, TCP, SYN No ACK (Unicast)	D-MAC+VLAN, IP-D, TCP-D	
5	NonF IPv6, TCP (Unicast)	D-MAC+VLAN, IP-S, IP-D, TCP-S, TCP-D	
UDP Packets			
6	NonF IPv4, UDP, Unicast	D-MAC+VLAN, Dest IP, Dest UDP port	Packet must match the APBVT to be a candidate for the QH filter. Then, it should match the QH filter to be a candidate for the PE.
7	NonF IPv6, UDP, Unicast	D-MAC+VLAN, Dest IP, Dest UDP port	
8	NonF IPv4, UDP, Multicast	D-MAC+VLAN, Dest IP, Dest UDP port	
9	NonF IPv6, UDP, Multicast	D-MAC+VLAN, Dest IP, Dest UDP port	
RoCEv2 Packets			
10	NonF IPv4, UDP-RoCEv2, Unicast	Dest Queue Pair(5)	Packet bypass both APBVT and QH filter.
11	NonF IPv6, UDP-RoCEv2, Unicast	Dest Queue Pair(5)	

Table 7-160. Default PE Filter Profiles and Input Sets (Loaded from NVM) [continued]

Profile ID	PTG and PFLAG_G	PE Filter FV and Input Set	Additional Match Criteria
12	NonF IPv4, UDP-RoCEv2, non-Unicast	D-MAC+VLAN, Dest IP, Dest Queue Pair(5)	Packet bypass the APBVT. It is forwarded to the PE regardless if it matches the QH filter or not.
13	NonF IPv6, UDP-RoCEv2, non-Unicast	D-MAC+VLAN, Dest IP, Dest Queue Pair(5)	

Notes:
- All PTGs above are derivatives of non-tunneled packet types. Tunneled packets would miss all packet profiles.
- By default, settings the profiles for the packet types depends on the VSIG, as follows:
  - VSIG 0x00 — PE is not enabled (all packet types Miss).
  - VSIG bit 0 = 1— TCP packets are enabled.
  - VSIG bit 1 = 1 — UDP (unicast and multicast) are enabled.
  - VSIG bit 2 = 1— Unicast RoCEv2 are enabled.
  - VSIG bit 3 = 1 — Multicast RoCEv2 are enabled.
- The match criteria in this column are set by the GLQF_PE_CTL2 registers per packet profile.
- In case of RoCE the *Queue Pair* field width is 24 bits.
- All "Unicast", "non-Unicast", and "Multicast" notations used in this table relate to the MAC DA.

Note: Whenever a partial field is needed (sub-word), a mask should be applied to mask out the non-relevant bits of the word. There are 16 GLQF_PEMASK registers. Each register contains a mask and the word it can be applied to. There is a GLQF_PEMASK_SEL register per profile. GLQF_PEMASK_SEL selects the set of GLQF_PEMASK registers that are be applied when the associated profile is selected.

7.11 Packages and Configuration

7.11.1 Introduction

A host system initializes many programmable aspects of the E810 packet processing pipeline through the use of AQ commands and **Packages**. A package contains low-level configuration data representing a broad category packet handling. For example, a package can be tailored to match the networking capabilities of a specific operating system.

Packages primarily contain static configuration information applied during initialization, and only one package can be active at a time. Firmware loads an initial package from NVM, which the host can override with a Download Package command. The E810 supports limited runtime alteration of the current package using the Update Package command. For example, a PF driver might use Update Package to add or remove Packet Profiles dynamically.

Packages have names and version numbers according to the Version Numbers convention in Section 7.11.4. The E810 devices are factory-configured with a default package named DEFAULT (case sensitive). By using the version number, the host can check for driver vs. package compatibility.

A package is a composite of smaller, often interdependent data structures, each mapping to a specific hardware block. A package provides the means to keep these interdependent structures and associated metadata together as an intact unit. For example, a package might contain configuration data for both the Parse Graph CAM and Parser Instruction Memory.

Off-line compiler tools typically produce packages. At runtime, the host can dynamically create package updates to alter the configuration of the current package. In either case, the data structures follow the format specified in this section.

7.11.2 Overriding the Default Package

Using the Download Package command (Section 7.11.9.1), the host system can override the default package loaded from NVM by firmware. The Download Package command changes the configuration of the packet processing pipeline, but does not modify the NVM. A subsequent Core Reset, Global Reset, or power cycle causes firmware to reload the default package and therefore discard the host's custom package. In this case, the host must re-issue another Download Package command.

In the pre-boot environment, the host operating system has not yet loaded and has no opportunity to override the default package. Deployment of a custom package in the pre-boot environment requires either a custom NVM image or host BIOS to issue the Download Package command.

7.11.3 Endianness

Unless otherwise specified, all values in a package use little-endian memory layout. When serialized to a storage device, bytes are placed starting from lowest address to highest address. See Table 7-161.

Table 7-161. Little-Endian Memory Layout for All Value Fields

31 24	23 16	15 8	7 0	Byte Offset
char 15 (Highest Address)	char 14	char 13	char 12	12
int 0				8
short 1		short 0		4
char 3	char 2	char 1	char 0 (Lowest Address)	0

7.11.4 Version Numbers

To convey version and compatibility information, packages use the Major.Minor.Update.Draft (M.m.u.d) convention described in this section.

Consider a hypothetical version 3.0.1.4

Table 7-162. Version Number Fields for Example Version 3.0.1.4

Digit	Name	Description
3	Major	The most significant version number. Configurations with differing Major version numbers might not be compatible with each other.
0	Minor	Within a Major version, the Minor version number indicates compatibility with less-then-or-equal Minor version numbers. A new Minor version number often indicates the addition of new features.
1	Update	A bug fix or refactoring for an existing Major.Minor version.
4	Draft	For internal use only and used to distinguish developmental versions. Shipping configurations should always have a 0 Draft digit.

Each part of the version number is stored in a byte, for a total of four bytes. When stored in memory, the Major number resides in the lowest address byte up to Draft number in the highest address byte. Version numbers are stored as unsigned integer bytes, not as UTF-8 characters. See Table 7-163 for an example.

Table 7-163. Version Number Encoding for Example Version 3.0.1.4

Address	Value	Description
0x1000	0x03	Major
0x1001	0x00	Minor
0x1002	0x01	Update
0x1003	0x04	Draft

7.11.5 Package Format

A package contains a nested hierarchy of structures. In the outermost layer, the package contains an 8-byte fixed-length Package Header. The Package Header contains a version number for the format of the package itself, and a field specifying the number of segments contained in the package. Following those fields, a Segment Table provides the byte offset from the start of package file to each segment in the file. See Figure 7-34.

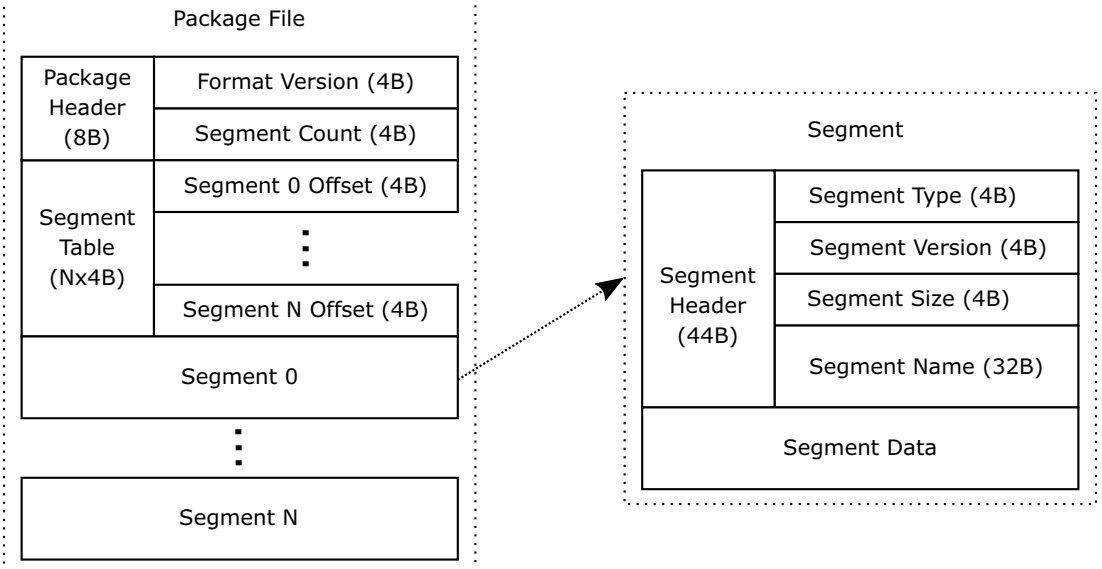

Figure 7-34. Basic Structure of a Package

Each Segment begins with a Segment Header, followed by segment specific data. Segments can contain any amount of data as appropriate for the specified Segment Type.

Table 7-164 describes each field of the Package Header in detail. The Segment Table is sorted from smallest to largest Segment Offset value. All segments start with the Segment Header as shown in Figure 7-34.

Table 7-164. Package Header

Field		Size (Bytes)	Offset	Description
Package Format Version		4	0	M.m.u.d style format for the package itself. The version number follows the convention described in Section 7.11.4. This document describes package format 1.0.1.0.
Segment Count		4	4	Number of segments in the segment table. A value of 0 is reserved.
Segment Table	Segment 0 Offset	4	8	Byte offset from the start of the package file to the first byte of the first segment. Values less than 12 are reserved.
	...			Offsets of all subsequent segments. The Segment Table is sorted from smallest to largest offset, so each Segment Offset value must be at least 44 bytes (Segment Header size) greater than the previous offset.

Table 7-165 describes the fields of the Segment Header in detail.

Table 7-165. Segment Header

Field	Size (Bytes)	Offset	Description
Segment Type	4	0	Type value identifying this segment.
Segment Format Version	4	4	M.m.u.d style format for the package itself. The version number follows the convention described in Section 7.11.4.
Segment Size	4	8	Size in bytes of this segment, including the Segment Header. Values less than 44 bytes are reserved.
Segment Identifier	32	12	Free form (UTF-8 by convention) null-terminated 31-byte name of the segment. The 32nd byte of the name must be a binary 0.

Table 7-166 defines Segment Type numbers relevant to the E810.

Table 7-166. Segment Type Numbers

Segment Type Number	Description	Section Reference
0x0	Reserved	
0x1	Global Metadata Segment	7.11.5.1
0x2	Package Notes Segment	7.11.5.2
0x3-0xF	Reserved	
0x10	E810 Configuration Segment	7.11.5.3

7.11.5.1 Global Metadata Segment

The Global Metadata Segment contains information about the entire package.

Table 7-167 describes the fields of the Global Metadata Segment in detail.

Table 7-167. Global Metadata Segment

Field		Size (Bytes)	Offset	Description
Segment Header	0x00000001	4	0	This segment has a Type value of 1.
	0x00000001	4	4	This document describes Version 1.0.0.0 of this segment.
	0x00000054	4	8	This segment has a length of 84 bytes.
	"Global Metadata"	32	12	This segment has case sensitive name "Global Metadata" without the quote characters. Bytes after the string are padded with binary 0 to full 32-byte length.
Segment Data	Package Version	4	44	Version of the entire Package file as specified by a *version* statement at global scope in an assembly source file. Software tools can use 255.255.255.255 as a reserved value meaning the version is unknown.
	Reserved	4	48	This value is reserved for the E810 and newer devices.
	Package Name	32	52	Free form (UTF-8 by convention) null-terminated 31-byte name of the entire package as specified by a *name* statement at global scope in an assembly source file. Software tools reserve a zero length string (first byte is binary 0) to mean the name is unknown. Software tools always set the 32nd byte of the name to a binary 0.

7.11.5.2 Package Notes Segment

The Package Notes Segment contains free form UTF-8 text about this package. The content of the notes segment is informational only. The notes segment does not affect the configuration of any hardware device.

Table 7-168 shows the content of the Package Notes Segment.

Table 7-168. Package Notes Segment

Field		Size (Bytes)	Offset	Description
Segment Header	0x00000002	4	0	This segment has a Type value of 2.
	0x00000001	4	4	This document describes Version 1.0.0.0 of this segment.
	<variable>	4	8	This segment has variable length.
	"Notes"	32	12	This segment has case sensitive name "Notes" without the quote characters. Bytes after the string are padded with binary 0 to full 32-byte length.
Segment Data	UTF-8 content	<variable>	44	UTF-8 text for informational purposes only. Line feed style is '\n'. The final note in the notes segment always ends with '\0'.

7.11.5.3 E810 Configuration Segment

Configuration data for the E810 resides in the E810 Configuration Segment with Segment Type value 0x10. Figure 7-35 shows an overview of this segment.

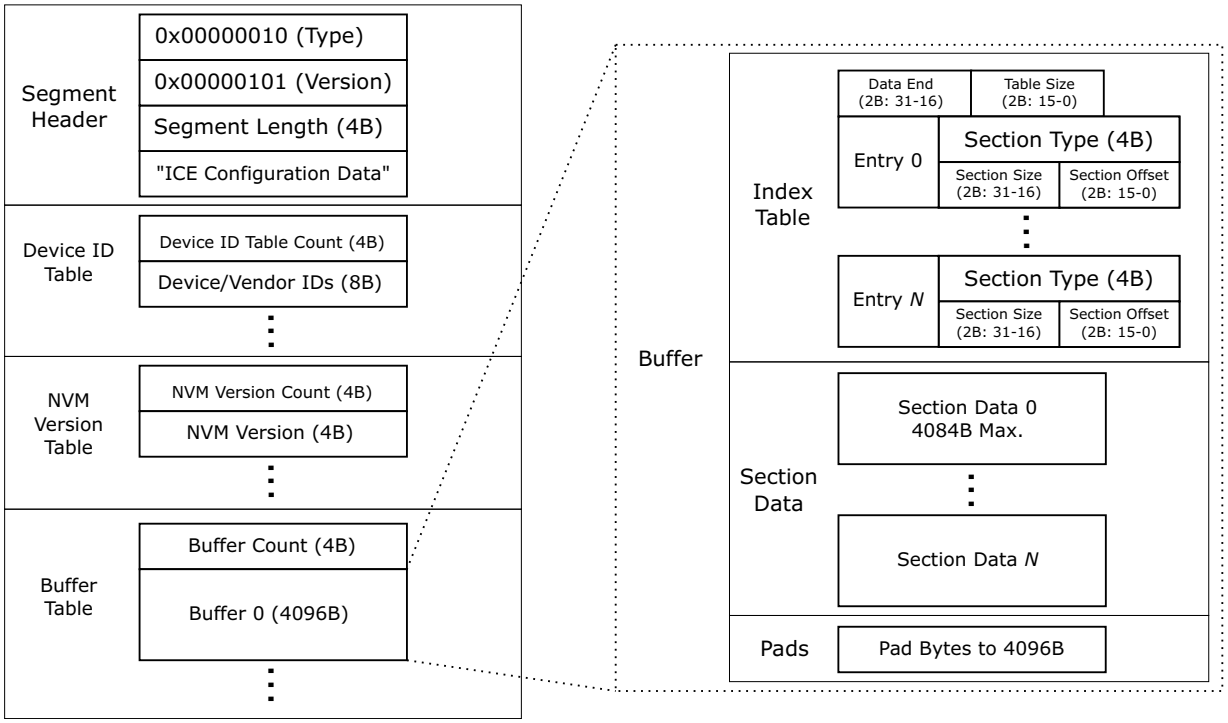

Figure 7-35. Overview of the E810 Configuration Segment

Table 7-169 shows the layout of this segment.

Table 7-169. E810 Configuration Segment

Field		Size (Bytes)	Description
Segment Header	0x00000010	4	This segment has a Type value of 0x10.
	0x00000001	4	This document describes Version 1.0.1.0 of this segment.
	<variable>	4	This segment has variable length.
	"ICE Configuration Data"	32	This segment has case sensitive name "ICE Configuration Data" without the quote characters. Bytes after the string are padded with binary 0 to full 32-byte length. For the version field specified by assembly language source code, see Section 7.11.7.

Table 7-169. E810 Configuration Segment [continued]

Field		Size (Bytes)	Description
Device ID Table	Device ID Table Count	4	Number of entries in the Device ID Table. May be zero.
	Device ID Table Entry 0	8	Device ID Table Entry consisting of two 4-byte fields. **Bytes 1-0:** Device ID PCI Device ID number of a device for which this configuration data applies. **Bytes 3-2:** Vendor ID PCI Vendor ID number of a device for which this configuration data applies. **Bytes 5-4:** Sub-Device ID PCI Sub-Device ID number of a device for which this configuration data applies. **Bytes 7-6:** Sub-Vendor ID PCI Sub-Vendor ID number of a device for which this configuration data applies.
	...	Nx4	All subsequent Device ID Table entries
NVM Version Table	NVM Version Count	4	Number of entries in the NVM version table. Maybe 0 if the table contains no entires.
	NVM Version Entry 0	4	NVM Version information. Details TBD.
	...		All subsequent NVM Version Table entires.
Buffers	Buffer Count	4	Number of 4KB buffers in this segment.
	Buffer 0	4096	First buffer in the segment
	...		All subsequent 4 KB buffers.

7.11.5.4 Package Buffers

A package contains one or more fixed-length Package Buffers. A Package Buffer contains a header, followed by a variable number of configuration data sections, followed by pad bytes for a total fixed size of 4096 bytes. As shown in Figure 7-34, a Package Buffer begins with a Package Buffer Header. The Package Buffer Header contains an *Index Table Size* field, a *Data End* field, and a variable length Index Table. Following the Index Table, the data for each section contained in the Package Buffer.

Table 7-170 shows the format of the Package Buffer Header.

Table 7-170. Package Buffer Header

Field	Size (Bytes)	Offset	Description
Index Table Size	2	0	Number of entries in the Index Table (1-511). A value of zero and values greater than 511 are reserved.
Data End	2	2	Byte offset from the start of the Package Buffer to the first unused byte in the buffer (12-4095). The minimum valid value of this field is 12, which accommodates the 4-byte Buffer Header and one 8-byte Index Table entry. If the entire buffer is used, this field must be set to 4096. Values less than 12 or greater than 4096 are reserved.

Table 7-170. Package Buffer Header [continued]

Field		Size (Bytes)	Offset	Description
Entry 0	Section Type	4	4	Section Type for the first section in the Package Buffer. Valid Section Type values are shown in Table 7-171.
	Section Offset	2	8	Byte offset from the start of the Package Buffer to the start of the first section in the Package Buffer (12-4095). Values less than 12 and greater than 4095 are reserved. The section offset for each entry in the index table must be aligned on a 32-bit boundary. All sections whose size is not a multiple of four bytes must be followed by pad bytes of 0xFF to the next 4-byte multiple.
	Section Size	2	10	Size in bytes of this section (1-4084). Values of zero and greater than 4084 are reserved. The section size must exclude any pad bytes added to acquire 32-bit alignment.
...	...	...	...	Subsequent Index Table entries, if any.

A Package Buffer can contain one or more Data Sections and these sections can appear in any order in the buffer. The format of a Data Section depends on the nature and purpose of the contained configuration data. The maximum possible size of a Data Section is 4084 bytes, which can occur when a Package Buffer contains only one section.

7.11.6 Section Type Enumeration

As described in Section 7.11.5, the Index Table field of the E810 Configuration Segment identifies the content, location and size of individual configuration sections. To unambiguously identify section content, the Section Type field provides a unique identifier for all possible content types.

Table 7-171 shows the Section Type values.

Table 7-171. E810 Configuration Segment Section Type Numbers

Table 7-172. Section Details and Sizes [continued]

Section	Maximum Number of Instances	Fixed Header Size (Bytes)	Entry Size (Bytes)	Number of Entries	Section Size (Bytes)	Owner Section Size (Bytes)[1]	Maximum Total (Bytes)
Flags Redirection	2	4	1	64	68	0	136
						Total:	**473142**

1. Owner section size of 0 indicates that the section cannot be modified with an Update Package command.

7.11.7 Segment Metadata Section

The E810 Configuration Segment Metadata Section contains user defined metadata about the segment. This section has a Section Type value of 1. The Get Package Info List command (see Section 7.11.9.4) returns the information contained in this section.

The structure of this section is shown in Table 7-173.

Table 7-173. Segment Metadata Section

Field	Size (Bytes)	Description
Segment Version	4	The version of the segment. The version number follows the convention defined in Section 7.11.4 Software tools set this value from the version statement in an assembly language source file. Software tools can reserve the value 255.255.255.255 to mean the version is unknown.
Segment Name	32	Free form UTF-8 null-terminated 28-byte name of the segment. Software tools set this value from the name statement in an assembly language source file. Software tools can reserve a zero length string (first byte is binary 0) to mean the name is unknown. Software tools enforce that at least the 28th byte of the name must be a binary 0.
Track ID	4	The Track ID is a numerical representation of the package type and uniquely identifies the type of package as specified by a track statement at segment scope in an assembly source file. The Track ID and package name are immutable for each package type; OS, Comms, etc. Software tools can use 0xFFFFFFFF as a reserved value meaning the Track ID is unknown.

7.11.8 Segment Security Manifest

This section defines the structure of the ICE Segment Security Manifest. This manifest enables firmware or other software to verify selected segment buffers are genuine before transferring configuration to control registers.

7.11.8.1 Security Manifest Overview

The segment security manifest consists of two parts.

- An ordered list of secure hashes, one for each 4 KB buffer in the remainder of the segment.
- The PKCS v2.2 structure returned from the signing server. This structure contains a signature, a manifest hash of the buffer hashes and the security version number.

The chain of trust for downloaded package buffers is as follows:

- Firmware verifies the manifest hash using the Intel RSA signature.
- Firmware verifies the list of buffer hashes using the manifest hash.

- Firmware verifies each buffer using corresponding buffer hash.

The error messages that are issued when firmware detects an issue in the security manifest are as follows:

- **Missing security manifest** — Return missing signature error on AQ command. Firmware should not issue CORER.
- **RSA signature mismatch on the manifest hash** - Return bad signature error on AQ command. Firmware should not issue CORER.
- S**ecure Version Number too low** — Return bad SVN error on AQ command. Firmware should not issue CORER.
- **Manifest hash mismatch on the buffer hashes** — Return bad manifest error on AQ command. Firmware must issue CORER.
- **Buffer hash mismatch on the buffer** — Return bad buffer hash error on AQ command. Firmware must issue CORER.
- **Non-security error in buffer processing** — Return appropriate error on AQ command. Firmware must issue CORER.

7.11.8.2 Protection Provided by a Segment Security Manifest

A segment security manifest provides a limited scope of protection within a package file. Specifically, the security manifest protects only parts of the ICE segment, not the entire segment nor package. The parts of a package not covered by a security segment rely on host security for protection, for example, file system root access. The rationale is that a corrupted host cannot be trusted to check itself, therefore a security manifest can protect only the buffers visible to firmware. See Table 7-174 for an overview.

Table 7-174. Content Protected or Excluded by a Segment Security Manifest

Package Content Type	Protected?
Package Header	No
Package Notes Segment	No
Package Global Metadata Segment	No
Segment Header	No
Other device configuration segments	No
Segment buffers transferred to firmware with Download Package AQ command	Yes
Segment buffers NOT transferred to firmware. (or example, segment metadata)	No

7.11.8.3 Segment Security Requirements

Production packages downloaded by the host via the Download Package AQ command must have a valid security manifest in the ICE configuration segment. Non-production packages might have a valid or invalid security manifest.

7.11.8.3.1 Development Mode

To facilitate package development, firmware must support a permissive mode that bypasses security manifest checking. In this mode, the downloaded package might omit the security manifest. If the package contains a security manifest, firmware must ignore the manifest content.

Table 7-175 shows the security enforcement options. These options depend on the CSR protection fuse and the NVM *Security Enable* bit.

Table 7-175. Package Manifest Enforcement Options

CSR Protection Enable (GL_UFUSE_SOC[6])	NVM_SEC_EN (NVM Offset 0x02)	Firmware Requires Valid Package Security Manifest
0	0	No
0	1	Yes
1	0	Yes
1	1	Yes

7.11.8.3.2 NVM Packages

The ICE NVM signature already provides protection for the packages stored in NVM. To conserve NVM storage, these package should omit the security manifest. If an NVM package does contain a security manifest, firmware must ignore the manifest content.

7.11.8.4 Security Manifest Section Numbers

Table 7-176 provides section numbers associated with the security manifest:

Table 7-176. Security Manifest Section Numbers

Section	Number
Security Manifest Header	2 (0x2)
Security Manifest	3 (0x3)

7.11.8.5 Security Manifest Header Section

The manifest header section consists of the PKCS v2.2 structure.

Table 7-177. Security Manifest Header Section Fields

Field	Size (Bits)	CSR	Description
Module Type	32	N/A	The module type. Must be 0x6.
Header Length	32	N/A	The header length. Must be 0xA1.
Header Version	32	N/A	The header version. Must be 0x000100000.
Module ID	32	N/A	The module ID. Must be 0x0.
Module Vendor	32	N/A	The vendor ID. Must be 0x8086.
Date	32	N/A	The date on which the signature was created.
Size	32	N/A	The number of 32-bit (DWORD) units. Must be 0xC8.

Table 7-177. Security Manifest Header Section Fields [continued]

Field	Size (Bits)	CSR	Description
Key Size	32	N/A	The size of the key. Must be 0x40.
Modulus Size	32	N/A	The modulus size. Must be 0x40.
Exponent Size	32	N/A	The size of the exponent. Must be 0x1.
SVN	32	N/A	Secure version number. This monotonically increasing number represents the security version of this package. If this number is less than the persistent SVN number stored in the NVM, then firmware will reject this package. Otherwise, firmware accepts the package.
Reserved	32	N/A	Reserved (0).
Reserved	32	N/A	Reserved (0).
Reserved	32	N/A	Reserved (0).
Unique ID	32	N/A	Unique ID of this configuration, taken from the support team ETrack ID.
Segment Type	16	N/A	The segment type. 0x10 for the ICE configuration segment.
Reserved	16	N/A	Reserved (0).
Reserved	512	N/A	Reserved (0).
Public Key Modulus	2048	N/A	The public key. The signing server generates the content of this field.
RSA Exponent	32	N/A	RSA Exponent used for the signature calculation. The signing server generates this field.
Signature	2048	N/A	The signature created by the signing server. The signature served must be passed the security manifest section header section only for signing.
Reserved	128	N/A	Reserved area used by the signing server.
Manifest Hash	256	N/A	The SHA-256 of the two buffers containing the security sections.
Reserved	864	N/A	Reserved (0).

7.11.8.6 Security Manifest Section

A manifest section contains SHA256 hash values corresponding to each buffer downloaded to firmware in the segment. Package build tools must place each hash value in the manifest section in the same order as the corresponding configuration buffer. A buffer containing a manifest section must not contain any other type of section.

Table 7-178 shows the format of a manifest section:

Table 7-178. Security Manifest Section Fields

Field	Size (Bits)	CSR	Description
Count	16	N/A	Number of SHA256 hashes in this section. Valid values are 0-127.
Offset	16	N/A	Offset to the first hash in this section.
Hash0	256	N/A	SHA256 hash corresponding to a 4 KB download package buffer.
...	Nx256	N/A	All other SHA256 hashes in this section.

7.11.8.7 Security Manifest Section Location in the ICE Segment

Package build tools must place security manifest sections before any other section downloaded to firmware. Specifically section 2 must be the first section, followed by exactly two section 3's. These sections occupy the first 4 KB buffers downloaded to firmware. In the package, build tools can place sections not downloaded to firmware before security manifest sections.

7.11.9 Package Configuration Admin Commands

7.11.9.1 Download Package Command (0x0C40)

This section specifies the Download Package AQ command. This command configures the packet processing pipeline, overwriting the previous configuration. During initialization, the host can issue multiple Download Package commands, each containing one Package Buffer, until package download completes. The host sets the *Last Buffer* Flag in the command descriptor for the last Download Package command of the sequence. The host must hold the Global Configuration Lock resource using the Request Resource Ownership Admin command (Section 9.5.13.6) to issue this command.

Table 7-179. Download Package Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C40	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return value. Cleared by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Flags	16		**Bit 0:** Last Buffer When set, this Download Package command is the last in the sequence. All other bits reserved.
Reserved	17-23		Reserved.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

Table 7-180. Download Package Command Buffer Format

Field	Size (Bytes)	Description
Package	12-4096	Package Buffer as defined in Section 7.11.5.4.

Table 7-181. Download Package Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C40	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return code written by firmware. In the case of a failure, the existing configuration is unmodified. SUCCESS = Package download succeeded. EFAULT = *Data Address* field was 0. ENOMEM = Insufficient hardware resources exist to perform this configuration. EINVAL = An element within the package data was invalid. *Error Offset* contains the byte offset into the package data of the invalid element. *Error Info* contains an additional error code describing the problem with the element. EACCES = Attempt to overwrite the default package. ENOSEC = Missing security manifest. EBADSIG = Bad RSA signature. ESVN = SVN number prohibits usage of this package. EBADMAN = Manifest hash mismatch. EBADBUF = Buffer hash mismatches expected value in manifest.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Error Offset	16-19		Offset to an invalid element detected by firmware in the downloaded package. Firmware sets this field to zero on success.
Error Info	20-23		Contains a code for additional error information that describes the nature of the problem found, if any. Firmware sets this field to zero on success.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

7.11.9.2 Upload Section Command (0x0C41)

This section specifies the Upload Section AQ command. This command retrieves hardware configuration for requested sections. The host can optionally acquire the Change Lock before issuing this command. Holding the Change Lock is not required, but guarantees that returned section data is not a partially modified state due to Update Package commands from another PF. This command is read-only and does not modify the current hardware configuration.

Table 7-182. Upload Section Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C41	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return value. Cleared by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Reserved	16-23		Reserved.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

Table 7-183. Upload Section Command Buffer Format

Field	Size (Bytes)	Description
Package	12-4096	Package Buffer as defined in Section 7.11.5.4.

Table 7-184. Upload Section Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C41	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return code written by firmware. SUCCESS = Section upload succeeded. EFAULT = *Data Address* field was 0. EINVAL = Unrecognized Section Number. ERANGE = Invalid Section Offset.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Reserved	16-23		Reserved.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

7.11.9.3 Update Package Command (0x0C42)

This section specifies the Update Package AQ command. This command modifies the configuration of the packet processing pipeline without erasing the existing configuration. The host can issue multiple Update Package commands, containing one Package Buffer each, until pipeline configuration update is complete. The host must hold the Global Configuration Lock or the Change Lock resources using the Request Resource Ownership Admin command (Section 9.5.13.6) to issue this command.

The AQ command format for this command is almost identical to the Download Package command (Section 7.11.9.1).

Table 7-185. Update Package Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C42	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return value. Cleared by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Flags	16		**Bit 0:** Last Buffer When set, this Update Package command is the last in the sequence. All other bits reserved.
Reserved	17-23		Reserved.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

Table 7-186. Update Package Command Buffer Format

Field	Size (Bytes)	Description
Package	12-4096	Package Buffer as defined in Section 7.11.5.4.

Table 7-187. Update Package Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0C42	Command opcode.
Data Length	4-5	28-4096	Length of command/response buffer. Varies depending on package content.
Return Value/VFID	6-7		Return code written by firmware. In the case of a failure, the existing configuration is unmodified. SUCCESS = Package download succeeded. EFAULT = *Data Address* field was 0. ENOMEM = Insufficient hardware resources exist to perform this configuration. EINVAL = An element within the package data was invalid. *Error Offset* contains the byte offset into the package data of the invalid element. *Error Info* contains an additional error code describing the problem with the element. EACCES = Attempt to overwrite the default package.

Table 7-187. Update Package Response [continued]

Name	Byte.Bit	Value	Remarks
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Error Offset	16-19		Offset to an invalid element detected by firmware in the downloaded package. Firmware sets this field to zero on success.
Error Info	20-23		Contains a code for additional error information that describes the nature of the problem found, if any. Firmware sets this field to zero on success.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

7.11.9.4 Get Package Info List Command (0x0C43)

This command populates a host buffer with information about the currently installed packages. The package information structure is defined in the Response Buffer table. This command blocks until no other driver holds the Change Lock nor the Global Configuration Lock. This command does not block when called by the driver currently holding the Change or Global Configuration lock. Firmware can return zero or more Package Info structures in the response buffer. Firmware returns zero Package Info structures when NVM does not contain any packages.

The information returned in by this command corresponds to the content of Section 1 within the E810 Configuration Segment (see Section 7.11.7).

Table 7-188. Get Package Info List Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0C43	Command opcode.
Data Length	4-5	4096	Length of command/response buffer.
Return Value/VFID	6-7		Return value. Cleared by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion descriptor for this command.
Reserved	16-23		Reserved.
Data Address High	24-27		Host memory address of the command buffer.
Data Address Low	28-31		

Table 7-189. Get Package Info List Command Response Buffer Format

Field	Size (Bytes)	Description
Count	4	Number of Package Info structures returned in this buffer.
Package Info Array	Variable	Packed array of Package Info structures. Table 7-190 shows the format of a Package Info structure.

Table 7-190. Package Info Structure

Field	Size (Bytes)	Description
Version	4	M.m.u.d version of this package as specified in Section 7.11.4.
Name	32	Free form (null terminated UTF-8 by convention) 32-byte name of the package. The 32nd byte of the name is always a binary 0. The Intel factory default package will have the name 'DEFAULT' padded with zeros to 32-byte length.
Is In NVM	1	1 if this package is stored in NVM. 0 otherwise.
Is Active	1	1 if this package is currently active (that is, able to process packets). 0 otherwise.
Is Active At Boot	1	1 if firmware enables this package automatically at boot time. 0 otherwise. This flag is always 0 if Is In NVM is 0.
Is Modified	1	1 if the host modified this package with an Update Package command. 0 otherwise.

7.11.10 Uniform TCAM Key Encoding

Some sections define the content of Ternary Content Addressable Memories (TCAMs). In addition to matching an input of 0 or 1, TCAM keys also define don't care and invalid input conditions. All TCAM keys use a key/key-invert encoding to represent the four input conditions, as show in Table 7-81, "Key and Key Invert Programming Effect".

The key is arranged as a sequence of key and key invert, as follows:

(key_invert << key.size()) | (key)

Tools must enforce that only a single invalid input bit (~) can be used in a TCAM key.

The TCAM keys must be encoded as described in Table 7-81.

7.11.10.1 Example 1

A 3-bit input value of 'b10? is represented in the TCAM with key=011 and key invert of 101. The key matches two possible binary input values 100 and 101.

7.11.10.2 Example 2

A 3-bit input value of 'b10~ is represented in the TCAM with key=010 and key invert=100. The key matches no input values due to the never-match condition in bit 0.

7.11.11 Ownership Configuration

The package can explicitly designate ownership of specific hardware resources. Firmware can use this ownership information to enforce correct runtime behavior. For example, firmware can prevent PF3 from issuing an Update Package command that alters a hardware resource belonging to PF1.

Ownership information for a package is contained in dedicated ownership sections. The host can download ownership sections only in a Download Package command. Ownership sections are not allowed in an Update Package command. Therefore, resource ownership is static and cannot be modified at runtime. The Host can retrieve ownership information using the Upload Section command.

The Section Type Number for ownership metadata is the Section Type Number of the resource itself plus 0x200. Table 7-171.

All ownership sections use a common format. The section number defines the specific hardware resource to which the ownership applies. Table 7-191 shows the format of an ownership section.

The package must specify ownership for any resource that cab be modified at runtime with an Update Package command (for example, for UDP tunnel configurations).

A package can omit an ownership section. In this case, the default policy to deny write-access applies to the corresponding hardware resource.

An ownership section can omit leading and trailing entries in the range of resources covered. For example, a hardware resource with 1024 entries can have an ownership section that defines only entries 100 to 200.

A package can contain multiple ownership sections for the same hardware resource. In the case of a conflict in ownership, the last section downloaded takes precedence.

Table 7-191. Package Format for Ownership Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Reserved	2	Reserved (0).
Starting Resource Number	4	A resource number appropriate for the corresponding hardware. The exact meaning of this number depends on the section number: CAM, TCAMs, BICAMS, TABLES: Resource number is the address. For example, ownership for a TCAM with 192 entries will have Resource Numbers 0-191. IMEM: Resource number is the IMEM address
Owner 0	1	Owner for this resource. Owners values are defined as follows: 0-7 = Write access allowed for a specific PF 0-7 8 = Global 9 = Unmanaged 10 = Shared (writable by any PF after allocation) 11-254 = Reserved 255 = Unspecified (access denied to any PF)
All other Entries	Nx1	Subsequent consecutive owner values. The Resource Number for each consecutive owner is the previous Resource Number plus one.

The specific behavior of each allocation type is shown in Table 7-192.

Table 7-192. Resource Ownership Types and Behavior

	PF# (0-7)	Global (8)	Unmanaged (9)	Shared[1] (10)	Unspecified
Description	Dedicated to a specific PF	Read-only resource available globally	The resource ownership is not managed by the firmware.	Any PF can allocate as shared or private	Package did not specify an owner
PF Allocate	No	No	No	Yes, by each owner	No
PF Release	No	No	No	Yes, last release returns resource to a free pool	No
PF Read Access	By owner	Yes by any PF	By any owner	By any owner	No

Table 7-192. Resource Ownership Types and Behavior [continued]

	PF# (0-7)	Global (8)	Unmanaged (9)	Shared[1] (10)	Unspecified
PF Write Access	By owner	No	By any owner	By any owner	No
Firmware Tracking	Static	Static	No tracking	Dynamic tracks all owners	None
Firmware Cleanup	PFR, CORER	CORER	CORER	On last release, PFR - PF related settings only, CORER	None

1. A shared owner can be assigned only for Profile ID TCAM (sections 0x20E, 0x218, 0x222, 0x22C, 0x254) and the Field Vector Table (sections 0x210, 0x21A, 0x224, 0x22E 0x256).

7.11.12 Common Packet Profile Commands

7.11.12.1 Introduction

Packets proceed down the pipeline accompanied by a variety of metadata, such as the packet type produced by the parser. Pipeline blocks use this metadata to help determine how to process the packet.

As-is, the metadata can be inconvenient or insufficient to directly control block behavior. For proper processing, each pipeline block contains a mechanism to map metadata to block specific Profile IDs. Each block uses its own unique Profile ID enumeration to precisely control packet processing.

Each block defines its own unique Profile IDs, but all blocks share a common methodology for this configuration. As described in this section, the E810 uses a common set of commands to define the Profile ID mappings for each block.

Configuration of Profile IDs can occur in three ways:

- As part of the initialization package loaded by firmware from NVM.
- As part of an initialization package provided by the host via the Download Package AQ command.
- Runtime configuration by the host.

7.11.12.2 Package Buffer Formats

This section specifies the format of package buffers related to Profile ID configuration.

7.11.12.2.1 Package Format for CDID Key Builder Tables

This section specifies the package format of the per-block CDID Key Builder Tables. These tables select metadata fields used as input in to the Control Domain ID table (XLT0).

Table 7-193 shows the section type enumeration.

Table 7-193. Package Section Type Numbers for CDID Key Builder Tables

Section Type Number	Allowed in Update Package?	Description
17	No	CDID Key Builder Table for the Switch.
27	No	CDID Key Builder Table for the ACL.

Table 7-193. Package Section Type Numbers for CDID Key Builder Tables [continued]

Section Type Number	Allowed in Update Package?	Description
37	No	CDID Key Builder Table for the Flow Director.
47	No	CDID Key Builder Table for RSS.
87	No	CDID Key Builder Table for PE.

Table 7-194 shows the format of the CDID Key Builder Table for each block.

Table 7-194. Package Buffer Format for the CDID Key Builder Table

Field	Size (Bytes)	Description
Direction Select Flag 0	2	Index of the first flag used to define the direction. Valid values are 0-511. Value of 0xFFFF is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. The value in this field corresponds to an individual bit from any metadata field with metadata ID in range 0-31. For example: Direction Select 0-15 selects bit 0-15 of Metadata ID 0. Direction Select 16-31 selects bit 0-15 of Metadata ID 1. Direction Select 32-47 selects bit 0-15 of Metadata ID 2. and so on up to Metadata ID 31. Relevant CSR: GL_<block>_FLGS_L1SEL0_1[8:0] When no direction flags are used, software tools write a zero to this field.
Direction Select Flag 1	2	Index of the second flag used to define the direction. Valid values are 0-511. Value of 0xFFFF is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. Values are defined in same manor as Direction Select Flag 0. Relevant CSR: GL_<block>_FLGS_L1SEL0_1[24:16] When no direction flags are used, software tools write a zero to this field.
Direction Select Flag 2	2	Index of the third flag used to define the direction. Valid values are 0-511. Value of 0xFFFF is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. Values are defined in same manor as Direction Select Flag 0. Relevant CSR: GL_<block>_FLGS_L1SEL2_3[8:0] When no direction flags are used, software tools write a zero to this field.
Direction Select Flag 3	2	Index of the fourth flag used to define the direction. Valid values are 0-511. Value of 0xFFFF is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. Values are defined in same manor as Direction Select Flag 0. Relevant CSR: GL_<block>_FLGS_L1SEL2_3[24:16] When no direction flags are used, software tools write a zero to this field.
Direction Select	4	This 32-bit value creates a bit mapping that produces the Dir[1:0] direction control. This field is partitioned into two 16-bit values as follows: [15:0] = These bits provide a 4-bit to 1 mapping to produce Dir[0]. The four flag bits selected above create an index value (0-15) selecting one bit of this [15:0] range. [31:16] = These bits provide a 4-bit to 1 mapping to produce Dir[1]. The four flag bits selected above create an index value (0-15) selecting one bit of this [31:16] range. Relevant CSR: GL_<block>EXT_FLGS_L1TBL[31:0] When no direction flags are used, software tools write a zero to this field.

Table 7-194. Package Buffer Format for the CDID Key Builder Table [continued]

Field	Size (Bytes)	Description
Metadata Rx Select (DIR=0)	1	This field specifies the Metadata ID value used to select the MD0 input into XLT0 for Receive (Rx) traffic or for all traffic when the XLT0 Partition Mode field is 0. Valid values are 0-31. Value of 0xFF is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. Relevant CSR: GL_<block>_CDMD_L1Sel[4:0]
Metadata Tx Select (DIR=1)	1	This field specifies the Metadata ID value used to select the MD0 input into XLT0 for Transmit (Tx) traffic. Valid values are 0-31. Value of 0xFF is reserved for internal use by assembler tools before conversion to a valid value or when the XLT0 Partition Mode field is 0. All other values are reserved. Relevant CSR: GL_<block>_CDMD_L1Sel[12:8]
Metadata Aux0 Select (DIR=2)	1	This field specifies the Metadata ID value used to select the MD0 input into XLT0 for Aux0 traffic. Valid values are 0-31. Value of 0xFF is reserved for internal use by assembler tools before conversion to a valid value or when the XLT0 Partition Mode field is 0. All other values are reserved. Relevant CSR: GL_<block>_CDMD_L1Sel[20:16]
Metadata Aux1 Select (DIR=3)	1	This field specifies the Metadata ID value used to select the MD0 input into XLT0 for Aux1 traffic. Valid values are 0-31. Value of 0xFF is reserved for internal use by assembler tools before conversion to a valid value or when the XLT0 Partition Mode field is 0. All other values are reserved. Relevant CSR: GL_<block>_CDMD_L1Sel[28:24]
XLT0 Partition Mode (Bi-dir. Pipe Enable)	1	This field controls the XLT0 Table MUX selection. Valid values are 0 to 2. All other values are reserved. See Table 7-195. Relevant CSR: GL_<block>_CDMD_L1Sel[31:30]

Table 7-195 defines the XLT0 Partition Mode values.

Table 7-195. XLT0 Partition Mode Selection Values

Value	Description
0	XLT0 Table lookup value is metadata[10:0].
1	XLT0 Table lookup value is composed as Dir[0] as the most significant bit, plus the selected metadata[9:0] as the least significant bits.
2	XLT0 Table lookup value is composed as Dir[1:0] as the most significant bits, plus the selected metadata[8:0] as the least significant bits.
3-254	Reserved.
255	Reserved for internal use by assembler tools before conversion to a valid value.

7.11.12.2.2 Package format of the XLT0 Table

This section specifies the package format for configuring the per-block XLT0 table. The XLT0 Table provides an intermediate stage during calculation of a Control Domain ID.

Each pipeline block uses a distinct XLT0 Table configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-196 shows the section type enumeration.

Table 7-196. Package Section Type Numbers for XLT0 Tables

Section Type Number	Allowed in Update Package?	Description
10	No	XLT0 Table for the Switch.
20	No	XLT0 Table for the ACL.
30	No	XLT0 Table for the Flow Director.
40	No	XLT0 Table for RSS.
80	No	XLT0 Table for PE.

The package format for XLT0 Table configuration is common for all blocks as shown in Table 7-197.

Table 7-197. Package Format for XLT0 Table Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section. If the XLT0 table is split into multiple sections, this field describes only the number of entries contained in this section.
Offset	2	Byte offset from the start of the table to the first value in this section. The maximum effective offset for any value is 2047. Effective offsets greater than 2047 are reserved. The offset field incorporate the direction, if used, in the key value. No Direction Bits: 0-2047 = Control Domain value 1 Direction Bit: 0-1023 = Control domain for DIR=0 1024-2047 =Control domain for DIR=1 2 Direction Bits: 0-511 = Control domain value for DIR=0 512-1023 = Control domain value for DIR=1 1024-1535 =Control domain value for DIR=2 1536-2047 =Control domain value for DIR=3 Relevant CSR: GL_<block>_XLT0_L1ADDR.*LINE_IDX*. Should be set together with *AUTO_INC* bit.
Value	1	Control Domain value of this XLT0 entry. Valid values are in range (0-7). Value of 255 is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. Relevant CSR from “Non-TCAM Tables”: GL_<block>_XLT0_L1DATA.*DATA*
...	...	Subsequent values at consecutive offsets.

7.11.12.2.3 CDID Redirection Table

After the XLT0 table generates the CDID, the CDID Redirection Table can change the CDID to a different value. The CDID Redirection Table always maps the input CDID to an output CDID. Therefore, to allow CDID values to pass through unchanged, the host must initialize this table to the trivial identity mapped case (for example, CDID 7 maps to CDID 7).

Each block in the pipeline contains its own CDID Redirection Table. Table 7-198 shows the relevant Package Section Type for each block.

Table 7-198. Package Section Type Numbers for CDID Redirection Tables

Section Type Number	Allowed in Update Package?	Description
18	No	CDID Redirection Table for the Switch.
28	No	CDID Redirection Table for the ACL.
38	No	CDID Redirection Table for the Flow Director.
48	No	CDID Redirection Table for RSS.
88	No	CDID Redirection Table for PE.

The package format for the CDID Redirection Table is common for all blocks as shown in Table 7-199.

Table 7-199. Package Format for CDID Redirection Table

Field	Size (Bits)	Description
CDID 0 Redirect Value	4	Redirected value for CDID 0. Relevant CSRs: GL_<block>_P2P_L1ADDR.*LINE_IDX* = 0 GL_<block>_P2P_L1DATA.*DATA*
CDID 1 Redirect Value	4	Redirected value for CDID 1. Relevant CSRs: GL_<block>_P2P_L1ADDR.*LINE_IDX* = 0 GL_<block>_P2P_L1DATA.*DATA*
CDID 2-15 Redirect Values	14 x 4	Redirected value for CDID 2 to 15. Relevant CSRs: GL_<block>_P2P_L1ADDR.*LINE_IDX* GL_<block>_P2P_L1DATA.*DATA*

Note: Initial value for GL_<block>_P2P_L1ADDR should be 0x1 << 31 (*AUTO_INC* field set).

7.11.12.2.4 Package Format of XLT Key Builder Tables

This section specifies the package format of per-block XLT Key Builder Tables. The XLT Key Builder Table selects the metadata and flags fields used as input into the Profile ID Compression (XLT1) and Expansion (XLT2) tables.

Each pipeline block uses a distinct XLT Key Builder Table configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-200 shows the section type enumeration.

Table 7-200. Package Section Type Numbers for XLT Key Builder Tables

Section Type Number	Allowed in Update Package?	Description
11	No	XLT Key Builder Table for the Switch.
21	No	XLT Key Builder Table for the ACL.
31	No	XLT Key Builder Table for the Flow Director.
41	No	XLT Key Builder Table for RSS.
81	No	XLT Key Builder Table for PE.

The format of the XLT Key Builder Table definition is common for all blocks as shown in Table 7-201.

Table 7-201. Package Buffer Format for the XLT Key Builder Table

Field	Size (Bytes)	Description
XLT1 Partition Mode	1	This field controls the XLT1 Table MUX selection. Valid values are 0 to 3. All other values are reserved. See Table 7-202. Relevant CSR from "Level-2 profile selection CSRs": GL_<block>_L2PRTMOD.*XLT1*
XLT2 Partition Mode	1	This field controls the XLT2 Table MUX selection. Valid values are 0 to 3. All other values are reserved. See Table 7-203. Relevant CSR from "Level-2 profile selection CSRs": GL_<block>_L2PRTMOD.XLT2
Profile ID Partition Mode	1	This field controls the Profile ID TCAM MUX selection. Valid values are 0 to 3. All other values are reserved. See Table 7-204. Relevant CSR from "Level-2 profile selection CSRs": GL_<block>_PID_L2GKTYPE.*PID_GKTYPE*
Reserved (0)	1	The host must set this value to 0.
Flag15 Mask[31:0]	4	Reduction flag, low 32 bits. Relevant CSR: GL_<block>_FL15_BMPLSB.*BMPLSB*
Flag15 Mask[63:32]	4	Reduction flag, high 32 bits. Relevant CSR: GL_<block>_FL15_BMPMSB.*BMPMSB*
XLT Key Builder Table	192 (8x24)	This table specifies how to construct the Profile ID lookup key for each of 8 possible CDID values, numbered 0 to 7. Each entry is structured as shown in Table 7-205. Relevant CSR from "Non-TCAM Tables": CTLTBL_L2ADDR / CTLTBL_L2DATA

Table 7-202 defines the XLT1 Partition Mode values.

Table 7-202. XLT1 Partition Mode Selection Values

Value	Description
0	XLT1 Table lookup value is metadata[12:0].
1	XLT1 Table lookup value is composed as XLT1_AdSel[0] as the most significant bit, plus the selected metadata[11:0] as the least significant bits.
2	XLT1 Table lookup value is composed as XLT1_AdSel[1:0] as the most significant bits, plus the selected metadata[10:0] as the least significant bits.
3	XLT1 Table lookup value is composed as XLT1_AdSel[2:0] as the most significant bits, plus the selected metadata[9:0] as the least significant bits.
Other	Reserved.

Table 7-203 defines the XLT2 Partition Mode values.

Table 7-203. XLT2 Partition Mode Selection Values

Value	Description
0	XLT2 Table lookup value is metadata[9:0].
1	XLT2 Table lookup value is composed as XLT2_AdSel[0] as the most significant bit, plus the selected metadata[8:0] as the least significant bits.
2	XLT2 Table lookup value is composed as XLT2_AdSel[1:0] as the most significant bits, plus the selected metadata[7:0] as the least significant bits.
3	XLT2 Table lookup value is composed as XLT2_AdSel[2:0] as the most significant bits, plus the selected metadata[6:0] as the least significant bits.
Other	Reserved.

Table 7-204 defines the Profile ID TCAM Partition Mode values. For modes 1,2 and 3, the CDID values is encoded as a one-hot bitmap.

Table 7-204. Profile ID TCAM Partition Mode Selection Values

Value	Description
0	Bits 39:32 of the Profile ID TCAM match value are bits 15:8 of XLT2 Table output.
1	Bits 39:38 of the Profile ID TCAM match value are a one-hot encoding of CDID[0]. Bits 37:32 of the Profile ID TCAM match value are bits 13:8 of XLT2 Table output.
2	Bits 39:36 of the Profile ID TCAM match value are a one-hot encoding of CDID[1:0]. Bits 35:32 of the Profile ID TCAM match value are bits 11:8 of XLT2 Table output.
3	Bits 39:32 of the Profile ID TCAM match value are a one-hot encoding of CDID[2:0].
Other	Reserved.

Table 7-205 defines the XLT Key Builder Table entries.

Table 7-205. Format for XLT Key Builder Table Entries

Field	Size (Bits)	Bit Offset	Description
Reserved	32	0	Reserved for programming tools use. Ignored by firmware.
XLT1 AdSel	3	32	If used, value driven on XTL1 AdSel lines. Relevant CSR: GL_<block>_CTLTBL_L2DATA[2:0][1] (*LINE_OFF*=0)
XLT2 AdSel	3	35	If used, value driven on XTL2 AdSel lines. Relevant CSR: GL_<block>_CTLTBL_L2DATA[5:3] (*LINE_OFF*=0)
Flag0 Select	9	38	Profile ID flags select (same for Flags 1-14 in following rows) Relevant CSR: GL_<block>_CTLTBL_L2DATA[14:6] (*LINE_OFF*=0)
Flag1 Select	9	47	Relevant CSR: GL_<block>_CTLTBL_L2DATA[23:15] (*LINE_OFF*=0)
Flag2 Select	9	56	Relevant CSRs: GL_<block>_CTLTBL_L2DATA[31:24] (*LINE_OFF*=0) GL_<block>_CTLTBL_L2DATA[0:0] (*LINE_OFF*=1)
Flag3 Select	9	65	Relevant CSR: GL_<block>_CTLTBL_L2DATA[9:1] (*LINE_OFF*=1)
Flag4 Select	9	74	Relevant CSR: GL_<block>_CTLTBL_L2DATA[18:10] (*LINE_OFF*=1)
Flag5 Select	9	83	Relevant CSR: GL_<block>_CTLTBL_L2DATA[27:19] (*LINE_OFF*=1)
Flag6 Select	9	92	Relevant CSRs: GL_<block>_CTLTBL_L2DATA[31:28] (*LINE_OFF*=1) GL_<block>_CTLTBL_L2DATA[4:0] (*LINE_OFF*=2)
Flag7 Select	9	101	Relevant CSR: GL_<block>_CTLTBL_L2DATA[13:5] (*LINE_OFF*=2)
Flag8 Select	9	110	Relevant CSR: GL_<block>_CTLTBL_L2DATA[22:14] (*LINE_OFF*=2)
Flag9 Select	9	119	Relevant CSR: GL_<block>_CTLTBL_L2DATA[31:23] (*LINE_OFF*=2)
Flag10 Select	9	128	Relevant CSR: GL_<block>_CTLTBL_L2DATA[8:0] (*LINE_OFF*=3)
Flag11 Select	9	137	Relevant CSR: GL_<block>_CTLTBL_L2DATA[17:9] (*LINE_OFF*=3)
Flag12 Select	9	146	Relevant CSR: GL_<block>_CTLTBL_L2DATA[26:18] (*LINE_OFF*=3)
Flag13 Select	9	155	Relevant CSRs: GL_<block>_CTLTBL_L2DATA[31:27] (*LINE_OFF*=3) GL_<block>_CTLTBL_L2DATA[3:0] (*LINE_OFF*=4)
Flag14 Select	9	164	Relevant CSR: GL_<block>_CTLTBL_L2DATA[12:4] (LINE_OFF=4)
Reserved	9	173	Reserved (0).

Table 7-205. Format for XLT Key Builder Table Entries [continued]

Field	Size (Bits)	Bit Offset	Description
XLT2 MdSel	5	182	XLT1 metadata selection Relevant CSR: GL_<block>_CTLTBL_L2DATA[26:22] (*LINE_OFF*=4) ***Note:*** *XLT2/1 MdSel* are in reverse order from *AdSel* fields
XLT1 MdSel	5	187	XLT1 metadata selection Relevant CSR: GL_<block>_CTLTBL_L2DATA[31:27] (*LINE_OFF*=4) ***Note:*** *XLT2/1 MdSel* are in reverse order from *AdSel* fields.

1. Set GL_<*block*>_CTLTBL_L2ADDR.*AUTO_INC* when writing data to GL_<*block*>_CTLTBL_L2DATA.

Note: Initial value for GL_<block>_CTLTBL_L2ADDR should be 0x1 << 31 (*AUTO_INC* field set). Later, only *LINE_OFF* field of this register should be changed.

7.11.12.2.5 Package Format of XLT1 Tables

This section specifies the package format for configuring the per-block XLT1 table. The XLT1 Table provides an intermediate stage during calculation of a Profile ID. The use of the XLT1 table is block specific, but can, for example, be used to generate a Packet Group ID.

Each pipeline block uses a distinct XLT1 Table configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-206 shows the section type enumeration. Because the size of the XLT1 Table exceeds the 4 KB maximum size for an AQ command buffer, the host must issue more than one AQ command to complete initialization of the entire table.

Table 7-206. Package Section Type Numbers for XLT1 Tables

Section Type Number	Allowed in Update Package?	Description
12	Yes	XLT1 Table for the Switch.
22	Yes	XLT1 Table for the ACL.
32	Yes	XLT1 Table for the Flow Director.
42	Yes	XLT1 Table for RSS.
82	Yes	XLT1 Table for PE.

The package format for XLT1 Table configuration is common for all blocks as shown in Table 7-207.

Table 7-207. Package Format for XLT1 Table Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section. If the XLT1 table is split into multiple sections, this field describes only the number of entries contained in this section.
Offset	2	Byte offset from the start of the table to the first value in this section. The maximum effective offset for any value is 8191. Effective offsets greater than 8191 are reserved. Relevant CSR: GL_<block>_XLT1_L2ADDR.*LINE_IDX* Should be set together with *AUTO_INC* bit.

Table 7-207. Package Format for XLT1 Table Configuration [continued]

Field	Size (Bytes)	Description
Value	1	Value for the offset specified by the *Offset* field. Relevant CSR from "Non-TCAM Tables": GL_<block>_XLT1_L2DATA.*DATA*
...	...	Subsequent consecutive values.

7.11.12.2.6 Package Format of XLT2 Tables

This section specifies the package format for configuring the per-block XLT2 table. The XLT2 Table provides an intermediate stage during calculation of a Profile ID. The use of the XLT2 table is block specific, but can, for example, be used to expand a set of metadata fields into additional information.

Each pipeline block uses a distinct XLT2 Table configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-208 shows the section type enumeration. Because the size of the XLT2 Table does not exceed the 4 KB maximum size for an AQ command buffer, the host can initialize the table in parts or as a single AQ command.

Table 7-208. Package Section Type Numbers for XLT2 Tables

Section Type Number	Allowed in Update Package?	Description
13	Yes	XLT2 Table for the Switch.
23	Yes	XLT2 Table for the ACL.
33	Yes	XLT2 Table for the Flow Director.
43	Yes	XLT2 Table for RSS.
83	Yes	XLT2 Table for PE.

The package format for XLT2 Table configuration is common for all blocks as shown in the Table 7-209.

Table 7-209. Package Format for XLT2 Table Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this download.
Offset	2	Byte offset from the start of the table to the first value in this section. The maximum effective offset for any value is 1023. Effective offsets greater than 1023 are reserved. Relevant CSR: GL_<block>_XLT2_L2ADDR.*LINE_IDX*. Should be set together with *AUTO_INC* bit.
Value	2	Value for the offset specified by the *Offset* field. Relevant CSR from "Non-TCAM Tables": GL_<block>_XLT2_L2DATA.*DATA*
...	...	Subsequent consecutive values.

7.11.12.2.7 Package Format of Profile ID TCAMs

This section specifies the package format for configuring the per-block Profile ID TCAM. The Profile ID TCAM provides the Profile ID based on the output of the XLT1 Table, the XLT2 Table, Flags, and the CDID. The use of the Profile ID TCAM is block-specific and directs block-specific functionality.

Each pipeline block uses a distinct Profile ID TCAM configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-210 shows the section type enumeration. Because the size of the Profile ID TCAM can exceed the 4 KB maximum size for an AQ command buffer, the host might have to issue multiple AQ command to initialize the entire table.

Table 7-210. Package Section Details for Profile ID TCAMs

Section Type Number	Allowed in Update Package?	Number of TCAM Entries	Number of Profile IDs	Description
14	Yes	512	256	Profile ID TCAM for the Switch.
24	Yes	512	128	Profile ID TCAM for the ACL.
34	Yes	512	128	Profile ID TCAM for the Flow Director.
44	Yes	512	128	Profile ID TCAM for RSS.
84	Yes	64	32	Profile ID TCAM for PE.

The package format for Profile ID TCAM configuration is common for all blocks as shown in Table 7-211.

Table 7-211. Package Format for Profile ID TCAM Configuration

Field		Size (Bytes)	Description
Count		2	Number of entries in this download.
Entry 0	Address	2	Address of this entry in the TCAM. Relevant CSR from "TCAM Programming": GL_<block>EXT_TCAM_L2ADDR
	Key/Key Invert	10	[79:40] = Encoded Key Invert for this entry. The key is composed of 40 input bits encoded according to Table 7-81. The layout is shown in Table 7-212. Relevant CSR from "TCAM Programming": GL_<block>EXT_TCAM_L2DATALSB.*DATALSB* (bytes 0-3) GL_<block>EXT_TCAM_L2DATAMSB.*DATAMSB* (byte 4) [39:0] = Encoded Key for this entry. The key is composed of 40 input bits encoded according to Table 7-81. The layout is shown in Table 7-212. Relevant CSR from "TCAM Programming": GL_<block>EXT_TCAM_L2DATALSB.*DATALSB* (bytes 0-3) GL_<block>EXT_TCAM_L2DATAMSB.*DATAMSB* (byte 4)
	Profile ID	1	Profile ID output value corresponding to this key. Firmware reserves the Profile ID value of 1 as the default "no match" value. GL_<BLOCK>EXT_K2N_L2ADDR.*LINE_IDX* should be set to (Address /4). GL_<BLOCK>EXT_K2N_L2DATA.*DATA*[Address % 4] should be set to Profile ID.
...		Nx13	All other entries.

Table 7-212 shows the format of the 10-byte Profile Key. The Profile Key occupies Bits 79-0 of the Profile ID TCAM Entry shown in Table 7-212.

Table 7-212. Format of 80-Bit Profile ID TCAM Key Field

Bits 39-32	Bits 31-24	Buts 23-16	Bits 15-0
Eight bits as specified in Table 7-204.	Eight bits produced by the XLT2 table	Eight bits produced by the XLT1 table	16 Flags

7.11.12.2.8 Package Format of Profile ID Redirection Tables

After the Profile ID TCAM generates the Profile ID, the Profile ID Redirection Table can change the Profile ID to a different value. The Profile ID Redirection Table controls this remapping. The Profile ID Redirection Table always maps the input Profile ID to an output Profile ID. Therefore, to allow Profile ID values to pass through unchanged, the host must initialize this table to the trivial identity mapped case (for example, Profile ID 7 maps to Profile ID 7).

Each block in the pipeline contains its own Profile ID Redirection Table. Table 7-213 shows the relevant Package Section Type for each block.

Table 7-213. Package Section Type Numbers for Profile ID Redirection Table

Section Type Number	Allowed in Update Package?	Number of Entries	Description
15	Yes	256	Profile ID Redirection Table for the Switch.
25	Yes	128	Profile ID Redirection Table for the ACL.
35	Yes	128	Profile ID Redirection Table for the Flow Director.
45	Yes	128	Profile ID Redirection Table for RSS.
85	Yes	32	Profile ID Redirection Table for PE.

The package format for Profile ID Redirection Table is common for all blocks as shown in Table 7-214. The size of the table varies depending on the number of Profile ID values supported by particular block.

Table 7-214. Package Format for Profile ID Redirection Table

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	Offset to the first entry (N) in this section. Offset must be in range 0 to the maximum number of profiles supported by the block as shown in Table 7-213.
Profile ID Redirect Value	1	Redirected value for the Profile ID specified by the *Offset* field. Relevant CSR: GL_<block>_N2N_L2DATA.*DATA0*
...	Nx1	All subsequent entries in consecutive order.[1]

1. Note for firmware: Initial value for GL_<*block*>_N2N_L2ADDR should be 0x1 << 31 (*AUTO_INC* field set).

7.11.12.3 Dynamic Configuration of Profile IDs

A host can program new Profile ID values at runtime. For this purpose, the host issues one or more Update Package AQ commands. The Update Package commands download an incremental package update to the Profile ID logic using the same package buffer formats described in the previous sections.

The host can change all aspects of Profile ID configuration dynamically via the Update Package AQ command. Firmware can provide some error checking, but responsibility for correct operation lies with the host software.

7.11.12.3.1 Field Vector Extraction Table

After the Profile ID Redirection Table generates the Profile ID, the field vector extraction logic takes the Profile ID as input and produces a field vector. The Field Vector Table configures this extraction logic.

Table 7-215. Package Section Type Numbers for Field Vector Extraction Tables

Section Type Number	Allowed in Update Package?	Number of Entries	FV Size (32-bit Words)	Description
16	Yes	256	48	Field Vector Table for the Switch.
26	Yes	128	32	Field Vector Table for the ACL.
36	Yes	128	24	Field Vector Table for the Flow Director.
46	Yes	128	24	Field Vector Table for RSS.
86	Yes	32	32	Field Vector Table for the PE.
99	No	1	32	Field Vector Table for Manageability. ***Note:*** PFR has no effect on this resource.

The number of 16-bit words available in a Field Vector varies by hardware block as specified by the Section Type Number. Regardless, all blocks use a common format as shown in Table 7-216.

Table 7-216. Package Format for Profile ID Redirection Table

Field	Extraction Word Fields	Size (Bits)	Description
Count		16	Number of entries in this section.
Offset (Base Profile ID)		16	Offset to the first table entry in this section. The offset value is the same as the logical Profile ID. Subsequent entries in this section occupy consecutive Profile ID values in the FV extraction table. Relevant CSR: GL_<block>_PRFLM_CTRL[n].*PRFL_IDX*

Table 7-216. Package Format for Profile ID Redirection Table [continued]

Field	Extraction Word Fields	Size (Bits)	Description
Entry 0 (for first Profile ID)	Word 0 Protocol ID	8	Protocol ID for extraction word 0. Relevant CSR: GL_<block>_PRFLM_DATA_[n][Word Offset].*PROT*
	Word 0 Offset	9	Byte offset for extraction word 0. Relevant CSR: GL_<block>_PRFLM_DATA_[n][Word Offset].*OFF*
	Reserved	15	Reserved (0).
	Word 1 Protocol ID	8	Protocol ID for extraction word 1.
	Word 1 Offset	9	Byte offset for extraction word 1.
	Reserved	15	Reserved (0).
	...		All intervening words.
	Word N Protocol ID	8	Last Protocol ID and Byte Offset for this FV entry, where N is one less than the number of 16 bit words in the FV. See Table 7-215 for the size of the FV per block.
	Word N Offset	9	
	Reserved	15	
All other entries		Size Varies	Each subsequent entry occupies placed at previous Profile ID plus one.

7.11.12.4 VSI Lists

The firmware reserves VSI Prune lists 0 through 7 as empty VSI lists.

7.11.12.5 Recipe Configuration

This section specifies the recipes for packet processing in the Switch block. At a minimum, a complete package must contain a recipe with a default action 'forward to VSI list 0'.

Table 7-217. Package Section Type Numbers for Recipe Configuration

Section Type Number	Allowed in Update Package?	Description
92	No	Recipe configuration for the Switch.

Table 7-218. Package Format of the Recipe Configuration Section

Field		Size (Bits)	Bit Offset	Description
Count		16	0	Number of entries in this section. Valid values 1-63.
Reserved		16	16	Reserved (0).
Entry 0	Recipe ID	8	32	The unique, incrementing Recipe ID automatically assigned by the tools.
	Reserved	24	40	Reserved (0).
	Dependent Recipes	64	64	A bitmap representation of the dependent Recipe IDs.
	Recipe	224	128	The 28-byte recipe content, as described in Table 7-9.
...		Nx320	352	All consecutive entries, 40 bytes each.

7.11.12.6 Recipe-to-Profile Associations

This section specifies the associations between profiles and recipes for packet processing in the Switch block.

Table 7-219. Package Section Type Numbers for Recipe-to-Profile Associations

Section Type Number	Allowed in Update Package?	Description
93	No	Recipe to Profile associations for the Switch.

Table 7-220. Package Format of the Recipe Configuration Section

Field		Size (Bits)	Bit Offset	Description
Count		16	0	Number of entries in this section. Valid values 1-63.
Offset (Base Profile ID)		16	16	Offset to the first table entry in this section. The offset value is the same as the logical Profile ID. Subsequent entries in this section occupy consecutive Profile ID values.
Entry 0	Recipe Associations	64	32	Bitmap of the recipe indexes associated with this profile. The bitmap should include both root and non-root recipes.
...		Nx8	96	All consecutive entries, eight bytes each.

7.11.12.6.1 Miscellaneous Profile and Control Domain Configuration

This section specifies the miscellaneous configuration section for profile and control domains.

Table 7-221. Package Section Type Numbers for Miscellaneous Profile and Control Domain Configuration

Section Type Number	Allowed in Update Package?	Description
100	Yes	Miscellaneous Profile and Control Domain Configuration for Switch.
101	Yes	Miscellaneous Profile and Control Domain Configuration for ACL.
102	Yes	Miscellaneous Profile and Control Domain Configuration for Flow Director.
103	Yes	Miscellaneous Profile and Control Domain Configuration for RSS.
104	Yes	Miscellaneous Profile and Control Domain Configuration for PE.

Table 7-222. Package Format of the Miscellaneous Profile and Control Domain

Field	Size (Bits)	Description
Static CDID Selection	32	Enable static CDID selection, and set the static CDID. The value of all FFs is reserved for internal use by tools before conversion to a valid value. [31] = Enable static CDID selection. [30:4] = Reserved (0). [3:0] = Static CDID value. Relevant CSR: GL_*EXT_FORCE_L1CDID

Table 7-222. Package Format of the Miscellaneous Profile and Control Domain [continued]

Field	Size (Bits)	Description
MDID Digest Mask	64	The MDID digest mask. The value of all 0 is reserved for internal use by tools before conversion to a valid value. [63:48] = Reserved (0). [47:32] = The 16 MSBs for the MDID digest mask. [31:0] = The 32 LSBs for the MDID digest mask. Relevant CSRs: GL_*EXT_L2_PMASK0, GL_*EXT_L2_PMASK1
TCAM Input Mask	64	The TCAM input mask. The value of all 0 is reserved for internal use by tools before conversion to a valid value. [63:40] = Reserved (0). [39:32] = The eight MSBs for the TCAM input mask. [31:0] = The 32 LSBs for the TCAM input mask. Relevant CSRs: GL_*EXT_L2_TMASK0, GL_*EXT_L2_TMASK1
Reserved	96	Reserved (0)

7.11.12.6.2 Mask Select Filters

This section specifies the mask select filters section.

Table 7-223. Package Section Type Numbers for Mask Select Filters Configuration

Section Type Number	Allowed in Update Package?	Description
105	No	Mask Select Filters for RSS.
106	No	Mask Select Filters for FD.
107	No	Mask Select Filters for PE.

Table 7-224. Package Format of Mask Select Filters

Field		Size (Bits)	Description
Count		16	Number of entries in this section.
Offset		16	Offset to the first Profile ID in this section. Valid values are 0..31 in the PE block and 0..127 in FD and RSS blocks.
Entry 0	Mask Select	32	The bitmap of registers to be enabled for the given Profile ID. Relevant CSR: GLQF_[FD|H|PE]MASK_SEL
---		Nx32	All consecutive entries, four bytes each.

7.11.12.6.3 Quad Hash Control Table

This section specifies the quad hash control table section.

Table 7-225. Package Section Type Numbers for Quad Hash Control Table

Section Type Number	Allowed in Update Package?	Description
108	No	Quad Hash Control Table for PE.

Table 7-226. Package Format of Mask Select Filters

Field		Size (Bits)	Description
Count		16	Number of entries in this section.
Offset		16	Offset to the first Profile ID in this section. Valid values are 0..31.
Entry 0	TO_QH	2	The target of given profile: 00b = Reserved. 01b = Packet is candidate for QH filter. 10b = Packet is candidate for the PE bypassing the QH filter. 11b = Packet is candidate for the QH filter and forward to the PE even if it does not match the filter. Relevant CSR: GLQF_PE_CTL2
	APBVT	1	Packet profile 'n' should hit the APBVT in order to be a candidate for the QH or directly to the PE. Relevant CSR: GLQF_PE_CTL2
	Reserved	29	Reserved (0)
...		Nx32	All consecutive entries, four bytes each.

7.11.13 Parser Configuration

7.11.13.1 Introduction

Parser logic performs initial packet analysis and generates metadata for use in subsequent pipeline stages. The packet processing pipeline contains two Parsers, one for the receive path (Rx Parser) and one for the transmit path (Tx Parser). Both Rx and Tx Parsers share the same design.

A parser is not a monolithic structure, but consists of many interdependent sub-components. A package contains dedicated sections for each of these sub-component within the Parser.

7.11.13.2 Parse Graph

The Parse Graph logic is the principle driver of the packet analysis process within the Parser. The Parse Graph system consists of a variety of tables, each with its package section. See Table 7-227.

Table 7-227. Package Section Type Numbers for Parse Graph CAMs

Section Type Number	Allowed in Update Package?	Description
50	No	Parse Graph CAM for the Rx Parser.
60	No	Parse Graph CAM for the Tx Parser.

7.11.13.2.1 CAM Entry Algorithm

During a CAM query, hardware uses a hash algorithm to select an entry index, then checks subsequent entries for a match. The algorithm is as follows:

1. Calculate the entry index from 0-max index using the hash algorithm on the lookup key. The maximum index for the Parse Graph CAM is 2047. The maximum index for the No-Match CAM is 1024.
2. Starting from the calculated entry index, check if the entry at index matches the key. If the entry matches return the corresponding value. If the entry does not match, iterate to the next entry up to the maximum count for the CAM. The Parse Graph CAM checks up to eight consecutive entries for a match. The No-Match CAM checks up to four consecutive entries for a match.
3. If no entry matched the key, query the Spill CAM starting at entry 0. If the Spill CAM contains a match, return the corresponding value. If the Spill CAM does not have a match, no match was found.

7.11.13.2.2 Determining CAM Entry Index

This section provides a pseudo-code algorithm to determine the correct CAM entry index for a given PG key. This algorithm produces the same result as the hardware algorithm.

The Parser Miscellaneous Configuration section (see Section 7.11.13.16) specifies the seed value used to compute the CAM Entry Index.

```
// bitset<N> is a collection of N bits
// myset[i] references the i'th bit of the biset 'myset'
// & is a bitwise logical AND operation
// ^ is a bitwise logical XOR operation
// << is a bitwise shift left with zero fill operation
```

```
bitset<11> GetPGCAMEntryIndex(bitset<72> Key, bitset<83> Seed)
    bitset<11> Hash;         // Computed hash value
    bitset<83> PadKey = Key; // Key in bottom 72 bits
    PadKey = PadKey << 11;   // Shift Key to top 72 bits
    for i = 0 to 11 do
        bitset<84> Temp = PadKey & (Seed << i)
        bitset<1> TempBit = Temp[0]
        for j = 1 to 84 do
            TempBit = TempBit ^ Temp[j]
        Hash[10-i] = TempBit
    return Hash
bitset<10> GetNoMatchCAMEntryIndex(bitset<40> Key, bitset<51> Seed)
    bitset<10> Hash; // Computed hash value
    bitset<51> PadKey = Key; // Key in bottom 40 bits
    PadKey = PadKey << 11; // Shift Key to top 40 bits
    for i = 0 to 10 do
        bitset<50> Temp = PadKey & (Seed << i)
        bitset<1> TempBit = Temp[0]
        for j = 1 to 50 d
            TempBit = TempBit ^ Temp[j]
        Hash[10-i] = TempBit
    return Hash
```

7.11.13.2.2.1 CAM Entry Index Examples

PG No-Match CAM slice entry index hash examples:

```
Input Seed = 0x1b0ce7ae9030f
Input Key = 0x0000008000
Output Hash = 0x2e9

Input Seed = 0x1b0ce7ae9030f
Input Key = 0x0000298808
Output Hash = 0x378
```

PG CAM slice entry index hash examples:

```
Input Seed = 0x05c5666c1b0ce7ae9030f
Input Key = 0x000000040000008000
Output Hash = 0x2df

Input Seed = 0x05c5666c1b0ce7ae9030f
Input Key = 0x0000002c00001a800d
Output Hash = 0x6d7
```

7.11.13.2.3 Determining CAM Slice

The entry is placed in the unoccupied entry at the calculated entry index. If an entry is already occupied, subsequent entries are searched in order up to the maximum for the CAM (0 to 7 for the PG CAM, and 0 to 3 for the No-Match CAM).

If the entry and all subsequent entries are occupied up to the maximum count for the CAM, the entry is placed in the corresponding Spill CAM at the first available location. If the Spill CAM is already full, the result is an error condition in which the entry cannot be placed.

7.11.13.2.4 Package Format of the Parse Graph CAM

The hub of the Parse Graph logic is the Parse Graph CAM. Table 7-228 shows the package buffer layout of the Parse Graph CAM.

Table 7-228. Package Format for Parse Graph CAM Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	Offset to the first entry in this section.All entries are contiguous from this offset. All entries must be in range 0 to 2047. Entries with an offset greater than 2047 are reserved. Relevant CSRs: GLGEN_ANA_CFG_CTRL.*LINE_IDX* = Offset >> 3 GLGEN_ANA_CFG_CTRL.*TABLE_ID* = 4 + (Offset % 8)
Entry 0	16	First CAM entry. Each CAM entry contains a key and value. Each entry is formatted as shown in Table 7-229. Relevant CSR uses Parser indirect interface with Table IDs 4 to 11 (PG mem0 to PG mem7). GLGEN_ANA_CFG_WRDATA.*WR_DATA*, 32 bits/write
---	Nx16 + 4	All other entries.

Table 7-229 shows the format of each 16-byte Parse Graph CAM entry.

Table 7-229. Package Format of the Parse Graph CAM Entry

	Field	Width (Bits)	Bit Offset	Description
Key (73 bits)	Valid	1	0	The parse graph entry is valid. The tools set this bit to 0 for undefined nodes in the parse graph.
	Node ID	11	11:1	Node ID of the protocol in the current analysis round.
	Flag 0	1	12	Optional Flag 0.
	Flag 1	1	13	Optional Flag 1.
	Flag 2	1	14	Optional Flag 2.
	Flag 3	1	15	Optional Flag 3.
	Boost Hit	1	16	Flag set when the Boost TCAM Search resulted in a match. Clear otherwise.
	Boost Index	8	24:17	Boost TCAM match index if Boost Hit Flag == 1. This field is zero otherwise.
	ALU Reg	16	40:25	Optional ALU register value if enabled. Zero otherwise.
	Next Proto Key	32	72:41	Next Protocol value extracted from the packet.

Table 7-229. Package Format of the Parse Graph CAM Entry [continued]

	Field	Width (Bits)	Bit Offset	Description
Action (55 bits)	Next Node ID	11	83:73	Node ID used for the next analysis round.
	Next PC	8	91:84	IMEM Program Counter used for the next analysis round.
	Is Protocol Group	1	92	Set if the Protocol ID value is a protocol group ID. Clear if the Protocol ID value is a Protocol ID. See Section 7.11.13.9.
	Reserved	3	95:93	Reserved (0).
	Protocol ID	8	103:96	Protocol ID (Is Protocol Group == 0) or Protocol Group ID (Is Protocol Group = 1)
	Is Marker Group	1	104	Set if the Marker ID value is a Marker Group ID. Clear if the Marker ID value is a Marker ID. See Section 7.11.13.10.
	Marker ID	8	112:105	Marker ID (Is Marker Group == 0) or Marker Group ID (Is Marker Group == 1)
	Is Last Round	1	113	Set if this is a last analysis round for this packet. Clear otherwise.
	Header Offset Polarity	1	114	Set if the Header Offset Inc value is added to the current Header Offset value. Clear if the Header Offset Inc value is subtracted from the current Header Offset.
	Header Offset Inc	9	123:115	Number of bytes to add or subtract from the Header Offset.
	Reserved	4	127:124	Reserved (0).

7.11.13.2.5 Package Format of the Parse Graph No-Match CAM

The Parse Graph No-Match logic defines the output values used when the Parse Graph CAM did not find a match for the input key.

Table 7-230. Package Section Type Numbers for Parse Graph No-Match CAMs

Section Type Number	Allowed in Update Package?	Description
51	No	Parse Graph No-Match CAM for the Rx Parser.
61	No	Parse Graph No-Match CAM for the Tx Parser.

Table 7-231 shows the package buffer layout of the PG No Match CAM.

Table 7-231. Package Format for Parse Graph No-Match CAM Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	Offset to the first entry in this section. All entries are contiguous from this offset. All entries must be in range 0 to 1023. Entries with an offset greater than 1023 are reserved.

Table 7-231. Package Format for Parse Graph No-Match CAM Configuration [continued]

Field	Size (Bytes)	Description
Entry 0	12	First CAM entry. Each CAM entry contains a key and value. Each entry is formatted as shown in Table 7-232. Relevant CSR uses Parser indirect interface with Table IDs 21 to 24 (no match PG mem0 to no match PG mem3).
---	Nx12 + 4	All other entries.

Table 7-232 shows the format of each 12-byte PG No-Match CAM entry. The format is identical to the Parse Graph CAM format, with the exception that the *Next Proto Key* field is not specified.

Table 7-232. Package Format of the Parse Graph CAM Entry

	Field	Width (Bits)	Bit Offset	Description
Key (41 bits)	Valid	1	0	The parse graph entry is valid. The tools set this bit to 0 for undefined nodes in the parse graph.
	Node ID	11	11:1	Node ID of the protocol in the current analysis round.
	Flag 0	1	12	Optional Flag 0.
	Flag 1	1	13	Optional Flag 1.
	Flag 2	1	14	Optional Flag 2.
	Flag 3	1	15	Optional Flag 3.
	Boost Hit	1	16	Flag set when the Boost TCAM Search resulted in a match. Clear otherwise.
	Boost Index	8	24:17	Boost TCAM match index if Boost Hit Flag == 1. This field is zero otherwise.
	ALU Reg	16	40:25	Optional ALU register value if enabled. Zero otherwise.
Action (55 bits)	Next Node ID	11	51:41	Node ID used for the next analysis round.
	Next PC	8	59:52	IMEM Program Counter used for the next analysis round.
	Is Protocol Group	1	60	Set if the Protocol ID value is a protocol group ID. Clear if the Protocol ID value is a Protocol ID.
	Reserved	3	63:61	Reserved(0)
	Protocol ID	8	71:64	Protocol ID (Is Protocol Group == 0) or Protocol Group ID (Is Protocol Group = 1)
	Is Marker Group	1	72	Set if the Marker ID value is a Marker Group ID. Clear if the Marker ID value is a Marker ID.
	Marker ID	8	80:73	Marker ID (Is Marker Group == 0) or Marker Group ID (Is Marker Group == 1)
	Is Last Round	1	81	Set if this is a last analysis round for this packet. Clear otherwise.
	Header Offset Polarity	1	82	Set if the Header Offset Inc value is added to the current Header Offset value. Clear if the Header Offset Inc value is subtracted from the current Header Offset.
	Header Offset Inc	9	91:83	Number of bytes to add or subtract from the Header Offset.
	Reserved	4	95:92	Reserved (0)

7.11.13.3 PG Spill CAM

The PG Spill CAM holds PG CAM entries that could not be placed in any CAM slice due to a hash collision.

Table 7-233. Package Section Type Numbers for PG Spill CAMs

Section Type Number	Allowed in Update Package?	Description
76	No	PG Spill CAM for the Rx Parser.
77	No	PG Spill CAM for the Tx Parser.

Table 7-234 shows the format of the PG Spill CAM section.

Table 7-234. PG Spill CAM Section Format

Field		Size (Bits)	Description
Count		16	Number of Key-Value pairs in this section.
Offset		16	Offset to the first entry in this section. All entries are contiguous from this offset. All entries must be in range 0 to 127. Entries with an offset greater than 127 are reserved. Relevant CSR uses Parser indirect interface, *Table Address* field.
Entry 0	Action	56	Parse Graph output value contains 55 bits as shown in Table 7-229 and one reserved bit (0). Relevant CSR uses Parser indirect interface with Table ID 2 (PG spill buffer action).
	Key	80	Match key for this PG entry contains 74 inputs bits as shown in Table 7-229 and seven reserved bits (0). Relevant CSR uses Parser indirect interface with Table ID 3 (PG spill buffer key).
---		Nx136 + 32	All other entries.

7.11.13.4 Parse Graph No-Match Spill CAM

The No-Match Spill CAM holds No-Match CAM entries that could not be placed in any CAM slice due to a hash collision.

Table 7-235. Package Section Type Numbers for Parse Graph No-Match Spill CAMs

Section Type Number	Allowed in Update Package?	Description
78	No	No-Match Spill CAM for the Rx Parser.
79	No	No-Match Spill CAM for the Tx Parser.

Table 7-236 shows the format of the No-Match Spill CAM section.

Table 7-236. No-Match Spill CAM Section Format

Field		Size (Bits)	Description
Count		16	Number of Key-Value pairs in this section.
Offset		16	Offset to the first entry in this section. All entries are contiguous from this offset. All entries must be in range 0 to 63. Entries with an offset greater than 63 are reserved. Relevant CSR uses Parser indirect interface, *Table Address* field.
Entry 0	Action	56	No-Match output value contains 55 bits as shown in Table 7-232 and one reserved bit (0). Relevant CSR uses Parser indirect interface with Table ID 19 (No-Match PG spill buffer action).
	Key	48	Match key for this PG entry contains 41 inputs bits as shown in Table 7-232 and seven bits reserved (0). Relevant CSR uses Parser indirect interface with Table ID 20 (No-Match PG spill buffer key).
---		Nx104 + 32	All other entries.

7.11.13.5 Node PTYPE Table

The Node PTYPE table defines the PTYPE value based on the NEXT_NODE_ID output from the Parse Graph or PG No-Match CAM. The PType value of 0 is defined to be INVALID_PTYPE. Software must set entries in this table to INVALID_PTYPE when the Marker PTYPE TCAM defines the PTYPE of the packet.

Table 7-237. Package Section Type Numbers for Node PTYPE Tables

Section Type Number	Allowed in Update Package?	Description
54	No	Node PTYPE Table for the Rx Parser.
64	No	Node PTYPE Table for the Tx Parser.

Table 7-238 shows the section format for the PTYPE table.

Table 7-238. Node PTYPE Table Section Format

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	PTYPE table address of the first entry in this section.
Entry 0	2	First PTYPE table entry containing the PTYPE value (0-1023) in bits 9:0. Bit 10 is the error output. All other bits are reserved. A PTYPE value of 0 represents an invalid PTYPE, which causes hardware to use the MARKER_PTYPE TCAM to determine the packet PTYPE. Relevant CSR uses Parser indirect interface with Table ID 15 (node cntx ID).
...	Nx2	All other entries.

7.11.13.6 Marker PTYPE TCAM

The Marker PTYPE TCAM defines the PTYPE value based on the accumulated marker bit vector.

Table 7-239. Package Section Type Numbers for Marker PTYPE TCAMs

Section Type Number	Allowed in Update Package?	Description
55	No	Marker PType Table for the Rx Parser.
65	No	Marker PType Table for the Tx Parser.

Table 7-240 shows the section format for the PTYPE table.

Table 7-240. Marker PTYPE TCAM Section Format

Field		Size (Bytes)	Description
Count		2	Number of Key-Value pairs in this section.
Reserved		2	Reserved (0).
Entry 0	Address	2	Address of this TCAM entry. Valid values are 0-1023. Values greater than 1023 are reserved. Relevant CSR uses Parser indirect interface, *Table Address* field.
	Value	2	PTYPE number (0-1023) associated with this key. Values greater than 1023 are reserved. Relevant CSR uses Parser indirect interface with Table ID 18 (PTYPE TCAM action RAM).
	Key	10	Match key for this PType value. The key contains 80 bits, encoded according to Table 7-81. The lower 72 bits represent 72 possible marker bits. The eight most significant input bits are a one-hot representation of the Control Domain ID. Relevant CSR uses Parser indirect interface with Table ID 17 (PTYPE TCAM key). Each key takes up two lines in the table.
	Key Invert	10	The key invert for this PTYPE value. The key-invert contains 80 input bits, encoded according to Table 7-81. The lower 72 bits represent the key-invert value for 72 possible marker bits. The eight most significant input bits are the key-invert of a one-hot representation of the Control Domain ID. Relevant CSR uses Parser indirect interface with Table ID 17 (PTYPE TCAM key). Each key takes up two lines in the table.
...		Nx24	All other entries.

7.11.13.7 IMEM

7.11.13.7.1 IMEM Section

The Instruction Memory (IMEM) section contains three VLIW instructions for the ALUs, a key extraction instruction for the Parse Graph CAM, and several other fields.

Table 7-241. Package Section Type Numbers for IMEM

Section Type Number	Allowed in Update Package?	Description
52	No	IMEM for the Rx Parser.
62	No	IMEM for the Tx Parser.

Table 7-242 shows the format of an IMEM section.

Table 7-242. IMEM Section Format

Field		Size (Bits)	Bit Offset	Description
Count		16	0	Number of IMEM instructions in this section. Must be at least 1. Values greater than 191 are reserved.
Offset		16	16	IMEM address of the first entry in this section. The effective offset of all IMEM entries in this section must be in range 0-191. Values greater than 191 are reserved. Relevant CSR uses Parser indirect interface, *Table Address* field. Instruction content is written using Parser indirect register interface with Table ID value 14.
Entry 0	Boost Master	4	32	Boost Master flags (see Section 7.11.13.7.7).
	Boost Key Build	10	36	Boost TCAM Key Build (see Section 7.11.13.7.6).
	PG Priority	2	46	Parse Graph resolver priority control (see Section 7.11.13.7.5).
	Next Proto Key Build	18	48	Next Protocol extraction directive (see Section 7.11.13.7.4).
	PG Key Build	35	66	Format directive for the Parse Graph key (see Section 7.11.13.7.3).
	ALU 0 Instruction	96	101	Instruction for ALU 0 (see Section 7.11.13.7.2).
	ALU 1 Instruction	96	197	Instruction for ALU 1 (see Section 7.11.13.7.2).
	ALU 2 Instruction	96	293	Instruction for ALU 2 (see Section 7.11.13.7.2).
	Reserved	27	389	Reserved (0).
...		Nx384		All subsequent entries, 48 bytes each.

7.11.13.7.2 ALU Instructions

The format of an individual ALU instruction is shown in Table 7-243.

Table 7-243. ALU Instruction Format, 3x per IMEM Entry

Field	Width (Bits)	Bit Offset	Description
Opcode	6	5:0	Instruction Opcode. See Table 7-244.
Source Start	8	13:6	Source register start bit, 0-255.
Source Length	5	18:14	Source register length, 0-31.
Shift/Xlate Select	1	19	0b = Shift Source Register by four bits. 1b = Fetch from the Xlate Table using 2-bit translate key.
Shift/Xlate Key	4	23:20	4-bit shift left operand, or 2-bit translate key.
Source Register ID	7	30:24	Source register ID.
Dest. Register ID	7	37:31	Destination register ID.
Inc 0	1	38	When set increment Counter 0.
Inc 1	1	39	When set increment Counter 1.
Protocol Offset Opcode	2	41:40	00b = Protocol Offset does not change. 01b = Protocol Offset = Header Offset + Protocol Offset. 10b = Protocol Offset = Header Offset - Protocol Offset. 11b = Reserved.
Protocol Offset	8	49:42	Number of bytes to add or remove from the protocol offset to calculate the next protocol offset.
Branch Address	8	57:50	Absolute value of Branch Address in IMEM, 0-191.
Immediate	16	73:58	Immediate value.
Dedicated Flags Enable	1	74	When set activates dedicated flags logic. ALU must not be configured to set flags when this bit is set.
Dest. Start	6	80:75	Destination start bit. When *Dedicated Flags Enable* is set, this field specifies that starting bit within the 64-bit Flags metadata. When *Dedicated Flags Enable* is clear, this field specifies a single bit of the destination register written by the SETEQ/NEQ/LT/GT, ANDEQ/NEQ/LT/GT, OREQ/NEQ/LT/GT instructions. Unused in all other cases.
Dest. Length	6	86:81	Destination length in the flags field. Used only when *Dedicated Flags Enable* is set.
Flags Extract Imm.	1	87	0b = Copies Dest. Length flags from packet starting from the bit specified by *Flags Start*. 1b = Copies Dest. Length flags from Flags Immediate field.
Flags Start/Immediate	8	95:88	Specifies the start bit in the packet header from which to extract flags, or an immediate value to copy to flags as controlled by the *Flags Extract Imm* field. Used only when *Dedicated Flags Enable* is set.

The six opcode fields define the ALU instruction as shown in Table 7-244.

Table 7-244. ALU Opcodes

Mnemonic	Opcode
PARK	0
MOV (with ADD expr.)	1
ADD	2
Reserved	3
MOV (with AND expr.)	4
AND	5
AND Immediate	6
MOV (with OR expr.)	7
OR	8
MOV (with XOR expr.)	9
XOR	10
NOP	11

Mnemonic	Opcode
BR	12
BREQ	13
BRNEQ	14
BRGT	15
BRLT	16
BRGEQ	17
BRLEQ	18
SETEQ	19
ANDEQ	20
OREQ	21
SETNEQ	22
ANDNEQ	23

Mnemonic	Opcode
ORNEQ	24
SETGT	25
ANDGT	26
ORGT	27
SETLT	28
ANDLT	29
ORLT	30
MOV (with SUB expr.)	31
SUB	32
Reserved	33-62
Invalid Opcode	63

7.11.13.7.3 Parse Graph Key Build

Each IMEM entry contains a directive for building a portion of the Parse Graph Key. The format of a Parse Graph Key Build directive is shown in Table 7-245.

Table 7-245. Parse Graph Key Build Directive per IMEM and Boost TCAM Entry

Field	Width (Bits)	Bit Offset	Description
Flag 0 Enable	1	0	When set, the flag at Flag 0 Index is copied to the *Flag 0* field of the Parse Graph key. When cleared, hardware set the *Flag 0* field of the key to 0.
Flag 0 Index	6	6:1	Index of the Flag0 component of the Parse Graph key, 0-63.
Flag 1 Enable	1	7	When set, the flag at Flag 1 Index is copied to the *Flag 1* field of the Parse Graph key. When cleared, hardware set the *Flag 1* field of the key to 0.
Flag 1 Index	6	13:8	Index of the Flag1 component of the Parse Graph key, 0-63.
Flag 2 Enable	1	14	When set, the flag at Flag 2 Index is copied to the *Flag 2* field of the Parse Graph key. When cleared, hardware set the *Flag 2* field of the key to 0.
Flag 2 Index	6	20:15	Index of the Flag2 component of the Parse Graph key, 0-63.
Flag 3 Enable	1	21	When set, the flag at Flag 3 Index is copied to the *Flag 3* field of the Parse Graph key. When cleared, hardware set the *Flag 3* field of the key to 0.
Flag 3 Index	6	27:22	Index of the Flag3 component of the Parse Graph key, 0-63.
ALU Register Index	7	34:28	Index of the ALU Register component of the Parse Graph key.

7.11.13.7.4 Next Protocol Key Build

Each IMEM and Boost TCAM entry contains a directive for extracting the next protocol from the packet header. The format of a Next Protocol Key Build directive is shown in Table 7-246.

Table 7-246. Next Protocol Key Build Directive per IMEM Entry

Field	Width (Bits)	Bit Offset	Description
Opcode	2	0	00b = Extract the *Next Protocol* field from the Header Value starting from the bit position specified in the *Start* field and for the number of bits specified in the *Length* field. 01b = Build *Next Protocol* field with the value of the register in the *Reg 0* field in *Next Protocol field* bits 15:0, and the value of the register in the *Reg 1* field in *Next Protocol* field bits 31:16. 10b = Bypass the Parse Graph, in which case the Parse Graph logic does not set the Next Protocol Key value. 11b = Reserved.
Start/Reg 0	8	2	*Start* field (Opcode = 0) or *Reg 0* field (Opcode = 1).
Length/Reg 1	8	10	*Length* field (Opcode = 0) or *Reg 1* field (Opcode = 1).

7.11.13.7.5 PG Priority Control

Each IMEM and Boost TCAM entry contains two bits to controlling how the hardware resolver determines precedence from among multiple sources of register update. The format of a PG Priority Control is shown in Table 7-247.

Table 7-247. PG Priority Control per IMEM and Boost TCAM Entry

Field	Width (Bits)	Description
Priority	2	00b = The resolver uses the following priority: ALU2 is priority 3 (highest) ALU 1 is priority 2 ALU 0 is priority 1 PG is priority 0 (lowest) 01b = The resolver uses the following priority: ALU2 is priority 3 (highest) ALU 1 is priority 2 PG is priority 1 ALU 0 is priority 0 (lowest) 10b = The resolver uses the following priority: ALU2 is priority 3 (highest) PG is priority 2 ALU 1 is priority 1 ALU 0 is priority 0 (lowest) 11b = The Resolver uses the following priority: PG is priority 3 (highest) ALU2 is priority 2 ALU 1 is priority 1 ALU 0 is priority 0 (lowest)

7.11.13.7.6 Boost Key Build

The Boost Key Build field controls the value used as the 8-bit Boost TCAM search key qualifier (TSR). The TSR field contains either an arbitrary 8-bit value, or the content of the TSR register.

Table 7-248. Boost Key Build per IMEM Entry

Field	Width (Bits)	Bit Offset	Description
Priority	8	7:0	Arbitrary 8-bit value used when the *TSR Control* bit is 0.
TSR Control	2	9:8	Control bit selecting the value used the Boost TCAM search key qualifier. 00b = The Boost TCAM search key qualifier is the value in bits 7:0. 01b = The Boost TCAM search key qualifier is the content of the TSR register. 10b = Reserved. 11b = Reserved.

7.11.13.7.7 Boost Master

This field contains four flags controlling the user of Boost TCAM output. For each bit set, Boost TCAM output overrides IMEM output for the corresponding hardware block. This override occurs only in the case of a Boost lookup match. When a Boost lookup fails, IMEM output is used.

For each 0 bit, the corresponding hardware block ignores Boost TCAM output, even in the case of a Boost lookup match.

Table 7-249. Boost Master Field

Bit	Description
0	ALU 0
1	ALU 1
2	ALU 2
3	Parse Graph

7.11.13.8 Boost TCAM

The Boost TCAM provides a wide 160-bit match on a combination of packet header and TSR bits. The least significant 152 bits match against the packet header, starting from the current header offset. The most significant eight bits match the selected TSR (see Section 7.11.13.7.6).

Table 7-250. Package Section Type Numbers for the Boost TCAMs

Section Type Number	Allowed in Update Package?	Description
56	Yes	Boost TCAM for the Rx Parser.
66	Yes	Boost TCAM for the Tx Parser.

The Boost TCAM contains 256 entries, with a format similar to IMEM content as shown in Table 7-251.

Table 7-251. Format of the Boost TCAM Section

Field		Size (Bits)	Bit Offset	Description
Count		16	0	Number of entries in this section. Must be at least 1.
Reserved		16	16	Reserved (0).
Entry 0	Address	16	32	Address of this entry in the TCAM, 0-255. Smaller numbers imply higher priority. Values > 255 are reserved. Relevant CSR is the *Table Address* field of the Parser indirect interface.
	Reserved	16	48	Reserved (0).
	Key/Key Invert	320	32	[319:160] = The key-invert used to match this TCAM entry. The key invert consists of 160 input bits, encoded according to Table 7-81. Relevant CSR uses the Parser indirect interface with Table ID 0 (TCAM key). Each key takes up two lines in the table. [159:0] = The key used to match this TCAM entry. The key consists of 160 input bits, encoded according to Table 7-81. The TCAM matches the lower 152 bits of the key against the next 152 bits of the packet header (%HDR register) starting from the current header offset (%HO register). The upper eight bits of the input value are matched against the TCAM Search Key (%TSR register). Relevant CSR uses the Parser indirect interface with Table ID 0 (TCAM key). Each key takes up two lines in the table.
	Boost Hit Index Group	8	384	Provides the Boost TCAM Hit Index part of the Parse Graph Key. Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	PG Priority	2	392	Parse Graph resolver priority control (see Section 7.11.13.7.5). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	Next Proto Key Build	18	394	Next Protocol extraction directive (see Section 7.11.13.7.4). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	PG Key Build	35	412	Format directive for the Parse Graph key (see Section 7.11.13.7.3). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	ALU 0 Instruction	96	447	Instruction for ALU 0 (see Section 7.11.13.7.2). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	ALU 1 Instruction	96	543	Instruction for ALU 1 (see Section 7.11.13.7.2). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	ALU 2 Instruction	96	639	Instruction for ALU 2 (see Section 7.11.13.7.2). Relevant CSR uses the Parser indirect interface with Table ID 13 (TCAM action RAM).
	Reserved	1	735	Reserved (0).
...			Nx704 + 32	Subsequent entries, 88 bytes each.

7.11.13.9 Protocol Group Table

The Protocol Group table controls hardware expansion of a protocol group into individual protocol and offset pairs in packet metadata. The table contains 192 entries indexed by the Protocol ID output from the Parse Graph. Hardware performs the expansion of the Protocol Group into individual protocols only when the Parse Graph sets the *Is Protocol Group* flag output.

Table 7-252. Package Section Type Numbers for the Protocol Group Tables

Section Type Number	Allowed in Update Package?	Description
57	No	Protocol Group Table for the Rx Parser.
67	No	Protocol Group Table for the Tx Parser.

Each entry in the Protocol Group table defines eight Protocol ID and offset pairs.

The relevant CSR for this table is accessed with GLGEN_ANA_CFG_CTRL.*TABLE_ID* = 12.

The format of this table is shown in Table 7-253.

Table 7-253. Protocol Group Table Section Format

Field		Size (Bits)	Bit Offset	Description
Count		16	0	Number of entries in this section.
Offset		16	16	Offset to the first table address in this section. All entries must be in range 0-191.
Entry 0	Protocol 0	1	32	Polarity of the *Protocol Offset* field. 0b = Positive offset 1b = Negative offset.
		8	33	Protocol ID.
		3	41	Reserved (0).
		10	44	10-bit Protocol Offset.
	Protocol 1	1	54	Polarity of the *Protocol Offset* field. 0b = Positive offset 1b = Negative offset.
		8	55	Protocol ID.
		3	63	Reserved (0).
		10	73	10-bit Protocol Offset.
	...			Entries for Protocols 2-6.
	Protocol 7	1	186	Polarity of the *Protocol Offset* field. 0b = Positive offset 1b = Negative offset.
		8	187	Protocol ID.
		3	195	Reserved (0).
		10	198	10-bit Protocol Offset.
	Reserved	16	208	Reserved(0).
...		192	224	All subsequent entries, 24 bytes each.

7.11.13.10 Marker Group Table

The Marker Group table controls hardware expansion of a marker group into individual marker bits in packet metadata. The table contains 128 entries indexed by the Marker ID output from the Parse Graph. Hardware performs the expansion of the Marker Group into individual marker bits only when the Parse Graph sets the *Is Marker Grou*p flag output.

Table 7-254. Package Section Type Numbers for the Marker Group Tables

Section Type Number	Allowed in Update Package?	Description
72	No	Marker Group Table for the Rx Parser.
73	No	Marker Group Table for the Tx Parser.

Each entry in the Marker Group table defines eight Marker ID values.

The relevant CSR for this table is accessed with GLGEN_ANA_CFG_CTRL.*TABLE_ID* = 16.

The format of this table is shown in Table 7-255.

Table 7-255. Marker Group Table Section Format

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	Offset to the first table address in this section. All entries must be in range 0-127. Values greater than 127 are reserved.
Entry 0	1	Marker ID 0. All Marker ID values must be in range 0-71, where value 71 represents an invalid (unused) Marker ID.
	1	Marker ID 1.
	1	Marker ID 2.
	1	Marker ID 3.
	1	Marker ID 4.
	1	Marker ID 5.
	1	Marker ID 6.
	1	Marker ID 7.
...	Nx8	All other entries. Each entry occupies a consecutive offset. Maximum number of entries is 128.

7.11.13.11 Parser XLT0 Key Builder Table

The ParserXLT0 Key Builder table specifies the index into the Parser's XLT0 table for each packet.

Hardware builds the key value by extracting bits from the specified metadata field.

Table 7-256. Package Section Type Numbers for the Parser XLT0 Builder Table

Section Type Number	Allowed in Update Package?	Description
53	No	XLT0 Key Builder Table for the Rx Parser.
63	No	XLT0 Key Builder Table for the Tx Parser.

The relevant CSR for this table is GLGEN_ANA_PROFIL_CTRL.

The format of the XLT0 Key Builder Table is shown in Table 7-257.

Table 7-257. Parser XLT0 Key Builder Table Section Format

Field	Size (Bytes)	Description
MDID	1	Specifies the MDID value from the Initialization ID is extracted. Valid range is 0-31. All other values are reserved.
MD Start	1	Start bit for the Initialization ID extraction from the metadata field. Valid range is 0-15. All other values are reserved.
MD Length	1	Length of the Initialization ID extraction from the metadata field. Valid range is 0-31. All other values are reserved.
CD Count	1	The domain key width in the PTYPE marker vector. The only supported value is 3, indicating 8 control domains (72 markers + 8b one-hot control domain bitmap).

7.11.13.12 Package Format of the Parser XLT0 Table

This section specifies the package format for configuring the per-parser XLT0 table. The XLT0 Table provides an intermediate stage during calculation of an Initialization ID. The Parser XLT0 Key Builder Table (see Section 7.11.13.11) builds the key used for XLT0 lookup. The output of the XLT0 table drives the input to the Initialization ID Redirection table (see Section 7.11.13.13).

Each parser uses a distinct XLT0 Table configuration and distinct Package Section Type Numbers to contain the configuration data. Table 7-258 shows the section type enumeration.

Table 7-258. Package Section Type Numbers for the Parser XLT0 Tables

Section Type Number	Allowed in Update Package?	Description
59	No	XLT0 Table for the Rx Parser.
69	No	XLT0 Table for the Tx Parser.

The package format for XLT0 Table configuration is common for all parser as shown in Table 7-259.

Table 7-259. Package Format for XLT0 Table Configuration

Field	Size (Bytes)	Description
Count	2	Number of entries in this section. If the XLT0 table is split into multiple sections, this field describes only the number of entries contained in this section.
Offset	2	Byte offset from the start of the table to the first value in this section. The maximum effective offset for any value is 1023. Effective offsets greater than 1023 are reserved. Relevant CSR: GLGEN_ANA_CFG_CTRL.*TABLE_ADDR*.
Value	1	Value of this XLT0 entry. Valid values are in range (0-15). The value 255 is reserved for internal use by assembler tools before conversion to a valid value. All other values are reserved. The relevant CSR for this table is accessed with GLGEN_ANA_CFG_CTRL.*TABLE_ID* = 26.
...	...	Subsequent values at consecutive offsets.

7.11.13.13 Initialization ID Redirection Table

After the XLT0 table generates the Initialization ID, the Initialization ID Redirection Table can change this ID to a different value. The Redirection Table always maps the input ID to an output ID. Therefore, to allow ID values to pass through unchanged, the host must initialize this table to the trivial identity mapped case (for example, ID 14 maps to ID 14).

Each parser contains its own Initialization ID Redirection Table. Table 7-260 shows the relevant Package Section Type for each block.

Table 7-260. Package Section Type Numbers for Initialization ID Redirection Tables

Section Type Number	Allowed in Update Package?	Description
70	No	Initialization ID Redirection Table for the Rx Parser.
71	No	Initialization ID Redirection Table for the Tx Parser.

The package format for the Initialization ID Redirection Table is common for all parsers as shown in Table 7-261.

Table 7-261. Package Format for Initialization ID Redirection Table

Field	Size (Bytes)	Description
Initialization ID 0 Redirect Value	1	Redirected value for Initialization ID 0. Relevant CSR: GLGEN_ANA_P2P0
Initialization ID 1-14	14 x 1	...
Initialization ID 15 Redirect Value	1	Redirected value for Initialization ID 15. Relevant CSR: GLGEN_ANA_P2P15

7.11.13.14 Metadata Initialization Table

The Metadata Initialization Table provides static values used to initialize packet metadata. The table is indexed using Initialization ID output from the Initialization ID table.

The relevant CSR for this table is accessed with GLGEN_ANA_CFG_CTRL.*TABLE_ID* = 25.

The format of this table is shown in Table 7-262.

Table 7-262. Metadata Initialization Table

Field	Size (Bits)	Bit Offset	Description
Count	16	0	Number of entries in this section.
Offset	16	16	Offset to the first Initialization ID in this section.

Table 7-262. Metadata Initialization Table [continued]

Field		Size (Bits)	Bit Offset	Description
Entry 0	TSR	8	32	TSR - Initial value of the TCAM Search Key register.
	HO	9	40	HO - Initial value of the Header Offset register. Valid range is 0 to 503. All other values are reserved.
	PC	8	49	PC - Initial value of the Program Counter register. Valid range is 0 to 191. All other values are reserved.
	NID	11	57	NID - Initial Parse Graph root node to start package processing. Valid range is 0 to 2047. All other values are reserved.
	CD	3	68	CD - Control Domain ID for this packet. Valid range is 0 to 7. All other values are reserved.
	GPR_A_CTL	1	71	Controls the GPR_A_DATA field. See the description for GPR_A_DATA.
	GPR_A_DATA	16	72	When the GPR_A_CTL is clear, copies a constant value to the GPR specified by GPR_A_ID: GPRS[GPR_A_ID] = GPR_A_DATA When the GPR_A_CTL is set, this field selects the MDID_A value as follows: [4:0] = ID of MDID_A metadata. [8:5] = START extraction start bit for MDID_A [13:9] = LEN extraction length for MDID_A [15:14] = Reserved (0) The specified MDID is copied to GPR_A_ID: GPRS[GPR_A_ID] = MDID_A[LEN+START -1 : START]
	GPR_A_ID	4	88	GPR ID of general purpose register as described above. This field cannot specify the same ID value used in any of the three other *GPR_n_ID* fields.
	GPR_B_CTL	1	92	Same behavior as GPR_A_CTL.
	GPR_B_DATA	16	93	Same behavior as GPR_A_DATA.
	GPR_B_ID	4	109	Same behavior as GPR_A_ID.
	GPR_C_CTL	1	113	Same behavior as GPR_A_CTL.
	GPR_C_DATA	16	114	Same behavior as GPR_A_DATA.
	GPR_C_ID	4	130	Same behavior as GPR_A_ID.
	GPR_D_CTL	1	134	Same behavior as GPR_A_CTL.
	GPR_D_DATA	16	135	Same behavior as GPR_A_DATA.
	GPR_D_ID	4	151	Same behavior as GPR_A_ID.
	Flags	64	155	Initial value for all Flags.
	Reserved	5	219	Reserved(0)
...		Nx192	224	All consecutive entries, 24 bytes each.

7.11.13.15 Last Protocol Table

The Last Protocol Table specifies which Protocol ID values receive special treatment from the parser hardware. The table specifies up to six protocol ID values treated as last protocols. Normally, when the Parse Graph outputs a Protocol ID value, hardware pushes the ID and corresponding Header Offset value onto the Protocol ID stack. However, when this Protocol ID value matches a last protocol, hardware instead records the offset in a side memory. When processing completes, hardware updates the stack with the Protocol ID and last Header Offset value recorded.

Each parser contains its own Last Protocol Table. Table 7-263 shows the relevant Package Section Type for each block.

Table 7-263. Package Section Type Numbers for Last Protocol Tables

Section Type Number	Allowed in Update Package?	Description
74	No	Last Protocol Table for the Rx Parser.
75	No	Last Protocol Table for the Tx Parser.

The package format for the Last Protocol Table is common for all parsers as shown in Table 7-264. The order of entries in table has no effect on functionality.

Table 7-264. Package Format of a Last Protocol Table

Field	Size (Bits)	Bit Offset	Description
Reserved	32	0	Reserved for programming tools use. Ignored by firmware.
Entry 0	1	32	Enable. 1b if this entry is valid, 0b otherwise. Relevant CSR for all fields of this entry: GLGEN_ANA_RX/TX_LAST_PROT_ID[0].
	8	33	
	23	41	Reserved (0).
...	Nx32		All consecutive entries 1-5 formatted as above. Relevant CSR for all fields of this entry: GLGEN_ANA_RX/TX_LAST_PROT_ID[N].

7.11.13.16 Miscellaneous Parser Configuration

The Miscellaneous Parser Configuration section collects together various one-off parser configuration items.

Each parser contains its own Miscellaneous Parser Configuration section. Table 7-265 shows the relevant Package Section Type for each block.

Table 7-265. Package Section Type Numbers for Parser Miscellaneous Configuration

Section Type Number	Allowed in Update Package?	Description
90	No	Miscellaneous configuration for the Rx Parser.
91	No	Miscellaneous configuration for the Tx Parser.

The package format for the Parser Miscellaneous Configuration section is shown in Table 7-266.

Table 7-266. Package Format of the Parser Miscellaneous Configuration Section

Field	Size (Bits)	Bit Offset	Description
PG CAM Hash Key	128	0	The hashing seed value used to calculate the PG CAM entry index as described in Section 7.11.13.2.2. The 45 most significant bits of this value must be 0. A zero value signifies that the hash key is not valid. Firmware ignores this field when the value is zero. Relevant CSR: GLGEN_ANA_PG0_HASHKEY.
No-Match Hash Key	64	128	The hashing seed value used to calculate the PG No-Match CAM entry index as described in Section 7.11.13.2.2. The 13 most significant bits of this value must be 0. A zero value signifies that this hash key is not valid. Firmware ignores this field when the value is zero. Relevant CSR: GLGEN_ANA_NMPG0_HASHKEY.

7.11.13.17 Flags Redirection Table

The Flags Redirection Table specifies if an external flags value is overridden by an internal analyzer flag.

Each parser contains its own Flags Redirection Table. Table 7-267 shows the relevant Package Section Type for each block.

Table 7-267. Package Section Type Numbers for Flags Redirection Tables

Section Type Number	Allowed in Update Package?	Description
97	No	Flags Redirection Table for the Rx Parser.
98	No	Flags Redirection Table for the Tx Parser.

The Package format for the Flags Redirection Table is common for all parsers as shown in Table 7-268. The order of entries in table has no effect on functionality.

Table 7-268. Package Format of a Flags Redirection Table

Field	Size (Bytes)	Offset (Bytes)	Description
Count	2	0	Number of entries in this section.
Offset	2	2	Offset to the first entry (N) in this section. Offset must be in the range 0 to 63.
Entry 0	1	4	The downstream flag identifier, where [0] = When set, the analyzer flag [N] should be exposed on the Flag ID. [6:1] = The internal Flag ID, valid only if the enable bit is set. [7] = Reserved (0) Relevant CSRs: GLGEN_ANA_TX_FLAG_MAP, GLGEN_ANA_FLAG_MAP
---	Nx1 + 4		All subsequent entries in consecutive order, 1 byte each

7.11.14 HIF Block Programming

7.11.14.1 Introduction

The flex descriptor feature allows software entities to program customized receive descriptors.

7.11.14.2 Flex Descriptor Table

The Flex Descriptor table contains descriptor format for a packet for a given descriptor builder profile. Each entry in the Flex Descriptor table defines six Flexible Metadata definitions and up to 18 flags.

Table 7-269. Package Section Type Numbers for Flex Descriptor Table

Section Type Number	Allowed in Update Package?	Description
94	Yes	Rx Flex Descriptors for HIP.

The format of this table is shown in Table 7-270.

Table 7-270. Flex Descriptor Table

Field	Size (Bits)	Bit Offset	Description
Count	16	0	Number of entries in this section.
Offset	16	16	Offset to the first RXDID in this section. The maximum effective offset for any value is 63. Effective offsets greater than 63 are reserved. Values of 0, 1 and 7 are reserved.

Table 7-270. Flex Descriptor Table [continued]

Field		Size (Bits)	Bit Offset	Description
Entry 0	FlexibleMD0	32	32	[7:0] = Protocol ID, MDID Fixed value depending on opcode [17:8] = Offset (for opcode 2), otherwise reserved(0) [29:18] = Reserved (0) [31:30] = Opcode: 00b = Fixed value 01b = Metadata offset 10b = Extraction offset 11b = Protocol offset Relevant CSR: GLFLXP_RXDID_FLX_WRD_0
	FlexibleMD1	32	64	Same format as FlexibleMD0. Relevant CSR: GLFLXP_RXDID_FLX_WRD_1
	...			
	FlexibleMD5	32	192	Same format as FlexibleMD0. Relevant CSR: GLFLXP_RXDID_FLX_WRD_5
	Flag0	32	224	[5:0] The flag index for Flag 0 [7:6] = Reserved (0) [13:8] = The flag index for Flag 1 [15:14] = Reserved (0) [21:16] = The flag index for Flag 2 [23:22] = Reserved (0) [29:24] = The flag index for Flag 3 [31:30] = Reserved (0) Relevant CSR: GLFLXP_RXDID_FLAGS[n, m=0]
	Flag1	32	256	Same format as Flag0. Relevant CSR: GLFLXP_RXDID_FLAGS[n, m=1]
	...			
	Flag4	32	352	[5:0] = The flag index for Flag 16 [7:6] = Reserved (0) [13:8] = The flag index for Flag 17 [31:14] = Reserved (0) Relevant CSR: GLFLXP_RXDID_FLAGS[n, m=4]
...		Nx320 + 32	384	All consecutive entries, 44 bytes each.

7.11.15 RDPU Block Configuration

7.11.15.1 Introduction

The RDPU Block Configuration defines the Receive Data Processing Unit.

7.11.15.2 PTYPE Translation Table

The PTYPE Translation table contains a mapping for E810 10-bit PTYPEs to legacy 8-bit PTYPEs.

Table 7-271. Package Section Type Numbers for PTYPE Redirection Table

Section Type Number	Allowed in Update Package?	Description
95	Yes	PTYPE Translation table for HIF.

Table 7-272. Package Format for PTYPE Redirection Table

Field	Size (Bytes)	Description
Count	2	Number of entries in this section.
Offset	2	Offset to the first PTYPE in this section. Offset must be in range 0 to 1023.
Legacy PTYPE ID	1	Redirected value for the PTYPE specified by the *Offset* field. Relevant CSR: GLFLXP_PTYPE_TRANSLATION
...	Nx1 + 4	Subsequent values in consecutive order.

7.11.15.3 PROTOCOL Table

The PROTOCOL table defines the presence of protocols for which the RDPU verify packet checksum values. If any of the four protocol IDs match for a given protocol table entry, that entry matches.

The PROTOCOL table contains 256 entries corresponding to each possible PTYPE8 value produced by the PTYPE_REMAP table.

Table 7-273. Package Section Type Numbers for the PROTOCOL Table

Section Type Number	Allowed in Update Package?	Description
96	No	PROTOCOL Table for RDPU.

Table 7-274. Package Format for PROTOCOL Table

Field	Size (Bits)	Bit Offset	Description
Count	16	0	Number of entries in this section.
Offset	16	16	Offset to the first entry in this section. Valid values are 0 to 255.

Table 7-274. Package Format for PROTOCOL Table [continued]

Field		Size (Bits)	Bit Offset	Description
Entry 0	Offset Index	3	32	The offset at which the INNER protocol is defined. Valid values are 1-5. A value of 3'b000 indicates not in use. Relevant CSR: GLFLXP_RX_CMD_LX_PROT_IDX
	Reserved	1	34	Reserved (0).
	L4 Offset Index	3	35	The offset at which the L4 Protocol is defined. Valid values are 1-5. A value of 3'000 indicates not in use. Relevant CSR: GLFLXP_RX_CMD_LX_PROT_IDX
	Reserved	1	38	Reserved (0).
	Payload Offset Index	3	39	The offset at which the packet payload is defined. Valid values are 0-5. Relevant CSR: GLFLXP_RX_CMD_LX_PROT_IDX
	Reserved	1	42	Reserved (0)
	L3 Protocol	2	43	The first L3 protocol of the packet. 00b = IPv4 01b = IPv6 10b = Invalid 11b = Other Relevant CSR: GLFLXP_RX_CMD_LX_PROT_IDX
	L4 Protocol	2	45	The last L4 protocol of the packet: 00b = TCP 01b = UDP 10b = SCTP 11b = Other Relevant CSR: GLFLXP_RX_CMD_LX_PROT_IDX
	Reserved	16	48	Reserved (0)
	Protocol Ids for Offset 0	32	64	The protocol IDs for creating offset 0 to RDPU. [7:0] = Protocol ID #0 [15:8] = Protocol ID #1 [23:16] = Protocol ID #2 [31:24] = Protocol ID #3 Relevant CSR: GLFLXP_RX_CMD_PROTIDS[n, m=0]
	Protocol IDs for Offset 1	32	96	Same format as Protocol IDs for Offset 0. Relevant CSR: GLFLXP_RX_CMD_PROTIDS[n, m=1]
	...	...	...	...
	Protocol IDs for Offset 5	32	224	The protocol IDs for creating offset 5 to RDPU. [7:0] = Protocol ID #0 [15:8] = Protocol ID #1 [23:16] = Protocol ID #2 [31:24] = Protocol ID #3 Relevant CSR: GLFLXP_RX_CMD_PROTIDS[n, m=5]
...		Nx224 + 32	256	All consecutive entries, 28 bytes each.

7.12 L2 Packet Processing

7.12.1 CRC Handling

7.12.1.1 Ethernet CRC Insertion

The E810 calculates and inserts the Ethernet CRC for all packets transmitted to the network.

7.12.1.2 Ethernet CRC Stripping

The E810 checks the integrity of the Ethernet CRC and possibly strips it. On packets that are posted to LAN queues, The Ethernet CRC bytes are stripped according to setting of the *CRCStrip* flag in the target LAN queue context

Packets that are routed to PE queue pairs are striped from the Ethernet CRC (with no setting option).

7.12.2 L2 Padding

Transmit packets to the network are padded with zeros to 60 bytes guaranteeing that their length including the CRC is at least 64 bytes. See description of the MAC functionality in Section 3.2.1.3.

Receive packets to the host are padded as well. Packets are padded with zero guaranteeing that they are never shorter than 60 bytes if the following conditions are met:

- Received packet to host memory from the network with no CRC bytes (stripped by the device) and additional stripped fields (like VLAN) that their remaining length is shorter than 60 bytes.
- Loopback packets to host memory (VM to VM) with or without stripped fields (like VLAN) that their remaining length is shorter than 60 bytes.
- Same rules for packets destined to the EMP.

7.12.3 L2 Tag Handling

7.12.3.1 Overview

This section describes the generic mechanism used to handle L2 tags in the E810.

The E810 supports up to eight tags. In general, the text herein applies to each tag independently.

The order these tags are expected in a packet is according to their index in the array described in Table 7-278. Index 7 is the most inner L2 tag (closest to the L3 header) and index 0 is the most outer L2 tag (closest to the MAC Address) as described in Figure 7-36.

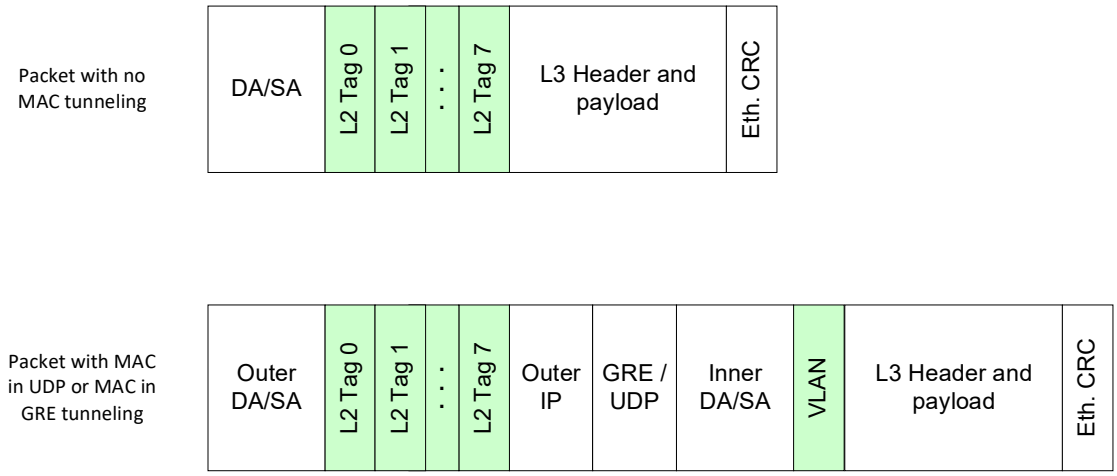

Figure 7-36. L2 Tags Order

Note: The text below refers to offloads provided by the device. A packet received from the network can have any number of tags, and a packet transmitted may have any number of tags added by software provided no offload is required.

Note: When priority bits are mentioned it refers to the 4-MSB-bits of the tag (including the DEI bit).

Note: The L2 tag handling does not use the L2 tag parsing as described in Section A.2, but uses the mechanism described below.

See Section 7.12.3.4 for the programming interface to describe the supported tags and the way to handle them.

7.12.3.2 Transmit Tag Handling

The transmit tag handling has three logical parts as described in the following diagram:

Figure 7-37. Transmit Tag Handling

The software-based tag insertion is described in Section 7.12.3.2.1. The port acceptance rules and port-based tag insertion are described in Section 7.12.3.2.2.

Section 7.12.3.3 describes the receive tag handling and Section 7.12.3.4 describes the software interface used to manipulate the tags.

7.12.3.2.1 Software-Based Tag Insertion Rules

The software can require to send packets with different L2 tag. It can do so either directly through the data for all the tags or using the transmit descriptor as described in Section 10.5.3.1 for up to two tags.

The tags available for the descriptor based insertion are fixed by the device according to the mode of operation.

The type of the tag taken from *L2TAG1* field in this descriptor when *IL2TAG1* field is set is defined by the VSI_L2TAGSTXVALID.*L2TAG1INSERTID* field when VSI_L2TAGSTXVALID.*L2TAG1INSERTID_VALID* is set. If the type of the L2 Tag requires more than two variable bytes, additional bytes are taken from the *L2TAG2* field while the *L2TAG1* is first on the wire. In this case, the *IL2TAG2* flag must be cleared.

The type of the tag taken from *L2TAG2* field in this descriptor when *IL2TAG2* field is set is defined by the VSI_L2TAGSTXVALID.*L2TAG2INSERTID* field when VSI_L2TAGSTXVALID.*L2TAG2INSERTID_VALID* is set.

After the tags are inserted according to the software request, the rules per VSI described in Section 7.12.3.2.2 are applied to decide if the packet can be sent.

7.12.3.2.1.1 Single Tag Handling

Table 7-275 describes the tag insertion in different cases when each tag is identified by a different EtherType:

Table 7-275. Single Tag Handling

Tag in the Data Buffer	Tag in the Tx-Descriptor	Software Requested Action
No	No	Do nothing (send untagged packet).
No	Yes	Insert Tag from the descriptor.
Yes	No	Do Nothing (send packet with the tag from the buffer).
Yes	Yes	This is not a valid configuration and should not be used.

Note: Table 7-275 relates to the configuration of a single tag. The configuration of different tags is independent.

7.12.3.2.1.2 Double Tag Handling

If L2 tags configuration table contains two tags with the same EtherType (for example, two VLANs with EtherType=0x8100) and both tags are enabled, there might be some cases where the hardware might not be able to identify which of the two tags were inserted by the driver directly in the packet.

In this case, if only one tag with that EtherType is seen in the packet and no insertion was requested by the driver or via port-based insertion, it is assumed to be the first of the two tags (in our example, the outer VLAN). Any further action (anti-spoof, UP translation, tag accept policy, and port-based tagging) interpret this tag according to this (so, if anti-spoof, for example, is applied only to inner VLAN, a packet with a single VLAN is treated as a packet with no VLAN for anti-spoof).

If a single tag of these two is present in the buffer sent by the host, but the descriptor requests insertion of one of the tags (for example, an outer VLAN), it is assumed that the tag present in the buffer is the tag for which offload was not requested (in this case, inner VLAN).

After the decision on the identity of each tag, the handling of each tag is as described in Section 7.12.3.2.1.1.

Note: If a tag is inserted by the driver or using port-based insertion, the explanation above is not relevant – the tag is offloaded as required.

7.12.3.2.2 Port (VSI) Based Tag Handling

7.12.3.2.2.1 Accept Rules

This section describes the rules applied per VSI to decide if the software request is acceptable. Table 7-276 summarizes the applied rule according to tag accept, tag insert and the tag presence in the packet for a specific tag.

Table 7-276. Port-Based Tag Handling - Transmit

Tag Accept Mode	Tag Inserted by Driver?	Port-Based Tag	Allowed Driver Behavior[1]	Action
Allow untagged only: VSI_TAR.*ACCEPTTAGGED* = 0 VSI_TAR.*ACCEPTUNTAGGED* = 1	No	No	Yes	Send the packet as is.
	No	Yes	Yes	Tag inserted by the VSI.
	Yes - from descriptor and VLAN ID != 0	Yes	No	VSIs VLAN Tag overrides software while keeping the priority and DEI bits provided by software.
	Yes - in packet	Yes	No	Drop packet.
	Yes	No	No	Drop packet.
	VLAN ID = 0[2]	No	Yes	Send the packet as is.
	VLAN ID = 0[2]	Yes	Yes	Port-based (VSIs) VLAN Tag overrides tag provided by software while keeping the priority and DEI bits provided by software. This mode is supported only if tag is inserted in the descriptor, and only if the insertion is from the first descriptor tag and first VSI tag or from the second descriptor tag and second VSI tag.
Allow tagged and untagged: VSI_TAR.*ACCEPTTAGGED* = 1 VSI_TAR.*ACCEPTUNTAGGED* = 1	X	Yes	Unexpected VSI Setting	Undefined.
	X	No	Yes	Send the packet as is
Allow tagged only: VSI_TAR.*ACCEPTTAGGED* = 1 VSI_TAR.*ACCEPTUNTAGGED* = 0	X	Yes	Unexpected VSI Setting	Undefined.
	No	No	No	Drop packet.
	Yes	No	Yes	Send the packet as is.
Accept nothing VSI_TAR.*ACCEPTTAGGED* = 0 VSI_TAR.*ACCEPTUNTAGGED* = 0	X	X	X	Non-legal configuration.

1. "Unexpected VSI setting" means that the combination of Tag Accept Mode and Port Based Tag should not be requested when creating a VSI.
2. If GL_SWT_L2TAGCTRL.*ISVLAN* is set (can be set only in one tag - inner VLAN).

7.12.3.2.2.2 Port-Based Tag Insertion Mechanism

After the packet sent by the software device driver was accepted, the E810 can add up to three tags based on the VSI that sent the packets. Two of the added tags can have a variable part of up to 16 bits, and one tag can have a variable part of up to 32 bits. The tags that are allowed to be port-based are determined via the VSI_L2TAGSTXVALID.*TIR[012]_INSERT* and VSI_L2TAGSTXVALID.*TIR[012]INSERTID* bits.

The tags for which port-based insertion is done are fixed by the device according to the mode of operation.

For tags up to eight bytes (not including the EtherType), the entire tag can be inserted by the hardware. Either as a request of the software via the descriptor as described in Section 7.12.3.2.1, or as part of a port-based tag insertion.

Each tag can contain the following parts:

- The EtherType
- A fixed part
- A variable part (up to 16 or 32 bits).

The EtherType is taken from the GL_SWT_L2TAGCTRL.*ETHERTYPE* field. The fixed part is taken from the GL_SWT_L2TAGDATA0 and GL_SWT_L2TAGDATA1 register. The GL_SWT_L2TAGCTRL.*LENGTH* field indicates the length of the EtherType payload.

Note: Unused part of the fixed part and the word in which the variable part is inserted should be set to zero.

The variable part is extracted from the descriptor or from the VSI_TIR register. The GL_SWT_L2TAGTXIB.*OFFSET* and the GL_SWT_L2TAGTXIB.*LENGTH* define the location and length of the variable part. Figure 7-38 describes the relationship between the different parameters.

The order of the tags inserted from the port-based tags is according to the order in the bit map. Thus the first bit set uses the value from the VSI_TIR[0] register, the second bit set uses the value from the VSI_TIR[1] register, and the third bit set uses the value from the VSI_TIR[2] register.

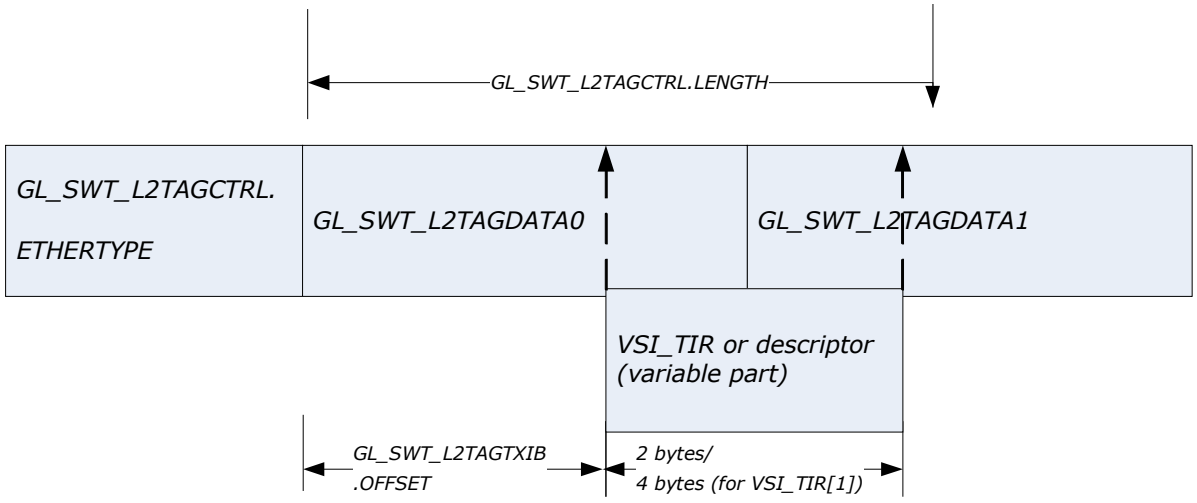

Figure 7-38. Tag Insertion

7.12.3.2.2.3 Queue-Based Tag Insertion

For one of the tags, the E810 can insert different port based tags based on the queue from which the packet was sent. If the ALT_VLAN bit in the transmit queue context is set, the tag is taken from the alternate tag register - VSI_TAIR instead of being taken from VSI_TIR.

This capability is available for each VSI in the tag inserted to the VSI_L2TAGSTXVALID.*TIR0INSERTID* tag.

7.12.3.3 Received Tag Extraction Rules

The tag extraction from receive packets and insertion in the receive descriptor write-back is controlled by the VSI_TSR.*STRIPTAG*, VSI_TSR.*SHOWTAG*, and VSI_TSR.*SHOWPRIONLY* bit fields. The options

supported for each tag are:

- Do nothing.
- Remove this tag from receive packets and do not insert into descriptor.
- Remove this tag from receive packets and insert into descriptor.
- Remove this tag from receive packets and insert only priority bits into descriptor.

Note: The *DEI* bit is considered part of the priority bits and is shown if the priority bits are shown.

Up to two L2 tags can be extracted into the Rx-Descriptor. One of the tags can supply up to 32 bits of data, and the other tag can supply up to 16 bits of data (a total of three 16-bit words max). If more than one word needs to be extracted, 32-byte descriptors need to be used (the *DSize* flag in the receive queue context is set to 32B_Descriptor) otherwise 16-byte descriptors can be used (the *DSize* flag is set to 16B_Descriptor).

The order of the tags extracted to the descriptor is according to the order in the VSI_TSR.*SHOWTAG* bitmap, and according to the *L2TSEL* field in the queue context. If *L2TSEL* bit is set, the first bit set extracts the value to the *L2TAG1* field in the receive descriptor, and the second bit set extracts the value to the *L2TAG2 (2nd)* and *L2TAG2 (1st)* fields in the receive descriptor. If *L2TSEL* bit is cleared, the first bit set extracts the value to the *L2TAG2 (2nd)* and *L2TAG2 (1st)* fields in the receive descriptor, and the second bit set extracts the value to the *L2TAG1* field in the receive descriptor.

Note: The *L2TAG2 (1st)* field is used only if the GL_SWT_L2TAGRXEB.*LENGTH* is 10b or 11b (24 or 32 bits extracted part). Otherwise, the entire tag is stored in L2TAG2 (2nd).

When removal from the packet of a tag is requested, the total L2 tag (determined by the GL_SWT_L2TAGCTRL[7:0].*LENGTH* field), including the EtherType is extracted from the packet.

Further details on the reporting in the descriptor can be found in Section 10.4.2.2.

If the *SHOWIV* bit is set in queue context, the inner VLAN value replaces the tag extracted to L2TAG2.

Table 7-277 describes the content of the tags in the receive descriptor write-back in different cases assuming the first tag is an STag and the second tag is a VLAN.

Table 7-277. Tag Extraction Example

SHOWIV	L2TSEL	Tag #1 (First Bit Set in SHOWTAG (e.g. STag))	TAG #2 (Second Bit Set in SHOWTAG (e.g. VLAN))	Packet			L2TAG1	L2TAG2 (2nd)	L2TAG2 (1st)
				Tag #1 Present	Tag #2 Present	Inner VLAN Present			
0	0	16 bits	16 bits	y	y	X	VLAN	STag	0
				y	n		Not Valid	STag	0
				n	y		VLAN	Not Valid	Not Valid
				n	n		Not Valid	Not Valid	Not Valid
		32 bits	32 bits	y	y		VLAN	Tag#1 LSW	Tag#1 MSW
				y	n		Not Valid	Tag#1 LSW	Tag#1 MSW
				n	y		VLAN	Not Valid	Not Valid
				n	n		Not Valid	Not Valid	Not Valid
		16/32 bits	32 bits	X	X		Not a valid configuration		
	1	16 bits	16 bits	y	y		STag	VLAN	0
				y	n		STag	Not Valid	Not Valid
				n	y		Not Valid	VLAN	0
				n	n		Not Valid	Not Valid	Not Valid
		32 bits	32 bits	y	y		STag	Tag #2 LSW	Tag#2 MSW
				y	n		STag	Not Valid	Not Valid
				n	y		Not Valid	Tag #2 LSW	Tag#2 MSW
				n	n		Not Valid	Not Valid	Not Valid
		16/32 bits	32 bits	X	X		Not a valid configuration		
1	0	16 bits	16/32 bits	y	X	n	Not Valid	STag	0
				n	X	y	Inner VLAN	Not Valid	Not Valid
				y	X	y	Inner VLAN	STag	0
				n	X	n	Not Valid	Not Valid	Not Valid
		32 bits	16/32 bits	y	X	n	Not Valid	Tag#1 LSW	Tag#1 MSW
				n	X	y	Inner VLAN	Not Valid	Not Valid
				y	X	y	Inner VLAN	Tag#1 LSW	Tag#1 MSW
				n	X	n	Not Valid	Not Valid	Not Valid
	1	16 bits	16/32 bits	y	X	y	STag	Inner VLAN	0
				n	X	y	not valid	Inner VLAN	0
				y	X	n	STag	Not Valid	Not Valid
				n	X	n	not valid	Not Valid	Not Valid
		32 bit	16/32 bit	X	X	X	Not a valid configuration		

7.12.3.4 Tag Handling - Programming Interface

This section describes the CSR interface available to control the L2 tags handling of the E810. The actual programming of these capabilities is either through NVM image loading of the device-wide behavior, through port-wide commands such as Set Port Parameters command for the port-wide behavior or through the Add VSI admin command (Section 7.8.12.3.1) for the per-VSI behavior.

The E810 support up to eight types of programmable L2 tags. The types of L2 tags are defined in the NVM and in registers. For each tag the following parameters are defined:

Table 7-278. L2 Tag Control Registers - Global

Register	Field	Description	Section Reference
GL_SWT_L2TAGCT RL [7:0]	ETHERTYPE	The EtherType of the L2 tag.	13.2.2.8.5
	ISVLAN	Is this Tag a VLAN tag. This information is used to define if priority tagging should be supported for this tag.	
	INNERUP	If this bit is set, the UP remapping is done on this field. If this bit is set, *ISVLAN* should also be set. If set in multiple tags, the Inner UP is taken from the first tag with this bit set in the packet.	
	OUTERUP	If this bit is set, this is the tag on which the inner to outer UP remapping is applied. Should be set only in one tag.	
	LENGTH	The length of the L2 tag (not including the EtherType). The length can be 2,4,6 or 8 bytes.	
	HAS_UP	Defines if this tag includes UP bits that should be used for UP to TC translation. The first such tag found in the packet is used for UP to TC translation	
	ISNSH	Identifies the tags that contains a NSH EtherType.	
	ISMPLS	Identifies the tags that contains a MPLS EtherType.	
PRT_L2TAGSEN	NONLAST_TAG	Indicates that there are more tags with the same EtherType expected.	13.2.2.26.1
GL_SWT_L2TAGTXIB [7:0]	OFFSET	Describes the offset in the header to which the variable data should be inserted (can be up to eight bytes)	13.2.2.8.3
GL_SWT_L2TAGDA TA0[7:0] GL_SWT_L2TAGDA TA1[7:0]	L2TAGDATA	The fixed part to insert in transmit packets	13.2.2.8.1 13.2.2.8.2

Each port defines which tags to expect in packets sent and received through this port using the GL_L2TAGSEN_<0/1/2/3>_<0/1> registers according to the following table per mode as defined by the GLGEN_MAC_LINK_TOPO register:

Table 7-279. Number of Ports to L2 Tags Enable Mapping

Port Number	Number of Ports		
	2	4	8
0	GL_L2TAGSEN_0_0 and GL_L2TAGSEN_1_0[1]	GL_L2TAGSEN_0_0	GL_L2TAGSEN_0_0
1	GL_L2TAGSEN_2_0 and GL_L2TAGSEN_3_0[1]	GL_L2TAGSEN_2_0	GL_L2TAGSEN_2_0
2		GL_L2TAGSEN_1_0	GL_L2TAGSEN_1_0
3		GL_L2TAGSEN_3_0	GL_L2TAGSEN_3_0
4			GL_L2TAGSEN_0_1
5			GL_L2TAGSEN_2_1
6			GL_L2TAGSEN_1_1
7			GL_L2TAGSEN_3_1

1. The two registers should have the same value.

The per-port PRT_TDPUL2TAGSEN defines which packets are expected in packets transmitted from this port.

Each VSI defines which of the eight L2 tags are offloaded for its Tx and Rx traffic using the VSI_L2TAGSTXVALID and VSI_TSR registers. These registers define which receive tags and transmit tags to handle.

Each VSI can be configured with a different behavior for each of the tags. The possible behaviors relate to the type of tags the driver is allowed to insert in transmit packets, the type of tags inserted by the switch, the tags removed from received packets, and the tags posted to the receive descriptor write-back.

Table 7-280 describes the registers fields used to set the expected behavior for each tag.

Table 7-280. L2 Tag Control Registers - per VSI

Register	Field	Description	Section Reference
VSI_L2TAGSTXVALID	L2TAG[12]INSERTID[1] L2TAG[12]INSERTID_VALID	Defines the tags for which descriptor-based insertion is supported. The ID is based on the L2 tags mapping described in Table 7-281.	13.2.2.12.6
	TIR[012]INSERTID TIR[012]_INSERT	Defines the tags for which port-based insertion is supported.	
VSI_TAR[2]	ACCEPTTAGGED[n]	A bitmap describing if a packet with tag N is accepted.	13.2.2.12.5
	ACCEPTUNTAGGED[n]	A bitmap describing if a packet without tag N is accepted.[3,4]	
VSI_TIR_n (n = 0..2)	PORT_TAG_ID	The tag to insert.	
VSI_TAIR	PORT_TAG_ID	The alternate tag that can be used instead of VSI_TIR[0]	

Table 7-280. L2 Tag Control Registers - per VSI [continued]

Register	Field	Description	Section Reference
VSI_TSR	STRIPTAG[n] (n = 0..9)	Defines if the tag should be extracted from the packet.	13.2.2.12.10
	SHOWTAG[n] (n = 0..9)	Defines which of the tags should be extracted to the descriptor. Valid only if corresponding bit in *STRIPTAG* is set. The *SHOWPRIONLY* field defines which part of the tag to extract to the descriptor. At most, two of these bits should be set. If more than two bits are set, only the first two are considered.	
	SHOWPRIONLY[n] (n = 0..9)	A per-tag bitmap defining which par of the tags to extract to the descriptor. If set, only the priority bits are extracted. Otherwise, the entire tag is used. Relevant only if the corresponding bit in *SHOWTAG* is set.	

1. To allow insertion of priority bits from a descriptor and the VLAN tag value from the hardware as described in Table 7-275, the same ID should be used for L2TAG1INSERTID and TIR0INSERTID or L2TAG2INSERTID and TIR1INSERTID.
2. The tag number in this register relates to the 10 tags defined in Section 7.12.3.5.
3. If GL_SWT_L2TAGCTRL.*ISVLAN* is set, admits also priority tagged packets (VLAN tag = 0).
4. This bit should be set for all the tags not expected in the packet.

7.12.3.5 L2 Tags Default Configuration

This section describes the value to set in the different registers to implement the E810 POR as loaded from NVM.

The following L2 tags are currently defined in the default configuration:

Table 7-281. L2 Tags

Tag	Tag ID (in Table)	Tag ID in VSI_TAR and VSI_TSR bitmaps
STag	0	2
ITag (MAC in MAC)	1	3
Outer VLAN (0x8100)	2	4
Outer VLAN (0x9100)	3	5
VLAN	4	6
NSHoE	5	7
MPLS 1	6	8
MPLS 2	7	9

Table 7-282 describes the configuration for each of the tags:

Table 7-282. L2 Headers Support

Register/Tag	STag	ITag (MAC in MAC)	Outer VLAN 1	Outer VLAN 2	VLAN	NSHoE	MPLS 1	MPLS 2
Index	0	1	2	3	4	5	6	7
Global Configuration								
GL_SWT_L2TAGCTRL. *ETHERTYPE*	0x88A8	0x88E7	0x8100	0x9100	0x8100	0x894F	0x8847	0x8848
GL_SWT_L2TAGCTRL.*ISVLAN*[1]	0	0	0	0	1	0	0	0
PRT_L2TAGSEN.*NON_LAST_TAG*	0	0	1	0	0	0	0	0
GL_SWT_L2TAGCTRL.*INNERUP*	0	0	0	0	1	1	0	0
GL_SWT_L2TAGCTRL.*OUTERUP*	1	0	1	1	0	0	0	0
GL_SWT_L2TAGCTRL.*LONG*	0	0	0	0	0	0	0	0
GL_SWT_L2TAGCTRL.*HAS_UP*	1	0	1	1	1	1	0	0
GL_SWT_L2TAGCTRL.*ISMPLS*	0	0	0	0	0	0	0	1
GL_SWT_L2TAGCTRL.*ISNSH*	0	0	0	0	0	0	1	0
GL_SWT_L2TAGCTRL.*LENGTH*	2	16	2	2	2	2	36	0
GL_SWT_L2TAGTXIB.*OFFSET*	0	N/A	0	0	0	N/A[2]	N/A	N/A
GL_SWT_L2TAGTXIB.*LENGTH*[3]	01b	N/A	01b	01b	01b	N/A	N/A	N/A
GL_SWT_L2TAGRXEB.*OFFSET*	0	N/A	0	0	0	N/A	N/A	N/A
GL_SWT_L2TAGRXEB.*LENGTH*[3]	01b	N/A	01b	01b	01b	N/A	N/A	N/A
GL_SWT_L2TAGDATA0, GL_SWT_L2TAGDATA1	All zeros							
Per Port Configuration (Controlled by Set Port Parameters command)								
PRT_L2TAGSEN.*ENABLE* and GL_L2TAGSEN_m_n (m= 0..3, n= 0..1)	1	1	0/1[4]	1	1	1	1	1
Per VSI Configuration (Controlled by Add VSI command)								
VSI_TSR.*STRIPTAG*	0/1[5,6]	0	0/1[5]	0/1[5]	0/1[7]	0	0[8]	0[8]
VSI_TSR.*SHOWTAG*	0/1[6,9]	0	0/1[9]	0/1[9]	0/1[10]	0	0[8]	0[8]
VSI_TSR.*SHOWPRIONLY*	0	0	0	0	0/1[11]	0	0[8]	0[8]
VSI_TAR.*ACCEPTTAGGED*	0/1[12]	1	0/1[12]	0/1[12]	0/1[13]	1	1[14]	1[14]
VSI_TAR.*ACCEPTUNTAGGED*	1	1	1	1	1[15]	1	1[14]	1[14]

1. The *ISVLAN* must be set on one Tag and only on one Tag (the inner VLAN).
2. Insertion and extraction of tag ID is not supported for this tag.
3. 00b = 8 bits, 01b = 16 bits, 10b = 24 bits, 11b = 32 bits.
4. Should be set if port expects double VLAN packets.
5. Set for the used outer tag if outer tag extract mode is set to Extract tag and do not insert in descriptor or Extract tag from packet and expose in descriptor.
6. If STag is used as part of a B-VLAN-ITag combo, bit should be cleared.
7. Set if *VLAN and UP Expose Mode (Rx)* is not set, do nothing (leave VLAN in packet).
8. No L2 tag extraction support for MPLS tags.
9. Set for the used outer tag if outer tag extract mode is set to Extract tag from packet and expose in descriptor.
10. Set if *VLAN and UP Expose Mode (Rx)* is set to Show VLAN, DEI and UP in descriptor.
11. Set if *VLAN and UP Expose Mode (Rx)* is set to Hide VLAN, show UP and DEI (VLAN ID = 0).
12. Set for the used outer tag if *Accept Tag from Host* is set. Set for all other tags.
13. Set if *VLAN Driver Insertion Mode* is set to Admit.1Q tagged only or Allow all packets.
14. No check of the insertion rules of MPLS headers.
15. Set if *VLAN Driver Insertion Mode* is set to Admit untagged/Priority tagged only or Allow all packets.

7.12.4 VLAN Handling

This section describes the handling of IEEE 802.1Q VLAN tags based on the features described above.

There can be up to two VLAN tags in the outer header of a packet identified as VLAN (tag index 5) and outer VLAN (tag index 3 or 4). In addition, the tunneled header can also include a VLAN. The handling of the tunneled VLAN is described in Section 7.12.4.3.

Each port can be set to expect packets with outer VLAN using the Set Port Parameters admin command (Section 7.8.12.2.2). When enabled, a packet with a single VLAN is treated as a packet with outer VLAN only. Otherwise, a single VLAN in a packet is treated as inner VLAN.

In any case, the outer VLAN is not part of the forwarding decision and should be handled by the software device driver or by the BMC both in transmit and receive. There is no offload of outer VLAN insertion or extraction.

The following sub-sections describe the handling of the inner VLAN.

In UDP tunnels, an internal VLAN can also be present, as described in Section A.5.5. The handling of this VLAN is described in Section 7.12.4.3.

UP translation in inner VLAN is described in Section 7.12.6.2.

7.12.4.1 Transmit Flow

This section describes the handling of VLAN as part of the flow of packets sent by the host, the BMC, or the EMP.

7.12.4.1.1 Tag Insertion

A VLAN tag can be inserted to the packets in three ways:

- As part of the packet buffer.
- As part of the transmit descriptor in the *L2TAG1* field if the *IL2TAG1* field is set.
- By the device from the VSI context.

The two first options are enabled if the VSI is allowed to add a VLAN tag by the *VLAN Driver Insertion Mode* in the Add VSI command (Section 7.8.12.3.1). If a packet is sent with a VLAN tag from a VSI that is not allowed to add a tag, it is dropped.

Note: If the *IL2TAG_IL2H* field in the transmit context descriptor is set, the *L2TAG1* represents the inner VLAN and regular VLAN insertion from the descriptor is not available. See Section 7.12.4.3.1 for details on the inner tag insertion. Inner tag insertion is allowed irrespective of the VLAN configuration in the Add VSI command.

The third option is enabled by setting the *Insert PVID* in the same command. The tag to insert is defined in the *PVID + Default UP* field of the command.

Note: Setting both *Insert PVID* and *VLAN Driver Insertion Mode* to allow software to insert VLAN is not allowed.

Note: It is expected that BMC traffic arrives with the right VLAN tagging.

7.12.4.1.2 VLAN Anti-Spoofing

After the packet is VLAN tagged by one of the methods above, if the *Enable VLAN Anti-Spoof* bit in the Add VSI command is set, it is compared to the ingress VLAN list and dropped if the inserted VLAN is not in the list.

7.12.4.1.3 VLAN Filtering

If the packet passed the previous stage, the VLAN tag is used as part of the forwarding process. It is compared as part of the {MAC, VLAN} filters added by the Add Switch Rules admin command (Section 7.8.12.6.1) to determine if the packet should be sent to a local address or should be sent to the network. It is also compared to the PRT_MNG_MAVTV filters as part of the manageability filtering as described in Section 12.4 to define if it should be sent to the BMC.

7.12.4.2 Receive Flow

This section describes the handling of VLAN as part of the flow of packets received by the host, the BMC, or the EMP.

7.12.4.2.1 VLAN Filtering

When a packet is received from the network (or from the host) the VLAN tag is used as part of the forwarding process. It is compared as part of the {MAC, VLAN} filters and to the VLAN egress filtering both set using the Add Switch Rules admin command (Section 7.8.12.6.1) to determine if the packet should be sent to a local VSI. It is also compared to the PRT_MNG_MAVTV filters as part of the manageability filtering as described in Section 12.4 to define if it should be sent to the BMC.

7.12.4.2.2 VLAN Extraction

Before a packet is stored in the host memory, the VLAN tag can be stripped and optionally stored in the receive descriptor. The action done is defined per VSI in the *VLAN and UP Expose Mode (Rx)* field in the Add VSI command. The possible actions are:

- Show VLAN and UP in descriptor (legacy behavior).
- Hide VLAN show UP in descriptor (VLAN ID exposed as 0).
- Hide VLAN and UP.
- Do nothing (leave VLAN in packet).

If the VLAN or the UP are exposed in the descriptor, it shows in the *L2TAG1* field and the *L2TAG1P* flag is set. If the *L2TSEL* bit is set, VLAN tag is extracted to the *L2TAG2 (1st)* field in the receive descriptor instead. In this case, 32-byte descriptors must be used (*DSize* field in the receive queue context must be set).

Note: When a packet is sent to the BMC the VLAN is kept in the packet.

7.12.4.3 VLAN in Tunnel Packets

In MAC-in-UDP and MAC-in-GRE encapsulations, a VLAN within the tunneled MAC header can also be present, as described in Section A.5.5.

7.12.4.3.1 Insertion of Tunneled VLAN from Descriptor

The insertion of this tag is controlled via the *IL2TAG_IL2H* field in the transmit descriptor. When set, the *L2TAG2* field in the context descriptor contains the tunneled VLAN. In this case, the values of VSI_L2TAGSTXVALID.*L2TAG2INSERTID* and VSI_L2TAGSTXVALID.*L2TAG2INSERTID_VALID* fields are ignored.

This mode is enabled irrespective of the VLAN configuration in the Add VSI command (Section 7.8.12.3.1).

Note: Insertion of inner VLAN should not be requested when IPsec encryption is requested.

Inner VLAN insertion is based on the inner IP offset in tunneled packets, and is assumed to be inserted before the inner IP header. For packets for which the insertion should be done elsewhere (for example, if an MPLS header is present between the inner VLAN and the inner IP), the VLAN cannot be inserted by the device.

7.12.4.3.2 Extraction of Tunneled VLAN to Descriptor

The *SHOWIV* field in the receive queue context controls the extraction of an internal VLAN to the receive descriptor. If set, the tunneled VLAN is inserted in *L2TAG2 (2nd)* field of the receive descriptor write-back. In this case, the second tag selected according to Section 7.12.3.3 is ignored. If the *L2TSEL* bit is cleared, the inner VLAN tag is extracted to the *L2TAG1* field in the receive descriptor instead. When the *SHOWIV* field is set and the *L2TSEL* bit is set, 32-byte descriptors must be used (*DSize* field in the receive queue context must be set).

7.12.4.3.3 Tunneled VLAN in Pass-Through Traffic

Tunneled VLAN is not offloaded (not inserted nor extracted) for BMC pass-through traffic.

7.12.4.4 Port-Based VLAN

The E810 supports port-based VLAN feature by allowing any VSI to specify the default VLAN that it belongs to. The port-based VLAN association is done when a packet received on the VSI is untagged or priority tagged and protocol VLAN association is not done. Port-based VLANs map packets received on a given VSI with the corresponding Port based VLAN identifier called PVID. The PVID list should be programmed with the Port VLAN IDs for each VSI.

The port VLAN list is provided which is part of the VSI context. Table 7-283 describes the port VLAN parameters in the Port VLAN list and the matching parameters in the Add VSI command.

Table 7-283. Port VLAN List and VSI Parameters

Port-Based VLAN List	Add VSI Parameter	Notes
VSI number	VSI Number	Returned by firmware in response.
PVID	PVID + Default UP	
Default UP		
Admit.1Q tagged only	VLAN Driver Insertion Mode	
Admit untagged/Priority tagged only		
Admit all		
Ingress VLAN check enable	Enable VLAN Anti-Spoof	
Insert PVID	Insert PVID	

Table 7-283. Port VLAN List and VSI Parameters [continued]

Port-Based VLAN List	Add VSI Parameter	Notes
Expose VID and UP of received packets	VLAN and UP Expose Mode (Rx)	
Expose UP only of received packets		
Do not expose VID or UP of received packets		
Ingress UP translation table	Ingress UP Translation Table	See Section 7.12.6.1
Egress UP translation table	Egress UP Translation Table	See Section 7.12.6.2

The switch should insert the PVID to the packet if the *Insert PVID* parameter is set for the VSI and replace the UP bits according to the algorithm described in Section 7.12.6.1.

Once the VLAN ID association is made, the packet forwarding is performed using the {VLAN, MAC} forwarding table and VLAN membership table.

7.12.5 Outer Tag Handling

This section describes the handling of outer VLAN tags (IEEE 802.1Qbg STags or 0x8100 /0x9100 VLAN tags) based on the features described above.

There can be up to one outer tag in a packet (tag index 1/3/4/). The sections below describes the handling of the STag.

Note: The outer tag EtherType can be either 0x88A8, 0x9100, or 0x8100 and can be different per VSI according to the *Outer Tag Type* defined in the Add VSI command.

7.12.5.1 Transmit Flow

This section describes the handling of outer tag as part of the flow of packets sent by the host, the BMC, or the EMP.

There is no anti-spoofing capability for outer tags.

7.12.5.1.1 Tag Insertion

An outer tag can be inserted to the packets in three ways:

- As part of the packet buffer.
- As part of the transmit descriptor in the *L2TAG2* field if the *IL2TAG2* field is set.
- By the device from the VSI context.

The two first option are enabled if the VSI is allowed to add an outer tag by the clearing the *Outer Tag Insert Enable* field and setting the *Accept Tag from Host* field in the Add VSI command (Section 7.8.12.3.1). If a packet is sent with an outer tag from a VSI not allowed to add a tag, it is dropped.

The third option is enabled by setting the *Outer Tag Insert Enable* in the same command. The tag to insert is defined in the *Outer Tag* field of the command.

Note: Setting both *Outer Tag Insert Enable* and *Accept Tag from Host* to allow software to insert VLAN is not allowed.

Note: As an outer tag of 0x8100 can be confused with an inner tag of the same value, it should be enabled in the Set Port Parameters command only if expected on all packets in this port. In this case, other outer tags (0x9100 or 0x88A8) can not be inserted by the hardware.

7.12.5.2 Receive Flow

This section describes the handling of STag as part of the flow of packets received by the host, the BMC or the EMP.

7.12.5.2.1 STag Extraction

Before a packet is stored in the host memory, the STag can be stripped and optionally stored in the receive descriptor. The action done is defined per VSI in the *STag Extract Mode* field in the Add VSI command. The possible actions are:

- Show STag and UP in descriptor (legacy behavior) — Used for cascaded Port Virtualizer with offload.
- Hide STag and UP.
- Do nothing (leave STag in packet) — Used for cascaded Port Virtualizer without offload.

If the STag is exposed in the descriptor, it shows in the *L2TAG2* field and the *L2TAG2P* flag is be set. In this case, 32-bytes descriptors must be used (*DSize* field in he receive queue context must be set).

Note: If the *SHOWIV* field is set in the queue context, the *L2TAG2* field is allocated for the inner VLAN of tunnel packet. In this case, the STag is never inserted in the descriptor.

7.12.6 User Priority Bits (802.1p) Handling

The UP bits are used to differentiate between multiple classes of traffic. The E810 supports multiple use cases related to the handling of the UP bits:

- An OS that is not DCB/traffic type aware and uses a single TCID.
- An OS that is traffic type aware, but not DCB aware. It can distribute the traffic to different queues, but cannot tag them with the right UP. This case refers to LAN and iWARP flows. The OS is not aware, but the driver knows the difference and hence can assign the different types of traffic to different flows. There is no DCBX agent and hence driver does not know the UP or TC for flows.
- An untrusted OS that can set UP bits of TCs it is not allowed to use.
- An OS that can use a single queue per TCID, but would like to use more UPs to gain from the differentiated QoS in the network.

The following sub-sections describe the handling of UP bits in transmit and receive to support the above use cases.

See Section 8.2.1.3.1 for details of UP handling in ports where the TC is DSCP-based.

7.12.6.1 Transmit Functionality

Each transmit packet is assigned a UP, either by the driver or as part of the port VLAN table as described in Section 7.12.4.4.

This UP is translated using two different translation vectors:

- The first vector is specific to a VSI and is part of the port VLAN table (Transmit UP translation table - VSI_TUPR). This vector reflects the mapping of the user priorities as seen by the operating system to the user priorities as seen by the network.
- The second vector is specific to a TCID in a physical port. It translates the UP received from the previous translation to a UP matching the TCID to which the packet is associated. These vectors can be configured through the PRT_TCTUPR registers.

Note: There is no drop of packets due to a wrong 802.1p tagging. If a wrong tag is requested, the tag is replaced. Thus, this functionality supports both UP anti-spoofing and port-based UP.

Untagged packets are kept as is. No translation is done on them.

Figure 7-39 shows the algorithm:

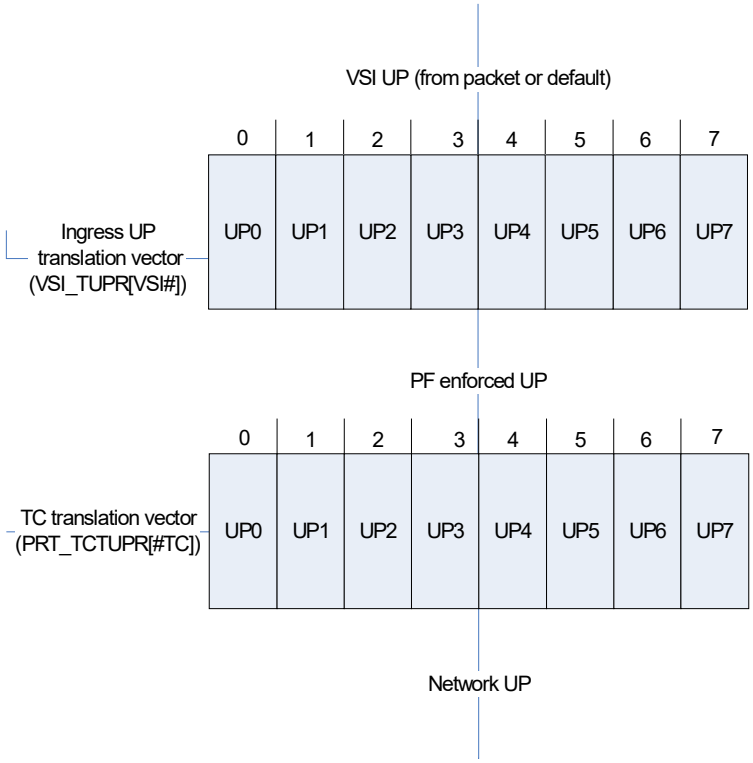

Figure 7-39. Example: Non-VLAN Aware, Non-DCB Aware OS

Assume a VF that queues LAN traffic and iSCSI traffic to different queues, but is not VLAN-aware. In this case, the packet is sent by the driver with no VLAN, and the default UP set in the port-based VLAN (for example, 0) is the initial UP of the packet. In this case, the Ingress UP translation vector (VSI_TUPR) is not relevant and might be, for example, {0,1,2,3,4,5,6,7} or {0,0,0,0,0,0,0,0}. The TC translation vector (PRT_TCTUPR) for LAN might be {0,1,2,0,0,0,0,0} and the TC table for storage might be {4,4,4,4,5,4,4,4}. So a LAN packet goes out with a UP of 0, and a storage packet goes out with a UP of 4.

Example: Non DCBX Tagging OS

Assume a VF that tags LAN high-priority traffic with a UP of 4, LAN low-priority traffic with a UP of 3, and the storage traffic as UP 7. In this case, the VF translation table might be {0,1,2,0,2,4,4} and the TC tables as above. The low-priority LAN goes out with a UP of 0, the high-priority LAN with a UP of 2 and, storage with a UP of 4.

The tag on which the transmit UP translation is done is identified by setting the *INNERUP* bit in the matching GL_SWT_L2TAGCTRL register.

The default mapping of both tables is identity mapping (that is, mapping a UP to itself). If UP translation is not needed, these mapping should not be changed.

7.12.6.1.1 Transmit Outer Tag User Priority

The transmit outer tag user priority can be handled in three different ways:

1. If the outer tag is received in the packet or the descriptor (for example, cascaded S-comp), the UP should be part of the packet sent by the driver or inserted from the descriptor.
2. If the outer tag is inserted by the hardware, the UP can be either:
   a. The UP defined as part of the inserted tag in the VSI_TIR register.
   b. A translation of the regular VLAN UP as defined in the VSI_TUPIOM register.

If the outer tag is defined as *OUTERUP* in the GL_SWT_L2TAGCTRL register, the UP is based on the first tag for which the *INNERUP* field is set in the GL_SWT_L2TAGCTRL register (usually the VLAN tag) (option 2.b). Otherwise, it is based on the default (option 2.a).

In case there is more than one tag in the packet with *OUTERUP* set, inner-to-outer UP translation should be performed to the most outer tag with *OUTERUP* bit set.

The tag to which translation is applied can be either STag or external VLAN.

Figure 7-40 describes the translation process.

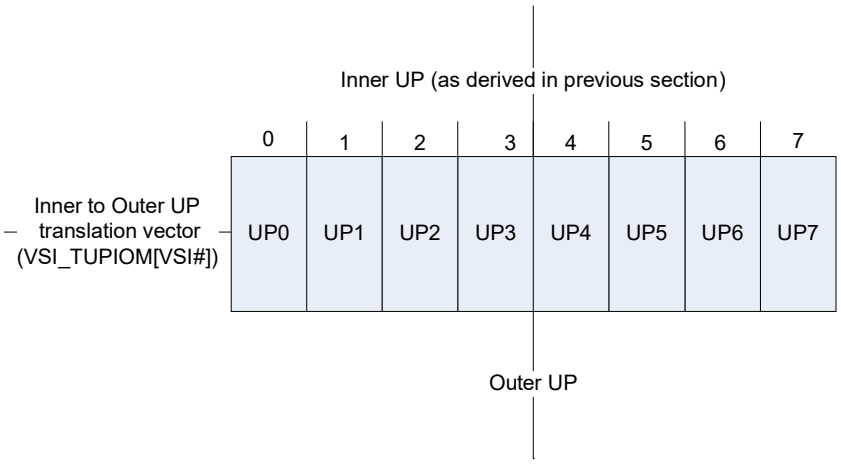

Figure 7-40. Tx Inner-to-Outer UP Translation

7.12.6.2 Receive Functionality

7.12.6.2.1 VLAN UP Translation

The priority bits of inner VLAN tag in received packets may be remapped using the Ingress UP translation table in the Add VSI command. This means the OS might get packets with 802.1p priority bits reflecting the local configuration and not the link configuration. By default (Ingress UP translation section is not valid) the translation is one-to-one, meaning that the received UP is not translated.

7.12.6.2.2 VLAN UP Exposure to Device Driver

The exposure of the received UP to operating systems is defined by the awareness of the OS controlling the VSI as follows:

- For a monolithic OS, VMM, or for a guest OS that is VLAN-aware, the UP is exposed as part of the VLAN as requested by driver (either in the packet or in the descriptor).
- If the guest OS is DCB-aware but not VLAN-aware, it gets the priority bits as part of the receive descriptor in the VLAN tag field. The VLAN ID is zero, but the priority bits are valid.
- A guest OS that is not VLAN-aware and not DC-aware does not get the user priority bits (UP) at all.

The configuration of the UP removal is part of the port VLAN configuration described in Section 7.12.4.4, and in the Add VSI command VLAN handling section (Section 7.8.12.3.1).

NOTE: ***This page intentionally left blank.***

Chapter 8 Quality of Service (QoS)

This chapter assumes the reader is familiar with the following specifications:

- IEEE P802.1Qbb-2011 — a.k.a. Priority-based Flow Control (PFC) specification.
- IEEE P802.1Qaz-2011 — a.k.a. Enhanced Transmission Selection for Bandwidth Sharing Between Traffic Classes (ETS) specification.
  - DCB Center Bridging Exchange Protocol (DCBX) spec refers to Clause 38 in ETS specification.
  - DCB Capability Exchange Protocol Base Specification.
- IEEE Std 802.1AB-2009 — a.k.a. Link Layer Discovery Protocol (LLDP) specification.
- RFC 2474—Definition of the differentiated services field (DS field) in the IPv4 and IPv6 headers.

8.1 E810 Usage Models: Number of Ports and Number of Congestion Domains

The E810 supports various port configuration and usage models.

- The E810 is integrated to the Network Acceleration Complex (NAC) SoC. It is targeted for COMMS, Cloud, and Enterprise markets. The E810 operates as a NIC configured with up to eight ports. The E810 is directly connected to PHYs with eight ONPI interfaces, each directly connected to one PHY for both Tx and Rx.
- **Congestion Notification:** Congestion notifications from the network (Link Flow Control or Priority-based flow control) is immediately forwarded to the E810 like other traffic.
- the E810 supports three main ports settings. Each Port is associated with a separate ONPI connectivity to the Network.
  - Two ports setting:
    - Each port can be independently run at 100/50/25/10/1 GbE, 100 Mb/s, or disabled.
    - Eight TCs (Congestion Domains) are supported per port in both Tx and Rx sides.
  - Four ports setting:
    - Each port can be independently run at 25/10/1 GbE, 100 Mb/s, or disabled.
    - Eight TCs (Congestion Domains) are supported per port in both Tx and Rx sides. Total 32 Congestion Domain (CGDs).
  - Eight ports setting (Device mode is set to this mode whenever more than four ports are available):
    - Each port can be independently run at 10/1 GbE, 100 Mb/s, or disabled.
    - Four TCs (Congestion Domains) are supported per port in both Tx and Rx sides. Total 32 Congestion Domain (CGDs).
    - Tx-Scheduler configuration in this usage model is detailed in Section 8.3.3.

    Note: This port setting supports two more ports sub settings:
    - Six ports setting: supports 2x25 GbE + 4x10 GbE ports setting.

- Seven ports setting: supports 1x25 GbE + 6x10 GbE ports setting.

From QoS perspective, the above modes are sub setting of eight ports mode and four TCs (Congestion Domains) are supported per port. Some CGD are not used in those modes.

— LLDP/DCBX: LLDP and DCBX agent runs in EMP firmware by default. Software can acquire the LLDP ownership.

8.2 E810 QoS and DCB Support

8.2.1 Receive Path QoS

This section discusses the QoS approach in the E810. QoS in receive includes DCB and DCBX support plus Rx-Pipe balancing to avoid starvations between Rx-Pipe units and between different types of service packets in the Rx processing pipeline. This section includes:

- Rx-Pipe overview of QoS aspect on the Rx-Pipe:
  - — Describes the potential congestion domains, Arbitration and drop points, and Priority support.
- Receive QoS, Algorithms, and Configuration:
  - — Rx QoS units Overview:
    - Incoming packet classification to CGD
    - Rx-Pipe - arbiters
    - Rx-Pipe - “pipe monitors”
  - — Rx QoS blocks, Implementation details, and Programming:
    - Incoming packet classification to CGD
    - Rx-Pipe - arbiters
    - Rx-Pipe - “pipe monitors”
- XOFF/XON methods differences in Device operation modes.
- Crosstalk prevention.

8.2.1.1 Rx-Pipe Congestions, Arbitration, and Priority Support - Overview

The E810’s Rx-Pipe processes incoming packets from the network as well as loopback traffic. Under normal configuration, the PCIe bandwidth provides high enough bandwidth for total incoming traffic and its control data (like the descriptors write-back).

The Rx-Pipe might be congested as a result of one or more of the below conditions:

- A thinner PCIe connectivity limits the Host interface.
- A burst of high-rate small packets, congest the Rx packet processing pipeline.
- A burst of RDMA packets, overflows the processing power of the PE (PE packet processing rate is lower than the LAN packet processing rate).

- Dual 100 GbE mode: The E810 can be configured to work in 2x100 GbE setting. In that topology, the receive Packet Buffer can be congested by receiving from the ports more packets than can be fed to the receive pipe (higher rate than Rx-Pipe processing power).
- A combination of Loopback and Mirroring Traffic in parallel to high-rate incoming packets from the network.
- Rx locality rules: The E810 performance commitment counts on a level of locality. The background behind the locality restriction for Rx performance is that some of the stages of Rx processing are dependent on fetching data from the Host memory, part of this data can be a Rx-Descriptor per each packet, other type of data is a context type like filters. To eliminate the need for the Host read operations per packet, the E810 manages an internal cache for all those data types. The E810 can benefit from those cache only under some locality assumptions. When the incoming traffic conditions do not follow those locality conditions, the Rx processing rate of the E810 suffers from some performance degradation, and part of the Rx-Pipe is congested.
- Unexpected collision numbers in Post Quad Hash (discussed later in this section) can also cause congestion.

When the Rx-Pipe is congested as a result of any of the above, internal processing queues are starting to build up. The Rx-Pipe is organized in per CGD queues/FIFOs. Packet reordering is only allowed between CGDs.

As detailed above, in the Rx side, the E810 can be configured to work in one of three main port topologies:

- Four ports with up to eight TCs
- Eight ports with up to four TCs

The Rx-Pipe is organized in up to 32 queues, one per congestion domain (CGD). The processing of packets belonging to a CGD is done in order.

Association of incoming packets with a CGD is done based on the port's QoS configuration and the packet's Class of Service (CoS) as detailed in Section 8.2.1.3.1.

Some stages of the pipe might need higher processing power and therefore two units are placed to meet the required performance. Those pipe stages operate internal re-ordering mechanism to keep the overall pipe ordering.

When internal queues are built up, the processing order in Rx-Pipe must implement an arbitration between the per CGD queue/FIFOs.

8.2.1.1.1 Pipe Monitor (PM) and Arbiter Pairs

The three Rx arbiters mentioned above select a head-of-line item across the 32 CGDs only if there is enough room for storing the selected item into the next buffering stage. If some CGDs are full, these CGDs are temporarily removed from the arbiter list of candidate items until room is freed again. CGDs that are temporarily removed from an arbitration point are handled as if there was no pending workload for them (in other words, like an empty list). This mechanism of looking ahead for available room is referred to as *Pipe Monitoring*.

For QoS support, each stage of the pipe consists of a set of an arbiter and a Pipe Monitor (PM), which act together to provide the required QoS performance while preventing head-of-line blocking and reducing to minimum the cross-effect between ports and between CGDs.

In each stage of the pipe, an arbiter is located at the beginning of the stage, selecting which packet is propagated into the next pipe stage. The PM counts the load per CGD and per port of this stage from the arbiter gate until the end of the stage, which can be the next pipe stage arbiter, or NIC's PCIe interface.

The pipe monitors are set of counters that track the load in this pipe stage, per-Port and per-CGDs. When a CGD or a port load reaches its load threshold, The PM signals the units that feed this pipe stage. Upon PM load signal, the related CGD(s) or port(s) are masked out in the arbitration flow of the arbiters of the predecessor units.

Each stage of the pipe listed above is paired with a PM.

8.2.1.2 Rx QoS Units Overview

8.2.1.2.1 Packet's Congestion Domain Mapping in Receive - Overview

The network ports are exposed to the E810 (up to eight ports). Ingress Rx packet processing is done in the E810. The E810 supports two PFC modes: VLAN PFC and DSCP PFC. The PFC modes is a configuration per port.

- **VLAN PFC** — Class of Service (CoS) is based on the 3-bit *PCP* field of the 802.1p header extracted from incoming packet. This value is the packet's UP (User Priority).
- **DSCP PFC** — CoS is based on the DSCP (IPv4)/Traffic Class (IPv6) field. This is a 6-bit value.

8.2.1.2.2 Remapping of the UP Field in Receive

Refer to Section 7.12.6 for the L2 equivalent.

This is a service for the software layer, it acts as a translation service between the software space UP mapping and the Network space UP mapping. The remapping scheme applies also to the traffic destined to EMP (or BMC), which is represented in the tables by its own VSI units.

VLAN UP might be included in the L2 header even when the port is configured for DSCP PFC mode.

8.2.1.2.3 Rx Ports and ETS Arbiters - Overview

The RPB egress arbiter and the RCB arbiter are in charge of Rx QoS support. They manage the Rx processing order through most of the Rx-Pipe. In principal the arbiters implement a three-layer arbitration scheme, one layer Ports arbiter and two layers ETS arbiter:

- **Port arbitration** — This is WRR arbitration between Rx ports. It ensures isolation between the Rx LAN ports. The total available PCIe bandwidth allocated for traffic reception is firstly allocated among the LAN ports. The weight, by default, is proportional to the ports' speed ratio.
- **ETS arbiter** — A two-layer arbitration among CGDs inside each port. The E810 supports two types of CGDs: "Regular" and "High-Priority". In this document, the Regular and High-Priority CGDs are also called "ETS" and "non-ETS", respectively. The regular (or ETS) CGDs involve token-based WRR arbitration. The high-priority (or non-ETS) CGDs get higher priority in each ETS arbiter with no bandwidth limit. The two layers of the ETS arbiters are:
  - **CGD arbitration** — Packet based RR arbitration among all non-ETS CGDs of the port in parallel to bytes based WRR arbitration among all regular CGDs of the port.
    - Each active CGD is associated with one and only one priority. If the CGD is declared as high-priority CGD, it is associated with the high-priority arbiter. Otherwise, it is associated with the regular arbiter.
  - **Strict Priority** — Between the high-priority traffic arbitration winner and the regular traffic arbitration winner. The winner of the arbitration among high-priority CGDs always wins. When the high-priority queue is empty, the regular queues passes.

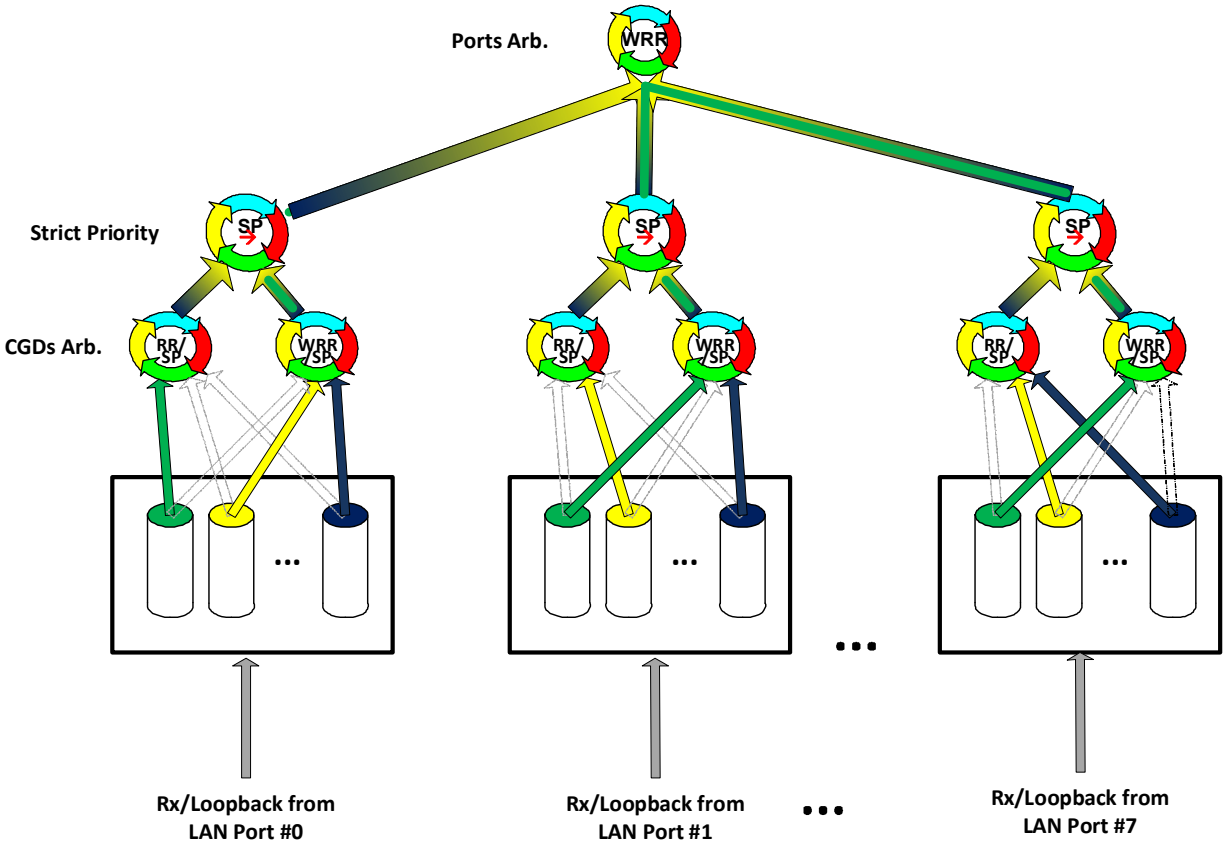

Figure 8-1. Rx QoS Arbiters Unit Scheme

Figure 8-1 shows the structure of CGD arbitration. Inside each port, the high-priority CGDs are associated with the left arbiter, while the low priority CGDs are associated with the right one. The middle arbiter is a simple strict priority arbiter between the winners of WRR arbiters. The upper arbiter is the ports' arbiter.

8.2.1.3 Rx QoS Blocks, Implementation Details and Programming

8.2.1.3.1 Packet's Congestion Domain Mapping in Receive - Implementation Details and Programming

The network ports are exposed to the E810 (up to eight ports). Ingress Rx packet processing is done in the E810.

The E810 supports two PFC modes: "VLAN PFC" and "DSCP PFC".

In both PFC and DSCP modes, congestions are notified using L2 Priority Flow Control (PFC) messages as detailed in Section 3.2.1.5.

8.2.1.3.1.1 Packet CoS Classification Flow in "VLAN PFC" Mode

- Class of Service (CoS) is based on the 3-bit *PCP* field of 802.1p header extracted from the incoming packet. This value is the packet's UP (User Priority).
- When the port is configured to expect multi-TAG packets, the *HAS_UP* bit in GL_SWT_L2TAGCTRL register indicates per-tag type if its UP is a candidate for DCB usage. The UP for DCB is taken from the first tag encountered in the packet that has this bit set. This bit should be set for STags and VLAN (internal and external) EtherTypes.
- The PRTDCB_RUP2TC register controls the mapping of incoming packets to TCs according to the UP field they carry (UP to TC mapping table).
- UP-to-TC mapping (UP2TC) is a table per port, the UP2TC table is configured by the LLDP owner, which can be firmware or software (software might decide to take LLDP ownership, as detailed in Section 8.2.4.5.1). The LLDP owner owns the DCBX as well. UP2TC is configured based on the port's DCB capabilities and DCB setting. The DCBX setting is detailed in Section 8.2.4.5.
- The same mapping is used for packets received from the wires and for those looped back internally. It defines on the account of which TC a packet is stored in the Rx packet buffer, and which UP's bits are set in the PFC XOFF/XON frames issued to the link partner when the filling state of a TC requires it.
- Packets received with no 802.1p tag are also mapped to a TC according the setting made in *NOVLANUP* field of PRTDCB_RUP register that is applied as an input to the UP to TC mapping table of PRTDCB_RUP2TC register. To ensure that LLDP and other MAC Control packets are not dropped internally by the device before they reach EMP or the host, it is recommended that the PRTDCB_RUP.*NOVLANUP* field be set to the No-Drop UP with the lowest index.
- Packet's CGD is calculated in a three-step flow:
  a. The UP of the packet is extracted from the VLAN header of the received packet. Packets received with no 802.1p tag are also mapped to a default UP configured in *NOVLANUP* field of PRTDCB_RUP register.
  b. Packet's TC is extracted based on the UP and per-port UP to TC mapping programmed in the PRTDCB_RUP2TC register.

     As mentioned above, the E810 can be configured as 1-4 port device that can support up to eight TCs per port, or as 5-8 port device that can support a maximum of four TCs per port.

     When the device is configured 5-8 port mode, the PF, when programming the PRTDCB_RUP2TC register, is responsible for configuring all TC values to be limited to 0-3.
  c. Packet CGD == Port num (0-7) * Max TC per port (4 or 8) + TC.

8.2.1.3.1.2 Packet CoS Classification Flow in "DSCP PFC" Mode

- Class of Service (CoS) is based on the *DSCP* (IPv4)/*Traffic Class* (IPv6) field. This is a 6-bit value.
- DSCP is extracted from outer IP header only.
- DSCP configuration is owned by software. DSCP mode is a per-port configuration. Software programs via EMP firmware DSCP translation tables and enables/disables the DSCP mode.
- Software calls EMP firmware using Set Local MIB AQC.
- DSCP-to-UP translation table is a 64-entries LUT that provides a translation from every one of the 64 DSCP values to a 3-bit UP value.

8.2.1.4 Rx-Pipe, Port, and CGD Configuration per Each Usage Model and CGD Type

The NVM is programmed with Rx-Pipe configuration registers and values per each port and DCB topology. The EMP firmware is responsible for reading the correct data set per topology and configuring the pipe accordingly.

8.2.1.4.1 Issuing XOFF and XON

When receiving a packet attached to a No-Drop TC, either from the LAN wire or from the internal loopback path, a PFC XOFF notification can be issued onto the wire and internally to the loopback path for all the UPs mapped to the CGD.

Issuing XOFF behaves differently under different configurations. This section details the different XOFF/XON models per configuration.

- **LFC** — The XOFF/ON mode is a per-port configuration, and the device can be configured to LFC. When the port is configured for LFC mode by the PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE and PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE CSRs, during the link negotiation flow, the device proposes LFC mode for the link partner. If LFC is in agreement with the link partner, the RPB is configured with one CGD for the port with all matching watermark settings. When XOFF/XON needs to be issued, it is done as a LFC message.
- **PFC** — When the port is configured for DCB, a DCBX agent is activated for the port. The DCBX agent runs by default in EMP firmware, Software can take the ownership on LLDP and DCBX. The DCBX is detailed in Section 8.2.4.5. XOFF/XON in this mode are issued as PFC messages.

The format of PFC and LFC messages are detailed in Section 3.2.1.5.

8.2.2 Transmit Path QoS

8.2.2.1 Transmit Path Enhanced Transmission Selection (ETS)

This section discusses the Tx QoS approach in the E810. QoS in transmit includes Tx Scheduling, DCB, and DCBX support, plus the Tx-Pipe balancing to avoid starvations between Tx-Pipe units and between different types of service packets in during the Tx processing pipeline. Special attention is dedicated to burst avoidance as an integral feature required for the COMMS market.

Transmit path ETS is basically managed in the Tx-Scheduler (refer to Section 8.3).

This section deals with the requirements on Tx data path to avoid distortions on the ETS scheme performed by the Tx-Scheduler. The approach relies on two principles:

- Maintain the order of requests issued by the Tx-Scheduler, as much as possible.
- Avoid misleading the scheduler decisions by inexact reports.

Other ETS requirements on Tx data path:

- Serve high-priority traffic as fast as possible in any condition, as long as it is not overtaking its allocated bandwidth.
- Limit packets burstiness beyond what is decided by the Tx-Scheduler.
- Guarantee that best effort TCs can be served at full-blown, regardless of the XOFF/XON events history over lossless TCs.

- Avoid starvation of one ETS traffic class by another, even in the case that it is dropping packets while the other CoSs offer sustained workload.

The section includes:

- Tx-Pipe overview of QoS aspect on the Tx-Pipe.
  - This discussion describes the potential congestion domains, Arbitration and Priority support.
- Transmit QoS, Algorithms, and Configuration.
  - Tx QoS units overview.
  - Tx QoS blocks, implementation details, and programming.
- XOFF/XON methods differences in device operation modes.

Note: Tx-Scheduler is a major partner in the Tx QoS. A dedicated section (Section 8.3, "Transmit Scheduling") details the Tx-Scheduler approach, algorithms, usage models, and configuration.

8.2.3 Tx-Pipe Overview

This section provides an overview for the Tx-Pipe from its QoS aspect. It is not intended to cover the packet processing of the Tx and/or other aspects except the QoS.

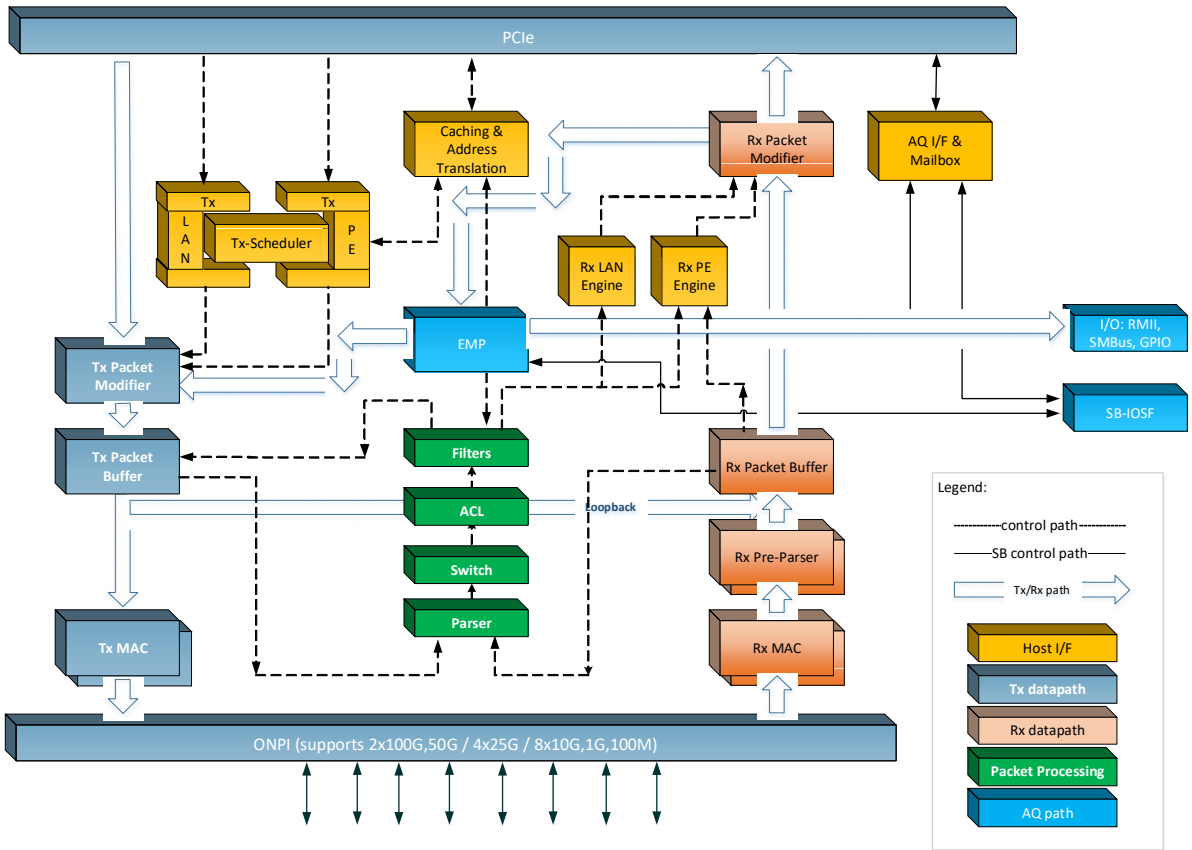

Figure 8-2. E810 Block Diagram

8.2.3.1 Tx Flow - Starting from Scheduling

In the E810, the Tx-Scheduler is located at the top of the Tx-Pipe. The scheduling process is performed prior to fetching the data and descriptors. This enables major memory and power savings as the Tx data and its descriptors are fetched to the device internal memory on demand. Scheduling decisions are made based on the packet sizes digest received by the Tx-Scheduler from the Doorbell messages, and from "Quanta Descriptors", which are explained in detail later in this document. The Advanced Doorbell with packet sizes is described in Section 10.5.6.2.

For a queue that is configured to act in legacy mode, the quanta is pre-configured per queue and is constant. The legacy Doorbell is described in Section 10.5.4.6, and an explanation of "Quanta" is provided in Section 8.3.2.2.1 and in Section 8.3.2.2.2.

The Tx-Scheduler controls and arbitrates both the LAN queue and RDMA transmission. The LAN and RDMA engines wrap the Tx-Scheduler IP. They feed it with transmission requests (Enqueue and Refill flows). When a queue is selected by the Tx-Scheduler, the Tx-Scheduler provides this call to the target unit (Dequeue flow).

8.2.4 Tx-Pipe QoS Next Level of Details

Each LAN Tx-Queue and RDMA QSet is associated with a single TC inside the port space and mapped into a single CGD. To handle sudden PFC XOFF notifications received from the link, the transmit data path is provided with buffers in its different stages. To reduce impact on-die size, provision is made for only two types of traffic: High-Priority (also called Low-Latency (LL) in this Document) and Bulk (B).

Each CGD in Tx is configured with four main behavioral parameters:

- **Advanced Mode Host Interface** — The Advanced Transmit mode enables software to control tightly the burstiness of the traffic from this queue, to interleave transmissions between multiple data sources while limiting the burst size from any one given queue. When a CGS is recognized as Burst Sensitive, all the Tx-Queues associated with this CGD must be configured to operate in Advanced Transmit Mode.
- **Bulk vs. Low Latency** — Each CGD is configured as LL (Low Latency) or B (Bulk) CGD. High-priority CGDs are selected first in the Tx arbiters, allowing them running faster through the Tx-Pipe.
- **Congested vs. Not Congested CGD** — This defines if the specific CGD is declared as Droppable in the network, and therefore no Priority Flow Control (PFC) is expected for the CGD or PFC support for it is required.
- **Congestion Location** — In a regular NIC and in E810 NIC mode, each PFC needs a fast response. To address this, any PFC event results with immediate pausing of the involved CGD traffic anywhere in the Tx-Pipe (that is, stop selecting it in the Tx-Scheduler as well as stop servicing it in TCB and TPB).

Table 8-1 summaries the recommended configuration of each type of traffic in each device mode.

Table 8-1. CGD Configuration for Each Usage

Traffic Type	Service	Host Interface Mode	LL/Bulk	Congested	Congestion Location
Droppable High-Priority	Lower latency relative to regular traffic. No PFC enabled.	Advanced or Legacy Mode	LL	No	Not any
Droppable Regular	No PFC.	Advanced or Legacy Mode	Bulk	No	Not any
No-Drop High-Priority	Lower latency relative to regular traffic. PFC enabled.	Advanced or Legacy Mode	LL	Yes	Tx-Scheduler and Tx-Pipe
No-Drop Regular	PFC enabled.	Advanced or Legacy Mode	Bulk	Yes	Tx-Scheduler and Tx-Pipe

Configuring the CGD for each usage is done by EMP firmware. Software uses the flow detailed in Section 8.2.4.6 to configure each CGD.

8.2.4.1 CoS Translation and Enforcement

The E810 supports two PFC modes: VLAN PFC and DSCP PFC. The PFC modes is a configuration per port.

- **VLAN PFC** — Class of Service (CoS) is based on the 3-bit PCP field of 802.1p header extracts from the incoming packet. This value is the packet's User Priority (UP).
- **DSCP PFC** — CoS is based on the DSCP (IPv4)/Traffic Class (IPv6) field. This is a 6-bit value.

The PFC mode is a per-port configuration. PFC mode can be changed on the fly per software call (port's Tx-Pipe is drained before changing the PFC mode).

Some translate services and enforcement rules are operated in the E810's Tx-Pipe, as detailed in the following paragraphs. For each one of the supported features, its relevancy for PFC mode is marked within each of those paragraphs.

8.2.4.1.1 Remapping of the UP Field in Transmit

Refer to Section 7.12.6 for the L2 equivalent.

This is a service for the software layer. It acts as a translation service between the software space UP mapping and the network space UP mapping. The remapping scheme also applies to the traffic destined to EMP (or BMC), which is represented in the tables by its own four VSI units.

VLAN UP can be included in the L2 header even when the port is configured for DSCP PFC mode.

Note: UP remapping is disabled when the port is configured to DSCP mode. Disabling of UP remapping is done by configuring it to one-to-one mapping, keeping the output to be equal to the input.

8.2.4.1.2 Mapping of UP to TC in Transmit

Register PRTDCB_TUP2TC controls the mapping of UPs to TCs in the transmit path with respect to PFC XOFF/XON notifications received from the link partner or internally from the loopback path. It defines which transmit CGD is paused/released when a UP bit is set in a PFC XOFF/XON frame received (or in internal notification).

Rx and Tx DCB settings are usually identical.

Tx manageability traffic issued by the BMC is bound to the lowest indexed Drop TC, or to TC0 if all TCs are configured as No-Drop.

This mapping is relevant in both PFC and DSCP modes. In DSCP mode, packet classification is based on L3 DSCP field, but the congestion notification is still done by the LLDP PFC messages.

8.2.4.1.3 UP Tag Enforcement in Transmit

In any PFC mode, the E810 enforces software behavior. The CoS of a packet marks the level of service it gets while forwarded through the network. Untrusted software can feed its packets with higher CoS value to get better network performance. This can affect the overall network performance.

In the E810, each Tx-Queue is associated with a single port/TC pair. In its Tx path, the E810 checks every transmitted packet if the CoS value provided by software in the packet's header is allowed for this port/TC.

When the port PFC mode is configured for VLAN PFC, a UP-to-UP translation table is configured per each port/TC pair. For the legal UP values, the output value equal to the input one. For the illegal values, the output value is configured for a default value for the port/TC. The packet is then modified with the correct UP value.

UP tag enforcement can be configured on the fly.

Note: Disabling of UP enforcement is done by configuring it to one-to-one mapping, keeping the output to be equal to the input.

8.2.4.1.4 DSCP Tag Enforcement in Transmit

DSCP enforcement is similar to the UP value enforcement detailed in Section 8.2.4.1.3. One difference is in the DSCP handling resultant from the fact that DSCP is part of L3 header. It is more complex to hardware to modify L3 header of a packet, so the DSCP enforcement is done by either dropping the packet that carries illegal DSCP tag, or raising a malicious event to the PF. The reaction option is configured per-port and it is done using the CSR GL_DCB_TDSCP2TC_BLOCK_IPV[4/6] register.

DSCP tag enforcement is configured per port per CGD, and independently for IPv4 and IPv6 packets.

1. A DSCP table is selected based on:
   a. Port, TC (Part of the Tx-Queue context, piggybacked with each packet through the Tx-Pipe).
   b. Packet's IP type (extracted from packet's header in the query flow).
2. Packet's outermost DSCP tag is extracted and is used as an index to the table selected above.
3. The value read from the table index is a flag that marks if this DSCP tag is legal for this port/TC.
4. If the flag == 0, then:
   a. The packet is dropped if configured so, based on CSR GL_DCB_TDSCP2TC_BLOCK_DIS.
   b. Malicious event is raised if configured so, based on global configuration in CSR GL_MDCK_TX_TDPU.*DSCP_CHECK_FAIL_ITR_DIS.*

Note: CSRs GL_DCB_TDSCP2TC_BLOCK_DIS and GL_MDCK_TX_TDPU.*DSCP_CHECK_FAIL_ITR_DIS* are device-wise configuration registers. They are uploaded from NVM as a global configuration and are not changed by PF.

Table 8-2 summarize the Translation and Enforcement rules per device mode and traffic type. L2 tag insertion and acceptance topics are explained in Section 7.12.6 for the L2 equivalent.

Table 8-2. VM CoS Translation and Enforcement - Summary Table

Traffic Type	UP Remapping	UP Enforcement	DSCP Enforcement	L2 Tags Acceptance	L2 Tags Insertion
Legacy	Yes	Yes	No	Yes	Yes
DSCP	No	No	Yes	Yes	Yes

8.2.4.2 Transmit Flow for ETS

The following flow documents the Tx data path only from an ETS perspective. The ETS Tx-Pipe is described above in Section 8.2.3.

8.2.4.2.1 Pipe Monitor (PM) and Arbiter Pairs

For QoS support, each stage of the pipe consists of a set of an arbiter and Pipe Monitor (PM), which act together to provide the required QoS performance while preventing head-of-line blocking and minimizing the cross-effect between ports and between CGDs.

In Each stage of the pipe, an arbiter is located at the beginning of the stage, selecting which packet is propagated into the next pipe stage. The PM counts the load per CGD and per port of this stage from the arbiter gate until the end of the stage, which can be the next pipe stage arbiter or the NIC's interface.

8.2.4.3 Tx Port and CGD Configuration per Each Usage Model and CGD Type

8.2.4.3.1 CGD Mode of Operation Configuration Parameters

Table 8-3 summaries the recommended configuration of each type of traffic.

Table 8-3. CGD Configuration for Each Usage

Traffic Type	Feature/Control Register Name	NIC Mode			
		Droppable High-Priority	Droppable Regular	No-Drop High-Priority	No-Drop Regular
LL/Bulk	GLDCB_TCB_TCLL_CFG.*LLTC*[0..31] GLDCB_TPB_TCLL_CFG.*LLTC*[0..31]	LL	Bulk	LL	Bulk
Congested	GLDCB_TC2PFC.*TC2PFC*[0..31][1] PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE[Port, UP][2]	No	No	Yes	Yes
Congestion Location	GLDCB_TLPM_IMM_TCB.*IMM_EN*[0..31] GLDCB_TLPM_IMM_TPB.*IMM_EN*[0..31]	Not any	Not any	Tx-Scheduler and Tx-Pipe	Tx-Scheduler and Tx-Pipe
Legacy Host Interface Allowed	GLDCB_TCUPM_LEGACY_TC.*LEGTC*[30..31] GLDCB_TLPM_LEGACY_TC.*LEGTC*[0..31]	Yes	Yes	Yes	Yes

1. This is a multicast register and affects the Tx-Pipe and Rx-Pipe.
2. The indexing of MAC PFC enable is done based on port/UP and not based on CGD.

8.2.4.3.2 Tx-Pipe Arbiters and PM Configuration

8.2.4.3.2.1 Pipe Monitors and Arbiters Configuration per Use Case

Table 8-4. Tx-Pipe Arbiters Configuration in All Ports Setups

1. The 10 GbE pipe monitor setup values also apply to link speed 5 GbE, 2.5 GbE, 1 GbE and 100 Mb/s.

Note: Some Dedicated RDMA Pipe Monitors must be configured in addition to the above. The RDMA Pipe Monitors setting is detailed in field.

8.2.4.4 Transmit Path Priority Flow Control (PFC)

This section deals with guaranteeing no packet loss at the link partner and inside the E810 further to receiving PFC pause frames from the link partner or further to PFC notifications received from the internal switch.

In each port, TCs are classified in two types relative to PFC: No-Drop TCs (or lossless), and Drop TCs (or best effort delivery).

8.2.4.4.1 PFC Dead-Lock Prevention

Tx traffic that belongs to PFC-enabled TCs can be halted in the Tx-Pipe due to endless XOFF received, either from the line or from the internal loopback path. Flushing out this traffic is a gating condition for the completion of the following operations: Tx-Queue disable, PFR, VFR, disabling the PFC of a TC, or DCBX UP-to-TC remapping.

The device implements a mechanism that automatically flushes out Tx traffic that belongs to a port for which the link goes down. However, there is no similar mechanism for flushing out traffic halted in the Tx data pipe due to endless XOFF conditions. In the case of PFR, an endless XOFF/congestion condition is detected autonomously by the device at the section end and handled as described below. For the other cases (listed above), it is the PF(s) responsibility to detect that the Tx data-path is halted for a long time by periodically monitoring the eight Tx PFC timers attached to a port, one per TC (PRTDCB_TPFCTS.*PFCTIMER*). Each timer (per CGD) is restarted by the device every time the TC is halted by an XOFF notification (received from the link). If any of these counters crosses a threshold defined by the ENDLESS_XOFF_THRESH parameter (in EMP setting module in the NVM), the PF(s) software should take the following actions:

- Post a PFC Ignore admin command (refer to Section 8.2.5.1) for the TC, requesting EMP to set *IGNORE_FC* bit(s) (32 bits - one per CGD) in the GLDCB_TFPFCI register. It causes the entire Tx data path to ignore PFC indications for the concerned TC/port, whether they were received from the line or from the internal loopback path. When in this state, the device flushes out the concerned frames without issuing them over the line or into the internal loopback path.
- When the endless XOFF condition disappeared, and/or when the Tx-Pipe is checked to have been cleaned up (Read PMs for pipe status), the PF clears the *IGNORE_FC* bit by posting a PFC Ignore admin command with *Ignore* flag cleared.

8.2.4.5 Data Center Bridging Exchange Protocol (DCBX)

The DCBX protocol relies on the exchange with the peer of untagged LLDP packets over the physical link.

8.2.4.5.1 DCBX/LLDP Ownership

By default, DCBX is handled by EMP, though the host can decide to take the DCBX ownership once system boot has been completed. Software initiates the transition on a per-port basis by posting the "Stop LLDP Agent" command.

When software owns the DCBX, it can give DCBX ownership back to EMP using "Start LLDP Agent" AQ command. Whenever the host that handles DCBX goes to sleep mode, DCBX is uncovered (EMP does not cover for DCBX). It is the host's responsibility to reset DCB configuration to its default settings (that is, single traffic class, PFC disabled) prior to entering the sleep state. When software handles DCBX, it is also responsible for configuring the DCB settings of the port by setting the DCB registers. In such a case, the end-station can be made by software as the DCBX "master" (the entity that propagates its DCB settings to the peer.

When LLDP/DCB is handled by EMP, the E810 behaves always as a DCBX "slave", retrieving its DCB settings from recommendations or configurations received from the peer.

If LLDP frames are sent by the PF, they are tagged with an outer VLAN tag by the device before issuing them on the lines. In receive, LLDP frames with an outer VLAN tag are directed to the appropriate PF.

Refer to Section 9.8 for the general handling of LLDP packets. The LLDP Agent embedded in EMP (including its DCBX agent) is reset by GLOBR. Further to such reset events, EMP restarts LLDP Agent and DCBX resolution for the ports on which LLDP was handled by EMP.

When LLDP is handled by EMP, following to a CORER event, EMP reconfigures the Tx/Rx paths (and any relevant hardware that was reset) with the DCB configuration that prevailed before the reset occurred.

8.2.4.5.2 DCBX Version

There are two known versions of DCBX standard: IEEE and CEE. The E810 supports both, and can adopt at runtime its peer's mode of operation or to determine the mode of operation based on NVM configuration word: "DCBX Mode".

The NVM configuration selects one of the three options: CEE, IEEE, or adopt peer's mode of operation.

When it configured to adopt peer's mode of operation, it is done based on DCBX TLVs received from the link peer using the flow detailed below.

1. Upon initialization (Linkup, GLOBR, or LLDP ownership hand-off from software to EMP, TLV counters expire) EMP runs IEEE/DCBX as default mode.
2. Upon receiving a DCBX TLVs from the partner:
   — EMP determines the actual DCBX mode it runs. This is done based on the OUI field in the DCBX TLV. In IEEE, the OUI TLV value is "00 80 C2". In CEE, this value is "00 1B 21".
   — If the message contains IEEE/DCBX TLVs, then
      - DCBX mode == IEEE
      - Ignore and CEE/DCBX TLV in the message
   — End If
   — Else If the message contains only CEE/DCBX TLVs, then
      - DCBX mode == CEE
   — End if
3. Whenever the DCBX mode is changed between CEE and IEEE, the whole DCB configuration is reinitialized to the default DCB setting.

Method used by software to find which version EMP runs:

Software sends down "GET_CEE_DCBX_OPER_CFG" AQ command and waits for its completion. Refer to Section 9.8.5.2.2.8 for more details on this command.

If retval == success

DCB Mode = CEE.

Negotiated DCB arbitration available in response buffer for this command.

End if

If retval == ENOENT

DCBX Mode = IEEE

Software sends down "GET_LLDP_MIB" AQ command to find out the DCB arbitration negotiated using DCBX protocol.

End if

If retval == EPERM

Software has taken control of DCBX. Query software DCB agent for any DCBX configuration

End if

8.2.4.5.2.1 CEE vs. IEEE DCBX

This section highlights the main difference between CEE and IEEE modes that affects the DCBX resolution. Refer to the two standard specifications for more details.

Operational Configuration:

IEEE DCBX TLVs always advertise the operational setting of the feature. CEE DCBX, on the other hand, computes the operational configuration based on local DesiredCfg and peer's DesiredCfg. If software wants to determine the OperCfg, it cannot use the "GET_LLDP_MIB" AQ command, for CEE as OperCfg is not the wire in case of CEE. Software must use the "GET_CEE_DCBX_OPER_CFG" AQ command for obtaining the OperCfg in CEE. Refer to Section 9.8.5.2.2.8 for detail on this command.

Priority Groups:

CEE DCBX has a concept of Priority Group, which is not present in IEEE DCBX. EMP is required to equate the Priority Group and Traffic Class concepts. That is, treat the Priority to Priority Group mapping received in the CEE DCBX TLV as the Priority to Traffic Class mapping as well.

Priority Flow Control:

For CEE DCBX, if the PFC does not become operational via CEE DCBX state machine, CEE DCBX disables PFC and enables link-level flow control. When EMP runs the DCBX agent in IEEE mode, this recommendation is irrelevant since it behaves in slave mode and aligns itself to the peer.

8.2.4.5.3 DCBX Managed Objects

When a port DCBX is handled by EMP, the DCBX Managed Objects are the DCBX parameters stored internally in EMP data RAM and/or in device registers. All DCBX objects are per LAN port. Two instances are stored per port: one issued by the device to the link partner referred as Local DCBX parameters, and one received from the link partner referred as Remote DCBX parameters.

When DCBX is handled by EMP, the PFs must restrain themselves from any write access to the DCB registers listed in Table 8-7. "RW" in the table refers to the EMP capability to write the object.

Table 8-7. Local DCBX Managed Objects

IEEE Object Name *CEE Object Name	Data Type	Width (in Bits)	Admin	Default
ETS Configuration TLV				
Willing	Boolean	1	RO	1
Credit-Based Shaper (CBS)	Boolean	1	RO	0
Max TCs *Num TCs Supported	Unsigned Integer	3	RW	0[1]
Priority Assignment Table *Priority Allocation Table	Unsigned Integer [0..7]	8x4	RW	0
TC Bandwidth Table *Priority Group Allocation Table	Unsigned Integer [0..7]	8x7	RW	0
TSA Assignment Table	Unsigned Integer [0..7]	8x8	RW	0[2]
PFC Configuration TLV				
Willing	Boolean	1	RO	1
MBC	Boolean	1	RO[3]	0
PFC Cap *Num TC PFC Supported	Unsigned Integer	4	RO	0x8[4]
PFC Enable *PFC Config Table	Boolean [0..7]	8x1	RW	0
Application Priority Configuration TLV				
Application Priority Table *App Protocol Config Table	Unsigned Integer	32x24	RW	0
MFS per TC Table	Unsigned Integer	8x15[5]	RW	1536

1. 0 is the encoding for 8.
2. Strict Priority algorithm is assumed by default (indicated by a zero value) on each user priority. Setting the value of 2 selects ETS bandwidth allocation scheme.
3. MACsec support.
4. The E810 is always able to support up to eight PFC-enabled traffic classes, though in some cases (when Jumbo is enabled) fully independent PFC behavior is partially achieved.
5. Max Frame Size is defined in bytes.

8.2.4.6 DCB Configuration Using MIB TLVs

The E810 manages internally a wider set of MIB TLVs, which allows configuring Tx and Rx DCB pipes and DSCP settings. Software configures the DCB hardware for both VLAN and DSCP modes using the same method by calling the AQCs "Get Local LLDP MIB" and "Set Local LLDP MIB". In addition, independent and optionally asymmetric setup for Tx and Rx is available using the same method.

Table 8-8 Provides the list of all the TLVs used for DCB configuration.

Table 8-8. DCB Configuration MIB TLVs

		TLV ID	Description	Comments
VLAN PFC MODE	Multicast (Rx and Tx)	0x09	ETS Configuration	Standard DCBX TLVs and OUI. Exchangeable with the link partner. Every "operational TLV" update in this section is immediately copied by EMP firmware to both Rx and Tx corresponding TLVs.
		0x0A	ETS Recommendation	
		0x0B	PFC per UP	
		0x0C	Application Priority	
	Rx	0x89	ETS Configuration	Separate Rx and Tx configuration TLVs. OUI == 0xFF_FF_FF Those TLVs are not exchanged in LLDP. Any update of a TLV in this section is translated to a hardware configuration of Rx or Tx DCB pipe. These TLVs are updated when the operational TLVs are updated. Software can set separately Rx or Tx TLVs (AQC Set Local MIB TLV) to activate different setup for Tx and Rx.
		0x8B	PFC per UP	
		0x8C	Application Priority	
	Tx	0x99	ETS Configuration	
		0x9B	PFC per UP	
		0x9C	Application Priority	
DSCP PFC MODE	Multicast (Rx and Tx)	0x41	DSCP to UP	OUI == 0xFF_FF_FF Those TLVs are not exchanged in LLDP. Every "Multicast TLV" update in this section is immediately copied by EMP firmware to both Rx and Tx corresponding TLVs.
		0x42	DSCP Enforcement	
		0x43	Bandwidth per TC and TC priority	
		0x44	PFC per UP/TC (Same ID)	
	Rx	0x45	DSCP to UP	Separate Rx and Tx configuration TLVs. OUI == 0xFF_FF_FF Those TLVs are not exchanged in LLDP. Any update of a TLV in this section is translated to a hardware configuration of Rx or Tx DCB pipe. These TLVs are updated when the operational TLVs are updated. Software can set separately Rx or Tx TLVs (AQC Set Local MIB TLV) to activate different setup for Tx and Rx.
		0x46	Bandwidth per TC and TC priority	
		0x47	PFC per UP/TC (Same ID)	
	Tx	0x48	DSCP Enforcement	
		0x49	Bandwidth per TC and TC priority	
		0x4A	PFC per UP/TC (Same ID)	

The format of the Rx (0x89, 0x8B, or 0x8C) and Tx (0x99, 0x9B, or 0x9C) TLVs are identical to the corresponding standard DCBX TLVs.

The rest are of non-standard TLV formats are as detailed below.

Notes and Restrictions:

- When software configures the Rx or the Tx separately (using the Rx or the Tx MIBs), Tx-Scheduler is configured with the Tx-Pipe according to the Tx MIBs. Software is responsible for issuing "Stop LLDP Agent" prior to configuring Rx and Tx separately.
- When a port acts in DSCP mode, DCBX protocol is disabled. Software is responsible for issuing "Stop LLDP Agent" prior to configuring a port for DSCP mode.
- When software feeds LLDP MIB, VLAN PFC mode TLVs "ETS configuration" and "PFC per UP" are configured as pairs. If software tries to program one without the other in a single AQ call, this call returns with the error code EINVAL.
- Same restriction and behavior for the DSCP. TLVs "Bandwidth per TC and TC priority" and "PFC per UP/TC" are pairs.
- If software tries to set the DSCP-related MIB while PFC mode != DSCP, the command is rejected with the error code EMODE. Likewise, if software tries to set the VLAN-related MIB while PFC mode != VLAN, the command is rejected with the error code EMODE.

8.2.4.6.1 UP-to-TC Mapping Configuration

The configuration of UP-to-TC for Rx is done using CSR PRTDCB_RUP2TC. EMP firmware uses this CSR when the Rx UP2TC is changed as part of the DCBX handling, or as a response to a software call for Set Local MIB (Rx only or multicast).

The configuration of UP-to-TC for Tx is done using CSR PRTDCB_TUP2TC. EMP firmware uses this CSR when the Rx UP2TC is changed as part of the DCBX handling or as a response to a software call for Set Local MIB (Tx only or Multicast).

8.2.4.6.2 DSCP-to-UP - Subtype 0x41 or 0x45

Table 8-9. DSCP-to-UP Format

TLV Type = 127 (7 bits)	TLV Information String Length = 148 (9 bits)	OUI FF-FF-FF (24 bits)	Subtype = 0x41 or 0x45 (8 bits)	DSCP-to-UP Table Table 8-10 (145 bytes)

Table 8-10. DSCP-to-UP Configuration

Name	Byte.Bit	Value	Remarks
IPv4 DSCP-to-UP mapping used for Rx. Affects packets coming from the network or form loopback (VM to VM).			
DSCP #0	0	UP value	Configured UP value for DSCP #0
DSCP #1	1	UP value	Configured UP value for DSCP #1
: :	: :	: :	
DSCP #63	63	UP value	Configured UP value for DSCP #63
Untagged	64	UP value	Configured UP value for Untagged (non-IP packets)
IPv6 DSCP-to-UP mapping used for Rx. Affects packets coming from the network or form loopback (VM to VM).			
Reserved	65-79		Padding for alignment.
DSCP #0	80	UP value	Configured UP value for DSCP #0
DSCP #1	81	UP value	Configured UP value for DSCP #1
: :	: :	: :	
DSCP #63	143	UP value	Configured UP value for DSCP #63

8.2.4.6.3 DSCP Enforcement - Subtype 0x42 or 0x48

Table 8-11. DSCP Enforcement Format

TLV Type = 127 (7 bits)	TLV Information String Length = 132 (9 bits)	OUI FF-FF-FF (24 bits)	Subtype = 0x42 or 0x48 (8 bits)	DSCP Enforcement Table Table 8-12 (128 bytes)

Table 8-12. DSCP Enforcement Configuration

Name	Byte.Bit	Value	Remarks
IPv4 DSCP enforcement[1]			
Port's TC#0 DSCP	0-7	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#1 DSCP	8-15	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#2 DSCP	16-23	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#3 DSCP	24-31	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#4 DSCP	32-39	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#5 DSCP	40-47	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#6 DSCP	48-55	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#7 DSCP	56-63	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
IPv6 DSCP enforcement[1]			
Port's TC#0 DSCP	64-71	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#1 DSCP	72-79	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#2 DSCP	80-87	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#3 DSCP	88-95	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#4 DSCP	96-103	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#5 DSCP	104-111	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#6 DSCP	112-119	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.
Port's TC#7 DSCP	120-127	Bitmap	Bit per DSCP value, marks if Block Tx of Packet uses this DSCP.

1. DSCP values enforcement. A per-CGD 64-bit bitmap. Signs per CGD per DSCP value if packet carries DSCP value X when the queue associated with CGD Y needs to be Blocked. Affects packets going to the network or to loopback (VM to VM). The behavior of the device in case of wrong DSCP value is configured by CSR GL_DCB_TDSCP2TC_BLOCK_DIS and GL_MDCK_TX_TDPU.DSCP_CHECK_FAIL_ITR_DIS as explained in Section 8.2.4.1.4.

8.2.4.6.4 DSCP Bandwidth per TC and TC Priority 0x43, 0x46, or 0x49

Table 8-13 details the DSCP bandwidth per TC and TC priority MIB TLV. Its format is identical to IEEE DCBX ETS configuration TLV. The irrelevant fields are marked as reserved.

Table 8-13. DSCP Bandwidth per TC and TC Priority Configuration Format

TLV Type = 127 (7 bits)	TLV Information String Length = 25 (9 bits)	OUI FF-FF-FF (24 bits)	Subtype = 0x43, 0x46, or 0x49 (8 bits)	RSV (1 bit)	CBS (1 bit)	RSV (3 bits)	Max TCs (3 bits)	Reserved (4 bytes)	TC B.W. Table (8 bytes)	TSA Assignment Table (8 bytes)

8.2.4.6.5 PFC per UP/TC 0x44, 0x47, or 0x4A

Table 8-14 details the PFC enable TLV. Its format is identical to IEEE DCBX Priority-based Flow Control TLV. The irrelevant fields are marked as reserved.

Table 8-14. PFC per UP/TC Configuration Format

TLV Type = 127 (7 bits)	TLV Information String Length = 6 (9 bits)	OUI FF-FF-FF (24 bits)	Subtype = 0x44, 0x47, or 0x4A (8 bits)	Reserved (1 byte)	PFC Enable (1 byte)

8.2.5 DCB Admin Commands

All parameters in the admin commands are defined in little endian.

8.2.5.1 PFC Ignore (0x0301)

This command is used to request the device to ignore PFC condition present on a Tx path for a TC. The same command is used to release PFC ignore request. When PFC packets are ignored, they are considered as regular packets and can be forwarded to host.

Table 8-15. PFC Ignore Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x0301	Command opcode.
Datalen	4-5		Must be zeroed by driver.
Return Value/VFID	6-7		Must be zeroed by driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command_flags	16-17		**Bits 16.7-16.0:** TC Bitmap Bitmap of the TCs concerned by the command. Bit n set to 1b means TC n is concerned by the request. When LFC is used instead of PFC, TC index 0 is used to request ignoring LFC. **Bits 17.6-17.0:** Reserved, must be zeroed. **Bit 17.7:** Ignore Flag 0b = The PF requests to release any ignore PFC condition request issued for the TC indexes set to 1b in the TC Bitmap. 1b = The PF requests to ignore PFC conditions on the TC indexes set to 1b in the TC Bitmap.
Reserved	18-31		Reserved. Must be zeroed.

Table 8-16. PFC Ignore Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0301	Command opcode.
Datalen	4-5		Must be zeroed.
Return Value	6-7		Return value: 0x0 = No error (success)
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Completion_flags	16		**Bits 16.7-16.0:** TC Status Bitmap Returns the TCs for which PFC is currently ignored. Bit n set to 1b means PFC condition on Tx path for TC n is ignored by the device.
Reserved	17-31		Reserved. Must be zeroed.

8.2.5.2 Query PFC Mode (0x0302)

This AQ call returns an indication if DSCP-based PFC or VLAN-based PFC is enabled.

This is a Direct Admin Queue command with additional command attributes, and completion attributes are provided within the data buffer. Table 8-17 describes command format and defines command-specific fields.

Table 8-17. Query PFC Mode Command and Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1 for details.
Opcode	2-3	0x0302	Command opcode.
Reserved	4-5		Reserved.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
PFC Mode	16		Zeroed by the Driver. Written by firmware provides the PFC mode setup. 0 = DCB is disabled for this port (by an NVM setting). 1 = VLAN based PFC is enabled. 2 = DSCP based PFC is enabled.
Reserved	17-23	0	Reserved. Must be set to 0.
Data Address High	24-27		0
Data Address Low	28-31		

8.2.5.3 Set PFC Mode (0x0303)

This AQ call configures the PFC mode to DSCP-based PFC mode or VLAN-based PFC.

This is a Direct Admin Queue command with additional command attributes, and completion attributes are provided within the data buffer. Table 8-18 describes command format and defines command-specific fields.

If DCB is disabled for this port by NVM setting, EMP firmware ignores this command, and in the response buffer the PFC mode is set to 0 “DCB is disabled for this port (by an NVM setting)”.

As part of flow of this command, EMP firmware resets all PFC parameters of both VLAN and DSCP modes. After setting the PFC mode, LLDP exchange or software AQ call can configure the PFC parameters.

Table 8-18. Set PFC Mode Command and Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1 for details.
Opcode	2-3	0x0303	Command opcode.
Reserved	4-5	0	Reserved.
Return Value/VFID	6-7		Return value, Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
PFC Mode	16		In Command: 0 = Reserved. 1 = VLAN based PFC is enabled. 2 = DSCP based PFC is enabled. In Response: 0 = PFC is not configured for this port. 1 = VLAN based PFC is enabled. 2 = DSCP based PFC is enabled.
Reserved	17-23	0	Reserved. Must be set to 0.
Data Address High	24-27		0
Data Address Low	28-31		

8.2.5.4 Set DCB Parameters (0x0306)

This command is used to request that the firmware apply the DCB configuration even when LLDP/DCBX is disabled.

Table 8-19. Set DCB Parameters Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1 for details.
Opcode	2-3	0x0306	Command opcode.
Reserved	4-5	0	Must be zeroed by driver.
Return Value	6-7		Must be zeroed by driver.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Command Flags	16		**Bit 0:** Link-up DCB configuration mode for the port 0b = Firmware does not apply any DCB configuration when a link up event occurs. 1b = Firmware applies the default DCB configuration when a link up event occurs. **Bit 1:** Persistently set the DCB configuration mode for the current port: 0b = No persistence of the DCB configuration mode settings 1b = Persistence for the selected DCB configuration mode.
Valid Flags	17	0	**Bit 0:** Bit 0 of the command flags is valid If the Valid Flag bit is 0, no change is made to the Link-up DCB configuration mode. **Bit 1:** (Valid only when Bit 0 is set to 1b.) 0b = Bit 1 of the command flags is not valid. 1b = Bit 1 of the command flags is valid.
Reserved	18-31	0x0	Reserved.

Table 8-20. Set DCB Parameters Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.2 for details.
Opcode	2-3	0x0306	Command opcode.
Datalen	4-5	0	No external buffer.
Return Value	6-7		Return code written by firmware. In the case of a failure, the existing configuration is unmodified.
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
Reserved	16-31		Reserved.

Table 8-21. Set DCB Parameters Expected Behavior

	Command Flags = 0	Command Flags = 1
DCBX Enabled	No change to existing behavior.	No change to existing behavior.
DCBX Disabled	No change to existing behavior (i.e., don't touch).	If software has not used Set Local LLDP MIB to change the MIB since GLOBR, apply the default settings. If software has changed the MIB, do nothing since software will handle it.

8.2.6 LLDP/DCBX Admin Commands

Refer to the LLDP Protocol commands described in Section 9.8.5.2.2.

8.2.6.1 LAN Queue Overflow Event (0x1001)

This event is sent from the device to a PF. It does not generate a response.

Table 8-22. LAN Queue Overflow Event

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x1001	Command opcode.
Datalen	4-5	0x0	N/A
Return Value	6-7	0x0	N/A
Cookie High	8-11	Cookie	Opaque value copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the EMP into the completion of this command.
PRTDCB_RUPTQ	16-19		Contains a copy of the PRTDCB_RUPTQ register reporting the absolute index (in the device space) of the reported receive queue.
QTX_CTL	20-23		Contains a copy of the QTX_CTL register of the matched transmit Queue Pair of the reported receive queue.
Reserved	24-31		Reserved. Must be zeroed.

Note: Software can reset the problematic function or resolve the issue in any other way. When the issue is resolved or the function is reset, the PF must clear the relevant timer by writing a 1b to the corresponding bit in CSR GLDCB_RCGDTI.

8.3 Transmit Scheduling

8.3.1 Hierarchical Scheduling

The E810 supports up to 16K Tx-Queues. The software manages packet enqueues for transmission to any one of the Tx-Queues, at any time, and in any order. For information on the Tx-Queue, refer to Section 10.5.5. Each Tx-Queue is associated with a single software entity (PF or VF), CPU core, and usage type called a user priority. The Tx-Scheduler is responsible for controlling the transmission of all Tx-Queues. It executes a scheduling algorithm and decides which the Tx-Queue is allowed to transmit and how many bytes. To meet all QoS agreements while considering the network capacity, and to reduce packet drop or flow control events, the Tx-Scheduler takes into account the following configuration parameters:

- Priority.
- Bandwidth allocation, bandwidth limit, minimum guaranteed bandwidth.
- Network topology, the network infrastructure fed by device ports, its capacity, and the deployment of the Rx units (switches, routers, target NICs, and so on) in the network.

- Those Rx units might be buffer-limited or limited by packet processing power. To address both types, the E810 can configure each topology node to arbitrate and shape for bytes per second (BPS) or packets per second (PPS).
- Quality of Service (QoS) and service level agreement (SLA).

The E810 Tx-Scheduler configured topology reflects the network topology to which the port is connected from one side, and the software functions (PFs, VFs, VMs, users, and so on) running on the Host on the other side. The network topology is ordered in layers, each layer representing a physical junction of the network. Each junction is also declared with its capacity that is derived by the line speed, the buffer sizes of the relevant routers, and so on.

Multiple Tx-Queues can feed every line in the network. These queues are also ordered in groups similar to VMs. The VMs themselves can be ordered in groups similar to PF.

The network resembles a tree, where each layer represents a physical junction (a router or a logical entity) with its QoS requirement. Section 8.3.3 shows some tree topology examples that can be used to represent the network topology in use cases such as cloud, enterprise, and COMMS.

To satisfy the QoS requirements of each layer of grouping and the deployment of the network, the Tx-Scheduler performs tree-based scheduling, which takes into account the QoS requirements and deployment limits of the network.

Tx-Scheduler Responsibilities:

The Tx-Scheduler accounts for the bandwidth allocation, bandwidth limit, and minimum bandwidth settings for payload and all headers generated by software and hardware. This is true for LAN traffic and payload as well as for headers generated by the Protocol Engine for RDMA traffic. It also includes the L2 tags, Ethernet, MPA, MPA Markers, and RDMA inserted by hardware on-the-fly. If hardware TEP is supported in Tx, the Tx-Scheduler also accounts these additional headers.

Section 8.3.2 describes the scheduling concept and its terms.

To support multiple usage models, abstract hardware configuration tables are used for the Tx-Scheduler and the usage model requirements are achieved by software and EMP firmware configuration parameters.

8.3.2 Hierarchical Scheduling Concept

8.3.2.1 Abstract Scheduling Tree

This section describes tree scheduling, its concept, terminology, and logical scheduling tree structure. The tree consists of the following components (examples relate to Figure 8-7):

- **Tree Node (or Node)** — The basic tree element. Each Tree Node can have at most one Parent Node, and one or more Child Nodes. The tree configuration establishes Parent/Child relations between all the Tree Nodes.
- **Root Node** — A Tree Node lacking a Parent Node. It occupies the lowest level on the tree - Level 0 (Node00 in this example). The Root Node is the end point of every scheduling flow.
- **Parent Node** — A Tree Node with one or more Child Nodes. Parent Nodes are always located at a lower tree level than Child Nodes. Node10 is a Parent Node, with two Child Nodes, Node20 and Node21. A Parent Node leads to its Child Nodes at scheduling tree traversal.
- **Child Node** — A Tree Node that has a Parent Node. A Child Node might be a Parent Node with respect to other Nodes. Node20 is a Child Node to Node10, and Parent Node with respect to Node300.

- **Sibling Nodes** — Tree Nodes that are Child Nodes of the same Parent Node. All Sibling Nodes are located on the same Tree Level. Nodes Node20 and Node21 are Sibling Nodes, whose Parent Node is Node10.
- **Leaf Node** — A Tree Node that does not have any Child Nodes. Leaf Nodes are located on the highest level of the Tree. Node300 is a Leaf Node. Every scheduling flow starts from a Leaf Node.
- **Tree Level** — A tree elevation. All the Tree Nodes located on the same tree elevation are at the same Tree Level. However, nodes on the same level do not necessarily have same Parent Node, since they might belong to different subtrees. Nodes Node21 and Node22 are located on the same Tree Level (Level 2), but they belong to different Subtrees, since they have different Parent Nodes, the parent of Node21 is Node10 and that of Node22 is Node11.
- **Subtree** — A portion of the tree comprised of the Tree Node as a Root Node and its descendants. The Subtree of Node10 includes Node20, Node21, Node300, Node301, Node302 and Node303.
- **Height of the Tree** — Number of Tree Levels + 1. Height of the tree is a number of steps in the scheduling tree traversal.
- **Blocked Node** — A node is considered to be blocked if it cannot satisfy the applied scheduling constraints or if all its Child Nodes are blocked. A Leaf Node is also defined as a blocked node when no work is available in its associated transmit descriptor queue or its RDMA QSet. Blocked Nodes cannot be included in scheduling tree traversal.
- **Branch** — In the context of Scheduling Tree, a branch is the pass from a Node to the Root Node. The Branch of a Node is its Parent's Node ID, Grandparent's Node, and so on, up until the Port's Root Node ID. The Branch of Node310 is Nodes list: Node24, Node11 and Node0. The Branch of Node20 is the list of Node10 and Node0. Most of the Scheduler operations are iterative walk from the Leaf Node to its root. Tx-Scheduler keeps the branch data of every Leaf Node in tables called "Branch Tables".

8.3.2.2 Scheduling Configuration Terms

8.3.2.2.1 Scheduling Quanta

As the network bandwidth exceeds 10 Gb/s, packet-by-packet scheduling requires the Tx-Scheduler to complete scheduling decisions within a few nanoseconds - this is not trivial. The E810's Tx-Scheduler schedules a "quanta" in each scheduling decision. A "quanta" is a configurable amount of bytes that can consist of one or more packets. The quanta size is configured per Tx-Queue and represents the number of transmitted bytes per scheduling cycle. The quanta size per queue varies from 250 bytes to 4 KB. The lower bound depends on LAN speed and topology configuration.

8.3.2.2.2 Configured Quanta vs. Actual Quanta Size

As noted above, a quanta is a number of bytes configured for each queue to be considered a single scheduling unit. The transmission unit must also take into account the boundaries of the transmitted packets - the device must not transmit a partial packet.

Packet boundaries are not synchronized with quanta boundaries. Therefore, to avoid transmitting partial packets, the packet queuing software flow is as follows:

- When a packet enters a Tx-Queue, its actual size is accumulated to the current active quanta of the queue.
- When the accumulated size of the current quanta exceeds the "per queue configured quanta size", the current quanta is locked and next packets are aggregated in the next quanta unit.

- The "Actual Quanta" is the accumulated size of the packets that are included in the quanta. Typically, the actual quanta size is larger than configured quanta size and it fits the packet boundaries.
- The actual quanta might include one or more packets. This quanta is queued to the Tx-Scheduler as a one unit request. The Tx-Scheduler grants this quanta to the queue as one unit.

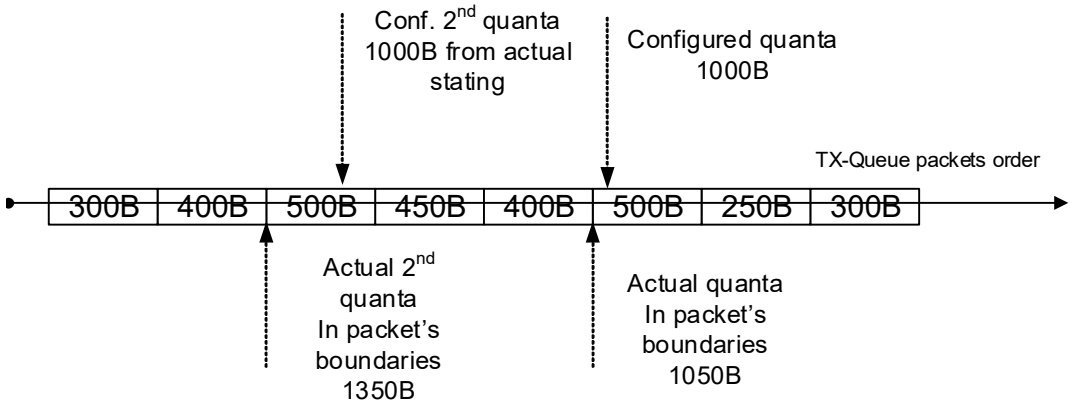

Figure 8-3. Configured Quanta and Actual Quanta Example

8.3.2.2.3 Bandwidth Allocation, Minimum Bandwidth Guarantee, and Bandwidth Limit

The E810 supports various bandwidth distribution mechanisms that can be applied to any node in the scheduling tree. These mechanisms define how Parent Node resources are used and shared by the Child Nodes. Those constrains are stated in the terms of bandwidth.

- **Relative Bandwidth Allocation or Bandwidth Share** — Allows to specifying a relative share of available bandwidth among Sibling Nodes. Sibling Nodes share the total amount of bandwidth available from the Parent Node. The share of the Parent bandwidth is relative, both with respect to the total amount of bandwidth available, and use of the bandwidth by other Sibling Nodes. If one of the Sibling Nodes cannot use its bandwidth share, the unused bandwidth can be utilized by other Sibling Nodes. Bandwidth share can be expressed in terms of weights or credits assigned to each tree Node.
- **Bandwidth Limit (PIR - Peak Information Rate) - Also known as Rate Limit (RL)** — Allows specifying a maximum bandwidth to be consumed by the Tree Node. RL is an absolute number specifying a maximum amount of byte or packets a Node can consume during the course of one second. Rate limit guarantees that a link does not oversaturate the receiver on the remote end, and also enforces an SLA between the subscriber and network provider.

  A Child Node cannot consume more bandwidth than the limit of its Parent Node. However, the sum of the bandwidth limits of the Child Nodes can exceed the bandwidth limit of the Parent Node, potentially enabling better utilization of the available bandwidth. Figure 8-7 illustrates this concept, where Child Nodes are represented by overlapping virtual pipes contained within the Parent Node virtual pipe.

  Each tree node can have an individually-assigned bandwidth limit. Some Nodes in the tree might need to share the Bandwidth Limit and use the Shared Rate Limiter scheme, explained below.

- **Shared Bandwidth Limit** — Allows specifying a bandwidth limit for a group of nodes that are not co-located in the tree, for example Child Nodes of different parent nodes. Another example of shared bandwidth usage is if you want to limit the bandwidth for a subgroup of a sibling group. You can define one sibling group that shares bandwidth allocation and still limit each subgroup individually.

  A node cannot be configured for both an individual bandwidth limit and a shared bandwidth limit at the same time. An exception for that statement is the ability to associate a node with a shared bandwidth limit group, but to configure it for credit contribution only. This means that this node contributes its bandwidth limit unused credits to the group but it is limited to its individual limit configuration. This is detailed later in this section.

- **Maximum Burst Size** — Specifies the maximum number of bytes that can be transmitted in a short period of time. When a node is configured with a bandwidth limit or a group is configured with shared bandwidth limit, the maximum burst size specifies the maximum amount of credits (in bytes) this rate limiter can collect (by the leaky bucket algorithm) when it is not transmitted for any reason (such as no work available for this node or other node with higher priority...).

- **BPS Scheduling vs. PPS Scheduling** — As stated in Section 8.3.1, the Tx-Scheduler configuration must take in account, among other parameters, the receive capabilities of the network nodes. A network node's receive capabilities can be declared as Rx packets buffering limited or as receive pipe processing limited. To address both limits, any node in the E810's Tx-Scheduler, can be configured to "Bytes Per Second" mode or to "Packets Per Second" mode. This configuration is applied to both bandwidth allocation and bandwidth limit.

In terms of configuration, each sibling group is configured either for BPS or for PPS mode. As an implementation, when a scheduling request is fed to the Tx-Scheduler, it includes both the quantity of bytes and number of packets. When this request is propagated through the Tx-Scheduler pipe, any node that is configured to PPS considers the request as bytes request of the number of requested packets multiplied by a constant number. From this point onwards, scheduling and shaping of PPS is similar to BPS shaping.

- **Minimum Bandwidth Guarantee (CIR - Committed Information Rate)** — Allows specifying a minimum bandwidth allocated to a tree node when it is not blocked. Like PIR (detailed above), CIR specifies an absolute bandwidth. While PIR defines the maximum bandwidth the node can consume, the CIR marks committed bandwidth for the Node.

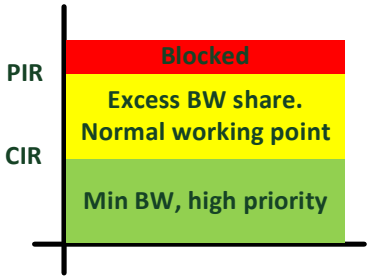

Figure 8-4. Per-Node CIR and PIR Levels

Figure 8-4 shows node bandwidth usage levels. The desired working point is the yellow area, where the node receives more than its minimum guaranteed bandwidth, shares excess bandwidth with its siblings, and does not reach its rate limit point.

The Tx-Scheduler tracks the bandwidth consumed by the nodes and manages the node state. Any non-blocked node that does not consume its configured minimum bandwidth is declared an **"Unsatisfied node"**. During arbitration flow, when selecting nodes from a sibling group, unsatisfied nodes receive higher priority to enable them to achieve the configured minimum bandwidth.

A Child Node cannot consume more bandwidth than allocated to its Parent Node. In the Tree topology configuration, the minimum guaranteed bandwidth must be fully provisioned. Hence, a node's minimum bandwidth must not be configured to be higher than the its own bandwidth limit or that of any of its ancestors all way to the Tree root. When configuring a minimum bandwidth for a node, it is also necessary to verify that its parent is able to receive this bandwidth as part of its minimum bandwidth guarantee setting.

Similarly, when multiple nodes are configured with minimum bandwidth, the sum of the minimum bandwidth of any sibling node group must not exceed that allocated for the parent. Each Tree Node can be assigned with an individual minimum bandwidth.

- **Excess Information Rate (EIR)** — Allows specifying a relative share of available bandwidth among Sibling Nodes. Sibling Nodes share a total bandwidth available from the Parent Node only after all the group's sibling nodes are in "satisfied" state (have received their minimum guaranteed bandwidth).

  The share of the Parent's bandwidth is relative, both with respect to the total amount of bandwidth available, and use of the bandwidth by other Sibling Nodes. If one of the Sibling Nodes cannot use its bandwidth share, the unused bandwidth can be utilized by other Sibling Nodes. "Bandwidth share" can be expressed in terms of weights or credits assigned to each tree Node.

- **Dual Rate Shaper** — A method that declares the bandwidth usage of a node. For a given Node, the Dual Rate Shaper configures all the following parameters: Bandwidth Limit (PIR), Minimum Bandwidth Guarantee (CIR), and its Excess Information Rate (EIR).

  In theory, "Unsatisfied Node" is a short transitional state of the node. As described in the CIR definition, the CIR setting must be fully provisioned to assure the Minimum bandwidth guarantee contract. Assuming this is true, the arbitration method between "Unsatisfied Nodes" can be any simple round-robin scheme, since the "Unsatisfied Nodes" node get higher priority to return to the "Satisfied" state.

  In some usage models, customers might prefer to configure the CIR to be Best Effort higher priority rather than a strict fully provisioned traffic. In practical terms, not all CIR users are really fully in use. Statistically, the bandwidth allocated for the CIR almost satisfies the real need. In some cases, more CIR user really try to use their CIR bandwidth, in this case the CIR users channels are oversubscribed. For these use cases, the above assumption that CIR traffic is always fully provisioned is true only in most cases, but not necessarily always. This means Nodes might be stacked in an "Unsatisfied State" for a longer period of time. To avoid bursty traffic in those cases, the E810's Tx-Scheduler also implements a WFQ algorithm with bandwidth allocation configuration for CIR nodes. Two sets of bandwidth allocation configuration parameters are declared for every node. One is used when the Node is in CIR state, and the other is used when it is in EIR state.

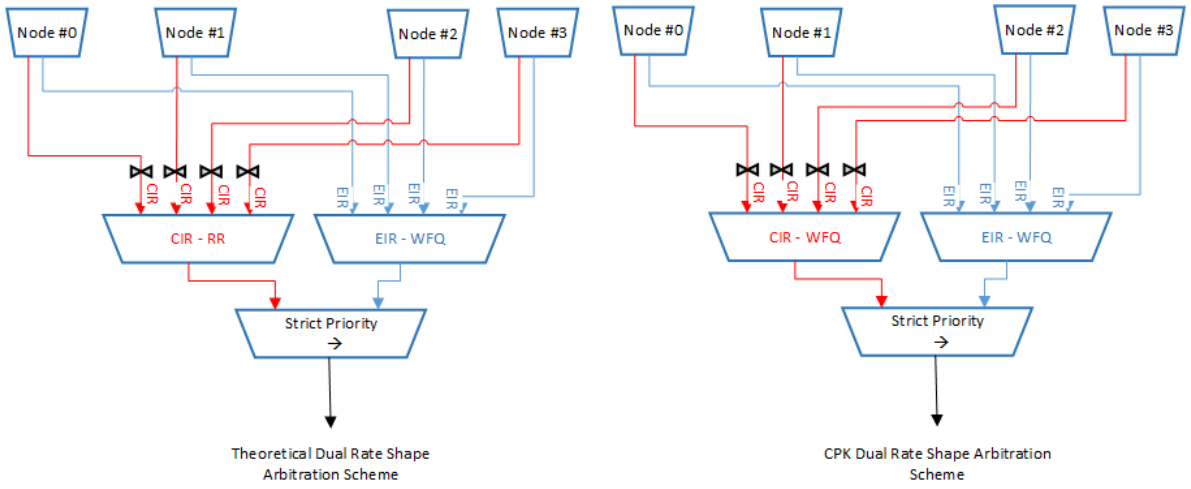

Figure 8-5. Dual Rate Shaper Arbitration Scheme

In Figure 8-5, the left scheme illustrates the usual implementation of Dual Rate Shaper Arbitration. Each node of the siblings group is connected to both EIR and CIR arbiters. The connection to the CIR arbiter is shaped to the CIR configuration of this node. A round-robin arbitration is implemented between all CIR nodes. Any CIR node has higher priority than the EIR nodes.

The right figure illustrates the E810's implementation. WFQ arbitration in both CIR and EIR. Implementation-wise, the Tx-Scheduler does not run two WFQ schemes in parallel. Instead, each of the eligible non-blocked sibling Nodes, sends its CIR value to the arbitration if it is in CIR state. Otherwise, it sends its EIR value. If at least one of the nodes is in CIR state, arbitration is performed among all CIR nodes. Otherwise, the arbitration is performed among all the available nodes.

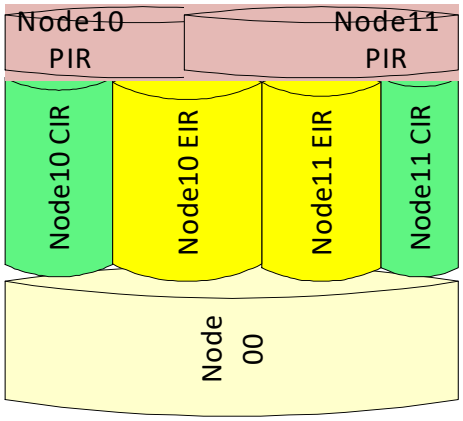

Figure 8-6. Parent Bandwidth Distribution Between Two Child Nodes

Figure 8-6 demonstrates the bandwidth distribution between two sibling nodes. The sum of CIRs of all siblings is less than or equal to the total bandwidth of the parent. The excess bandwidth is the part which is above the CIR for all siblings is shared between the siblings according the rate of each node. The PIR bandwidth of the nodes can overlap so the sum of the max bandwidth of all the siblings can be more than the total amount of parent's bandwidth.

Figure 8-7 demonstrates a wider picture of hierarchal bandwidth distribution.

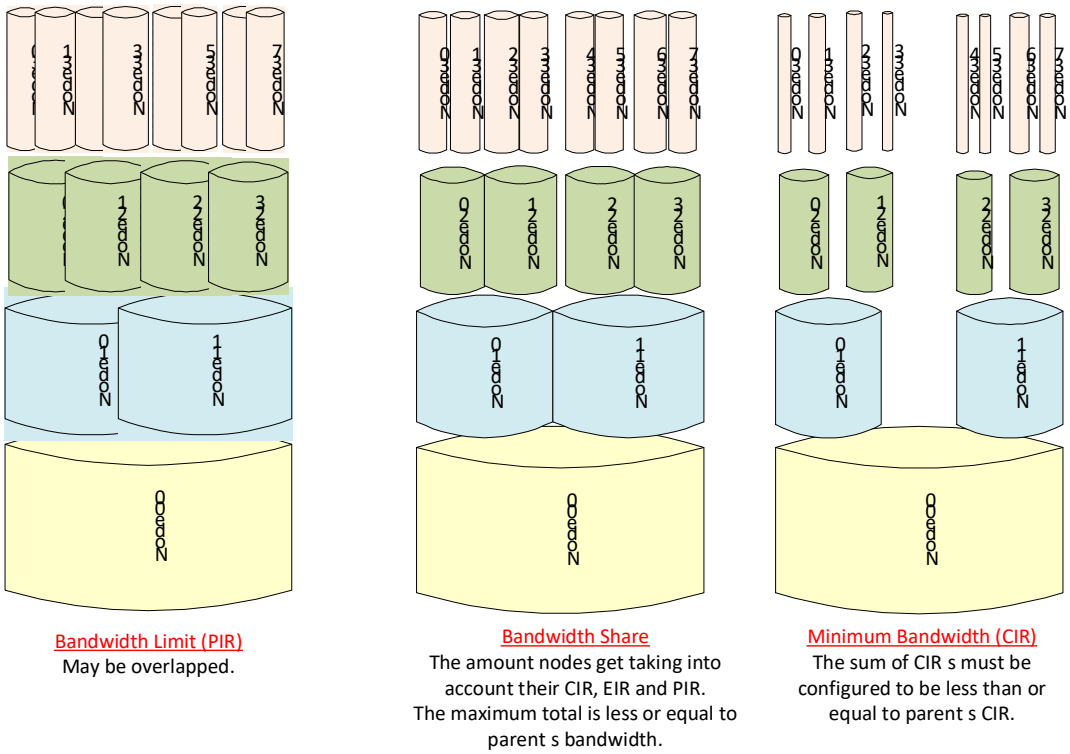

Figure 8-7. Hierarchal Bandwidth Distribution

8.3.2.3 Arbitration Schemes within a Sibling Group

The E810 supports several arbitration schemes that can be used to select a Node among Siblings in a hierarchal tree-based scheduling process. The selected node is called the group winner or "winner". This section explains the way the hierarchal tree-based scheduling process uses the selection or how the scheduling tree winner is selected.

Each set of Sibling Nodes has a configurable arbitration scheme assigned to it. Siblings participate in arbitration only if they are not blocked. Siblings can be configured to modify their arbitration scheme under different situations or in different states.

- **Strict Priority (SP)** — This arbitration scheme attempts to schedule Nodes based on their priority as long as the Nodes remain within their bandwidth limit.

  A Node can be pre-configured with constant priority, or can be configured to dynamically adopt a propagated priority from the previous layer. Another dynamic priority option is when a node or group of nodes is configured with minimum guaranteed bandwidth. In that case, every node whose current bandwidth consumption is below its configured minimum guaranteed bandwidth (node in unsatisfied state), is temporarily set with the higher priority. For more details on minimum bandwidth guarantee, see Section 8.3.2.2.3.

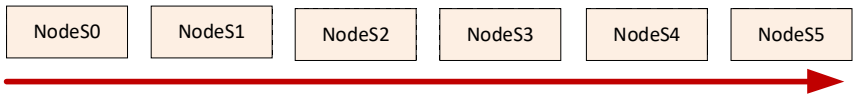

Figure 8-8. Arbitration Options - Strict Priority

- **Round Robin (RR)** — This arbitration scheme equally prioritizes Nodes, giving every Sibling Node a chance to be selected in cyclic round-robin fashion as long as it is not blocked.

  The arbiter iterates Sibling Nodes in cyclic round-robin fashion. In every scheduling cycle, the arbiter moves to the next Sibling Node and grants it another quanta (the quanta size for each node can be different). If the Node is blocked, the arbiter moves to the next Sibling Node. This arbitration allows even distribution of bandwidth among Sibling Nodes when all the Nodes are configured with the same quanta size.

  Note: This arbitration is not implemented in the E810 and is described here for background information.

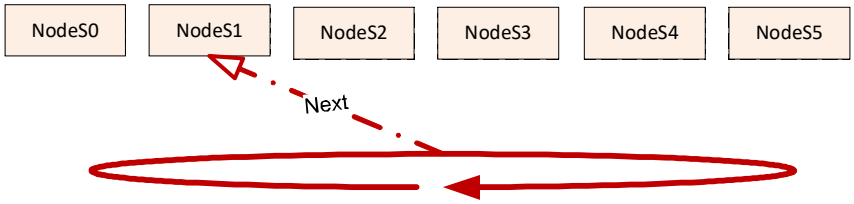

Figure 8-9. Arbitration Options - Round-Robin

- **Weighted Round-Robin (WRR)** — This arbitration scheme equally prioritizes Nodes and allows configuring each node with a different bandwidth by configuring each node with credits. The arbiter allows every Sibling Node a chance to be selected in cyclic round-robin fashion as long as it has credits and is not blocked. The node with most configured credits, survives more round-robin cycles and is granted greater bandwidth. When the credits of all siblings are exhausted, all the sibling nodes replenish their credits to the configured value.

  Note: This arbitration is not implemented in the E810 and is described here to clarify the WFQ description in the next paragraph.

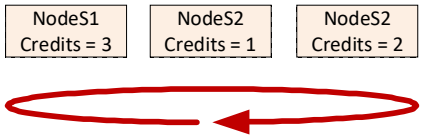

Figure 8-10. Weighted Round Robin Example Bandwidth Distribution: 50%, 33% and 17% for Nodes 1, 2 and 3 Correspondingly Credit Configuration is 3, 2 and 1

- **Deficit Weighted Round Robin (DWRR)** — This is an improved WRR scheme. In WRR, a quanta is granted for a node or queue without taking into account the actual size of the transmitted packet. A quanta almost never fits exactly to the packet boundaries. DWRR, however, is a responsive mechanism. After transmission, the delta between the quanta size and the actual transmission size is fed back to the Tx-Scheduler (Credit Update) and taken into account for the next scheduling decisions.

Note: DWRR is supported by previous NIC generations, but is **not implemented in the E810's Tx-Scheduler**. It is described here to provide clarification for the WFQ description in the next paragraph. Instead of DWRR, the E810 provides a better arbitration scheme called Weighted Fair Queuing (WFQ). WFQ is described in the next section.

- **Weighted Fair Queuing (WFQ)** — From the output perspective, WFQ arbitration appears similar to weighted bit-by-bit round-robin arbitration output. The transmitter does not interleave bits of different packets on the line, but when the last bit of a packet or a quanta is scheduled, the whole packet is scheduled. This point of time is called the departure time (DT) of the packet/quanta, and the scheduling grant flow for a packet/quanta transmission is called "dequeue". When a queue is selected for transmission, the DT of the winner is registered as the group DT call Last DT (LDT).

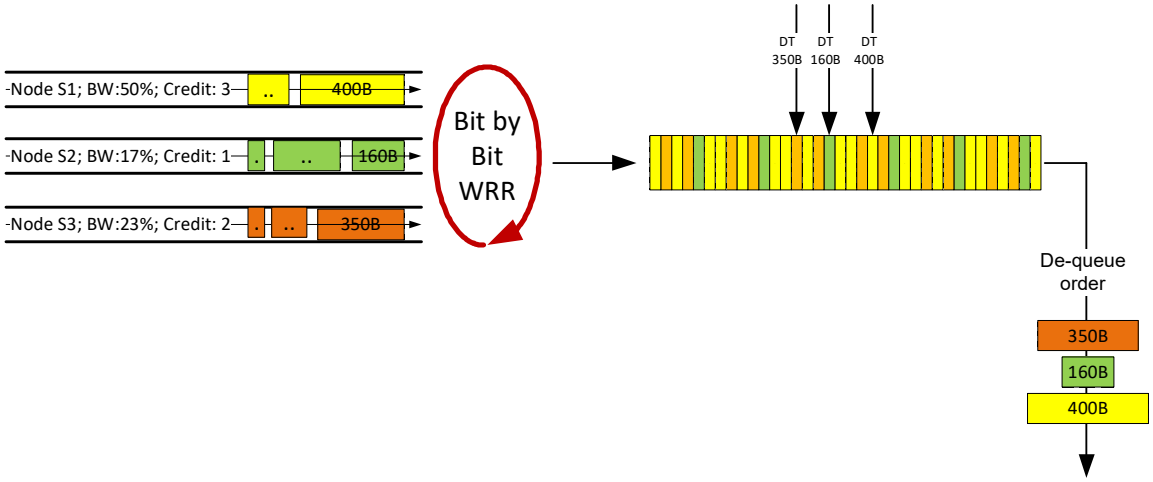

Figure 8-11. WFQ - Pseudo Bit-by-Bit WRR Arbitration

The WFQ arbitration method provides better (smaller) burstiness than DWRR. Its main advantages are:

— It takes in account the actual packet sizes in advance so less deficit update is required.

— Smaller packets naturally have a higher priority. Large packets never starve out small packets even momentarily.

As mentioned above, the Tx-Scheduler does not really run a bit-by-bit WRR for arbitration. Rather, it calculates the DT for each sibling node directly.

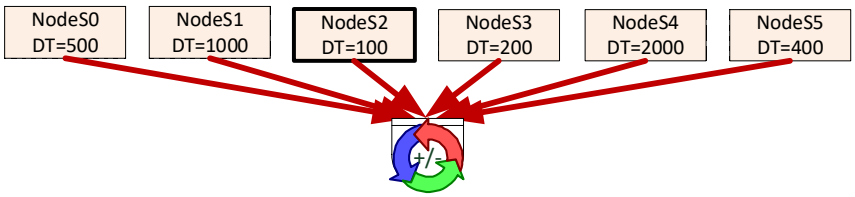

Figure 8-12. Arbitration Options - WFQ: Calculate DT for All Siblings and Pick the Lowest

The example in Figure 8-12 illustrates a sibling group of nodes in a WFQ arbitration. Node S2 is the winner in that particular example.

- **Combination of Strict Priority and Weighted Fair Queuing** — As described above, any node in any group can carry its own priority. This priority can be constant pre-configured, or dynamic. In each arbitration flow, the winning node is selected from the group's non-blocked siblings with the highest priority. Thus, different nodes can be configured with different priorities, even if they are siblings in the same group.

  Figure 8-13 shows two possible schemes of mixed arbitration. The basic rule is that each sibling group consists of a sub group with high priority nodes, a WFQ sub group with intermediate priority nodes, and a sub group with low priority nodes. In the lower example of Figure 8-13, NodeS0 is configured with the highest priority, NodeS1 with the next highest priority, NodeS2 and NodeS3 have the same priority, NodeS4 has a lower priority, and NodeS5 has the lowest priority in the group. In each sibling group, only one subgroup of nodes can carry one priority, all other nodes must carry a different priority each node. The upper example in Figure 8-13 is a subset of the general case.

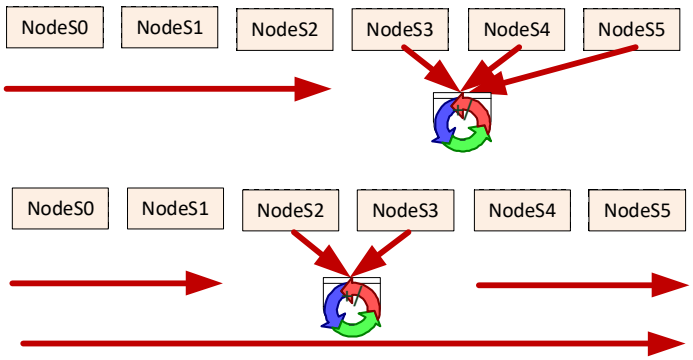

Figure 8-13. Combination of Strict Priority and Weighted Fair Queuing

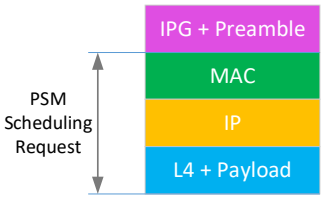
8.3.2.4 Credit Update

As described in the overview in Section 8.2.3.1, each stage of the Tx pipeline can receive more or less data on the actual Tx packet length, and can make a decision of packet length change or even drop the packet. Each of those changes are reflected as updates to the Tx-Scheduler. The report to the Tx-Scheduler is made as soon as the Tx-Pipe processing discover is required.

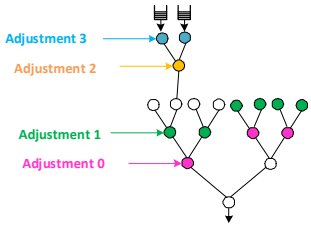
8.3.2.4.1 Four-Level Packet Adjustment Credit Update - Requirements

- Transmitted packets pass through different hierarchies in the network. The network hierarchies are reflected in the Tx-Scheduler layers structure. The capacity of each network unit is reflected in the rate limit and bandwidth allocation configuration of the nodes.
- Each unit in the network branch can deal with different portions of the packets.
- Typically, for the network hop, the whole packet including the IPG and the L1 header needs to be taken into account in the bandwidth calculation. Next hops, bridges, or the target station can consider a portion of the packet. For example, in tunneled environment, the target station does not see the whole packet, but only inner L4 part.
- The Tx-Scheduler is required to calculate up to four different adjustments of packets lengths for different Tx-Scheduler layers or nodes.
- The Tx-Scheduler is also required to calculate different adjustments of packets lengths for different types of packets.

- By default, the four adjustments point to:
  - Actual packet length on the wire including preamble and IPG.
  - Ethernet-layer (MAC to end of packet including padding. CRC is optional.
  - IP-layer (L3 IP header + L3 IP payload, inclusive) including ESP trailer.
  - TCP/UDP/… - layer (L4 header + L4 payload, inclusive).



- This way, the bandwidth consumption for different hops in the hops of the network is dependent on the actual portion of the packet run through this network unit.
- In the Tx-Scheduler, each nodes group is configured with the appropriate adjustment (2-bit setting). According to this configuration, each node is updated with the credits according the packets' format.
- When the credit update is propagated through the Tx-Scheduler pipeline and the tree structure, each node is updated with one of the four credit update values calculated as described above.



- This way, different adjustment can be configured per node in the scheduler.
- The credit update adjustment values should be programmable. Each COMMS customer (especially the Base station providers), has its own view on the network structure and restrictions.

8.3.2.4.2 Four-Level Packet Adjustment Credit Update - Implementation

As stated above, every transmitted packet is analyzed as part of the query flow to identify if it is transmitted, sent as loopback packet inside the platform, both, or dropped. In this query flow, the packet structure is analyzed by the E810's FlexiParser, described in Section 7.7

The E810 packet's FlexiParser, is a programmable packets analyzer. For each packet it analyzes, it generates up to 16 protocol reports. Each protocol report points to a packet field location inside the analyzed packet.

Protocol report is delivered to the E810 pipeline in the format:

- **{ProtocolID 8b; Offset 9b}**
  - ProtocolID = Identification of the protocol header found.
  - Offset = Octet offset from the beginning of the packet to the protocol header.

Packet Adjustment Calculator (PAC) is located after FlexiParser, it gets these 16 protocol reports and offsets (OCLs – Offset Collectors) per packet, and generates the 4 x length adjustments to the Scheduler. The PAC contains a table of 64 Adjustment Profiles (APs).

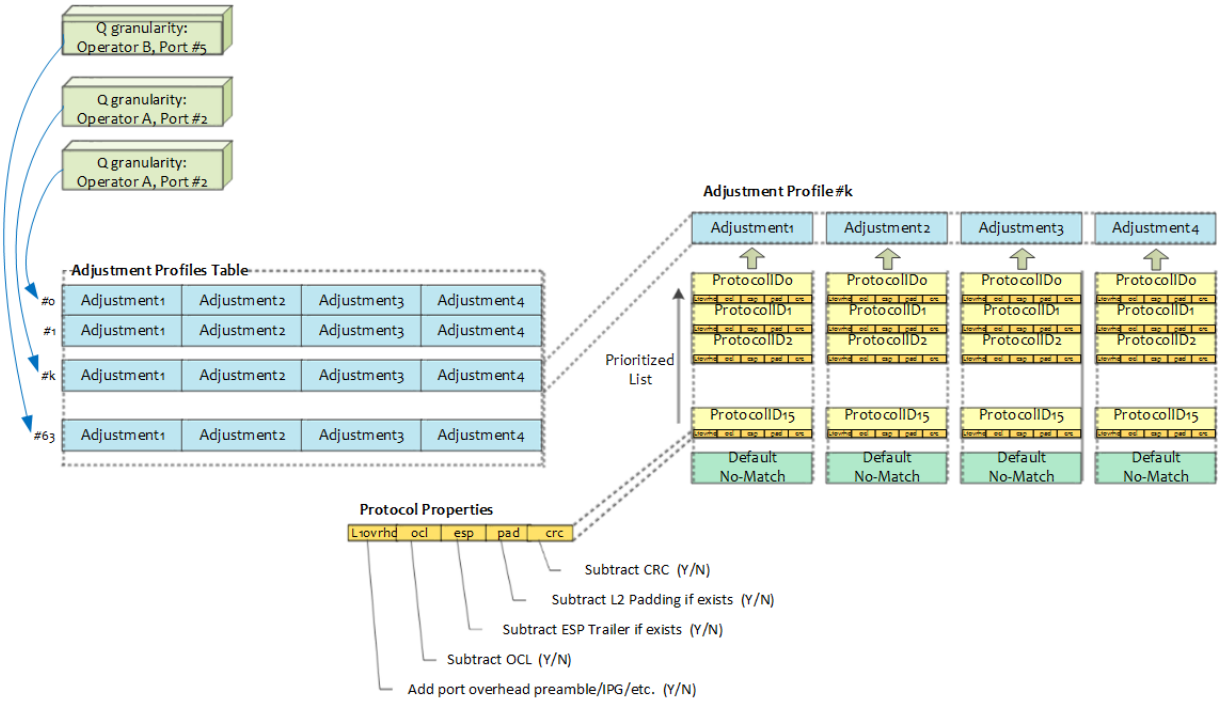


Figure 8-14. PAC Profile Structure

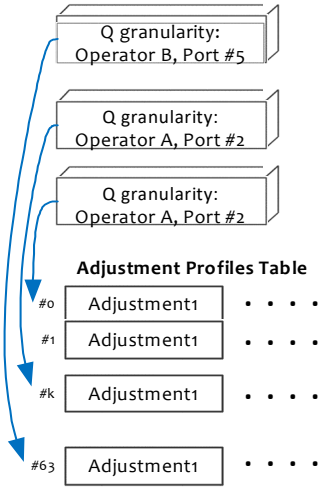
8.3.2.4.2.1 PAC - Adjustment Profile (AP) Association

Each AP is associated with a port and optionally with a Service Provider. This association is managed directly by PF. Per-PF allocation of APs is managed by software. The profile allocation is aligned with the FlexiParser root nodes allocation.

The FlexiParser gets the sourceVSI with the packet's header. The sourceVSI is used by the FlexiParser to determine the analyzing parse graph.

Each Tx-Queue is associated with an AP ID. This is configured in the Tx-Queue context by the PF. The AP ID is propagated with the packet's metadata and provided to PAC.



8.3.2.4.2.2 AP Profile Structure and Flow

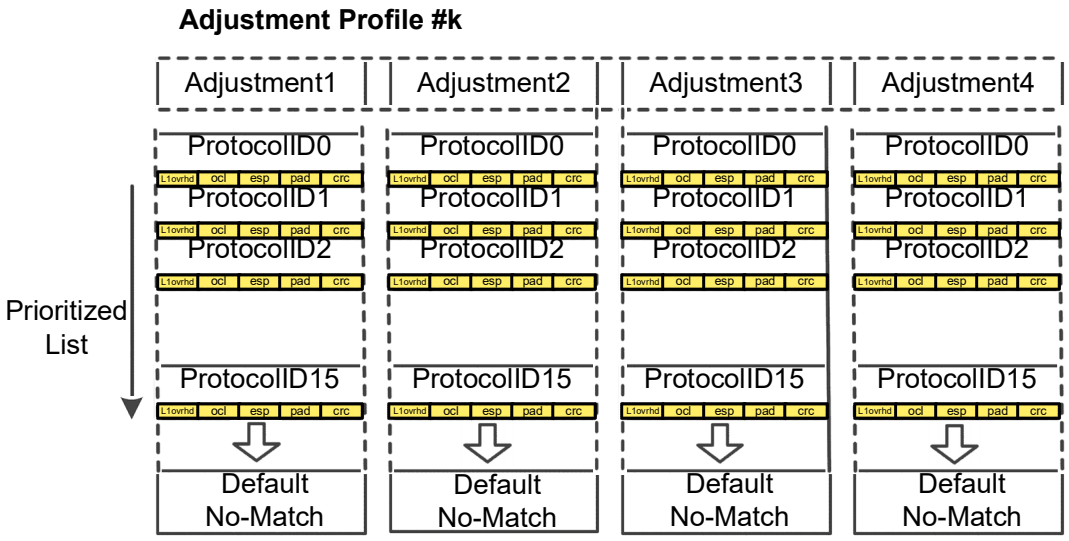


Figure 8-15. Adjustment Profile (AP) Structure

Each Adjustment Profile (AP) is made of 4 x adjustment components that generate the length adjustments. Each component defines a list of up to 16 x ProtocolIDs in prioritized order (Protocol ID 0 has the highest priority).

Each one of 16 protocol IDs FlexiParser provided per each packet, are compared with the list of the protocol ID lists of the relevant AP. The comparison is priority-based. Per adjustment, when a ProtocolID N matches a FlexiParser output protocol ID, The next protocol IDs in this list are ignored.

The offset of the matched protocol is captured in an Offset Collector (OCL) for calculating the length adjustment. The selected OCLs [1...4] are used for packet length adjustments [1...4], which are sent as update to the Tx-Scheduler in Update #2 flow.

Per each adjustment, if there is no match between the FlexiParser outputs and the AP's Protocol IDs, a hard-coded 0x1FF value is used as an adjustment value.

8.3.2.4.2.2.1 Adjustment Profiles Properties

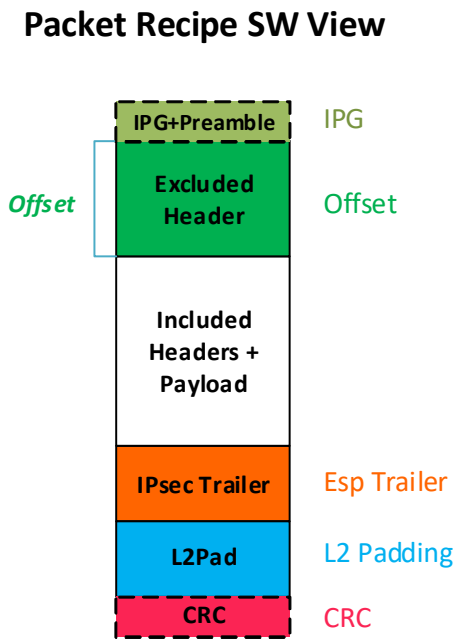

Figure 8-16. Adjustment Profile Properties (APP)

Each protocol ID of the AP is configured with a set of five flags. Those flags define the way this adjustment is calculated.

- The "CRC" flag marks if packet's CRC field is included in packet length for scheduling purposes.
- The "PAD" flag marks if in case of small packets. The 64B padding is included in packet length for scheduling purposes.
- The "OCL" flag marks if for this protocol ID. All headers until this header are included in packet length for scheduling purposes.
- The "L1ovrhd" flag marks if the L1 preamble and the IPG is included in packet length for scheduling purposes.

8.3.2.4.2.3 Packets Adjustment Examples

Example #1: Adjust for True L1 Length on the Wire:

- Adjustment #1 =

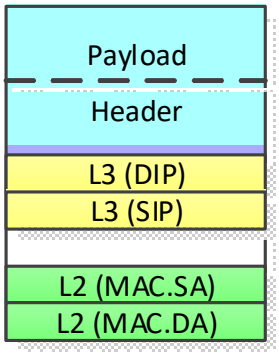
Flag	Operation Value	Description
L1ovrhd	1	Overhead Preamble/IPG = 20.
OCL	1	OCL not relevant, consider start of packet offset.
PacketData	Pkt Data	PacketData beyond OCL.
ESP	1	Do not subtract ESP trailer.
L2PAD	1	Do not subtract ESP padding.
CRC	1	Do not subtract ESP CRC field.

Packet length for Scheduling = Scheduled packet length + IPG preamble + CRC

Example #2: Adjust for L3 Length:

- Adjustment #3 =

Flag	Operation Value	Description
L1ovrhd	0	Overhead Preamble/IPG = 20.
OCL	0	OCL Outer IP header offset
PacketData	Pkt Data	PacketData beyond OCL.
ESP	1	Do not subtract ESP trailer.
PAD	0	Do not subtract padding.
CRC	0	Subtract CRC field.



Packet length for Scheduling = Scheduled_Pkt_Length – OCL (IP) – L2PAD

8.3.2.4.3 Four-Level Packet Adjustment Credit Update - Programming Registers

The configuration of the four adjustment functions are listed below. This list includes the adjustment calculation based on the parser output. The parser configuration is part of the parser chapter.

- GL_TDPU_PSM_DEFAULT_RECIPE
- GL_TDPU_PSM_PE_PROF_ID
- GLTDPU_NEG_PSM_CREDIT_UPDATE_EN

8.3.3 Network Topologies in Tx-Scheduler

The E810 supports various network topologies and various usage model targets. Each topology is reflected in the Tx-Scheduler topology. The E810 can work as a single-port or a multi-port device. At initialization, EMP reads basic configuration from the NVM and configures the Tx-Scheduler with an initial configuration. The parameters read from the NVM (words Logical Layer Config and Logical Layer Structure) are number of ports, and number of scheduling layers (5, 7, or 9).

The E810 supports up to 16K LAN Tx-Queue. For RDMA, The E810 supports up to 256K Queue Pairs (QPs). The 256K QPs of RDMA are organized in Queue Sets (QSets). Each QSet represents a group of QPs belonging to a function/TC. Typically, the number of RDMA QSets is the number of RDMA-enabled functions multiplied by the number of supported TCs. For scheduling purposes, a QSet is considered as one scheduling unit with its configuration for priority, bandwidth allocation, and limit. When the Tx-Scheduler schedules a quanta to a RDMA QSet, the PE shares this quanta between the QPs belonging to the QSet in a Round Robin manner.

The Tx-Scheduler supports up to 16K leaf nodes. Each leaf node can be associated with one LAN Tx-Queue or one RDMA QSet.

As mentioned above, the number of scheduling layers is a parameter loaded from the NVM, and can take one of the following values: 5, 7, 9. As the number of layers is lower, the performance of the Tx-Scheduler is higher since each decision flow covers fewer layers.

Table 8-23. Tx-Scheduler Performance as Function of Number of Active Layers

Topology Depth	# Clock Cycles / Quanta per Second	Quanta Size @ 100G Part
9 layers	24 cc / 18.58 M	673B
7 layers	20 cc / 22.3 M	561B
5 layers	16 cc / 27.9 M	448B

Note: In the first generation of the E810, the options for 5 and 7 layers are off POR.

When operating in 7 layer mode, Layers 5 and 7 are skipped. All other layers are fully functional.

8.3.3.1 ETS-Based Scheduler Configuration

Figure 8-17 shows a logical diagram describing the ETS-based bandwidth distribution scheme.

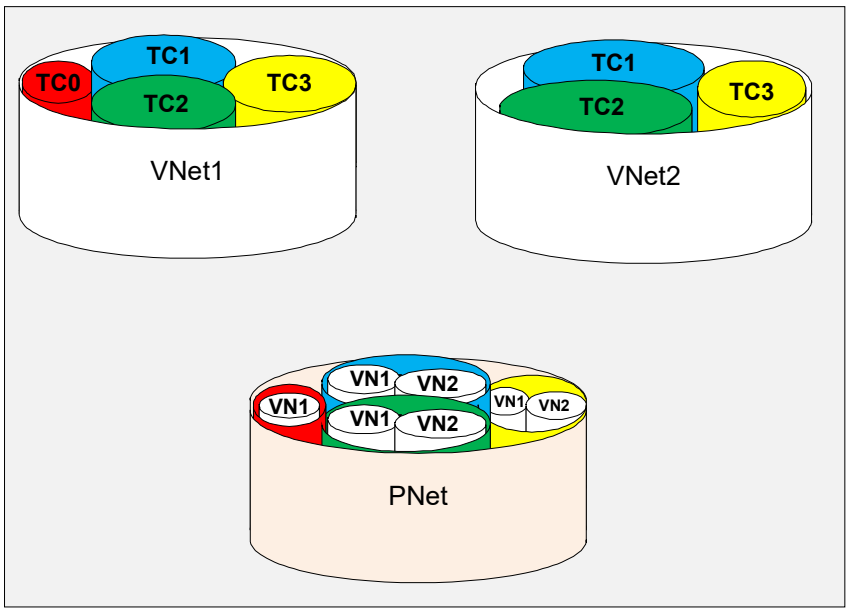


Figure 8-17. ETS-Based Bandwidth Distribution

This figure shows two Virtual Networks VNet1 and VNet2. Each virtual network carries traffic of different types by Traffic Class (TC). Both virtual networks merge into the Physical Network. The physical network is configured accordingly to ETS specification. The bandwidth of the physical network is divided between TCs. Each TC carries traffic belonging to respective traffic types of both virtual networks. The bandwidth distribution between virtual networks within same TC is invisible outside of the chip.

The diagram of the physical network shows the concept of bandwidth distribution in an ETS-based configuration. Bandwidth is first distributed between types of traffic (or Traffic Classes) and then distributed between virtual networks within each TC. Therefore, if one of the virtual networks does not have traffic of the certain type currently available, the remaining bandwidth is consumed by the same traffic type from other virtual networks. For example, if VNet2.TC3 does not have any work to perform, the remaining TC3 bandwidth is consumed by VNet1.TC3, as long as it has enough work to occupy it, and as long as it does not exceed any bandwidth limit.

This scheme allows bandwidth allocation per traffic type for each scheduling component and VSI, and does not support a bandwidth allocation per virtual network.

This is the default bandwidth allocation scheme for in DCB networks.

Figure 8-18 shows an example of system configuration and bandwidth allocation using the ETS-based scheduler configuration scheme.

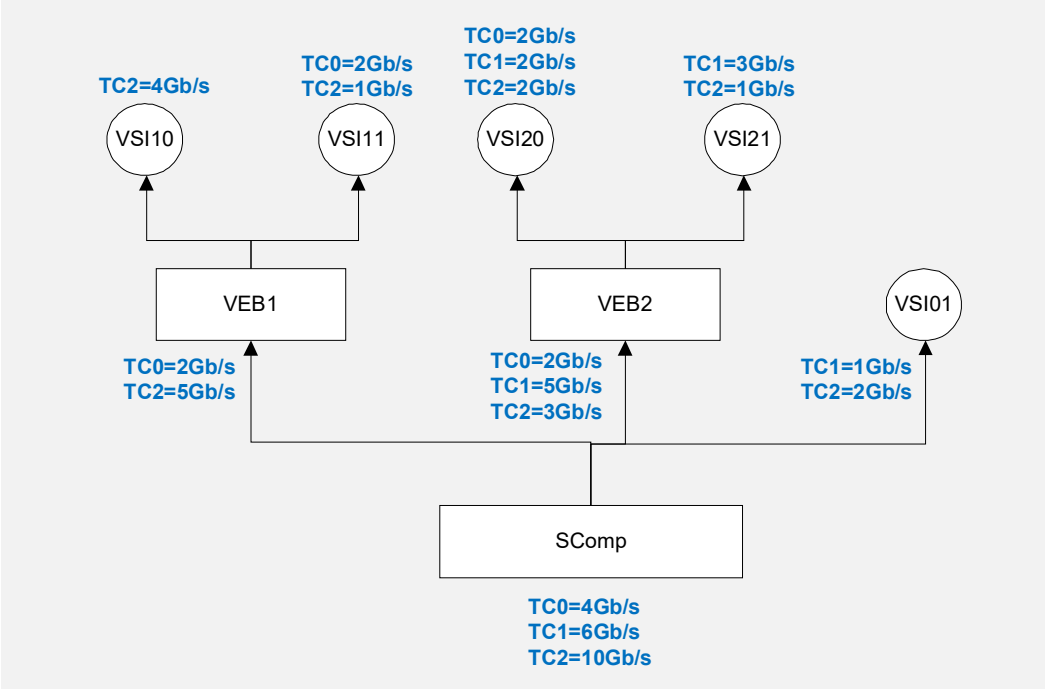

Figure 8-18. Example of ETS-Based System Configuration

Each of the Scheduling components (SComp, VEB1 and VEB2) and VSIs can be configured with ETS (bandwidth allocation per traffic type or TC) and bandwidth limit. Bandwidth allocation must be consistent. That is, if TC has a certain bandwidth allocated on the egress SComp port, the sum of the bandwidth allocated to the same TC on each level of tree hierarchy should be equal to the bandwidth allocated on SComp egress port. For example, if:

SComp.TC0 = 4 Gb/s

then:

VEB1.TC0 + VEB2.TC0 + VSI01.TC0 = 4Gb/s

and:

VSI10.TC0 + VSI11.TC0 = VEB1.TC0

Figure 8-19 shows an ETS-based scheduling tree configuration corresponding to the system configuration shown in Figure 8-18.

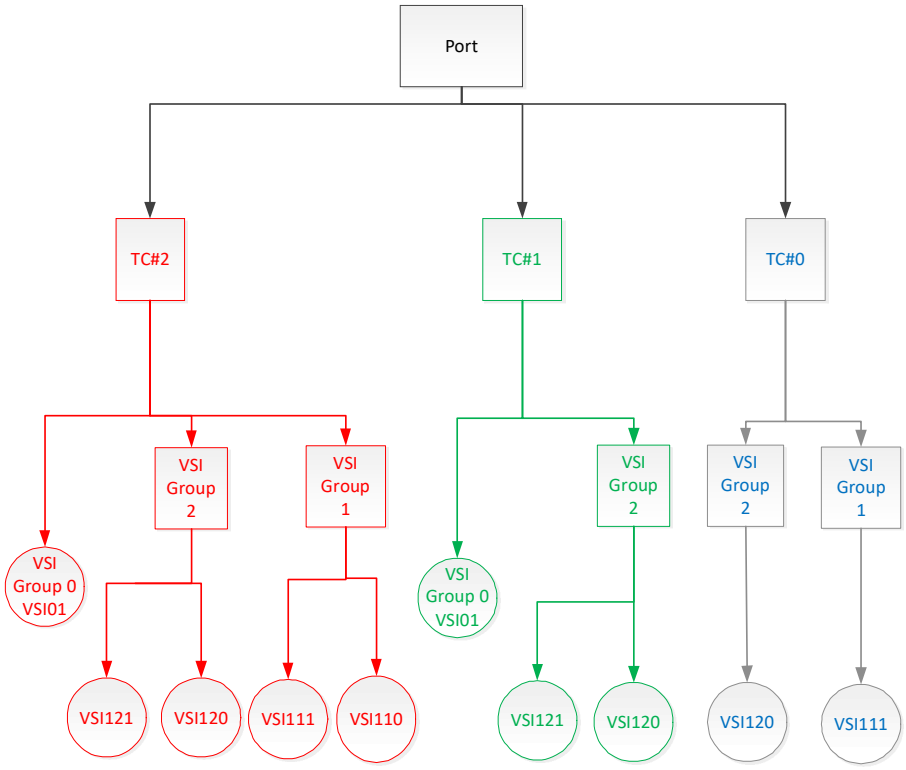

Figure 8-19. ETS-Based Scheduling Tree Configuration Example

The structure of this scheduling tree resembles the topology of the system configuration shown in Figure 8-18. This tree has four tree levels (one not shown):

- **Port Level** — This is the level that arbitrates between the physical ports.
- **TC Level** — This is the lowest tree level above the physical port. It is configured with physical port or SComp egress port ETS bandwidth allocation and priority (for example, nodes TC0, TC1 and TC2 in Figure 8-19).
- **Scheduling Component Level** — The next scheduling tree level. This level consists of Scheduling Components (VEB/PA) and VSIs directly attached to SComp. Each tree node corresponds to the TC/UP configured for the Scheduling Component/VSI. A single scheduling component and VSI can appear in the tree multiple times, once for each instance configured as TC/UP (for example, nodes VEB1_TC0, VEB1_TC2, VEB2_TC0, VEB2_TC1, VEB2_TC2, VSI01_TC1 and VSI01_TC2 in Figure 8-19).
- **VSI Level** — Last tree scheduling level. This level consists of the VSIs of scheduling components. Each tree node corresponds to the TC configured for the VSI. A single VSI can appear in the tree multiple times, once for each configured TC/UP (for example, VSI10_TC2, VSI11_TC0, VSI11_TC2, VSI20_TC0, VSI20_TC1, VSI02_TC2, VSI21_TC1 and VSI21_TC2).

Internal Scheduling Tree configuration is not visible to software. The EMP firmware creates and manages the internal scheduler configuration tree and translates software controls to the actual scheduler configuration. For example, when software provides an ETS configuration of VEB1, it lists TCs enabled for VEB1 (TC0 and TC2), and specifies an ETS bandwidth allocation per TC. The EMP firmware allocates multiple scheduling nodes for VEB (VEB1_TC0 and VEB1_TC2) and configures those nodes with credits provided by software.

Since the ETS configuration of VEB results in the creation of multiple tree nodes (one per TC), and those nodes reside on different subtrees, the credits provided should be relative to other VEBs/VSIs belonging to the same TC, and not relative to the TCs enabled for VEB/VSI. For example, VEB1_TC0 credits must be relative to VEB2_TC0 credits, and not to VEB1_TC2 credits.

Software can enable a bandwidth limit for any scheduling component and VSI. If a scheduling component or VSI has more than single traffic class enabled, it appears multiple instances in the Transmit Scheduling Tree. Use of shared or basic bandwidth limits is hidden from the software, and the decision whether to use basic or shared bandwidth limits is taken by EMP firmware depending on the selected bandwidth allocation mode and system configuration.

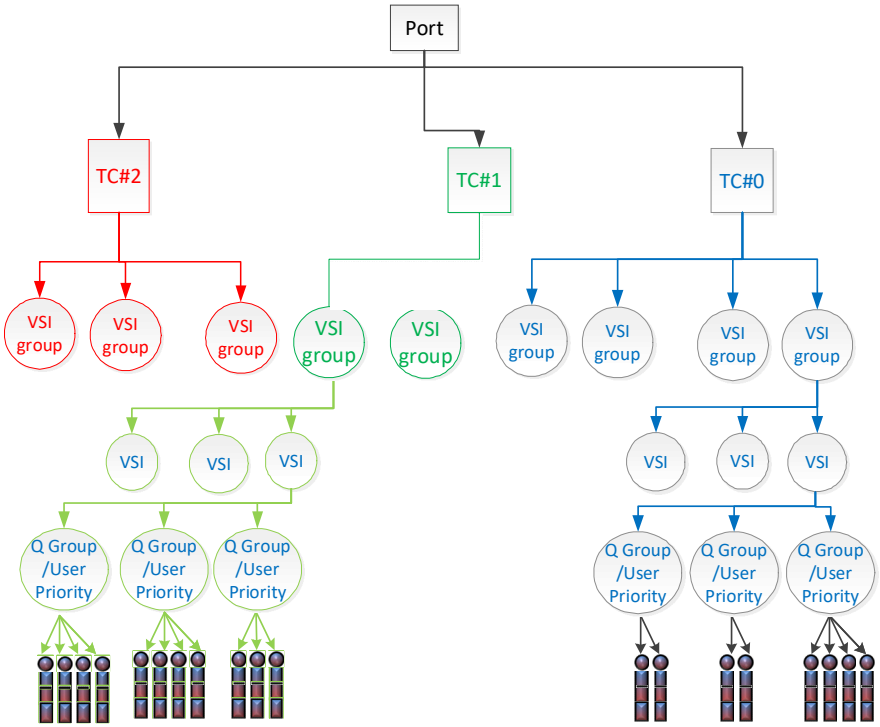

Figure 8-20. ETS-Based Scheduling Super Set Tree Configuration Example

Figure 8-20 illustrates an example of a super set topology for a DCB network, mainly used in the Cloud/ Enterprise market as detailed below:

- **Port Level** — This is the level that arbitrates between the physical ports.
- **TC Level** — This is the lowest tree level above of the physical port. It is configured with physical port or SComp egress port ETS bandwidth allocation and priority (for example, nodes TC0, TC1 and TC2 in Figure 8-20).
- **Scheduling Component Level** — The next scheduling tree level. This level consists of Scheduling Components (VEB/PA) and VSIs directly attached to SComp. Each tree node corresponds to the TC/ UP configured for the Scheduling Component/VSI. A single scheduling component and VSI can appear in the tree multiple times, once for each configured TC/UP (for example, nodes VEB1_TC0, VEB1_TC2, VEB2_TC0, VEB2_TC1, VEB2_TC2, VSI01_TC1 and VSI01_TC2 in Figure 8-20).
- **VSI Group Level** — This level consists of the groups of VSIs scheduling components. Some customers can use this intermediate level to bunch multiple VSIs into a scheduling groups. Each tree node corresponds to the TC configured for the VSI group.

- **VSI Level** — This level consists of the VSIs of scheduling components inside the VSI group. Each tree node corresponds to the TC configured for the VSI. A single VSI can appear in the tree multiple times, once for each configured TC (for example, VSI10_TC2, VSI11_TC0, VSI11_TC2, VSI20_TC0, VSI20_TC1, VSI02_TC2, VSI21_TC1 and VSI21_TC2).
- **Queue Group Level** — This level consists of the groups of queues inside VSI scheduling components. Some customers can use this intermediate level to bunch multiple Tx-Queues into scheduling groups. The queue groups of a VSI can be configured with the same priority or with different scheduling priorities. The queue group might act as a User Priority Level.
- **Queue Level** — This level consists of Queue Scheduling Components. Each Tx-Queue or RDMA QSet is scheduled individually.

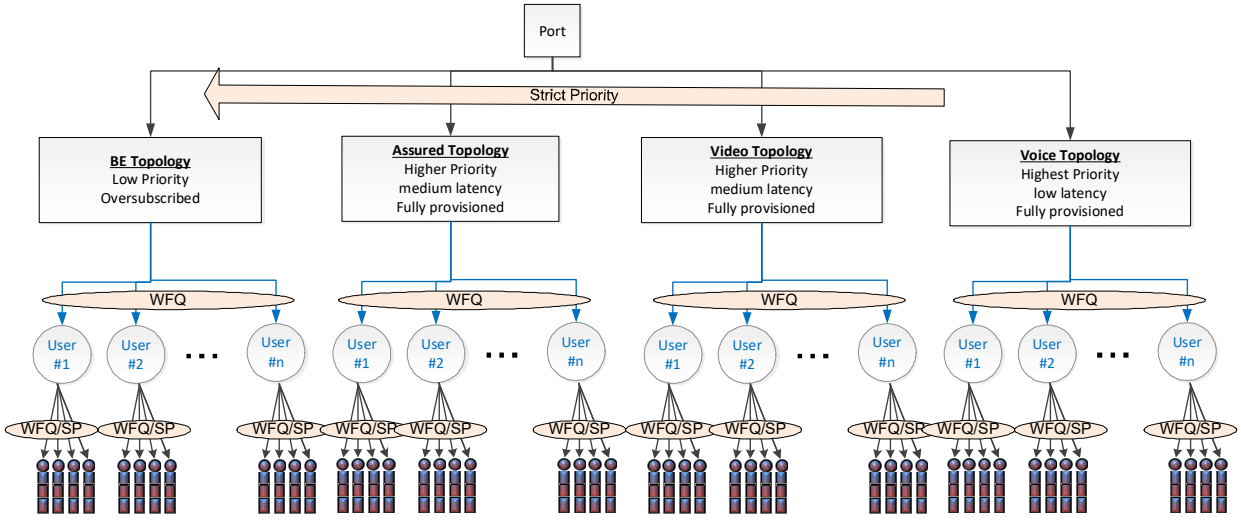

Figure 8-21. ETS-Based Scheduling Tree in BRAS Example

Figure 8-21 shows an example for BRAS scheduling tree in ETS-based topology mode.

- **Port Level** — This is the level which arbitrates between the physical ports.
- **Traffic Type/Priority Level** — This is the lowest tree level above the physical port. It is configured with physical port ETS bandwidth allocation and priority. Usually in the BRAS usage model, this layer is configured with Strict priority. The Voice Traffic with the highest priority, followed by Video Traffic, Assured Traffic, and Best Effort traffic with the lowest priority. All traffic types are fully provisioned and rate-limited to their provisioned rate.
- **User Level** — In ETS-based topology, this Layer arbitrates between the users/subscribers separately in each traffic type subtree.
  - In Voice, Video, and Assured Traffic types, the user nodes are rate limited to their provision rate. Since the parent node is also fully provisioned, there is no real congestion in the user layer for those traffic types.
  - In the Best Effort traffic type there is real congestion and scheduling between the users. This traffic is usually oversubscribed. Usually in COMMS application three types (or SLA levels) of users are served. The distinction between user levels can be implemented by dedicating minimum bandwidth allocation for high level users. Allocating higher weight bandwidth allocation. The rate limit configuration of user node also depends on user level.

- **Queue Level** — This level consists of Queue Scheduling Components. Each Tx-Queue is scheduled individually. Queue bandwidth configuration can be evenly shared between the user queues or setting different SLA per queues of the same level can be used for providing different levels of service for the queue user (for example, when the user is called by the Skype application, he prefers to give higher bandwidth/priority to this traffic inside the allocated bandwidth share). Thus, queue level can also be used for user level priority.

8.3.3.1.1 Shared RL in ETS-Based Scheduler Configuration

When building an ETS-based topology, Shared Rate Limiter (SRL) must be available. The SRL is used to limit the total amount of bandwidth consumed by a specific user (in BRAS case) or by a VF (cloud/ enterprise case).

8.3.3.2 VNet-Based Scheduler Configuration

Figure 8-22 shows a logical depiction of a VNet-based bandwidth distribution scheme.

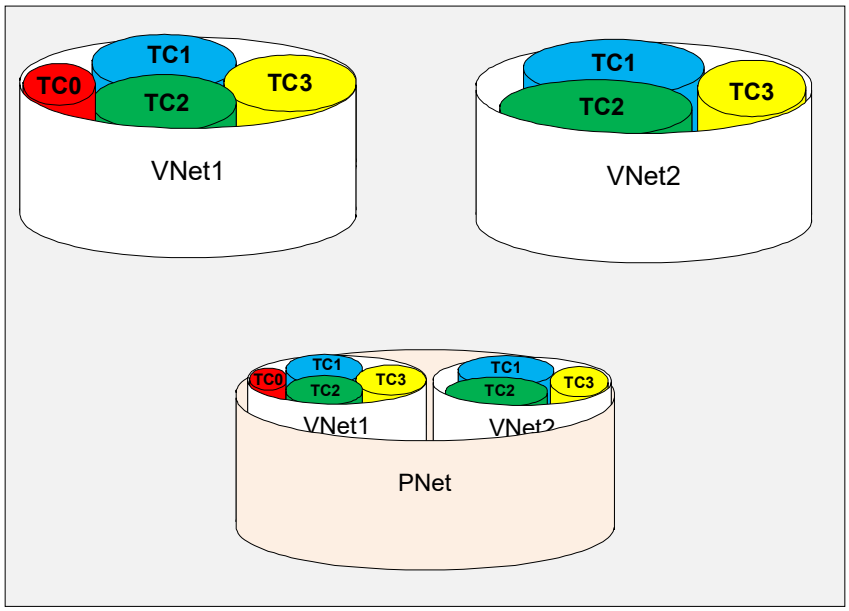

Figure 8-22. VNet-Based Bandwidth Distribution

Each of the two Virtual Networks VNet1 and VNet2 carries traffic of different types according to Traffic Class (TC). Both virtual networks are merged into the Physical Network, which is configured to distribute the available bandwidth between virtual networks first, then within each virtual network according to traffic types configured for that virtual network.

This bandwidth distribution scheme is logical for cloud-based environments with multiple tenants willing to share physical resources, and provides isolation of bandwidth allocation throughout the fabric. This scheme is also used in the COMMS market by some of the service providers.

This scheme also enables distribution of bandwidth between virtual networks, and provides global SLA guaranty without being limited to particular traffic type, as is the case with ETS-based schemes. Bandwidth can be then allocated according to traffic type within each virtual network. For example, if there is not enough demand to use all the resources of VNet2.TC3, the remaining bandwidth can be consumed by other traffic types configured for VNet2 (VNet2.TC1 and VNet2.TC2), as long as there is demand and no bandwidth limit is exceeded, rather than VNet1.TC3 consuming the unused bandwidth, as would happen in an ETS-based scheme.

Figure 8-23 shows an example of the system configuration and bandwidth allocation using a VNet-based scheduler configuration scheme.

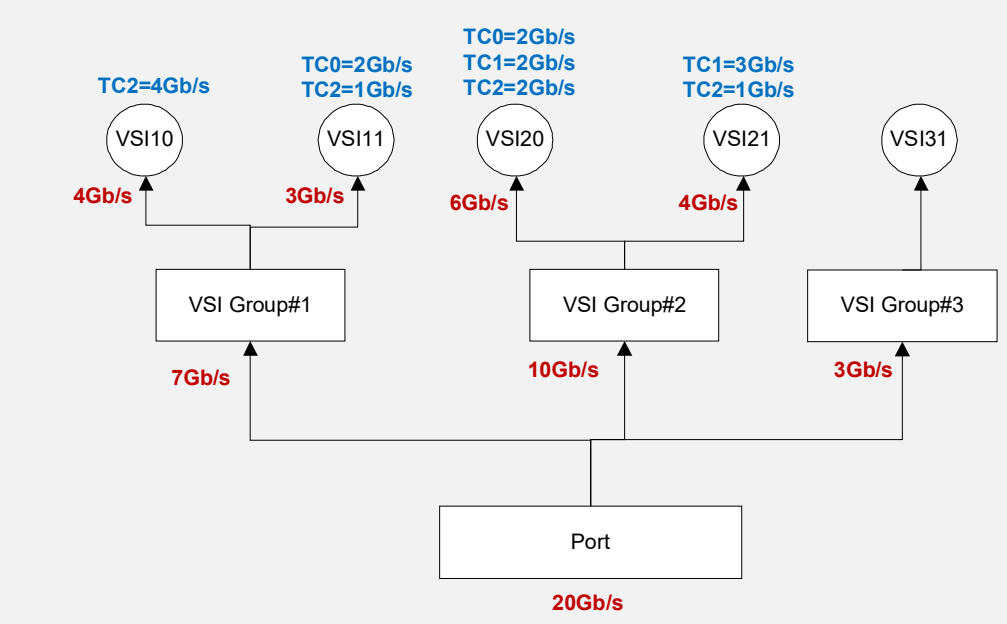

Figure 8-23. Example of VNet-Based System Configuration

Each of the scheduling components and VSIs has an allocated bandwidth and can have an associated bandwidth limit. VSIs are also configured with ETS, or per traffic type bandwidth allocation. Bandwidth allocation must be consistent. The bandwidth allocated to the scheduling component should be equal to the sum of bandwidth allocated to all VSIs, and the bandwidth allocated for VSI must be equal to the sum of bandwidth allocated to all the TCs. For example, the bandwidth allocated to VSI10 (4 Gb/s) and VSI11 (3 Gb/s) should be equal to the bandwidth allocated to PF#1 (7 Gb/s).

Figure 8-24 below shows a VNet-based scheduling tree configuration corresponding to the system configuration described in Figure 8-23.

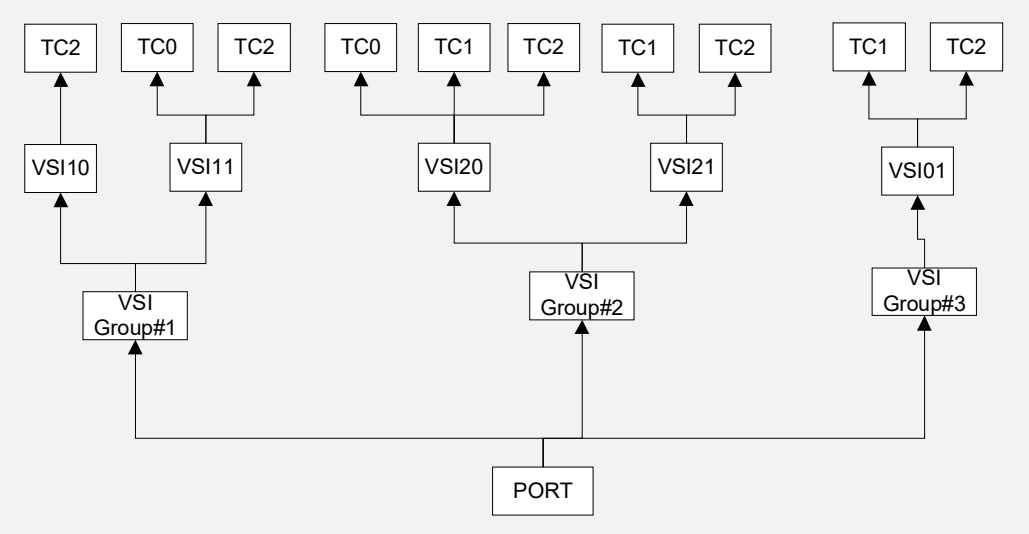

Figure 8-24. VNet-Based Scheduling Tree Configuration Example

The software is not aware of the internal scheduler configuration tree structure and uses a logical representation (shown in Figure 8-24) to program scheduler configuration tables. EMP firmware, translates software Admin Queue commands, and performs the actual configuration of the scheduler configuration tables.

If the software needs to instantiate a bandwidth limit for the scheduling component or VSI, EMP firmware should use a basic bandwidth limit, since each scheduling component and VSI is represented by a single tree node.

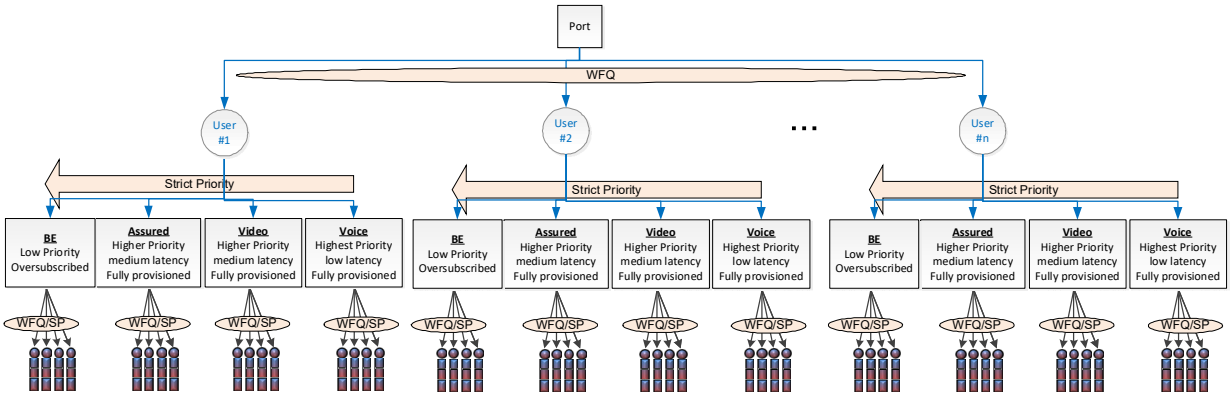

Figure 8-25. VNet-Based Scheduling Tree in BRAS Example

Figure 8-25 shows an example of a VNet-based topology usage in a BRAS network.

- **Port Level** — This is the level that arbitrates between the physical ports.
- **User Level** — In VNet-based topology, port bandwidth is shared among users according to their SLA, as follows:
  - In Voice, Video and Assured Traffic types, the user nodes are rate-limited according to their provision rate. Since the parent node is also fully provisioned, there is no real congestion in the user layer for those traffic types.
  - In the Best Effort traffic type, there is significant congestion and scheduling between the users, as this traffic is usually oversubscribed. Usually in COMMS applications, three types (or SLA levels) of users are served. The distinction between user levels can be implemented by setting a minimum bandwidth allocation for high level users, this allocating higher weight bandwidth allocation. The Rate limit configuration of user nodes also depends on user level.
- **Traffic Type/Priority Level** — In each user's subtree, bandwidth is shared between the four traffic types. Usually in the BRAS usage model, this layer is configured with strict priority: Voice Traffic with the highest priority, followed by Video Traffic, Assured Traffic and Best Effort traffic with the lowest priority. All traffic types are fully provisioned and rate limited according to their provisioned rate.
- **Queue Level** — This level consists of Queue Scheduling Components. Each Tx-Queue is scheduled individually. Queue bandwidth configuration can be evenly shared between the user queues or can be set to different SLAs so that queues of the same level can be used for providing different levels of service to the queue user. (For example, when a user calls by the Skype application, it is desirable to set a higher bandwidth/priority to this traffic in the relevant bandwidth share). In this way, queue level can also be used for user level priority.

8.3.3.3 VNET and ETS Topologies Support by One General Purpose Tree Structure in the E810

The previous products (like the X710/XXV710/XL710) limit the scheduling structure to ETS-based topology. In this product generation, the ETS vs. VNet support was a product mode. The firmware in these products supports ETS-based topology and was sufficient for enterprise usage models in DCB networks.

In the E810, both modes are supported. There is no need to set a mode. When DCB is enabled, TC level is added to the root of the tree, so ETS is always supported. The PF is allowed to configure node priority in any layer of the tree it owns. Thus, user priority is always supported.

Therefore, without mode changing, both modes are opened for PF programming by configuring the TC layer with priority or by setting the leaf layer with different priorities. This is a mixed mode where both TC level priority and user level priority are also supported per PF configuration.

A simple way to have a VNet topology support, is to enable only one of the TCs in layer 2 and leave the user-level priority active.

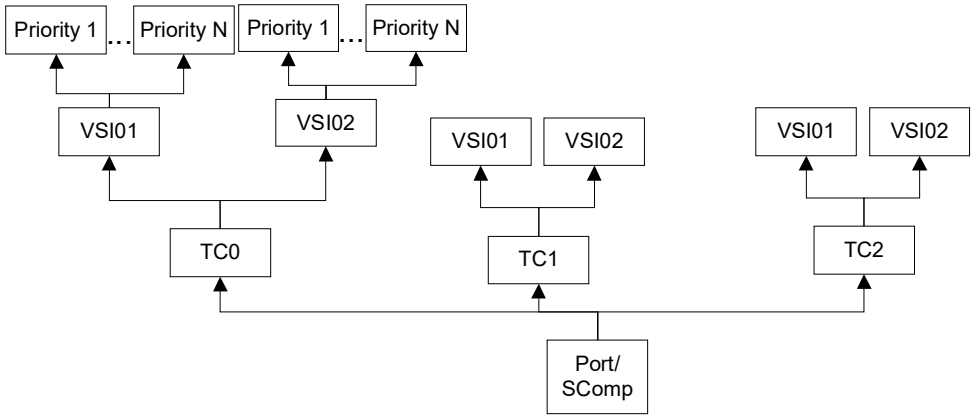

Figure 8-26. Mixed Topology VNet +ETS Example

8.3.3.4 Tx-Scheduler Configuration Process

The Scheduler implements one set of configuration tables shared by all PCIe functions. To synchronize access to the shared configuration table and maintain configuration consistency, direct access to the internal scheduler configuration is restricted to EMP.

The Scheduler does not expose its internal configuration tables to the standard deployment software. A set of registers allowing indirect access to the internal scheduler structures is exposed to firmware to allow programming of the Scheduler configuration tables. These registers are exposed in debug mode to other privileged software. A default configuration of the scheduling tables is performed by EMP firmware and based on the internal scheduling configuration profiles kept in NVRAM. NVRAM data includes the number of ports, number of scheduling layers (5, 7, or 9).

A physical function driver is considered to be trusted software and is allowed to modify the default configuration by proxying its requests through firmware using Admin Queue commands (see Section 8.3.4.3.6). Software should use an Admin Queue interface to communicate its scheduler configuration requests with EMP. EMP is responsible for constraining access to the scheduling configuration tables based on the software privilege level, shared resources, management mandatory, and resource ownership.

Most of the scheduling components are shared among physical functions. Once a scheduling component is allocated with a function, it is owned by a single physical function. If a scheduling component is shared among physical functions (for example, DCB bandwidth configuration), this component is configured and owned by the DCB agent running in EMP firmware.

8.3.3.4.1 Tx-Scheduler Configuration and Management Principles

- At initialization, a default topology is built, providing a subtree root for each PF. More details are provided in Section 8.3.4.1.
- The PF is able to build the required topology inside its subtree.
- EMP serves the PF in its task of Tx-Scheduler configuration and enforces basic topology rules. For example:
  - — Prevents the PF from affecting the behavior and performance of other PFs.
  - — Limits sibling groups size to NVM setting per logical layer.

  - — Does not let software remove nodes that have children.
- Some examples for rules that are not enforced by EMP firmware, but that PF software is responsible for keeping:
  - — TC or node priority consistency between nodes and layers.
  - — PPS/BPS group consistency.
  - — Tx-Queue and leaf node priority setting.
- A minimal set of scheduling components is used:
  - — **Port** — For each LAN port, a port node is allocated. This point reflects the physical port bandwidth.
  - — **TC** — This layer supports the DCB operation if it is active. The TC nodes are connected as child objects nested under the port node. When the DCBX message changes the DCB setting, this is reflected in this layer. The EMP adds TC nodes according the DCBX parameters. The bandwidth management for the TC layer is also configured by the EMP firmware according the DCBX parameters. After setting the TC layer, the PFs are notified and adjust their subtree with the new DCB setting. At init time, prior to receiving the DCBX message, TC0 is active and the entire topology is built on it. In this way, when further TCs are required, the tree layer remains unchanged.
  - — **VSI** — VSI is a scheduling component. It can reflect VM, VF, or PF.
  - — **LAN Tx-Queue/RDMA QSet** — This is a Tx-Scheduler leaf node. A LAN Tx-Queue or a PE QSet is connected to the leaf node.
  - — **Aggregator** — Additional general purpose scheduling component (called aggregator).
    - Aggregator can be added and located anywhere in the tree.
    - The aggregator is used to build subgroups of scheduling components when it is required. The subgroup can be configured with bandwidth allocation, minimum bandwidth, and limit.
- Queue can be connected to any Tx-Scheduler leaf node.
- When DCBX adds or removes TCs:
  - — The port's TC is expanded.
  - — PF builds the topology connected to the enabled PF/TC nodes. It can move existing subtrees and Tx-Queues, or add/delete scheduling components.
- Section 8.3.3 provides some examples of typical tree topologies for different usage models illustrating the usage of all scheduling components as well the topology building flows.

8.3.4 Flows

8.3.4.1 Tx-Scheduler Initialization Flow

As part of the device initialization flow, the Tx-Scheduler is initialized in two main steps:

- Hardware initialization.
- EMP basic topology configuration.

8.3.4.1.1 Hardware Initialization

- All the CSRs of the Tx-Scheduler block are reset to their default values and then auto-loaded according NVM settings.
- All Tx-Scheduler tables are cleared (all fields a zeroed).

8.3.4.1.2 EMP Initial Topology Configuration

For each PF, EMP allocates one Port node with one VSI node connected to it. If DCB is supported (NVM configuration), a TC layer is allocated as layer #2 topology. This VSI is the initial VSI of this PF. At a later stage, as part of the PF driver init flow, one initial queue is allocated to each initial VSI. Like for every VSI, PF can add more queues to the VSI. It can also organize the queues belonging to a VSI in groups according to bandwidth, with or without QoS (user Level TC or just queue groups) configuration.

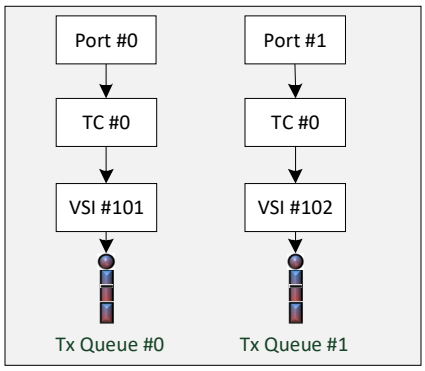

Figure 8-27. Example of Initial Configuration of a Dual Port Device

8.3.4.2 Resets Flows

Tx-Scheduler responds differently to different reset signal types. The following paragraphs detail the expected behavior for each reset type.

8.3.4.2.1 Power On Reset (POR), Core Reset (CORER), or Global Reset (GLOBR)

All data in the Tx-Scheduler tables are cleared. EMP configures all Tx-Scheduler tables according to the NVM setting of the device mode. For more details, see Section 8.3.3.4 and Section 8.3.4.1.

8.3.4.2.2 EMP Reset (EMPR)

EMP reset followed by GLOBR. Tx-Scheduler is reset according the CORER flow detailed in Section 8.3.4.2.1.

As part of the GLOBR reset as shown above, Tx-Scheduler registers and tables are reset and the EMP reconfigures the initial topology. Refer to Section 8.3.3.4 and Section 8.3.4.1 for details.

8.3.4.2.3 Function-Level Reset (FLR), PF Reset (PFR), VM Reset (VMR), VF Reset (VFR), or VFLR

Function-level reset events are not directly propagated to the Tx-Scheduler and no activity is expected in hardware for those events.

As part of the function-level reset flows, depends on the Reset Type the PF or the EMP firmware is responsible for function resources cleanup. The cleanup flow includes Tx-Scheduler resources cleanup using Delete Element(s) AQ Command detailed in Section 8.3.4.3.6.12.

8.3.4.2.4 PCIe Reset (PERST) or In-Band Reset (PCIR)

8.3.4.2.4.1 Single-Home Device

PCIe Reset in a Single-Home topology is followed by GLOBE and/or CORR (depending on the *veto* bit).

8.3.4.3 Tx-Scheduler Configuration Process

This section describes how to configure Scheduling configuration principles, and guides firmware through implementation of the Admin Queue commands defined in Section 8.3.4.3.6.

8.3.4.3.1 Scheduling Structure Representation

The internal structure of the Scheduler configuration tables is not exposed to software. EMP firmware is responsible for the Scheduler configuration, and provides software with an Admin Queue interface allowing alternative scheduler configuration.

Allocation and deallocation of nodes is also hidden from software and performed by EMP firmware based on software resource allocation/deallocation requests. EMP firmware manages the shared pool of the Tx-Scheduler leaf nodes as well as all other nodes.

A new added scheduling component is configured with a minimal default bandwidth allocation. Minimum bandwidth and bandwidth limit are disabled. Software can modify the default bandwidth allocations using the Admin Queue commands described in Section 8.3.4.3.6.

To create a common language between the different components in the system (drivers, firmware, and hardware) a logical representation of the Tx-Scheduler nodes is required. The objects represented in the models are identified by a device with Tx-Scheduler element identifier (TEID). The TEID of a component is returned upon creation of the component and is referenced when creating ties between components. The TEID of components created automatically can be retrieved using the "Query Default Scheduling Tree Topology" Admin Queue command. See Section 8.3.4.3.6.1 for more details.

If the scheduler runs out of resources (for example, leaf nodes), the respective allocation command fails and the requesting software is notified with an error return code.

8.3.4.3.2 Scheduler Configuration Tables

Tx-Scheduler is configured using a set of Scheduler configuration tables. Tx-Scheduler configuration tables are shared by all PCI functions, and managed by EMP firmware. Scheduler table configuration is performed by EMP firmware, and software can use Admin Queue commands described in Section 8.3.4.3.6 to alter default scheduler tables configuration.

8.3.4.3.3 Firmware Scheduler Interface

EMP firmware uses a register-based interface to access and program Tx-Scheduler configuration tables. In the normal operation mode, those registers are accessible and controlled by firmware only. In debug mode, all scheduler interface registers are mapped to the PCIe address space, and can be accessed by other CPUs or host software. No access synchronization mechanism is provided by hardware. Therefore, in debug mode, it would be up to software and firmware to coordinate their access to the Scheduler programming interface.

Scheduler provides two types of accesses to its configuration structures:

- **Immediate Access** — A basic operation allowing to read and write one entry of the scheduler configuration tables. Usually, firmware performs one table access at a time using this interface.
- **Batched Access** — A more advanced operation mode, allowing firmware to post multiple commands and have them executed as a single operation that can be executed in atomic manner when required. Scope of commands that can be used for batch operation is more limited than immediate commands, and primarily includes operations of copying an existing entry to the new location, or updating a field in the table entry.

Firmware is allowed to concurrently use both interfaces. Tx-Scheduler does not guarantee ordering between Batched and Immediate commands, and executes them in round-robin sequence along with other scheduling operations.

The table below lists all scheduler interface commands supported via Immediate or Batched interface. The majority of the commands can be posted via either one of interfaces. Any invalid command leads to a critical error and suspends a respective interface. Detected errors are reported in TSCDIFSTATUS register. The interface can be re-enabled by setting a *ICMDCLRERR* or *BCMDCLRERR* bit in the GLCD_IFCTRL register.

Submission of Immediate is performed using GLPSM_IFICMDL and GLPSM_IFICMDH CSRs. Batched commands are performed using GLPSM_IFBCMDL and GLPSM_IFBCMDH CSRs. CSR GLPSM_IFSTATUS provides the status for both interfaces. Not all the commands use the high DWord part. When the high part is required, it should be fed first. Write to low register indicates to hardware that command is ready and can be processed.

Both Immediate and Batched interface support a limited number of outstanding commands (Immediate: single command; Batched: up to 128 commands). Firmware must use the GLPSM_IFSTATUS register to validate that the interface has a free space for the new command. Overflow of immediate or batched interfaces is forbidden; any overflow command is silently dropped. EMP firmware is considered a trusted entity, and it is instructed to prevent any overflow event.

8.3.4.3.3.1 Immediate Command Interface

Firmware flow usually includes:

1. Read the GLPSM_IFSTATUS register to make sure that no Immediate command is pending. This operation can be skipped if previously posted immediate operation has been completed.
2. Write data to the GLPSM_IFDATA[n] registers (for WriteEntry operations). Order of writing data is not important.
3. Write command to the GLPSM_IFICMDH/L registers. Only few commands use the GLPSM_IFDATA[n] register. If posting a different command, firmware can skip writing to the GLPSM_IFDATA[n] register, and fill the GLPSM_IFICMDH/L register only. Content of the GLPSM_IFDATA[n] register should the be ignored.
4. Read data from the GLPSM_IFDATA[n] register for ReadEntry operations.

Though the Immediate interface is primarily designed for ReadEntry and WriteEntry operations, it can be used by firmware to post other commands.

8.3.4.3.3.2 Batched Command Interface

Batched Command interface allows firmware to post multiple commands and gain faster execution. Batch commands can be executed in atomic fashion if required. This interface allows firmware to perform the majority of Tx-Scheduler configuration tables without suspending normal Scheduler operation flow.

Batched Command interface allows firmware to post up to 128 outstanding commands. Each sequence of commands posted to Batched interface should be completed with BatchDone Control command posted to Batched interface. This command indicates that Batch sequence is completed. Commands posted to Batched interface are not executed immediately, but are queued to the 128-deep Batch FIFO. Firmware should "ring DB" by writing to the GLPSM_IFCTRL register to request execution of the posted sequence of batched commands.

Following is an example of posting Batched command sequence:

1. Read the GLPSM_IFSTATUS register to make sure that Batched interface has enough space available.
2. Write one or more commands to the GLPSM_IFBCMDH/L registers.
3. Complete the sequence by writing the BatchDone command to the GLPSM_IFBCMDL register
4. Write to the GLPSM_IFCTRL register to ring DB.

Firmware is allowed to interleave commands posted via Immediate and Batched interface. One usage model of that would be gathering information using ReadEntry Immediate commands to build a sequence of Batched commands.

Firmware is allowed to post multiple sequences of commands to Batched interface, each terminated by the BatchDone command. Each time firmware posts the BatchDone command to the Batched interface, it must ring DB. Hardware increments an internal counter with each DB ring, and decrements with each processed BatchDone command. If the counter remains positive, hardware processes the next batch after it completes a round of performing other scheduling flows.

8.3.4.3.4 LAN Queue or RDMA Queue Set Assignment

As a part of the scheduler configuration, each Tx-Scheduler Leaf node is supplied with a logical queue handle for LAN queue or RDMA Queue Set.

For basic operation (Prior adding the RDMA support), two look-up tables (LUT) are managed by EMP firmware and used for Tx-Scheduler: "Tx-Queue ID to Leaf node ID" and "Leaf node ID to Tx-Queue ID". The Tx-Queue context does not point directly to the leaf node ID. The Tx-Scheduler block activities relate to the leaf node ID. The LUTs are used in the interface between the Tx-Scheduler block and the transmit pipe. This way EMP firmware can update the internal structure and node locations internally without involving other blocks.

When RDMA is served in parallel to the LAN traffic, the RDMA Queue Set IDs are managed independently from the LAN Queue IDs. The LAN Queue at PSM interface is a number between 0-16K. The RDMA Queue Set ID is a number between 0-511. To allow parallel operation of LAN Queue and RDMA QSets, an additional table is added called "RDMA QSet ID to Leaf Node ID". This is the LUT for RDMA. For the calls from the RDMA interface, this table is used to find the Leaf Node ID. Calls from PSM to the Pipe, Leaf node ID to Tx-Queue ID include a flag in each entry that indicates whether if this call is targeted at the LAN or the RDMA interface.

The Queue or QSet ID that is propagated in the Tx-Pipe also includes the RDMA or LAN flag. The Update operation from TDPU carries this flag as well for correct update operations.

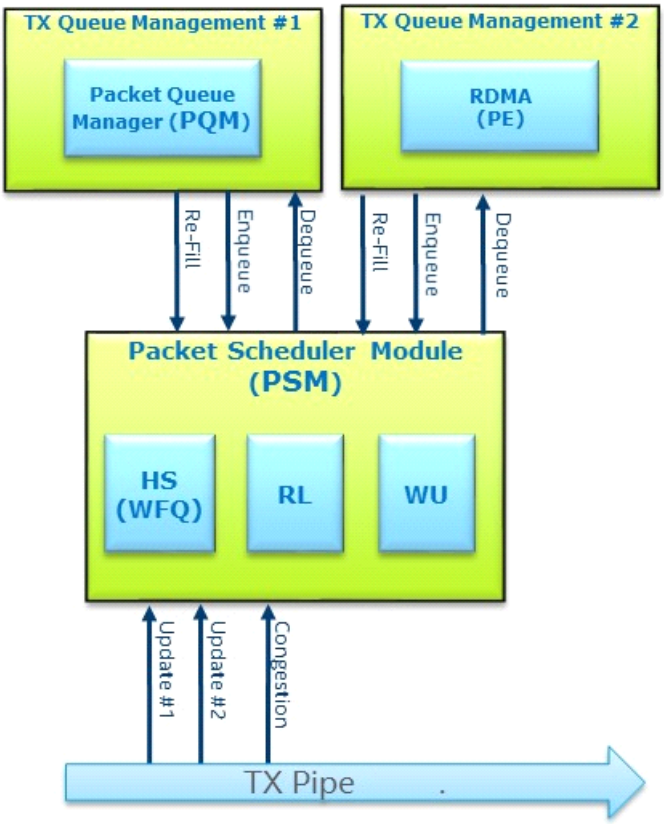

Figure 8-28. Parallel RDMA-PQM Connectivity to PSM

8.3.4.3.5 Releasing of Scheduling Elements

The software can use the AQ Command: Delete a Scheduling Component. Removal of the Scheduling Component is allowed only if the respective uplink Scheduling element has been previously removed. Software can request to remove a Leaf node only if the Queue/Queue Set associated with that Leaf node is disabled.

8.3.4.3.6 Admin Queue Commands

The internal structure of the Scheduler configuration tables is not exposed to software. This section defines Admin Queue commands used by software to program Scheduler configuration attributes.

The standard E810 Scheduler topology configuration is based on the network topology. The Scheduler configuration adds bandwidth management attributes to the configured scheduling components. Bandwidth configuration is based on the network topology deployment and capacity. The bandwidth management also reflects the QoS definition (SLA) required for the connected users and tenants.

The Admin Queue commands described in this section are intended for use by the PF driver only. The VF driver is not allowed to directly participate in the Scheduler configuration. The PF driver is considered to be a trusted software component within this PF. EMP firmware validates that Admin Queue commands do not impact configuration of components not owned by the PF driver issuing the commands. This is performed using association of the Admin Queue with particular PF and ownership information stored in the scheduling configuration tables. When the PF performs configuration on behalf of the VF, the corresponding VF must be provided with the Admin Queue command.

Table 8-24 provides a list of Admin Queue commands that allow configuration of the internal scheduler structures.

EMP firmware must avoid unrecoverable partial command execution. Some commands that configure larger amount of entities are broken into a groups of configured entities. In that case, each group must not be partially configured. All command validation and resource availability checks must be performed prior to updating Scheduler Configuration tables. Aborting a command with a partially updated Scheduler Configuration table can lead to unpredictable hardware behavior.

Notes: Bandwidth allocation setup among sibling nodes is configured in weights. As a node is configured with higher rate, it gets more bandwidth relative to its siblings. The E810 supports a 0.5% granularity of bandwidth allocation weight setup. In all bandwidth setup commands, the bandwidth allocation weight is a field of integer in the range of 1..200. Refer to Section 10.5.4.3, "LAN Transmit Queue Modes", A scheduling subtree is considered fine-grained only if all its descendant Tx-Queues are configured for "Advanced Transmit Mode" using the Quanta Queue interface. The full range of 1..200 of the bandwidth allocation is allowed only inside a fine-grained subtree. If any of the descendant Tx-Queues of the node are configured for "Legacy Mode", the node bandwidth weight range is 4..200.

It is the caller PF's responsibility to limit the range if there is a Legacy Tx-Queue in the subtree.

Table 8-24. Scheduler Configuration Admin Queue Commands

Command	Opcode	Brief Description	Section Reference
Query Default Scheduling Tree Topology	0x0400	Retrieve the scheduler topology from the EMP firmware for a given port.	8.3.4.3.6.1
Add Scheduling Elements	0x0401	Allocate a list of new scheduling elements as a child of the specified parent's TEID in the command buffer.	8.3.4.3.6.3
Configure Scheduling Elements	0x0403	Configure scheduling parameters for a list of existing scheduling elements as specified by parent's TEID.	8.3.4.3.6.4
Query Scheduling Elements Configuration	0x0404	Retrieve the bandwidth and scheduler configuration information for the list of scheduling elements as specified by their TEIDs from the EMP firmware.	8.3.4.3.6.2
Move Scheduling Element	0x0408	Move multiple siblings in a scheduling tree from one parent node to another parent node. This command works on any node in any layer. If the nodes being moved have children, the whole subtree is moved. If the old and new parent nodes belong to the same scheduling layer, the move is done without disrupting any scheduling operation.	8.3.4.3.6.5

Table 8-24. Scheduler Configuration Admin Queue Commands [continued]

Command	Opcode	Brief Description	Section Reference
Suspend Nodes	0x0409	Suspend scheduling operations for a list of scheduler elements as specified by their TEIDs. If the suspended nodes have children, the whole subtree starting as the scheduling element TEID to the leaf nodes of that element is suspended.	8.3.4.3.6.6
Resume Nodes	0x040A	Resume scheduling operations for a list of scheduler element as specified by their TEIDs; that were previously suspended using "Suspend Nodes" AQ.	8.3.4.3.6.7
Suspend Port's Tx Traffic per Traffic Class	0x040B	Suspend a port's Tx traffic for a given traffic class. The command is completed once the LAN Queues and RDMA QSets belonging to a given traffic class for the given port are suspended and drained.	8.3.4.3.6.8
Resume Port's Tx Traffic per Traffic Class	0x040C	Resume a port's Tx traffic for a given traffic class that was previously suspended.	8.3.4.3.6.9
Configure Port ETS	0x040D	Configure a port's ETS configuration. This command is typically used when software owns LLDP/DCBX processing and can also control port's ETS configuration.	8.3.4.3.6.10
Query Port ETS	0x040E	Retrieve a port's ETS configuration.	8.3.4.3.6.11
Delete Scheduling Elements	0x040F	Delete scheduling elements identified by their TEIDs. EMP Firmware checks for validity of the specified TEIDs, and if there are any children still connected to any of the TEIDs before attempting to delete the elements.	8.3.4.3.6.12
Add RL Profiles	0x0410	Add Rate Limiter profiles.	8.3.4.3.7.2
Query RL Profiles	0x0411	Retrieve a number of Rate Limiter profiles from the EMP firmware.	8.3.4.3.7.3
Remove RL Profiles	0x0415	Delete 1-4 Rate Limiter profiles.	8.3.4.3.7.4
Query Scheduling Resource Allocation	0x0412	Retrieve the schedule resources allocated by EMP firmware to the given PF.	8.3.4.3.7.1
Query Node-to-Root Topology	0x0413	Retrieve the scheduler topology from the EMP firmware for a given TEID to the Root node.	8.3.4.3.6.13
Configure L2 Node CGD	0x0414	Association of CGD's and L2 nodes.	8.3.4.3.6.14
Query L2 Node Physical ID	0x0415	Retrieve physical node ID for specified L2 nodes.	8.3.4.3.6.15

8.3.4.3.6.1 Query Default Scheduling Tree Topology (0x0400)

This command retrieves the scheduler topology from the EMP firmware for a given port.

The EMP firmware, as response to this command, returns all the scheduling elements that are visible to the software in the provided data buffer. The EMP firmware includes only the elements that were created by firmware as part of initial scheduler tree configuration creation for the given port.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-25 describes command format and defines command-specific fields.

This command is called by PF only at init time and retrieves the default topology. Once the topology is modified (by calling a proper AQ), EMP firmware stops serving this command and returns with the error code EPERM (Operation not permitted).

Table 8-25. Query Default Scheduling Tree Topology Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0400	
Datalen	4-5		Length of response buffer. Software provides a buffer of 4 KB. Firmware writes here the actual length of the response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16	0	The value is ignored by firmware and the port number is implicit to the calling function. Reserved. Must be set to 0.
Total Branches	17		Must be set to 0 as part of command. In Command Response this field is the total number of port-to-queue branches created by firmware (value of 1-8).
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-26 describes format of the data returned by firmware in the response buffer for each branch. EMP firmware returns all the elements starting from Root node to the Scheduling Elements it has added for a given branch.

Table 8-26. Query Default Scheduling Tree Topology Command Response Buffer per Branch Structure

Name	Byte.Bit	Value	Remarks
Reserved	0-3		
Number of Elements	4-5	2-9	Total number of elements created for given branch (TC).
Reserved	6-7		
Element 0	8-31		First element in the tree for this branch (Root node).

Table 8-26. Query Default Scheduling Tree Topology Command Response Buffer per Branch Structure [continued]

Name	Byte.Bit	Value	Remarks
. . .			
Element 9			9th element in the tree for this branch.

Table 8-27 describes format of the data returned by firmware in the response buffer for each element in the scheduling tree within a given branch.

Table 8-27. Query Default Scheduling Tree Topology Command Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Parent TEID	0-3		Element's parent TEID. ***Note:*** For the Element Type "Root Port" this would be set to 0xFFFFFFFF.
Node TEID	4-7		Element TEID.
Element Type	8	0 = Undefined 1 = Root Port 2 = TC 3 = SE Generic 4 = Software entry point SE 5 = Leaf 6-255 = Reserved	In some cases, Element Type can be both software entry point SE and a Leaf. In that case, the Element is marked as a software entry point SE. ***Note:*** Root Port, TC nodes are typically in firmware control.
Valid Sections	9	**Bit 9.0:** Generic section (Must be set to 1b) **Bit 9.1:** CIR BW **Bit 9.2:** EIR BW **Bit 9.3:** Shared BW **Bits 9.4-9.7:** Reserved	Multiple sections can be valid at given time. EIR BW and Shared BW profiles are mutually exclusive and hence only one of them can be set for any given element.
Generic	10	**Bit 10.0:** Scheduling Mode 0b = BPS 1b = PPS **Bits 10.1–10.3:** Priority among siblings (0-7) **Bit 10.4:** Single Priority 0b = Node 1b = WFQ **Bits 10.5-10.6:** Adjustment value (0-3) used in PSM Credit Update flow **Bit 10.7:** Reserved

EIR BW Profile ID	16-17		
EIR BW Weight	18-19	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
Shared RL Profile ID	20-21		
Reserved	22-23		

8.3.4.3.6.2 Query Scheduling Elements Configuration (0x0404)

This command retrieves the bandwidth and scheduler configuration information for the list of scheduling elements as specified by their TEIDs from the EMP firmware.

The software provides the list of TEIDs as part of the command buffer, whereas the EMP firmware, as response to this command, returns bandwidth information on all the scheduling elements to the software in the software-provided data buffer for the specified TEIDs. EMP firmware validates that all the TEIDs are owned by the calling PF.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-28 describes command format and defines command-specific fields.

Table 8-28. Query Scheduling Elements Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0404	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Elements Requested	16-17		Total number of scheduling elements.
Number of Elements Returned	18-19		Command: Set to 0 by driver. Response: Firmware puts the number of elements returned.
Reserved	20-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-29 describes the format for providing the list of scheduling elements' TEIDs by software as part of the command buffer.

Table 8-29. Query Scheduling Elements Command and Response Fields

Name	Byte.Bit	Value	Remarks
Reserved	0-3	0	
Node TEID	4-7		Element TEID of the scheduling element. Set by software for retrieving the bandwidth configuration from the firmware.
Reserved	8-23	0	

Table 8-30 describes format of the data returned by firmware in the response buffer for each element in the scheduling tree.

Table 8-30. Query Scheduling Elements Configuration Command Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Parent TEID	0-3		Element's parent TEID. ***Note:*** For the Element Type "Root Port" this would be set to 0xFFFFFFFF.
Node TEID	4-7		Element TEID.
Element Type	8	0 = Undefined 1 = Root Port 2 = TC 3 = SE Generic 4 = Software entry point SE 5 = Leaf 6 = SE Padded 7-255 = Reserved	***Note:*** Root Port, TC nodes are typically in firmware control.
Valid Sections	9	**Bit 9.0:** Generic section (Must be set to 1b) **Bit 9.1:** CIR BW **Bit 9.2:** EIR BW **Bit 9.3:** Shared BW **Bits 9.4-9.7:** Reserved	Multiple sections can be valid at given time.
Generic	10	**Bit 10.0:** Scheduling Mode 0b = BPS 1b = PPS **Bits 10.1–10.3:** Priority among siblings (0-7) **Bit 10.4:** Single Priority 0b = Node 1b = WFQ **Bits 10.5-10.6:** Adjustment value (0-3) used in PSM Credit Update flow **Bit 10.7:** Reserved	
Flags	11	**Bit 11.0:** If set to 1, indicates node is suspended. **Bits 11.1-11.7:** Reserved.	
CIR BW Profile ID	12-13		
CIR BW Weight	14-15	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
EIR BW Profile ID	16-17		
EIR BW Weight	18-19	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
Shared RL Profile ID	20-21		
Reserved	22-23		

8.3.4.3.6.3 Add Scheduling Elements (0x0401)

This command allocates a list of new scheduling elements as a child of the specified parent's TEID in the command buffer.

The EMP firmware as response to this command returns the TEID for the newly added scheduling elements for each element.

Leaf nodes must be attached to a LAN Tx-Queue or a RDMA QSet. Therefore, Leaf nodes are added only with the AQ commands field.

EMP firmware verifies that a Leaf node is not added by the "Add Scheduling Elements" command. This verification must be done prior adding any queue of the Queue Group to prevent partial execution of the command.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-31 describes command format and defines command-specific fields.

Table 8-31. Add Scheduling Elements Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0401	
Datalen	4-5		Length of command and response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. Response: 0 = Success. Otherwise = Not all Groups could be added successfully. Software should look at the Number of Groups Added Value and the Response Buffer for the Scheduling Elements added for those groups.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Groups Requested	16-17		Number of Scheduling element groups to be added per Parent TEID.
Number of Groups Returned	18-19		Command: Set to 0 by driver. Response: Firmware puts the number of groups successfully added.
Reserved	20-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-32 describes format of the command buffer per Group, and Table 8-33 describes the format of the command data set by software for each element that is part of the group. Software can create multiples of such Groups as identified by the "Number of Groups" field in the command. The EMP firmware updates the *Node TEID* field in the response buffer for each element that was added to the scheduler tree.

Table 8-32. Add Scheduling Elements Command Buffer per Group

Name	Byte.Bit	Value	Remarks
Parent TEID	0-3		
Number of Elements	4-5		
Reserved	6-7		
Element 0	8-31		Contains first Element entry (See Table 8-33).
. . .			
Element *n*			Contains *nth* Element entry.

Table 8-33. Add Scheduling Elements Command and Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Reserved	0-3		
Node TEID	4-7		Reserved (0): When part of command buffer, firmware sets this field to Element TEID as part of the response buffer.
Reserved	8

EIR BW Profile ID	16-17		
EIR BW Weight	18-19	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
Shared RL Profile ID	20-21		
Reserved	22-23		

8.3.4.3.6.5 Move Scheduling Elements (0x0408)

This command allows software to move multiple siblings in a scheduling tree from one parent node to another parent node. This command works on any node in any layer, except the *root* and *leaf* layers. If the nodes being moved have children, the whole subtree is moved. If the old and new parent nodes belong to the same scheduling layer, the move is done without disrupting any scheduling operation.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-36 describes command format and defines command-specific fields.

Table 8-36. Configure Scheduling Elements Command and Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0408	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Sibling Groups	16-17		Set by the driver. Unchanged by the firmware.
Number of Actually Moved Sibling Groups	18-19		Zeroed by the driver. Set by the firmware.
Reserved	20-23	0	Reserved. Must be set to 0.

Table 8-36. Configure Scheduling Elements Command and Response Buffer per Element Structure [continued]

Name	Byte.Bit	Value	Remarks
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-37 describes the per sibling group structure that provided by software.

Table 8-37. Move Scheduling Elements Buffer per Sibling Group

Name	Byte.Bit	Value	Remarks
Existing Parent TEID	0-3[1]		Current TEID of the parent of the siblings being moved in this group.
New Parent TEID	4-7		New Parent TEID where the siblings are moved to as children.
Number of Siblings to be Moved	8-9	0	
Reserved	10-11		

1. The existing parent must be a direct parent of the moved nodes in the logical space (hidden layers remain hidden for that command). EMP firmware enforces this and returns error if required.

Software provides a list of Scheduling Element TEIDs for each sibling as part of the command buffer.

Table 8-38 describes the per-sibling TEID provided by software.

Table 8-38. Move Scheduling Elements Buffer per Sibling in the Command Buffer

Name	Byte.Bit	Value	Remarks
Element TEID	0-3		

Table 8-39 describes an example of the command buffer (***n*** Siblings need to be moved by software).

	. . .
	Element #n-1

8.3.4.3.6.6 Suspend Nodes (0x0409)

This command allows software to suspend scheduling operations for a list of scheduler elements as specified by their TEIDs.

If the suspended nodes have children, the whole subtree starting at the scheduling element TEID to the leaf nodes of that element are not scheduled until the suspended parent is resumed.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-40 describes command format and defines command-specific fields.

Table 8-40. Suspend Node Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.

Name	Byte.Bit	Value	Remarks
Element TEID	0-3		

8.3.4.3.6.8 Suspend Port's Tx Traffic per Traffic Class (0x040B)

This command allows software to suspend a port's Tx traffic for a given traffic class. The command is completed once the LAN Queues and RDMA QSets belonging to given traffic class for the given port are suspended and drained.

This helps software to modify port's traffic class configuration whenever there are changes required due to DCB/DCBX settings when software owns LLDP/DCBX processing.

This is a Direct Admin Queue command with additional command attributes, and completion attributes are provided within the data buffer. Table 8-44 describes command format and defines command-specific fields.

Table 8-44. Suspend Port's Tx Traffic per Traffic Class Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x040B	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TC Bitmap	16		Bitmap of Traffic Classes to be suspended.

Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

8.3.4.3.6.9 Resume Port's Tx Traffic per Traffic Class (0x040C)

This command allows software to resume a port's Tx traffic for a given traffic class that was previously suspended

This command is used by software to resume port's Tx traffic for a TC after port's traffic class configuration was changed due to DCB/DCBX.

This is a Direct Admin Queue command with additional command attributes, and completion attributes are provided within the data buffer. Table 8-45 describes command format and defines command-specific fields.

Table 8-45. Resume Port's Tx Traffic per Traffic Class Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.1.1 for details.
Opcode	2-3	0x040C	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.

Data Address Low	28-31		

8.3.4.3.6.10 Configure Port ETS (0x040D)

This command allows software to configure a port's ETS configuration. This command is typically used when software owns LLDP/DCBX processing and can also control port's ETS configuration. When LLDP/DCBX processing is owned by the EMP firmware, this command returns an EPERM error.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-46 describes command format and defines command-specific fields.

Table 8-46. Configure Port ETS Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x040D

8.3.4.3.6.12 Delete Scheduling Elements (0x040F)

This command allows deletion of a scheduling elements identified by their TEIDs. EMP firmware checks for validity of the specified TEIDs, and if there are any children still connected to any of the TEIDs before attempting to delete the elements (EPERM error code is return if software attempts to remove a node that is associated with children). If the TEID for a specified element is a Leaf Node with a queue associated with it, EMP firmware should return an error (EPERM).

ENOENT error code is returned if software attempts to delete an non-existent TEID.

Leaf nodes must be attached to a LAN Tx-Queue or a RDMA QSet. Therefore, Leaf nodes are deleted only with the AQ command field.

EMP firmware verifies that a Leaf node is not added by the "Delete Scheduling Elements" command. This verification must be done prior deleting any queue of the Queue Group to prevent partial execution of the command.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-50 describes command format and defines command-specific fields.

Table 8-50. Delete Scheduling Elements Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.

8.3.4.3.6.13 Query Node-to-Root Topology (0x0413)

This command retrieves the scheduler topology from the EMP firmware for a given TEID to the Root Node.

The EMP firmware, as response to this command, returns all the scheduling elements that are visible to the software in the provided data buffer, including any padded layers it might have added for the given hierarchy.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-52 describes command format and defines command-specific fields.

Table 8-52. Query Node-to-Root Topology Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.

Name	Byte.Bit	Value	Remarks
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
TEID	16-19		Element TEID.
Number of Nodes	20-23	0	Zeroed by driver. EMP firmware returns the number of elements in the branch.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-53 describes format of the data returned by firmware in the response buffer for each element in the hierarchy of scheduling tree for the given TEID.

Table 8-53. Query Node-to-Root Topology Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Parent TEID	0-3		Element's parent TEID. ***Note:*** For the Element Type "Root Port" this would be set to 0xFFFFFFFF.
Node TEID	4-7		Element TEID.
Element Type	8	0 = Undefined 1 = Root Port 2 = TC 3 = SE Generic 4 = Software entry point SE 5 = Leaf 6 = SE Padded 7-255 = Reserved	Root Port, TC nodes are typically in firmware control.
Valid Sections	9	**Bit 9.0:** Generic section (Must be set to 1b) **Bit 9.1:** CIR BW **Bit 9.2:** EIR BW **Bit 9.3:** Shared BW **Bits 9.4-9.7:** Reserved	Multiple sections can be valid at given time. *EIR BW* and *Shared BW* profiles are mutually exclusive and hence only one of them can be set for any given element.
Generic	10	**Bit 10.0:** Scheduling Mode 0b = BPS 1b = PPS **Bits 10.1–10.3:** Priority among siblings (0-7) **Bit 10.4:** Single Priority 0b = Node 1b = WFQ **Bits 10.5-10.6:** Adjustment value (0-3) used in PSM Credit Update flow **Bit 10.7:** Reserved	
Flags	11	**Bit 11.0:** If set to 1, indicates node is suspended. **Bits 11.1-11.7:** Reserved.	
CIR BW Profile ID	12-13		
CIR BW Weight	14-15	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
EIR BW Profile ID	16-17		When the valid section has *Shared BW* field set this field points to Share RL Profile ID. When the valid section has *EIR BW* field set this field points to EIR RL Profile ID.

Table 8-53. Query Node-to-Root Topology Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
EIR BW Weight	18-19	WFQ Weight (1..200) in Precise subtree, (4..200) otherwise. (See note in Section 8.3.4.3.6)	
Shared RL Profile ID	20-21		
Reserved	22-23		

8.3.4.3.6.14 Configure L2 Node CGD (0x0414)

This command allows configuring a congestion domain for given L2 node TEIDs in the scheduler topology.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-54 describes command format and defines command-specific fields.

Table 8-54. Configure L2 Node CGD Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0415	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of L2 Nodes	16-17		Number of L2 Nodes (1-64).
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-55 describes format of the data sent by software as part of the command buffer for each L2 scheduling element

Table 8-55. Configure L2 Node CGD Command Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Node TEID	0-3		L2 Node Element TEID
CGD	4	CGD value (0-31)	Root Port, TC nodes are typically in firmware control.
Reserved	5-7		

8.3.4.3.6.14.1 Default CGD Setup per Usage Model

Four or less ports setup:

Eight CGDs and eight L2 nodes are statically allocated in order per each port. In each port's space, the CGD's and the L2 are associated in one-to-one mapping.

Eight ports setup:

Four CGD's are statically allocated in order per each port (0-3 for port #0...). Eight L2 nodes are statically allocated in order per each port (0-7 for port #0...). In each port's space, one L2 node is associated with one CGD's. Four L2 nodes are free for PF's configuration.

8.3.4.3.6.15 Query L2 Node Physical ID (0x0415)

This command allows querying a physical node ID for given L2 node TEIDs in the Tx-Scheduler topology.

This is an Indirect Admin Queue command with additional command attributes and completion attributes are provided within the data buffer. Table 8-56 describes command format and defines command specific fields.

Table 8-56. Query L2 Node Physical ID Command and Response Fields

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0414	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. EINVAL = If software sets the Number of L2 nodes to 0. EINVAL = If any of the specified L2 Node TEIDs do not exist or is invalid value (0xFFFFFFFF).
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of L2 Nodes	16-17		Number of L2 Nodes (1-64).
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-57 describes format of the data sent by software as part of the command buffer for each L2 scheduling element.

Table 8-57. Query L2 Node Physical ID Command and Response Buffer per Element Structure

Name	Byte.Bit	Value	Remarks
Node TEID	0-3		L2 Node Element TEID
Physical Node ID	4-7		Command: This is a reserved field when sent as part of command and should be set to 0. Response: Firmware will fill in the L2 node's Physical Node ID in response in this location.

8.3.4.3.7 Tx-Scheduler Resource Allocation and Management

All Tx-Scheduler entities are shared and can be used by any PF. The EMP firmware manages two types of Tx-Scheduler shared resources:

- **Generic Tx-Scheduler topology structure:**
  - This structure describes the generic scheme of Tx-Scheduler configuration. It includes the following:
    - The number of supported layers in the Tx-Scheduler topology.
    - The number of CGDs available for the entire device and for the calling PF.
    - The number of available RDMA QSets.
  - In addition, this type includes also a definition per logical layer of Max number of siblings available in each sibling group and the definition of the chunk size. Chunk size defines the granularity of resource allocation in this layer.
  - This structure is built at reset, based on NVM configuration.
  - This structure is static and is not changed during runtime.
- **Dedicated usage resources:**
  - This type of resources includes, Nodes, Profiles, and Shared rate limiters.
  - It is managed separately per each logical layer.
  - Each PF is allocated with a basic set of guaranteed resources, in addition to a shared pool of resources.
  - When a PF allocates a resource, EMP firmware allocates it from its guaranteed pool. If the guaranteed pool is exhausted and the shared pool is not, the resource is allocated from the shared pool.
  - On resource deallocation, the resource is first released from the shared pool. If the PF shared pool usage == 0, a guaranteed pool is released.
  - Once a resource of type is allocated for a PF, it is uniquely used by this PF until it is released by its owner.

Notes: An exception for the above: Rate Limit Profile #0 in both CIR and EIR is pre-allocated by the device. CIR profile #0 represents a “no committed rate” profile. EIR profile #0 represents a “no RL” profile. Those profiles are available for shared usage of all the PF's. Those Profiles are owned by EMP firmware and must not be neither modified nor deleted by any one of the PF's.

In the hardware, setting a profile which all its bits are set to zero, configuring it to “No RL” in the EIR or to “No committed rate” in the CIR.

Beside those two RL profile #0, no other RL profile can be configured same way. Any attempt of a PF to configure a profile where all its bits are set to zero, is rejected by the EMP firmware.

8.3.4.3.7.1 Query Scheduler Resource Allocation (0x0412)

This command retrieves the schedule resources allocated by EMP firmware to the given PF.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-58 describes command format and defines command-specific fields.

Table 8-58. Query Scheduler Resource Allocation Command

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0412	Command opcode.
Datalen	4-5	(2-2048)	Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-59 lists the content of the data buffer received by software as a response to Query Scheduler Resource Allocation command.

Table 8-59. Query Scheduler Resource Allocation Command Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.2 for details.
Opcode	2-3	0x0412	Command opcode.
Datalen	4-5	16 + 32x9	Length of response buffer. Should be Number of resource returned x resource entry size.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Reserved	16-23		0
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-60 lists the content of the data buffer received by software as a response to Query Scheduler Resource Allocation command. Table 8-61 and Table 8-62 lists the content of data specific to different resource types.

Table 8-60. Query Scheduler Resource Allocation Response Buffer

Offset (Bytes)	Description
0-31	Generic Scheduler properties.
32-63	Logical Layer 1 properties.
. . .	
(32 x n) - (32 x (n + 1) - 1)	Logical Layer n properties (maximum 9 layers).

Table 8-61. Data Structure for Generic Scheduler Properties

Offset (Bytes)	Description
0-1	Total number of available physical scheduling layers.
2-3	Total number of available logical scheduling layers (software visible).
4	A bitmap indicating for layers 2-9, the layers that are flattened if flattening is enabled. Bit 0 points to L2 and Bit 7 points to L9
5	Total Number of CGDs supported by the device.
6	Total Number of CGDs available for this PF.
7	Reserved.
8-9	Total number of RDMA QSets in the device.
10-31	Reserved (for future use).

Table 8-62. Data Structure for Each Logical Layer

Offset (Bytes)	Description
0	Logical Layer number.
1	Chunk Size: Amount of nodes which allocated as a chunk whenever a PF gains nodes.
2-3	Total number of nodes that can be configured at this layer for the whole device.
4-9	Reserved
10-11	Max sibling group size at this layer.
12-13	Shared number of CIR RL Profiles available at this layer for the PF, including its dedicated and the available shared ones.
14-15	Shared number of EIR RL Profiles available at this layer for the PF, including its dedicated and the available shared ones.
16-17	Shared number of SRL Profiles available at this layer for the PF, including its dedicated and the available shared ones.
18-31	Reserved.

8.3.4.3.7.2 Add RL Profiles (0x0410)

This Command adds a number of Rate Limiter Profiles.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-63 describes command format and defines command-specific fields.

Table 8-63. Add RL Profiles Command and Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x0410	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number or Profiles	16-17		Number of RL profiles to be retrieved for given PF.
Number of Actually Added Profiles	18-19	Zeroed by software. Written by EMP firmware.	Number of added profiles by EMP firmware.
Reserved	20-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-64 lists the content of the data buffer provided by software to configure RL profiles for each profile.

Table 8-64. Add RL Profiles Data in Command Buffer per Each RL Profile

Name	Byte.Bit	Value	Remarks
Tx-Scheduler Layer	0	Valid values = 1-9	Logical Layer number visible to software (Max = 9). ***Note:*** In case of RLs aimed to Queues, the layer is the max logical layer independently of where the queue was attached.
Flags	1	**Bits 1.0-1.1:** Profile Type 00b = CIR 01b = EIR 10b = Shared 11b = Reserved **Bits 1.2-1.7:** Reserved (0)	Type of RL profile to be added.
Profile ID	2-3		Command: Reserved as part of command (0). Response: The profile index value returned by firmware.
Max Burst Size	4-5	Max valid value is 0xFFF (12 bits in hardware).	Max burst size.
RL Multiply	6-7	Max valid value is 0x7FF (11 bits in hardware).	Reserved when adding shared RL.

Table 8-64. Add RL Profiles Data in Command Buffer per Each RL Profile [continued]

Name	Byte.Bit	Value	Remarks
Wake-Up Calculation	8-9	When 9.7 is set to 0b: Bits 8.0-9.0 = Sub-integer granularity of number of cycles (1/128…127/128). Bits 9.1-9.6 = Number of cycles. When 9.7 is set to 1b: Bits 8.0-9.6 = Number of cycles.	Reserved when adding shared RL.
RL Encode	10-11	Max valid value is 0x3F (6 bits in hardware).	Reserved when adding shared RL.

Note: As noted above, software is allowed to add a profile where all its bits are set to zero. Any attempt to do this is rejected by EMP firmware with the error code EPERM.

8.3.4.3.7.3 Query RL Profiles (0x0411)

This command retrieves a number of Rate Limiter Profiles from the EMP firmware.

This is an Indirect Admin Queue command, with additional command attributes and completion attributes provided within the data buffer. Table 8-65 describes command format and defines command-specific fields.

Table 8-65. Query RL Profiles Command and Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2.1 for details.
Opcode	2-3	0x0411	
Datalen	4-5		Length of response buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number or Profiles	16-17		Number of RL profiles to be retrieved for given PF.
Number of Retrieved Profiles	18-23		Number of actually retrieved profiles. If this number is not equal to the requested number, an error is reported as well.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-66 lists the content of the data buffer set by software as part of the Query RL Profile command for each requested profile.

Table 8-66. Query RL Profile Data in Command Buffer for Each Profile

Name	Byte.Bit	Value	Remarks
Tx-Scheduler Layer	0	Valid values = 1-9	Logical Layer number visible to software (Max = 9).
Flags	1	**Bits 1.0-1.1:** Profile Type 00b = CIR 01b = EIR 10b = Shared 11b = Reserved **Bits 1.2-1.7:** Reserved (0)	Type of RL profile to be retrieved.
Profile ID	2-3		The profile index value.
Reserved	4-11		

Table 8-67 lists the content of the data buffer received by software as a response to Query RL Profile command.

Table 8-67. Query RL Profile Data in Response Buffer for Each Profile

Name	Byte.Bit	Value	Remarks
Tx-Scheduler Layer	0	Valid values = 1-9	Logical Layer number visible to software (Max = 9).
Flags	1	**Bits 1.0-1.1:** Profile Type 00b = CIR 01b = EIR 10b = Shared 11b = Reserved **Bits 1.2-1.6:** Reserved (0) **Bit 1.7:** Profile Allocation 0b = Profile is allocated. 1b = Profile is not allocated by any PF.	Type of RL profile to be retrieved.
Profile ID	2-3		The profile index value.
Max Burst Size	4-5	0 - 0xFFF	Max burst size.
RL Multiply	6-7	0- 0x7FF	Reserved when retrieving shared RL.
Wake-Up Calculation	8-9	When 9.7 is set to 0b: Bits 8.0-9.0 = Sub-integer granularity of number of cycles (1/128…127/128). Bits 9.1-9.6 = Number of cycles. When 9.7 is set to 1b: Bits 8.0-9.6 = Number of cycles.	Reserved when retrieving shared RL.
RL Encode	10-11	0 - 0x3F	Reserved when retrieving shared RL.

8.3.4.3.7.4 Remove RL Profiles (0x0415)

This command allows PF software to delete a number of Rate Limiter Profiles.

It is the PF's responsibility to verify that each deleted profile is not associated with any node prior to removing it. It is the PF's responsibility to limit itself for removing profiles which it owns only.

PF must never remove RL profile #0 of CIR or EIR. Attempting to remove a RL profile #0, is rejected by EMP firmware with the Error code EPERM.

This is an Indirect Admin Queue command. Table 8-68 describes command format and defines command-specific fields.

Table 8-68. Remove RL Profile Command and Response

Name	Byte.Bit	Value	Remarks
Flags	0-1	0	See Section 9.5.5.2 for details.
Opcode	2-3	0x415	
Datalen	4-5	0	Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value copied by the firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value copied by the firmware into the completion of this command.
Number of Profiles to Remove	16-17		
Number of Actually Removed RL Profiles	18-19		Zeroed by the driver. Written by the EMP firmware.
Reserved	20-23		
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 8-69 lists the content of the data buffer set by software as part of the Remove RL Profile command for each requested profile

Table 8-69. Remove RL Profile Data in Command Buffer for Each Profile

Name	Byte.Bit	Value	Remarks
Tx-Scheduler Layer	0	Valid values = 1-9	Logical Layer number visible to software (Max = 9).
Flags	1	**Bits 1.0-1.1:** Profile Type 00b = CIR 01b = EIR 10b = Shared 11b = Reserved **Bits 1.2-1.7:** Reserved (0)	Type of RL profile to be retrieved.
Profile ID	2-3		The profile index value. Valid values according to layer. If software provides out-of-range value, EMP firmware responds with ERANGE. Same response if ID == 0.
Reserved	4-11		

The generic structure of the Admin Queue command is defined in Section 9.5.5. All the Transmit Scheduler Admin Queue commands described in the following sections are derived from the generic Admin Queue commands, using a generic Admin Queue command structure as a baseline.

Sections describing Transmit Scheduler Admin Queue commands relate to the Admin Queue command fields that are specific to the particular command. For a description of the common Admin Queue command fields, see Section 9.5.5.

The Transmit Scheduler uses various types of Admin Queue commands. Some of them are Direct Admin Queue commands (all command information is provided within the body of the command) and some are Indirect (additional data is provided within the buffer referred to by the Admin Queue command). Some commands report completion within the Admin Queue command body and others carry completion information in the buffer provided by the original command. Each Transmit Scheduler Admin Queue command indicates its type in the command description. For a detailed description of all the Admin Queue command types and their differences, see Section 9.5.5.

8.3.4.3.8 Common Processing and Error Handling

Transmit Scheduler Admin Queue commands use a generic error reporting structure described in Section 9.5.9. Table 8-70 lists errors specific to the Transmit Scheduler Admin Queue commands and reported in Admin Queue Completions, providing their cause and a reported error code.

Table 8-70. Transmit Scheduler Admin Queue Completion Errors

Error Name	Error Code	Description
Invalid Handle	ENOENT	Upon allocation of the Transmit Scheduler resources, software is provided with various handles, such as TC Handle, UP Handle, and QS Handle. Those handles must be used by software for future reference to the allocated resources. This error indicates that the handle provided by the software is not valid.
Invalid TEID	ENOENT	TEID provided within Admin Queue command is not valid.
Parameter out of range	ERANGE	Provided argument does not match definition (for example, not within allowed range).
Resource allocation failure	ENOSPC	Failed to allocate Transmit Scheduler resource.
Operation not permitted	EPERM	Depending on the scheduler configuration scheme, certain Admin Queue commands should not be used by the software (for example, ETS-based configuration software should not attempt configure bandwidth allocation to a VSI or Scheduling Component). This error indicates that the software attempted to execute an Admin Queue command that is not valid in the current context.

Chapter 9 Device Services

9.1 Interrupts

9.1.1 Interrupt Signaling

The E810 supports the following interrupt signaling according to per-PF setting options:

- Legacy INTA/INTB/INTC/INTD interrupt message on the PCIe is supported for the PFs. The E810 exposes legacy interrupt support in the *Interrupt Pin* field in the PCI configuration space of the PF. The *Interrupt Pin* parameter is loaded from the NVM (to the PFPCI_CNF register), defining the interrupt pin (A,B,C,D or none) per PF. It is the NVM programmer's responsibility to follow the PCI rules for allocating orderly interrupt pins for the PCI functions. The PFPCI_CNF register can be modified in the NVM using the adaptive NVM admin command. The legacy interrupt is triggered by the interrupt vector zero of the PF.
- MSI is exposed in the MSI capability structure in the PCI configuration space of each PF. The MSI interrupt is triggered by the interrupt vector zero of the PF. The MSI capability is enabled per PF by the *MSI_EN* bit in the PFPCI_CNF register (loaded from the NVM). The PFPCI_CNF register can be modified in the NVM using the adaptive NVM admin command.
- MSI-X enables multiple interrupts for the PFs as well as the VFs. MSI-X is exposed in the MSI-X capability structure in the PCI configuration space of all PFs and VFs. The number of supported MSI-X vectors is defined by the *Table Size* parameters in the MSI-X capability structure in the PCI configuration space of the PFs and the VFs. The *Table Size* parameters are loaded from the NVM for each PF and for each of its VFs following FLR. The *Table Size* parameters setting in the NVM (according to the values loaded to the PFINT_ALLOC.*FIRST*/*LAST* register) must obey the following limitations:
  - The total number of MSI-X vectors in the device is 2048. The sum of the *Table Size* parameters for all functions (PFs and VFs) must not exceed it.
  - The maximum number of supported MSI-X vectors for the PFs is 2048.
  - The maximum number of supported MSI-X vectors for the VFs is 2048.
  - The interrupt vectors of the functions are mapped to the internal physical space of the device.
  - The settings of *FIRST* and *LAST* fields in the PFINT_ALLOC registers can be modified in the NVM using the adaptive NVM admin command.
  - The mapping of all VFs of a PF must be contained within the space of the PF (shown in the example in Figure 9-1). The GLINT_VECT2FUNC registers provide the inverse mapping from the internal physical space to the functions. At the PF driver initialization phase, the software should set the registers of the PF interrupts according to the PFINT_ALLOC and VPINT_ALLOC settings.
  - The mappings for VFs ownership are loaded by software to the VPINT_ALLOC and GLINT_VECT2FUNC registers when allocating vectors to a VF before SR-IOV enablement.

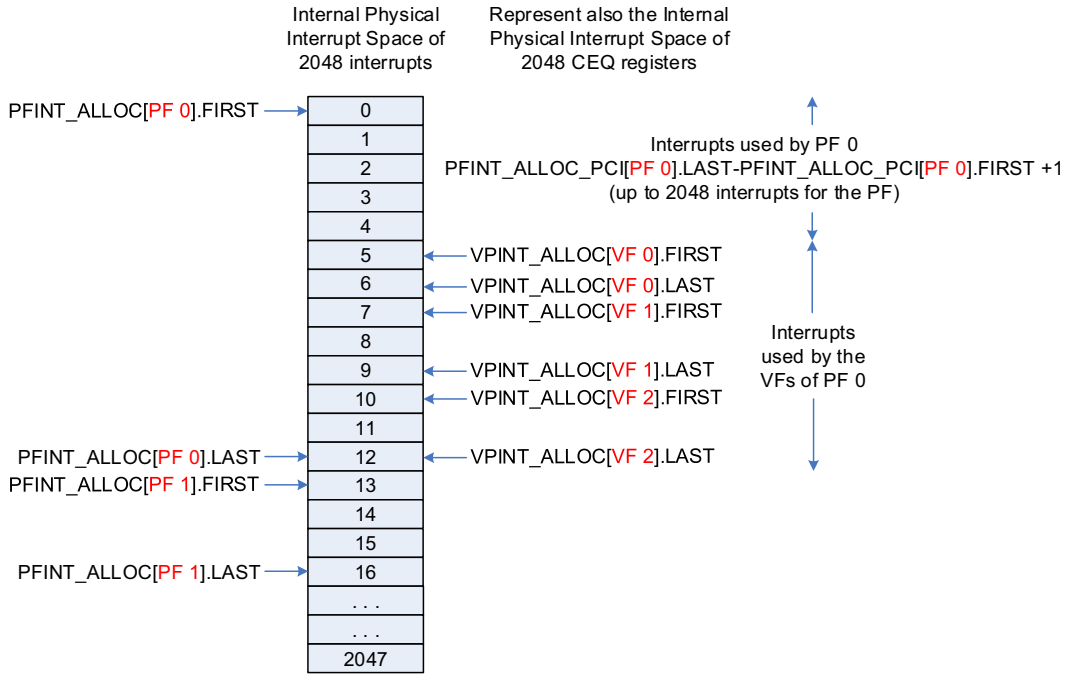

Figure 9-1. Example for Interrupt Vectors and CEQ Interrupt Control Registers Mapping to the Internals Space

9.1.1.1 Interrupt Enable Procedure

Interrupts are enabled at three levels:

- Enablement on the PCIe interface by PCI configuration registers programmed by the OS.
  - Legacy INTA/INTB/INTC/INTD interrupt message is controlled by the *Interrupt Disable* flag in the Command Register in the PCI configuration space per PF.
  - MSI is enabled by the *MSI Enable* flag in the MSI Capability structure in the PCI configuration space per PF.
  - MSI-X is enabled by the *MSI-X Enable* flag in the MSI-X Capability structure in the PCI configuration space per PF and per VF, and further enablement by the *Mask* bit per MSI-X vector in the MSI-X Table Structure.
- Enablement of the interrupts by the driver by the *INTENA* flag in the *xx*INT_DYN_CTL0 and *xx*INT_DYN_CTLN registers (where *xx*=VF), or GLINT_DYN_CTL for PF.
  - The software driver sets the *INTENA* flag and clears the *WB_ON_ITR* flag to enable the relevant interrupt signal. Upon interrupt assertion, the *INTENA* flag and, in case of legacy interrupts, the interrupt level are auto-cleared.
  - Enablement of the interrupts per cause by the *CAUSE_ENA* flag in cause control registers (see Section 9.1.2).
- Interrupt moderation:
  - Interrupt Throttling (ITR) is described in Section 9.1.4.1.
  - Interrupt rate limiting (INTRL) is described in Section 9.1.4.2.

9.1.1.2 Pending Interrupt Array - PBA

On top of the interrupt signaling on the PCIe bus, the E810 also supports the standard PBA structure in the MSI-X BAR (see BAR description in Section 14.2.6.1). The PBA is relevant only when MSI-X is enabled. It is described as part of the MSI-X Capability structure in Section 14.3.3 for the PF, and Section 14.5.3.1 for the VFs. A bit in the PBA is set to one when an interrupt is triggered internally, and cleared when the MSI-X vector is sent on the PCIe bus.

9.1.1.3 Interrupt Sequence

This section describes the interrupt sequence of events started by an internal event that triggers an interrupt until it is sent to the PCIe bus, and the expected software response. Note that the description of the interrupt sequence refers to flags that are explained in the following sections.

MSI and MSI-X interrupts while interrupts are enabled:

1. Any of the interrupt causes has an event that sets an internal *INTEVENT* flag for the matched interrupt signal.
2. If the interrupt is enabled by *INTENA* and also enabled by the interrupt moderation policy (ITR and rate limiting), the hardware executes the following steps in order:
   a. Scan all queues associated with this interrupt by a linked list explained in Section 9.1.3. Write back the status of all completed descriptors that were not reported so far, and clear the internal *EVENT* flags of these queues.
   b. Set the matched bit in the pending interrupt block array (PBA).
   c. The *INTEVENT* and *INTENA* are auto-cleared.
3. If the interrupt is enabled by the OS (by PCIe setting), the interrupt message is sent to the PCIe.
   - The interrupt indication in the PBA is auto-cleared.
4. During the interrupt handler, the software processes each individual interrupt cause.
5. At the end of the interrupt handler, the software re-enables the interrupts by setting *INTENA*.
   - On the same register, the software also sets the *CLEARPBA* flag, which clears the matched bit in the PBA.
   - On the same register, the software can update one of three ITRs of this interrupt by setting the *ITR_INDX* and *INTERVAL* fields. Setting the *ITR_INDX* to 11b does not impact the ITRs. See the ITR explanation in Section 9.1.4.1.

MSI/MSI-X interrupts while interrupts are disabled by the OS:

1. Same as above.
2. Same as above.
3. The OS polls the PBA and schedules the interrupt handler
4. Same as above.
5. Same as above.

Legacy interrupts while interrupts are enabled by the OS (mapped to interrupt zero of the PF):

1. Same as above.
2. Same as above.
3. If the interrupt is enabled by the OS (by PCIe setting), the interrupt message is sent to the PCIe.
4. At the very beginning of the interrupt service routine, the software driver clears the internal PBA by setting the *CLEARPBA* flag in the relevant GLINT_DYN_CTL register.
   - As a result, an interrupt de-assertion message is sent on the PCIe bus.

   Note: When several PFs are assigned to the same legacy interrupt, the interrupt de-assertion message must be sent only when all PFs associated with that interrupt have cleared the internal PBA as mentioned above.
5. During the interrupt handler, the software processes each individual interrupt cause.
6. At the end of the interrupt handler, the software re-enables the interrupts by setting *INTENA*.
   - On the same register, the software can update one of three ITRs as explained above.

9.1.2 Interrupt Causes

This section lists all interrupts causes (sources), while mapping these causes to the interrupt vectors is described in Section 9.1.3. Note that only the PF has access to any of the cause registers listed in this subsection. Therefore, VF is required to request its cause-mapping programming from the PF by admin command or any other sideband channel out of the scope of this document.

9.1.2.1 LAN Transmit Queues

The E810 supports 2K LAN transmit queues in legacy mode and up to 16K queues in comm mode for the whole device, where each queue is a potential interrupt cause. A status reporting of a completed descriptor with *EOP* bit set is considered as a transmit "event" that can trigger an interrupt (if the interrupt is enabled).

LAN transmit queue 'n' is enabled for interrupts by the *CAUSE_ENA* flag in its QINT_TQCTL[n] register. The queues are mapped to any interrupt vector within the function space by the *MSIX_INDX* field in the QINT_TQCTL[n] register, and mapped to any of it's ITRs (or immediate interrupt) by the *ITR_INDX* field in this register. See ITR description in Section 9.1.4.1.

9.1.2.1.1 Transmit Descriptors Write-Back and Interrupts

Completed transmit descriptors are posted to host memory or its Completion Queue (if applicable) in one of the following cases:

- Unrelated events to interrupts.
  - Transmit descriptors with active *RS* or *RE* flags are completed.
  - Completion Queue cache line contains an indication of 16 completed transmit descriptors.
- Interrupt scheduling impact on transmit descriptor write-back is a function of the *NoExpire* flag in the queue context, plus the *CAUSE_ENA* bit in the QINT_TQCTL register, plus the *INTENA* settings in the *xx*INT_DYN_CTL*x* register for the interrupt, as presented in Table 9-1.

Notes:

1. The *NoExpire* flag is expected to be set at queue initialization and remain static.
2. All transmit queues associated with the same Completion Queue must have the same *NoExpire* setting.

Table 9-1. Tx-Queue Interrupt Setting

NoExpire[1]	CAUSE_ENA	INTENA	WB_ON_ITR	Functionality[2]
N/A	0	N/A	N/A	Transmit queue is not associated with any interrupt. Descriptors write-back do not affect and are not affected by the interrupt logic. This setting cannot be used with queues associated with a Completion Queue (since nothing triggers the flush of Completion Queue).
0	1	1	0	Default LAN driver setting. Completed descriptors with EOP trigger the ITR. Completed descriptors with *RS* or *RE* flags are written back. At ITR expiration, the most recent completed descriptors with EOP is WB for all queues associated with this interrupt. Then, if Completion Queue(s) are used, its cache line is posted to host memory. Then the interrupt is initiated.
0	1	Any	1	Polling driver setting. Same as above while interrupt is NOT initiated.
1	1	1	0	This setting is used only if Completion Queues are used. Flow is the same as above, while following ITR expiration only the most recent completed descriptors with EOP are written back for ONLY one Tx-Queue per Completion Queue, and then the Completion Queue's cache line is posted to host memory. Then the interrupt is initiated.
1	1	Any	1	Same as above while interrupt is NOT initiated.

1. The "NoExpire" setting for Tx-Queues is only applicable for Completion Queues usage.
2. See Section 9.1.4.1 for details on ITR.

9.1.2.2 LAN Receive Queues

The E810 supports 2K LAN receive queues for the whole device, where each queue is a potential interrupt cause. A DMA completion of a descriptor with an *EOP* flag and its buffer is considered as a receive "event" that triggers an interrupt (if the interrupt is enabled). Furthermore, if the number of free descriptors on the receive queue drops below threshold, it is considered as "immediate event" (described in the following subsections). The low threshold is defined by the *LRXQTRESH* parameter in the receive queue context.

Similar to the LAN Transmit Queues, the LAN Receive Queues are mapped to any ITR of any interrupt vector by the matched QINT_RQCTL registers.

9.1.2.2.1 Receive Descriptors Write-Back and Interrupts

Completed receive descriptors are posted to host memory in one of the following cases:

- Unrelated events to interrupts.
  - — Whole internal cache line of descriptors are completed.
  - — All completed descriptors in the internal cache are posted to host memory when the receive queue context is evicted from the cache.

— Interrupt scheduling impact on receive descriptors write-back is a function of the *NoExpire* flag in the queue context, plus the *CAUSE_ENA* in the QINT_RQCTL register, plus the *WB_ON_ITR* and *INTENA* settings in the *xx*INT_DYN_CTL*x* register for the interrupt, as in Table 9-2.

Table 9-2. Rx-Queue Interrupt Setting

NoExpire	CAUSE_ENA	INTENA	WB_ON_ITR	Functionality[1]
0	0	N/A	N/A	Receive queue is not associated with any interrupt and descriptors write-back are made only according to the internal cache policy (in other words, when a full cache line is available for write-back).
0	1	1	0	Completed descriptors are posted to host memory according to the internal descriptor cache policy (in other words when a full cache line is available for write-back). Completed descriptors also trigger the ITR. Following ITR expiration, all leftover completed descriptors are posted to host memory, and then the interrupt is triggered. ***Note:*** This means that in case the ITR expires when the relevant cache line is not full, the same cache line is written back twice (once when the ITR expires and once when the cache line becomes full).
0	1	Any	1	Same as above but the interrupt signal is NOT triggered.
1	0	N/A	N/A	Each completed descriptor is written immediately to host memory. No interrupts are associated with the queue.
Else				Reserved. Forbidden setting options.

1. See Section 9.1.4.1 for details on ITR.

Note: Software can dynamically switch between WB_ON_ITR mode and ITR mode by setting/clearing the *WB_ON_ITR* flag.

Warning: The NoExpire mode specified in Table 9-2 can cause excessive PCIe transaction traffic that is not limited by any rate control/throttling mechanism. It is advised to enable it only for traffic types requiring low latency, and with consideration to the packet rate supported by the platform in this mode.

9.1.2.3 Protocol Engine Queues

A completion of an Asynchronous Event Queue Entry or a Completion Event Queue Entry is considered as an "event" that triggers an interrupt (if the interrupt is enabled). PE Completion Event Queues (CEQs) and Asynchronous Event Queues (AEQs) can be mapped to any interrupt, with optional interrupt moderation described in the following subsections.

The E810 supports a single Asynchronous Event Queue interrupt control register (per function). It is enabled for interrupts by the *CAUSE_ENA* flag and is mapped to any ITR of any interrupt vector by the *xx*INT_AEQCTL register (where *xx*=PF or VP).

Completion Event Queues (per function) are enabled for interrupts by the *CAUSE_ENA* flag and are mapped to any interrupt vector and its ITRs by the GLINT_CEQCTL registers. The GLINT_CEQCTL registers are allocated to the functions by the PFINT_ALLOC and VPINT_ALLOC registers (the same as the interrupts allocation). See Figure 9-1 that illustrates an example of an allocation.

Note: All PFs and up to 32 VFs can be enabled for the PE. Each enabled function has a single AEQ and a set of global CEQs. All the functions have the a full set of *xx*INT_AEQCTL and GLINT_CEQCTL registers (total of 264 AEQ interrupt control registers and 2048 CEQ interrupt control registers).

A CEQ[n] of a function is mapped to the GLINT_CEQCTL[k]. It is expected that the software uses only those registers that represent "real" AEQs and CEQs behind them.

9.1.2.3.1 CEQ Write-Back and Interrupts

Completed CEQ descriptors are posted to host memory by a similar scheme to the receive descriptors write-back policy. It depends on the settings of the *NoExpire* flag in the TBD register, plus the *CAUSE_ENA* in the GLINT_CEQCTL, plus the *WB_ON_ITR* and *INTENA* settings in the *xx*INT_DYN_CTL*x* register for the interrupt.

9.1.2.4 Admin Queues

The E810 supports three types of Control Queues: Firmware Admin Queues (supported also in predecessor devices), PF/VF Mailbox queues, and Sideband queues.

A completion of an admin command on the transmit queue or posting a structure on the receive queue is considered an event for the queue pair that can trigger an interrupt (depending on if it was configured to do so in the relevant descriptor). The registers that map these queue pairs to interrupt vectors are listed in the following table:

Control Queue Pairs	Mapping to Interrupt Registers
PF Mailbox queues	• PFINT_MBX_CTL maps the PF/VF mailbox of PF0...PF7 to its interrupts. • PF0INT_MBX_CPM_CTL maps the CPM PFVF MBX to its interrupt. • PF0INT_MBX_HLP_CTL maps the HLP PFVF MBX to its interrupt. • PF0INT_MBX_PSM_CTL maps the PSM PFVF MBX to its interrupt.
VF Mailbox queues	• VPINT_MBX_CTL maps the PF/VF mailbox of VF0...VF767 to its interrupts. • VPINT_MBX_CPM_CTL maps the CPM PFVF MBX of VF0...VF127 to its interrupts. • VPINT_MBX_HLP_CTL maps the HLP PFVF MBX of VF0...VF15 to its interrupts. • VPINT_MBX_PSM_CTL maps the PSM PFVF MBX of VF0...VF15 to its interrupts.
PF Sideband queues	• PFINT_SB_CTL maps the SB-IOSF mailbox of PF0...PF7 to its interrupts. • PF0INT_SB_CPM_CTL maps the CPM SB-IOSF MBX to its interrupt. • PF0INT_SB_HLP_CTL maps the HLP SB-IOSF MBX to its interrupt.
Firmware Admin Queues: PF, HLP, and PSM AQs	• PFINT_FW_CTL map the firmware AQ of PF0...PF7 to its interrupts. • PF0INT_FW_HLP_CTL maps the HLP FW AQ to its interrupts. • PF0INT_FW_PSM_CTL maps the PSM FW AQ to its interrupts.

9.1.2.5 Other Interrupt Causes

The E810 supports asynchronous events that can generate interrupts for the PFs. The "other" causes interrupt events supported by the PFs are indicated by the PFINT_OICR registers and enabled by the PFINT_OICR_ENA registers per PF. The register's fields are shown in the Table 9-3.

The "other" causes are mapped to an interrupt vector per PF by the PFINT_OICR_CTL registers.

Note: The "other" causes must be mapped to an interrupt vector index that is within the boundaries of the allocating PF and cannot be mapped to an interrupt vector allocated to any of the VFs. Reusing the example given in Figure 9-1, for PF #0, the OICR can only be mapped to interrupt vector index in the range [0..4], which are the only vectors in PF #0 range that are not mapped to any VF.

Any "other" cause event sets its matched bit in the PFINT_OICR register. If enabled by the PFINT_OICR_ENA register, it triggers an interrupt defined by the PFINT_OCTL register.

During nominal operation it is expected that the software reads the PFINT_OICR register that indicates the "other" cause events (this register is read/clear). Setting the flags in the PFINT_OICR register (other than the queue flags and the *SWINT* flag), emulates an interrupt event of the specific cause (if enabled by the PFINT_OICR_ENA register).

Note: Other causes are latched by the hardware even when the interrupt is not initialized or enabled by the software. Therefore, when software first enables the interrupt, the hardware can trigger an interrupt of events that occurred while the interrupt was not enabled. If software wishes to avoid such behavior, it can read and clear the other causes CSR PFINT_OICR before enabling the interrupt. This behavior is changed from previous generations.

Table 9-3. "Other" Interrupt Causes of the PFs

"Other" Cause	Description	Affected Functions
Queue	Any LAN or PE queues linked to the other cause interrupt (with the exception of an AEQ).	
TSYN_TX	Tx packet time is sampled in the PHY(s).	Indicated PFs according to port to PF mapping (configured by PFGEN_PORTNUM) for ports 0…7 and to PF0 for ports 8 and above.
TSYN_EVNT	Event is sampled by the 1588 timer due to a transition in one of the 1588 input GPIOs.	Indicated PFs according to the *PF_MASTER* field in the GLINT_TSYN_PFMSTR registers.
TSYN_TGT	One of the target time of the 1588 timer is expired.	Same as TSYN_EVNT.
ECC_ERR	Unrecoverable ECC Error. This bit is set when an unrecoverable error is detected in one of the device memories.	Reported to all PFs.
MAL_DETECT	Malicious programming detected.	Reflected to the parent PF of the malicious VF.
GRST	Global Resets Requested (CORER, GLOBR or EMPR).	Reported to all PFs.
GPIO	GPIO Event indicates an event on any of the GPIO pins enabled for interrupt by the PFINT_GPIO_ENA register. The GPIO state can be fetched on the GLGEN_GPIO_STAT register. The level transition that generates an interrupt is set for GPIO 'n' by the *INT_MODE* field in the matched GLGEN_GPIO_CTL[n] register.	Reported to the relevant PF
STORM_DETECT	Indicates a change entering the storm control state of the LAN port that is connected to this PF. The storm control state is reflected in the PRT_SWT_SCSTS register.	Reflected to the PF associated with the port.
HMC_ERR	HMC errors: PEPMAT or FPMAT. Specific PEMAT errors are reported in the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. Specific FPMAT errors are reported in the PFHMC_ERRORINFO_FPMAT and PFCHMC_ERRORDATA_FPMAT registers.	Reported to the relevant PF.
PE_CRITERR	Protocol Engine Critical Error. Indicates that the Protocol Engine has encountered a critical error.	Reported to all PFs.
VFLR	VFLR was initiated by one of the VFs of the PF. The PF software should read the GLGEN_VFLRSTAT getting an indication for the VF that generated the VFLR.	Reported to the parent PF.
VFR_DONE	VFR sequence by the hardware is completed. The PF software should read the GLGEN_VFRDONE indicating it to the VF driver.	Reported to the parent PF.
SWINT	Software interrupt (detailed in Section 9.1.2.6.	Reported to the PF that generated the interrupt.
PE_PUSH_OVERFLOW	Indication that the PE push buffer is overflowing.	Reported to all PFs.

9.1.2.6 Software Initiated Interrupt

In some cases, the software might not be able to process all events in a single interrupt handler. In such cases, the software can schedule another interrupt to complete processing all interrupt events. The software can trigger an interrupt on any vector and any of its ITRs or NoITR. The software interrupt is mapped to one of three ITRs or immediate interrupt by the *SW_ITR_INDX* field in the *xx*INT_DYN_CTL*x* registers (where *xx*=PF or VF and x=0 or N). When programming the *SW_ITR_INDX* parameter, the *SW_ITR_INDX_ENA* flag in this register should be set as well.

The software initiates the interrupt by setting the *SWINT_TRIG* flag in the *xx*INT_DYN_CTL*x* registers.

Software has the option of setting the *SWINT_TRIG* flag in the *xx*INT_DYN_CTL*x* registers with or without setting the *INTENA* flag by using the *INTENA_MSK* flag in the same register. Setting or clearing the *INTENA* flag, not as part of an interrupt handling routine, can lead to race conditions. Therefore, it is expected that software never clears the *INTENA* flag, and clearing of the *INTENA* flag is always done by hardware for non-debug conditions. Also, it is expected that software sets *SWINT_TRIG* together with *INTENA* only as part of the interrupt handling routine (in other words, at the end of handling an interrupt).

Setting the software interrupt in the vector of the PF that is assigned for the other causes, the software *INT* flag is set in the OICR register of that PF (on top of the interrupt triggering).

9.1.2.7 Interrupt Status Registers

During nominal operation, the software avoids any possible read accesses. The other causes interrupts of the PFs is an exception. Following an other causes interrupt, the software is expected to read the OICR register identifying the source of the interrupt. The OICR register provides indication for the following events:

- Any of the "other" interrupt causes.
- An indication for LAN receive or transmit queues CEQs that might be associated with the OICR interrupt.
- SWINT indication, which is a result of software initiated interrupt.

9.1.3 Interrupt Linked List

The queues are linked to a specific interrupt vector by the MSIX_INDX field in the *xxx*QCTL registers. Specifically, the LAN queues and the PE completion event queues are associated with an interrupt vector by the following registers: QINT_RQCTL, QINT_TQCTL, and GLINT_CEQCTL. Once an event is initiated on any of these queues, it is added to the linked list of its associated interrupt (unless the *NoExpire* flag is set for the event). Interrupt causes mapping to the interrupt vectors are illustrated in Figure 9-2.

When an interrupt sequence is triggered, the E810 process all active queues in the linked list of this interrupt. While processing the queues in the linked list, the hardware writes back the status for those completed descriptors that were not reported already, as listed below:

- **LAN Receive Queues** — The hardware triggers a status write-back of all completed descriptors.
- **LAN Transmit Queues (in legacy mode)** — The hardware writes back the completion indication of the last completed transmit descriptor that has an *EOP* flag (regardless of the *RS* bit) and was not already reported to host memory.

- **LAN Transmit Queues (in comm mode)** — The hardware writes back the completion indication of the last completed transmit descriptor that has an *EOP* flag (regardless of the *RS* bit) and was not already reported to its Completion Queue. Once a whole cache line of 64 bytes of the Completion Queue is written internally, it is posted to host memory. When all Tx-Queues in the interrupt linked list that are associated with a specific Completion Queue are processed, any remaining cache line residual is posted to host memory as well.

  Note: Multiple Completion Queues can be assigned to the same interrupt. Yet, all transmit queues that are associated with a specific Completion Queue must be linked by the software to the same interrupt.

- **PE CEQ entries** — The hardware writes back the completion indication of all completed CEQ entries.

Note: The *xxx*QCTL registers are accessible only to the PF. A VF can assign causes to interrupts with the help of the PF using an admin command or any other sideband message (out of the scope of this document).

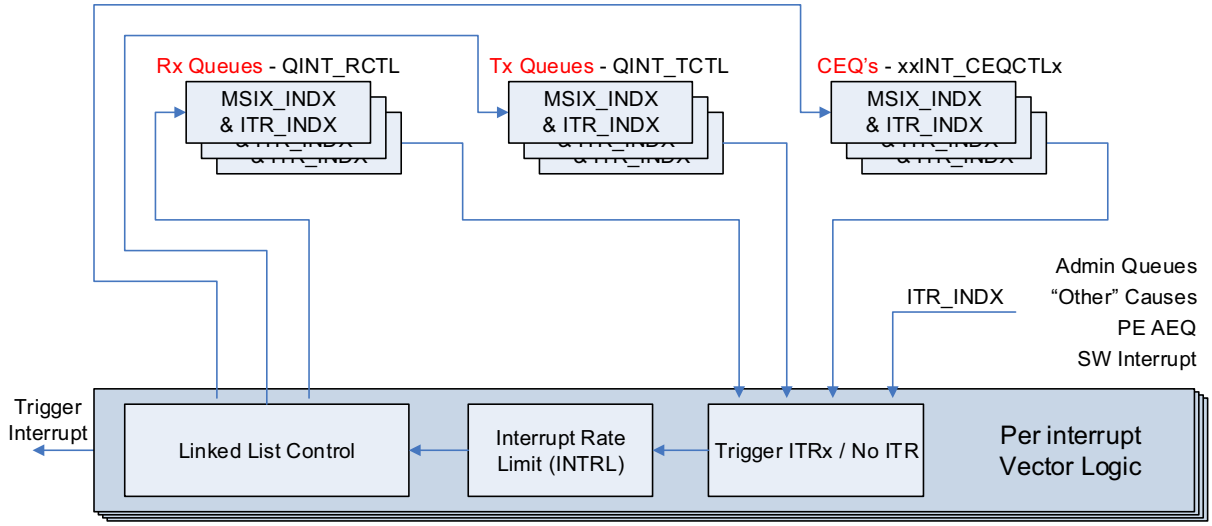

Figure 9-2. Mapping Interrupt Causes to Interrupt Signaling

9.1.3.1 Interrupt Linked List Management

This section describes the required software flow for adding and removing an interrupt cause from an interrupt linked list.

9.1.3.1.1 Initial Linked List Setting and Adding Interrupt Causes

Any interrupt cause can be added to an interrupt vector at any time (either before or after the interrupt is already active). The interrupt causes are linked to an interrupt vector by setting the *MSIX_INDX* field in the *xxx*QCTL register of the cause. These registers also map the cause to a specific *ITR_INDX* of the interrupt and also contain the interrupt *CAUSE_ENA* flag.

9.1.3.1.2 Removing an Interrupt Cause from an Active Interrupt

An interrupt cause (queue) can be removed from an active interrupt during run time according to the following steps. This flow is needed as part of a queue disable flow or a VM reset.

1. Disable the interrupt for the cause by clearing the *CAUSE_ENA* flag in the *xxx*QCTL register of the cause.
2. Generate a software interrupt on the same vector.
3. After the interrupt is generated, it is safe to disable the queue or initiate the VM reset.

Note: This flow is not required for VF or PR resets or any higher reset source.

9.1.3.1.3 Migrating a Queue Between Interrupt Vectors

Migrating a queue (or other cause) from one interrupt to another one is done as follows:

1. Software remaps the queue by simply setting of the *MSIX_INDX* field to the new interrupt, together with the *ITR_INDX* and *CAUSE_ENA* flag in the *xxx*QCTL register of the cause.

   Note: Depending on timing, the previous interrupt could still be initiated for the queue even after this action.

2. To ensure that the original interrupt vector is no longer triggered by events associated with the migrated queue, software should trigger a software interrupt to force the processing of all causes associated with the original interrupt.

Note: Transmit queues associated with a Completion Queue cannot be migrated dynamically. Migrating a queue in this case violates the rule by which all transmit queues of a specific Completion Queue must belong to the same interrupt.

9.1.4 Interrupt Moderation

The E810 is able to throttle interrupts in two layered methods:

- Interrupt Throttling (ITR)
- Interrupt Rate limiting (INTRL).

These methods are detailed in the following subsections.

9.1.4.1 Interrupt Throttling (ITR)

Interrupt throttling is a mechanism that guarantees a minimum gap between two consecutive interrupts (other than possible jitter caused by handling the interrupts). The E810 counts the time since the last interrupt is scheduled and compares it against the ITR setting. If an event associated with this ITR happens before the ITR expires, the interrupt assertion is delayed until the ITR expires. If the ITR expires before any event associated with this interrupt, the interrupt logic is "armed" and the interrupt can be asserted the moment the event happens. The ITR intervals per vector are programmed by the *xx*INT_ITR*x* registers. The ITR is measured in units corresponding to the maximal aggregated port speeds allowed by the device (see Section 9.1.4.3). Note that ITR expiration sequence is triggered only when all the following conditions are met:

- The ITR timer is expired.
- The *INTENA* or the *WB_ON_ITR* flags in the matched GLINT_DYN_CTL register is set.

- The interrupt has credit(s) by the "Interrupt rate limiting" logic explained in Section 9.1.4.2.

Additionally, to the terms mentioned above, the ITR expires when the interval setting for that ITR is changed.

The E810 supports three ITRs per MSI-X vector, as well as a NoITR option. The interrupt causes are mapped to one of the ITRs by the *ITR_INDX* field (per cause). The ITR intervals can be programmed directly to the *xx*INT_ITR*x* registers or via the *xx*INT_DYN_CTL*x* registers. It might be useful to set the initial values using the *xx*INT_ITR*x* registers and dynamic update by the *xx*INT_DYN_CTL*x* registers, as explained in Step 4 of the interrupt sequence explained in Section 9.1.1.3.

When any ITR interval of an interrupt with a pending event is expired and the INTRL[1] credit is positive, the hardware follows these steps:

1. Clear the other ITRs of the same interrupt.
2. Process all causes of the same interrupt (associated with all ITRs).

9.1.4.2 Interrupt Rate Limiting (INTRL)

Interrupt rate limiting is a credit based mechanism that limits the maximum average number of interrupts per second. The PF controls the rate limit for the vectors in its space (including his VFs) using the GLINT_RATE registers. The control parameters of these registers are detailed below.

- ***INTRL_ENA*** — Enable/Disable option for the INTRL scheme. When disabled, interrupts can be generated without rate limiting control.
- ***INTERVAL*** — The INTRL is a 6-bit interval defined in units determined by the device configuration (see Section 9.1.4.3). The value determines the time gap on which new interrupt credit is gained.

9.1.4.3 INTRL/ITR Timing Granularity

Due to the optimization of the internal clock speed in the E810 according to the total aggregated bandwidth allowed by the device (in other words, the sum of all allowed ports linked at the highest allowable speed), the timing granularity (time units) used for configuring the INTRL and ITR intervals changes in accordance with the prior. The granularity is determined according to the device's configuration during the power-on phase, and is static throughout its operation.

Table 9-4 specifies the INT and INTRL timing granularity values as a function of the relevant device configuration.

Table 9-4. ITR/INTRL Granularity Values

Aggregated Bandwidth	ITR Granularity	INTRL Granularity
Less than or equal to 25 Gb/s	4 µs	8 µs
Less than or equal to 50 Gb/s	2 µs	4 µs
Above 50 Gb/s	2 µs	4 µs

1. See Section 9.1.4.2 description of the Interrupt Rate Limiting (INTRL).

9.2 Virtualization

9.2.1 Overview

I/O virtualization is a mechanism to share I/O resources among several consumers. For example, in a virtual system, multiple operating systems are loaded and each executes as though the whole system's resources are at its disposal. However, for the limited number of I/O devices, this presents a problem because each operating system might be in a separate memory domain, and all the data movement and device management must be done by a Virtual Machine Monitor (VMM). VMM access adds latency and delay to I/O accesses, and degrades I/O performance. Virtualized devices are designed to reduce the burden of the VMM by making certain functions of an I/O device are shared. Thus, they can be accessed directly from each guest operating system or Virtual Machine (VM).

Two modes to support operation in a virtualized environment were implemented in previous products:

1. Direct assignment of part of the port resources to different guest operating systems using the PCI-SIG SR-IOV standard (also known as "Native mode" or pass-through mode). This mode is called IOV mode in this section.
2. Central management of the networking resources by an IOVM or by the VMM (also known as software switch acceleration mode). This mode is called Next Generation VMDq mode.

The E810 fully supports Next Generation VMDq mode and SR-IOV. The E810 supports two modes of offloads as part of Next Generation VMDq: VMDq1 and VMDq2.

In VMDq1, all the VMs are part of the same VSI, and each VM is allocated a single queue. There is no replication of packets to different VMs, and there is no forwarding of traffic from one VMDq1 VM to another.

In VMDq2, each VM is assigned a switch port (VSI). Thus, there can be full switching between ports, including VM-to-VM switching and replication of multicast packets.

On top of these modes, The E810 supports Scalable I/O (which is a lightweight version of SR-IOV), in which traffic and resources are assigned to VMs through an Assignable Interface (AI) that is a CSR space within the PF space exposed to the VM. Traffic belonging to an AI is identified through a PASID prefix. See Section 9.2.3 for details on Scalable I/O and PASID.

In a virtualized environment, the E810 serves up to 768 Virtual Machines (VMs) per device; 256 of these can be directly assigned and any of them can be accessed in Next Generation VMDq mode. See Section 9.2.2.4 for details of the VFs and VMs resource allocation.

Most configurations and resources of the device are shared across VMs. The PF driver must resolve any conflicts in configuration between the VMs. For example, the PF driver should manage all the link configuration requests of the VFs.

Most of the virtualization offload capabilities provided by the E810, apart from the replication of functions defined in the PCI-SIG IOV specification, are also part of Next Generation VMDq.

A hybrid model, where some of the virtual machines are assigned a dedicated share of the port and the others are serviced by an IOVM, is also supported. This model can be used when some of the VMs run operating systems for which VF drivers are available. Such configurations can benefit from IOV. Others can run older operating Systems for which VF drivers are not available, and are serviced by an intermediary or models where VFs are assigned to VMs requiring a higher networking bandwidth. In this last case, the IOVM or VMM is assigned some VSIs and receives all the packets with MAC Addresses of the VMs behind it. VSIs are described in Section 7.8.8.

The following section describes the support that the E810 provides for virtualization. This section assumes a single-root implementation of IOV and no support for multi-root.

9.2.1.1 Direct Assignment Model

The direct assignment support in the E810 is built according to the software model defined by the SR-IOV specification.

The Physical function (PF) driver is responsible for the initialization and the handling of the common resources of the port. Other drivers (VF drivers) might read part of the status of the common parts, but cannot change it. The PF driver might run either in the VMM or in some service operating system. It might be part of an IOVM or part of a dedicated service operating system.

In addition, part of the non-time-critical tasks are also handled by the PF driver. For example, access to CSR through the I/O space or access to the configuration space are available only through the master interface. Time-critical CSR space, like control of the Tx-Queue and Rx-Queue or interrupt handling, is replicated per VF. It is directly accessible by the VF driver.

Note: In some systems with a Thick Hypervisor, the service operating system might be an integral part of the VMM. For these systems, each reference to the service operating system in this section refers to the VMM.

A channel is provided between the VF driver and the PF driver through the use of admin commands. See Section 9.5.14.

9.2.1.1.1 Rationale

The purpose of direct assignment is to enable each of the virtual machines to receive and transmit packets with minimum overhead. The non-time-critical operations (such as init and error handling) can be done via the PF driver. In addition, it is important that the VMs can operate independently with minimal disturbance. It is also preferable that the VM interface to the hardware should be as close as possible to the native interface in non-virtualized systems to minimize the software development effort.

The main time-critical operations that require direct handling by the VM are:

- Maintenance of the data buffers and descriptor rings in host memory. To support this, the DMA accesses of the queues associated to a VM should be identified as such on the PCIe using a different Requester ID.
- Handling of the hardware ring (tail bump and head updates).
- Interrupt handling.

The capabilities needed to provide independence between VMs are:

- Per VM reset and enable capabilities.
- Tx QoS control.
- Allocation of separate CSR space per VM.

The queue context creation, rate control, and VF enable capabilities are controlled by the PF.

9.2.1.2 Virtualized System Overview

The following drawings describe the various elements involved in the I/O process in a virtualized system. Figure 9-3 describes the flow in software Next Generation VMDq operation mode, while Figure 9-4 describes the flow in IOV mode.

This document assumes that in IOV mode, the driver on the guest operating system is aware that it works in a virtual system (para-virtualized) and there is a channel between each of the virtual machine drivers and the PF driver, allowing message passing (such as configuration request or interrupt messages). This channel might use the mailbox implemented in the E810 or any other means provided by the VMM vendor.

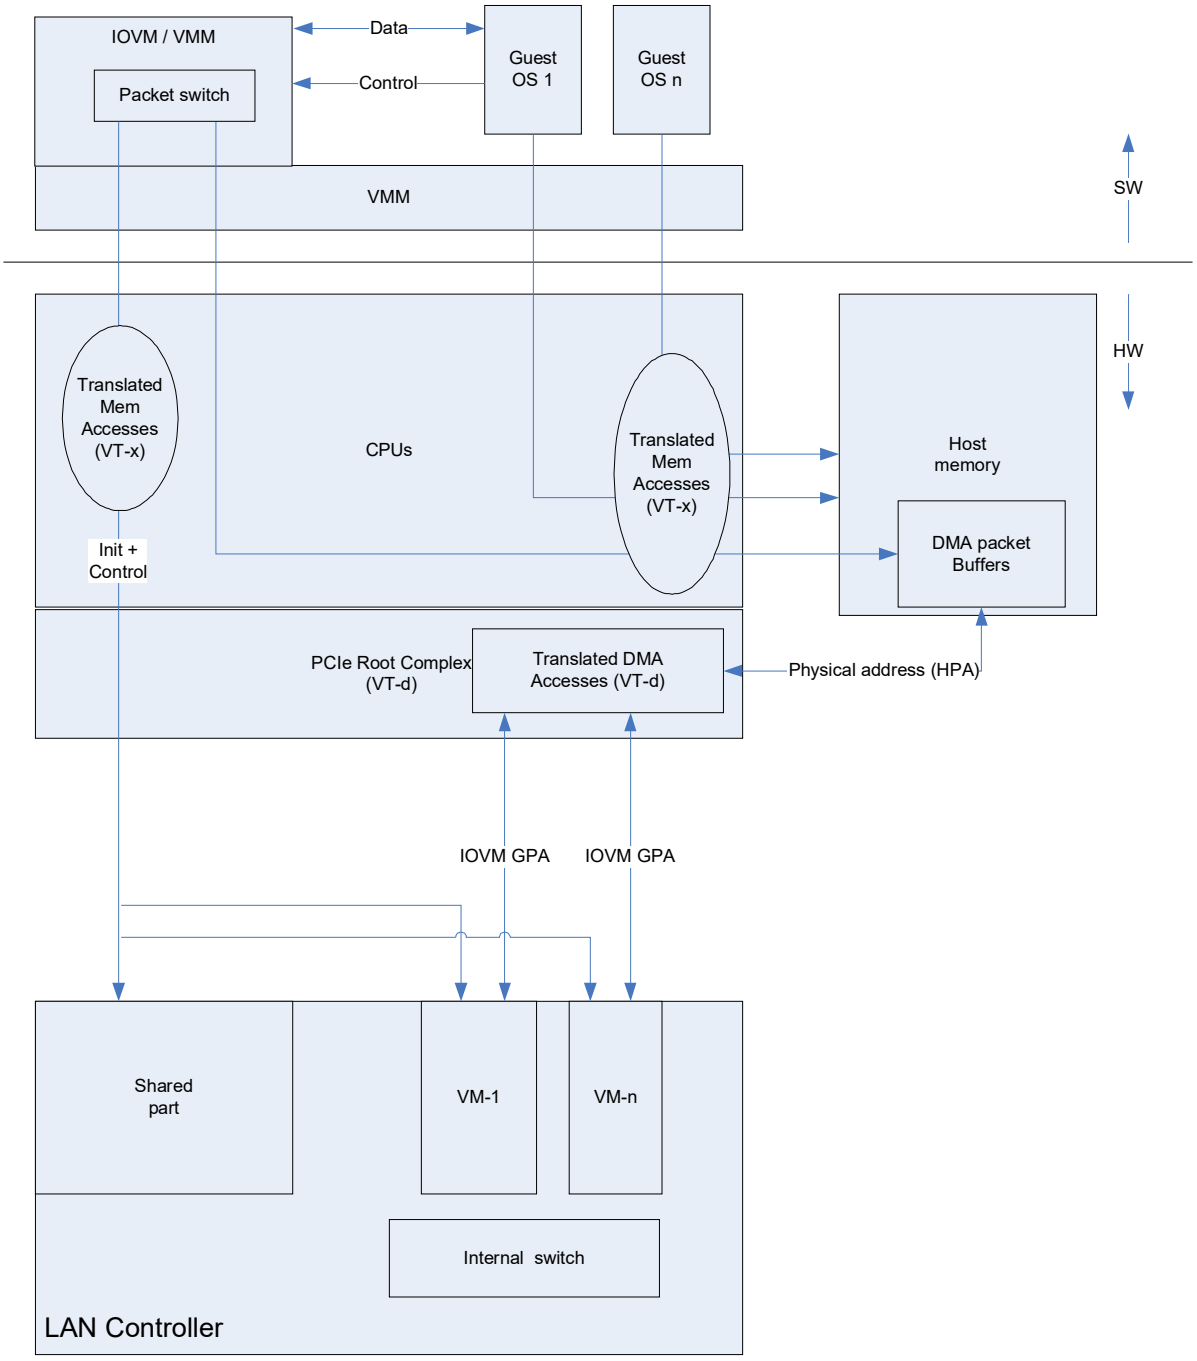

Figure 9-3. VMDq System

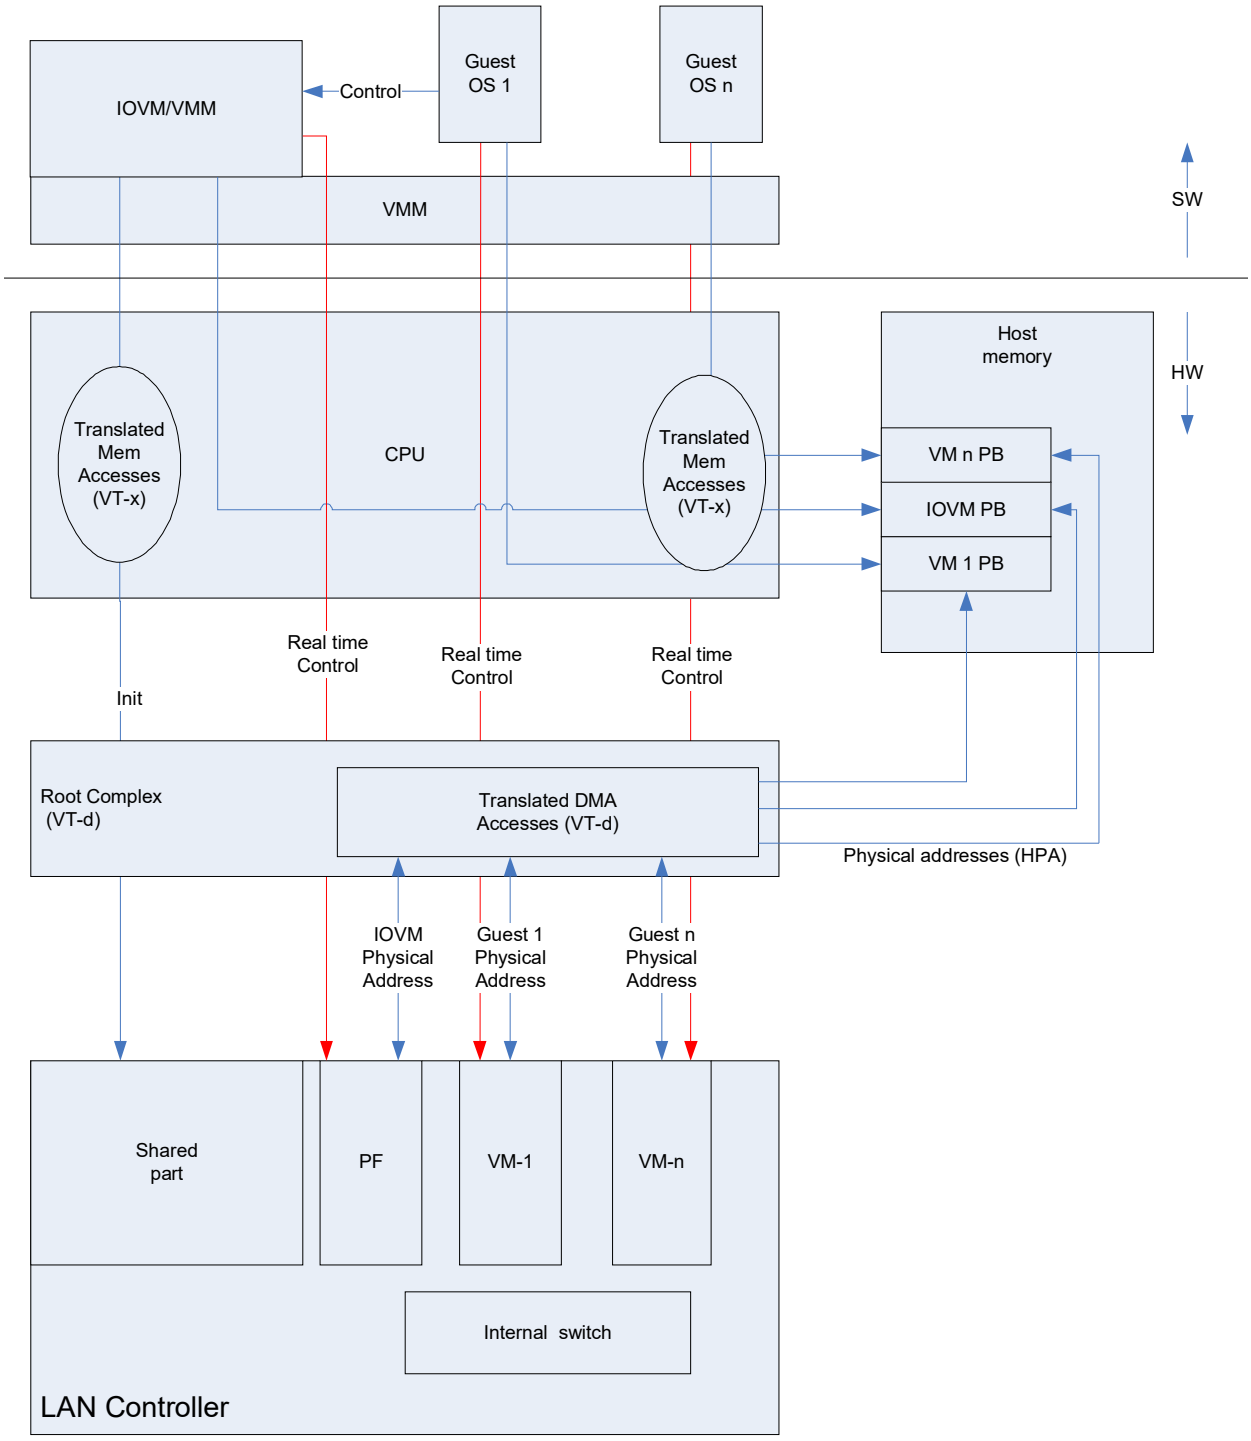

Figure 9-4. SR-IOV Based System

9.2.1.3 Virtualization Supported Features

The E810 supports a superset of the virtualization features supported in previous products. The following table compares the virtualization features of the E810 with these of the X710/XXV710/XL710.

Table 9-5. E810 Versus X710/XXV710/XL710 Virtualization Support

Feature	E810 Support	X710/XXV710/XL710 Support
Virtualization-Specific Capabilities		
SR-IOV support	Yes	Yes
VMDq1 support	Yes	Yes
VMDq2 support	Yes	Yes
ATS support	No	No
VF-to-PF mailbox	Yes (in hardware).	Yes (via firmware).
Base mode VF support	Yes. Compatible with the X710/XXV710/ XL710.	Yes.
Support for Generic Capabilities		
RSS	Yes (per VSI). Small or medium size tables.	Yes (per VSI). Small or medium size tables.
DCB	Yes	Yes
Queue selection criteria	Programmable	SA, VLAN pairs or SA or VLAN
Statistics	Per VSI	Per VSI
Stateless Offloads	Per queue	Per queue
RDMA	Supported for 32 VFs	Supported for 32 VFs
Quantities		
Max number of Virtual Machines (VMs)	768	256
Max number of Virtual functions (VFs)	256 per device (globally)	128 per device (globally)
Max number of queues per VF	16 arbitrary or 256 contiguous	16 arbitrary or 256 contiguous
Max number of queues per VMDq2 VSI	16K (Tx) + 2K (Rx)	1536
Max number of queues per VMDq1 VM	According to Hash Filter configuration	1
Max number of VMDq2 VSIs	768	256
Interrupt vectors	Up to 9 or 65 per VF	Up to 9 per VF
Switching Capabilities		
MAC Addresses	Up to switch capacity	1024 per device (globally)
VLAN tags	Up to switch capacity	512 per device (globally)
Switching modes	VEB, VEPA	VEB, VEPA
VM-to-VM switching	Yes	Yes
Broadcast and multicast replication	Yes	Yes
MAC and VLAN anti-spoof protection	Yes	Yes
VLAN filtering	Global and per pool	Global and per pool
Drop if no VIS selected	Yes	Yes
Mirroring	Yes	Yes
Promiscuous modes per VM	VLAN, multicast, unicast	VLAN, multicast, unicast

For more details about the switching support, see Section 7.8.

9.2.1.3.1 Enablement of Virtualization Features

Table 9-6 describes the way to enable each virtualization feature.

Table 9-6. Virtualization Features Enablement

Technology	Included Features	Enablement
SR-IOV		Set the GLPCI_CAPSUP.*IOV_EN* bit.
VEB	VEB, VEPA, VMDq2, mirroring	Always enabled.

9.2.2 SR-IOV Implementation

9.2.2.1 IOV Concepts

The SR-IOV specification defines the following entities in relation to I/O virtualization:

- **Virtual Machine (VM)** — A virtual machine to which I/O resources are assigned.
- **A PCIe device** — The physical device that might contain a few physical functions. In this case, the E810.
- **Physical function (PF)** — A function representing a physical instance. In this case, a PCIe function that represents a physical port or a logical port. The PF driver is responsible for the configuration and management of the shared resources in the function.
- **Virtual function (VF)** — A part of a PF assigned to a VM.

9.2.2.2 IOV Control

To control the IOV operation, the physical driver is provided with a set of registers and capabilities. These include:

- The PF_VIRT_STATUS register, which indicates whether SR-IOV is enabled and the number of VFs enabled.
- Driver-to-driver communication provided by the virtualization admin commands (see Section 9.5.14).
- Switch and filtering control admin commands (described in Section 7.8.12).
- Reset indications and traffic enables registers per VF using the GLGEN_VFLRSTAT.*VFLRS* bit, indicating that a VFLR reset occurred in one of the VFs. When the GLGEN_VFLRSTAT.*VFLRS* bit is set for a given VF, this VF cannot send or receive packets. The PF should clear this bit to enable a VF.
- Malicious driver detection (described in Section 9.2.2.2.1).

The flow used to configure a function when SR-IOV is enabled is described in Section 4.4.1.2.

9.2.2.2.1 Interrupt on Misbehavior of VM (Malicious Driver Detection)

The E810 can protect itself from faulty or malicious behavior on the part of a VM driver. This is done by checking for specific illegal events.

The bits that enable these checks are grouped into four categories: Rx checks, Tx-Descriptor checks, Tx tail bump and quanta queue checks, and Tx data checks. Individual checks are controlled by global registers GL_MDCK_RX, GL_MDCK_TCMD_TCLAN, GL_MDCK_EN_TX_PQM, and GL_TDPU_DROP_DIS, respectively. If a check is not enabled (the bit is cleared) and such an event happens, the monitoring hardware does not react to the condition, and the device might malfunction.

Table 9-7, Table 9-8, and Table 9-9 list the checks in each group, the register bits used to enable them, and the value read from the MDET registers when an event is detected.

The default values for these registers are loaded from NVM.

The checks apply both to VF and PF activity. If such behavior is detected, the queue is stopped and an interrupt is sent to the PF that owns the function and should be re-initialized. For Rx-Queues, the *Queue_Block Indication* bit (bit 21) is set in the context descriptor. This bit must be cleared as part of the queue init before it can be reused.

Note: This means that a PF will be interrupted both on events from its queues and on events from its VFs queues.

Tracking which functions have caused an event is done by reading each function's VP_MDET_RX, VP_MDET_TX_TCLAN, VP_MDET_TX_PQM, and VP_MDET_TX_TDPU registers for VFs or PF_MDET_RX PF_MDET_TX_TCLAN, PF_MDET_TX_PQM, and PF_MDET_TX_TDPU for PFs. The registers are cleared by writing 1's to them. After such an event the function needs to reset the queue. Tx Data protection is different in that it does not stop the queue; it drops the offending packet.

Four global debug registers (GL_MDET_TX_PQM, GL_MDET_TX_TDPU, GL_MDET_TX_TCLAN, and GL_MDET_RX) record the function number event ID and queue number for the first event observed on Tx and Rx, respectively. These registers are cleared by writing 1's.

Note: For Tx events (GL_MDET_TX_PQM, GL_MDET_TX_TDPU, GL_MDET_TX_TCLAN), the *VF_NUM* field in the global registers can indicate the VF, the VM or if 0, an error in a PF owned VSI. The software device driver should deduct the actual offending agent from the reported queue number and the reporting in the per agent registers. For Rx events (GL_MDET_RX), only the queue number is valid. The offending function should be derived from the owner of the offending queue.

Since the malicious driver event indication in the various Tx registers is per function, and the details of the event in the GL_MDET_TX_PQM, GL_MDET_TX_TDPU, and GL_MDET_TX_TLAN registers are common to all functions, it might not be simple to determine which queue caused the event. Therefore, the driver might elect to reset the whole function. The PRTDCB_TDPUC contains information per port for the first malicious event that was detected.

9.2.2.2.1.1 Tx Data Checks (GL_MDCK_TX _TDPU Register)

The list below describes the checks that are done by the E810 on data fetches for Tx data:

- TTL error
- Anti-spoof fail[1]
- PCIe unsupported request (wrong buffer address)
- Malicious offset detected

1. During a function level reset (PFR, FLR, VFR, VMR), spurious malicious events due to anti-spoof event might occur.

- Malicious command detected
- Packet size bigger than allowed
- L2 acceptance failed
- DSI packet requested
- Malicious IPsec offload detected
- DSCP enforcement - packet is blocked

9.2.2.2.1.2 Tx Descriptor Validity Checks (GL_MDCK_TCMD Register)

Table 9-7 describes the checks that are done by the E810 on Tx-Descriptor.

Table 9-7. Malicious Driver - Tx-Descriptor Checks (GL_MDCK_TDAT_TCLAN)

Index	Event	Mode[1]	Comments
0	Wrong order/Format of descriptors	BC+COMS	• Wrong Descriptor type. • Wrong order/format of descriptors. • DSI traffic with TSO request. • Non data buffer in the middle of a packet (before EOP arrived). • Wrong descriptor type. • Non NOP descriptor arrives after TLEN reached and before total_descs_in_tso reached. ***Note:*** A null buffer triggers an event even if this bit is cleared.
1	Unsupported Requests	BC+COMS	Descriptor fetch failed.
2	Tail descriptor is not DDESC with EOP/NOP	BC+COMS	
3	False Scheduling	BC+COMS	tail == head (No new descriptors)
4	Tail value is bigger than ring length	BC+COMS	Non endless transmit mode.
5	More than 8 data commands in packet	BC+COMS	
6	Zero packets sent in quanta and no head update in this quanta	BC+COMS	
7	Packet too small or packet too big	BC+COMS	LSO mode: Check that headers + MSS/Last Segment size <= GLCOMM_MIN_MAX_PKT.*MAHDL*. Check that headers + MSS/Last Segment size >= GLCOMM_MIN_MAX_PKT.*LSO_COMS_MIHDL* (COMS mode). Check that headers + MSS/Last Segment size >= GLCOMM_MIN_MAX_PKT.*MIHDL* (BC mode). SSO Mode: Check that packet <=GLCOMM_MIN_MAX_PKT.*MAHDL*. Check that packet >= GLCOMM_MIN_MAX_PKT.*MIHDL*.
8	TSO: TLEN is not coherent with sum {LSO buffers}	BC+COMS	DataDesc.EOP arrives before TSO data ended. TLEN ended and DataDesc.EOP==0. TLEN ended, data descriptor buffer is not fully used.
9	TSO: Tail reached before TLEN ended	BC+COMS	
10	TSO: Headers are spread on more than 3 descriptors	BC+COMS	
11	TSO: Sum of TSO buffers < sum of headers	BC+COMS	EOP on header descriptor.

Table 9-7. Malicious Driver - Tx-Descriptor Checks (GL_MDCK_TDAT_TCLAN) [continued]

Index	Event	Mode[1]	Comments
12	TSO: Sum of headers is 0/MSS is 0/TLEN is 0	BC+COMS	Iplen==l4len==maclen == 0 Mss == 0 Tlen == 0 COMS:total_descs_in_lso == 0
13	TSO: CTX descriptor wrong IPSEC fields	BC+COMS	CDESC.cipherblk == 1 or > 3 | CDESC.ICVLEN >1000
14	SSO: Quanta does not include a whole number of SSO packets	COMS	Quanta must finish with NOP/Ddesc.EOP. CDESC with TSO bit set is not allowed.
15	SSO+TSO: Quanta bytes before additions exceed pkt_len*64	COMS	SSO LSO last quanta
16	SSO+TSO: Quanta commands exceed max_cmds_in_sq	COMS	Can be disabled by CSR (sometimes it can happen).
17	TSO: total_descs_in_lso is not coherent with last_lso_quanta	COMS	total_descs_in_tso reached and last_lso_quanta not reached (is 0). last_lso_quanta reached (== 1) and total_descs_in_tso not reached.
18	TSO: total_descs_in_lso is not coherent with TLEN	COMS	total_descs_in_lso descriptors processed but TLEN was not reached.
19	TSO: Quanta bytes is spread on more than max descriptors in quanta	COMS	last_quanta_in_lso = 0, quanta max descriptors finished, and (pktlen-1)* 64 bytes were not reached.
20	Number of packets in quanta mismatch	COMS	Number of sent packets in quanta does not equal number of packets in scheduling command.

1. BC - Backward Compatible. COMS - uses quanta queue.

9.2.2.2.1.3 Tx Checks (GL_MCK_EN_TX_PQM)

The following checks are done on the tail bump events and quanta queues:

Table 9-8. Malicious Driver - Tx-Descriptor Checks (GL_MDCK_EN_TX_PQM)

Index	Event	Comments
0	PCI_DUMMY_COMP	Enable detection of PCI Dummy Completion (for a QD Fetch Request).
1	PCI_UR_COMP	Enable detection of PCI "Unsupported Request" Completion (for a QD Fetch Request).
3	RCV_SH_BE_LSO	Empty Q fetch (initiated by PQMMNG after 1st Quanta was delivered to PQMMNG by DBL) and LSO QD is expected in completion. Completion is received however received QD is NOT LSO.
4	Q_FL_MNG_EPY_CH	In fetch command (initiated by PQMMNG) force_fetch is set (Q is full PQMMNG wise) but PQMQDC concluded that the Q is empty.
5	Q_EPY_MNG_FL_CH	In fetch command (initiated by PQMMNG) force_fetch is clear (Q is empty PQMMNG wise) but PQMQDC concludes that the Q is not empty.
6	LSO_NUMDESCS_ZERO	Enable detection of LSO QD whose Number of Descriptor is zero.
7	LSO_LENGTH_ZERO	Enable detection of LSO QD whose Length is zero.
8	LSO_MSS_BELOW_MIN	Enable detection of LSO QD whose MSS is below GL_MDCK_CFG2_TX_PQM.*LSO_MIN_MSS*.
9	LSO_MSS_ABOVE_MAX	Enable detection of LSO QD whose MSS is above GL_MDCK_CFG2_TX_PQM.*LSO_MAX_MSS*.
10	LSO_HDR_SIZE_ZERO	Enable detection of LSO QD whose Header Size is zero.
11	RCV_CNT_BE_LSO	Enable detection of LSO QD for a Q which is LSO disabled.

Table 9-8. Malicious Driver - Tx-Descriptor Checks (GL_MDCK_EN_TX_PQM) [continued]

Index	Event	Comments
12	SKIP_ONE_QT_ONLY	The 1st Quanta of a LSO QD which is composed of multiple Quantas is delivered to hardware. The 1st Quanta is scheduled and hardware fetches LSO QD so it can schedule the other Quantas of the same LSO QD. During processing of the fetched LSO QD, hardware concludes it is a single Quanta (which already been scheduled) although doorbell suggested it is a multiple Quantas.
13	LSO_PKTCNT_ZERO	Enable detection of LSO DBL whose first Quanta Number of Segments is zero
14	SSO_LENGTH_ZERO	Enable detection of SSO QD whose Length is Zero.
15	SSO_LENGTH_EXCEED	Enable detection of SSO QD whose Length exceeds GL_MDCK_CFG1_TX_PQM.*SSO_MAX_DATA_LEN*.
16	SSO_PKTCNT_ZERO	Enable detection of SSO QD whose Packet Count is Zero.
17	SSO_PKTCNT_EXCEED	Enable detection of SSO QD whose Packet Count exceeds GL_MDCK_CFG1_TX_PQM.*SSO_MAX_PKT_CNT*.
18	SSO_NUMDESCS_ZERO	Enable detection of SSO QD whose Number of Descriptor is zero.
19	SSO_NUMDESCS_EXCEED	Enable detection of SSO QD whose Number of Descriptor exceed Minimum of {Remain-Ring-Length and GL_MDCK_CFG1_TX_PQM.SSO_MAX_DESC_CNT}.
20	TAIL_GT_RING_LENGTH	Enable detection of DBL whose Tail is greater than Ring Length. Applicable for both QD and Legacy Interfaces.
21	RESERVED_DBL_TYPE	Enable detection of DBL whose {Type} field is Reserved (2'b11) which is considered malicious.
22	ILLEGAL_HEAD_DROP_DBL	Enable detection of Head Drop DBL over Comms Queue for which Head Drop is disabled.
23	LSO_OVER_COMMS_Q	Enable detection of LSO DBL over Comms Queue for which LSO is disabled.
24	ILLEGAL_VF_QNUM	Enable detection of VF-TYPE DBLQ element which is associated with illegal Q number.
25	QTAIL_GT_RING_LENGTH	Enable detection of DBL whose QDTail is greater than Ring Length. Applicable for QD Interface.

9.2.2.2.1.4 Rx Checks (GL_MDCK_RX Register)

Table 9-9 describes the checks that are done by the E810 on data fetches for Rx.

Table 9-9. Malicious Driver - Tx-Descriptor Checks (GL_MDCK_TDAT_TCLAN)

Check Type	GL_MDET_RX Bit	Event ID on MDET_RX Register	Comments
Rx-Descriptor Address	0 DESC_ADDR	1	Descriptor fetch failed[1]

1. A read can time-out or return a UR, It might possibly be poisoned or it might be internally blocked for being outside of the physical address space. The PCIe error registers can be read to distinguish between the reasons.

When a malicious event is detected in a receive queue, all packets received by this queue are dropped and no descriptors are fetched until the queue is re-initialized according to the following flow:

1. Disable queue.
2. Re-configure ring head/tail.
3. Reconfigure context (at least clear the *Queue_Block Indication* bit).
4. Enable queue.

9.2.2.3 Hardware Resources Not Assigned to VFs

Certain device capabilities are not exposed to VFs, neither directly nor via a PF. The following features are available only to PFs or controlled solely by the PF:

- Power management and WoL are PF resources and are not supported per VF.
- Link Control - The link is a shared resource and as such is controllable only by the PF. This includes PHY settings, speed and duplex settings, flow control settings, and so on. Flow control packets are sent using the station MAC Address stored in the EEPROM. The watermarks of the flow control process and the timeout value are also controllable by the PF only. In a DCB environment, the parameters of per-TC flow control and the ETS settings are also PF responsibilities.
- Configuration of Control Domains and Profiles is done solely by the PFs and is not exposed to VFs
- DCB policy and configuration of the device (either via DCBX or otherwise) is not open to VFs' control. A VF can still associate its queues with specific TCs, can request (via its PF) for Tx-Scheduler nodes to be added under specific VFs, and to set the appropriate QoS fields in its transmitted packets.
- Special Filtering Options - Save Bad Packets is a debug feature. As such, Save Bad Packets is available only to the PF. Bad packets are forwarded to a control VSI and thus should not be seen by a VF in regular operation.
- Reception of long packets is controlled separately per queue. As this impacts flow control thresholds, the PF should be made aware of the decisions of all VMs. Because of this, the setup of large send packets is centralized by the PF and each VF might request this setting.

9.2.2.4 Hardware Resources Assignment to VFs

Table 9-10 describes how the E810 shared resources are distributed between different VFs. Details for each type of resource can be found in the relevant section of this document.

Table 9-10. VF Resource Allocation

Resource	Allocation Method	Section Reference
General Resources:		
Tx-Queues and Rx-Queues	Dynamic allocation. Each VF can have a different number of queues (up to 256). Each PF allocates the queues to its VFs and their VSIs. Queue initialization is done by the PF. Following initialization, the VF manages its queues for Tx/Rx operation.	10.2 10.2.2
Admin Queues	An Admin Queue is allocated to each VF to communicate with its PF. The queue accesses a shared mailbox in the device. In SNR-BTS, a DSI VF is allocated multiple mailbox AQs for its device drivers to communicate with each other.	9.5
Interrupt Causes and Vectors	The allocation of interrupt vectors to VFs is fully flexible, loaded from NVM with a limit on the max number of vectors. Assignment of interrupt causes: • Causes for Tx-Queues, Tx-Queues, PE Queues, Admin Queues to interrupt vectors are done by each VF. • Other causes are handled only by the PFs. The PF driver can then propagate the interrupt to the VFs via Admin Queues or some other mechanism. VFs operate with MSI-X interrupts only.	9.1
Transmit Scheduling	The Scheduler Tree can be programmed to assign a subtree to a VF and its resources (for example, to its VSIs, and its queues). The nodes in the sub-tree can be configured with all supported attributes, such as guaranteed bandwidth, rate limiting, and arbitration scheme. Configuration is done by the PF and not directly by the VF.	8.3

Table 9-10. VF Resource Allocation [continued]

Resource	Allocation Method	Section Reference
Stateless Offloads	**Tx:** All the regular transmit offloads, like checksum and TSO, are available to VFs. Enabling these offloads is done by the PF as part of the queue initialization process. **Rx:** All the regular receive offloads, like checksum and header split, are available to VFs. Enabling these offloads is done by the PF as part of the queue initialization process.	10.4.4 (Rx) 10.5.8 (Tx)
Packet Analyzer		
ACLs	A VF can request its PF to add/modify/remove an ACL entry on its behalf. The entry can be potentially associated with the VSI or the VF.	7.9.2
Statistics	The VF is not directly exposed to statistics counters. If a VF needs to get statistics for its traffic, it is done via its PF.	9.6
IEEE 1588	IEEE 1588 is a per-link function and thus is controlled by the PF driver.	
RDMA Resources:		
RDMA Capabilities	32 VFs can have RDMA capabilities. The GLPE_VFPFMAP table is used to map RDMA enabled VFs to the RDMA register sets.	11.10
QPs/CQs/CQEs/SDs	According to the profile of the device, the QP/CQ/CQE/SD resources are distributed evenly between the physical functions supporting iWARP. The resources of a PF can be evenly distributed between the VFs supporting RDMA.	
CSRs	All VFs have a set of registers to control RDMA functionality. However, only 32 of these sets are active. The RDMA register set contains registers in regular VF CSR space. These registers are accessible to the VF driver and provide a common doorbell page accessible to all the userspace processes in the VF.	
Switching Resources:		
Switch Resources	Switch configuration and resource allocation are not done by a VF directly, but through its PF. See more details in the lines below.	7.8
VSIs	Up to 768 VSIs can be directly supported by the E810. These VSI resources are distributed between the different PFs dynamically. Each VF is guaranteed to receive at least one VSI. The PF can allocate multiple VSIs to a VF. There is no limit on the number of VSIs that can be assigned to a VF apart from the limit due to the number of Tx/Rx-Queue pairs the VF is allocated.	7.8.8
Unicast MAC Addresses, Multicast addresses, and VLAN tags	The PF driver is responsible for the resource allocation to its VFs. The E810 does not manage the per-VF resources of the switch. The PF assigns filters to VFs VSI using the admin commands listed in Section 7.8.12.5.2.	7.8.10
Filtering Resources:		
RSS	Directly controlled by each VF. RSS per VSI with either Small or Medium RSS Table.	7.10.7
Flow Director	Flexible population of FD entries with VF rules. Programming is done through the PF or directly by a VF.	7.10.8
Quad Hash Filtering	Each PF allocates a private memory region for itself and its VFs. Each PF populates its private memory region with its VFs' entries. The on-die Quad Hash filter caches entries for both PFs and VFs	7.10.9

9.2.3 Scalable I/O and PASID

Scalable I/O Virtualization is a way to expose thousands of lightweight Assignable Device Interfaces (ADIs) to non-Kernel processes without paying the cost of a lot of SR-IOV functions.

Each ADI exposes part of the fast path interface of the device to a process that can directly define the buffer content with no need of intervention by the regular Kernel driver for par packet processing.

Each ADI has the same trust level as a VF. The address translation of GPA to HPA uses the PASID tag that is appended to all the TLPs associated with a process instead of the BDF used in SR-IOV. The VT-d uses this information to make sure the process is only accessing pages it is allowed to and with the right access type (R/W).

All the malicious driver protections are in effect for queues assigned to VMs via a valid PASID.

9.2.3.1 Assumptions

The capabilities to be exposed as part of an ADI are:

- Tx-Queues (Quanta queues access uses the same PASID as the matching Tx-Queue)
- Rx-Queues
- RDMA QPs
- Interrupts
- A mailbox queue

All other capabilities, such as Doorbell Queues and Completion Queues, are either not used for PASID scenarios, or owned by the PF driver.

9.2.3.2 PASID

PASID is a new capability of PCIe 3.1 that allows identification of DMA traffic belonging to specific flows. It is used by the VT-d engine to do the GPA-to-HPA translation.

9.2.3.2.1 PASID Context

The PASID context is stored per VSI as described below:

- VSI_PASID.*PASID*[19:0]
- VSI_PASID.*EN*[31]

This context is used for all the LAN descriptors and data buffers transactions, and RDMA transactions associated with this VSI.

Note: VSI_PASID.*EN* should not be set for VSIs belonging to a PF that did not enable PASID in its config space.

9.2.3.2.2 PASID Stop Mechanism

The specification requires support of a mechanism to gracefully stop using a specific PASID. The mechanism to support this is disabling of all the queues associated with this PASID.

9.2.3.3 Assignable Device Interface

The following resources can be assigned to an ADI:

- **A mailbox** — Exposed through the 4K page range of mailboxes (32-35 MB).
- **A set of interrupts** — Exposed through the 4K page range of interrupts (48-56 MB).
- **A set of Rx-Queues** — Exposed through the 4K page range of Rx-Queues (56 - 64 MB).
- **A set of Tx-Queues** — Exposed through the 4K page range of Tx-Queues (64 - 128 MB).
- **MSI-X vectors** — Accessible to the PF either through regular MSI-X BAR or through a table in the regular BAR.
- **RDMA QPs** — Using regular user mode RDMA interface.

To be able to access these registers, the BAR0 userspace extension should be enabled by setting GLPCI_LBARCTL.*PAGES_SPACE_EN_PF* bit.

9.3 Host Memory Cache

The E810 uses host memory as backing store for a number of context objects used to track queue state and iWARP objects. The Host Memory Cache (HMC) is the component responsible for managing the iWARP context objects stored in host memory. The HMC manages host memory on a per PCI function basis and further breaks down each PCI function's HMC memory space into memory used to manage each context object that is in use for a given PCI function. Host software is responsible for allocation of the host pages used by the HMC before accessing a specific object. Additionally, the amount of memory that can be used for HMC backing store for a specific function is dictated by the active resource profile, which is determined by the software driver's operating environment and the number of PCI functions that are currently active. Resource profiles can be selected at driver initialization time.

9.3.1 Host Memory Usage

The HMC requires backing store for numerous data structures to be resident in host memory to perform its functions. Table 9-11 provides a list of the data structures and the amount of memory that needs to be allocated for each data structure. The "HMC Object Location" column indicates if the HMC object (and the associated backing store pages) is located only in the PF HMC object space or if it is located in both the PF and the VF HMC object space.

In general, Protocol Engine HMC objects are separated into PF- and VF-specific HMC object spaces. The resources can be sparsely populated. For example, if a function is allotted 512 QPs and only eight are used, only 4K of memory needs to be allocated, not the entire memory for all 512 QPs. Some HMC objects need to be fully populated at driver initialization, such as Protocol Engine Hash Table entries. See Section 11.5 for more information on the HMC resource allocation policies for the Protocol Engine.

Table 9-11. HMC Objects

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
Protocol Engine QP Context	PE-enabled PFs and VFs	512	256K	512 bytes are reserved for QP context. There is a maximum of 256K QP contexts per device. This number is divided amongst all Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). In the case of a single function device, hardware reserves one of the 256K QPs for internal use.
Protocol Engine CQ Context	PE-enabled PFs and VFs	64	512K	64 bytes are reserved for CQ context. There is a maximum of 512K CQ contexts per device. This number is divided amongst all Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Protocol Engine TCP Timers	PE-enabled PFs and VFs	64	2^{28} per PCI function	This structure is allocated per PCI function. The number of elements allocated for this structure is dependent on the number of QPs associated with the PCI function. The equation for the number of objects is: ((ROUNDUP512(number of QPs)/512) + 1) * 4096. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Protocol Engine Hash Table Entry	PE-enabled PFs and VFs	64	(#Protocol Engine QPs + #Multicast Groups) * HTMULTIPLIER per function	This structure is allocated per PCI function. The number of elements allocated for this structure needs to be: (round_up_512(number of QPs + number of Multicast Groups) rounded up to the next power of two) * HTMULTIPLIER. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). The actual number of Hash Table entries for the PF is programmed using the PFQF_PE_CTL1, PFQF_PE_CTL2, VPQF_PE_CTL1, and VPQF_PE_CTL1 registers.
ARP Table Entry	PE-enabled PFs and VFs	16	65536 per PCI function	The maximum size of the ARP table is 65536 entries per Protocol Engine enabled PCI function. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Accelerated Port Bit Vector In-Use	PE-enabled PFs and VFs	8K	1 per PCI function	This table is used for the E810 to track each PCI functions usage of the Accelerated Port Bit Vector Table, and is only required for Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Memory Region Table Entry (MRTE)	PE-enabled PFs and VFs	32	4M per PCI function	Each Protocol Engine enabled PCI function can have up to 4M MRTE entries allocated. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Physical Buffer List Entry (PBLE)	PE-enabled PFs and VFs	8	256M per PCI function	Each Protocol Engine enabled PCI function can have up to 256M PBLE entries allocated. The memory for the VF objects is allocated by the VF driver and accessed using the VF Requester ID (RID). Any associated Page Descriptors are accessed allocated by the PF driver and accessed using the PF RID.

Table 9-11. HMC Objects [continued]

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
Xmit FIFO	PE-enabled PFs and VFs	32	128M per PCI function	Each Protocol Engine enabled PCI function can have up to 128M Xmit FIFO entries per PCI function. Xmit FIFO entries are used to track unacknowledged Protocol Engine Send Queue work requests (WQEs). The number of XMIT FIFO entries to allocate for a given PCI function can be calculated based on expected network performance and workload pattern. Allocating too few XMIT FIFO entries will result in head-of-line blocking for PE QPs running on a particular PCI function. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). Must be specified as a power of two.
Xmit FIFO Free List	PE-enabled PFs and VFs	4	32M per PCI function	Each Protocol Engine enabled PCI function can have up to 32M Xmit FIFO Free List entries per PCI function. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Inbound RDMA Read Queue (IRRQ or Q1)	PE-enabled PFs and VFs	64	128M per PCI function	Each Protocol Engine enabled PCI function can have up to 128M IRRQ entries. IRRQ entries are allocated on a per QP basis and in quanta's of the maximum number of outstanding RDMA Reads that are allowed multiplied by 2. In other words, if a PE-enabled PCI function has 64K QPs enabled and each is allowed up to 64 outstanding RDMA Reads, space for 8M (64K*(64*2)) IRRQ entries (512MB) must be allocated by the driver. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). Must be specified as a power of two.
Inbound RDMA Read Queue (IRRQ or Q1) Free List	PE-enabled PFs and VFs	4	32M per PCI function	Each Protocol Engine enabled PCI function can have up to 32M IRRQ Free List entries. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Read Response FIFO	PE-enabled PFs and VFs	32	128M per PCI function	Each Protocol Engine enabled PCI function can have up to 128M Read Response FIFO entries per PCI function. Read Response FIFO entries are used to track unacknowledged RDMA Read work requests (WQEs). The number of Read Response FIFO entries to allocate for a given PCI function can be calculated based on expected network performance and workload pattern. Allocating too few Read Response FIFO entries will result in head-of-line blocking for PE QPs running on a particular PCIe function. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). Must be specified as a power of two.
Read Response FIFO Free List	PE-enabled PFs and VFs	4	32M per PCI function	Each Protocol Engine enabled PCI function can have up to 32M Read Response FIFO Free List entries per PCI function. The memory of the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Header	PE-enabled PFs and VFs	64	256K	64 bytes are reserved for the QP-specific static data, which is used when building a packet. There is a maximum of 256K Header objects per device (one per QP). This number is divided amongst all Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).

Table 9-11. HMC Objects [continued]

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
Metadata	PE-enabled PFs and VFs	16	8M	128 bytes are reserved for metadata, which is used when building a packet. It is the packet specific, non-static data. There are a maximum of 1M Metadata objects per device. This number is divided amongst all Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Out-of-Order Send Completion (OOISC) FIFO	PE-enabled PFs and VFs	32	256K	32 bytes are reserved for the Out-of-Order Send Completion Object. There is one of these per QP. It is the packet specific, non-static data. This number is divided amongst all Protocol Engine enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Out-of-Order Send Completion (OOISC) FIFO Free List	PE-enabled PFs and VFs	4	256K	Each Protocol Engine enabled PCI function can have up to 256K OOISC FIFO Free List entries. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Multicast Group	PE-enabled PFs	64	8192K per PCI function	Each Protocol Engine enabled PCI Physical Function can have up to 8K multicast groups. Virtual Functions do not have multicast groups. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).
Address Handles	PE-enabled PFs and VFs	64	128K per PCI function	Each Protocol Engine enabled PCI Function can have up to 128K Address Handles. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID).

To access (and cache in on-chip memory) the data structures defined in Table 9-11, the HMC uses the concept of private memory address space. The E810 has an 8GB private memory address space that can be sparsely backed with host memory based on actual context usage. Drivers do not need to allocate pages for HMC objects that are not currently being used by the driver. The private memory address space is first broken down by PCI function, then by object or data structure type, and finally by object index. The portion of the private memory address space that is allocated to a particular PCI function is termed Function Private Memory (FPM). Also note that the VF FPMs are not programmed directly by the VF drivers. The PF driver uses the HMC function index to select the VF FPM to be programmed.

Figure 9-5 shows how the E810 provides the address mapping between Private Memory and Host Physical Addresses. PM address shown on the left side of the figure indicates E810 Private Memory address from 0 to 8GB-1. The E810 works with PM address space internally, which is converted to Host Physical Addresses in order to access host memory.

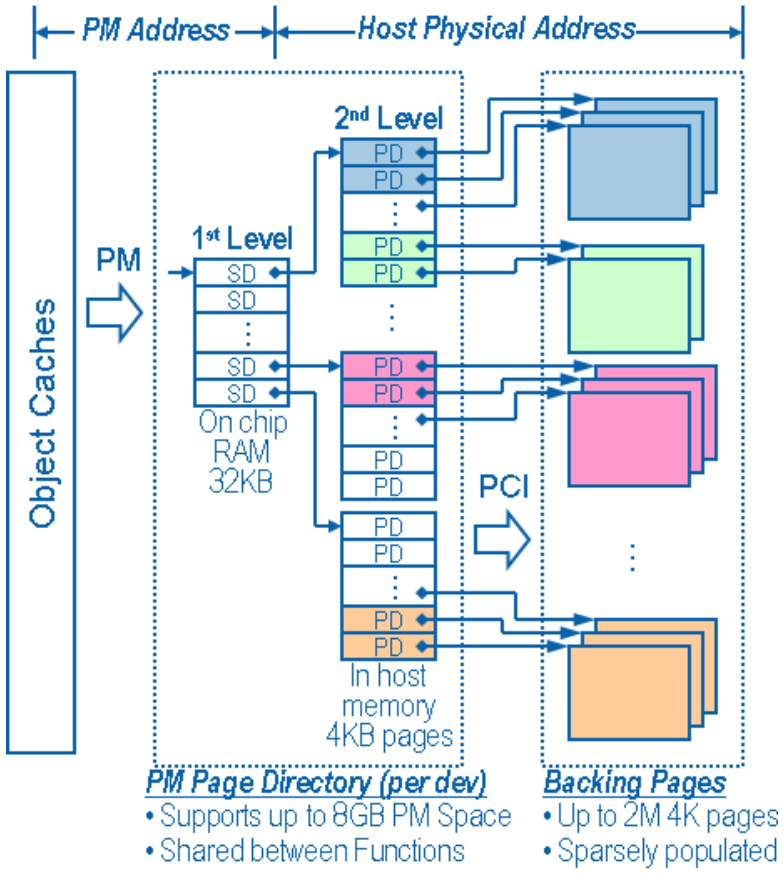

Figure 9-5. Host Memory Cache Private Memory Address Space

See Section 9.3.2 for information on the Quad Hash cache.

The left portion of Figure 9-5 shows portions of the HMC that are resident on-chip. This portion includes the actual object caches that retain portions of the data from host memory to improve performance and the Segment Descriptors (SD). The SDs reside in a 32 KB RAM on-chip called the Segment Descriptor Table. The Segment Descriptor Table holds 4096 pointers to host memory pages. Unique ranges of sequential SDs in the Segment Descriptor Table are allocated to a each PCI function that is active. The Segment Descriptor Table is the first level of private memory address translation provided by the E810. SDs are programmed using the PFHMC_SDCMD (Section 13.2.2.20.35), PFHMC_SDDATALOW (Section 13.2.2.20.36), and PFHMC_SDDATAHIGH (Section 13.2.2.20.37) registers. Protocol Engine CQP operations can also be used to program Segment Descriptors.

Everything to the right of the Segment Descriptor Table in Figure 9-5 resides in host memory. Each PCI function has a set of registers (GLHMC_SDPART[n] and GLHMC_VFSDPART[n]) that define the base and number of SDs that belong to the PCI function. The GLHMC_SDPART[n] and GLHMC_VFSDPART[n] registers are programmed from NVM and can also be programmed by firmware during the Create Control Queue Pair operation (Section 11.5.2.1).

The E810 provides range checking for each internal access to ensure that a given PCI function is never allowed to access memory outside of its valid range of SDs. The E810 manages the SD base and number registers internally based on the resource profile that is either loaded at NVM load or selected by the first E810 driver to load for a device during the Create Control Queue Pair operation (Section 11.5.2.1).

The second level of private memory address translation provided by the E810 is Page Descriptors (PDs). Each SD points to a single host page that is divided into 512 PDs that are simply 64-bit physical memory addresses. Each PD points to a backing page for the private memory address space. The total 8 GB private memory address space is derived using a fully-populated Segment Descriptor Table pointing to 4096 4KB Host pages that hold the 2M PDs. Each of the 2M PDs point to host memory backing pages for a total of 8 GB of address space. As previously mentioned, there is no requirement to populate all SDs or PDs with memory if the portion of private memory address space is not in use by software. The format of the PD structure in host memory is shown in Table 9-12.

Table 9-12. HMC Page Descriptor Format

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:12]	HMC Backing Page Physical Address	[0]	PD_Valid
	[11:1]	Reserved		

The HMC Backing Page Physical Address is the address of a driver allocated page that will hold HMC object context. This address must be aligned to a 4 KB address in host memory. The PD Valid bit allows software to sparsely-populate the PD entries on an as-needed basis once HMC context objects are needed. Software must allocate host memory pages which hold packed arrays of PDs as shown in Figure 9-5. The physical addresses of these PD pages are used to populate SD entries by using the PFHMC_SDCMD (Section 13.2.2.20.35), PFHMC_SDDATALOW (Section 13.2.2.20.36), and PFHMC_SDDATAHIGH (Section 13.2.2.20.37) registers. For more information on how to program SDs using these registers, see Section 9.3.8.

The Private Memory is further divided into separate PCI Function Private Memory (FPM) Addresses. A PCI function can be either a physical function or a virtual function. The first eight FPM address spaces are reserved for NIC PFs. The next eight FPM address spaces are used for PFs that support Protocol Engine provided accelerations for iWARP, RoCEv2, or UDA. The final 32 FPM address spaces are used for VFs that support Protocol Engine provided accelerations for iWARP, RoCEv2, or UDA.

Figure 9-6 shows how the private memory address space is divided up for each PCI function. The smallest amount of private memory that can be allocated to a function is 2 MB (1 SD). The maximum that could be allocated to a function would be the entire segment table, in which case no other function can have any private memory resources. Note that the object caches address HMC objects using HMC function number to determine the correct FPM. The FPM identifies the range of private memory address space that belongs to a PCI function. Since each SD represents 2 MB of HMC PM address space, the FPM also identifies the range of SDs that belong to a PCI function.

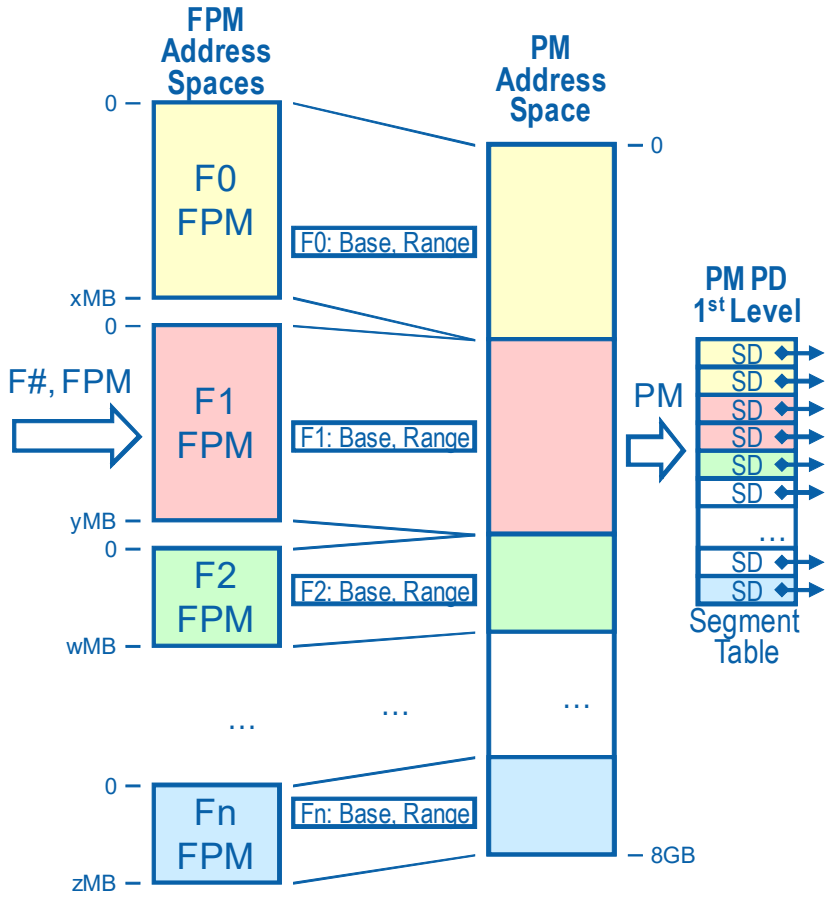

Figure 9-6. Host Memory Cache Function Private Memory Space

Each PCI Function's Private Memory space is further divided into separate memory spaces for each object in host memory. Each PCI function has a set of registers per function that define the object's base address in FPM space and the bounds (or maximum number of entries) of a particular object.

Figure 9-7 depicts some of the current objects that reside in the private memory space (see Table 9-11 for a complete list of the objects). The FPM address is calculated based on the object type (which identifies the object base register) and object index (the FPM base has already been calculated). Ultimately, the FPM base address, object base address, object size, and object index are all used to determine the private memory address.

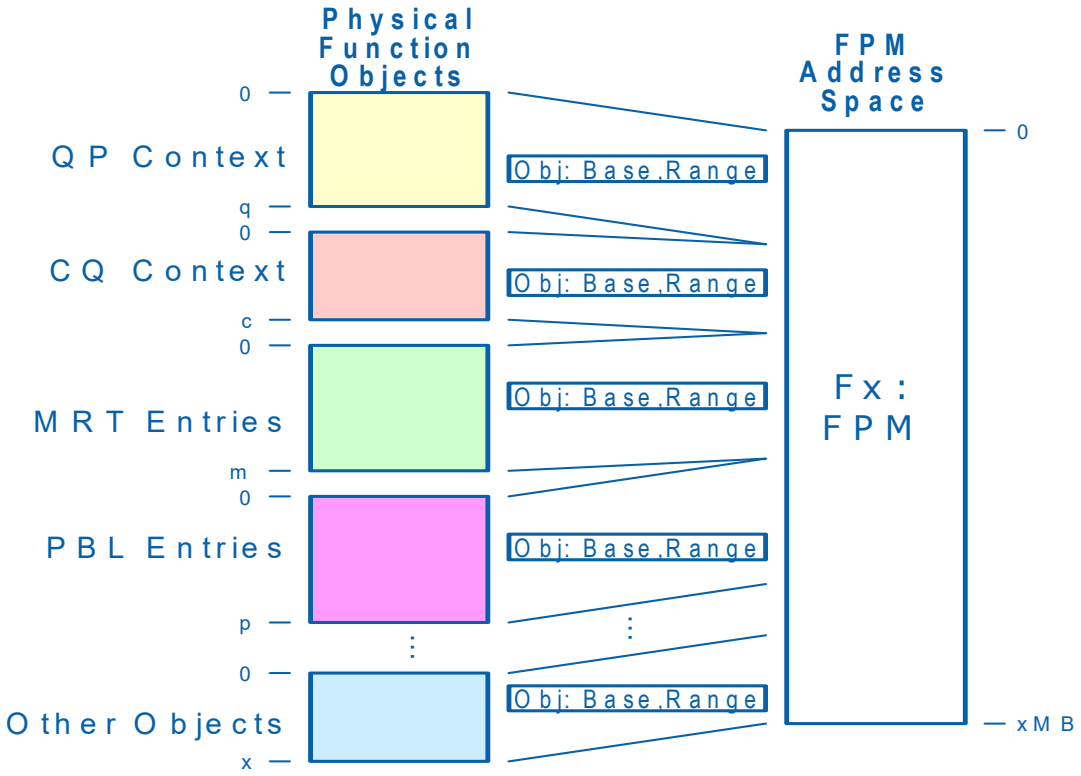

Figure 9-7. Host Memory Cache FPM Object Access

Figure 9-8 describes the decoding of the Private Memory Address into Host Address. Additionally, Figure 9-8 depicts an SD addressing a private memory space backing page directly instead of using the second level of indirect addressing (PD).

Each PCI function can set any SD within its range of SDs to be either pointing to a PD or directly to a backing page. The segment type is specified in the PFHMC_SDDATALOW.*PMSDTYPE* register field. The direct segment approach can be used for PCI functions that do not have large requirement for FPM space to reduce overhead incurred while accessing HMC objects.

Additional usage of the direct segment approach is possible if the driver is able to allocate a physically-contiguous range of pages large enough to hold the entire PD space needed to support the FPM required by the driver loading on a specific PCI function. This mode prevents an additional address lookup and increases the performance if the driver happens to allocate a block of physically-contiguous memory, or the operating system has support for 2 MB pages.

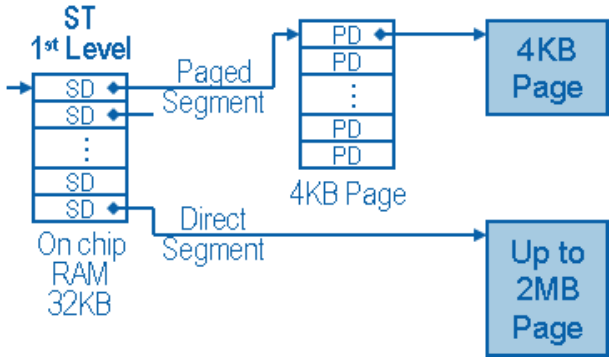

Figure 9-8. Host Memory Cache Direct Segment

See Section 9.3.7 for more details on the specific formats of the SD entries for Paged and Direct addressing modes.

9.3.2 Object Caches

The Host Memory Cache for RDMA is split into two caches. One cache contains all RDMA objects except the Quad Hash entries. The Quad Hash entries are placed in a different cache so they can be referenced by the filtering mechanism.

When Quad Hash objects are added or deleted, the RDMA firmware is responsible for updating the Quad Hash objects in the Quad Hash cache.

The two caches have separate registers, but share the same basic mechanisms. Since there are two components referencing the Quad Hash cache, the registers for both caches must remain consistent.

For more information on the Quad Hash Host Memory Cache (including registers and interrupts) see section Section 9.4.

9.3.3 Private Memory Space Profiles

The E810 private memory address space configuration is a two step process:

1. Partition the HMC-related resources into per PCI function resources.
2. Divide the resulting Function Private Memory (FPM) into individual objects.

To simplify resource allocation, the E810 provides a resource profile concept that takes into account the number of PCI functions, the number of Protocol Engine enabled PCI functions, and the Operating System environment to divide HMC private memory space and Protocol Engine Doorbell resources. These HMC Resource Profiles are used to partition the HMC Segment Descriptor table and Protocol Engine Doorbell resources. Software performs the FPM division on a per PCI function basis. The currently-defined HMC Resource profiles are described in Table 9-13.

Protocol Engine Doorbell resources place constraints on the HMC resource profiles since there is a fixed number of these resources on-die. There are enough doorbell resources for 256K Protocol Queue Pairs and 512K Protocol Engine Completion Queues. These resources must be partitioned between PCI functions that require Protocol Engine functionality. Protocol Engine resources are further discussed in Section 11.1.

The resource profiles drive the values found in the following registers:

- **GLHMC_SDPART** — Configures the HMC Segment Descriptor range per PF.
- **GLHMC_PFPESDPART** — Configures the Protocol Engine HMC Segment Descriptor range per PF.
- **GLHMC_VFSDPART** — Configures the HMC Segment Descriptor range per Protocol Engine enabled VF.
- **GLHMC_DBQPPART** — Configures the range of Protocol Engine QP doorbells per PF.
- **GLHMC_VFDBQPPART** — Configures the range of Protocol Engine QP doorbells per Protocol Engine enabled VF.
- **GLHMC_DBCQPART** — Configures the range of Protocol Engine CQ doorbells per PF.
- **GLHMC_VFDBCQPART** — Configures the range of Protocol Engine CQ doorbells per Protocol Engine enabled VF.
- **GLHMC_CEQPART** — Configures the range of Protocol Engine CEQs per PF.
- **GLHMC_VFCEQPART** — Configures the range of Protocol Engine CEQs per Protocol Engine enabled VF.

These registers are loaded from NVM to match the Default profile. The Protocol Engine firmware can be used to change the programming of these registers to match any of the following resource profiles.

Table 9-13. E810 HMC Resource Profiles

Profile Name	Description
Default	The default profile evenly distributes all HMC Segment Descriptor table entries and Protocol Engine doorbell resources among all active Physical Functions. No Protocol Engine resources are allocated to Virtual Functions. See Section 9.3.5 for more details.
SR-IOV VF Primary	The SR-IOV VF Primary HMC resource profile distributes a relatively small number of HMC Protocol Engine resources to the active PFs, and then evenly distributes the remaining HMC Protocol Engine resources among the Protocol Engine enabled VFs. This resource profile assumes that the Protocol Engine functionality will primarily be used by VFs when running a Virtualized Operating System. See Section 9.3.5.1 for more details.
SR-IOV Even Distribution	The SR-IOV Even Distribution HMC resource profile evenly distributes the HMC Protocol Engine resources among the PFs and Protocol Engine enabled VFs. This resource profile assumes that the Protocol Engine functionality will be used by PFs and VFs when running a Virtualized Operating System. See Section 9.3.5.2 for more details.

Each of these profiles are simply a set of equations that the E810 uses to configure the HMC. This first phase of the HMC initialization is activated by an NVM reload (all settings revert back to the default profile), or by selecting a resource profile when creating a Protocol Engine Control Queue Pair, as specified in Section 11.5.2.1.

Host software will only need to change from the default profile based upon the need for Protocol Engine functionality in a VF. If this is not the case, the default profile covers all usage models. In the case where the Protocol Engine functionality is required in a VF, the driver determines which of the two resource profiles best fits the users needs and selects that profile at driver initialization time.

9.3.4 Host HMC Resource Partitioning

The HMC resource profile can be selected by Expansion ROM code before the operating system loads, and also by the first Protocol Engine driver that loads within the operating system. It is expected that Expansion ROM boot code (PXE, iSCSI) does not need to change the profile, but it can change the profile if needed. Once the Protocol Engine operating system driver loads, it is also allowed to change the HMC resource profile.

9.3.5 Default HMC Profile Equations

The default HMC resource profile distributes all Protocol Engine resources evenly among all active PFs (no Protocol Engine Resources are available for VFs). This includes partitioning the SD table, the Protocol Engine QP and CQ doorbell resources, and the Protocol Engine Completion Event Queues. The number of active Physical Functions is reported in the GLGEN_PCIFCNCNT registers.

Table 9-14. Default HMC Profile Examples

Number of Active PFs	PF Index	SD Base Index	SD Count	PE QP Doorbell Base Index	PE QP Doorbell Count	PE CQ Doorbell Base Index	PE CQ Doorbell Count	PE CEQ Base Index	PE CEQ Count
1	0	Prot Eng: 0	Prot Eng: 4096	0	256K	0	512K	0	768
	1-7	Prot Eng: 0	Prot Eng: 0	0	0	0	0	0	0
2	0	Prot Eng: 0	Prot Eng: 2048	0	128K	0	256K	0	384
	1	Prot Eng: 2048	Prot Eng: 2048	128K	128K	256K	256K	128	384
	2-7	Prot Eng: 0	Prot Eng: 0	0	0	0	0	0	0
4	0	Prot Eng: 0	Prot Eng: 1024	0	64K	0	128K	0	192
	1	Prot Eng: 1024	Prot Eng: 1024	64K	64K	128K	128K	64	192
	2	Prot Eng: 2048	Prot Eng: 1024	128K	64K	256K	128K	128	192
	3	Prot Eng: 3072	Prot Eng: 1024	192K	64K	384K	128K	192	192
	4-7	Prot Eng: 0	Prot Eng: 0	0	0	0	0	0	0
8	0	Prot Eng: 0	Prot Eng: 512	0	32K	0	64K	0	96
	1	Prot Eng: 512	Prot Eng: 512	32K	32K	64K	64K	32	96
	2	Prot Eng: 1024	Prot Eng: 512	64K	32K	128K	64K	64	96
	3	Prot Eng: 1536	Prot Eng: 512	96K	32K	192K	64K	96	96
	4	Prot Eng: 2048	Prot Eng: 512	128K	32K	256K	64K	128	96
	5	Prot Eng: 2560	Prot Eng: 512	160K	32K	320K	64K	160	96
	6	Prot Eng: 3072	Prot Eng: 512	192K	32K	384K	64K	192	96
	7	Prot Eng: 3584	Prot Eng: 512	224K	32K	448K	64K	224	96

The calculation used by the E810 for the number of Segment Descriptors for the Protocol Engine should be SDs (4096) divided by the number of PFs, then rounded down to the next integer. The calculation for the number of PE QPs is the number of PE QPs (256K) divided by the number of PFs, then rounded down to the next full page size that would be needed for context. PE QP context size is 512 bytes per QP.

The calculation for the number of PE CQs is similar, except that the max number of PE CQs is 512K and the CQ context size is 64 bytes.

The PE CEQ calculation is similar to the Segment Descriptor Calculation, except that the number of PE CEQs total is 256 and the maximum number or CEQs for any single PCI function is 768.

Table 9-15 shows the resource counts for all possible PF counts in the Default HMC resource profile assuming that VFs are evenly distributed to active PFs.

Table 9-15. Initial Host Memory Cache Partitioning per PF

PE Count	#PE SDs	#PE QPs	#PE CQs	#PE CEQs
1	4096	262144	524288	786
2	2048	131072	256144	384
3	1365	87376	174762	256
4	1024	65536	131072	192
5	819	52424	104857	153
6	682	43688	87381	128
7	585	37448	74898	109
8	512	32768	65536	96

9.3.5.1 SR-IOV VF Primary HMC Profile Equations

The SR-IOV VF Primary HMC resource profile allocates Protocol Engine resources in favor of the VFs. In this case, the FPM spaces are broken down into two sets:

1. PFs
2. Protocol Engine Enabled VFs

The first eight FPMs are always reserved for PFs even if less than eight PFs are enabled. In the case where less than eight PFs are enabled, some of the FPMs will have zero resources allocated to them.

The next set of FPMs (8-39) are the Protocol Engine Enabled VFs. The maximum number of VFs in this set is 32, but can be limited to less by setting PE Enabled VF Count during the Create Control Queue Pair operation (Section 11.5.2.1).

In this resource profile, all enabled PFs are allocated the following resources:

- 10 SDs for PF Protocol Engine
- 1024 Protocol Engine Queue Pairs
- 2048 Protocol Engine Completion Queues
- 8 Protocol Engine Completion Event Queues

After allocating the resources for the PFs and the NIC VF resources that reside in the PF, the remaining resources are evenly distributed across all Protocol Engine enabled VFs. Assuming that there are two PFs active and 128 VFs (32 of which can be enabled for Protocol Engine support), the HMC resources would be distributed as shown in Table 9-16.

Table 9-16. Example SR-IOV VF Primary Profile Resource Partitioning per FPM

Function Type	FPM Index Range	#SDs	#PE QPs	#PE CQs	#PE CEQs
PF (2)	Prot Eng: 8-9	Prot Eng: 10	1024	2048	8
Inactive PF (6)	Prot Eng: 10-15	Prot Eng: 0	0	0	0
Protocol Engine Enabled VFs (32)	Prot Eng: 16-47	Prot Eng: 127	8128	16256	23
Totals		**4084**	**262144**	**524288**	**752**

The equations for distributing PE QPs and CQs are similar to those used to distribute resources among PFs in the default HMC resource profile.

9.3.5.2 SR-IOV Even Distribution HMC Profile Equations

The SR-IOV Even Distribution HMC profile is used for environments where there is equal need for Protocol Engine resources in the PFs and all Protocol Engine Enabled VFs in operating systems that support I/O virtualization. Typically the number of Protocol Engine enabled VFs is reduced in this profile to allow sufficient Protocol Engine resources for a VF to run HPC workloads.

In this resource profile, all enabled PFs are allocated the following resources:

- 1 SDs for PF NIC
- Remaining SDs/(Active PFs+RDMA Enabled VFs) SDs for Protocol Engine
- 256K/(Active PFs+RDMA Enabled VFs) Protocol Engine Queue Pairs
- 512K/(Active PFs+RDMA Enabled VFs) Protocol Engine Completion Queues
- 256/(Active PFs+RDMA Enabled VFs) Protocol Engine Completion Event Queues

In this resource profile, all enabled VFs are allocated the following resources:

- Remaining SDs/(Active PFs+RDMA Enabled VFs) SDs for Protocol Engine
- 256K/(Active PFs+RDMA Enabled VFs) Protocol Engine Queue Pairs
- 512K/(Active PFs+RDMA Enabled VFs) Protocol Engine Completion Queues
- 256/(Active PFs+RDMA Enabled VFs) Protocol Engine Completion Event Queues

Assuming the two PFs are enabled, 128 VFs are enabled, and 16 Protocol Engine enabled VFs are configured, Table 9-17 shows the distribution of resources to the HMC FPMs.

Table 9-17. SR-IOV Even Distribution Profile Resource Partitioning per FPM

Function Type	FPM Index Range	#SDs	#PE QPs	#PE CQs	#PE CEQs
PF (2)	Prot Eng: 8-9	Prot Eng: 22	14560	29127	42
Inactive PF (14)	Prot Eng: 10-15	Prot Eng: 0	0	0	0
Protocol Engine Enabled VFs (16)	Prot Eng: 16-31	227	14560	29127	42
Totals		**4088**	**262080**	**524286**	**756**

9.3.6 Function Private Memory Space

Once NVM has set the default profile or the profile was changed during the Create Control Queue Pair operation (Section 11.5.2.1), the driver can then continue on with the second step of HMC configuration, which is to break down the FPM space into individual object regions. To do this, the driver must perform the following steps:

1. Determine the HMC function index to be configured. In the case of a PF, the HMC function number is equal to the PCI function number. In the case of a VF when the Protocol Engine resources are configured, the HMC index depends on the programming of the HMC PM Function table using the CQP Manage HMC PM Function Table operation. See Section 11.5.3.3 for more information on the CQP operation.

   Note: There are two arrays defined for each HMC FPM register. One array for PFs and a second array for the Protocol Engine enabled VFs.

2. For Protocol Engine objects, read the current HMC configuration information to determine how to calculate the numbers of each HMC object that needs to be requested.

   a. The GLHMC_SDPART[n] (or GLHMC_VFSDPART[n] in the case of a Protocol Engine enabled VF) register associated with the HMC FPM reports the currently available SDs for a given PCI function, which can be used to calculate the maximum FPM space.

   b. GLHMC_DBQPPART[n] (or GLHMC_VFDBQPPART[n] in the case of a Protocol Engine enabled VF) reports the maximum number of Protocol Engine QPs that can be used. The driver does not have to allocate maximum FPM space based on PMDBMAXQP if less QPs are needed for the active driver deployment model.

   c. GLHMC_DBCQPART[n] (or GLHMC_VFDBCQPART[n] in the case of a Protocol Engine enabled VF) is used to determine the maximum number of Protocol Engine Completion Queues that can be used by a given PCI function. Similarly to the maximum QP count, the driver is not required to allocate the maximum amount of FPM space for CQs if the driver deployment model requires less.

   d. GLHMC_CEQPART[n] (or GLHMC_VFCEQPART[n] in the case of a Protocol Engine enabled VF) is used to determine the maximum number of Protocol Completion Event Queues that can be used with a given PCI function.

      Note: Protocol Engine CEQs do not consume FPM space, but are still partitioned as part of the HMC resource profiles.

   e. Other object maximum values are found in the registers named GLHMC_{object}MAX. See Table 9-18 for the specific register names.

3. Each FPM object size register is written with the minimum of the values determined in Step 2 or the actual driver needs.

For Protocol Engine objects, issue the Commit FPM Values CQP operations to program the object base registers.

Table 9-18 describes all the HMC objects and the registers used to determine the object location within Function Private Memory space, the size, and limit of each object.

Table 9-18. FPM Object Registers

HMC Object	Base Register Array	Object Counter Register Array	Maximum Object Count Register	Object Element Size Register
Protocol Engine QP Context	GLHMC_PEQPBASE GLHMC_VFPEQPBASE	GLHMC_PEQPCNT GLHMC_VFPEQPCNT	GLHMC_DBQPMAX	GLHMC_PEQPOBJSZ

1. For PFs, the sum of PFQF_PE_CTL1.PEHSIZE and PFQF_PE_CTL2.PEDSIZE must be smaller than or equal to GLHMC_PEHTCNT. For VFs, the sum of VPQF_PE_CTL1.PEHSIZE and VPQF_PE_CTL2.PEDSIZE must be smaller than GLHMC_VFPEHTCNT.

9.3.6.1 Programming the HMC FPM Base Registers

All settings of FPM registers impact only the function associated with the registers. In other words, the driver on a given PCI function must program only the GLHMC_{object}CNT and GLHMC_{object}BASE registers for HMC PMs that are owned by that same PCI function or HMC PMs that are associated with Protocol Engine enabled VFs that the PF owns. The FPM base of the first HMC object for each PCI function is always 0. The FPM base of subsequent HMC objects increment from previous HMC object base, the number of elements for the previous HMC object, and the size of the previous HMC object element. Additional rounding is necessary to get to the next FPM address that is properly aligned for the HMC object under consideration.

Table 9-19 shows the FPM object order that must be maintained for proper HMC operation and the alignment requirements for each object.

Table 9-19. FPM Object Order and Alignment

HMC Object Order	HMC Object	Alignment Requirement
1	RSVD	
2	Protocol Engine QP Context	2MB (Must be start of an SD)
3	Protocol Engine CQ Context	512B
4	Protocol Engine Hash Table Entry	512B
5	ARP Table Entry	512B
6	Accelerated Port Bit Vector In-Use	512B
7	Memory Region Table Entry (MRTE)	512B
8	Xmit FIFO	512B
9	Xmit FIFO Free List	512B
10	Inbound RDMA Read Queue (IRRQ or Q1)	512B
11	Inbound RDMA Read Queue (IRRQ or Q1) Free List	512B
12	Protocol Engine TCP Timers	512B
13	Physical Buffer List Entry (PBLE)	512B (4KB for VFs, handled by CQP firmware)
14	Multicast Group	512B
15	Address Handles	512B
16	Read Response FIFO Free List	512B
17	Read Response FIFO	512B
20	Header Information	512B
21	Metadata	512B
22	Out-of-Order Send Completion (OOISC) FIFO	512B
23	Out-of-Order Send Completion (OOISC) FIFO Free List	512B

The special case of Protocol Engine QPs must be rounded up to the next SD boundary. The base registers for Protocol Engine Objects (indexes 4 and up) can be set using the Commit FPM Values CQP operation.

Note: The driver can choose to set the GLHMC_{obj}CNT register to 0 if it does not need to utilize an object.

9.3.7 Populating HMC Backing Pages

Once the HMC resource profile has been picked (Section 9.3.3) and the Function Private Memory space has been programmed (Section 9.3.6), the driver must populate the HMC backing pages for the PCI function that it is initializing. The first step in this phase of initialization is to allocate 4KB pages for the PDs. Each 4KB PD page holds 512 PDs and occupies a single SD entry. Once a 4KB page has been allocated, initialized to zero, and pinned by software, the PFHMC_SDCMD (Section 13.2.2.20.35), PFHMC_SDDATALOW (Section 13.2.2.20.36), and PFHMC_SDDATAHIGH (Section 13.2.2.20.37) registers are used to populate the SD table for the PCI Function. Protocol Engine enabled VFs use the GLHMC_VFSDCMD[n], GLHMC_VFSDDATALOW[n], and GLHMC_SDDATAHIGH[n] registers, where n is the HMC Virtual Function index. Protocol Engine related SDs are programmed using the Update Protocol Engine SDs CQP operation.

A driver on a given PCI function mus manipulate only SD table entries that are allocated for that PCI function via the SD partitioning process that involved picking an HMC resource profile. SDs are addressed on a per PCI function basis starting at 0, and is limited by GLHMC_SDPART[n].*PMSDSIZE*. In other words, software is not aware of the actual portion of the SD table that it is using. Accesses outside of the SD range configured by NVM or a HMC resource profile using the PFHMC_SDCMD or GLHMC_VFSDCMD registers is ignored (operation is not performed) by the E810, and an error is returned in the completion for the operation that is in error.

The second step in this phase of driver initialization is to allocate additional host pages for backing HMC FPM objects for use by the E810 before the driver attempts to access the object. The breakdown of the FPM address into components is shown in Table 9-19.

Direct-mapped pages in the VF object cache must be fully populated for the entire 2MB space of the SD.

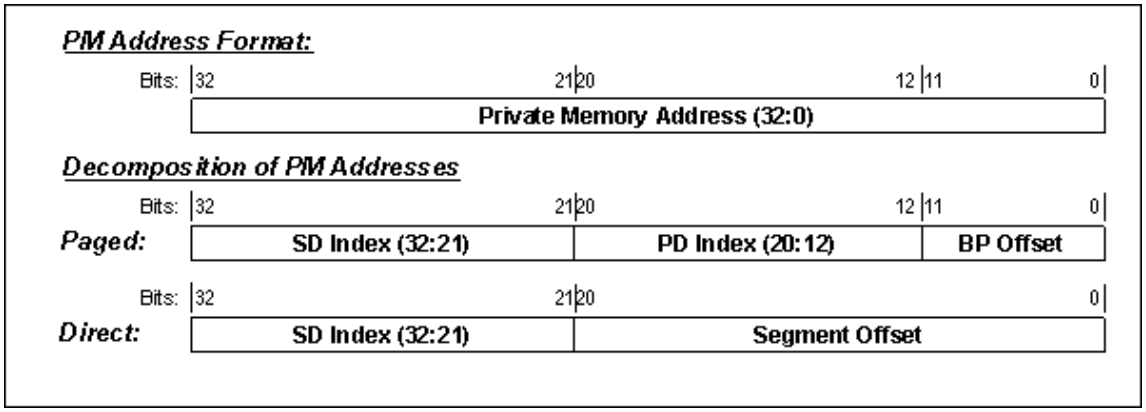

Figure 9-9. FPM Address Decomposition

The identification of which SDs to populate and which HMC FPM backing pages to populate in the PD pages can be calculated as follows in the paged scenario:

FPM_object_address = (GLHMC_{object}BASE * 512) + ($2^{GLHMC\_\{object\}OBJSZ}$ * element_index)

SD_index = INT(FPM_object_address / 2MB)

PD_index = INT(FPM_object_address / 4KB) & 0x1FF

HMC_PM_index = PF index or the HMC VF FPM index

Following is an example of populating the backing pages the HMC, assuming that a driver wants to allocate FPM backing pages for 1024 Protocol Engine QPs starting at index 8 assuming no previous SDs for Protocol Engine QPs had been allocated:

1. Allocate one PD page (capable of holding 512 backing pages of 4KB each).
2. Identify the first SD necessary:
   a. FPM_object_address = (GLHMC_PEQPBASE[HMC_PM_index] * 512) + ($2^{GLHMC\_PEQPOBJSZ}$ * 8)
   b. FPM_object_limit = FPM_object_address + ($2^{GLHMC\_PEQPOBJSZ}$ * 1024)
   c. SD_index = FPM_object_address / 2MB
   d. Last_SD_index = (FPM_object_limit - 1) / 2MB
3. Allocate, zero, and pin a host memory page (PD page) for each SD needed from SD_index to Last_SD_index.
4. Calculate the number of PDs that need to be allocated:
   a. FPM_PD_index = (FPM_object_address / 4KB) & 0x1FF
   b. FPM_PD_limit_index = (FPM_object_limit - 1) / 4KB) & 0x1FF
   c. FPM_PD_count = FPM_PD_limit_index + 1 - FPM_PD_index
5. Initialize the PDs:
   a. Allocate/zero/pin FPM_PD_count pages (these are the FPM object backing pages).
   b. Initialize each of the PDs with the physical address of a page allocated in Step 5a and set the PD valid bit (see Table 9-12 for the format). The PDs are in the PD pages allocated in Step 3.
6. Update the SD table using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers for each PD page allocated in Step 3 (if the PDs are associated with a Protocol Engine enabled VF, the GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index], and GLHMC_VFSDDATAHIGH[HMC_PM_index] registers must be used). These registers are programmed via the Update Protocol Engine SDs CQP operation for backing pages related to Protocol Engine objects.
   a. Write the most significant 32 bits of the physical address of the PD page to the PFHMC_SDDATAHIGH register.
   b. Write the last significant 32 bits of the physical address of the PD page to the PFHMC_SDDATALOW register, ensuring that the lower 12 bits are 0.
   c. Write 512 to PFHMC_SDDATALOW.*PMSDBPCOUNT*. If this was the last SD of the FPM, the value might be lower than 512, but PE QPs are in the middle of FPM space so the value must be 512. The *PMSDBPCOUNT* field is used by the E810 to calculate the end of the FPM space without having to read the valid bit for each individual PD entry.
   d. Write 0 to PFHMC_SDDATALOW.*PMSDTYPE*.
   e. Write 1 to PFHMC_SDDATALOW.*PMSDVALID*.
   f. Write PFHMC_SDCMD with *PMSDIDX* set to the proper SD index value and *PMSDWR*=1.

When this process is complete for typical configurations, the second SD is populated with the address of a single PD page, and entries 1-129 are populated with the address of the 128 FPM object backing pages that have been allocated.

9.3.8 De-Populating HMC Backing Pages

The process of de-populating and freeing HMC object backing pages is as follows:

1. Ensure that software and hardware are not going to access objects in the pages.
2. Calculate the SD range and/or PD range that provide the address mapping to the E810.
3. Update the associated PD entries.
4. Invalidate the on-die PD cache entries using the PFHMC_PDINV (or GLHMC_VFPDINV[HMC_PM_index]) register.
5. Update the SDs using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers to notify the E810 that the pages are no longer valid for use. If the PDs are associated with a Protocol Engine enabled VF, the GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index], and GLHMC_VFSDDATAHIGH[HMC_PM_index] registers must be used. These registers are programmed via the Update Protocol Engine SDs CQP operation for backing pages related to Protocol Engine objects.

9.3.8.1 Removing a Backing Page

Once software has determined that a backing page is no longer needed, the software must clear the *PD_Valid* bit (see Table 9-12) in the PD entry that references the backing page. After clearing the *PD_Valid* bit in the PD in host memory, software must then write the PFHMC_PDINV register with the SD index and PD index of the newly-invalidated PD entry. This is to ensure that references to the invalid PD entry have been removed from any E810 cache. Once this write is complete, the backing page can be freed by software. The write to the PFHMC_PDINV register is not required for direct SDs since there is not a PD involved in addressing the HMC backing pages. If the backing pages are associated with a Protocol Engine enabled VF, the GLHMC_VFPDINV[HMC_PM_index] register must be used.

9.3.8.2 Removing a Page Descriptor Page

Once software has determined that an entire PD page is no longer needed, the PFHMC_SDDATALOW register must be written with PFHMC_SDDATALOW.*PMSDVALID* set to 0, and then the PFHMC_SDCMD register must be written with *PMSDIDX* set to the proper SD index value and *PMSDWR*=1. Once this sequence is complete, software is free to deallocate or re-use the PD page. If the PDs are associated with a Protocol Engine enabled VF, the GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index], and GLHMC_VFSDDATAHIGH[HMC_PM_index] registers must be used. These registers are programmed via the Update Protocol Engine SDs CQP operation for backing pages related to Protocol Engine objects.

9.3.9 Special Cases for Protocol Engine Objects

Since there are less HMC VF FPM spaces than there are VFs, there is a mapping required that is described in Section 9.3.9.1.

9.3.9.1 Virtual Function Support

The HMC supports eight HMC FPM spaces that are dedicated to PFs (index 0-7) and 32 HMC FPM spaces that are available for VFs. Since there are less HMC FPM VF spaces available than actual VFs for the E810, a mapping is required. The virtual function mapping is performed by CQP firmware using the Manage HMC PM Function Table operation found in Section 11.5.3.10.

9.3.10 HMC Error Reporting

HMC-related errors are reported through the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. The *HMC_ERR* interrupt status bit in the PFINT_OICR register can also deliver an interrupt for HMC errors if the interrupt is enabled in the PFINT_OICR_ENA register. When the HMC detects an error, it sets the PFHMC_ERRORINFO.*ERROR_DETECTED* bit along with the relevant information in the other fields of the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. No further notification of subsequent HMC errors associated with any given PF are issued until the current error is acknowledged by writing a 0 to the PFHMC_ERRORINFO.*ERROR_DETECTED* bit.

Table 9-20 describes the errors detected for each HMC object and the behavior associated with each error.

Table 9-20. HMC Errors

HMC Object	Error Type(s)	Error Behavior
Protocol Engine QP Context	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the PE QP is reported in the PFHMC_ERRORDATA register. Packets associated with the QP are dropped. Protocol Engine Asynchronous Events are not reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the PE QP object is reported in the PFHMC_ERRORDATA register. Packets associated with the QP are dropped. Protocol Engine Asynchronous Events are not reported.
Protocol Engine CQ Context	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the PE CQ is reported in the PFHMC_ERRORDATA register. Completions for all QPs associated with the CQ are dropped. Protocol Engine Asynchronous Events are not reported.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The Private Memory Address of the PE CQ object is reported in the PFHMC_ERRORDATA register. Completions for all QPs associated with the CQ are dropped. Protocol Engine Asynchronous Events are not reported.
Protocol Engine TCP Timers	• PMF Invalid • Invalid PMF Index • HMC Object Index Too Large	The index of the PE timer object is reported in the PFHMC_ERRORDATA register. Timer operation associated with the function will go idle. Host software is responsible for cleaning up all Protocol Engine resources associated with the PCI function and reporting a fatal adapter error to the RDMA protocol stack.
	• HMC Private Memory Address Too Large • Segment Descriptor Invalid • Segment Descriptor Too Small • Page Descriptor Invalid	The index of the PE timer object is reported in the PFHMC_ERRORDATA register. Timer operation associated with the function will go idle. Host software is responsible for cleaning up all Protocol Engine resources associated with the PCI function and reporting a fatal adapter error to the RDMA protocol stack.

Table 9-20. HMC Errors [continued]

HMC Object	Error Type(s)	Error Behavior
