In a simple port aggregator mode, there is no change to the Ethernet frame format. During the ingress direction, the operation is similar to VEB, the packets are forwarded to the VMs by querying into the forwarding database in the embedded switch. In the egress direction all traffic including the VM-to-VM traffic is forwarded the external switch. The external switch performs lookup on the packets and turns-around the packet back to the end node (called reflexive relay service or hairpin forwarding) if the packet has to go to another VM residing in the same end station. Since all packets flow through the external switch, all advanced features of the external switch (such as advanced ACLs and flow monitoring features) are available for VM-to-VM traffic. However, the bandwidth of the uplink is shared between the VM-to-VM traffic and the uplink traffic; also there is additional latency for externally switched VM-to-VM traffic.

In port aggregator mode, hardware performs broadcast and multicast replication functions. During multicast and broadcast, the packet is forwarded by the external switch once to the end station and the port aggregator in the 10 GbE controller replicates the packet multiple times to all the multicast member VMs attached to the port aggregator.

The VSIs of a port aggregator can be directly connected to the VMs through PCIe functions or VFs in SR-IOV mode. A cascaded port aggregator configuration is also allowed where a software based port aggregator in VMM can be connected through one of the virtual ports. In this case, the port is designated as a cascaded port (See Section 38.21.7.2.4).

The discovery and configuration of port aggregator mode is handled by a software port aggregator control agent residing in the VMM. The hardware switch element is managed through a set of APIs accessible to the port aggregator control agent.

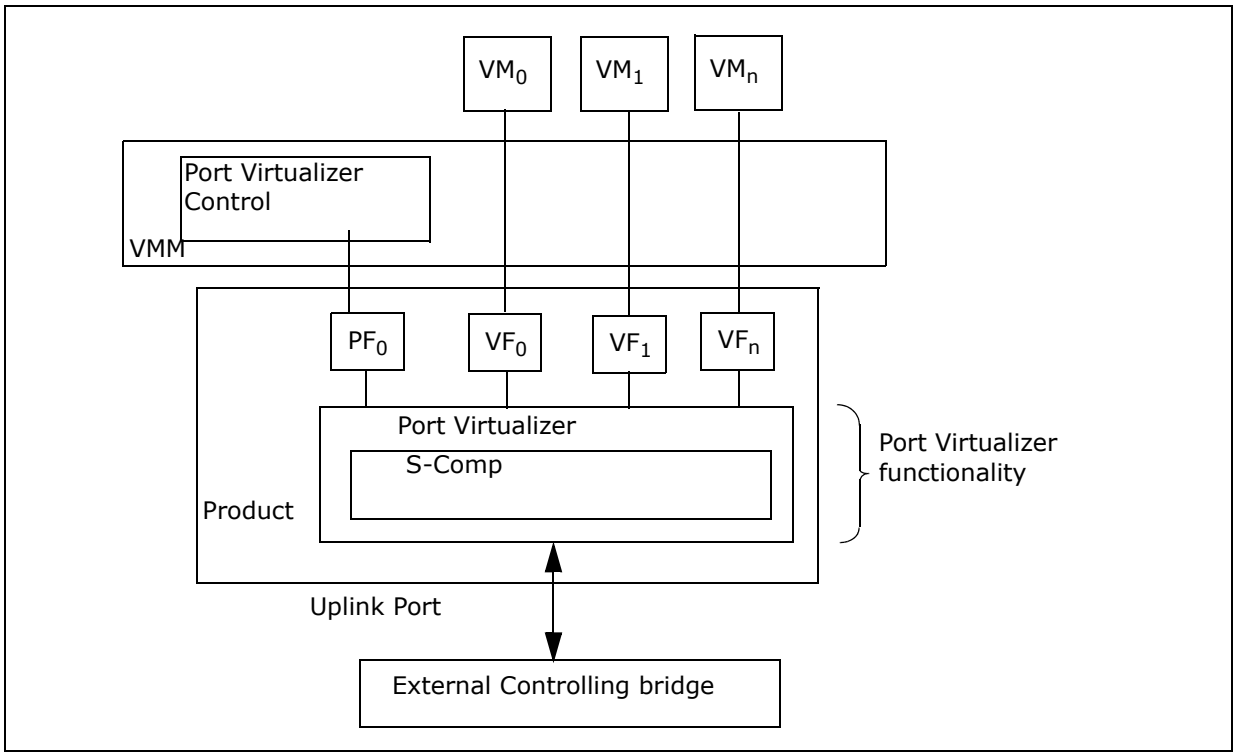
Port Virtualizer Model

There are two ways to divide the link to channels:

- A port mapping S-VLAN component (S-comp) defined in the IEEE 802.1Qbg specification. The S-comp uses S-tags (EtherType = 0x88A8) to define S-channels that do not support replication. See S-comp Model and Service-VLAN Component (S-comp) for more detail.
- A port mapping based on MAC address. This mode is used when a function is dedicated to storage function and uses a small and exclusive set of MAC addresses. This mode supports two channels only. A storage channel and a default channel receive all the other traffic. See Section 38.21.7.3.

The following figure shows the hardware switch element in the 10 GbE controller configured to operate in S-comp configuration.

Figure 38-37.External Switching Configuration — Port Virtualizer



S-comp Model

In an S-comp port virtualizer configuration, the controlling bridge's ports are logically extended to the virtual stations (or VMs). A physical port in the controlling bridge is configured to have multiple logical channels (or logical ports), typically one per VM. Correspondingly the physical port in the end node is also configured to have same number of logical channels (or logical ports) that are associated with VMs. The packets need to explicitly carry a tag to identify the logical channels (or logical ports). An S-component (service VLAN component) is configured to provide this multi-channel capability. The S-tag indicates a logical channel or logical port on the controlling bridge. In this mode of operation, each VSI in the hardware switching element is associated with a logical channel in the S-component.

Connection to the Host

The VSIs of a port virtualizer can be directly connected to the VMs through PCIe functions or VFs in SR-IOV mode. A cascaded port virtualizer configuration is also allowed where a software-based port virtualizer in VMM can be connected through one of the virtual ports. In this case, the port is designated as a cascaded port (See Section 38.21.7.2.4). The discovery and configuration of port virtualizer mode is handled by a software port virtualizer control agent residing in the VMM. The hardware switch element is managed through a set of APIs accessible to the port virtualizer control agent in VMM or IOVM.

38.21.7.2.3 Coexistence of Internal/External Switch Configurations

Both internal and external switching configurations can coexist within an end station accessible through the same uplink port. Legacy VMs or applications that need higher performance for VM-to-VM traffic requires VEB functionality to perform internal switching. In such usage models, the VEB coexists with either a port aggregator or port virtualizer in the same end station.

The following figure shows a combination of VEBs with a port aggregator.

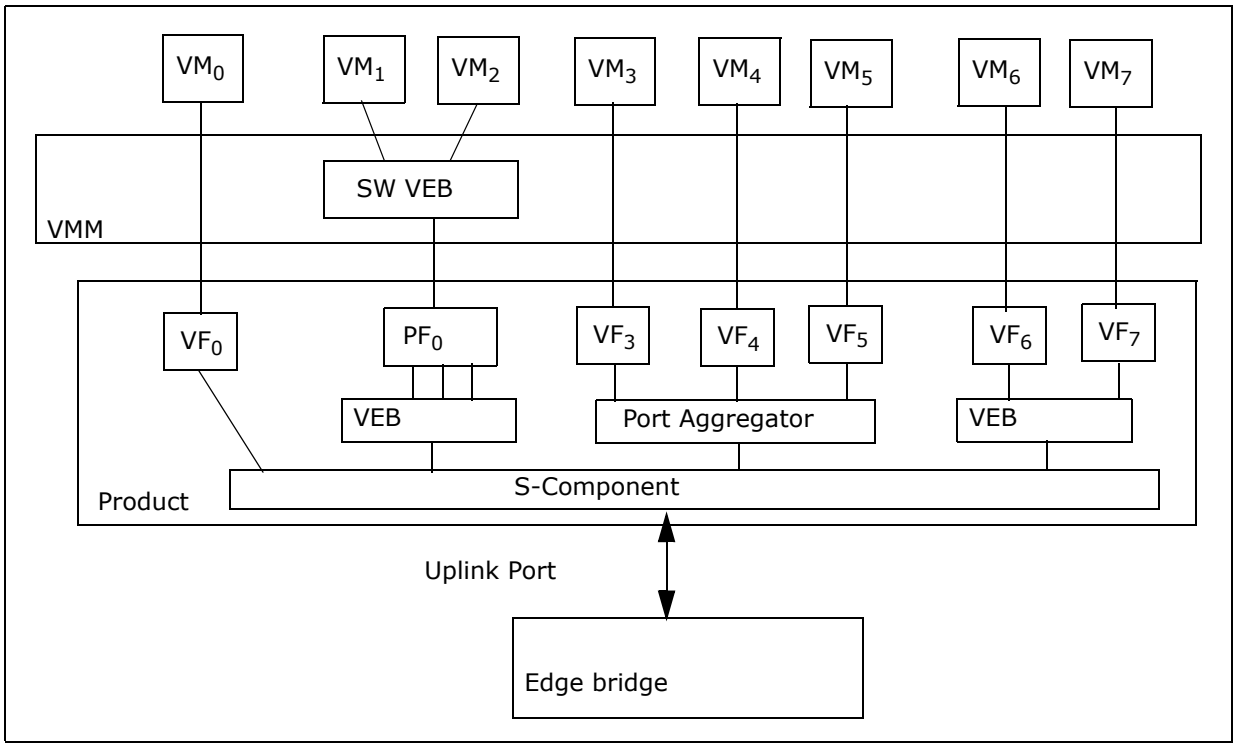
In this configuration, multiple switching elements are instantiated in the 10 GbE controller on the same uplink port. Each instance is accessible through a multi-channel S-component. The S-component is used to mux/demux multiple logical channels (S-channels) from the same physical port. The S-tag identifies the logical channels (S-channels) or logical ports that are extended from the adjacent bridge.

In this example configuration, the legacy VMs are connected through a software-based VEB connected through one of the S-channel ports. A second VM (that hosts a virtual appliance) is directly connected to the external switch through the second S-channel port. In addition, a port aggregator is configured through the third S-channel port that provides external switching functionality to VMs. Certain higher performance applications that require heavy VM-to-VM traffic (such as co-located front end and mid tier application servers) are configured through directly connected VFs to an embedded bridge. This embedded bridge is accessible through fourth S-channel port.

Discovery and configuration of individual switching components is performed through appropriate control agents in the VMM or IOVM.

The configuration of the switch is done using the CDCP protocol as defined in 802.1Qbg specification.

Figure 38-38.Cascaded VEB



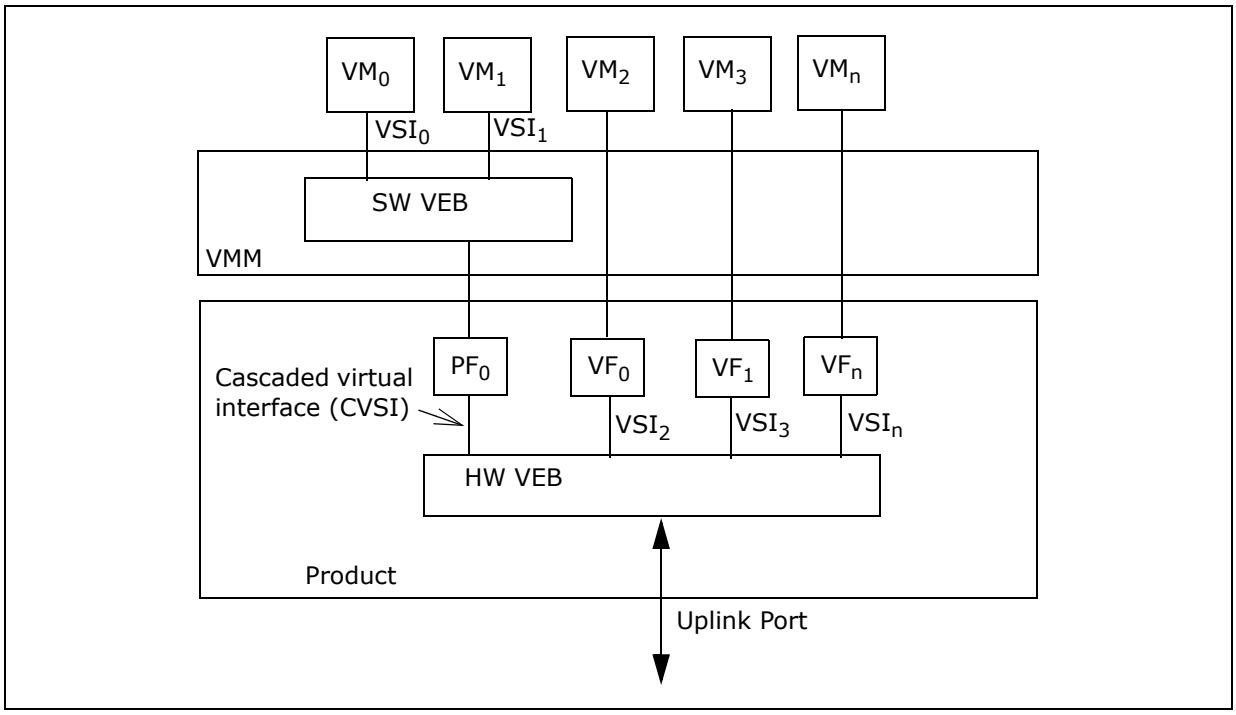
38.21.7.2.4 Cascading of Software VEBs, Port Aggregators and Port Virtualizers

Software-based VEBs, port aggregators and port virtualizers could be cascaded over hardware-based VEBs, PVs and PAs in the NIC. This section provides illustrations of typical cascaded configurations allowed by the 10 GbE controller.

Cascaded Hardware and Software VEBs

The following figure shows a software VEB cascaded over a hardware VEB.

Figure 38-39.Cascaded



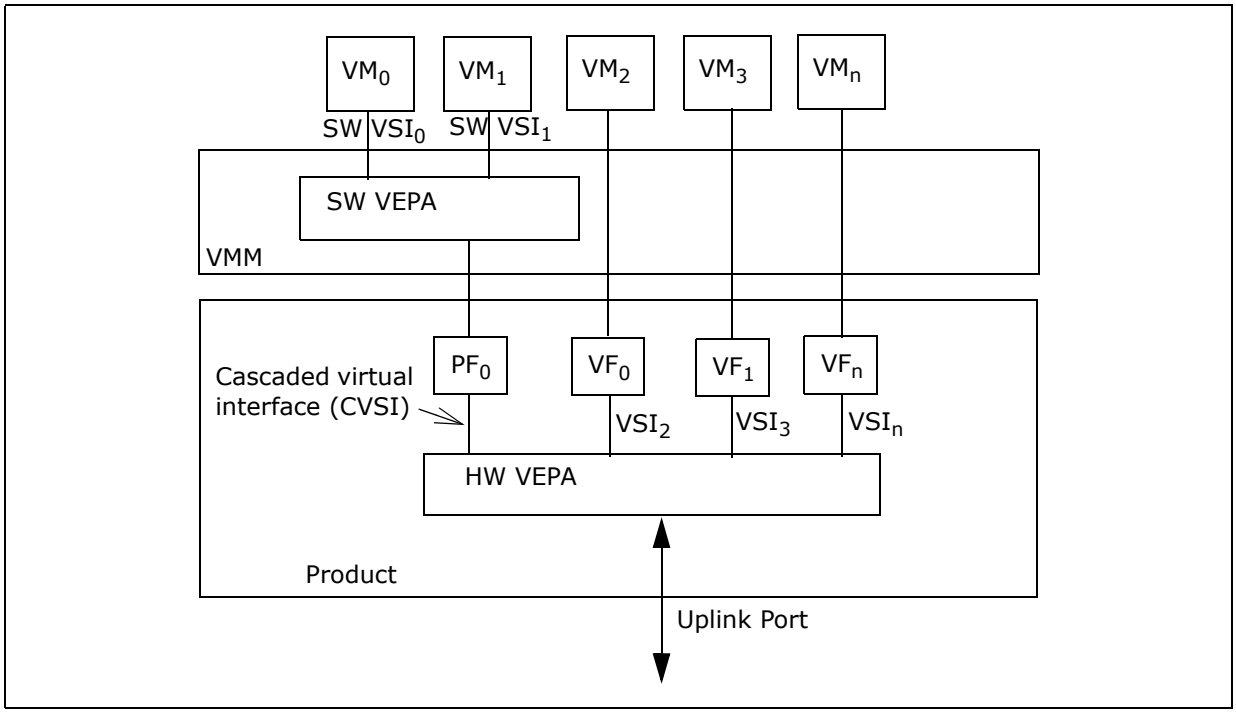
In this configuration, a hardware VEB is instantiated in the 10 GbE controller controller. The VEB is configured with multiple VSIs. A VSI refers to a connection between the VEB and a virtual end station and its associated resources such as MAC address, VLAN, BW/QoS attributes etc. Typically a VSI is configured with a single MAC address and VLAN. A software VEB is configured in the VMM and the connection between the software VEB and a port in the hardware VEB is referred to as a cascaded VSI (or simply a downlink port). The cascaded interface is a special VSI that is used as a downlink to a software VEB. This type of port is referred to as a trunk port in typical Ethernet switches. The downlink ports are typically configured with multiple MAC addresses and multiple VLANs serviced by the software VEB. Security features such as MAC anti spoofing and VLAN ingress checks should not be configured on the downlink ports since those functions are performed at the ingress VSIs of the software VEB.

The 10 GbE controller can be configured to perform VLAN offload functions on the downlink VSIs. In this case, the VLAN information is carried in the transmit descriptor and the 10 GbE controller inserts the VLAN in the transmit direction. The 10 GbE controller can strip the VLAN in the receive direction and store the VLAN tag information in the receive descriptor.

Cascaded Hardware and Software Port Aggregators

The following figure shows a software VEPA cascaded over a hardware VEPA.

Figure 38-40.Cascaded Virtual Ethernet Port Aggregator (VEPA)



In this configuration, a hardware VEPA is instantiated in the 10 GbE controller controller. The hardware VEPA is configured with multiple VSIs. A software VEPA is configured in the VMM and the connection between the software VEPA and a port in the hardware VEPA is referred to as a cascaded VSI (or simply a downlink port). The cascaded interface in this case is a special VSI that is used as a downlink to a software VEPA. The only cascaded configuration allowed over a hardware VEPA is a software VEPA. A software VEB cannot be cascaded over a hardware VEPA because this configuration is not allowed by the IEEE P802.3bg specification.

The downlink ports in a VEPA are similar to a VEB trunk port (see Cascaded Hardware and Software VEBs) except that multicast source address pruning functionality specified by IEEE P802.3bg is not configured on a downlink port to a software VEPA; this functionality is performed at the egress of the software VEPA VSIs connected to the VMs.

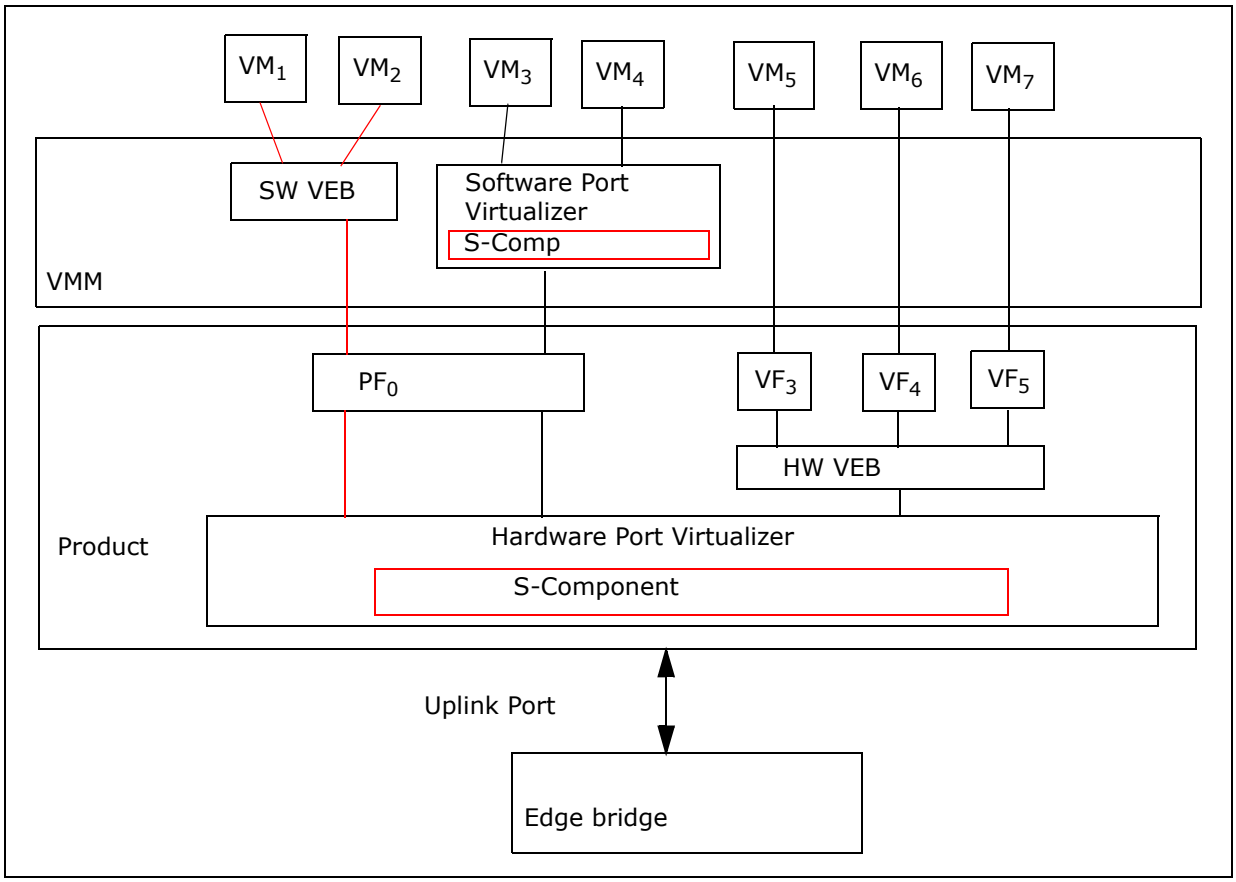
Security features such as MAC anti-spoofing and VLAN ingress checks should not be configured on the downlink ports since those functions are also performed at the ingress VSIs of the software VEPA.

The 10 GbE controller can be configured to perform VLAN offload functions on the downlink VSIs. In this case, the VLAN information is carried in the transmit descriptor and the 10 GbE controller inserts the VLAN in the transmit direction. The 10 GbE controller can strip the VLAN in the receive direction and optionally store the VLAN tag information in the receive descriptor.

Cascaded VEB and Port Virtualizers

The following figure shows a software VEB, hardware VEB and a software port virtualizer cascaded over a hardware port virtualizer. A port virtualizer logically extends the ports of an external bridge to virtual end stations as explained in Port Virtualizer Model. The 10 GbE controller supports a hardware-based port virtualizer for directly connecting virtual end stations to extended bridge ports using VFs in SR-IOV configuration.

Figure 38-41.Cascaded VEB and Port Virtualizer



Cascaded Software Port Virtualizer over a Hardware Port Virtualizer

The 10 GbE controller supports cascading a software-based port virtualizer in VMM to the hardware-based port virtualizer in the network controller. A software port virtualizer is configured in the VMM and the connection between the software port virtualizer and a port in the hardware port virtualizer is referred to as a cascaded VSI (or simply a downlink port). The cascaded interface in this case is a special VSI that is used as a downlink to a software port virtualizer. A VSI connection between a VM and a port virtualizer uses a single S-tag to identify the logical bridge port. However, a cascaded VSI (downlink port) connected to a software-based port virtualizer carries traffic to multiple software-based VSIs serviced by the software port virtualizer. So multiple S-tags need to be configured on this downlink VSI. Receive multicast replication functionality and source pruning functionality should be disabled on these downlink ports.

The 10 GbE controller supports VLAN and S-tag offload functions for software-based port virtualizers connected to the downlink VSI. The 10 GbE controller performs S-tag and VLAN tag insertion functionality on transmit direction and can optionally strip the VLAN tag and S-tags in the receive direction. In this case, the VLAN tag and S-tag information is carried in the transmit descriptor and the 10 GbE controller inserts the VLAN tag and S-tag in the transmit direction. The 10 GbE controller can strip the VLAN tag and S-tag in the receive direction and store the VLAN and S-tag information in the receive descriptor.

The 10 GbE controller can also classify ingress frames based on S-tag and forward to selected queues within the downlink VSI connected to software port virtualizers (similar to VMDq1 mode). The 10 GbE controller offload functions as previously described enhance the performance of software-based port virtualizers. See Section 38.21.7.11.2 for additional details on software port virtualizer offload functionality.

Note: A VSI used as a cascaded port virtualizer should not activate L2 filters on the aggregated S-channels. The VSI should be defined with a *connection type* of *default port*.

Cascaded Software/Hardware VEB over a Hardware Port Extender (Multichannel S-comp)

The 10 GbE controller supports software VEBs cascading to a hardware port virtualizer. In this configuration, a software VEB can be configured in the VMM and the connection between the software VEB and a port in the hardware port virtualizer is referred to as a cascaded VSI (or simply downlink port). The 10 GbE controller supports VLAN offload functions for software VEBs. The software VEB is not aware of the S-tag functionality. The hardware port virtualizer (or multichannel S-component) performs the insertion and stripping of S-tag to the cascaded VSI (downlink port) connected to the VEB. The 10 GbE controller can classify the ingress frames based on (VLAN, MAC address) pair and forward to selected queues within the downlink VSI connected to software VEBs (VMDq1 mode).

The 10 GbE controller supports hardware VEBs to hardware port virtualizer cascading. A hardware VEB is configured in the 10 GbE controller to support direct connected VMs in SR-IOV mode of operation. In this configuration, a hardware port virtualizer (or multichannel S-component) and a hardware VEB can be instantiated in the 10 GbE controller. The hardware VEB can be connected through a cascaded (or downlink) port in the hardware port virtualizer. Logically the hardware VEB's trunk port is connected to the external controlling bridge through a logically extended bridge port identified by an S-tag. The hardware port virtualizer (or multichannel S-component) performs insertion and stripping of S-tags to the cascaded downlink port connected to the hardware VEB.

38.21.7.3 Edge Virtual Bridging (EVB) Management Protocol

This section describes the control and management protocol for discovery and configuration of EVB components between the end stations and external edge switches. The current IEEE 802.1Qbg EVB supports multiple different switching elements: VEB, VEPA and for virtual networking. A control protocol is required to discover the capabilities of the end stations and external switches and configure the appropriate switching elements at both ends.

To enable EVB in the device, all of the following must be set:

- The GLGEN_STAT.EVBEN bit must be set to 1b either from the NVM or through a soft SKU.
- The NVM EVB protocols *Enabled* field should be set to 1b.

- The NVM *Switching Mode* field should be set to the EVB switching value.

EVB is configured and manages via the following stages:

- S-channels are enabled, defined and enumerated between the endpoint (station) and switch (bridge) by exchanging CDCP TLVs over LLDP. The 10 GbE controller sets a default VSI per S-channel.
- Software might then instantiate Edge Relay (ER) bridges, one per each S-channel.
- Support for the relay protocol (VEB/VEPA) of each ER is negotiated through LLDP EVB TLVs. Note that reflective relay might be enabled and common variables for VDP/ECP are negotiated.
- A reliable control protocol, Edge Control Protocol (ECP), is then established.
- A VSI discovery and configuration protocol (VDP) runs over ECP to associate VSIs with bridge ports

38.21.7.3.1 S-tag Allocation Through CDCP TLVs

CDCP TLVs are exchanges over LLDP.

Following initialization of an LLDP agent, and once the conditions for CDCP support are met, a local copy of the CDCP TLV is established and exchanged with the other end.

Once the device receives S-tag setting from the remote CDCP TLVs, it continues with EVB configuration. Specifically, the S-tags extracted from the CDCP MIB are handled as if received through CLP strings or NCSI depends on customer.

Mapping of the SCID/SVID pairs may change as a result of the following events:

- The LLDP agent reverts to the local MIB event. In such a case, all SCID/SVID pairs are deleted
- A CDCP TLV is received with a modified list of SCID/SVID pairs. SCID/SVID pairs may be removed, modified, or added.
- SCID/SVID pair removal: Remove all the VSIs associated with the VEB on this S-channel and remove the optional VEB associated with it.
- SCID change:
  - Remove all filters associated with VSIs on this SCID.
  - Change the switch ID and inserted S-tag for all the VSIs associated with this SCID using Update VSI command.
  - Add back all the removed filters.
- SCID/SVID pair addition: Add a VSI and optionally a VEB on top of this VSI.

38.21.7.3.2 VSI Setup Through VPD TLVs

A new protocol, VSI Discovery Protocol (VDP) is defined by IEEE. VDP protocol is transported over Edge Control Protocol (ECP) that enables an exchange of VSI specific TLVs between the edge switch and the control plane of appropriate switching element (VEB, VEPA or port virtualizer). The TLV transfer protocol is expected to use the same group multicast destination address(es) reserved for LLDP as previously described with a new EtherType (to be defined). A new EtherType enables forwarding the protocol frames to the appropriate control plane of the respective switching element.

VDP protocol uses TLVs to discover and configure the VSIs in the end station. The VDP protocol is used for establishing a new VSI and exchanging VSI attributes such as VSI ID, MAC, VLAN, QoS parameters, etc. The VDP protocol can also be used for

exchanging VSI statistics from end station to edge switches. The 10 GbE controller has the ability to filter for appropriate Edge Virtual Bridge (EVB) control frames and forward to appropriate management ports (VSIs or VSI queues) of the respective switching elements. The control frames (such as LLDP or VDP) are expected to be exchanged by the respective control plane agent in the VMM (or IOVM) and the external switch. LLDP is a link level protocol, so a VM is not expected to directly exchange LLDP control frames with an external switch. For example, the control frames cannot cross the virtual bridge. If a VM is configured to exchange control frames, it does so with the appropriate virtual bridge control agent in the VMM. The 10 GbE controller has a mechanism to either filter and/or forward the control frames from the VSIs to the management port of the switching element to which the VM is connected.

When a VEB or VEPA is instantiated over a port virtualizer, this is the equivalent of a VEB or VEPA uplink directly connected to a logical port in the external bridge. So the external bridge can exchange bridge control frames over the logical link to the VEB or VEPA. In this case the external bridge can send or receive LLDP frames to VEB or VEPA in the end station. These frames are identified using the S-tags that correspond to the extended bridge ports. Any of the bridge control frames can pass through this S-channel (like LACP or a new TLV transfer protocol/VDP). The bridge control frames over the S-channels are not expected to be VLAN tagged, so these control packets are untagged when delivered to the VEB or VEPA by the S-component. The 10 GbE controller can forward those control frames to the respective VEB or VEPA control ports (VSIs).

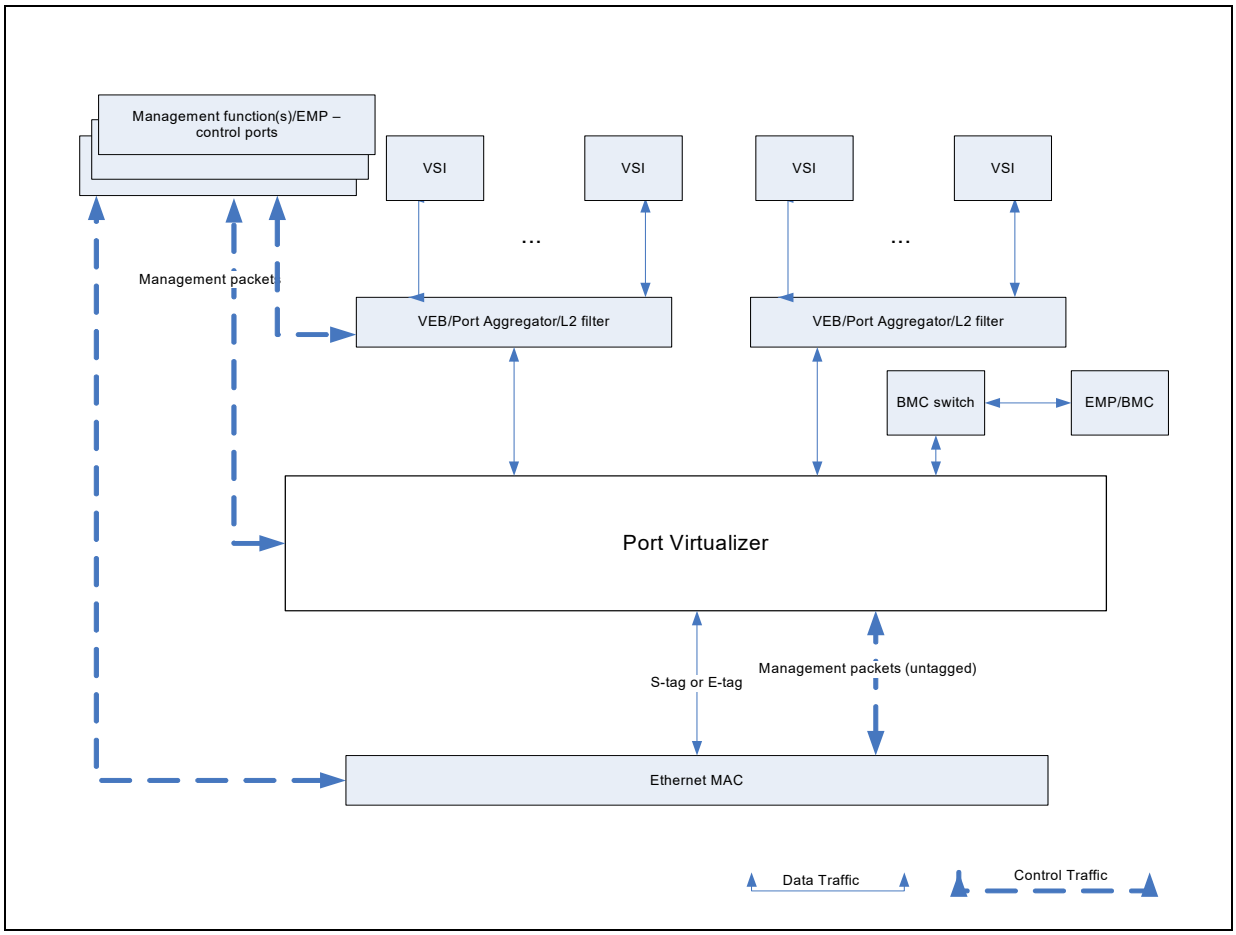
In a multi-channel configuration, there could be multiple LLDP agents (peer-to-peer) established between the external bridge through extended bridge ports (S-channels) and the corresponding VEB, VEPA or port virtualizer components in the end station.

Note: After a link down/link up event, the switch configuration protocol should be run again because the partner (and its capabilities) might have changed.

38.21.7.4 Switch Elements

The following figure shows the possible switching elements on one of the 10 GbE controller ports and the connections between them. Every switching element is optional. In the minimal case, the Ethernet port might be connected to a PCI function (VSI) with no switching capabilities at all. In this minimal case, an L2 filter is used as in regular NICs.

Figure 38-42.Switching Elements Per Port



There can be up to one port virtualizer per physical port. There can be up to 16 concurrent VEB or port multicasting defined in the device. There can be up to one L2 filter per VSI.

38.21.7.4.1 MAC

This section describes the switching decisions of the MAC.

The MAC switching behavior is set according to the following parameters:

- Port Enable
- Link Status
- Save Bad Packets (Stored in the *PRT_SBPVSI.SBP* field)
- Default Port VSI (Stored in the *PRT_SWT_DEFPORTS.DEFAULT_VSI* field)

- Local MAC Address (per LAN port)
- One or more control ports of the MAC. If a port virtualizer or a VEB is directly connected to this MAC, they might share the same control ports. At initialization time, a single control port is connected to the EMP. At a later time, if requested by the software device driver, an additional control port on a VSI of one of the physical function might be added or might replace the EMP control port.

As a rule, the MAC forwards all the packets to the next stage, apart from the following packets:

- Packets with L2 error — These packets are dropped, unless the *Save Bad Packets* attribute of the MAC is set. In this case, the MAC must define a control port and all the error packets are forwarded to this port. The errors included in this category are:
  - — CRC errors
  - — Alignment errors
  - — Length errors (either too big or too small)
- Packets with the MAC local MAC address. If a *Station MAC address* is defined, packets with this address might be forwarded to one of the control ports of the MAC in combination with some EtherType filters. Each control port might require forwarding of these packets using the *Add Control Packet Filter* or the *Add MAC, VLAN pair* admin commands.
- Link local packets without S-tag:
  - — Flow control packets (both 802.3x link flow control and 802.3bd priority flow control frames) are handled by the MAC and are not forwarded.
  - — Any packet defined in the control VSI forwarding rules (see Control VSI).

38.21.7.4.2 Port Virtualizer

An Ethernet port can be connected to a port virtualizer.

A port virtualizer can be either an S-comp, see Service-VLAN Component (S-comp), or a port extender (see Section 38.21.7.4.3). Each port virtualizer should be connected to a control port that receives the control protocol (CDCP or PE-CSP) packets.

There can be one port virtualizer per physical port. These two elements are mutually exclusive and in a given device only one type of port virtualizer can be initiated on all ports.

A port virtualizer can be created using the *Add Port Virtualizer* admin command described in Add Port Virtualizer.

If a port virtualizer is not implemented on a port, S-tagged packets are dropped.

Service-VLAN Component (S-comp)

An S-component is a typical mux/demux component that divides the Ethernet port to a set of S-channels.

Each channel in the S-component can be attached as a physical port to one of the switches. If no switch is needed, an S-comp is used to directly connect S-channels to VSIs.

S-tag Format

The S-tag format is the format defined for S-tags in the IEEE 802.1ad specification as listed in Table 38-187.

Table 38-187.S-tag Format

0	15	16	18	19	20	31
88-a8		PCP		DEI	S-VID	

- 88-a8 — The S-tag EtherType
- PCP — Priority Code Point (the priority bits of the S-tag). These bits can be derived from the VLAN priority bits.
- DEI — Drop Eligible Indicator (this bit is ignored)
- S-VID — the S-tag ID

S-comp Receive Flow

The S-comp acts only on packets with an S-tag received from the uplink. These packets are forwarded to one of multiple S-comp channels according to the S-tag forwarding table and then forwarded directly to VEB switches or VSIs.

Note: If no VEB is defined, then the VSI connected to the S-channel should be put in promiscuous mode using the Set VSI Promiscuous Modes command in order to receive all the traffic with the given S-tag.

Note: If an S-component is defined in the system, packets without S-tag or with an unrecognized S-tag not forwarded to one of the control ports are sent to the default port. If such a port is not defined, they are dropped.

The S-tag is usually removed by the S-component and is not forwarded to the host or to the sideband interface. This functionality is controlled by the *SS-tag extract mode* parameter of the *Add VSI* admin command. For cascaded S-comp ports that represent multiple S-channels, the S-tag can be either left in the packet or removed and stored in the *L2TAG2 (1st)* field of the receive descriptor. The *L2TAG2 (1st)* field of the receive descriptor contains the S-tag if the *S-tag extract mode* parameter of the VSI is set to 10b and is valid if the *L2TAG2P* flag in the descriptor is set. If S-tag extraction to a descriptor is required, the VSI must use 32-byte receive descriptors.

The algorithm used by an S-comp is described in Section 38.21.7.13.1.

S-comp Transmit Flow

S-comp adds the S-tag matching to the S-channel from which the transmit packet is received and forwards it to the physical port. It also forwards packets received from the control ports to the physical port.

Switch-based insertion of the S-tag can be disabled using the *S-tag insert enable* parameter of the *Add VSI* admin command. For cascaded S-comp ports that represents multiple S-channels, S-tag insertion should be disabled. In this case, software can either send untagged packets, ask for S-tag insertion via the transmit descriptor or add it in-line in the packet. This functionality is enabled by the *Accept Tag from host* parameter in the *Add VSI* admin command.

An S-comp only transfers packets from the S-channels to an Ethernet link or vice versa. It does not replicate packets or forward packets between virtual ports or physical ports. The only exception to this rule are local iWARP packets, where the connection is

defined as loopback in which case the packet is not tagged and is sent back to the same VSI. A VEB connected on top of an S-channel can forward packets between VSIs contained by this VEB.

38.21.7.4.3 Port Virtualizer (S-comp) Parameters

A port virtualizer is defined by the following parameters:

1. The port virtualizer connectivity:
   a. Uplink connected.
   b. Control ports that receive link local packets. Note that the control ports might be VSIs or the internal embedded controller or both.
2. Demux rule — The rule used to demux ingress packets. Typically, this rule uses an S-tag as previously described.
3. Default port — This port receives all the traffic not identified as control packets and not forwarded to any of the S-channels. If this port is not defined, such traffic is dropped.
4. Set of channels — Each channel is defined by the following parameters:
   a. Connected VSI or next level switch.
   b. S-tag (S-VID) - see S-tag Format.
   c. Maximum and minimum rate.
   d. S-tag strip enable.
   e. S-tag insert enable.
   f. Report S-tag.
   g. Accept tag from host.

LAN S-comp

The LAN port extender divides the uplink port traffic. The LAN channel can be attached to a switch (for example a VEB).

This S-comp differs from the standard 802.1Qbg port extender in that it uses the MAC address as the channel classifier. The MAC address behaves the same way as the S-tag, and it can translate to a single switch ID. In this case, the traffic is untagged (no S-tag).

Receive Flow

The S-comp filters on unicast and multicast addresses are forwarded to the LAN channel.

Note: The MAC address is used twice in the switch process, first to define the S-channel and second to define the VSI within this S-channel.

Contrary to other port extenders, the MAC address is never stripped and it is always forwarded to the host.

The algorithm used by LAN S-comp is described in Section 38.21.7.13.

Transmit Flow

The S-comp only transfers packets from the S-channels to an Ethernet link or vice versa. It does not replicate packets or forward packets between virtual ports or physical ports. The only exception to this rule are local iWARP packets, where the connection is defined as loopback in which case the packet is not tagged and is sent back to the same VSI.

No tag is added to the transmitted packet.

Port Virtualizer Control Ports

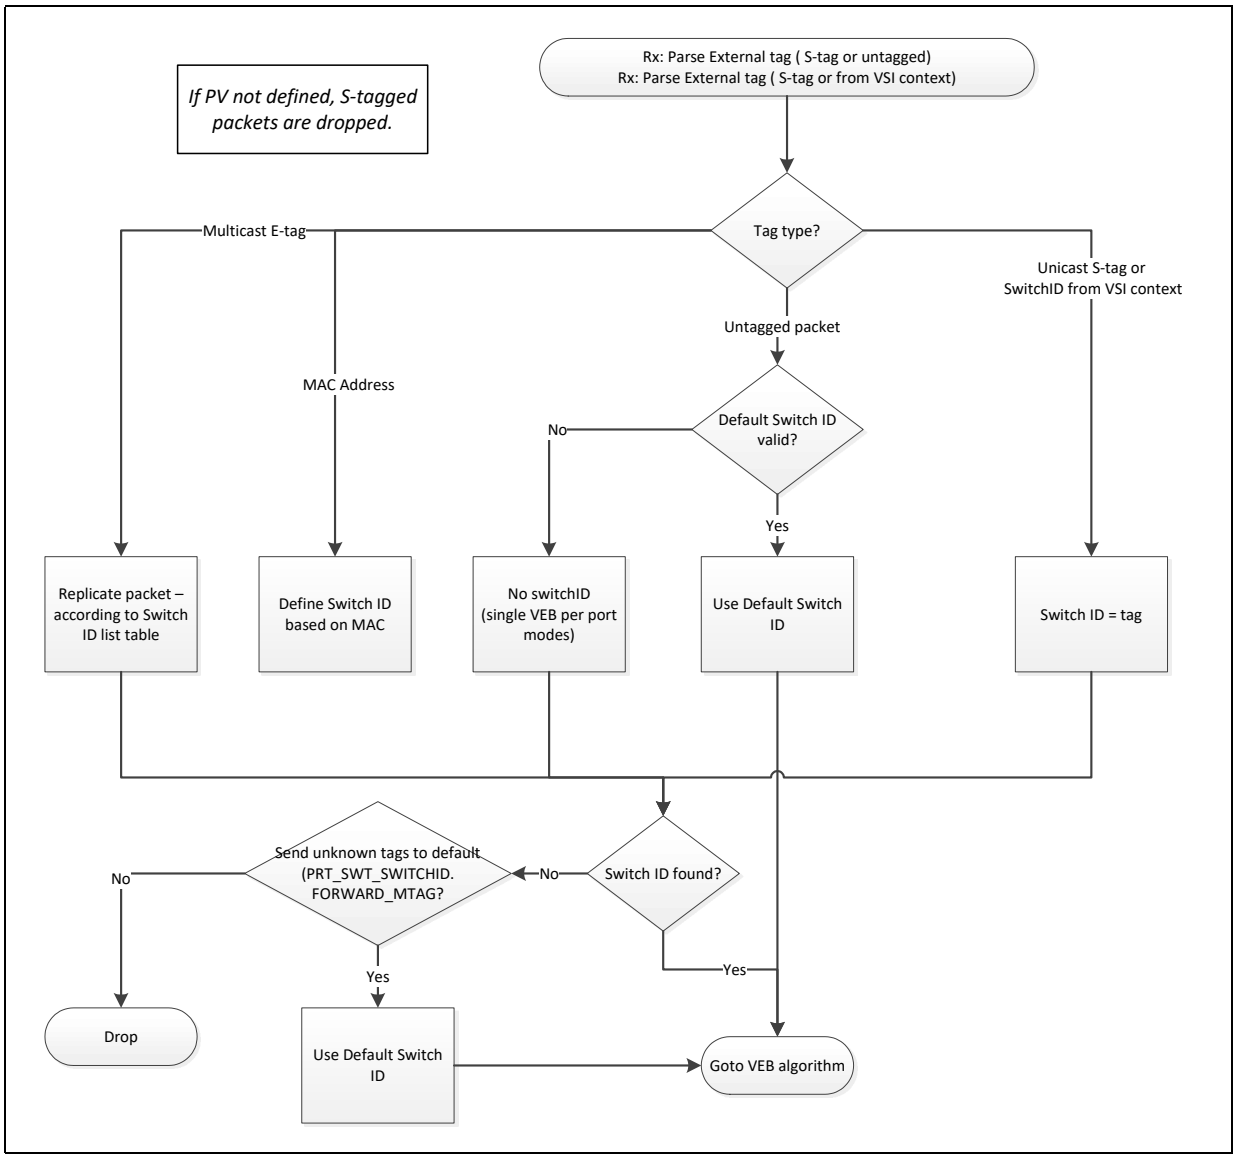
The port virtualizer might forward control packets to the associated control port.

Port virtualizer control packets are untagged LLDP or enhanced LLDP packets combined with specific MAC addresses as described in Section 38.21.7.3. Each control port might require forwarding of specific control packets forwarding using the *Add Control Packet Filter* admin command.

Port Virtualizer Flow Diagram

The following describes the high level flow used to define the switch ID associated with a packet. The details can be found in the algorithm sections (Section 38.21.7.13).

Figure 38-43.Port Virtualizer Flow



38.21.7.4.4 L2 Filters

A VSI directly connected to a physical port, to a port extender or to an S-comp, still needs the ability to filter incoming traffic as done in traditional NICs. The L2 filtering element provides this ability. An L2 filtering element is relevant only for receive or sideband traffic and does not apply to transmit traffic. An L2 element has no control port and is controlled directly by the function.

An L2 filter element is not represented as part of the topology and is implicitly created by adding L2 filters to existing VSIs.

This section describes L2 filters used when no VEB or VEPA element is initiated. If a VEB or VEPA element is added, the L2 filtering is done as part of the VEB forwarding as described in the following sections.

An L2 filtering element includes a set of filters used to define whether a packet is received by the function or is dropped. There are two type of filters: exclusive filters that identify the packet as exclusive to this function and non-exclusive filters that might pass as well as packets that might be forwarded to other ports or functions.

Non-exclusive traffic can be further defined as perfect or imperfect, where perfect means that a packet that passed these filters was requested by the host, and imperfect filters can pass packets the host did not request.

In addition, a packet might be filtered out if it is larger than the maximum size defined by the port.

Note: Even if a packet passed the length filter of the port, it might yet be filtered by the length limitation of the receive queues.

An L2 filter is applicable only to receive traffic and does not refer to transmit traffic. Thus, if there is only an L2 filtering element, transmit traffic is forwarded to the network. The only exception is the case of a local iWARP connection. A packet sent by this connection is a loopback to the sending VSI.

Note: The cloud filtering includes an L2 filter as part of its VEB or VEPA. This L2 filter is described in Section 38.21.7.4.5.

Exclusive Filters

The following exclusive filters are available as part of an L2 filtering element:

- MAC:VLAN Unicast Table — Used to forward to a port packets matching both the MAC and VLAN pair. A VLAN value of zero includes untagged packets. Only unicast addresses are considered as exclusive.
- MAC Unicast Table — Used to forward to a port packets matching MAC addresses ignoring the VLAN tag.
- VLAN Table — Used to define the VLAN to which the port belongs. A VLAN value of zero indicates the port can receive untagged packets.
- EtherType Table — Used to forward to a port packets matching an EtherType ignoring the MAC address and VLAN tag.

Non-Exclusive Filters

The following non-exclusive perfect filters are available as part of an L2 filtering element:

- MAC VLAN Multicast Table — Used to forward to a port packets matching both the MAC and VLAN pair. A VLAN value of zero includes untagged packets. Only unicast addresses are considered as exclusive.
- MAC Multicast Table — Used to forward to a port packets matching MAC addresses ignoring the VLAN tag.
- UPE — Promiscuous Unicast
- MPE — Promiscuous multicast
- BAM — Accept broadcast packets

The following non-exclusive imperfect filters are available as part of an L2 filtering element:

- HashMAC, VLAN, Address Type — Used to accept packets whose multicast/unicast MAC address match a given MAC address and their VLAN match the VLAN tag in the pair. A VLAN value of zero includes untagged packets.
- HashMAC, Address Type — Used to accept packets whose multicast/unicast MAC address match a given MAC address.

The algorithm used by an L2 filter is described in Section 38.21.7.13.3.

38.21.7.4.5 Virtual Ethernet Bridge with Cloud Support (Cloud VEB)

A VEB is used to switch packets between a set of virtual ports, a physical port or an S-channel and a control port. The VEB behaves like a managed 802.1d transparent switch. All the configuration of the switch is done by a software agent. There are no auto configuration capabilities in the VEB. For example, there is no auto-learning of MAC addresses.

A VEB can forward packets received from any of its ports to a list of ports (including, optionally the originating port. The VEB uses the rules described in Cloud VEB Switching Rules to define the egress ports of each packet.

A packet is associated with a VEB using the SwitchID associated to it. A switchID can be either 0, S-tag or a switch ID based on the SwitchID VSI parameter or the Port SWID parameter (*PRT_SWT_SWITCHID.SWID*).

There can be up to 16 VEBs or port aggregators in the 10 GbE controller. They can be assigned dynamically to PFs. All the virtual ports associated with a VEB must belong to a single PF or its VFs.

Note: A VEB can be added only by a PF and cannot be added by a VF or the EMP.

A VEB can be created using the *Add VEB* admin command described in *Add VEB.*

A cloud VEB can also be configured to VEPA mode. The exact algorithm used by a cloud VEB is described in Section 38.21.7.13.4.

VEB with Cloud Support Parameters

A VEB is defined by the following parameters:

1. A control port that receives link local packets (such as 802.1X packets or LLDP packets).
2. An optional default port that can receive packets received from the physical port and not forwarded to any virtual port.
3. Definitions of local and private VLANs.
   a. Local VLANs — A list of VLAN tags defined as local that do not include the physical port.
   b. Private VLANs — A list of VLAN tags defined as private. For each private VLAN tag, define the promiscuous ports list, the community ports list, and the isolated ports list.

Note: Refer to the special VLANs section for more details.

4. A set of VSIs — Each VSI is defined by the following parameters:
   a. Connected PCIe function.
   b. Transmit enable and receive enable.
   c. Set of forwarding tables and parameters rules used to forward packets to the port.
   d. Security features:
      - Port-based VLAN insertion
      - Anti-spoofing enables
   e. Optionally, a maximum and minimum rate.

Cloud VEB Switching Rules

The following parameters are used to define which egress ports (VSIs and LAN) receives a packet received by the VEB.

Forwarding Tables and Parameters

- Priority 1 filters (control filters):
  — EtherType Table — Used to forward to port(s) packets matching an EtherType ignoring the MAC address (usually used for the control VSI).
  — MAC, EtherType Table — Used to forward to port(s) packets whose MAC address match a given MAC address and EtherType match an EtherType (usually used for the control VSI).
- Priority 2 filters (cloud filters):
  — Inner MAC, Inner VLAN (for NVGRE, VXLAN or Geneve packets)
  — Inner MAC, Inner VLAN, Tenant ID (for NVGRE, VXLAN or Geneve packets)
  — Inner MAC, Tenant ID (NVGRE packet or VXLAN/Geneve packets).
  — Inner MAC filter
  — Outer MAC, Tenant ID, Inner MAC filter
  — Inner IP filter
  — Inner Source IP, inner destination MAC filter

Note: The network key is extracted from the GRE or UDP headers in MAC in GRE or MAC in UDP packets.

GRE key is a 4-byte field enabled by the k flag in the GRE header. The key is extracted only if the GRE header includes a key as indicated by active K flag in the header.

The UDP port used for MAC in UDP tunneling is defined by a shared 16-entry table with Tunneling port numbers. The key is extracted if the UDP port number contains a key as defined by the UDP protocol index, which is programmed by the *Add Tunneling Port command*.

- Priority 3 filters (L2 Filters):
  — MAC, VLAN Table — Used to forward to VSI(s) packets matching both the MAC and VLAN pair.
  — MAC Table — Used to forward to a VSI(s) packets matching MAC addresses ignoring the VLAN tag.
  — HashMAC, Packet Type — Used to forward to port(s) packets whose multicast or unicast MAC address match a given MAC address. Packet type is unicast or multicast.

— HashMAC, VLAN, Packet Type — Used to forward to port(s) packets whose Multicast or Unicast MAC address match a given MAC address and their VLAN match the VLAN tag in the pair. Packet Type is unicast or multicast.

— VLAN Table — Used to define the VLANs to which a VSI(s) belongs for egress and ingress checks. This table can point to two lists: one list that is used for ingress VLAN filtering and one used for egress VLAN filtering.

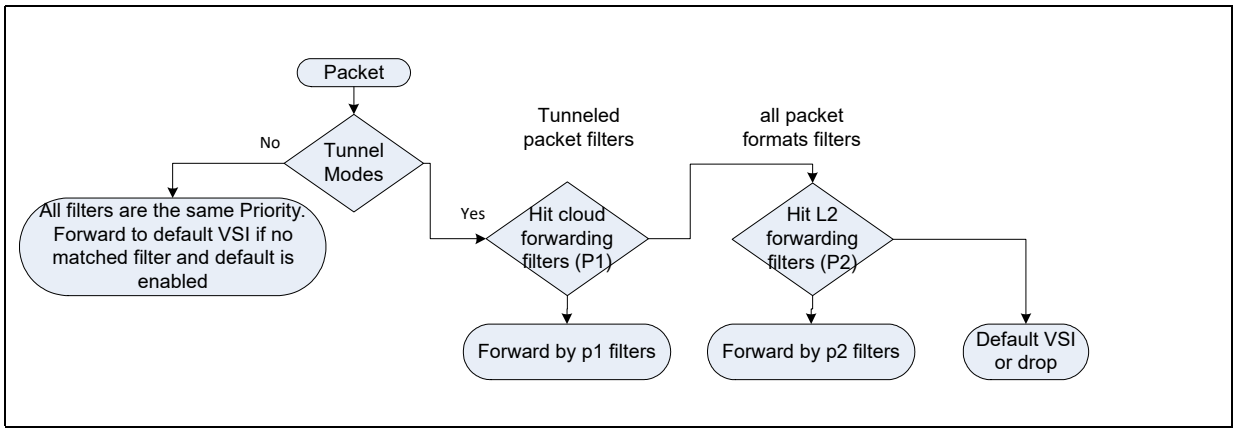
Note: In all previous tables, a VLAN value of zero includes untagged packets.

A port in these tables means either a VSI or the LAN port for transmit packets and a VSI for receive packets.

- Promiscuous modes per VSI:
  - — UPE — Used to forward to a VSI, all unicast packets.
  - — MPE — Used to forward to a VSI, all multicast packets.
  - — BAM — Used to forward to a VSI, broadcast packets.
  - — VPE — Used to forward to a VSI, packets with any VLAN tag.
- Loopback rules:
  - — ALLOWLOOPBACK — Allowed to send packets to other virtual ports
  - — PruneEnable — This mode is useful to enable offload of a software switch connected to this virtual port.
- Anti-spoofing parameters — These parameters define if a packet should be allowed to enter the switch.
  - — MAC anti-spoofing enable
  - — VLAN anti-spoofing enable

The forwarding filters are divided into groups. Those filters that are needed for tunneled packet formats and those ones that are shared for all packet formats (based on the outer MAC or VLAN). Filters that match tunneled packet formats take precedence on those filters that match all packet formats.

Figure 38-44.Cloud Forwarding Filters Priority



The Add Control Packet Filter (0x025A) and Remove Control Packet Filter (0x025B) commands are used to add or remove control filters settings. Each control filter can point to a single VSI. There is no support for packet replication based on control filters. An error is returned if an existing control filter is added to point to another VSI.

The Add Cloud Filters (0x025C) and Remove Cloud Filters (0x025D) commands are used to control cloud-specific filters settings. Each cloud filter can point to a single VSI. There is no support for packet replication based on cloud filters. In addition to those filters, in order for a packet to be received by one of the VSIs, it must also pass the L2 MAC filter. In order to enable L2 filtering, the *Flags.Enable L2 filtering* bit in the *Add VEB* command should be set when creating the cloud VEB.

Note: This L2 filtering is not related to the L2 filtering defined in Section 38.21.7.4.4.

- The Add MAC, VLAN Pair (0x0250), Remove MAC,VLAN Pair (0x0251), Add VLAN (0x0252), and Remove VLAN (0x0253) commands are used to set regular MAC/VLAN filters.

Note: The *Add MAC, VLAN pair* command enables filtering based on a MAC address (any VLAN) or on a MAC, VLAN pair. The *Add VLAN* command is used to define the VLAN membership of ports and is not used to add destination VSIs. Using this method, the VEB can allow MAC-based filtering and promiscuous modes within specific VLANs.

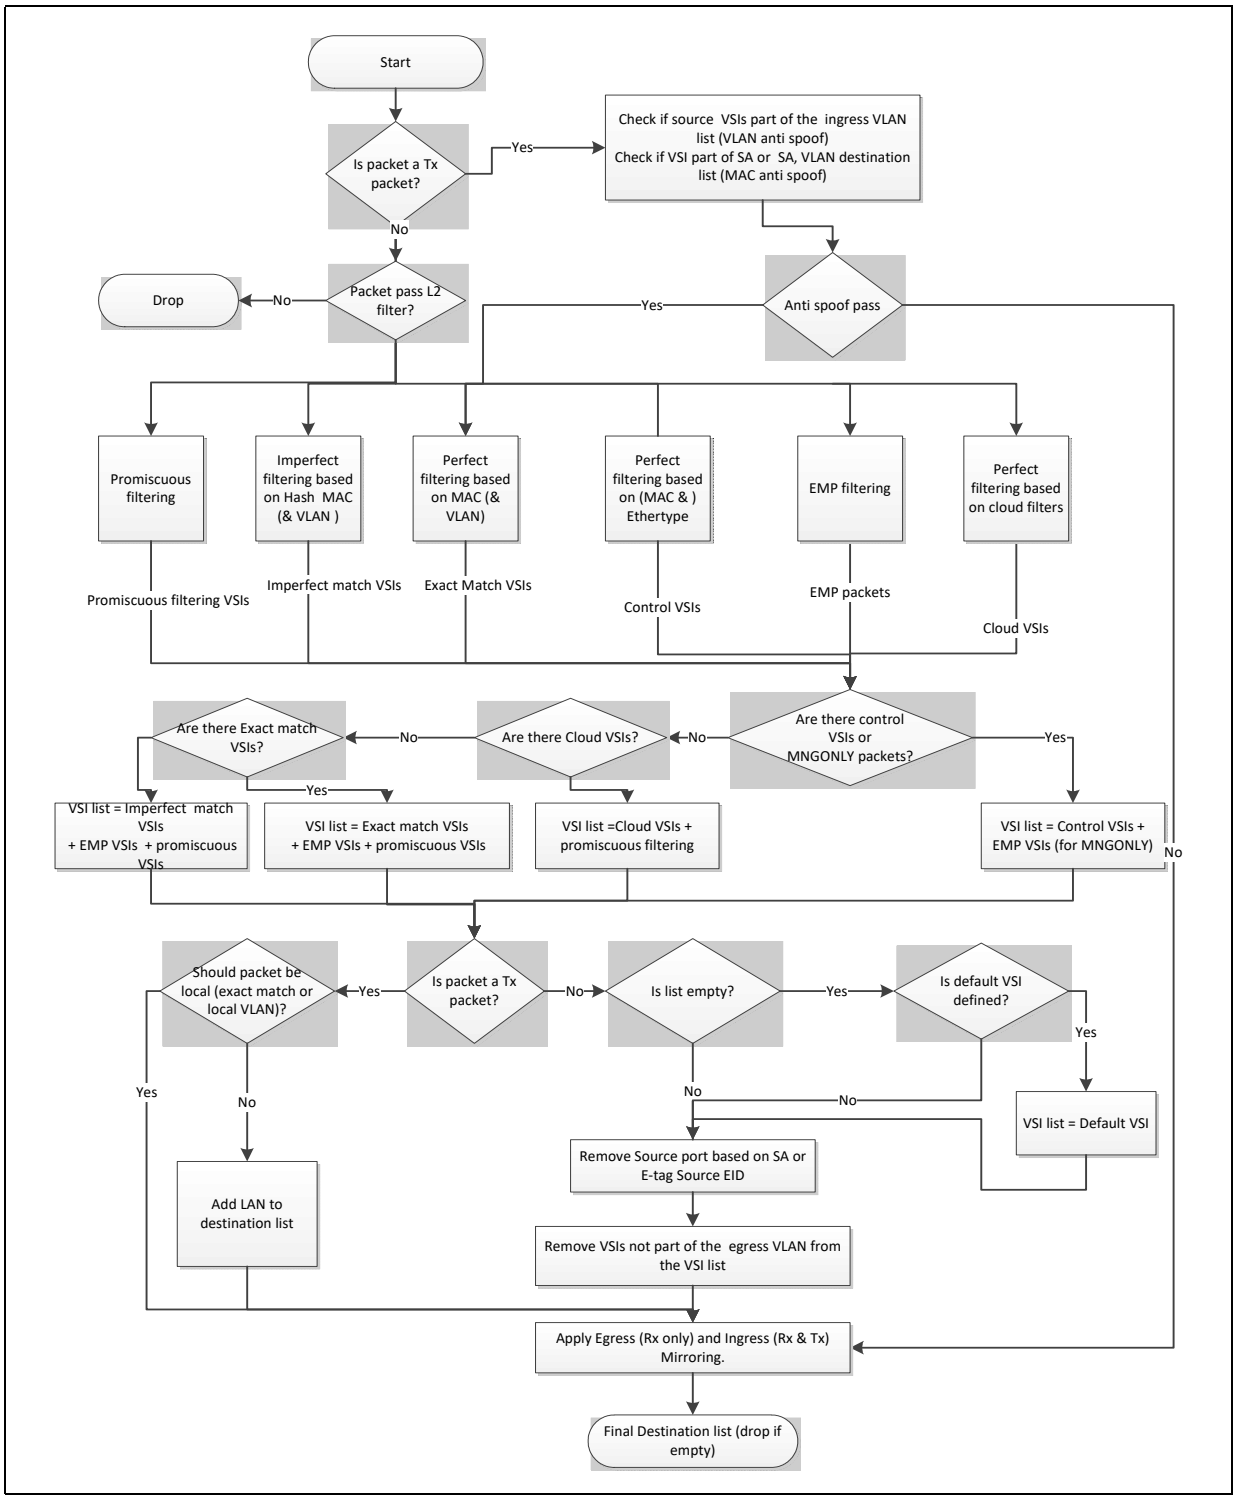
- The Set VSI Promiscuous Modes (0x0254) command is used to set promiscuous filters.
- The Add Mirror Rule (0x0260) and Delete Mirror Rule (0x0261) commands are used to control mirror rules.

Note: It is assumed that manageability packets and control port packets are not encapsulated.

Cloud VEB flow

The following figure shows the generic flow of the cloud VEB element. The exact algorithm implementing this flow is described in Section 38.21.7.13.4.

Figure 38-45.Cloud VEB Flow Diagram



38.21.7.5 Port Aggregator

The port aggregators (VEPA) usage model is described in the "Virtual port Aggregator Model" section.

38.21.7.5.1 Port Aggregator Switching Rules

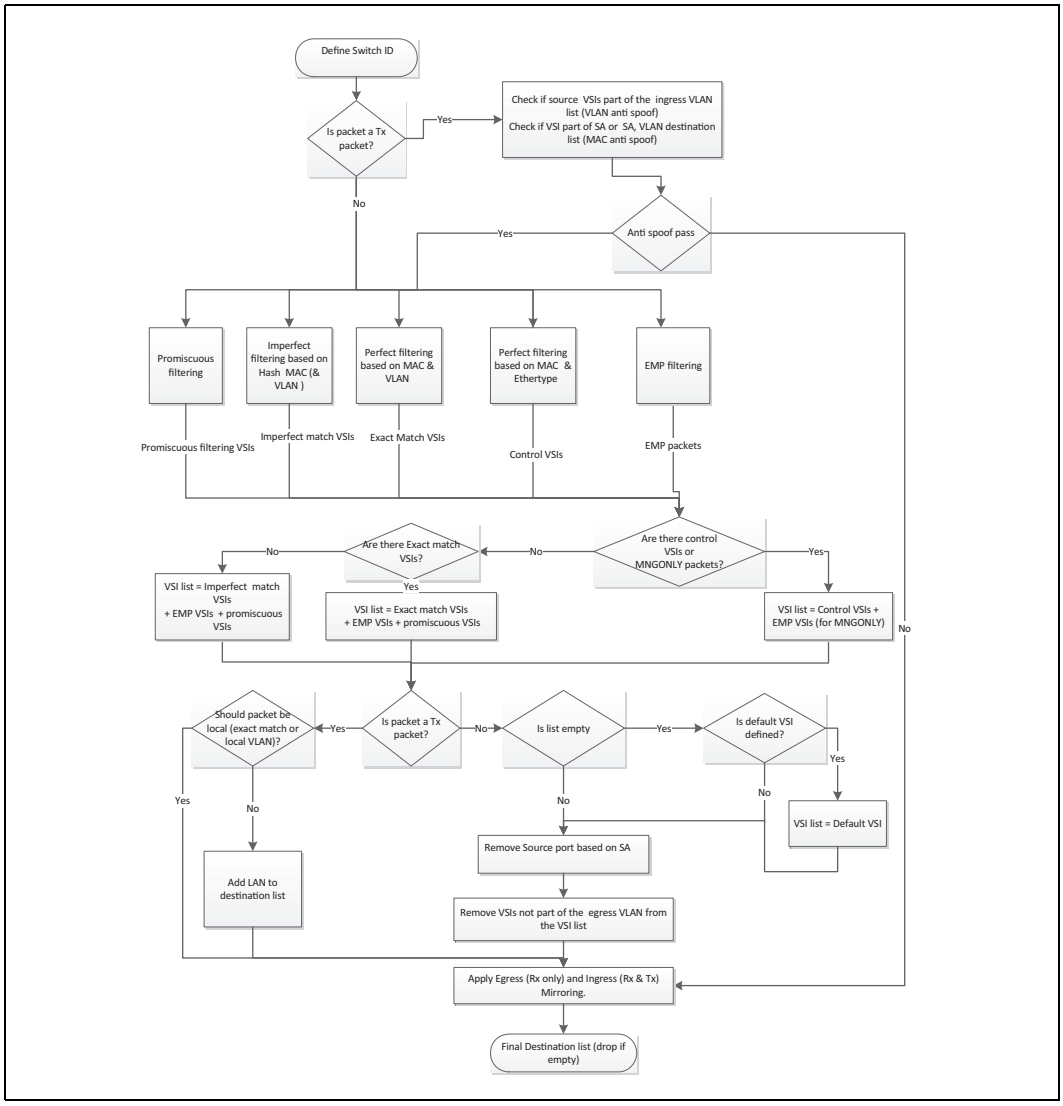
The behavior of a port aggregator is the same as the behavior of a VEB. The only difference is that in a port aggregator, loopback should be disabled for all virtual ports (ALLOWLOOPBACK = 0b).

A VEPA can be created using the *Add VEB* admin command described in *the* "Add VEB" *section* and by disabling loopback in the VSIs connected to this VEB.

38.21.7.5.2 Port Aggregator Flow

Figure 38-46 shows the generic flow of the VEPA element. The exact algorithm implementing this flow is described in Section 38.21.7.13.4.

Figure 38-46.VEPA Flow Diagram



38.21.7.6 Floating VEB

A floating VEB is a VEB not connected to the network, allowing only local traffic between the VSIs members of this VEB. This is useful in case one of the VSIs acts as a gateway to another network for all the other VSIs within the floating VEB. It can be used to isolate a set of VSIs behind a firewall or to implement NFV functionalities.

A floating VEB is created by setting the *floating VEB* flag and setting a *downlink SEID* of zero in the Add VEB command. The AQ response returns the switch ID used for this floating VEB.

Traffic in a floating VEB is identified using a special S-tag inserted and removed by the hardware. Hence the C*ascaded Port Virtualizer section is valid* bit should be cleared in floating VEB VSIs. Firmware internally sets:

- S-tag = Switch ID of the floating VEB
- Switch ID = Switch ID of the floating VEB
- S-tag extract mode = 01b
- S-tag insert enable = 1b
- Accept tag from host = 0b

In addition, the *Allow Loopback* flag should be set.

Note: A VSI in a floating VEB might still bypass the switch if allowed via the SWTCH flag in the Tx descriptor. A packet sent to the LAN via this mechanism goes out on the VEB with the floating VEB internal S-tag. This is not an expected use case, as only trusted VSIs are allowed to use the SWTCH flag.

Note: As VSIs on a floating VEB adds and remove an S-tag, the RXMAX value of the Rx queues in these VSIs should be updated to account for the additional 4 bytes.

Note: Although floating VEB creates an isolated environment for the PF, it cannot completely disconnect the PF from the network. A try to call the Delete Element AQ (0x0243) for VSI, connected directly to port results in an error.

38.21.7.7 Manageability Sideband Switching

The network interface might be shared between the host and a sideband manageability interface. The sideband interface can be either over a 100 Mb/s Ethernet interface using NC-SI, over SMBus using a legacy pass through mode or NC-SI over MCTP transport, or over PCIe using NC-SI over MCTP transport.

The specific filters used to define which packets are forwarded to the sideband interface. The current section only describes the relationships between the sideband and other switching elements.

38.21.7.7.1 Network to BMC Filtering

The relationships between the sideband filtering and other switching elements follow:

- If no switching elements are defined such as no VEB or port virtualizer), the sideband decision filters are applied to the network traffic. Packets which pass these filters are forwarded to the sideband interface.
- If an S-comp is defined on the port, the sideband might be defined as part of one of the channels in the S-comp. In this case, the sideband decision filters are applied only to the traffic with the matching S-tag. The same S-tag is added to packets sent from the sideband interface.

- The sideband switching is never part of a VEB, port aggregator or port virtualizer and is done in parallel to the forwarding decisions of these elements.

38.21.7.7.2 OS to BMC Traffic Filtering

The following rules are used to decide whether OS traffic should be sent to the sideband interface:

- If no switching elements are defined, for each function associated with a given port, the sideband decision filters associated to this port and applicable to host traffic are applied to the function traffic. Packets that passes these filters are forwarded to the sideband interface. If the sideband interface defines these packets as exclusive (*PRT_MNG_MNGONLY* is set for this filter), the packets are not sent to the network. Otherwise, they are sent both to the sideband interface and to the network.
- If an S-comp is defined on the port, the sideband may be defined as part of one of the channels in the S-comp. In this case, the sideband decision filters are applied only to host traffic with the matching S-tag. Traffic from the host to the BMC is sent to the BMC without the S-tag.

Note: It is assumed that traffic sent from an S-channel different than the S-channel of the BMC is forwarded by an external switch.

- If a VEB, port aggregator or Port Virtualizer is defined, they will not receive packets exclusively sent to the sideband interface.

38.21.7.7.3 BMC to OS Traffic Filtering

The following rules are used to decide whether traffic received from the sideband interface should be sent to the host:

- If no switching elements are defined, the port L2 filters are applied to the sideband traffic. Packets that passes these filters are forwarded to the host. Unicast packets that pass exclusive L2 filtering as defined in "Exclusive Filters" are sent only to the host. Multicast or broadcast packets and unicast packets that pass non exclusive filtering as defined in "Non-Exclusive Filters", are sent both to the host and to the network. Other packets are sent only to the network.
- If a VEB or port aggregator are defined, the switching algorithms of the VEB or port aggregator are applied to the sideband traffic. Packets which pass these filters are forwarded to the host. Unicast packets that pass perfect L2 filtering as defined in "Non-Exclusive Filters" are sent only to the host. Multicast or broadcast packets and unicast packets that pass imperfect filtering as defined in "Non-Exclusive Filters", are sent both to the host and to the network. Other packets are sent only to the network.
- If an S-comp is defined on the port, the sideband might be defined as part of one of the channels in the S-comp. In this case, the switching elements relevant to this channel are applied to the sideband traffic. Traffic from the BMC to the host has no S-tag appended.

Note: It is assumed that traffic sent from the S-channel of the BMC to a function on a different S-channel is forwarded by an external switch.

- If a port virtualizer is defined on the port or S-channel of the sideband interface, it does not receive traffic from the BMC directly. It might still receive such traffic through an external switch.

38.21.7.8 Out-of-band Filtering Operation

Part of the type of traffics are expected to be operational also in Sx (equivalent to D3 or Dr state of the device). The following types of network inbound traffic are included in this category:

- Wake-up per PF
- Manageability traffic (two channels)
- LLDP traffic (untagged only).

In order to support this traffic, a separate simplified switch mechanism (PF classifier) is provided that is independent of the regular switch and is used to forward packets to these specific locations.

38.21.7.9 Ports

38.21.7.9.1 Physical Ports

Physical ports are considered as uplink ports and are not part of the L2 forwarding table. In each switch, there can be one physical port only. All the traffic that is not forwarded to one of the other ports is sent to the uplink egress port. In addition, multicast or broadcast traffic not received from the uplink ingress port is always forwarded to the uplink port, unless it is part of a local VLAN or the switch has no connection to an uplink. Local VLANs are defined in Local VLANs.

Ethernet ports

Each of the Ethernet ports can be assigned as an uplink port of a switch if not connected to an S-component. In this case, all the traffic received from this Ethernet port is handed to the switch.

38.21.7.9.2 VSIs

VSIs are the connections from the switch to entities interfacing with the host. It can be either the entire queue set of a PCIe function or part of the queues of a function.

There can be up to 384 VSIs in the 10 GbE controller. All the VSIs are equivalent.

At initialization time, each PF is assigned a VSI. A default VSI can also be used to provide the VMDq1 or control VSIs functionality described in the text that follows.

Other VSIs can be assigned to the PF or to VFs and used for the following purposes:

1. VMDq2
2. VMDq1
3. Control ports
4. iWARP traffic
5. Mirroring

In addition, EMP VSIs can also be defined. The EMP VSIs are used for:

1. Pass through traffic
2. Control ports

The different types of VSIs and their attributes are described in the following sections.

Mapping of queues to VSIs is described in Mapping of Functions and Queues to VSIs.

Host VSIs Types

VMDq2 VSI

The 10 GbE controller supports offloading of a VMM software switch. In this mode, the switching between VMs is done using a VEB element or a port virtualizer element. However, all or part of the ports might not be directly connected to the VEB/port virtualizer as SR-IOV functions (VFs) as they can be hidden behind the VMM or a service VM. These VMs can be represented to the VEB as groups of queues in a single physical function. There can be up to 256 VSIs for VMDq2.

The only difference between a VMDq2 VSI and a regular VSI associated with the PF is the ability to apply the VM reset flow.

VMDq1 Cascaded VEB/S-comp VSI

A VSI might be used for VMDq1 offload. There are two types of VMDq1 offloads:

- A cascaded VEB
- A cascaded S-comp

In a cascaded VEB, a software switch is tied to this VSI and uses the MAC, VLAN pairs to queue packets to the right receive queue.

In a cascaded S-comp, the VMDq1 VSI is used to offload a software-based S-comp. A cascaded S-comp VSI is created by setting the *Cascaded Port Virtualizer* flag in the *Add VSI* command. When an S-channel is used to convey multiple S-tags, it should be connected directly to a VSI; VEB or VEPA elements should not be connected on top of it. Filtering of packets to be sent to a cascaded S-comp VSI should be based only on S-tag and not on MAC, VLAN or other filters.

Control VSI

A single PCI function can be used to control one or multiple switching elements. For example, a single function can be used to control a port virtualizer and a VEB element associated with the function. Designers need to separate the control packets of different elements to different queues in receive and identify the switch element that should process the packets in transmit, a separate control VSI should be defined for each element.

A control VSI can receive part or all the link local traffic received by the controlled element. For example, a port virtualizer control VSI should receive LLDP untagged packets. A VEB control VSI behind a port virtualizer gets LLDP packets tagged with the S-tag associated with this VEB. As the control packet's traffic might be handled by a different control port, each control port driver should request forwarding of the relevant packets using the *Add Control Packet Filter* admin command.

Any VSI can be used as a control VSI as long as the adequate packets are routed to it. A control VSI should have the *Allow Destination Override* flag set to enable it to bypass the switch when sending packets.

At initialization time, the control VSI of the MAC is assigned to the EMP. If at a later stage, one of the PFs decides to take ownership of this control port, it should assign one of its VSI as the control port of the MAC. The EMP should be notified of the change using *Stop LLDP Agent* command and should disconnect the EMP control port. The PF might elect to add a control port in addition to the EMP control port. If a control port is added to a VEB or a VEPA (either connected to the LAN via a port virtualizer or floating), it does not impact the connectivity MAC control port to the EMP. A control port

of a VEB directly connected to the MAC might use the MAC control port or might use a separate VSI. After a port is defined, the owner of the control port (firmware or software device driver) should set the right filters using the *Add Control Packet Filter* admin command.

A typical configuration might be:

- Untagged (no S-tag) LLDP packets with a nearest bridge (01-80-C2-00-00-0E) address are forwarded to the control port of the MAC or of a switch element directly connected to the MAC (port virtualizer or VEB) on the EMP. These packets include DCBx TLVs.
- Untagged (no S-tag) LLDP packets with a nearest non-TPMR (01-80-C2-00-00-03) or nearest customer bridge (01-80-C2-00-00-00) addresses are forwarded to the control port of the switch element directly connected to the MAC (port virtualizer or VEB) on the host. These packets includes CDCP TLVs.
- Untagged ECP packets are forwarded to the control port of the switch element directly connected to the MAC (port virtualizer or VEB) on the host. These packets includes VDP and PE CSP TLVs.
- S-Tagged LLDP packets with a nearest customer bridge (01-80-C2-00-00-00) address are forwarded to the control port of a VEB connected to this S-channel.

Note: A control port can also be used as a default port.

Transmitting Packets from a Control VSI

A control VSI might need to send directed multicast packets. For example, sending an LLDP packet with a link local multicast address to the link partner or to one of the VSIs. According to the regular forwarding rules of the switch, such packets are forwarded back to the control port or dropped. To overcome this, the control VSI should set the *SWTCH* field and optional the *DEST_VSI* field in the transmit context descriptor to indicate the desired destination of the packet.

iWARP VSI

In some operating systems, the iWARP and the LAN functionality uses different MAC addresses. The LAN traffic uses the default VSI and the iWARP traffic (both stateless and stateful) uses a separate VSI. Both VSIs are part of the same PCIe function. There can be up to 16 VSIs for iWARP traffic in PFs and up to 32 VSIs for iWARP traffic over VFs.

An iWARP VSI is not created differently than a data VSI. After the creation of the VSI, iWARP resources should be assigned to this VSI.

Mirroring VSI

A VSI might be used to direct mirror traffic as defined by the mirroring rules in the associated VEB/VEPA. In this case, such a VSI is not expected to receive any traffic apart from the mirrored traffic. Any VSI in the VEB can be set as a mirror port.

A mirror VSI should be set to promiscuous VLAN mode to enable reception packets from any VLAN.

Default VSI

In each port, or each VEB one VSI can be defined as the default VSI. A port default VSI is available only if a port virtualizer is instantiated on this port; otherwise, a VEB default port should be used.

A port default VSI is added by defining the connected VSI port type in the *Add Port Virtualizer* command to Default.

A VEB default VSI is added by defining the downlink VSI port type in the *Add VEB* command to Default.

If a default port is defined, all the received traffic within the port/VEB not matching any forwarding rule is sent to the default port; otherwise, it is dropped.

Transmit traffic is not impacted by the default port. Unmatched transmit traffic is sent to the LAN.

A default port is subject to VLAN filtering rules. In order to allow all the unmatched traffic to be default VSI, it should be set to promiscuous VLAN using the *Set VSI Promiscuous Modes* command.

EMP VSI Types

Pass-through VSI

A pass-through VSI is used to send and receive traffic from an out of band manageability interface. If this VSI is located behind a Port Virtualizer, S-tag insertion and removal for packets sent to or received from the manageability interface is done by the device. VLAN tagging is done by the external BMC.

Control VSI

An EMP control VSI behaves as a host control VSI (see Control VSI). It sends and receive packets without S-tag and can send or receive VLAN-tagged or VLAN-untagged packets.

Mapping of Functions and Queues to VSIs

The function to which each VSI belongs is indicated by the VSI_VSI2F register in the VSI context. This register is initiated by the *Add VSI* admin command. See Add VSI (0x0210) for more detail.

Transmit queues are grouped in queue groups. Each queue group is associated with a VSI, thus creating an association between transmit queues and VSIs. This association is used when applying the VSI policies to transmit traffic.

Receive queues are mapped to VSIs using the *VSILAN_QTABLE* registers. These registers are also initiated by the *Add VSI* admin command.

Mapping can be either contiguous within the function queues or scattered. In case of scattered mapping, up to 16 queues can be associated with a VSI. Both receive and transmit queues should be associated within the queue set of the VF/PF to which this VSI is associated. So for VSIs associated to a VF, up to 16 queues can be associated with the VSI. For VSIs associated with a PF, all the queues of the PF can be associated with a VSI.

A VSI might choose to queue packets to different receive queues either using the RSS and TC information or using some other dedicated filters.

VSI Connections to the Switching Elements

Most VSIs can be connected to the following switching elements as regular ports:

- MAC, VEB, port virtualizer or port aggregator

- Port virtualizer

VSI Context

The context of a VSI contains the following parameters.

Table 38-188.VSI Context (Sheet 1 of 2)

Parameter	Description	Register.Field	Notes
Function pairing			
Function Type	Defines the owner this VSI can be either a PF, a VF or the EMP.	*VSI2_VSI_VSI2F.FUNCTIONTYPE*	00b = VF. 01b = VM. 10b = PF. 11b = EMP.
VF Function Number	The VF number of the function this VSI belongs to.	*VSI_VSI2F.VFVMNUMBER*	
PF Function Number	The PF number of the function this VSI belongs to.	*VSI_VSI2F.PFNUMBER*	This field should be set also for VFs.
VSI_ENABLE	Enables transmit and receive from VSI.	VSI_VSI2F.VS_ENABLE	
Switching parameters			
SwitchID	Defines the Switch to which this VSI belongs. If a VSI connected to a VEB/VEPA/MAC, this should be the same as the uplink switch ID. In case of a VSI connected to a port virtualizer, this is the S-tag associated with the S-channel of this VSI.	*VSI_SRCSWCTRL.SWID[11:0]* *VSI_SRCSWCTRL.ISNSTAG* *VSI_SRCSWCTRL.SWIDVALID*	The ISNSTAG should be set if the switchID is not an S-tag.
Enable VLAN Anti-spoof		*VSI_SRCSWCTRL.VLANAS*	
Enable MAC Anti-spoof		*VSI_SRCSWCTRL.MACAS*	
Allow Destination Override	Enables this VSI to set the destination of a packet.	*VSI_SRCSWCTRL.ALLOWDESTOVERRIDE*	
Enable Local Loopback	Allows forwarding to a VSI of packets sent from this VSI.	*VSI_RXSWCTRL.PRUNEENABLE* (inverse logic)	
Enable Loopback	Allows forwarding of packets from this VSI to local VSIs.	*VSI_SRCSWCTRL.ENABLELLOOPBACK*	
LAN Enable	Defines if the VSI is part of a VEB connected to the network.	*VSI_SRCSWCTRL.LANENABLE*	
Tag insertion and admission parameters			
Tag Accept Mode	Defines which tags to accept.	*VSI_TAR.ACCEPTTAGGED* and *VSI_TAR.ACCEPTUNTAGGED.*	
Port-based Tag	Define the VLAN/S-tag or other tags to insert into packet.	*VSI_TIR.PORT_TAG_ID*	
Port-based Tag Insert	Defines whether to use the tags previously described.	*VSI_L2TAGSTXVALID.PORTBASEDTAGS*	
Tag Strip Policy	Defines for each tag, if it should be left in packet, extracted to descriptor or removed.	*VSI_TSR*	
Queue mapping			
Queue base	The first queue allocated to this VSI.	*VSILAN_QBASE.VSIBASE*	
Number Of Receive Queues Per TC	Defines for each TC how many receive queues are allocated.	*VSIQF_TCREGION*	
Queue Mapping	Maps 16 virtual queues to physical queues.	*VSILAN_QTABLE* and *VSILAN_QBASE.VSIQTABLE_ENA*	

Table 38-188.VSI Context (Sheet 2 of 2)

Parameter	Description	Register.Field	Notes
PE Forwarding Enable	Enable TCP packets by the quad hash filter for the VSI.	VSIQF_CTL.PETCP_EN	
DCB control			
Enabled UPs	Defines the user priorities used by this VSI.	Implemented in scheduler.	

VSI Add and Remove Flows

Adding or removing a VSI can be done only by the PF. The following sections describes the flow a PF driver should use to add or remove a VSI.

VSI Init Flow

In order to initialize a VSI, software should use the *Add VSI* command to create the required VSI context. As part of this command, the queues allocated to the VSI should be specified. After this command runs the queues can be initiated.

VSI Disable Flow

VSIs can be disabled either individually or as part of their function. For example, when a VF is disabled, the VF reset stops the VSIs associated with this VF. There are cases where a PF might need to disable a single VSI. The use case for this flow is when a VSI is used as a VMDq interface to a VM that is disabled or moved to another system. In order to enable a quick disable of a VSI, the following flow should be used.

1. Software should stop scheduling packets to the transmit queues assigned to the VSI(s).
2. Stop the VSI traffic:
   a. For VMDQ VSIs, assert the VM reset using the *VSIGEN_RTRIG.VMSWR* bit and wait until the *VSIGEN_RSTAT.VMRD* bit clears. This step stops the traffic in all the queues associated with this VSI.
   b. For VFs, assert the VF reset using the *VPGEN_VFRTRIG.VFSWR* bit and wait until the *VPGEN_VFRSTAT.VFRD* bit clears. This step stops the traffic in all the queues associated with this VF.
3. Stop the relevant queues.
4. The PF polls the *Transactions Pending* flag of the VM, verifying that there are no transaction pending of the VM, as follows:
   - Set the VSI index in the *PFPCI_VMINDEX* register and then poll the *PFPCI_VMPEND* register.
5. Remove all filters pointing to this VSI/VF.
6. Clear the RSS table and key of the VSI using *Set RSS Key* and *Set RSS LUT* commands with zero values.
7. Send a *Delete Element* admin command with the VSI SEID (for each VSI associated to the VF). This step clears all VSI context values. Remove the VSI from the switch topology and remove it from the scheduler nodes.
8. Wait until the *Delete Element* command completes.
9. Clear the reset bit (*VSIGEN_RTRIG.VMSWR* or *VPGEN_VFRTRIG.VFSWR*).

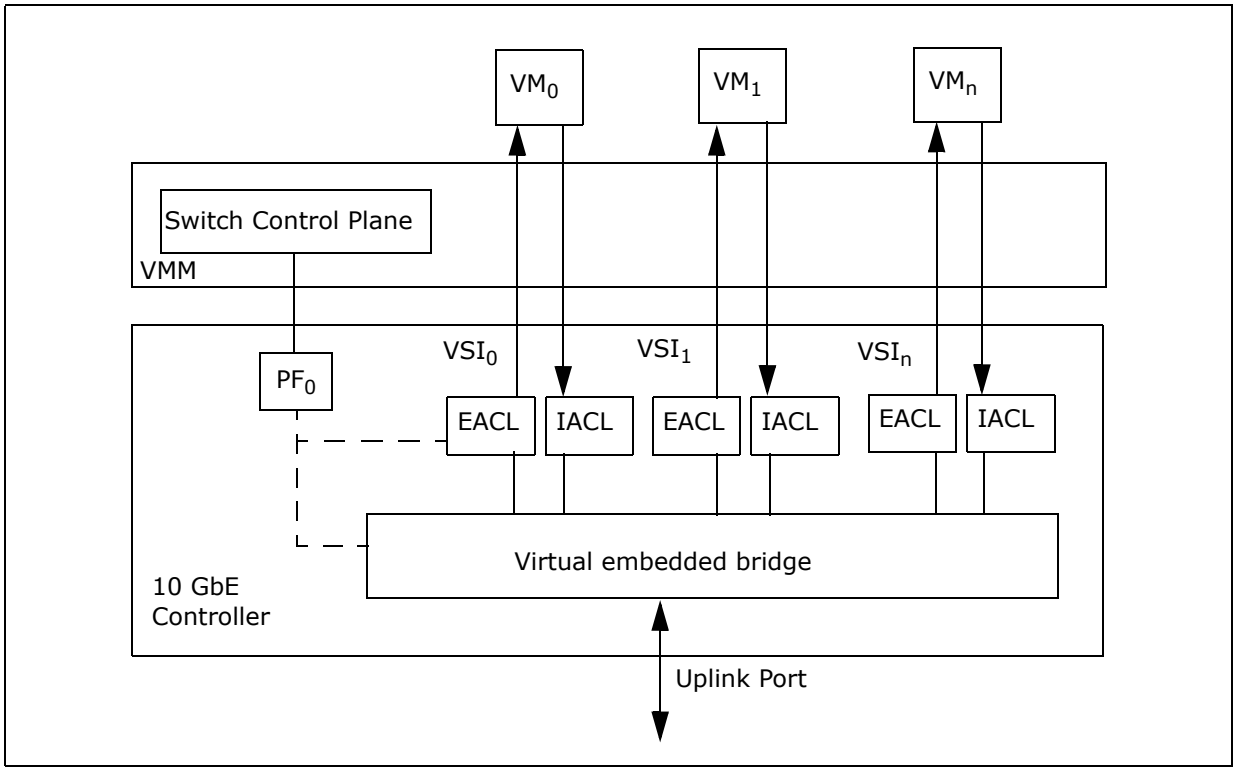
It's assumed that a VMDq VSI is not used for offloaded traffic (iWARP or UDA).

38.21.7.10 Advanced Switching Capabilities

38.21.7.11 Security Features

Security features implemented as part of the L2 tag handling such as port based VLAN and UP handling are described in Port-based VLAN section and Section 38.21.5, respectively.

Figure 38-47.Advanced Switching Capabilities



Anti-Spoofing

The 10 GbE controller supports anti-spoofing functionality. This is a security feature that ensures a VM is sending frames with MAC address and VLAN associated with that VSI. A malicious guest can impersonate as a trusted host by performing MAC address spoofing. If the anti-spoofing feature is turned on then only trusted MAC addresses are allowed on the ingress VSI.

MAC Anti-Spoofing

Trusted MAC address check is performed by performing a MAC address or VLAN, MAC lookup on the forwarding database. Since the forwarding database is populated by the VMM or control plane software when the VM/VSI is created, performing a MAC source address lookup on this database ensures that the VSI is transmitting with a source MAC assigned to that VSI.

MAC anti-spoofing is enabled by the *VSI.Enable MAC anti spoof* field in the VSI context.

VLAN Anti-Spoofing (Ingress Check)

VLAN ingress check is performed on incoming packets from VMs to ensure if the VSI is a member of the VLAN. This check is performed on the ingress VLAN membership table. VLAN ingress check can be enabled or disabled on each VSI. So a VM cannot transmit with a VLAN on which the VSI is not a member. This is applicable for VLAN aware guests. If a port or protocol-based VLAN is configured, a guest is not expected to send packets with 802.1Q tags then the admit untagged/priority tagged entry has to be set in port list.

VLAN ingress filtering is enabled by the *VSI.Enable VLAN anti spoof* field in the VSI context.

Port-Based VLAN

The 10 GbE controller supports a port-based VLAN feature by enabling any VSI to specify the default VLAN that it belongs to. The port-based VLAN association is done when a packet received on the VSI is untagged or priority tagged and protocol VLAN association is not done. Port-based VLANs map packets received on a given VSI with the corresponding port-based VLAN identifier called PVID. The PVID list should be programmed with the port VLAN IDs for each VSI.

The port VLAN list is provided, which is part of the VSI context. Table 38-189 lists the port VLAN parameters in the port VLAN list and the matching parameters in the Add VSI command.

Table 38-189.Port VLAN List and VSI Parameters

Port Based VLAN List	Add VSI Parameter	Notes
VSI Number	VSI number.	Returned by firmware in response.
PVID	PVID + default UP.	
Default UP		
Admit.1Q Tagged Only	VLAN driver insertion mode.	
Admit Untagged/Priority Tagged Only		
Admit All		
Ingress VLAN Check Enable	Enable VLAN anti-spoof.	
Insert PVID	Insert PVID.	
Expose VID And UP Of Received Packets	VLAN and UP expose mode (Rx).	
Expose UP Only Of Received Packets		
Do Not Expose VID Or UP Of Received Packets		
Ingress UP Translation Table	Ingress UP translation table.	see Transmit Functionality.
Egress UP Translation Table	Egress UP translation table.	see Receive Functionality.

The switch should insert the PVID to the packet if the *Insert PVID* parameter is set for the VSI and replace the UP bits according to the algorithm described in Transmit Functionality.

Once the VLAN ID association is made, the packet forwarding is performed using the VLAN, MAC forwarding table and VLAN membership table.

Private VLAN

The 10 GbE controller supports configuration of Private VLANs (PVLAN) in VEB mode. Private VLANs are used to provide Layer 2 level security by isolation of VMs within a VLAN (or IP subnet). Since VLAN defines a broadcast domain, all servers connected to the same VLAN can listen to broadcast packets. So a malicious VM can listen to neighboring virtual servers and launch direct attacks bypassing the security policies enforced by enterprise network switches. PVLAN provides Layer 2 security by creating sub-domains within the same primary VLAN without the need for an L3 router. These sub-domains are called secondary VLANs.

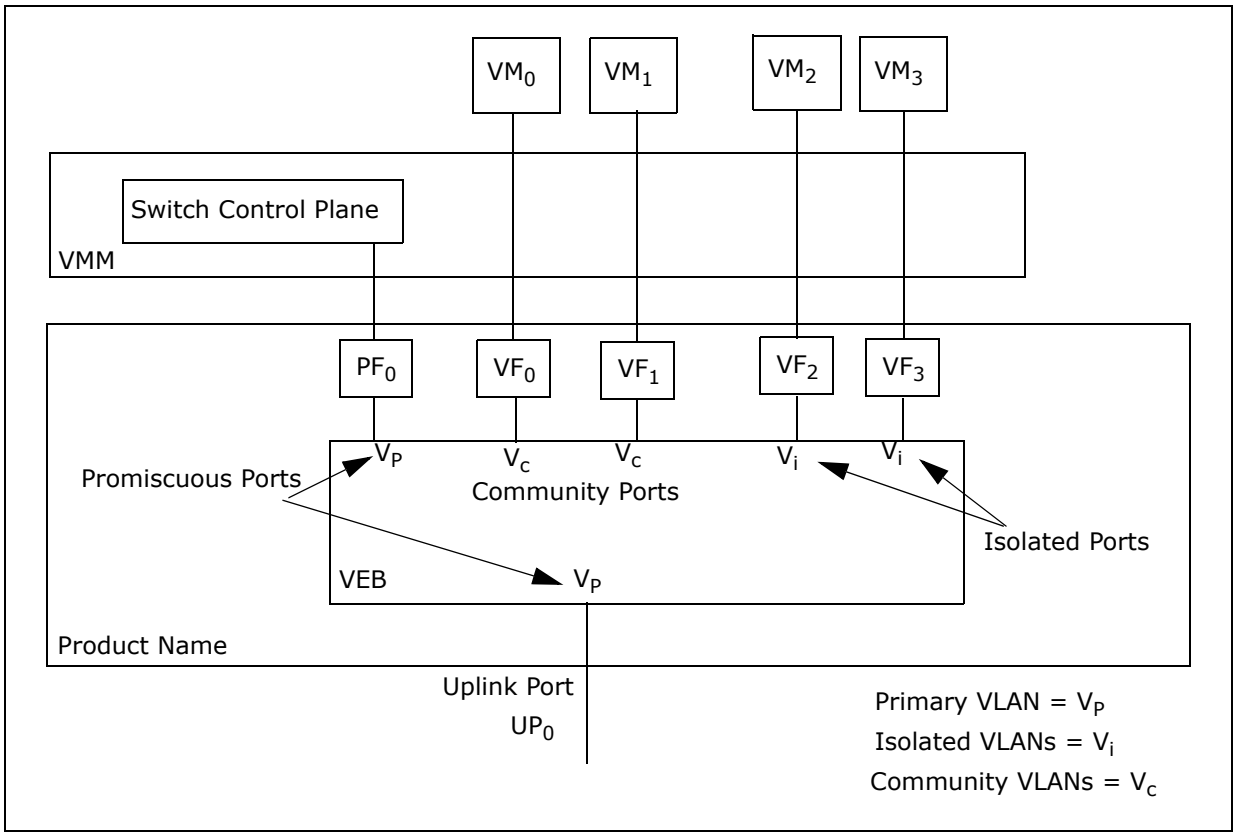
A virtual port in a private VLAN can be configured to one of three modes as follows:

- **Isolated Ports** — These cannot talk to any other virtual ports except to ports that are configured as promiscuous ports in the same primary VLAN. So a VM that only needs access to external network through uplink port has to be connected to isolated ports.
- **Community Ports** — The ports within a PVLAN community can talk to one another within the same community group (community VLAN) and also to the promiscuous ports in the same primary VLAN. There can be one or more PVLAN communities within the same primary VLAN. So a group of VMs that need to communicate with each other and also need external network access can be configured as members to one of PVLAN communities in the primary VLAN.
- **Promiscuous Ports** — These can talk to all of the ports in the same primary VLAN. Typically uplink ports and virtual ports that are connected to service VMs (for management purposes) can be designated as promiscuous ports.

Note: The meaning of promiscuous ports within the context of PVLAN is different from the generic promiscuous definition.

The following figure provides an illustration of PVLAN configuration.

Figure 38-48.Private VLAN Configuration



A primary VLAN V_P is configured on the VEB. Secondary VLANs, V_c is configured as community VLAN, and V_{i1}, V_{i2} are configured as isolated VLANs. The uplink port and the VEB management ports are configured as promiscuous ports. These ports communicate with all ports in the primary VLAN (V_p), including the community VLAN (V_p,V_c), and isolated VLAN (V_p,V_i).

The community VLAN ports (VF_0 and VF_1) can communicate only the between themselves and the uplink port UP_0 (and the management port PF_0). Isolated ports VF_2 and VF_3 can only communicate with uplink UP_0 (and the management port PF_0). The isolated ports cannot communicate with other isolated ports (VF_2 cannot communicate with VF_3) or to ports in community VLAN (VF_0 or VF_1).

VLAN pairing is used to represent secondary VLANs. There can be multiple community VLANs configured within a single primary VLAN (for example Vc1, Vc2, etc.); however, only one VLANID Vi is used to represent isolated VLANs.

The virtual port configuration and associated VLAN IDs are created as VLAN pairs as follows:

- Virtual ports (connected to VMs) are configured with VLAN pairs (primary VLAN, secondary VLAN).
- The distinction between the different roles is done by defining the ingress and egress membership of each VSI for the primary and secondary VLAN as described in Table 38-190.

Table 38-190.Private VLAN Membership

Port Type	Member of Primary Egress List	Member of Primary Ingress List	Member of Secondary Egress List	Member of Secondary Ingress List
Regular VLAN	Yes	Yes	N/A	N/A
Promiscuous	Yes	Yes	Yes	Yes
Community	Yes	Yes	Yes	No
Isolated	No	Yes	Yes	No

Isolated VLAN Configuration and Forwarding

Virtual port VF2, VF3 are configured as isolated ports to be members of both Vp and Vi. Frames from the network to virtual port (ingress) are arriving with primary VLAN ID Vp. However, frames from the virtual port to the network (egress) are always assigned a secondary VLAN ID Vi. Broadcast and multicast frames from the virtual port are not forwarded to other isolated ports in the isolated secondary VLAN Vi; they are only forwarded to uplinks (or ports configured as promiscuous ports in primary VLAN).

The forwarding database has one entry (Vp, MAC2) pairing for virtual port VF2. If a port-based VLAN is assigned to the port, then this is Vi. Otherwise, Vi is the only VLAN ID in the private VLAN to be part of the egress VLAN list for VF2. Packets arriving from a network carry a primary VLAN ID (Vp, MAC2). Only Vp will be part of the ingress VLAN list for this port.

If a unicast packet arrives from network that is designated as isolated VLAN, then it cannot be forwarded to isolated ports. Such frames should be dropped. If a multicast or broadcast packet arrives from the network with VLAN ID Vi, then it cannot be forwarded to isolated ports. It can only be forwarded to promiscuous ports, in this case it is management port PF0.

Community VLAN Configuration and Forwarding

Virtual port VF0, VF1 are configured as community ports to be members of both Vp and Vc. Frames from the network to virtual port (ingress) are arriving with either primary VLAN ID Vp or secondary VLAN ID Vc. However, frames from the virtual port to the network (egress) are always assigned a secondary VLAN ID Vc. Broadcast and multicast frames from the virtual port are only forwarded to other virtual ports that are members of the community VLAN Vc and to uplinks (or ports configured as promiscuous ports in primary VLAN).

The forwarding database has two entries Vp, MAC1 and Vc, MAC1 pairing for virtual port VF1. If a port-based VLAN is assigned to the port, then this is Vc. Otherwise, Vc is the only VLAN ID in the private VLAN to be part of the egress VLAN list for VF2. Ingress packets from a network towards VF2 uses either (Vp, MAC1) or (Vc, MAC2) for forwarding. Both Vp and Vc are part of the ingress VLAN list for this port.

If a unicast packet arrives from network that is designated as community VLAN Vc then it can be forwarded only to community ports that are members to the same community VLAN Vc. If a multicast or broadcast packet arrives from the network with VLAN ID Vc then they can be forwarded to other community ports in the same community VLAN Vc and to promiscuous ports, in this case it is management port PF0.

Primary VLAN, Promiscuous Port Configuration and Forwarding

A primary VLAN Vp is created with all the community ports, isolated ports and promiscuous ports as members. Unicast packets arriving from the network with primary VLAN Vp are forwarded based on (Vp, MACx). Egress check is performed to find out the member ports. Multicast or broadcast packets are forwarded to based on (Vp, Multicast MACx) and forwarded to member ports. Broadcast is forwarded to all members of primary VLAN.

Ports that are configured as promiscuous ports are typically uplink ports (UP0) and switch management ports (PF0). The promiscuous ports are members of primary VLAN Vc and all secondary VLANs, Vc, Vi. So the promiscuous ports can receive broadcast packets from any of the secondary VLANs.

Note: In order to assure proper operation of private VLANs both internal VEB and external access switch need to be configured with the same private VLAN designations.

Local VLANs

A VLAN can be defined as local. In this case, packets sent with this VLAN ID is not forwarded to the network and packets from the network with this VLAN are dropped.

Locality is defined at the VEB level.

A VLAN can be defined as local using the *Add VLAN* admin command with the *LocalVLAN* attribute set.

User Priority Bits (802.1p) Handling

The *UP* bits are used to differentiate between multiple classes of traffic. The 10 GbE controller supports multiple use cases related to the handling of the UP bits:

1. An operating system that is not DCB/traffic type aware and uses a single TCID.
2. An operation system that is traffic type aware, but not DCB aware. It can distribute the traffic to different queues, but cannot tag them with the right UP and iWARP. The operating system is not aware but the software device driver knows the difference and hence can assign the different types of traffic to different flows. There is no DCBX agent so the software device driver does not know the UP or TC for flows.
3. An untrusted operating system that might set *UP* bits of TCs it is not allowed for use.
4. An operating system that can use a single queue per TCID, but would like to use more UPs in order to gain from the differentiated QoS in the network.

The following sections describe the handling of *UP* bits in transmit and receive to support the previous use cases.

Transmit Functionality

Each transmit packet is assigned a UP, either by the software device driver or as part of the port VLAN table.

This UP is translated using two different translation vectors.

The first vector is specific to a VSI and is part of the port VLAN table (*transmit UP translation table - VSI_TUPR*). This vector reflects the mapping of the user priorities as seen by the operating system to the user priorities as seen by the network.

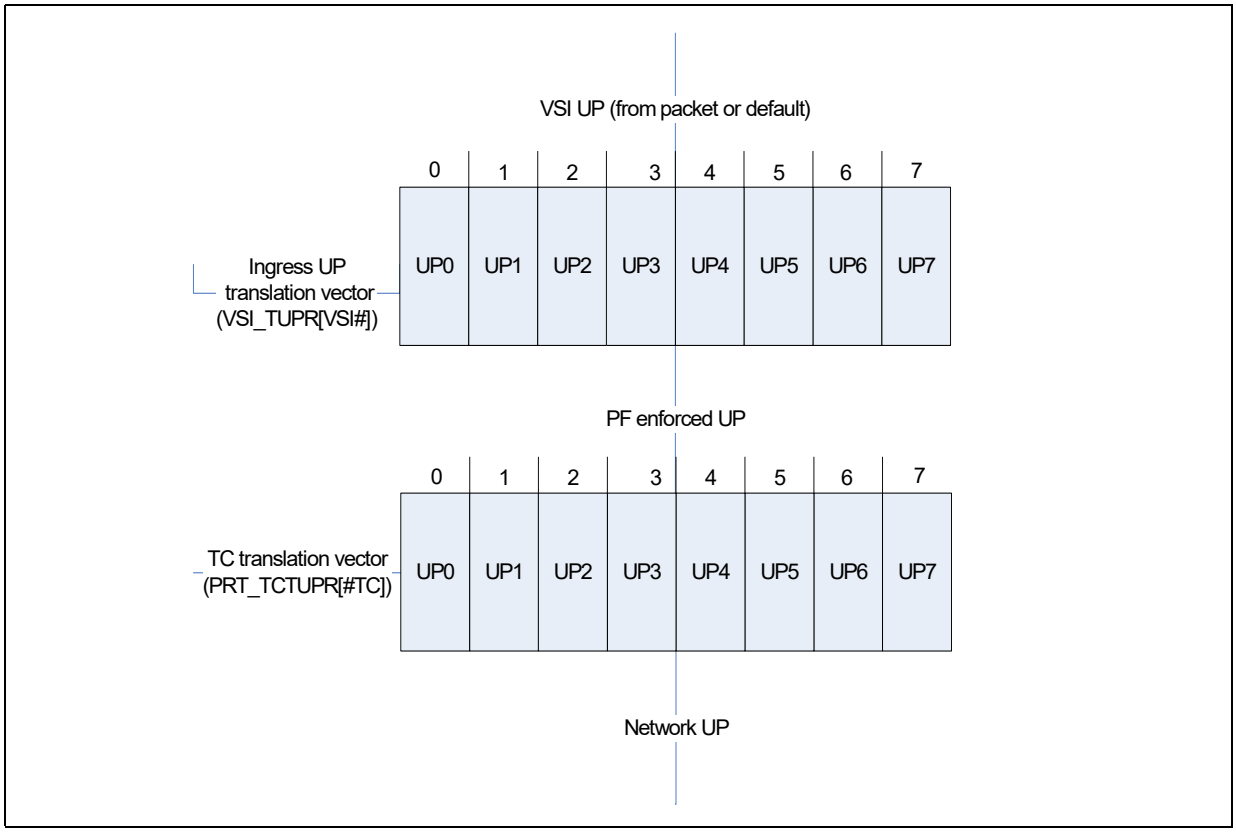
The second vector is specific to a TCID in a physical port. It translates the UP received from the previous translation to a UP matching the TCID to which the packet is associated. These vectors can be configured through the *PRT_TCTUPR* registers.

Note: There is no drop of packets due to incorrect 802.1p tagging. If an incorrect tag is requested the tag is replaced. Thus, this functionality supports both UP anti-spoofing and port based UP.

Untagged packets are kept as is. No translation is done on them.

The following figure shows the algorithm.

Figure 38-49.Example: Non-VLAN Aware, Non-DCB Aware Operating System



Assume a VF that queues LAN traffic and iSCSI traffic to different queues, but is not VLAN aware. In this case, the packet is sent by the software device driver with no VLAN and the default UP set in the port-based VLAN (such as 0) is the initial UP of the packet. In this case, the *Ingress UP translation vector* (*VSI_TUPR*) is not relevant and might be for example {0,1,2,3,4,5,6,7} or {0,0,0,0,0,0,0,0}. The *TC translation vector* (*PRT_TCTUPR)* for LAN might be {0,1,2,0,0,0,0,0} and the TC table for storage might be {4,4,4,4,5,4,4,4}. So a LAN packet goes out with a UP of 0, and a storage packet goes out with a UP of 4.

Example: Non DCBx tagging operating system

Assume a VF that tags LAN high priority traffic with a UP of 4 and LAN low priority traffic with a UP of 3 and the storage traffic as UP 7. In this case, the VF translation table might be {0,1,2,0,2,4,4} and the TC tables as previously described. The low priority LAN goes out with a UP of 0, the high priority LAN with a UP of 2 and storage with a UP of 4.

The tag on which the transmit UP translation is done is identified by setting the *INNERUP* bit in the matching GL_SWT_L2TAGCTRL register.

The default mapping of both tables is identity mapping. For example, mapping a UP to itself. If UP translation is not needed these mappings should not be changed.

Transmit Outer Tag User Priority

The transmit outer tag user priority can be handled in three different ways:

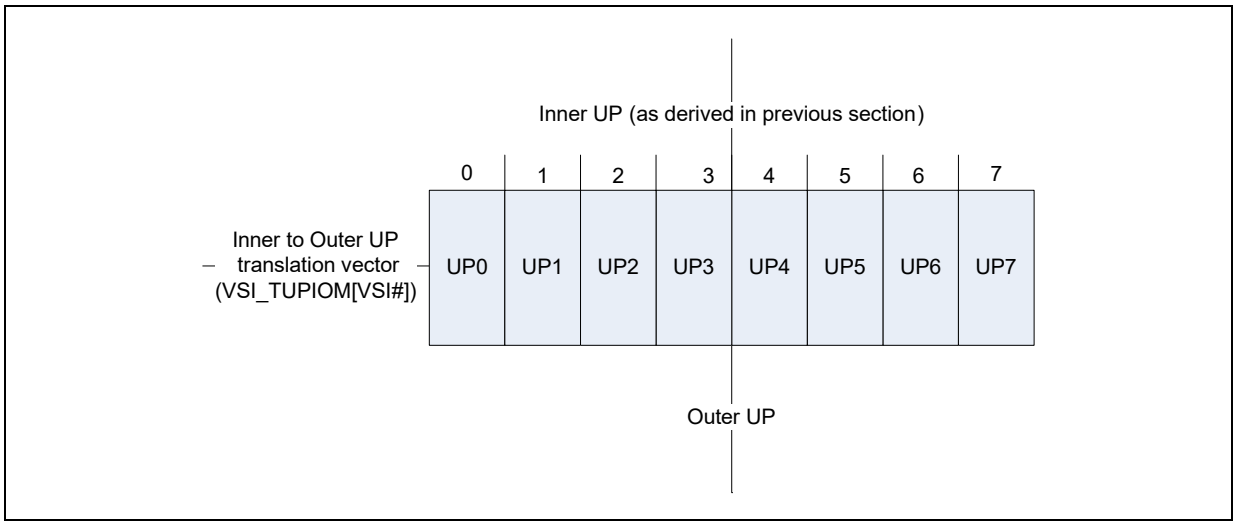
1. If the outer tag is received in the packet or the descriptor (such as cascaded S-comp), the UP should be part of the packet sent by the software device driver or inserted from the descriptor.
2. If the outer tag is inserted by hardware then the UP might be either:
   a. The UP defined as part of the inserted tag in the VSI_TIR register.
   b. A translation of the regular VLAN UP as defined in the *VSI_TUPIOM* register.

If the outer tag is defined as *OuterUP* in the GL_SWT_L2TAGCTRL register, then the UP is based on the first tag for which the *InnerUP* field is set in the GL_SWT_L2TAGCTRL register; usually the VLAN tag (option 2.b); otherwise, it is based on the default (option 2.a).

The tag to which translation is applied can be either S-tag or external VLAN.

The following figure shows the translation process.

Figure 38-50.Tx Inner-to-outer UP Translation



Receive Functionality

VLAN UP Translation

The priority bits of inner VLAN tag in received packets might be remapped using the *Ingress UP translation table* in the *Add VSI* command. This means the operating system might get packets with 802.1p priority bits reflecting the local configuration and not the link configuration. By default (ingress UP translation section is not valid) the translation is one-to-one, meaning that the received UP is not translated.

VLAN UP Exposure to Software Device Driver

The exposure of the received UP to operating systems is defined by the awareness of the operating system controlling the VSI as follow:

1. For a monolithic operating system, VMM or for a guest operating system that is VLAN aware, the UP is exposed as part of the VLAN as requested by the software device driver (either in the packet or in the descriptor).
2. If the guest operating system is DCB aware but not VLAN aware, it gets the priority bits as part of the receive descriptor in the VLAN tag field. The VLAN ID is zero, but the priority bits are valid.
3. A guest operating system that is not VLAN aware and not DCB aware does not get the user priority bits (UP) at all.

The configuration of the UP removal is part of the port VLAN configuration described in Port-Based VLAN and in the Add VSI command VLAN handling section. See Add VSI (0x0210).

38.21.7.11.1 Switch Diagnostics

This section describes the mirroring and loopback features.

Mirroring

The 10 GbE controller supports 64 mirroring rules. Each rule can be coupled to any of the VEB or port aggregator in the device. The destination port of each rule (the mirror port) must be connected to the switching element in which the rule is applied. Packets that match any of the mirroring rules assigned to this element are forwarded to the VSI defined in the mirror rule. The setup of a mirror VSI is described in Mirror VSI Setup.

In order to differentiate packets received according to the different rules, the matched rule is indicated in the Mirror Rule ID *(MIRR)* field in the receive descriptor.

Note: The switching algorithm enables mirroring-to-mirror ports even if the loopback is disabled for this port. The controlling software needs to make sure mirror ports are assigned only to ports that can receive local traffic.

Each rule can is defined by the following parameters:

1. A rule ID — A value in the 0..63 range reflected in the *MIRR* field in the receive descriptor.
2. A mirror port to which packets matching the mirroring conditions are sent.
3. A set of mirrored ingress VSIs — All packets received by these VSIs are also sent to the mirror port.
4. A set of mirrored egress VSIs - All packets sent by these VSIs are also sent to the mirror port.

Additional rules can be defined to create ingress VLAN mirroring — When such a rule is created, all traffic received in a set of given VLANs by any of the virtual ports either from the uplink or from local VMs within a given VEB are forwarded to a mirror port.

Note: Packets forwarded by ingress VLAN mirroring are not identified by the *MIRR* field and the *UMBCAST* field as a mirror packet. The matched mirror rules can be inferred from the VLAN of the packet. Mirroring according to ingress VLAN mirroring of transmit packets might add an additional copy of the packet to the default VSI of the VEB or the port.

Mirroring rules can be applied using the following admin commands:

- Add Mirror rule (Add Mirror Rule (0x0260)).
- Remove Mirror rule (Delete Mirror Rule (0x0261)).

Note: A mirror port cannot be defined in the ingress mirroring list of another mirroring rules.

A single rule can be either ingress VSI, egress VSI or VLAN and cannot include multiple types of rule.

Ingress or egress VSI traffic cannot be mirrored to multiple mirrored ports.

A VSI cannot be part of more than a single port mirror rule (cannot be mirrored twice). This limitation does not include VLAN mirroring.

A control VSI that uses the switch override field (SWTCH) in transmitted packets descriptor cannot be part of an ingress mirror rule.

Ingress Mirroring Flow

Ingress mirroring acts on all the packets that are sent from a given VSI, no matter if the packet is sent to the network or to a local VSI and does not depend on the *Allow Loopback* flag in the VSI context.

Packets dropped due to anti-spoofing are also mirrored.

Egress Mirroring Flow

Egress mirroring acts on all the packets that are received by a given VSI no matter if the packet was received from the network or from a local VLAN.

Mirror VSI Setup

A VSI used to receive mirror traffic should be dedicated to this type of traffic and thus should not be used to send or receive other traffic.

VSI Loopback

Some systems require a local loopback capability at the switch level allowing to receive all the packets sent from a VSI back to the same VSI.

This capability is achieved by using the following steps:

1. When creating the VSI using the *Add VSI* command, set the *Allow destination override* bit.
2. When sending a packet, set in the descriptor the *SWTCH* field to 11b (target VSI) and set the *Segmentation Parameters.VSI* field to the value of this VSI.

Packets sent using descriptors with the attributes previously mentioned are sent back to a receive queue of the same VSI.

38.21.7.11.2 Cascaded Port Virtualizer Offloads

The 10 GbE controller supports VSIs used as cascaded port virtualizers as described in Cascaded VEB and Port Virtualizers. Such a VSI provides some special offloads to support this mode.

Transmit Offloads

S-tag insertion — As this VSI supports multiple S-tags, the S-tag cannot be inserted by the 10 GbE controller using the port-based tagging mechanism. The software device driver might indicate the S-tag to insert in the *L2TAG2* field in the transmit descriptor and set the *IL2TAG2* bit. Hardware then inserts the right tag to the packet.

The ability of a VSI to control the S-tag from the descriptor or from the packet is set by the *Accept tag from host* in the *Add VSI* command.

Note: If a packet is sent by the software device driver with the S-tag as part of the packet, it must also include the VLAN.

If an S-tag needs to be inserted, a 32-byte transmit descriptors must be used.

Receive Offloads

- S-tag extraction — This VSI supports multiple S-tags so the software device driver must receive the S-tag in order to process the packet. These tags can be extracted from the packet and stored in the receive descriptor in the *L2TAG2 (1st)* field. The presence of these tags is indicated by the *L2TAG2P* bit. This offload is activated via the *Report S-tag* field in the *Add VSI* command.

Note: This capability is orthogonal to the VLAN tag extraction and might be requested with or without VLAN extraction.

- Source Pruning — This capability should be disabled in a cascaded S-comp by clearing the *Prune based on ingress E-PID* enable field in the VSI context.
- VMDq1 Queueing — A cascaded port virtualizer might request to queue packets with different tag values to different queues, similar to the VMDq1 mode supported for cascaded VEBs. In this mode, packets with an unrecognized S-tag is forwarded to the default queue of the VSI.

38.21.7.11.3 DCB and Rate Limit Support

Each VSI can be associated with a scheduling element and with a set of user priorities and TCs. Each user priority is represented by a set of queue pairs and a scheduler element. If multiple UPs are associated with the same TC, a scheduler element might be added later to group those UPs into a single TC. The VSI scheduling element can be used to define an SLA for this VSI. The UP and TC scheduling elements are used to set an ETS policy for this VSI. Each S-channel created is also associated with a scheduler element allowing a different SLA for each channel.

Assigning scheduling elements is done internally when an *Add VSI* or an *Add VEB* admin command is received. The dis-association is done when a *Delete Element* admin command is received.

The TCs created are set according to the *Enabled UPs* field in the *Add VSI* command. The handles to the TC rate limiters are returned as part of the *Add VSI* response. The addition of TC scheduler elements can be done after the VSI exists using the *Configure VSI Bandwidth per Traffic Class* admin command).

In order to control the rate limiter behavior, the scheduler admin commands should be used. When accessing a switching element (VSI or S-channel) scheduler element, the SEID is used as the handle to the node. When accessing a TC the handles returned in the *Add VSI* response are used.

38.21.7.12 Flows

This section provides a summary of the processing across all the switching elements in Tx and Rx.

38.21.7.12.1 Tx Flow

The following steps are taken once a packet is accepted for transmission by the switching engine. This flow assumes any state offload needed had been applied to the packet:

1. **Anti-spoofing —** If enabled in the Add VSI command VSI sending the packet is part of those addresses destination, the packet is allowed to proceed.
2. **VLAN insertion —** If needed, insert the VLAN tag to the packet, either as a host request or as a port-based VLAN.
3. **S-tag insertion —** If the VEB or the function is connected to an S-comp, add the S-tag of the channel to the packet.
4. **UP replacement —** Replace the *UP* bits.
5. **VEB filtering —** If the port/queue that sends the packet is connected to a VEB, the algorithm described in Section 38.21.7.13.4 is applied to create a list of destination ports. Otherwise, the list of destination ports is simply the network. The VEB filtering for Tx packets includes the following steps:
   a. Defining the list of VSIs that are candidate for reception of the packet. These VSIs are defined according to the filters set using the *Add MAC, VLAN pair*, *Add Cloud filters* and *Add EtherType filters* commands (Section 38.21.7.18.8).
   b. Add an EMP-owned VSI that should receive the packet. This includes forwarding to the MC channel using decision filters and control packets.
   c. Potentially removing from this list the VSIs that do not belong to the VLAN group as defined by the *Add VLAN* command. See Add VLAN (0x0252) for more detail.
   d. Potentially removing from this list the VSI that sent the packet. This removal can be based on comparison of the SA of the packet to the MAC table.
   e. Add ingress mirror VSI as defined by the *Add Mirror Rules* admin command.
6. For a copy of the packet sent to the sideband interface follow the steps in step 8. For copies of the packet sent to local functions follow the steps in step 9
7. **Processing of packets sent to the network:**
   a. **MAC processing** — If it applies, insert a CRC on the packet.
   b. Forward to the network.
8. **Processing of packets sent to the sideband interface**:
   a. Forward the packet to the sideband interface.
9. **Processing of packets sent to local functions**:
   a. **Security and MAC processing** — If it applies, encrypt or decrypt the packet using IPSec.
   b. **Forward to function** — Forward the packet to the selected function for further processing.

38.21.7.12.2 Rx Flow

The following steps are taken for each packet received from the network by the switching engine:

1. **MAC processing** — Check the CRC and other error conditions. If *Pass Bad Packets* is set (PRT_SBPVSI.SBP), add the bad frames VSI (*PRT_SBPVSI.BAD_FRAMES_VSI*) to the VSI list. Identify flow control packets and priority flow control packets and react to them.
2. **VEB/port aggregator/L2 filter** — According to the configured switching element connected to the S-channel/physical port, apply the algorithms defined in Section 38.21.7.13.2, or Section 38.21.7.13.4 to define a list of destination ports. This includes the following steps:
   a. Defining the list of VSIs that are a candidate for receiving the packet. These VSIs are defined according to the filters set using the *Add MAC, VLAN pair*, *Add Cloud filters* and *Add EtherType filters* commands (Section 38.21.7.18.8).
   b. Add an EMP-owned VSI that should receive the packet. This includes forwarding to the MC channel using decision filters and control packets.
   c. Potentially removing from this list the VSIs that do not belong to the VLAN group as defined by the *Add VLAN* command (Add VLAN (0x0252)).
   d. Potentially removing from this list the VSI that sent the packet. This removal can be based on comparison of the SA of the packet to the MAC table.
   e. Add egress mirror VSIs as defined by the *Add Mirror Rules* admin command.
3. The resulting list of destination ports can include local ports or sideband interface.
4. For a copy of the packet sent to the sideband interface follow the steps in step 6. For copies of the packet sent to local functions follow the steps in step 8.
5. **Processing of packets sent to local functions**:
   a. **S-tag and VLAN removal** — If it applies, remove the S-tag and VLAN tag from the packet and optionally report them in the Rx descriptor.
   b. **UP replacement** — Replace the *UP* bits as described in Receive Functionality.
   c. **Forward to function** — Forward the packet to the selected function for further processing including queuing and iWARP offload.
6. **Processing of packets sent to the sideband interface or to the EMP**:
   a. Forward the packet to the sideband interface or to the EMP. The VSI context defines the destination within the EMP VSI (one of the sideband interfaces or the EMP) either using the regular switch or the packet classifier.

38.21.7.13 Switching Algorithms

38.21.7.13.1 LAN Port Extender Algorithm

This algorithm translates a destination MAC address to a switch ID. After this algorithm is applied, the regular per switch forwarding algorithm should be applied to each of the switch IDs. The algorithm is relevant only to receive traffic.

```
// Global parameters

Port.DefaultStag; Can be Null or an S-tag.

// Define Lookup tables

DA Table: Array of {DA ,LAN , Switch ID}

EComp_function(Packet) {
```

```
// Variables

STag = Port.DefaultStag

SourceStagFlag = FALSE // SourceStagFlag is not used by this algorithm.

//Define packet parameters

DA = Packet.DA: the DA of the packet.

Source Port // The port from where the packet was received.

// Switching algorithm

// Selection of S-tag using DA

If ({DA, source port} match entry e in DA table): DSTag = e.S-tag;

Return DStag, SourceStagFlag;

}
```

38.21.7.13.2 S-comp Forwarding Algorithm

The following algorithm refers only to S-comp receive traffic. As previously described, transmit traffic is always sent to the LAN apart from the iWARP loopback case.

Packets with unmatched S-tag are forwarded to a default VSI of the port, if enabled.

Packets forwarded to the default VSI cannot be subject to L2 filtering.

This algorithm defines a switch ID that identify the S-channel to which the packet should be forwarded. The switch ID is used to identify a potential VEB connected to this S-channel. The forwarding inside this channel is defined according to the L2 forwarding algorithm (Section 38.21.7.13.4) or VEB/VEPA algorithm (Section 38.21.7.13.3).

If no VEB is defined, then the VSI connected to the S-channel should be put in promiscuous mode using the Set VSI Promiscuous Modes command in order to receive all the traffic with the given S-tag.

If an S-comp is not defined on the port, then all the packets with an S-tag are dropped.

```
// Global parameters

Port.DefaultVSI; Can be Null or a VSI

Port.Default_Switch_ID; // The switch ID to use for untagged.

DefaultVSIValid - per port// If set, packets with an S-tag that do not match any of

these programmed S-tags or an untagged packet that do not match the expected

ethertypes will be sent to the default VSI, otherwise the packet is dropped.

// Define Lookup tables

StagTable: Array of {STAG}

// Control Port forwarding rules

SComp_function(Packet) {

// Variables

Dest_VSI - Null; // Destination VSI in case of default VSI;
```

```
Switch_ID = Null;
//Define packet parameters
STag = Packet.Stag: the S-Tag of the packet.
Untagged // True if packet has no S-tag.
// Switching algortihm
// control port forwarding
// Note - the usual case of a control VSI is to receive LLDP packets or other
packets based on special Ethertypes. However, the device allows any L2 forwarding
to the control VSI assuming the right forwarding rule is added. See
Section 10.21.4.8.4 for details of the available rules.
If (Untagged) { Switch_ID = Port.Default_Switch_ID;}
// S-tag forwarding
If(Stag match entry e in StagTable) {
Switch_ID = S-tag
} else if (DefaultVSIValid)
Dest_VSI = Port.DefaultVSI
else drop packet.
Return Switch_ID, Dest_VSI;
}
```

38.21.7.13.3 L2 Filtering Algorithm

The following pseudo code describes the algorithm used to determine if a packet passes the L2 filtering element.

```
// Global parameters
// Define Lookup tables
MacVlan Table: Array of {MAC (MAC Address), VLAN (VLAN tag)}
Mac Table: Array of {MAC (MAC Address)}
VLAN table: Array of {VLAN (VLAN tag)}
HashMacVlan Table: Array of {HashMAC (Hash Values), VLAN (VLAN tag), AddressType}
HashMac Table: Array of {HashMAC (Hash Values) , AddressType}
EtherType Table : Array of {Etype (Ethertypes Values)}
MacEtherType Table: Array of {MAC (MAC Address), Etype (Ethertype value)}

38.21.7.14 Switch Programming Model

38.21.7.14.1 Switching Structure Representation

This section describes the model used to represent the switching elements.

The objects represented in the models are identified by a 10-bit device-wide Switch Element Identifier (SEID). The SEID of an element is returned after creating the element and should be referenced when creating ties between elements. The SEID of elements created automatically can be retrieved using the *Describe Structure* command.

The objects represented can be either external or internal to the switch. Possible external elements are listed in Table 38-191.

Table 38-191.External Elements

External Element	Abbreviation	Element Type	Description
Physical Port MAC	MAC	1	This element is always present. An SEID is allocated at power on for each enabled port.
Physical Functions	PF	2	PF elements is created at PCIe reset for each enabled PF.
Virtual Functions	VF	3	VF elements are created when SR-IOV is enabled on a physical function.
Embedded Micro Processor	EMP	4	The embedded micro processor can be used as a control port for the different switching elements. All the ties to the EMP should be explicitly created when creating an element. An EMP can contain multiple EMP queues that are only used to represent logical connections to the switch. This is used to enable multiple control ports in the EMP. This element includes the MC interface used to enable pass-through traffic to an external MC via an out-of-band connection.

The internal elements are elements that are used as part of the switching decision. The following elements are listed in Table 38-192.

Table 38-192.Internal Elements

Internal Element	Abbreviation	Element Type	Description	Related Commands	Described In Section
Port Virtualizer (S-comp or Port Extender)	PV	16	Defines an S-comp or a port extender. Together with a PV, create a set of S-channels elements	Add port virtualizer. Update Port Virtualizer parameters. Get Port Virtualizer parameters.	38.21.7.4.2
S-channel	SC	N/A	An S-channel created as part of an S-comp/M-comp element. There is no separate S-channel element. An S-channel connected directly to an external element (PF/VF/EMP) is considered a VSI. An S-channel connected to a VEB or a VEPA is considered as part of the VEB/VEPA.	N/A	38.21.7.4.2
L2 Filter	L2	N/A	An L2 filter element. Such an element is created by default to connect a MAC and the first PF tied to this MAC. An L2 is not created as part of the topology. Rather it is implemented using the filtering options to the VSI tied to it.	N/A	38.21.7.4.4
VEB/Port Aggregator	VEB/VEPA	17	A VEB or a virtual port aggregator.	Add VEB Get VEB parameters	
Virtual Station Interface	VSI	19	A VSI can be part of a VEB, VEPA or PV element and is connected to an host external element (PF, VF or EMP).	Add VSI. Update VSI parameters. Get VSI parameters. Delete element.	38.21.7.9.2

The SEIDs are allocated according to firmware. Note that a fixed mapping should not be assumed.

Table 38-193 lists the representation of the switching hierarchy and should be used by embedded firmware and the host software as a common database.

Table 38-193.Switching Structure Representation

Entry in Table	Description	Notes
SEID	The handle to the element.	
Element Type	As listed in Table 38-191 and Table 38-192.	
Up Link Connection(s)	Indicates the SEID of the switching element connected directly below the current element. Below means towards the network in this case.	For sub-elements of a composed switch element, the uplink is the containing element.
Down Link Connection(s)	Indicates the SEID of the switching element connected directly above the current element. Above means towards the host in this case.	The downlink is provided only for elements connected to PFs, VFs or to the EMP. In other cases, the value is zero.
Control Port	For elements with a control port (points to the control port).	
Scheduler Node	The scheduler node associated with this switch element.	

Table 38-194 lists an example of the representation of a switching configuration as shown in Figure 38-51.

Figure 38-51.Switching Structure Example

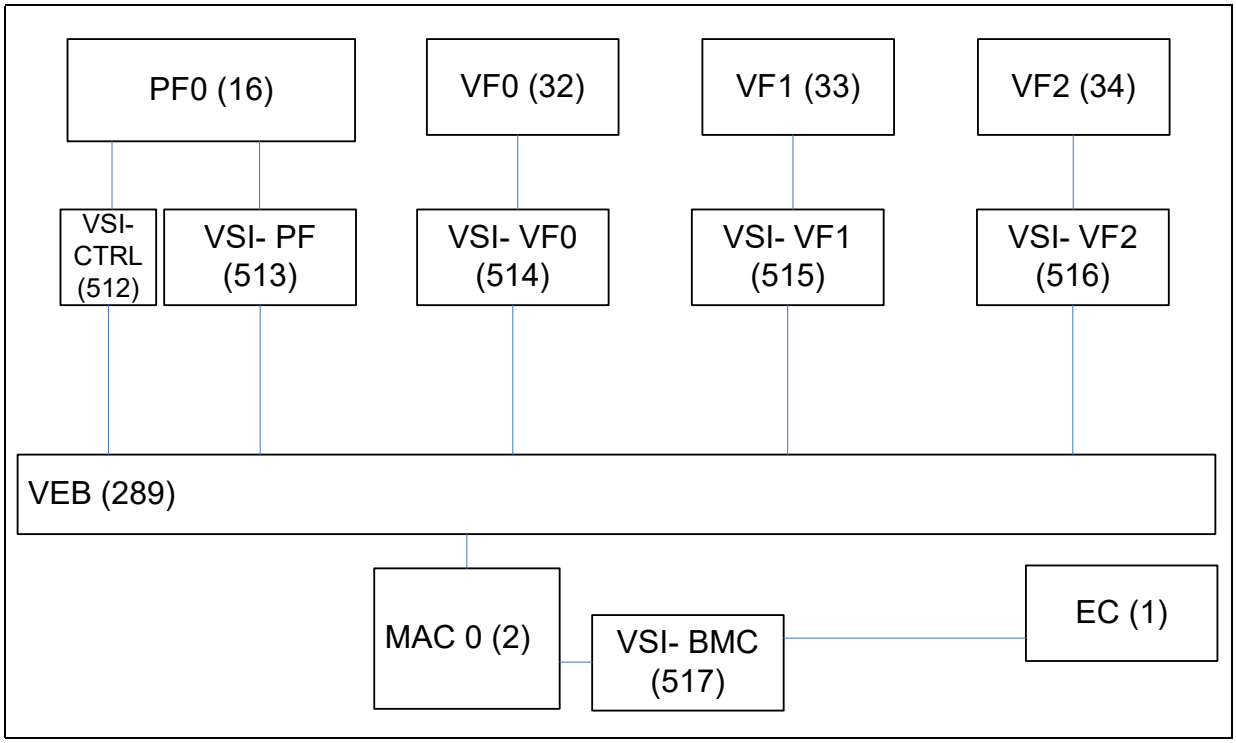

Table 38-194.Switching Structure Representation - Examples

SEID	Description	Element Type	Uplink	Downlink
0	Null	Null	0	0

38.21.7.15 Supported Switch Profiles

This section describes the supported switching profiles.

The profiles described are per port.

The following profiles are supported by the 10 GbE controller:

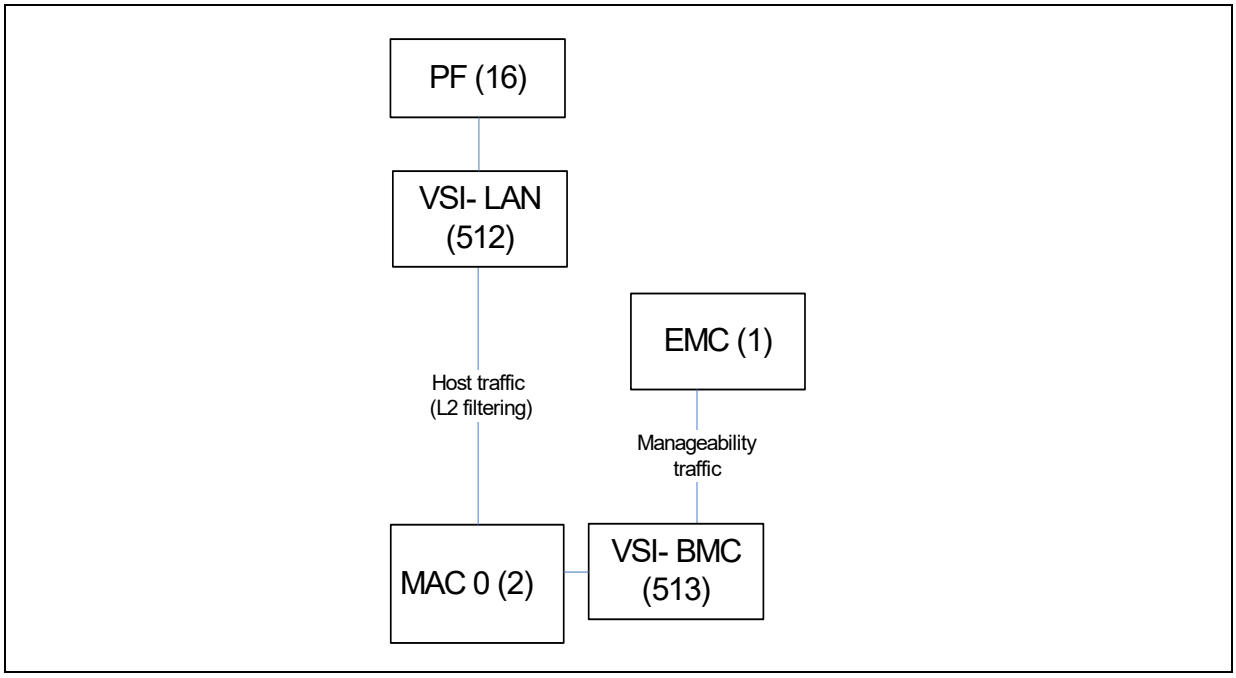
1. Basic L2 (default configuration).
2. Basic L2 + iWARP.
3. VEB/VEPA only (with or without iWARP).
4. Port Virtualizer.
5. Port Virtualizer + VEB/VEPA.

Note: There is no central location in which a profile is set. These profiles are examples of possible configuration that are expected in the 10 GbE controller. The configuration of each profile is done using the admin commands described in Section 38.21.7.17.2

38.21.7.15.1 Basic L2

A basic L2 configuration is used for monolithic OSes (non virtualized) systems where an iWARP function is not using a separate MAC, VLAN pair and the network is not distributed to virtual channels. In this case, the switch configuration is as follow:

Figure 38-52.Switch Configuration (Basic L2)



Basic L2 (Resource Allocation)

In this profile, all resources allocated in the NVM to the port are available to this single function.

38.21.7.15.2 Basic L2 + iWARP

A basic L2 configuration is used for monolithic operating systems (non-virtualized) where an iWARP function is exposed and the network is not distributed to virtual channels.

Note: The control port of the VEB can be either a separate VSI or part of the regular VSI of the PF.

Basic L2 + iWARP (Resource Allocation)

In this mode, a single queue of the PF is assigned for iWARP stateless traffic. All the other queues are used by the LAN function.

38.21.7.15.3 VEB/VEPA

A VEB configuration is used for virtualized operating systems where the network is not distributed to virtual channels. The switch configuration for the VEB/VEPA case is described in the following figure.

The use cases for VEB and VEPA are described in VEB for Direct Connected VMs and Virtual port Aggregator Model, respectively.

Note: The following figure shows both VFs with a separate VSI for iWARP traffic and VFs with a single VSI.

The control port of the VEB can be either a separate VSI or part of the regular VSI of the PF.

VEB (Resource Allocation)

There is no limitation on the number VSIs on a single VEB (apart from the total numbers of VSIs supported) and up to 4 VEBs connected to a single PF.

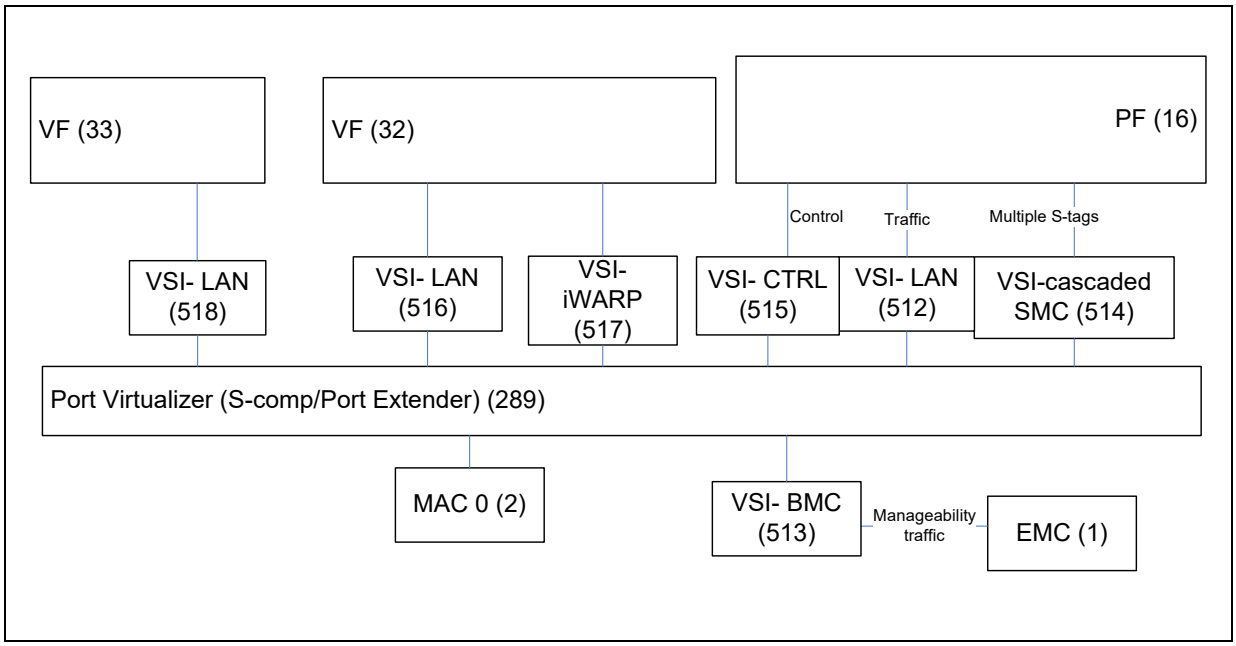
The switching resources are allocated to the PF. The PF can decide to allocate the resources to any of the VEBs or to any of the VSIs according to its own policy.

38.21.7.15.4 Port Virtualizer

This mode is used when all the switching decisions are done in an external switch and each VSI is connected directly to one or more virtual channels. The usage models of the port virtualizer profile are described in Port Virtualizer Model. The switch configuration for the port virtualizer case is shown in the following figure. In the case of a VF requiring multiple VSIs, it might request a new VSI using the *Add VSI* command. This command is forwarded to the PF for completion.

Note: The control port of the port virtualizer can be either a separate VSI or part of the regular VSI of the PF. In this case, the tagging of packets is controlled by the host. Packets sent from the control port should be non-tagged.

Figure 38-54.Port Virtualizer



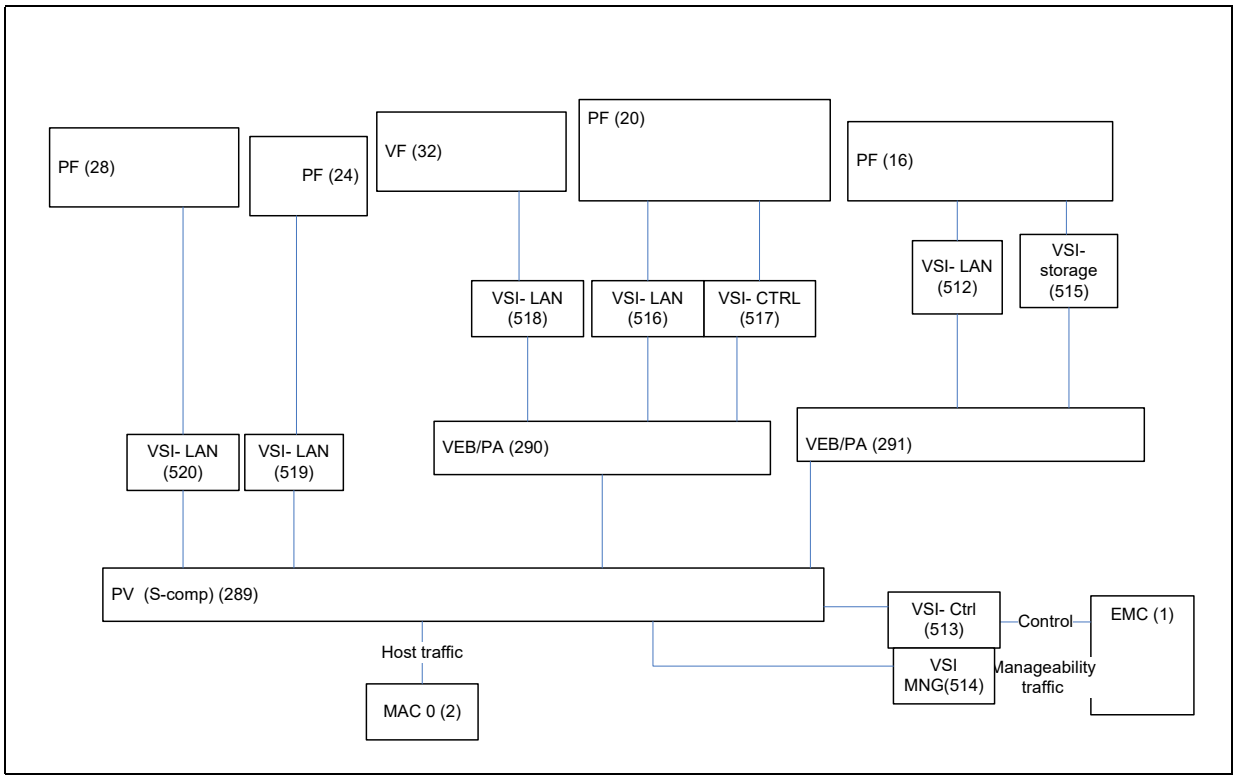
38.21.7.15.5 Port Virtualizer + VEB/VEPA

A port virtualizer +VEB/VEPA configuration is used for virtualized operating systems where the network is distributed to virtual channels. The switch configuration for the port virtualizer +VEB/VEPA case is shown in the following figure. For a VF requiring multiple VSIs, it might request a new VSI using the *Add VSI* command. This command is forwarded to the PF for completion.

Note: The control port of the port virtualizer in this mode is the EMP, as there are multiple PFs connected to the same port virtualizer.

A special case of this mode is the mode where the link is divided to virtual channels and each channel is connected to a PF, but none of these are virtualized. In this case, there are no VEB/PAs in the device (unless needed for VLAN and iWARP traffic as described in Section 38.21.7.15.2).

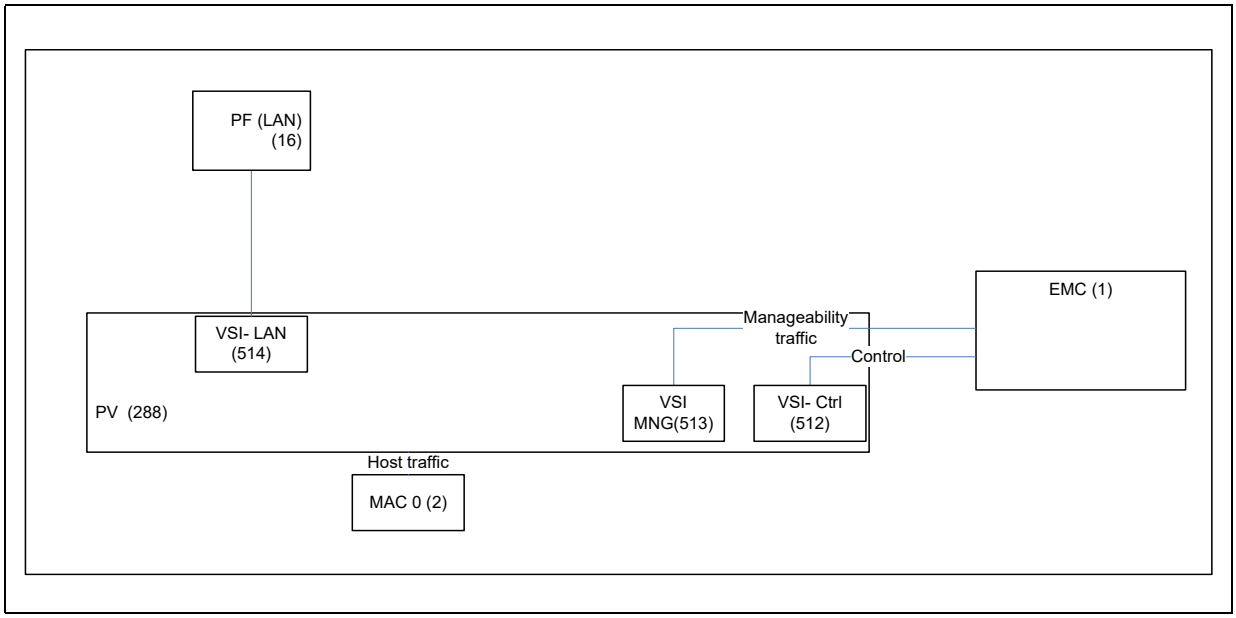
Figure 38-55.Port Virtualizer + VEB/VEPA



38.21.7.15.6 LAN S-comp

The initial configuration as exposed by the device is shown in the following figure.

Figure 38-56.LAN Initial Configuration



38.21.7.16 Switch Resource Allocation

38.21.7.16.1 Allocated Resources

Table 38-195 lists the resources that are part of the switch and should be allocated to the different switch elements.

Table 38-195 also lists the switching elements resources. These resources are available no matter what the configuration of the forwarding tables is. Table 38-196 lists the forwarding rules resources. These resources are different for different configuration of the forwarding tables.

Note: Each element is associated with a port, so two ports using the same value (such as the same MAC address) consumes two entries.

Table 38-195.Switching Elements Resources

Resource	Total Available	Notes
VEBs	16	There is no limitation on the number of VEBs assigned to a PF.
VSIs	384	Up to 12 of the 384 VSIs are reserved for EMP traffic (LLDP and pass-through traffic forwarding per port) and should not be allocated.
VSI List Entries	6144	Three 3 VSIs in each entry. These entries are used to create up to 2048 VSI lists such as multicast VSI lists or VLAN membership lists.
VLAN Statistic Pools	128	
TC Statistic Pools	128	Statically associated with the 16 VEBs (8 sets for 8 TCs for each of the VEBs).
Mirror Rules	64	
Queue Sets	1024	
Teredo UDP Ports	16	

Table 38-196 lists the resources allocated according to the filters configuration used. The image used is defined in the *Features enable.Switching mode* NVM field.

Table 38-196.Switching Rules Resources (Sheet 1 of 2)

Resource	Total Available	Notes
NVM Map	**Unified Image (B0)**	
First level filters		
Perfect Match MAC Addresses	1535	Each MAC address can be used for multiple VEBs within the same port. There can be up to 2048 VEB, MAC associations. One MAC address is statically allocated to the EMP.
VLANs	256	The entire range of 4096 VIDs can be covered; however, only 256 different VLANs can be stored in the forwarding tables. Each VLAN can be used in multiple VEB within a port. There can be 1024 VEB, VLAN associations.
EtherType Filters	64	These filters are tuples of switch ID, EtherTypes and direction.
S-tags	448	The entire range of 4096 S-VIDs can be covered, however, only 448 different S-tags can be stored in the forwarding tables.
Promiscuous Rules	1024	Unicast, broadcast or multicast promiscuous for different VEBs.
VLAN Promiscuous		The entire range of 4096 VIDs can be covered, however, only 1024 different VLANs/packet types (unicast, multicast, broadcast) /VEB can be stored in the forwarding tables.
Multicast Hash Entries	512	
Unicast Hash Entries	512	

Table 38-196.Switching Rules Resources (Sheet 2 of 2)

Resource	Total Available	Notes
NVM Map	**Unified Image (B0)**	
Inner VLAN	512	Inner VLAN used for UDP cloud filtering.
VN Key Low / GRE Key/Tenant ID		
Inner MAC	1024	Each such filter added occupies an entry in the table shared with the S-tag, VLAN mirroring filters.
S-tag, VLAN pairs (mirroring)	1024	Each such filter added occupies an entry in the table shared with the inner MAC filters.
Destination IPv4 / IPv6 Address (Application IP)	1024	Each such filter added occupies an entry in the table shared with the inner MAC, inner VLAN filters.
Source IPv4 / IPv6 Address (Application IP)	1024	Each such filter added occupies an entry in the table shared with the MAC-EtherType filters.
Combined filters		
MAC,VLAN Pairs	3072	For each entry in this table, an entry in the perfect match MAC addresses and a VLAN entry is used. The same is true for all the other types of filters.
Hash MAC,VLAN Pairs	1024	For each entry in this table, an entry in the hash MAC addresses and a VLAN entry is used. The same is true for all the other types of filters.
MAC-EtherType Filters	1024	Each entry is associated with an S-tag or switch ID. For each entry in this table, an entry in the Perfect match MAC addresses and a EtherType filters entry is used.
MAC L2 Filtering	512	This filter shares the same entries as the perfect match MAC address.
Inner MAC, Tenant ID	1024	
Outer MAC, Tenant ID, Inner MAC		
Inner MAC, Inner VLAN, Tenant ID	1024[1]	For each entry in this table, an entry in the inner MAC addresses, in the inner VLAN and a tenant ID filters entry is used.
Inner MAC, Inner VLAN Pair	1024[2]	For each entry in this table, an entry in the inner MAC addresses, in the inner VLAN filters entry is used.

Notes:

1. Shared between inner MAC, inner VLAN, tenant ID filters and inner MAC filters.
2. Shared between inner MAC, inner VLAN filters and inner IP filters.

38.21.7.16.2 PFs Allocation Method

The resources can be categorized as shared resources that are used by multiple PFs and resources that are allocated to a single PF. Resources used by multiple PFs are inherently shared and thus cannot be allocated to any PF. Each PF requesting a resource gets it given there are still empty entries in the shared pool. It is the responsibility of each software device driver to release resources it does not use.

For resources allocated to a single PF, there is a basic allocation in the NVM for each PF (that can be zero). The resources not reserved to a PF are allocated on a first come first served basis.

The *PF allocations* structure in the NVM contains the resource allocation initial values.

If, after the enumeration stage, a PF is not enabled, its resources are given back to the shared pool.

Resources are allocated first from the dedicated pools and only if the dedicated pool of a PF is exhausted, a resource from the shared pool is given.

The resources that can be dedicated to a PF are:

- VEBs (TCs statistics pools are also allocated as part of the VEB)
- VSIs
- Perfect match MAC addresses
- S-tags
- VLAN statistic pools
- Mirror rules
- Queue sets

All the other resources are considered as shared.

Note: The response of commands used to allocate dedicated resources includes information about the dedicated and shared resource left after the command is applied. The response of commands used to allocate shared resources includes information about the shared resource left after the command is applied.

The *Get Switch Resources Allocation* command returns the reserved allocation of each type of resource and the current level of usage of each resource.

Statistics Allocation

There are a few sets of statistics used by the switch. The allocation of statistics resources to the different switching elements is as follows:

- For each VSI, a set of per VSI statistics is allocated. The set to use is returned in the *Add VSI* response buffer in the *Statistic Counters* field.
- For each port and port virtualizer, a set of per-port/port virtualizer statistics accessed using per-port registers is allocated.
- For each VEB allocated to a function, a set of VEB uplink statistics and per VEB per TC statistics might be allocated if statistics gathering is not disabled in the Add VEB command. The set to use is returned in the response of the Add VEB command in the *Statistic Counter* field.
  - In addition, a VEB can be allocated a set of statistics per VLAN per VEB using the *Add Statistics* admin command. The set to use is returned in the *Statistic Counters* field in the response of this command. This request might fail if there are no free sets.

When statistics are not gathered, the following statistics are not valid for this VEB:

- GLPRT_RUPP[0]
- GLSW_GOTCH/L
- GLVEBVL_GOTC_[n]
- GLVEB_TCBCH/L[n]
- GLVEB_TCPCH/L[n]
- GLSW_UPTCH/L[n]
- GLSW_MPTCH/L[n]
- GLSW_BPTCH/L[n]
- GLSW_GORCH/L[n]

- GLVEB_VLBCH/L[n]
- GLVEB_RCBCH/L[n]
- GLVEB_RCPCH[n]
- GLSW_UPRCH/L[n]
- GLSW_MPRCH/L[n]
- GLSW_BPRCH/L[n]
- GLSW_RUPP_[n]
- GLVEB_VLUPCH/L[n]
- GLVEB_VLMPCH/L[n]
- GLVEB_VLBPCH/L[n]

38.21.7.16.3 VFs Allocation Method

The 10 GbE controller manages VF resources as part of the PF resources. The PF driver should manage the VF requests based on the PF allocation.

38.21.7.17 Switch Init Flow

The init flow of the switch is composed of the following steps:

1. Pre BIOS stages:
   a. Initializing the switch hardware (Section 38.21.7.17.1).
   b. Initializing a basic switch configuration according to the NVM (Section 38.21.7.17.2).
   c. Define the supported virtualization modes.
   d. Update from external configuration source like the EVB management protocol.
2. BIOS configuration (Section 38.21.7.17.3).
   a. Update of the switch configuration according to SMASH CLP.
   b. Configuring switch according to the updated configuration.
3. Software configuration (Section 38.21.7.17.4).
   a. Optionally, creating VEB or VEPA elements by a VMM.
   b. Allocating MAC addresses and VLANs to VSIs.

At the end of stage 1, basic connectivity to the pass-through management traffic and the EMP is enabled. In addition, WoL functionality is also available. If already known, the connectivity to PFs is also provided.

At the end of stage 2, connectivity to the host is added This is the configuration exposed to the pre-boot software device driver and to the operating system.

38.21.7.17.1 Initializing Switch Hardware

The switch is implemented using a programmable logic, enabling parsing of different packet types and implementing different forwarding rules. This programmable hardware is configured as part of the 10 GbE controller auto load of the CORE Registers Auto-load NVM section. The lookup tables and the switching rules logic are configured at this stage.

This stage is activated at each core reset.

38.21.7.17.2 Initial Switch Configuration

The internal EMP firmware defines the initial switch structure. This stage is done after all the hardware auto load is done and the number of currently enabled PCIe PF functions is known. Before any NVM configuration the following elements are defined by firmware:

Table 38-197. Initial Elements

Elements	SEID	Note
EMP	1	
Ports	2-5	Only for the ports enabled.
Physical functions	16-31	Only for the functions enabled.
Virtual functions	32-159	For all VFs. VFs not used will not be connected to VSIs.

At this stage, firmware loads the switch configuration from the NVM. The *EMP Settings* NVM module contains the entire configuration needed. It also contains the following information relevant to the switch operation:

- A list of capabilities supported by the switch (type of filtering, types of connections).
- PF allocations module (see PF Allocations).

This stage is part of the firmware initialization stage.

This stage is activated at each core reset.

Initial VSIs

At initialization time, only minimal forwarding capabilities are needed:

- Forwarding of pass-through traffic to manageability interface
- Forwarding of LLDP traffic to the EMP
- WoL detection

The initial switching configuration includes only the forwarding rules needed to support these flows.

At this stage, the host is not connected to the network and cannot get traffic. If an additional pre-boot configuration is not expected, then the connectivity to the host is also done at this stage.

The basic configuration for port connectivity is achieved by connecting a single VSI to each port to one PF. The connection is from the port to the function connected to it with the lowest function number. The mapping of functions to port is reflected in the *PFGEN_PORTNUM.PORT_NUM* field. These VSIs are created with a *Regular Data Port* connection type and a PF VSI type.

All the VSIs created at this stage have the default switch ID of the port. The following parameters should be set to a non-default value in these VSIs:

- Allow destination override should be set.
- For the PF VSIs, *Queue Mapping* should be set to contiguous and all the queues of the PF should be allocated to this VSI. The first queue is always queue 0 (of the PF).

As this flow is applied on each core reset, it is possible that a valid alternate RAM already exists. In this case, the alternate RAM based configuration, as described in Section 38.21.7.17.3, is applied.

PF Allocations

For each PF, the *PF allocation* sub-module in the *EMP Core Module* contains guaranteed allocations for the following resources:

- VEBs (TCs statistics pools are also allocated as part of the VEB)
- VSIs
- Perfect match MAC addresses
- S-tags
- VLAN statistic pools
- Mirror rules
- Queue sets
- Inner MAC
- IP addresses

After the basic topology is defined, an L2 filter should be added for each PF using the factory MAC address of this PF as stored in the PF allocations structure in the NVM or any alternate RAM override of those addresses. The *Load PF MAC Address* field in the *PF flags* word in the *PF allocation* sub-module is used to define which MAC addresses to add to the switching decision. If this bit is set, only packets that passes the MAC and if needed, the S-tag are forwarded to the PF.

In addition an L2 filter forwarding packets to the EMP should be added for each port using the port MAC addresses stored in the *PRTGL_SAL* and *PRTGL_SAH* registers.

By default, resources are allocated from the dedicated pool first and only when the dedicated pool is consumed or a *Use Shared* flag is set, the shared pool is used. A resource assigned from the dedicated pool can be used by a single PF only. An attempt to use it by another PF is treated as an error.

Firmware tracks and reports only the dedicated resources used by a function and not the shared ones.

Software can indicate a MAC address should be allocated from the shared pool, in which case it can be used by multiple PFs. This indication should be set for any resource expected to be used by multiple PFs (such as multicast addresses). MAC addresses assigned/removed as part of the Add/Remove Control Filter AQs are taken from the shared pool.

VSIs are always allocated from the dedicated pool first and from the shared pool after that. Release of VSIs is from shared first and then from dedicated.

In order to use a resource from the shared pool, the Use Shared <resource name> flag should be set in the Add MAC, VLAN pair and in Add Cloud Filter Admin commands. Such a resource might be used by multiple PFs. If not set, it is expected the resource is used by a single PF.

Note: Teamed ports using the same MAC address might allocate the MAC address from the dedicated pool, as MAC addresses are qualified with the port number.

38.21.7.17.3 BIOS Configuration

As part of the SMASH CLP stage, commands affecting the switch configuration might be received. These commands should be translated by the SMASH CLP code to the updates of the alternate RAM.

After all the SMASH CLP commands are received, the CLP code should update the firmware with the content of the alternate RAM.

For each of the enabled functions, a VSI is added and is connected to the MAC.

The VSIs created at this stage have the default switch ID of the port. The following parameters should be set to a non-default value in these VSIs:

- Allow destination override should be set.
- Queue mapping should be set to contiguous and all the queues of the PF should be allocated to this VSI. The first queue is always queue 0 (of the PF).

Once the alternate RAM is updated and executed by the firmware, it might, depending on the configuration, disable some of the admin commands software is allowed to execute.

38.21.7.17.4 Operating System Initialization

After the operating system boot, each PF is connected to a physical port or an S-channel. Before adding further switching elements, the PF driver should use the *Get Switch Configuration* admin command to get the SEID of the switch element to which this function is connected. See Get Switch Configuration (0x0200) for more detail.

After that, it might add VEB, VEPA or port virtualizer elements according to the instructions received from the switch control plane in the operating system using the admin commands described in Section 38.21.7.18.

Note: In operating systems where two separate VSIs are used for LAN and iWARP, the software device driver should create a VEB using the *Add VEB* command and connect a separate VSI for the LAN queues and the iWARP traffic. If a VEB is created for virtualization purposes, the same VEB can be used to connect the iWARP and LAN traffic VSIs.

38.21.7.18 Programming Interface

The programming of the different switching elements is done using admin commands. Commands to configure a switching element can be received only from the control port of the element.

38.21.7.18.1 Switch Configuration Admin Commands Summary

Table 38-198 lists the different commands used to configure switch elements.

Table 38-198. Switch Configuration Admin Commands (0x02xx) (Sheet 1 of 2)

Command	Opcode	Brief Description	Detailed Description
Generic Commands (0x020x)			
Get Switch Configuration	0x0200	Describe the networking structure of the port	Get Switch Configuration (0x0200)
Add Statistics	0x0201	Add a statistics block to a VLAN in a switch.	Add Statistics (0x0201)
Remove Statistics	0x0202	Remove a statistics block for a VLAN in a switch.	Remove Statistics (0x0202)

Table 38-198.Switch Configuration Admin Commands (0x02xx) (Sheet 2 of 2)

Command	Opcode	Brief Description	Detailed Description
Set Port Parameters	0x0203	Defines the default parameters of a LAN port	Set Port Parameters (0x0203)
Get Resources Allocation	0x0204	Reports the resources allocated to the PF.	Get Switch Resources Allocation (0x0204)
Set Switch Configuration	0x0205	Configure Switch global settings	"Set Switch Configuration Command (0x0205)"
VSI Commands (0x021x)			
Add VSI	0x0210	Add a VSI to a switching element	Add VSI (0x0210)
Update VSI Parameters	0x0211	Update parameters of a VSI	Update VSI (0x0211)
Get VSI Parameters	0x0212	Get the parameters of a VSI.	Get VSI Parameters (0x0212)
Port Virtualizer control (0x022x)			
Add Port Virtualizer	0x0220	Create an S-comp or a port extender	Add Port Virtualizer
Update Port Virtualizer Parameters	0x0221		Update Port Virtualizer Parameters
Get Port Virtualizer Parameters	0x0222		Get Port Virtualizer Parameters
VEB/Port aggregator Control (0x023x)			
Add VEB	0x0230	Create a VEB/Port aggregator	Add VEB
Get VEB Parameters	0x0232	Get the parameters of a VEB/VEPA	Get VEB Parameters (0x0232)
Switch Connectivity Configuration (0x024x)			
Delete Element	0x0243		Delete Element
Forwarding Table Configuration (0x025x)			
Add MAC,VLAN Pair	0x0250	Add a MAC/VLAN pair to the lookup table.	Add MAC, VLAN Pair (0x0250)
Remove MAC,VLAN Pair	0x0251	Remove a MAC/VLAN pair from the lookup table.	Remove MAC,VLAN Pair (0x0251)
Add VLAN	0x0252	Add a VLAN to the VEB/port aggregator (can be regular or local, primary or secondary).	Add VLAN (0x0252)
Remove VLAN	0x0253	Remove a VLAN or members of a VLAN from the VEB/port aggregator.	Remove VLAN (0x0253)
Set VSI Promiscuous Modes	0x0254		Set VSI Promiscuous Modes (0x0254)
Add S-tag	0x0255	Add an of S-tags to a VSI.	Add S-tag (0x0255)
Remove S-tag	0x0256	Remove an S-tag from a VSI.	Remove S-tag (0x0256)
Update S-tag	0x0259	Update the default S-tag of a VSI.	Update S-tag (0x0259)
Add Control Packet Filter	0x025A	Add EtherType (+MAC) filter to control port.	Add Control Packet Filter (0x025A)
Remove Control Packet Filter	0x025B	Remove EtherType (+MAC) filter from control port.	Remove Control Packet Filter (0x025B)
Add Cloud Filters	0x025C	Add a set of filters for cloud connections.	Add Cloud Filters (0x025C)
Remove Cloud Filters	0x025D	Remove a set of filters for cloud connections.	Remove Cloud Filters (0x025D)
Clear All WoL Switch Filters	0x025E	Remove all WoL related filters.	"Clear All WoL Switch Filters (0x0025E)"
Mirroring Configuration (0x026x)			
Add Mirror Rule	0x0260	Define a mirroring rule.	Add Mirror Rule (0x0260)
Delete Mirror Rule	0x0261	Remove a mirroring rule.	Delete Mirror Rule (0x0261)

38.21.7.18.2 Configuration Flow Examples

This section describes examples of software configuration flows for different types of switch topologies.

The following examples are provided:

- An SFP with a port virtualizer used to distribute the VM traffic. In this mode, each VF/VM is assigned a different S-channel.
- An SFP with a VEB used to distribute VM traffic. In this mode, each VF/VM is assigned a VSI within the VEB. The same flow can be used to add a VEPA element.

More complex network topologies are supported. The configuration of such topologies can be inferred from the examples that follow.

For each example, the admin command to use and the main parameters in each command are described.

Port Virtualizer (SFP)

In this mode, the internal firmware initiates a single VSI per port. This VSI is connected to the PF. Other VSIs might be connected to the EMP for MC or local traffic.

The software device driver should use the following command to create a port virtualizer and connect a set of VSIs to it:

- *Get Switch Configuration* — This command provides the default VSI connected to the port.
- *Get VSI* — This command provides the content of the current VSI context. The PF might then update this context using an *Update VSI* command.
- *Add* Port Virtualizer — This command adds a port virtualizer on top of the port. The *uplink SEID* should be the physical port. The *default VSI SEID* should be the default VSI received in the previous command.
- If needed, a separate control port can be added by using an *Add VSI* with the port virtualizer as the *uplink SEID* and a control port *connection type*.
- For each of the VMs/VFs that needs to be connected to the port virtualizer, an *Add VSI* should be sent with the port virtualizer as the uplink SEID, a regular data port *connection type* and a switch ID value equal to the S-tag assigned to this VM/VF. For VMs, the VSI type should be *VM*.

VEB (SFP)

In this mode, the internal firmware initiates a single VSI per port. This VSI is connected to the PF. Other VSIs might be connected to the EMP for MC or local traffic.

The software device driver should use the following command to create a VEB and connect a set of VSIs to it:

- *Get Switch Configuration* — This command provides the default VSI connected to the port.
- *Get VSI* — This command provides the content of the current VSI context. The PF might then update this context using an *Update VSI* command.
- *Add VEB* — This command adds a VEB on top of the port. The *uplink SEID* should be the physical port. The *default VSI SEID* should be the default VSI received in the previous command. The software device driver should register the switch ID assigned to this VEB.

- If needed, a separate control port might be added by using an *Add VSI* with the VEB as the *uplink SEID* and a control port *connection type*.
- For each of the VMs/VFs that needs to be connected to the VEB, an *Add VSI* should be sent with the port virtualizer as the uplink SEID, a regular data port *connection type* and a switch ID value equal to the switch ID of the VEB. For VMs, the VSI type should be *VM.*
- For each VM/VF, *Add MAC, VLAN pair* commands should be sent to allow adequate forwarding of the traffic.

38.21.7.18.3 Generic Commands (opcode 0x020x)

Get Switch Configuration (0x0200)

This command is used to discover the switch configuration of the port. The software device driver must use this command as part of the initialization flow before adding new switching elements or manipulating existing ones.

This function is available to any PF. This usually includes the switching structure from the port virtualizer and upwards.

Table 38-199.Get Switch Configuration Command (Opcode: 0x0200)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0200	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
First SEID	16-17	0x0	If not zero, start the report from the requested SEID (used for continuation commands).
Reserved	18-23	0x0	Must be zero.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

Table 38-200 lists the response buffer for the Get Switch Configuration command.

Table 38-200.Get Switch Configuration Response (Opcode: 0x0200) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0200	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Next SEID	16-17	0x0	If not zero, indicates that not all the configuration was returned and a new command should be sent with this value in the First SEID field.
Reserved	18-23	0x0	Must be zero.

Table 38-200.Get Switch Configuration Response (Opcode: 0x0200) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		

Table 38-201 lists the structure of the response buffer for the Get Switch Configuration command.

Table 38-201.Get Switch Configuration Command Response Buffer

Offset (bytes)	Description
0-15	Header. See Table 38-202 for details
16-31	Switch element #1. See Table 38-203 for details.
....	
16*n+15-16*n	Switch element #n. See Table 38-203 for details.

Table 38-202.Get Switch Configuration Command Response Header

Offset (bytes)	Description
0-1	Number of switching elements in the structure. The size of the buffer is 16 * (number of elements + 1) If the buffer size is too small to return all the switching elements, only the elements fitting the buffer is returned and the software device driver might request the subsequent elements using a different first element. The maximum number of entries that can be returned in a single command is 255.
2-3	Total number of switching elements. The total number of switching elements. This might be larger than the number of elements in the structure.
4-15	Reserved.

Table 38-203.Get Switch Configuration (Switch Element) (Sheet 1 of 2)

Offset (bytes)	Description	Notes
0	Element Type. Listed in Table 38-191 and Table 38-192.	
1	Revision. Describes the revision of the element type. For the 10 GbE controller, the revision is always 1.	
2-3	SEID. Defines the switch element ID of this element.	
4-5	Uplink Connection. Indicates the SEID of the switching element connected directly below the current element. Below means towards the network in this case.	For sub-elements of a composed switch element, the uplink is the uplink of the entire switch element.
6-7	Downlink Connection. Indicates the SEID of the switching element connected directly above the current element. Above means towards the host in this case.	The Downlink of a composed element is the default port of this element.
8-10	Reserved.	Reserved.
11	Connection Type. 0x0 = Reserved. 0x1 = Regular Data Port. 0x2 = Default Port. 0x3 = Cascaded Port Virtualizer port. 0x4:0xFF = Reserved.	Defines the type of connection to the uplink element.
12-13	Reserved.	

Table 38-203.Get Switch Configuration (Switch Element) (Sheet 2 of 2)

Offset (bytes)	Description	Notes
14-15	Element Specific information. Provides additional information according to the element type as follows: **Element type** **Information.** MAC (1) The physical port number. PF (2) The physical function number. VF (3) The virtual function number. VSI (19) The VSI number. This field is reserved for all other element types.	

Add Statistics (0x0201)

The 10 GbE controller supports 128 smonVlanStats counters. This command is used to allocate a set of smonVlanStats counters to a specific VLAN in a specific switch.

Table 38-204.Add Statistics Command (Opcode: 0x0201)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0201	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switch SEID	16-17		Defines the SEID of the switch for which the stats are requested.
VLAN ID	18-19		The VLAN ID for which the statistics are requested. 15:12 = Reserved. 11:0 = VLAN ID.
Statistic Counter	20-21	Statistic counters index	Zeroed by driver, firmware returns an index of the statistics counters block assigned to this VLAN.
Reserved	22-31	0x0	Reserved.

Table 38-205.Add Statistics Response (Opcode: 0x0201)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0201	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID does not point to a valid switch. ENOSPC - If there are not enough resources to assign a statistics block.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switch SEID	16-17		Copied from command.
VLAN ID	18-19		Copied from command.
Statistic Counter	20-21	Statistic Counters Index	Zeroed by driver, firmware returns an index of the statistics counters block assigned to this VLAN.
Reserved	22-31	0x0	Reserved.

Remove Statistics (0x0202)

The 10 GbE controller supports 128 smonVlanStats counters. This command is used to deallocate a set of smonVlanStats counters from a specific VLAN in a specific switch.

Table 38-206.Remove Statistics Command (Opcode: 0x0202)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0202	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switch SEID	16-17		Defines the SEID of the switch for which the stats are currently allocated.
VLAN ID	18-19		The VLAN ID for which the statistics are currently allocated. 15:12 = Reserved. 11:0 = VLAN ID.
Statistic Counter	20-21	Statistic Counters Index	The statistics counters block assigned to this VLAN.
Reserved	22-31	0x0	Reserved.

Table 38-207.Remove Statistics Response (Opcode: 0x0202)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0202	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID does not point to a valid switch. EINVAL - If the statistic block mentioned is not pointed by this VLAN, switch combination.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		Reserved.

Set Port Parameters (0x0203)

This command is used to define the default parameters of a physical port.

Table 38-208.Set Port Parameters Command (Opcode: 0x0203) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0203	Command opcode
Datalen	4-5	0x0	Length of buffer
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.

Table 38-208.Set Port Parameters Command (Opcode: 0x0203) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Command Flags	16-17	Bitfield	0 = Save Bad Packets. If set, packets with errors are forwarded to the bad frames VSI. 2 = Enable Double VLAN. If set, this port expects double VLAN packets. The remainder of the bits are reserved.
Bad Frames SEID	18-19		Defines the SEID of the VSI to which bad frames are forwarded. Bit 15 = Valid SEID. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI. Relevant only if Command Flags.Save Bad Packets is set.
Reserved	20-31	0x0	Reserved.

Table 38-209.Set Port Parameters Response (Opcode: 0x0203)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0203	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following response might be returned by this command: EPERM - If the operation is not permitted.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command,
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Command Flags	16-17	Bitfield	
Bad Frames VSI	18-19		
Default Switch ID	20-21		returns the switch ID assigned to the port.
Reserved	22-31	0x0	Reserved.

Get Switch Resources Allocation (0x0204)

This command is used to query the resources allocated to a function.

Table 38-210.Get Switch Resources Allocation Command (Opcode: 0x0204)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0204	Command opcode.
Datalen	4-5		Length of response buffer. Should be big enough to contain the expected response buffer size.
Return value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-23	0x0	Reserved.
Data Address high	24-27		Return buffer address.
Data Address low	28-31		

Table 38-211.Get Switch Resources Response (Opcode: 0x0204)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0204	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. There are no specific errors to this command.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Number Of Entries	16	0xD/0x14[1]	Number of resource entries.
Reserved	17-23	0x0	Reserved.
Data Address High	24-27		Return buffer address.
Data Address Low	28-31		

Notes:

1. In cloud images (*Features Enable.Switching mode* is set to Cloud or UDP cloud, then the relevant filters are also returned.

The return buffer contains structures of 16 bytes for each resource type of the following format. The number of entries is returned in the number of entries field in the response.

Table 38-212.Return Buffer Structures for Resource Type Format (Sheet 1 of 2)

Name	Bytes.Bits	Description
Resource Type	0	0x0 = VEBs. 0x1 = VSIs. 0x2 = Perfect match MAC addresses. 0x3 = S-tags. 0x4 = Reserved. 0x5 = Multicast hash entries. 0x6 = Unicast hash entries. 0x7 = VLANs. 0x8= VSI List entries (3 VSI in each entry). 0x9 = Reserved. 0xA = VLAN statistic pools. 0xB = Mirror rules. 0xC = Queue sets. 0xD = Inner VLAN forward filters. 0xE = Reserved. 0xF = Inner MACs. 0x10 = IPs. 0x11 = GRE/VN1 keys. 0x12 = VN2 keys. 0x13 = Tunneling ports. 0x14:0xFF = Reserved.
Reserved	1	Reserved
Guaranteed Allocation	2-3	Number of resources from this type guaranteed to this function. For example, the value set in NVM for this PF and this resource type in the SR PF Allocations NVM section.
Total	4-5	Total number of resources from this type available to all functions (physical size of table).
Currently Used	6-7	Number of guaranteed resources from this type used by this function.
Total Un-allocated	8-9	Total number of resources from this type still un-allocated and not reserved by any function (Number of free shared resources currently available plus unallocated dedicated resources of PF).

Table 38-212.Return Buffer Structures for Resource Type Format (Sheet 2 of 2)

Name	Bytes.Bits	Description
Reserved	10-15	Reserved.

Set Switch Configuration Command (0x0205)

This command is used to set device wide switch configurations. The last configuration of any driver is used and overrides previous settings, apart from the Enable Automatic ATR Eviction, which is set if any function requests it.

Table 38-213.Set Switch Configuration command (Opcode: 0x0205)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0205	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return value/VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Flags	16-17	0x0	0: Promiscuous behavior: • 0: Packets are forwarded according to promiscuous filter even if matching an exact match filter. • 1: Packets are forwarded according to promiscuous filter only if not matching an exact match filter. 1: Enable L2 filtering. If set, the L2 filter table should pass in addition to the regular forwarding decision. 2: Enable Automatic ATR Eviction. 15:3: Reserved.
Valid Flags	18-19	0x0	0: Promiscuous behavior valid. 1: Enable L2 filtering valid. 2: Enable Automatic ATR Eviction is valid. 15:3: Reserved.
Reserved	20-31	0x0	Reserved.

Table 38-214.Set Switch Configuration response (Opcode: 0x0205)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0205	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return value/VFID	6-7		Return value.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		Reserved.

38.21.7.18.4 VSI Commands (Opcode 0x021x)

Add VSI (0x0210)

This command is used to add a new VSI. A VSI must connect to an existing switching element. A function can connect a VSI only to a switching element it controls.

When an Add VSI command is received, the internal firmware checks if all the requested resources are available and allocate them to the VSI. If part of the resources are not available, the command returns a list of unavailable resources

Table 38-215. Add VSI Command (Opcode: 0x0210)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0210	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/ VFID	6-7	0x0	Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Uplink SEID	16-17	0x0	Defines the uplink SEID to which this VSI should be connected.
Connection Type	18	0x0	Defines to which port of the uplink element this VSI connects. 0x0 = Reserved. 0x1 = Regular data port. 0x2 = Default port. 0x3:0xFF = Reserved. ***Note:*** If set as default port, replaces the existing default port of the underlying switching element.
Reserved	19	0x0	Reserved
VF Function Number	20		Defines the VF function to which this VSI connects. Valid only if function type is VF. Should be ignored if VSI type is not VF. The VF number here is the absolute VF number (0-127) and not the number relative to the PF first VF.
Reserved	21		Reserved.
Command Flags	22-23		1:0: VSI type. 0 = VF. 1 = VMDq2 (a.k.a. VM). 2 = PF. 3 = EMP/MNG. 2: Cascaded port virtualizer. The S-tag manipulation commands can be used only if this bit is set. Bit 15:3 = Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-216 lists the structure of the command buffer for the Add VSI command.

Table 38-216.Add VSI Command Buffer (Sheet 1 of 5)

Category	Byte/ Bit	Field	Description
Valid Sections	0-1	Defines which sections are valid in the command.	0 = Switching section is valid. Must be set for *Add VSI* commands when containing SEID is a port virtualizer. 1 = Security section is valid. 2 = VLAN handling section is valid. 3 = Cascaded port virtualizer section is valid. 4 = Ingress UP translation section is valid. 5 = Egress UP translation section is valid. 6 = Queue mapping section is valid. Must be set for *Add VSI* commands. If set for *Update VSI* command, modified queues must be disabled. 7 = Queuing option section is valid. 8 = Outer UP translation section is valid. Should not be set if inner UP to outer UP mapping is the identity mapping. 9 = Scheduler section is valid. This bit is ignored in *Update VSI* command. 10:15 = Reserved.
Switching	2-3.3	Switch ID	Defines the switch ID to which this VSI belongs. If it is not, S-tag is cleared, then this switch ID is an S-tag; otherwise, it is a virtual switch ID. If the VSI is connected to a port virtualizer, this value must be set. For a port connected to a VEB or directly to the MAC, this value is not an S-tag field and might be left at zero and the VEB switch ID or the default switch ID is used. For the Update VSI command it should be a valid tag (could be zero for VEB).
	3.4	Is not S-tag	See description of the switch ID parameter for the usage of this bit.
	3.5	Allow loopback	This bit should be set for VSIs that are connected to a VEB and should be cleared otherwise. A VSI connected to a VEB might have this bit cleared if used only for connection to the link (such as a management VSI). Cleared if section not valid.
	3.6	Allow local loopback.	This bit should be set for VSIs that are used as uplink of a software (cascaded) VEB, VEPA or port virtualizer. Cleared if section not valid.
	3.7-5.7	Reserved.	Reserved for future switching parameters. Must be zero.
Security	6.0	Allow destination override.	Allow the VSI to override the switching decision and fix the destination of a transmit packet. This bit should be set only for control ports. Cleared if section not valid.
	6.1	Enable VLAN anti-spoof	Cleared if section not valid. Enabling this mode might impact the transmit performance. It is recommended to use only the MAC anti-spoof mode.
	6.2	Enable MAC anti-spoof.	Cleared if section not valid.
	6.3 - 7.7	Reserved.	Reserved for future security parameters. Must be zero.

Table 38-216.Add VSI Command Buffer (Sheet 2 of 5)

Category	Byte/ Bit	Field	Description
VLAN Handling	8-9	PVID+ Default UP (16 bits).	VLAN ID to use in port-based VLAN insertion. This field is relevant only if the *Insert PVID* field is set. Cleared if section not valid.
	10-11	Reserved.	Reserved.
	12.0:1	VLAN driver insertion mode.	This field defines if the software device driver is allowed/should add a VLAN tag to the packets it sends. If *Insert PVID* field is set, this field should be set to 01b. 00b = Reserved. 10b = Admit.1Q tagged only. Allow only packets with VLAN. 01b = Admit untagged/Priority tagged only. Allow only packets without VLAN or with VLAN tag = zero. 11b = Allow all packets. If section not valid, the default value is 11b.
	12.2	Insert PVID.	Port-based VLAN insertion. This bit controls the port-based insertion of VLANs. Should be set for VFs/VMDq2 VSIs according to the VMM request. If this field is set, the *PVID* + *Default UP* field should be set to the port-based VLAN. Cleared if section not valid.
	12.3:4	VLAN and UP expose mode (Rx).	This field defines how received VLANs are handled. For non-VF VSIs, 00b or 11b should be used. For VF VSIs, the mode should be set according to the VLAN awareness of the VM and the offload requested. 00b = Show VLAN and UP in descriptor (legacy behavior). 01b = Hide VLAN show UP (VLAN ID = 0). 10b = Hide VLAN and UP. 11b = Do nothing (leave VLAN in packet). If section not valid, the default value is 11b.
	12.5-15.7	Reserved.	Reserved for future port VLAN parameters. Must be zero.
Ingress UP Translation	16-19	Ingress UP translation table.	Defines the UP translation table for received packets according to the following list: 16.0:16.2 UP set if received UP is 0. 16.3:16.5 UP set if received UP is 1. 16.6:17.0 UP set if received UP is 2. 17.1:17.3 UP set if received UP is 3. 17.4:17.6 UP set if received UP is 4. 17.7:18.1 UP set if received UP is 5. 18.2:18:4 UP set if received UP is 6. 18.5:18.7 UP set if received UP is 7. 19: Reserved. This map is used to translate the 802.1P user priority bits received in the packet to the user priority exposed to the host. Relevant only if the UP is exposed to the host (VLAN and UP expose mode not equal 10b). If section is not valid, the default value is identity mapping.

Table 38-216.Add VSI Command Buffer (Sheet 3 of 5)

Category	Byte/ Bit	Field	Description
Egress UP Translation	20-23	Egress UP translation table.	Defines the UP translation table for transmit packets according to the following list: 20.0:20.2 UP set if sent UP is 0. 20.3:20.5 UP set if sent UP is 1. 20.6:21.0 UP set if sent UP is 2. 21.1:21.3 UP set if sent UP is 3. 21.4:21.6 UP set if sent UP is 4. 21.7:22.1 UP set if sent UP is 5. 22.2:22.4 UP set if sent UP is 6. 22.5:22.7 UP set if sent UP is 7. 23: Reserved. This map is used to translate the 802.1P user priority bits sent by the host to the i user priority sent to the network. Note that the resulting user priority is further translated using the per TC translation table. If section is not valid, the default value is identity mapping.
Cascaded Port Virtualizer	24-25	S-tag.	The S-tag (S-VID) to be inserted in transmit packets. If *Switch ID* parameter is set and is an S-tag and not a cascaded port virtualizer, should be set to the same value as the *switch ID* parameter. This field is relevant only if *S-tag insert enable* field is set. This field is 16 bits and should include also the default PCP priority bits to insert in the S-tag. Cleared in SFP mode.
	26.0:1	S-tag extract mode.	This field defines how received S-tags are handled. 00b = Do nothing (cascaded port virtualizer without offload). 01b = Extract tag and do not insert in descriptor (regular VM). 10b = Extract tag from packet and expose in descriptor (cascaded port virtualizer with offload). 11b = Reserved. If section not valid, the default value is 00b in SFP mode.
	26.2:3	Reserved.	Reserved.
	26.4	S-tag insert enable.	This bit controls the port-based insertion of S-tags. Should be set, if VSI is part of an S-channel and is not a cascaded port virtualizer VSI. If the section is not valid, the default value is cleared in SFP mode. When this bit is set, the *Accept tag from host* bit should be cleared.
	26.5	Reserved.	Reserved.
	26.6	Accept tag from host.	Allow host to insert an S-tag in a descriptor or in a packet. Should be set only for cascaded port virtualizer or control ports. Set in SFP mode if section not valid. When this bit is set, the *S-tag insert enable* bit should be cleared.
	26.7-27.7	Reserved.	Reserved for future port S-tags parameters. Must be zero.

Table 38-216.Add VSI Command Buffer (Sheet 4 of 5)

Category	Byte/ Bit	Field	Description
Queue Mapping	28.0	Mapping method.	Selects between contiguous range of queues for this VSI vs. scattered range. 0b = The VSI is assigned a contiguous range of PF queues. 1b = The VSI is assigned a scattered range of PF queues.
	28.1 - 29	Reserved.	Reserved. Must be zero.
	30-61	Queue mapping.	If mapping method = 0 (contiguous): 30.0:31.2 = The first queue allocated for this VSI in the PF space. This VSI can access all the queues from this queue to the end of the PF queues allocation, but is bounded by the receive queues per TC configuration. 31.3:61 = Reserved. If mapping method = 1 (scattered). For each of the queues in the VSI, defines the actual queue in the PF according to the following encoding: For queue 'n' of the VSI offsets 30+2n - 31+2n are used the define the mapping to PF queues. For example for queue 0: 30.0:31.2 = The PF queue matching allocated to queue 'n' of the VSI. For non-allocated queue, a value of 0x7FF should be set. 31.3:31.7 = Reserved. The same mapping is used for the next queues. In this method, up to 16 queues can be assigned. For VSIs assigned to VFs, only the scattered method can be used. The first queue (in both modes) is the default queue of the VSI to which packets not queued by any filter is sent.
	62-77	Number and offset of queue pairs per TCs.	Fixes the number of queue pairs assigned to the VSI for each TC and the offset of these queues. 62.0 - 63.0 = Queue offset for TC0. 63.1 - 63.3 = Number of queues allocated to TC0. The actual number is 2^n. The allowed number of queues are: 1; 2; 4; 8; 16; 32; 64; 128. 63.4 - 63.7 = Reserved. If no queues needs to be associated to a TC, the queue offset should be set to 0 and the number of queues to 0 (1 queue). This way, traffic associated with this TC is sent to the default queue. The following addresses are used with the same format for the next TCs: 64:65 = TC1. 66:67 = TC2. 68:69 = TC3. 70:71 = TC4. 72:73 = TC5. 74:75 = TC6. 76:77 = TC7.
Queueing Options	78.0:1	Reserved.	Reserved.
	78.2	Multicast UDP packets enable.	Enable multicast UDP packets by the quad hash filter for the VSI. Cleared if section not valid.
	78.3	Unicast UDP packets enable.	Enable unicast UDP packets by the quad hash filter for the VSI. Cleared if section not valid.
	78.4	TCP packets enable.	Enable TCP packets by the quad hash filter for the VSI. Should be set for iWARP VSIs. Cleared if section not valid.

Table 38-216.Add VSI Command Buffer (Sheet 5 of 5)

Category	Byte/ Bit	Field	Description
	78.5.	Reserved.	Reserved.
	78.6	RSS LUT.	RSS LUT used. 0b = Use PF LUT 1b = Use VSI LUT. If section not valid, PF LUT is used for PF VSIs and VSI LUT for VFs VSI. A VF VSI should use the VSI LUT.
	78.7 - 81	Reserved.	Reserved for future queueing parameters. Must be zero.
Scheduler	82	Enabled TCs.	A bitmap indicating which TCs are enabled in this VSI. If section not valid, only TC0 is enabled.
	83	Reserved.	Reserved.
Outer UP Mapping	84-87	Egress inner UP to outer translation table.	Defines the UP translation table for transmit packets from inner-to-outer UP according to the following list: 84.0:84.2 Outer UP set if inner UP is 0. 84.3:84.5 Outer UP set if inner UP is 1. 84.6:85.0 Outer UP set if inner UP is 2. 85.1:85.3 Outer UP set if inner UP is 3. 85.4:85.6 Outer UP set if inner UP is 4. 85.7:86.1 Outer UP set if inner UP is 5. 86.2:86.4 Outer UP set if inner UP is 6. 86.5:86.7 Outer UP set if inner UP is 7. 87: Reserved. This map is used to translate the 802.1P user priority bits on the inner UP-to-outer UP. If section is not valid, the default value is identity mapping. In order to get a fixed outer UP, all values should be set to the requested outer UP.
Reserved		Reserved.	Reserved.
Response Space	96-127	Reserved.	Reserved for response space.

Table 38-217 and Table 38-218 list the add VSI response and the response buffer.

Table 38-217.Add VSI Response Buffer

Category	Byte/Bit	Field	Description
Command Space	0-95	Reserved	Reserved for command space. Should contain the values provided by the software device driver.
Queue Set Handles	96-97	QS_Handle 0.	The handle for queue set of TC0. Bits [9:0] of this handle are used by software to program the *RDYList* field in the transmit queues context for queues associated with TC0.
	98-99	QS_Handle 1.	The handle for queue set of TC1. Same format as QS_Handle 0.
	100-101	QS_Handle 2.	The handle for queue set of TC2. Same format as QS_Handle 0.
	102-103	QS_Handle 3.	The handle for queue set of TC3. Same format as QS_Handle 0.
	104-105	QS_Handle 4.	The handle for queue set of TC4. Same format as QS_Handle 0.
	106-107	QS_Handle 5.	The handle for queue set of TC5. Same format as QS_Handle 0.
	108-109	QS_Handle 6.	The handle for queue set of TC6. Same format as QS_Handle 0.
	110-111	QS_Handle 7.	The handle for queue set of TC7. Same format as QS_Handle 0.
Statistic Counter	112-113	Statistic counters index.	Returns an index of the statistics counters block assigned to this VSI.
Reserved	116-127	Reserved.	Reserved.

Table 38-218.Add VSI Response (Opcode: 0x0210) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0210	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the uplink SEID or the function number do not point to valid elements. EINVAL - If the topology created is not valid. EEXIST - If a default port is requested and it already exists. ENOSPC - If there are not enough resources to assign a VSI.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17		If the return value is zero, returns the SEID of the VSI. If return value is ENOSPC, contains a bitmap that indicates which resources are missing: 0 = No VSI left. 1 = Not enough scheduler nodes. 2 = Not enough statistics counters. 3 = Not enough switching entries. 4:15 = Reserved.
VSI Number	18-19		Returns the assigned VSI number.
VSIs Used	20-21		Number of VSIs used by this function.

Table 38-218.Add VSI Response (Opcode: 0x0210) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Total VSIs Un-allocated	22-23		Total number of VSIs still un-allocated and not reserved by any function.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Add VSI Settings Recommendations

Table 38-219 lists the recommended settings for common types of VSIs.

Table 38-219.Add VSI Recommended Settings (Sheet 1 of 2)

Category	Field	VSI Type						
		PF	VF	VMDq2	VMDq1	Cascaded VEB	Cascaded S-comp	Floating VEB
Valid Sections	Switching section is valid.	0	1	1	1	1	1	1
	Security section is valid.	1						
	VLAN handling section is valid.	1						
	Cascaded port virtualizer section is valid.	1						0
	Ingress UP translation section is valid.	0						
	Egress UP translation section is valid.	0						
	Queue mapping section is valid.	1						
	Queuing option section is valid.	1						
	Scheduler section is valid.	0 if non-DCB						
Switching	Switch ID.	If the VSI is connected directly to a port virtualizer, this value must be set. For a port connected to a VEB or directly to the MAC, this value might be left at zero and the VEB switch ID or the default switch ID is used. When connecting to a port virtualizer, the switch ID should be set to the S-tag of the channel and is not a S-tag that should be cleared.					Set to the first tag covered by this S-comp.	VEB switch ID
	Is not S-tag.						0	1
	Allow loopback.	0	1 if VEB 0 if VEPA		1 if part of a VEB, 0 otherwise [1]	1 if VEB 0 if VEPA	0	1
	Allow local loopback.	0	0	0	1 if part of a VEB, 0 otherwise	1 if VEB 0 if VEPA	0	0
Security	Allow destination override.	1	0	1	1	1	1	0/1
	Enable VLAN anti-spoof.	0	1	0	0	0	0 [2]	0/1
	Enable MAC anti-spoof.	0	1	0	0	0	0	0/1

Table 38-219.Add VSI Recommended Settings (Sheet 2 of 2)

Category	Field	VSI Type						
		PF	VF	VMDq2	VMDq1	Cascaded VEB	Cascaded S-comp	Floating VEB
VLAN Handling	PVID+ default UP (16 bits).	N/A	Port-based VLAN	N/A	N/A	N/A	N/A	N/A
	VLAN driver insertion mode.	11b	Depends on VLAN awareness	11b	11b	11b	11b	11b
	Insert PVID.	0		0	0	0	0	0
	VLAN and UP expose mode (Rx).	00b (extract and show)		00b (extract and show)	00b (extract and show)	00b (extract and show)	00b (extract and show)	00b (extract and show)
Ingress UP Translation	Ingress UP translation table.	Identity mapping (default).						
Egress UP Translation	Egress UP translation table.	Identity mapping (default).						
Cascaded Port Virtualizer	S-tag.	Same as Switch ID if Port Virtualizer is part of the switch, N/A otherwise.					N/A	Switch ID of the floating VEB
	S-tag extract mode.	01b (Extract S-tag and do not insert in descriptor)					10b (extract S-tag from packet and expose in descriptor).	01b
	S-tag insert enable.	1 if port virtualizer is part of the switch topology, 0 otherwise.					0	1
	Prune based on internal S-tag enable.	1					0	1
	Accept tag from host.	0					1	0
Queue Mapping	Mapping method.	Depends on queue mapping method.						
	Queue mapping.							
	Number and offset of receive queues per TCs.	According to allocation to TCs.						
	Fragmented multicast UDP enable	0 unless used for UDA					0	0 unless used for UDA
	Fragmented unicast UDP enable	0 unless used for UDA					0	
	Multicast UDP packets enable	0 unless used for UDA					0	
	Unicast UDP packets enable	0 unless used for UDA					0	
Queueing Options	TCP packets enable.	1						
	RSS LUT.	PF	VSI	VSI	N/A	N/A	N/A	VSI
Scheduler	Enabled TCs.	According to allocated TCs (0x1 for non-DCB environment).						

Notes:

1. Different VSIs within a VEB may have different loopback modes.
2. VLAN anti-spoof does not work in cascaded S-comp mode.

Update VSI (0x0211)

This command is used to update the parameters of an existing VSI. A function can update only a VSI it controls. Not all the parameters of a VSI can be updated. Only parameters that do not impact the scheduler tree structure can be modified. In order to change the traffic classes allocated to a VSI, the *Configure VSI Bandwidth per Traffic Class* command should be used.

Table 38-220.Update VSI Command (Opcode: 0x0211)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0211	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID Number	16-17		VSI SEID number.
Reserved	18-21		Reserved.
Command Flags	22-23		15:0 = Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer and the completion buffer used to update a VSI is the same as the command and completion buffers of the Add VSI command (Table 38-216 and Table 38-217). Specific limitations are listed in the tables.

All the filters set before the VSI type updates are kept, and the software device driver should guarantee they are compliant with the new VSI type.

Table 38-221.Update VSI Response (Opcode: 0x0211)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0211	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: ENOENT - If the SEID do not point to a valid VSI. EACCES - If the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID Number	16-17	0x0	Copied from command.
VSI Number	18-19		Returns the assigned VSI number.
VSI Used	20-21		Number of VSIs used by this function.
Total VSIs Un-allocated	22-23		Total number of VSIs still un-allocated and not reserved by any function.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Get VSI Parameters (0x0212)

This command is used to get the parameters of an existing VSI. A function can query only a VSI it controls.

Table 38-222.Get VSI Parameters Response (Opcode: 0x0212)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0212	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: ENOENT - If the SEID do not point to a valid VSI. EACCES - If the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID Number	16-17		VSI SEID number (copied from command).
VSI Number	18-19		Returns the assigned VSI number.
VSIs Used	20-21		Number of VSIs used by this function.
Total VSIs Un-allocated	22-23		Total number of VSIs still un-allocated and not reserved by any function.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-223.Get VSI Parameters Command (Opcode: 0x0212)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0212	Command opcode.
Datalen	4-5	0x80	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID Number	16-17		VSI SEID number.
Reserved	18-23		Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-224 lists the response buffer received when querying a VSI.

Table 38-224.Get VSI Parameters Response Buffer

Byte/Bit	Description
0-95	Same parameters as listed in Table 38-216.
96-127	Same parameters as listed in Table 38-217.

38.21.7.18.5 Port Virtualizer Commands (opcode 0x022x)

Add Port Virtualizer

This command is used to instantiate a port virtualizer on a port. A port virtualizer can be instantiated only when a single VSI is connected between the MAC and a PF. If additional switching elements are active on this port, they must be first disconnected before the port virtualizer can be added.

When an Add Port Virtualizer command is received, the internal firmware checks if all the requested resources are available and allocate them to the port virtualizer. If part of the resources are not available, the command returns a list of unavailable resources

Table 38-225.Add Port Virtualizer Command (Opcode: 0x0220)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0220	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Command Flags	16-17	0x0	0 = Port virtualizer type. Must be set to zero. 1 = Forward unknown S-tag. If set, packets with unknown S-tags are forwarded to the default VSI. *2* = Reserved. If bit 1 is set, the port type should be default; otherwise, these bits are ignored. 3 = Port type: 0 = Default. 1 = Control. 4:15 = Reserved.
Uplink SEID	18-19	0x0	Defines the SEID to which this port virtualizer should be connected. This can be only the MAC of the port on which this function resides.
Connected VSI SEID	20-21	0x	Defines the SEID of the first VSI connected to this port virtualizer. Port type is defined by the *Port Type* flag. Should point to a valid VSI, connected to the uplink SEID as uplink.
Reserved	22-31		Reserved.

Table 38-226.Add Port Virtualizer Response (Opcode: 0x0220)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0220	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the port SEID do not point to a valid element. ENOSPC - If there are not enough resources to assign a port virtualizer. ESRCH - If the operation is not permitted (like virtualization is disabled). EACCES - If the port is not owned by this PF. EINVAL - If a software device driver tries to create a port virtualizer of a type contradicting the previously created port virtualizer type.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Port Virtualizer SEID/Error Reasons	16-17		If the return value is zero: Bytes 25:24 = Returns the SEID of the port virtualizer. If the return value is ENOSPC, it contains a bitmap that indicates which resources are missing: 0 = No port virtualizer left. 1 = Not enough scheduler nodes. 2 = Reserved. 3 = Not enough switching entries. 4:31 = Reserved.
Reserved	18-31		Reserved.

Update Port Virtualizer Parameters

This command is used to modify the parameters of a port virtualizer. In this command, the flags of the port virtualizer can be modified. Note that the default VSI cannot be modified using this command, only the routing of unknown packets.

In order to enable forwarding of unknown packets, a default VSI should be defined beforehand.

Table 38-227.Update Port Virtualizer Command (Opcode: 0x0221)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0221	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Command Flags	16-19	0x0	0 = Reserved (the port virtualizer type cannot be modified on the fly). 1 = Forward unknown S-tag. If set, packets with unknown S-tags are forwarded to the default VSI. 2-31 = Reserved.
Reserved	20-31	0x0	Reserved.

Table 38-228.Update Port Virtualizer Response (Opcode: 0x0221)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0221	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return value	6-7		The following error values can be returned: ENOENT - If the SEID do not point to a port virtualizer. EACCES - If the port virtualizer is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		Reserved.

Get Port Virtualizer Parameters

This command is used to get the parameters of a port virtualizer.

Table 38-229.Get Port Virtualizer Command (Opcode: 0x0222)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0222	Command opcode.
Datalen	4-5	0x0	Length of buffer
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17		The SEID of the port virtualizer.
Reserved	18-31		Reserved.

Table 38-230.Get Port Virtualizer Response (Opcode: 0x0222)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0222	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		The following error values can be returned: ENOENT - If the SEID do not point to a port virtualizer. EACCES - If the port virtualizer is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-17		The SEID of the requested port virtualizer (reflects the command).
Reserved	18-19		Reserved.
Command Flags	20-21	0x0	0 = Port virtualizer type: 0 = S-comp. 1 = Port extender. 1 = Forward unknown S-tag. If set, packets with unknown S-tags are forwarded to the default VSI. 2:15 = Reserved.
Reserved	22-29	Reserved	Reserved.
Default Port SEID	30-31		Returns the SEID of the default port.

38.21.7.18.6 VEB/VEPA Commands (Opcode 0x023x)

Add VEB

This command is used to instantiate an VEB on a port/port virtualizer. A VEB can be instantiated either as a floating element or can be inserted between an existing VSI and its uplink.

When an Add VEB command is received, the internal firmware checks if all the requested resources are available and allocate them to the VEB. If part of the resources are not available, the command returns a list of unavailable resources.

Note: After a VEB is added, the *Allow Loopback* flag of the original VSI should be set using the Update VSI command.

Table 38-231.Add VEB Command (Opcode: 0x0230)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0230	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
uplink SEID	16-17	0x0	Defines the SEID to which this VEB should be connected. If the *Floating VEB* flag is set, the uplink element should be null (0).
Downlink SEID	18-19	0x0	Defines the SEID of the downlink VSI to which this VEB is connected. Port type is defined by flags. Should point to valid VSI, currently connected to uplink SEID. Should be null(0) for floating VEB.
Flags.Floating VEB	20.0	0x0	If set it can only send packets to attached VSIs; if cleared it can send and receive packets from the LAN.
Flags. Port Type	20.2:-20.1	0x0	Defines the type of the VSI defined by the Downlink SEID field. 00b = Reserved. 01b = Default. 10b = Data Port. 11b = Reserved. Should be default (01b) for floating VEB.
Flags. Reserved	20.3	0x0	Reserved.
Flags. Disable Statistics Gathering	20.4	0x0	Disable Statistics Gathering. 0b = Statistics are gathered for this VEB. 1b = Statistics are not gathered for this VEB.
Flags. Reserved	20.5:21	0x0	Reserved.
Enabled TCs	22	0x0	A bitmap of the TCs that should be enabled in this VEB. The TCs enabled should be already enabled in the uplink element (should already have a node in the scheduler in the uplink element).
Reserved	23-31	0x0	Reserved

Note: The enable L2 filtering flag should be set to the same values for all VEB instances in the device. Firmware uses the value set by the first *Add VEB* AQ and rejects subsequent *Add VEB* AQ with a conflicting setting with an EINVAL error.

Table 38-232.Add VEB Response (Opcode: 0x0230)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0230	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the uplink SEID do not point to valid elements. ENOSPC - If there are not enough resources to assign a VEB. EACCES - If the uplink element is not owned by this PF. ERANGE - A TC not enabled in the uplink element was requested. EPERM - If the command is not permitted (such as virtualization is disabled).
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-21		Reserved.
Switch ID	22-23		Assigned switch ID. If connected to an S-channel, this is equal to the S-tag; otherwise, it is the switch ID assigned internally by firmware.
VEB SEID/Error Reasons.	24-25		If the return value is zero: Bytes 25:24 = Returns the SEID of the VEB. If return value is ENOSPC, contains a bitmap that indicates which resources are missing: 0 = No VEB left. 1 = Not enough Scheduler nodes. 2 = Not enough statistics counters. 3 = Not enough switching entries. 4:31 = Reserved.
Statistic Counter	26-27	Statistic Counters Index	Returns an index of the statistics counters block assigned to this VEB. This number is in the 0-15 range and points to the VEB statistics set. Relevant only if *Disable Statistics Gathering* flag is cleared in the command.
VEBs Used	28-29		Number of VEBs used by this function.
Total VEBs Un-allocated	30-31		Total number of VEBs still un-allocated and not reserved by any function.

Get VEB Parameters (0x0232)

This command returns the parameters of the VEB/VEPA

Table 38-233.Get VEB Parameters Command (Opcode: 0x0232)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0232	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17	0x0	Defines the SEID of the VEB.
Reserved	18-31	0x0	Reserved.

Table 38-234.Get VEB Parameters Response (Opcode: 0x0232)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0232	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID do not point to a valid VEB/VEPA element. EACCES - If the VEB is not owned by this PF. EPERM - If the command is not permitted (such as virtualization is disabled).
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17		The SEID requested in the command.
Switch ID	18-19		Assigned switch ID. If connected to an S-channel, this is equal to the S-tag; otherwise, it is the switch ID assigned internally by firmware.
Flags	20-21	0x0	0 = Floating VEB. If set, it can only send packets to attached VSIs If cleared it can send and receive packets from the LAN. 2:1 = Reserved. 3 = L2 filtering is enabled. If set, the L2 filter table should pass in addition to the regular forwarding decision. Relevant only for cloud and UDP cloud NVM images. Reserved otherwise. 15:4 = Reserved.
Statistic Counter	22-23	Statistic Counters Index	Returns an index of the statistics counters block assigned to this VEB.
VEBs Used	24-25		Number of VEBs used by this function.
Total VEBs Un-allocated	26-27		Total number of VEBs still un-allocated and not reserved by any function.
Reserved	28-31		Reserved.

38.21.7.18.7Switch Connectivity Commands (Opcode 0x024x)

Delete Element

This command is used to remove a switching element. A function can remove only an element it controls. The software device driver should make sure every queue in a VSI is disabled before a VSI is removed; however, queue groups tied to the VSI can be removed together with the VSI. It should also make sure the removed element is not tied to any other element before removing it. An exception to this rule is the case of a VEB, that when removed with a single VSI tied to it is replaced with this VSI.

Table 38-235.Delete Element Command (Opcode: 0x0243)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0243	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17	SEID	The SEID of the element to remove.
Reserved	18-31	0x0	Must be zero.

Table 38-236.Delete Element Response (Opcode: 0x0243)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0243	Command opcode.
Datalen	4-5	0x0	Reserved.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. The following error values can be returned: ENOENT - If SEID do not point to a valid element. EACCES - If the element is not owned by this PF. EBUSY - If the element to remove has more than one uplink element tied to it.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		Reserved.

38.21.7.18.8 Forwarding Table Configuration Commands (Opcode 0x025x)

Note: All the MAC addresses in the forwarding table configuration commands should be given in big endian format.

Add MAC, VLAN Pair (0x0250)

This command is used to add a set of MAC or MAC, VLAN pairs to a set of VSIs. If one of the allocations fail due to lack of resources, the *Set VSI Promiscuous modes* command can be used to enable forwarding of all the packets of a given type to this VSI. See Set VSI Promiscuous Modes (0x0254) for more detail.

All the VSIs must have the same SwitchID.

Enables receiving untagged packets only, a MAC, VLAN = 0 filter should be added.

This command should not be used to forward broadcast packets using hash based filtering. The *Set VSI Promiscuous Modes* command should be used if broadcast forwarding without VLAN filtering is required or using this command with *Use Hash* flag cleared if broadcast filtering with VLAN filtering is needed. See Set VSI Promiscuous Modes (0x0254) for more detail.

Note: The ToQueue action might be ignored if the packet is forwarded due to multiple rules match (such as an exact match and promiscuous unicast).

Table 38-237.Add MAC, VLAN Pair Command (Opcode: 0x0250) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0250	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to Num_addresses * 16 bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_addresses	16-17		The number of MAC, VLAN pairs to add.
SEID 0	18-19	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.

Table 38-237.Add MAC, VLAN Pair Command (Opcode: 0x0250) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID 1	20-21	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.
SEID 2	22-23	0x0	Bit 15 = Valid SEID. Bit 14:8 = Reserved. Bit 9:0 = SEID number of the VSI.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the MAC, VLAN pairs to add. It contains a set of *Num_addresses* 16-byte structures as listed in Table 38-238.

Table 38-238.MAC, VLAN Pairs to Add Detail

Field	Offset	Description
MAC Address	0-5	MAC address to add.
VLAN Tag	6-7	VLAN tag to add. Enables receiving untagged packets only, a VLAN ID of zero should be set and the *Ignore VLAN* flag should be cleared. 23:12 = Reserved. 11:0 = VLAN ID.
Flags	8-9	0: Use perfect match = If set, an perfect match MAC address can be used to create this MAC, VLAN pair. 1: Use Hash = If set, a hash MAC address can be used to create this MAC, VLAN pair. 2: Ignore VLAN = If set, the VLAN tag is ignored and the MAC address is used to forward packets from all VLANs. 3: ToQueue = Use MAC, VLAN to point to a queue. This flag should be set only if the filter points to a single VSI. If a filter points to multiple VSIs, an error is returned. 4: Use shared MAC: If set, the MAC address is taken from the shared pool. 15:5 = Reserved. At least one of the use perfect match or *Use Hash* flags should be set. If both are set, firmware attempts to use perfect match and falls back to using hash if the exact match table is full.
Queue Number		Bit 15:11 = Reserved. Bit 10:0 = Queue number. Valid only if the *Flags.ToQueue*e bit is set. The queue number is relative to the VSI.
Reserved		Reserved for response part.

Table 38-239.Add MAC, VLAN Pair Response (Opcode: 0x0250) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0250	Command opcode.
Datalen	4-5		Length of buffer. equals to Num_addresses * 16 bytes.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOSPC - If there are not enough resources to assign all the MAC, VLAN pairs or an attempt to add a VSI to an existing filter with ToQueue set. The return buffer details which of the allocations failed. ENOENT - If the SEID does not point to a valid VSI. EACCES - If the VSI is not owned by this PF. EEXIST - If a queue is assigned to a multicast filter (more than one VSI). EINVAL - If a *ToQueue* flag is set for a multicast filter. ENOMEM - no space for WoL filters.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command

Table 38-239.Add MAC, VLAN Pair Response (Opcode: 0x0250) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Perfect Match MAC Used	16-17		Number of perfect match MAC used by this function.
Perfect Match MAC Un-allocated	18-19		Total number of perfect match MAC still un-allocated and not reserved by any function.
Unicast Hash MAC Un-allocated	20-21		Total number of unicast hash MAC still un-allocated.
Multicast Hash MAC Un-allocated	22-23		Total number of multicast hash MAC still un-allocated.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The response buffer of this command contains the results of the MAC, VLAN pairs allocation. It contains a set of *Num_addresses* 16-byte structures as listed in Table 38-240.

Table 38-240.MAC, VLAN Pairs Allocation Detail

Field	Offset	Description
Reserved		Reserved for command part.
Matching Method		0x0 = Perfect match was used. 0x1 = Hash match was used. 0x2:0xFE = Reserved. 0xFF = Request failed due to lack of resources.
Reserved		Reserved.

Remove MAC,VLAN Pair (0x0251)

This command is used to remove a set of MAC or a MAC, VLAN pairs from up to three VSIs.

All the VSIs must have the same SwitchID.

If a hash MAC was used, the address should be removed only if this hash value is no longer needed for this VSI(s).

Table 38-241.Remove MAC, VLAN Pair Command (Opcode: 0x0251) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0251	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to Num_addresses * 16 bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num Addresses	16-17		The number of addresses in the command buffer.
SEID 0	18-19	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID Number of the VSI.

Table 38-241.Remove MAC, VLAN Pair Command (Opcode: 0x0251) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID 1	20-21	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID Number of the VSI.
SEID 2	22-23	0x0	Bit 15 = Valid SEID. Bit 14:8 = Reserved. Bit 9:0 = SEID Number of the VSI.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the MAC, VLAN pairs to remove. It contains a set of *Num_addresses* 16-byte structures as listed in Table 38-242.

Table 38-242.Remove MAC, VLAN Pair Response (Opcode: 0x0251)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0251	Command opcode
Datalen	4-5		Length of buffer. Indicates the number of entries filled by firmware (16*Num Addresses) even if the *Datalen* in the command was larger than that.
Return Value/ VFID	6-7		Return value. The following error values can be returned: EINVAL - If all the VSIs do not point to the same switchID. ENOENT- If the MAC, VLAN pair does not exist or if one of the SEID does not point to a valid VSI. The details of which remove request failed is found in the response buffer. If a VSI is not connected to one of the MAC, VLAN to remove, it is silently ignored. EACCES - If one of the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Perfect Match MAC Used	16-17		Number of perfect match MAC used by this function.
Perfect Match MAC Un-allocated	18-19		Total number of perfect match MAC still un-allocated and not reserved by any function.
Unicast Hash MAC Un-allocated	20-21		Total number of unicast hash MAC still un-allocated.
Multicast Hash MAC Uun-allocated	22-23		Total number of multicast hash MAC still un-allocated.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-243.MAC, VLAN Pairs to Remove Detail

Field	Offset	Description
MAC Address	0-5	MAC address to remove VSI from.
VLAN Tag		VLAN tag to remove VSI from.
Flags		0: perfect match: If set, an perfect match MAC address was used to create this MAC, VLAN pair. 1: Hash: If set, a hash MAC address was used to create this MAC, VLAN pair. 2: Reserved. 3: Ignore VLAN: If set, the forwarding is currently based only on MAC. 4: Remove from all VSIs. This will remove the filter from all the VSIs owned by this PF. 7:5: Reserved.
Reserved		Reserved.

The response buffer of this command contains the results of the MAC, VLAN pairs removal. It contains a set of *Num_addresses* 16-byte structures as listed in Table 38-244.

Table 38-244.Response Buffer Results (MAC, VLAN Pairs Removal)

Field	Offset	Description
Reserved	0-11	Reserved for command part.
Error Code	12	0x0 = Successful removal. 0x1:0xFE = Reserved. 0xFF = Request failed (The MAC, VLAN pair does not exist).
Reserved	13-15	Reserved.

Add VLAN (0x0252)

This command is used to add a set of VLANs to the VLAN table or to add a set of VLAN filters to up to three VSIs. All the VSIs must have the same SwitchID.

Note: In order to support egress (Tx) VLAN filtering, the *Enable VLAN anti spoof* flag should be set in the relevant Add VSI command. In order to support ingress (Rx) VLAN filtering, the *Promiscuous VLAN* flag in the Set VSI Promiscuous Modes command should be cleared.

For Private VLAN functionality both ingress and egress VLAN filtering are needed.

Note: By default VLAN filtering is disabled. The first time this command is applied, VLAN filtering is enabled.

Table 38-245.Add VLAN Command (Opcode: 0x0252) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0252	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to Num_VLAN * 8 bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_VLAN	16-17		Number of VLANs to add.

Table 38-245.Add VLAN Command (Opcode: 0x0252) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID 0	18-19	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.
SEID 1	20-21	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.
SEID 2	22-23	0x0	Bit 15 = Valid SEID. Bit 14:8 = Reserved. Bit 9:0 = SEID number of the VSI.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the VLAN IDs to add. It contains a set of *Num_VLAN* 8-byte structures as listed in Table 38-246.

Table 38-246.Add VLAN Response (Opcode: 0x0252)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0252	Command opcode.
Datalen	4-5		Length of buffer - equals to Num_VLAN * 8 bytes.
Return Value/ VFID	6-7		Return value. The following error values can be returned: EINVAL - If all the VSIs do not point to the same switchID. ENOSPC - If there are not enough resources to assign the VLANs. The response buffer details which of the allocations failed. ENOENT - If one of the VSIs is not valid. EACCES - If one of the VSIs is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-19		Reserved.
VLAN Used	20-21		Total Number of VLAN used (VLAN is a shared resource).
VLAN Un-allocated	22-23		Total number of VLAN still un-allocated.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-247.Command Buffer - VLAN IDs to Add Detail

Field	Offset	Description
VLAN Tag	0-1	VLAN tag to add.
Flags	2	0 = Local VLAN 2:1 = Private VLAN type: 00b = Regular VLAN (not private) 01b = Primary VLAN 10b = Secondary VLAN 11b = Reserved 4:3 = Private VLAN Port type (valid only if Private VLAN type is Primary or Secondary VLAN): 00b = Regular VLAN 01b = Promiscuous VSIs 10b = Community VSIs 11b = Isolated VSIs ***Note:*** If primary or secondary VLAN is set, the port type can not be zero. If both are not set, it must be zero. ***Note:*** The definition of a VLAN ID should be consistent within a VEB. Thus, subsequent commands should set the same private VLAN type an local VLAN flags when adding VSIs to the same VLAN ID. The private VLAN port type can be different for various VSIs within the same VLAN.
Reserved	3-7	Reserved for response part.

The response buffer of this command contains the results of the VLANs allocation. It contains a set of *Num_VLAN* 8-byte structures as listed in Table 38-248.

Table 38-248.Response Buffer - VLANs Allocation Detail

Field	Offset	Description
Reserved	0-3	Reserved for command part.
Result	4	0x0 = Allocation success. 0x1:0xFD = Reserved. 0xFE = Request failed due to inconsistent VLAN definition. 0xFF = Request failed due to lack of resources.
Reserved	5-7	Reserved.

Remove VLAN (0x0253)

This command is used to remove a set of VLANs from the VLAN table or to remove VLAN filters from up to three VSIs.

All the VSIs must have the same SwitchID.

Table 38-249.Remove VLAN Command (Opcode: 0x0253) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0253	Command opcode.
Datalen	4-5	0x0	Length of buffer. Should be equal to Num_VLAN * 8 bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_VLAN	16-17		Number of VLANs to add.

Table 38-249.Remove VLAN Command (Opcode: 0x0253) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID 0	18-19	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.
SEID 1	20-21	0x0	Bit 15 = Valid SEID. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.
SEID 2	22-23	0x0	Bit 15 = Valid SEID. Bit 14:8 = Reserved. Bit 9:0 = SEID number of the VSI.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the VLAN pairs to remove. It contains a set of *Num_VLAN* 8-byte structures as listed in Table 38-250.

Table 38-250.Command Buffer - VLAN Pairs to Remove Detail

Field	Offset	Description
VLAN tag	0-1	VLAN tag to remove VSI(s) from.
Flags	2	0 = Remove entire VLAN. 7:1 = Reserved.
Reserved	3	Reserved.
Reserved	4-7	Reserved for response part.

Table 38-251.Remove VLAN Response (Opcode: 0x0253)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0253	Command opcode.
Datalen	4-5		Length of buffer. Equal to Num_VLAN * 8 bytes.
Return Value/ VFID	6-7		Return value. The following error values can be returned: EINVAL - If all the VSIs do not point to the same switchID. ENOENT - If the VLAN does not exist or if one of the SEID does not point to a valid VSI. The response buffer details which of the removal failed. If a VSI is not connected to one of the MACs, VLAN to remove, it is silently ignored. EACCES - If one of the VSIs is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-19		Reserved.
VLAN Used	20-21		Total Number of VLAN used (VLAN is a shared resource).
VLAN Un-allocated	22-23		Total number of VLAN still un-allocated.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The response buffer of this command contains the results of the MAC, VLAN pairs removal. It contains a set of *Num_VLAN* 8-byte structures as listed in Table 38-252.

Table 38-252.Response Buffer - MAC, VLAN Pairs Removal Detail

Field	Offset	Description
Reserved	0-3	Reserved for command part.
Error code	4	0x0 = Successful removal. 0x1:0xFE = Reserved. 0xFF = Request failed (the VLAN do not exist or if one of the VSIs is not valid).
Reserved	5-7	Reserved.

Set VSI Promiscuous Modes (0x0254)

This command is used to enable a VSI to set various promiscuous mode and other generic filtering options.

Note: If the *Default VSI* flag is set for a VSI within a VEB, this command changes the default VSI of the VEB to the VSI pointed by this command.

Table 38-253.Set VSI Promiscuous Modes Command (Opcode: 0x0254) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0254	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Flags	16-17		0 = Promiscuous unicast. 1 = Promiscuous multicast. 2 = Promiscuous broadcast. 3 = Default VSI. Accept packets within the switch ID not matching any specific address to this VSI. 4 = Promiscuous VLAN. 14:5 = Reserved. 15: Apply promiscuous mode to Rx traffic only. This bit is relevant only if one of options 0,1,2 is used. This bit is relevant only if switch is configured to work in limited promiscuous mode, and packet is not hitting VLAN mirroring rule. Multiple flags might be set. Default VSI is supposed to be used only for VMDq1 scenarios where there is no VEB. If this command is used in presence of a VEB, it changes the default VSI of the VEB. Default VSI should not be set if the VSI is connected directly to the port (not via a VEB or a PV).
Valid Flags	18-19		0 = Promiscuous unicast flag is valid. 1 = Promiscuous multicast is valid. 2 = Promiscuous broadcast is valid. 3 = Default VSI is valid. 4 = Promiscuous VLAN is valid. 15:6 = Reserved. Multiple valid bits might be set.
SEID Number	20-21		Bit 15 = Valid SEID. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI.

Table 38-253.Set VSI Promiscuous Modes Command (Opcode: 0x0254) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
VLAN ID	22-23		15 = VLAN is valid. 14:12 = Reserved. 11:0 = VLAN ID. If bit 15 is set, the *Promiscuous Unicast*, *Multicast*, and *Broadcast* flags applies only to this VLAN; otherwise, these modes apply to all VLANs. If VSI is in promiscuous VLAN mode, the VLAN ID should not be used.
Reserved	24-31	0x0	Reserved.

Table 38-254.Set VSI Promiscuous Modes Response (Opcode: 0x0254)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0254	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID does not point to a valid VSI. ENOSPC - If there are not enough resources to apply the promiscuous rules. EACCES - If the VSI is not owned by this PF. ENOMEM - No space for WoL filters.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		Reserved. Should contain the parameters from the command.

Add S-tag (0x0255)

This command is used to associate an S-tag with a VSI. This command can be given only by the port controlling the port virtualizer. This command should be used for cascaded port virtualizer VSIs where more than one S-tag points to the same VSI. For regular channels, the *Add VSI* command already adds the single S-tag of the VSI.

An S-tag can be directed to a specific queue in the VSI. This is done by setting the *ToQueue* flag and providing a valid queue in the *QueueNumber* field. In order to assign a queue to the default VSI, this command should be used with the default S-tag as tag value.

Note: The first S-tag added to the cascaded port virtualizer VSI via the *Add VSI* command is considered as the switch ID for this VSI and should not be manipulated by the Add S-tag and Remove S-tag commands.

Note: A VEB or L2 filters cannot be applied to a cascaded VSI on any S-tag. The VSI should be in default mode for its initial S-tag. The VSI should be defined with a *Connection Type* of *Default Port command*.

Table 38-255.Add S-tag Command (Opcode: 0x0255) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0255	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7	0x0	Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.

Table 38-255.Add S-tag Command (Opcode: 0x0255) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Flags	16-17		0 = ToQueue. 15:1 = Reserved.
SEID	18-19	0x0	Bit 15 = Valid SEID. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI. Defines the VSI that uses this S-tag. This VSI should belong to the port virtualizer through which this command is received.
Tag	20-21	0x0	The value of the S-tag.
Queue Number	22-23	0x0	Bit 15:11 = Reserved. Bit 10:0 = Queue number. Valid only if the *Flags.ToQueue* bit is set. The queue number is relative to the VSI.
Reserved	24-31		Reserved.

Table 38-256.Add S-tag Response (Opcode: 0x0255)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0255	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID do not point to a valid element. ENOSPC - If there are not enough resources to assign a tag. EACCES - If the VSI is not owned by this PF. EEXIST - If this tag already points to another VSI. EPERM - Attempt to add tags to a VSI which is not a cascaded type.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-27	0x0	
S-tags Used	28-29		Number of tags used by this PF.
S-tags Un-allocated	30-31		Total number of tags still un-allocated.

Remove S-tag (0x0256)

This command is used to remove an S-tag from the forwarding table of a VSI.

Note: This command should be used only to remove tags in a cascaded port virtualizer VSIs.

Table 38-257.Remove S-tag Response (Opcode: 0x0256)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0256	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID do not point to a valid element. EACCES - If the VSI is not owned by this PF. ENXIO - This S-tag does not point to this VSI. EPERM - Attempt to remove tags from a VSI which is not a cascaded type.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-27		Reserved.
S-tag Used	28-29		Number of S-tags used by this function.
S-tag Un-allocated	30-31		Total number of S-tags still un-allocated.

Table 38-258.Remove S-tag Command (Opcode: 0x0256)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0256	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
VSI SEID	16-17	0x0	Bit 15 = Valid SEID. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = SEID number of the VSI. Defines the VSI SEID that uses this tag. This VSI should belong to the port virtualizer through which this command is received.
S-tag	18-19	0x0	The value of the tag.
Reserved	20-31	0x0	Reserved.

Update S-tag (0x0259)

This command is used to update the S-tags associated with a VSI. This command can be given only by the port controlling the port virtualizer. This command can be used only for cascaded port virtualizer VSIs.

If a queue was associated with the previous tag, the association is kept for the new tag.

Table 38-259.Update S-tag Command (Opcode: 0x0259)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0259	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7	0x0	Return value. Zeroed by driver. Written by Firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID Number	16-17	0x0	Bit 15 = SEID Valid. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = Defines the SEID of the VSI that uses this tag. This VSI should belong to the PF through which this command is received.
Old Tag	18-19	0x0	The original value of the S-tag. If the value is zero, it is assumed the VSI does not have a tag.
New Tag	20-21	0x0	The new value of the tag.
Reserved	22-31		Reserved.

Table 38-260.Update S-tag Response (Opcode: 0x0259)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0259	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID do not point to a valid element. ENOSPC - If there are not enough resources to assign a new tag. EACCES - If the VSI is not owned by this PF. EEXIST - If the new tag already points to another VSI. EPERM - An attempt to modify a tag in a VSI which is not a cascaded port extender type.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-27	0x0	
S-tags Used	28-29		Number of S-tags used by this PF.
S-tags Un-allocated	30-31		Total number of S-tags still un-allocated.

Add Control Packet Filter (0x025A)

This command is used to add a control filter to forward packets to a control VSI. This function should be used to forward packets to control VSIs; however, there is no enforcement of this rule and the software device driver might use it to forward control packets to other VSIs. Only packets reaching the switching element is forwarded by this rule. This means that:

- If the VSI is connected as a control port of the MAC, a port virtualizer or a VEB directly connected to the MAC, this filter applies to untagged packets (no S-tag).
- If the VSI is connected to an S-channel, either directly or as a VEB port, only packets tagged with the S-channel tag is forwarded.

Note: These filters are exclusive. If a request to set a filter on an existing flow type is received, it is rejected with an EEXIST reason code. If a filter is set to forward an EtherType ignoring the MAC address (Ignore MAC = 1), a filter with the same EtherType and a MAC address should not be applied within the same switch.

Note: The EtherType programmed by this command should not be one of the L2 tags EtherType (VLAN, S-tag, etc.) and should not be IP or IPv6.

Table 38-261.Add Control Packet Filter Command (Opcode: 0x025A)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025A	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
MAC Address	16-21		The MAC address to use in the filter.
EtherType	22-23		The EtherType to use: The 16-bit value of the EtherType.
Command Flags	24-25		0 = Ignore MAC. If set, forwarding is based only on EtherType. 1 = Drop filter. If set, packets received or sent with this destination MAC address and EtherType are dropped. 2 = ToQueue. If set, the packets matching this filter is sent to a specific queue. If cleared, the regular queuing mechanism is used. A queue defined by a lower priority switch filter (such as MAC filter) is ignored. 3 = Direction: • 0 = Apply to Rx traffic. • 1 = Apply to Tx traffic. 15:4 = Reserved.
SEID Number	26-27		Bit 15 = SEID Valid Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = Defines the SEID of the VSI that should get the packet. ***Note:*** This field is ignored if the *Drop Filter* flag is set.
Queue Number	28-29		Queue to send the packet to if the *ToQueue* flag is set. The queue number is relative to the VSI.
Reserved	30-31		Reserved.

Table 38-262.Add Control Packet Filter Response (Opcode: 0x025A)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025A	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOSPC - If there are not enough resources to assign the requested filter. ENOENT - If the VSI is not valid. EACCES - If the VSI is not owned by this PF. EEXIST - If such a filter already exists and is allocated to another VSI. ENOMEM - No space for WoL filters.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
MAC, EtherType Used	16-17		Number of perfect match MAC, EtherType used by the device.
EtherType Used	18-19		Number of perfect EtherType used by the device.
MAC, EtherType Not Allocated	20-21		Number of perfect match MAC, EtherType still un-allocated.
EtherType Not Allocated	22-23		Number of perfect EtherType still un-allocated.
Reserved	24-31		Reserved.

Remove Control Packet Filter (0x025B)

This command is used to remove a control filter. The filter to remove is defined by the switching element to which the VSI is connected. This means that:

- If the VSI is connected as a control port of the MAC, a port virtualizer or a VEB directly connected to the MAC, the removed filter relates to untagged packets (no S-tag).
- If the VSI is connected to an S-channel, either directly or as a VEB port, the removed filter relates to packet tagged with the S-channel tag.

Table 38-263.Remove Control Packet Filter Command (Opcode: 0x025B) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025B	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
MAC Address	16-21		The MAC address in the filter.
EtherType	22-23		The EtherType used: The 16-bit value of the EtherType.
Command Flags	24-25		0 = Ignore MAC. If set, forwarding is based only on EtherType. 2:1 = Reserved 3 =: Direction: • 0 = Apply to Rx traffic. • 1 = Apply to Tx traffic. 15:4 = Reserved.

Table 38-263.Remove Control Packet Filter Command (Opcode: 0x025B) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID Number	26-27		Bit 15 = SEID Valid. I - ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = Defines the SEID of the VSI to which the filter is associated.
Reserved	28-31		Reserved.

Table 38-264.Remove Control Packet Filter Response (Opcode: 0x025B)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025B	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT- If the VSI is not connected to the MAC, EtherType or EtherType filter to remove. EACCES - If the VSI is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
MAC, EtherType Used	16-17		Number of perfect match MAC, EtherType used by the device.
EtherType Used	18-19		Number of perfect EtherType used by the device.
MAC, EtherType Not Allocated	20-21		Number of perfect match MAC, EtherType still un-allocated.
EtherType Not Allocated	22-23		Number of perfect EtherType still un-allocated.
Reserved	24-31		Reserved.

Add Cloud Filters (0x025C)

This command is used to add a set of cloud filters to a VSI. The filters set by this commands are the filters specific to cloud formats. To add MAC or MAC, VLAN filters, the *Add MAC, VLAN pairs* (0x0250) command should be used.

Note: The response cannot contain all the cloud resources available, the software device driver needs to use the *Get Switch Resources Allocation* command (0x0204) to get the resources left after allocation of a filter. See Get Switch Resources Allocation (0x0204) for more detail.

Table 38-265.Add Cloud Filters Command (Opcode: 0x025C) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025C	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to 64 * Num_filters bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_filters	16		The number of filters to add.
Reserved	17	0x0	Reserved.

Table 38-265.Add Cloud Filters Command (Opcode: 0x025C) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
SEID	18-19	0x0	Bit 15 = SEID Valid. Ignored in this field (SEID is always valid). Bit 14:10 = Reserved. Bit 9:0 = Defines the SEID of the VSI.
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the filters to add. It contains a set of *Num_filters* 64-byte structures as listed in Table 38-266.

Table 38-266.Add Cloud Filters Response (Opcode: 0x025C)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025C	Command opcode.
Datalen	4-5		Length of buffer Equals to 64 * Num_filters bytes.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOSPC - If there are not enough resources to assign all the filters. The return buffer details which of the allocations failed. ENOENT - If the VSI is not valid. EACCES - If the VSI is not owned by the offload PF. EEXIST - This filter is already allocated to another VSI. ENOMEM - No space for WoL filters.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_filters	16		The number of filters in the response buffer.
Reserved	17-23		
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-267.Add Cloud Filters - Command Buffer (Sheet 1 of 2)

Field	Offset	Description
Outer MAC Address	0-5	Outer MAC Address to add.
Inner MAC Address	6-11	Inner MAC Address add.
Inner VLAN Tag	12-13	Inner VLAN tag to add (only 12 LSBits are relevant to filter).
IP	14-29	IP address to add. For IPv4 addresses, bytes 14-25 are reserved.

Table 38-267.Add Cloud Filters - Command Buffer (Sheet 2 of 2)

Field	Offset	Description
Command Flags	30-31	6:0 = Filter type: • 0x0 = Reserved. • 0x1 = Reserved. • 0x2 = Reserved. • 0x3 = Inner MAC, inner VLAN (for NVGRE, VXLAN or Geneve packets). • 0x4 = Inner MAC, inner VLAN, Tenant ID (for NVGRE, VXLAN or Geneve packets). • 0x5 = Reserved. • 0x6 = (Inner MAC, tenant ID) (NVGRE packet or VXLAN/Geneve packets). • 0x7 = Reserved. • 0x8 = Reserved. • 0x9 = Outer MAC L2 filter. • 0xA = Inner MAC filter. • 0xB = Outer MAC, tenant ID, inner MAC. • 0xC = Application destination IP. • 0xD:0x3F = Reserved. ***Note:*** Filter 0xB should not be used in modes with port extenders. An outer MAC L2 filter (0x9) should be added only once per relevant MAC address. This filter applies to all the VSI of type cloud. 7 = ToQueue: If set, a packet matching this filter is sent to a specific queue. Not relevant if filter type = 0x9. 8 = IP address type: • 0 = IPv4. • 1 = IPv6. Relevant only for filter type 0xC. 12:9 = Tunnel Type: • 0x0 = VXLAN. • 0x1 = NVGRE or other MAC in GRE. • 0x2 = Geneve. • 0x3 = IP in GRE. • 0x4 = Reserved. • 0x5:0xF = Reserved. Relevant only for filter types 0x4, 0x6, and 0xB. Relevant only for filter types 0x4, 0x6, and 0xB. 13: Use shared outer MAC: If set, the outer MAC is taken from the shared pool. Relevant only for filters involving outer MAC. 14: Use shared inner MAC: If set, the inner MAC address is taken from the shared pool. Relevant only for filters involving inner MAC. 15: Use shared Outer IP: If set, the outer IP address is taken from the shared pool. Relevant only for filters involving outer IP.
Tenant ID	32-35	Key to add: • NVGRE tunnel type: TNI. • VXLAN/Geneve tunnel type: VNI. • Other GRE tunnel type: GRE Key. ***Note:*** The tenant ID is 3 bytes (32..34) and byte 35 is reserved.
Reserved	36-39	Reserved.
Queue Number	40-41	Bit 15:11: Reserved. Bit 10:0: Queue number. Valid only if the *Command Flags.ToQueue* bit is set. The queue number is relative to the VSI.
Reserved	42-55	Reserved.
Reserved	56-63	Reserved for response part.

The response buffer of this command contains the results of the filters allocation. It contains a set of *Num_filters* 64-byte structures as listed in Table 38-268.

Table 38-268.Add Cloud Filters - Response Buffer

Field	Offset	Description
Reserved	0-55	Reserved for command part.
Allocation result	56	0x0 = Filter assigned. 0x1:0xFE = Reserved. 0xFF = Request failed due to lack of resources.
Reserved	57-63	Reserved.

Remove Cloud Filters (0x025D)

This command is used to remove a set of cloud filters from a VSI. The filters removed by this command is the filters specific to cloud formats. To remove MAC or MAC, VLAN filters, the *Remove MAC, VLAN pairs* (0x0251) command should be used.

Table 38-269.Remove Cloud Filters Command (Opcode: 0x025D)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025D	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to 64 * Num_filters bytes.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_filters	16		The number of filters to remove.
Reserved	17	0x0	Reserved.
SEID	18-19	0x0	Bit 15 = SEID Valid. Ignored in this field. Bit 14:10 = Reserved. Bit 9:0 = Defines the SEID of the VSI.
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer of this command contains the details of the filters to remove. It contains a set of *Num_filters* 16-byte structures as defined in the *Add Cloud filters* command buffer (see Table 38-267).

Note: The *ToQueue* flag and *Queue Number* field are not used by the *Remove Cloud Filter* command.

Table 38-270.Remove Cloud Filters Response (Opcode: 0x025D) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025D	Command opcode.
Datalen	4-5		Length of buffer. Equals to 64 * Num_filters bytes.

Table 38-270.Remove Cloud Filters Response (Opcode: 0x025D) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the VSI is not connected to one of the cloud filters or the cloud filter entry does not exist or if one of the VSIs is not valid. The details of which remove request failed is found in the response buffer. EACCES - If the VSI is not owned by the offload PF (VSI is on another port).
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Num_filters	16		The number of filters in the response buffer.
Reserved	17-23	0x0	Reserved.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The response buffer of this command contains the results of the filters allocation. It contains a set of *Num_filters* 16 bytes structures as defined below.

Table 38-271.Remove Cloud Filters - Response Buffer

Field	Offset	Description
Reserved	0-13	Reserved for command part.
Allocation Result	14	0x0 = Successful removal. 0x1:0xFE = Reserved. 0xFF = Request failed (one of the VSIs is not connected to this filter or the filter entry does not exist).
Reserved	15	Reserved.

Clear All WoL Switch Filters (0x0025E)

This command clears all the switch filters directed to the WoL VSI of the PF that sent the command.

Table 38-272.Clear All WoL Switch Filters Command (Opcode: 0x0025E)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x025E	Command opcode.
Datalen	4-5	0	
Return value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.

Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31		

38.21.7.18.9 Mirroring Commands (Opcode 0x026x)

Add Mirror Rule (0x0260)

This command is used to add a mirror rule to a specific switch. Mirror rules are supported for VEBs or VEPA elements only.

Table 38-274.Add Mirror Rule Command (Opcode: 0x0260)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0260	Command opcode.
Datalen	4-5		Length of buffer. Should be equal to 2 * Number of mirrored entries.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
SEID	16-17		Defines the SEID of the switch to which the rule refers.
Rule Type	18-19		2:0 = Rule Type: • 000b = Reserved. • 001b = Virtual port ingress mirroring. • 010b = Virtual port egress mirroring. • 011b = VLAN mirroring. • 100b = All ingress traffic (to this switch). Includes traffic sent from all VSIs connected to this switch. Does not include traffic received from LAN. • 101b = All egress traffic (from this switch). Includes traffic sent to all VSI in this switch. Does not include traffic sent to the LAN. • 11xb = Reserved. 15:3 = Reserved. If the rule type is 100b (all ingress) or 101b (all egress), then there is no associated buffer. The flags in bytes 0-1 should be set accordingly. If all egress or all ingress is needed, then no other egress/ingress rules respectively within the VEB/VEPA should be set, as a packet cannot be replicated by two rules. VSIs added to a switch after the all ingress/all egress rule was added are not included in the rule and the rule should be removed and re-applied to include them.
Number Of Mirrored Entries	20-21		Defines the number of VSI/VLANs that should be mirrored. The values are in the command buffer.
Destination VSI	22-23		Defines the VSI SEID to which the packets matching the mirror rule are mirrored.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

The command buffer is built as a number of mirrored entries of two bytes each containing a single VSI/VLAN, depending on the rule requested as listed in Table 38-275.

Table 38-275.Add Mirror Rule Command Buffer

Byte	Description
0-1	Mirrored VSI (SEID) or VLAN ID. For all rule types but ingress VLAN mirroring, the values are SEIDs of VSI. For ingress VLAN mirroring rule type, the values are VLAN IDs. The VSIs in the list should be part of the switch defined by the SEID.

Table 38-276 lists the add mirror rule response (with no buffer)

Table 38-276.Add Mirror Rule Response (Opcode: 0x0260)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0260	Command opcode.
Datalen	4-5		Length of buffer - equals to 2 * Number of mirrored entries.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the mirror SEID do not point to a valid switch element or the SEID of the mirrored VSI does not point to a valid VSI. ENOSPC - If there are not enough resources to assign an mirror rule. EACCES - If the VEB is not owned by this PF. EINVAL - If the same VLAN mirroring rule is added twice. EEXIST - rule already assigned. The rule should be removed before being assigned again.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-17		Reserved.
Rule ID	18-19		Defines the rule ID that is returned in the receive descriptor. This number is assigned by firmware and should be used as a handle when requesting deletion of an existing rule. The rule ID is not relevant for the ingress VLAN mirroring rule type (011b).
Mirror Rules Used	20-21		Number of mirror dedicated rules used by this function.
Mirror rules Un-allocated	22-23		Total number of mirror rules still un-allocated.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Delete Mirror Rule (0x0261)

This command is used to delete an existing mirror rule. If the rule to remove is of ingress VLAN mirroring type, a buffer should be provided containing the currently mirrored VLAN to remove.

Table 38-277.Delete Mirror Rule Command (Opcode: 0x0261) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0261	Command opcode.
Datalen	4-5	0x0	Length of buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.

Table 38-277.Delete Mirror Rule Command (Opcode: 0x0261) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command
SEID	16-17		Defines the SEID of the switch to which the rule refers.
Rule Type	18-19		2:0 = Rule Type: • 000b = Reserved. • 001b = Virtual port ingress mirroring. • 010b = Virtual port egress mirroring. • 011b = Ingress VLAN mirroring. • 100b = All ingress traffic (to this switch). • 101b = All egress traffic (from this switch). • 11xb = Reserved. 15:3 = Reserved.
Number Of Mirrored Entries	20-21		Defines the number of VSI/VLANs that should be mirrored. The values are in the command buffer.
Rule ID	22-23		Defines the rule ID that is returned in the receive descriptor. This ID identifies the rule to delete. This ID is the number returned from the Add Mirror Rule response. Relevant only if rule type is not *Ingress VLAN mirroring* (011b).
Data Address High	24-27		Address of buffer. Relevant only if rule type is *Ingress VLAN mirroring* (011b).
Data Address Low	28-31		

The structure of the buffer used to indicate the VLAN to remove is listed in Table 38-278.

Table 38-278.Delete Mirror Rule - Command Buffer

Byte	Description
0-1	Mirrored VLAN ID to remove. 15:12 = Reserved. 11:0 = VLAN ID.

Table 38-279 lists the delete mirror rule response (with no buffer).

Table 38-279.Delete Mirror Rule Response (Opcode: 0x0261) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0261	Command opcode.
Datalen	4-5		Length of buffer.
Return Value/ VFID	6-7		Return value. The following error values can be returned: ENOENT - If the SEID do not point to a valid switch element. EINVAL - If the rule ID does not exist. EACCES - If the VEB is not owned by this PF.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-19		
Mirror Rules Used	20-21		Number of mirror rules used by this function.
Mirror rules Un-Allocated	22-23		Total number of mirror rules still un-allocated.

Table 38-279.Delete Mirror Rule Response (Opcode: 0x0261) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

38.22 Interrupts

38.22.1 Interrupt Signaling

The 10 GbE controller supports the following interrupt signaling according to per PF setting options:

- Legacy INTA/INTB/INTC/INTD interrupt message on the PCIe is supported for the PFs. The 10 GbE controller exposes legacy interrupt support in the *Interrupt Pin* field in the PCI configuration space of the PF. The interrupt pin parameter is loaded from the *INTPIN* field in the NVM (to the PFPCI_CNF register) defining the interrupt pin (A,B,C,D or none) per PF. It is the NVM programmer's responsibility to follow the PCI rules for allocating orderly interrupt pins for the PCI functions. The legacy interrupt is triggered by the interrupt vector zero of the PF.
- MSI is exposed in the MSI capability structure in the PCI configuration space of each PF. The MSI interrupt is triggered by the interrupt vector zero of the PF. The MSI capability is enabled per PF by the MSI_En bit in the PFPCI_CNF (loaded from the NVM).
- MSI-X enables multiple interrupts for the PFs as well as the VFs. MSI-X is exposed in the MSI-X capability structure in the PCI configuration space of all PFs and VFs. The number of supported MSI-X vectors is defined by the table size parameters in the MSI-X capability structure in the PCI configuration space of the PFs and the VFs. The table size parameters is loaded from a global MSI_X_PF_N and MSI_X_VF_N parameters in the GLPCI_CNF2 register (loaded from the NVM), shared for all PFs and all VFs respectively. The MSI_X_PF_N and MSI_X_PF_N parameters must be lower or equal than the maximum number of MSI-X vectors per functions as described in the text that follows. The 10 GbE controller supports up to 1168 MSI-X vectors that are allocated to PFs and VFs uniformly as a function of the number of enabled PFs and the number of enabled VFs. The maximum number of MSI-X vectors per function is listed in the Table 38-280.

Table 38-280.MSI-X Vector Allocation per Function

Index of Max Enabled PF	Max Number Of MSI-X Vectors Per PF	Number of Registers Per PF Indicated As INTPF
1 ... 4	1 + 128	128
5 ... 8	1 + 64	64
9 ... 16	1 + 32	32

Index Of Max Enabled VF	Max Number Of MSI-X Vectors Per VF	Number of Registers Per VF Indicated As INTVF Or INTVP
1 ... 32	1 + 16	16
33 ... 64	1 + 8	8
65 ... 128	1 + 4	4

Note: The Index of max enabled PF and the index of max enabled VF are defined by the values of the *PCIPFCNT* and *PCIVFCNT* fields, respectively, in the GLGEN_PCIFCNCNT register (loaded from the NVM)

Note: All registers with attribute INTPF, INTVF and INTVP are reflected in the function's space as 512 registers, which is the total number of these registers in the device. Still each function might only access its own registers (starting at register index zero) according to the number of registers listed in Table 38-280.

The INTVP registers are mapped in the PF space in the following manner:

The register index in the PF space for register ‘n’ of VF ‘m’ = Number of Registers per VF * ‘m’ + ‘n’, while ‘m’ is the relative VF index within the PF and the Number of Registers per VF can be 4, 8 or 16 as listed in Table 38-280.

The VP registers are mapped in the PF space in the following manner:

The register index in the PF space for VF 'm' = 'm', while 'm' is defined the same as previously described.

A register address in the PF space = base address of the specific registers + register index * 4.

38.22.1.1 Interrupt Enable Procedure

Interrupts are enabled at three levels:

- Enablement on the PCIe interface by PCI configuration registers programmed by the operating system.
  - Legacy INTA/INTB/INTC/INTD interrupt message is controlled by the *Interrupt Disable* flag in the Command register in the PCI config space per PF.
  - MSI is enabled by the *MSI Enable* flag in the MSI capability structure in the PCI config space per PF.
  - MSI-X is enabled by the *MSI-X Enable* flag in the MSI-X capability structure in the PCI config space per PF and per VF and further enablement by the *Mask* bit per MSI-X vector in the MSI-X table structure.
- Enablement of the interrupts by the software device driver by the *INTENA* flag in the xxINT_DYN_CTL0 and xxINT_DYN_CTLN registers (where xx=PF or VF).
  - The software device driver sets the *INTENA* flag to enable the relevant interrupt signal. Upon interrupt assertion, the *INTENA* flag and the interrupt level are auto-cleared. Auto-clearing the INTENA can be disabled globally by the GLINT_CTL.
- Enablement of the interrupts per cause by the *CAUSE_ENA* flag in the cause control registers (see Section 38.22.2).
- Interrupt moderation:
  - Interrupt Throttling (ITR) is described in Section 38.22.4.1.
  - Interrupt rate limiting (INTRL) is described in Section 38.22.4.2.

38.22.1.2 Pending Interrupt Array - PBA

Including the interrupt signaling on the PCIe bus, the 10 GbE controller also supports the standard PBA structure in the MSI-X BAR. The PBA is relevant only when MSI-X is enabled. It is described as part of the MSI-X capability structure for the PF for the VFs. A bit in the PBA is set to 1b when an interrupt is triggered internally and cleared when the MSI-X vector is sent on the PCIe bus.

38.22.1.3 Interrupt Sequence

This section describes the interrupt sequence of events starting by an internal events that triggers an interrupt until it is sent to the PCIe bus and the expected software response. Note that the description of the interrupt sequence refers to flags that are explained in the following sections.

MSI and MSI-X interrupts while interrupts are enabled

1. Any of the interrupt causes has an event that sets an internal *INTEVENT* flag for the matched interrupt signal.
2. If the interrupt is enabled by *INTENA and also enabled by the interrupt moderation policy (ITR and rate limiting)*, hardware executes the following steps in the following order:
   a. Scan all queues associated with this interrupt by a linked list. Write back the status of all completed descriptors that were not reported so far and clear the internal EVENT flags of these queues.
   b. Set the matched bit in the pending interrupt block array (PBA) (represented by the ARB block). Note that the PBA is reflected externally only with MSI-X (and not with legacy interrupts nor MSI).
   c. The *INTEVENT* and *INTENA* are auto-cleared.
3. If the interrupt is enabled by the operating system (by PCIe setting), the interrupt message is sent to the PCIe.
   a. The interrupt indication in the PBA is auto-cleared.
4. During the interrupt handler, software processes each individual interrupt causes. Specific to interrupt zero of the function (the other causes interrupt), software can optionally read the ICR0 register identifying the interrupt causes to be processed. Reading the ICR0 register clears it making it ready to reflect the events of the next interrupt.
5. At the end of the interrupt handler, software re-enables the interrupts by setting the *INTENA*.
   a. On the same register, software also sets the *CLEARPBA* flag that clears the matched bit in the PBA.
   b. On the same register, software can update one of three ITRs of this interrupt by setting the *ITR_INDX* and *INTERVAL* fields. Setting the *ITR_INDX* to 11b does not impact the ITRs. See ITR explanation in Section 38.22.4.1.

MSI-X interrupts while interrupts are disabled by the operating system

Steps 1 and 2 are the same as previously described.

6. The operating system polls the PBA and schedules the interrupt handler.

Steps 4 and 5 are the same as previously described.

Legacy interrupts while interrupts are enabled by the operating system (mapped to interrupt zero of the PF)

Steps 1 and 2 are the same as previously described.

1. If the interrupt is enabled by the operating system (by PCIe setting), the interrupt message is sent to the PCIe.

2. At the very beginning of the interrupt service routing, the software device driver clears the internal PBA by setting the *CLEARPBA* flag in the PFINT_DYN_CTL0 register.
   a. As a result, an interrupt de-assertion message is sent on the PCIe bus.

Note: When several PFs are assigned to the same legacy interrupt, the interrupt de-assertion message must be only sent when all PFs associated with that interrupt have cleared the internal PBA previously mentioned.

   b. The software device driver also reads PFINT_ICR0 the schedules the matched processes for the active flags in the register.
3. During the interrupt handler, software processes each individual interrupt causes. Software can optionally read the ICR0 register identifying the interrupt causes to be processed. Reading the ICR0 register clears it making it ready to reflect the events of the next interrupt.
4. At the end of the interrupt handler, software re-enables the interrupts by setting *INTENA*.
   a. On the same register, software can update one of three ITRs as previously explained.

Figure 38-57.Conceptual Interrupt Logic

38.22.2 Interrupt Causes

This section lists all interrupts causes (sources) while mapping these causes to the interrupt vectors as described in Section 38.22.3. Note that only the PF has access to any of the cause registers listed in this sub-section. Therefore, VF is required to request its registers programming from the PF by admin command or any other sideband channel.

38.22.2.1 LAN Transmit Queues

The 10 GbE controller supports 1536 LAN transmit queues for the entire device while each queue is a potential interrupt cause. A status reporting of a completed transmit descriptor with the *EOP* bit set is considered as a transmit event that can trigger an interrupt (if the interrupt is enabled).

LAN transmit queue ‘n’ is enabled for interrupts by the CAUSE_ENA flag in its QINT_TQCTL[n] register. The queues are mapped to any interrupt vector within the function space by the MSIX_INDX field in the QINT_TQCTL[n] register and mapped to any of it’s ITRs (or immediate interrupt) by the ITR_INDX in this register. See ITR description in Section 38.22.4.1. Using interrupt vector zero, the transmit queues are mapped by the MSIX0_INDX field in the QINT_TQCTL[n] register to one of the QUEUE_x flags in the xxINT_ICR0 registers. The MSIX0_INDX of PF queues can be set to 0...7 while VF queues can be set only to 0...3.

38.22.2.2 LAN Receive Queues

The 10 GbE controller supports 1536 LAN receive queues for the entire device while each queue is a potential interrupt cause. A DMA completion of a descriptor with an *EOP* flag and its buffer is considered as a receive event that triggers an interrupt (if the interrupt is enabled). Furthermore, if the number of free descriptors on the receive queue drops below the threshold, it is considered as an immediate event (described in the following sub-sections). The low threshold is defined by the LRXQTRESH parameter in the receive queue context.

Similar to the LAN transmit queues, the LAN receive queues are mapped to any ITR of any interrupt vector by the matched QINT_RQCTL registers.

38.22.2.3 PE Queues

A completion of an AEQ entry or a CEQ entry is considered as an event that triggers an interrupt (if the interrupt is enabled). PE CEQs and AEQs can be mapped to any interrupt with optional interrupt moderation described in the following sub-sections.

The 10 GbE controller supports a single AEQ interrupt control register (per function). It is enabled for interrupts by the *CAUSE_ENA* flag and mapped to any ITR of any interrupt vector by the xxINT_AEQCTL register ('xx' equals to 'PF' or 'VP').

CEQs (per function) are enabled for interrupts by the *CAUSE_ENA* flag and mapped to any ITR of any interrupt vector by the xxINT_CEQCTL registers ('xx' equals to 'PF' or 'VP'). These registers are allocated evenly to PFs and VFs depending on the number of the functions (as listed in Table 38-280).

Using interrupt vector zero, the queues are mapped to one of the *QUEUE_x* flags in the xxINT_ICR0 registers by the *MSIX0_INDX* field in the previously identified registers. The *MSIX0_INDX* of PF queues can be set to 0...7 while VF queues can be set only to 0...3.

Note that all PFs and up to 32 VFs can be enabled for the PE. Each enabled function has a single AEQ and a total of 256 global CEQs. Yet, all functions have the xxINT_AEQCTL and VPINT_CEQCTL registers (total of 144 AEQ interrupt control registers and 1024 CEQ interrupt control registers). Mapping the physical 256 CEQs to the xxINT_CEQCTL registers is done by the PE firmware. It is expected that software uses only those registers that represent real AEQs and CEQs behind them.

38.22.2.4 Other Interrupt Causes

The 10 GbE controller supports asynchronous events that can generate interrupts for the PFs and the VFs. The other interrupt events supported by the PFs are indicated in the PFINT_ICR0 register and enabled by the PFINT_ICR0_ENA register (per PF) as listed in Table 38-281. The other interrupt events supported by the VFs are indicated in the *VFINT_ICR0* register and enabled by the *VFINT_ICR0_ENA* register (per VF) as listed in the Table 38-282.

The other interrupt cause is mapped to MSI-X vector zero of the functions. It is mapped to any of its ITRs (or immediate interrupt) as programmed by the *OTHER_ITR_INDX* field in the *PFINT_STAT_CTL0* register for the PF and the VFINT_STAT_CTL0 register for the VF (see Section 38.22.4.1).

During normal operation it is expected that *xxINT_ICR0* is used only as a read/clear register by software. Setting the flags in the *xxINT_ICR0* register (other than the queue flags and the *SWINT* flag), emulates an interrupt event of the specific cause (if enabled by the *xxINT_ICR0_ENA* register).

Table 38-281.Other Interrupt Causes of the PFs

PF Other Cause	Description
ECC_ERR	Unrecoverable ECC Error. This bit is set when an unrecoverable error is detected in one of the device memories.
MAL_DETECT	Malicious programming detected.
GRST	Global Resets Requested (CORER, GLOBR or EMPR).
GPIO	GPIO event indicates an event on any of the GPIO pins enabled for interrupt by the PFINT_GPIO_ENA register. The GPIO state can be fetched on the GLGEN_GPIO_STAT register. The level transition that generates an interrupt is set for GPIO 'n' by the *INT_MODE* field in the matched GLGEN_GPIO_CTL[n] register.
TIMESYNC	Any of the TimeSync interrupt causes.
HMC_ERR	HMC error as indicated in the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers.
PE_CRITERR	Protocol Engine Critical Error. Indicates that the PE has encountered a critical error. See the GLPE_CRITERR register to determine the specific error that caused the interrupt.
VFLR	VFLR was initiated by one of the VFs of the PF. The PF should read the GLGEN_VFLRSTAT getting an indication for the VF that generated the VFLR.
ADMINQ	Send / receive admin queues interrupt.
SWINT	Software interrupt (see Section 38.22.2.5).

Table 38-282.Other interrupt causes of the VFs

PF Other Cause	Description
ADMINQ	Send / receive admin queues interrupt.
SWINT	Software interrupt (see Section 38.22.2.5).

38.22.2.5 Software Initiated Interrupt

In some cases, software might not be able to process all events in a single interrupt handler. In such cases, software might schedule another interrupt to complete processing all interrupt events. Software can trigger an interrupt on any vector and any of its ITRs or NoITR. The software interrupt is mapped to one of three ITRs or immediate interrupt by the *SW_ITR_INDX* field in the *xxINT_DYN_CTLx* registers ('xx' stands for PF or VF and 'x' stands for '0' or 'N'). When programming the *SW_ITR_INDX* parameter, the *SW_ITR_INDX_ENA* flag in this register should be set as well.

Software initiates the interrupt by setting the *SWINT_TRIG* flag in the *xxINT_DYN_CTLx* registers. When setting the *SWINT_TRIG* flag, software should set also the *INTENA* flag in the same register.

Setting the software interrupt in vector 0 of the PFs, its status indication is reflected in the *PFINT_ICR0* register (including interrupt triggering).

38.22.2.6 Interrupt Status Registers

During normal operation, software avoids any possible read accesses. Interrupt zero is used for all the other causes, which enforces read cycles. The 10 GbE controller provides a status indication of all causes of interrupt zero of the PFs and the VFs. The xxINT_ICR0 registers ('xx' stands for PF or VF) provide indication for the following events:

- Any of the other interrupt causes.
- Up to eight status flags (QUEUE_0 ... QUEUE_7) in the PFs and up to four status flags (QUEUE_0 ... QUEUE_3) in the VFs for any LAN transmit or receive queues or PE_CEQ associated with interrupt zero.

- *SWINT* indication, which is a result of software initiated interrupt.

The status indication in the xxINT_ICR0 registers is independent on the xxINT_ICR0_ENA registers setting. The xxINT_ICR0_ENA registers enable interrupt assertion by each of the ICR0 causes. Interrupt on the PCIe is further enabled by the interrupt vector 0 logic (legacy interrupt or MSI or MSI-X 0).

38.22.3 Interrupt Linked List

The queues are linked to a specific interrupt vector by the MSIX_INDX field in the xxxQCTL registers. Specifically, the LAN queues and the PE completion event queues are associated to an interrupt vector by the following registers: QINT_RQCTL, QINT_TQCTL, PFINT_CEQCTL, VPINT_CEQCTL. These queues are chained together in a linked list that is configured by these xxxQCTL registers. Interrupt causes mapping to the interrupt vectors and the interrupt linked list are illustrated in Figure 38-58.

When an interrupt sequence is triggered, the 10 GbE controller processes all queues in the linked list of this interrupt. While processing the queues in the linked list, hardware writes back the status for those completed descriptors that were not reported already as listed as follows:

- LAN receive queues — Hardware triggers a status write back of all completed descriptors.
- LAN transmit queues — Hardware write back the completion indication of the last completed transmit descriptor that has an EOP flag (regardless of the RS bit) and was not reported already.
- PE CEQ entries — Hardware write back the completion indication of all completed CEQ entries.

Note: The xxxQCTL registers are accessible only to the PF. A VF can assign causes to interrupts with the help of the PF using an admin command or any other sideband message (out of scope of this document).

Note: The linked list could contain LAN transmit and receive queues as well as PE completion event queues. If multiple types of interrupt causes are mapped to the same interrupt, Intel recommends (for optimized performance) to interleave them in the linked list as possible.

The beginning of the linked list is indicated per interrupt signal by the following parameters in the xxINT_LNKLSTx registers (while ‘xx’ stands for PF or VP and ‘x’ stands for ‘0’ or ‘N’).

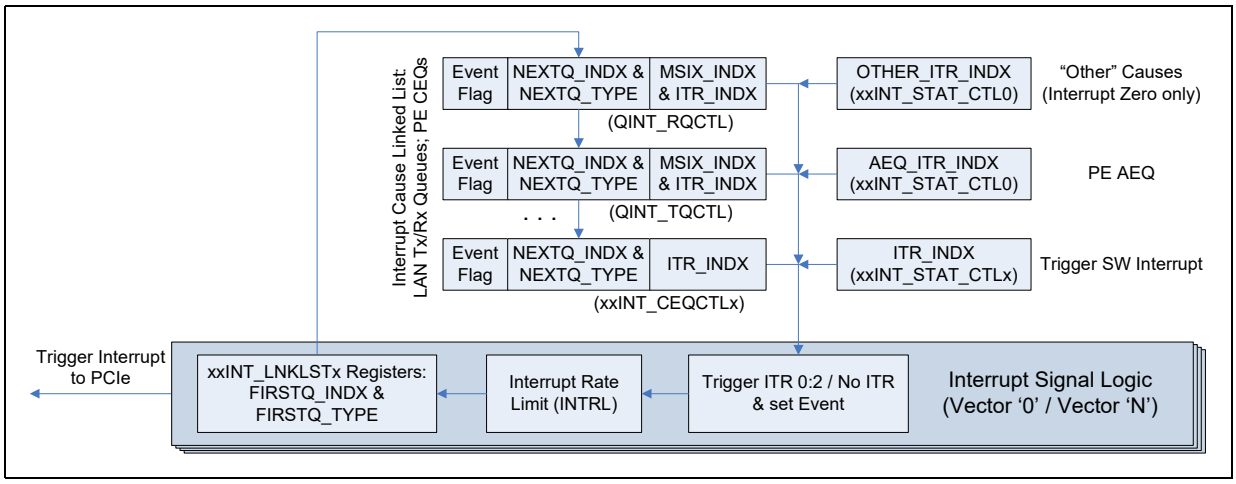
- FIRSTQ_TYPE — The type of the first cause in the list assigned to the interrupt signal. The type can be one of the following: receive queues, transmit queues and PE CEQ.
- FIRSTQ_INDX — The queue index of the first cause in the linked list assigned to this interrupt signal. For receive and transmit queues it is the index within the PF space (both PF and its VF queues are defined relative to the PF queue space). For CEQ, it is an index within the function space (VF queues are relative to the VF space and the PF queues are relative to the PF space). The FIRSTQ_INDX could be NULL pointer for no linked list.

An interrupt vector assigned only to the other causes and possibly to AEQ as well, does not have a linked list. In this case, software should set the FIRSTQ_INDX to a NULL value (0x7FF).

The interrupt causes are linked to each other by similar parameters as previously described in the following cause control registers: QINT_RQCTL; QINT_TQCTL and xxINT_CEQCTLx registers ('xx' stands for PF or VP and 'x' stands for '0' or 'N').

- NEXTQ_TYPE — The type of the next cause in the list assigned to the same interrupt signal. It is the same definition as the FIRSTQ_INDX previously described.
- NEXTQ_INDX — The queue index of the next cause in the linked list assigned to this interrupt signal. For receive and transmit queues it is the index within the PF space (both PF and its VF queues are defined relative to the PF queue space). For CEQ, it is an index within the function space (VF queues are relative to the VF space and the PF queues are relative to the PF space). The NEXTQ_INDX is a NULL pointer for the last cause in the linked list (equals to 0x7FF).

Figure 38-58.Mapping Interrupt Causes to Interrupt Signaling



38.22.3.1 Interrupt Linked List Management

This section describes the required software flow for adding and removing an interrupt cause from an interrupt linked list.

38.22.3.1.1 Initial Setting of a Linked List

Associating interrupt causes to an interrupt signal can be programmed by software by any arbitrary order. As long as interrupts are not generated, the linked list is considered as static so any programming order is acceptable.

38.22.3.1.2 Adding an Interrupt Cause to an Active Interrupt

Once an interrupt is active, its linked list is considered as dynamic resource. Special programming ordering is required when adding an interrupt cause as follows:

- Program the cause register as required while the NEXTQ_INDX and NEXTQ_TYPE parameters point to the next cause in the linked list.
- Update the NEXTQ_INDX and NEXTQ_TYPE parameters in the previous cause pointing to the added one.
- Note that there is no need to disable the interrupt before these two steps.

38.22.3.1.3 Removing an Interrupt Cause from an Active Interrupt

Removing an interrupt cause from an interrupt linked list can be done in one of the following two cases:

Case 1 — The interrupt is disabled and it is guaranteed that this interrupt does not have any possible pending interrupts. In this case, the linked list is considered static and there are no special programing ordering. Software should update the NEXTQ_INDX and NEXTQ_TYPE parameters in the previous cause to the next cause, skipping the cause that is removed from the linked list. At this point, software can modify the cause register of the removed interrupt cause if required.

Case 2 — The interrupt is active. In this case, the linked list is considered dynamic resource and the software should follow a strict flow.

- Update the NEXTQ_INDX and NEXTQ_TYPE parameters in the previous cause to the next cause, skipping the cause that is removed from the linked list. In case it is the first cause in the linked list then update the FIRSTQ_INDX and FIRSTQ_TYPE parameters in the matched xxINT_LNKLSTx register, skipping the cause that is removed from the linked list.
- Clear the CAUSE_ENA flag in the matched xINT_xQCTL register.
- Software should wait a sufficient amount of time until it is guaranteed that hardware fetched the updated value of the previous cause. Waiting a sufficient amount of time could be done by scheduling a software interrupt and waiting for that interrupt that follows.
- At this point, software can modify the cause register of the removed interrupt cause if required.
- Note that there is no need to disable the interrupt before starting the previous sequence.

38.22.4 Interrupt Moderation

The 10 GbE controller is able to throttle interrupts in two layered methods: Interrupt Throttling (ITR) and Interrupt Rate limiting (INTRL). These methods are detailed in the following sub-sections.

38.22.4.1 Interrupt Throttling (ITR)

ITR is a mechanism that guarantees a minimum gap between two consecutive interrupts (other than possible jitter caused by handling the interrupts). The 10 GbE controller counts the time since the last interrupt is scheduled and compares it against the ITR setting. If an event associated with this ITR happens before the ITR expires, the interrupt assertion is delayed until the ITR expires. If the ITR expires before any event associated with this interrupt, the interrupt logic is armed and the interrupt can be asserted the moment the event happens. The ITR intervals-per-vector are programmed by the xxINT_ITRx registers (xx stands for PF or VF and x stands for 0 or N). The ITR is measure in units of 2 usec. Note that the ITR expiration sequence is triggered only when all the following conditions are met:

- The ITR timer is expired.
- The INTENA or the WB_ON_ITR flags in the matched GLINT_DYN_CTL register is set.
- The interrupt has credit(s) by the interrupt rate limiting logic described in the section that follows.

The 10 GbE controller supports three ITRs per MSI-X vector as well as a NoITR option. The interrupt causes are mapped to one of the ITRs by the ITR_INDX field (per cause). The ITR intervals can be programmed directly to the xxINT_ITRx registers or via the xxINT_DYN_CTLx registers (xx stands for PF or VF and x stands for 0 or N). It might be useful to set the initial values using the xxINT_ITRx registers and dynamic update by the xxINT_DYN_CTLx registers as explained in step #4 of the interrupt sequence explained in Section 38.22.1.3. When any ITR interval of an interrupt with pending event is expired and the INTRL (Section 38.22.4.2) credit is positive, hardware follows these steps:

- Clear the other ITRs of the same interrupt.
- Process all causes of the same interrupt (associated to all ITRs) as defined by the linked list (see Section 38.22.3).
- (*) See next section for a description of the interrupt rate limiting (INTRL)

38.22.4.2 Interrupt Rate Limiting (INTRL)

INTRL is a credit-based mechanism that limits the maximum average number of interrupts per second. The PF controls its interrupt rate limit by the PFINT_RATE0 and PFINT_RATEN registers. The PF also controls its VF's interrupt rate limit by the VPINT_RATE0 and VPINT_RATEN registers. The control parameters of these registers are detailed as follows:

- INTRL_ENA — Enable / disable option for the INTRL scheme. When disabled, interrupts can be generated without rate limiting control.
- INTERVAL — The INTRL is a 6-bit interval defined in 4 µs units that controls the time gap on which new interrupt credit is gained.

38.22.5 Write Back on Interrupts

Following packet reception, the status of completed descriptors are posted (write back) to host memory once every several packets or at ITR expiration. Similarly, following transmit packet DMA completion, its completed descriptors are reported to host memory as well. It is reported if the descriptors were programmed with active *RS* flag or at ITR expiration (either descriptor write back or header write back). In some cases queues should not generate interrupts. Associating these queues to an interrupt vector with active *WB_ON_ITR* and inactive INTENA generates no interrupts and maintains the previous rules for reported status on packet reception and transmission. This option is called write back on ITR.

Note: *WB_ON_ITR* and *INTENA* are mutually exclusive. Only one can be enabled for a given interrupt vector.

Note: Queues that should generate no interrupts and should not be reported on ITR completion should not be associated to any interrupt linked list.

38.23 Virtualization

38.23.1 Overview

I/O virtualization is a mechanism to share I/O resources among several consumers. For example, in a virtual system, multiple operating systems are loaded and each executes as though the entire system's resources were at its disposal. However, for the limited number of I/O devices, this presents a problem because each operating system might be in a separate memory domain and all the data movement and device management

has to be done by a Virtual Machine Monitor (VMM). VMM access adds latency and delay to I/O accesses and degrades I/O performance. Virtualized devices are designed to reduce the burden of VMM by making certain functions of an I/O device shared. Thus, they can be accessed directly from each guest operating system or Virtual Machine (VM).

Two modes to support operation in a virtualized environment were implemented in previous products:

1. Direct assignment of part of the port resources to different guest OSes using the PCI sig SR-IOV standard (also known as native mode or pass-through mode). This mode is called IOV mode in this chapter.
2. Central management of the networking resources by an IOVM or by the VMM (also known as software switch acceleration mode). This mode is called Next Generation VMDq mode.

The 10 GbE controller supports fully Next Generation VMDq mode and SR-IOV.

The 10 GbE controller supports two modes of offloads as part of Next Generation VMDq: VMDq1 and VMDq2.

In VMDq1, all the VMs are part of the same VSI and each VM is allocated a single queue. There is no replication of packets to different VMs and there is no forwarding of traffic from one VMDq1 VM to another.

In VMDq2, each VM is assigned a switch port (VSI). Thus there can be full switching between ports, including VM to VM switching and replication of multicast packets.

In a virtualized environment, the 10 GbE controller serves up to 256 virtual machines (VMs) per device; 128 of these can be directly assigned and any of them can be accessed in Next Generation VMDq mode. See Section 38.23.2.4 for details of the VFs and VMs resource allocation.

Most configurations and resources of the device are shared across VMs. The PF driver must resolve any conflicts in configuration between the VMs. For example, the PF driver should manage all the link configuration requests of the VFs.

Most of the virtualization offload capabilities provided by the 10 GbE controller, apart from the replication of functions defined in the PCI-sig IOV specification, are also part of Next Generation VMDq.

A hybrid model, where some of the virtual machines are assigned a dedicated share of the port and the others are serviced by an IOVM is also supported. This model can be used when some of the VMs run operating systems for which VF drivers are available. Such configurations can benefit from IOV. Others may run older operating systems for which VF drivers are not available and are serviced by an intermediary or models where VFs are assigned to VMs requiring a higher networking bandwidth. In this last case, the IOVM or VMM is assigned some VSIs and receives all the packets with MAC addresses of the VMs behind it.

The following section describes the support the 10 GbE controller provides for virtualization. This chapter assumes a single-root implementation of IOV and no support for multi-root.

38.23.1.1 Direct Assignment Model

The direct assignment support in the 10 GbE controller is built according to the software model defined by the SR-IOV specification.

The PF driver is responsible for the initialization and the handling of the common resources of the port. Other drivers (VF drivers) might read part of the status of the common parts but can not change it. The PF driver might run either in the VMM or in some service operating system. It might be part of an IOVM or part of a dedicated service operating system.

In addition, part of the non time-critical tasks are also handled by the PF driver. For example, access to CSR through the I/O space or access to the configuration space are available only through the master interface. Time critical CSR space, like control of the Tx and Rx queue or interrupt handling, is replicated per VF. It is directly accessible by the VF driver.

Note: In some systems with a thick hypervisor, the service operating system might be an integral part of the VMM. For these systems, each reference to the service operating system in this document refers to the VMM.

A channel is provided between the VF driver and the PF driver through the use of admin commands.

38.23.1.1.1 Rationale

Direct assignment's purpose is to enable each of the VMs to receive and transmit packets with minimum overhead. The non time-critical operations (such as init and error handling) can be done via the PF driver. In addition, it is important that the VMs can operate independently with minimal disturbance. It is also preferable that the VM interface to the hardware should be as close as possible to the native interface in non-virtualized systems in order to minimize the software development effort.

The main time critical operations that require direct handling by the VM are:

1. Maintenance of the data buffers and descriptor rings in host memory. In order to support this, the DMA accesses of the queues associated to a VM should be identified as such on the PCIe using a different requester ID.
2. Handling of the hardware ring (tail bump and head updates).
3. Interrupt handling.

The capabilities needed to provide independence between VMs are:

1. Per VM reset and enable capabilities.
2. TX QoS control.
3. Allocation of separate CSR space per VM.

The queue context creation, rate control and VF enable capabilities are controlled by the PF.

38.23.1.2 Virtualized System Overview

The following diagrams show the various elements involved in the I/O process in a virtualized system. Figure 38-59 shows the flow in software Next Generation VMDq operation mode and Figure 38-60 shows the flow in IOV mode.

This document assumes that in IOV mode, the software device driver on the guest operating system is aware that it works in a virtual system (para-virtualized) and there is a channel between each of the VM drivers and the PF driver allowing message passing (such as configuration request or interrupt messages). This channel might use the mailbox implemented in the 10 GbE controller or any other means provided by the VMM vendor.

Figure 38-59.VMDq System

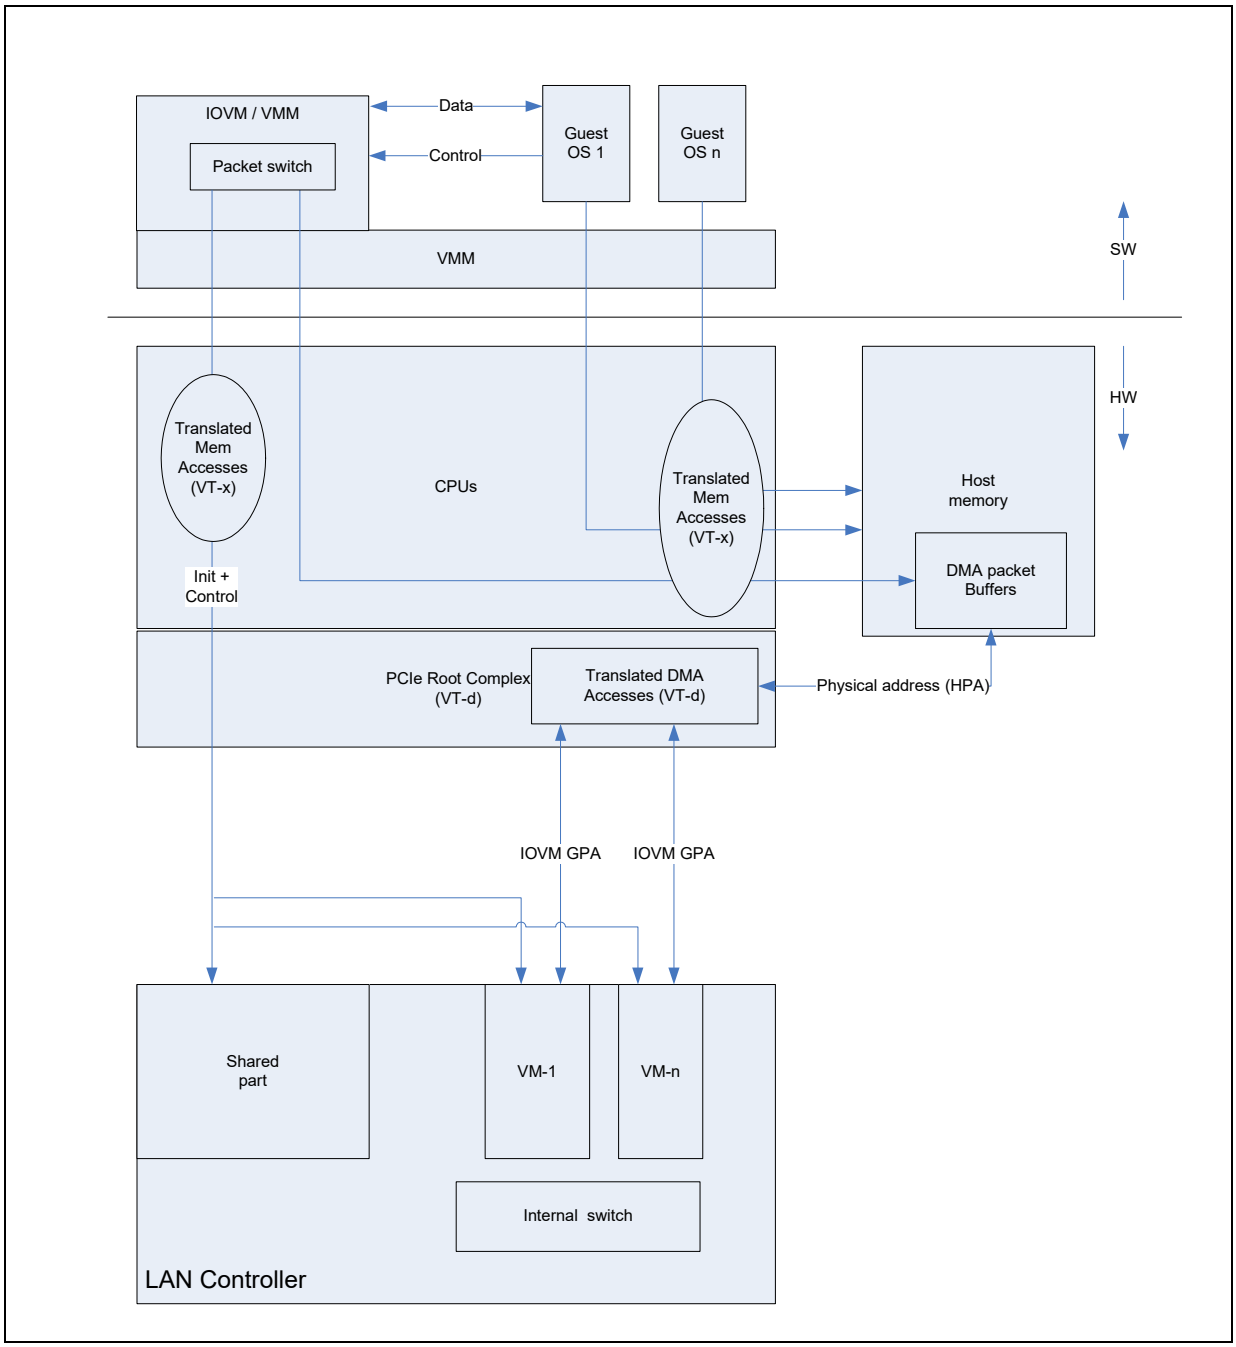


Figure 38-60.SR-IOV-Based System

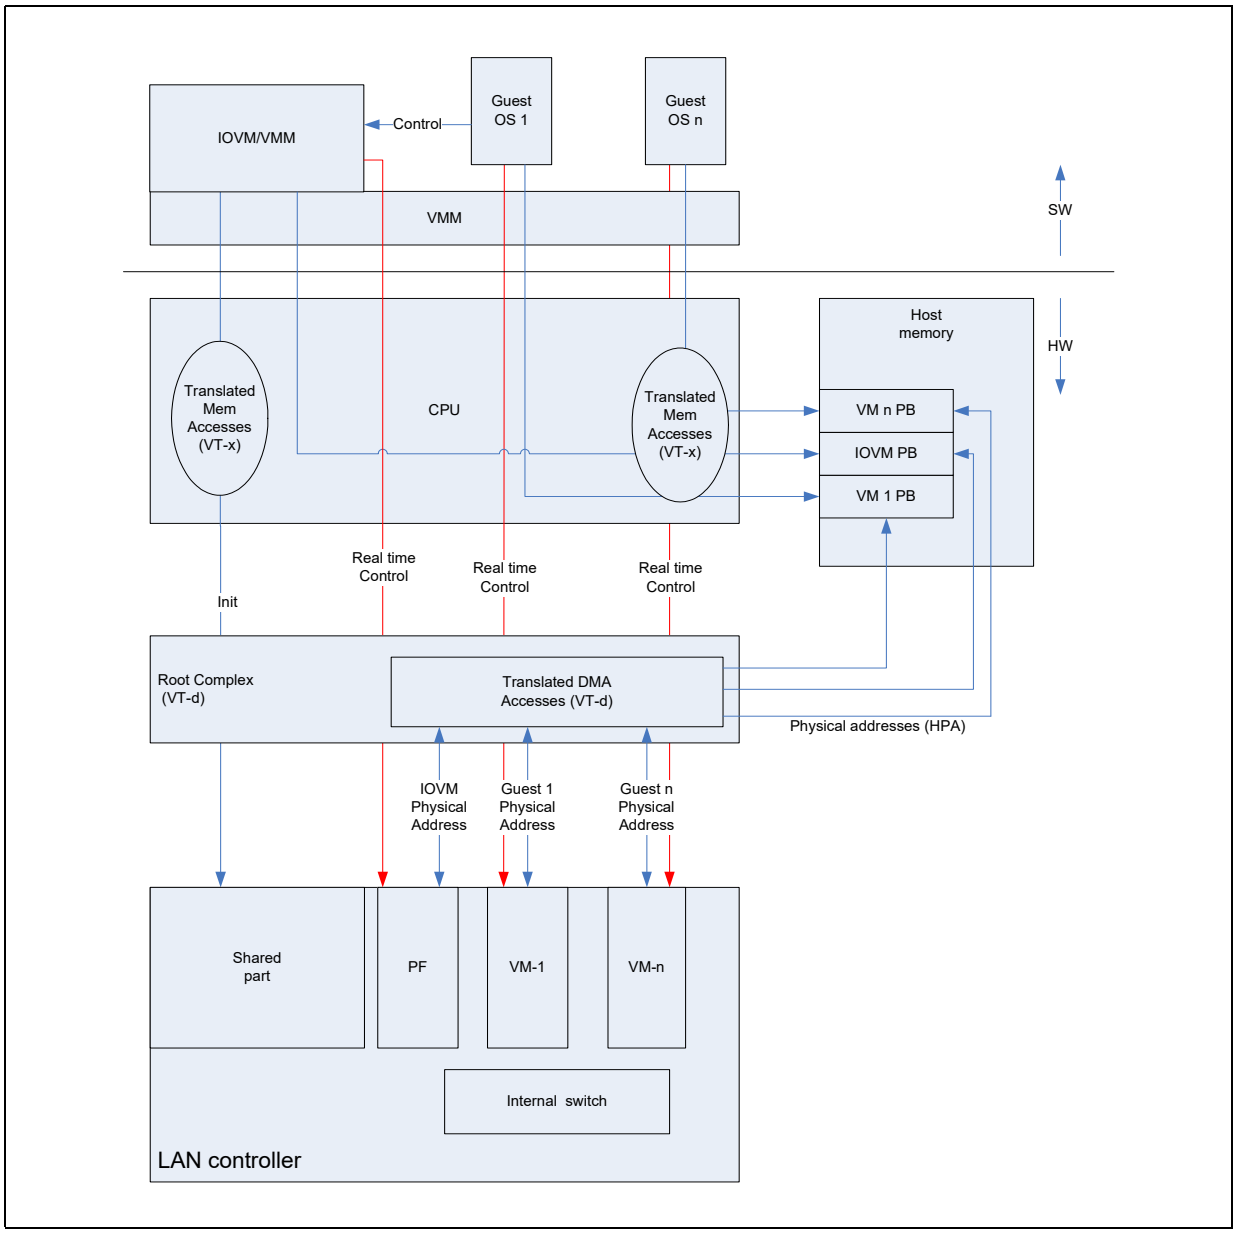


38.23.1.3 Virtualization Supported Features

The 10 GbE controller supports a super set of the virtualization features supported in previous products. Table 38-283 lists the virtualization features of the 10 GbE controller with these of the 82599.

Table 38-283.Product Name Versus the 82599 Virtualization Support

Feature	10 GbE Controller Support	82599 Support
Direct attach (SR-IOV) features		
SR-IOV Support	Yes	Yes
ATS Support	No	No
VF-to-PF Mailbox	Yes	Yes
Max Number of Virtual Functions	128 per device (globally)	64 per port (single queue)
VMDq features		
Max number of Queues Allocatable to VMs	1536	128
Max Number of Queues per VF	16	8
Max Number of Queues per VMDq2 VSI	16	8
Max Number of Queues per VMDq1 VM	1 (A VMDq1 VSI may support multiple VMs).	8
Max Number of VMDq2 Ports	256 per device (globally)	64 per port (single queue)
MAC Addresses	1024 per device (globally)	128 per port
VLAN Tags	512 per device (global)	64 per port
Queuing to Pool Method	SA, VLAN pairs or SA or VLAN	SA or VLAN or (SA and VLAN)
RSS per VF	Yes	No (Single RSS used for all VFs).
DCB in VF	Yes	Yes
Switching Modes	VEB, VEPA, EVB	VEB
VM-to-VM Switching	Yes	Yes
Broadcast and Multicast Replication	Yes	Yes
MAC and VLAN Anti-spoof Protection	Yes	Yes
VLAN Filtering	Global and per pool	Global and per pool
Drop If No Pool	Yes	Yes
per Pool Statistics	Yes	Yes
Per Pool Offloads	Yes	Yes
Mirroring	Yes	Yes
Long Packet Filtering	Global and per pool	Global and per pool
Promiscuous Modes per VM	VLAN, Multicast, Unicast	Multicast

38.23.1.3.1 Enablement of Virtualization Features

Virtualization feature enablement can be controlled using soft SKU. Table 38-284 lists the way to enable each of virtualization feature.

Table 38-284.Virtualization Features Enablement

Technology	Included features	Enablement
SR-IOV		Set the *GLPCI_CAPSUP.IOV_EN* bit.
VEB	VEB, VEPA, VMDq2, mirroring.	Set the *GLGEN_STAT.VTEN* bit.
802.1BR/802.1Qbg	Port extender creation. CDCP handling.	Set the *GLGEN_STAT.EVBEN* bit.

38.23.2 SR-IOV Implementation

38.23.2.1 IOV Concepts

The SR-IOV specification defines the following entities in relation to I/O virtualization:

1. VVM — A VM to which I/O resources are assigned.
2. A PCIe device — The physical device that might contain a few physical functions. In this case, the 10 GbE controller.
3. PF — A function representing a physical instance. I in this case, a PCIe function that represents a physical port or a logical port. The PF driver is responsible for the configuration and management of the shared resources in the function.
4. VF — A part of a PF assigned to a VM.

38.23.2.2 IOV Control

In order to control the IOV operation, the physical driver is provided with a set of registers and capabilities. These include:

1. The *PF_VIRT_STATUS* register — Indicates whether SR-IOV is enabled and the number of VFs enabled.
2. Driver-to-driver communication provided by the virtualization admin commands.
3. Switch and filtering control admin commands.
4. Reset indications and traffic enables registers per VF using the *GLGEN_VFLRSTAT.VFLRE* bit indicating that a VFLR reset occurred in one of the VFs. When the *GLGEN_VFLRSTAT.VFLRE* bit is set for a given VF, this VF cannot send or receive packets. The PF should clear this bit to enable a VF.
5. Malicious driver detection (described later in this section).

Refer to the flow used to configure a function when SR-IOV is enabled.

38.23.2.2.1 Interrupt on Misbehavior of VM (Malicious Driver Detection)

The 10 GbE controller can protect itself from faulty or malicious behavior on the part of a VM driver. This is done by checking for specific illegal events.

The bits that enable these checks are grouped into three categories: RX checks, TX descriptor checks and TX data checks. Individual checks are controlled by global registers GL_MDCK_RX, GL_MDCK_TCMD and GL_MDCK_TDAT respectively. If a check is not enabled (the bit is cleared) and such an event happens, the monitoring hardware will not react to the condition and the device may malfunction.

Table 38-285, Table 38-286 and Table 38-287 list the checks in each group, the register bits used to enable them and the value read from the MDET registers when an event is detected.

The default values for these registers are loaded from NVM.

The checks apply both to VF and PF activity. If such behavior is detected, the queue is stopped and an interrupt is sent to the PF that owns the function. This means that a PF will be interrupted both on events from it's queues and on events from it's VFs queues. Tracking which functions have caused an event is done by reading each function's VP_MDET_RX and VP_MDET_TX registers for VFs or PF_MDET_RX and PF_MDET_TX for PFs. The registers are cleared by writing 1s to them. After such an event the function needs to reset the queue. Since the malicious driver event indication in the *VP/PF_MDET_TX* registers is per function and the details of the event in the *GL_MDET_TX* register is common to all functions, it may not be simple to determine which queue caused the event, therefore the driver may elect to reset the whole function.

TX Data protection is different in that it does not stop the queue; it drops the offending packet.

Two global debug registers (GL_MDET_TX and GL_MDET_RX) record the function number event ID and queue number for the first event observed on TX and RX, respectively. These registers are cleared by writing 1s.

38.23.2.2.2 TX Data Checks (GL_MDCK_TDAT register)

The table below describes the checks that are done by the 10 GbE controller on data fetches for TX data.

Table 38-285.Data Checks on Fetches for Tx Data

Check type	GL_MDET_TDAT bit	Description
Bad Header Length	2 MAL_LENGTH_DIS	Malicious detection of bad header length in the transmit descriptor.
Illegal Commands	3 MAL_CMD_DIS	Malicious detection of bad combination of commands in the transmit descriptor.

38.23.2.2.3 TX Descriptor Validity Checks (GL_MDCK_TCMD register)

The table below describes the checks that are done by the 10 GbE controller on TX descriptor.

Table 38-286.Tx Descriptor Validity Checks

Check type	GL_MDCK_TCMD bit	Event ID on MDET_TX register	Description
TX descriptor address	0 DESC_ADDR	10	descriptor fetch failed
Too many buffers	2 MAX_BUFF	14	Single send packet or large send segment is spread on more than 8 data descriptors
Too many header buffers	3 MAX_HEAD	15	LSO with header spanning more than 3 buffers.
No header buffers	4 NO_HEAD	24	Zero header length when large send offload is enabled
Wrong Size	5 WRONG_SIZE	16	A single send packet or large send segment that is not between min / max sizes defined in the GLTLAN_MIN_MAX_PKT register

Table 38-286.Tx Descriptor Validity Checks

Check type	GL_MDCK_TCMD bit	Event ID on MDET_TX register	Description
Tail update bigger than ring size	7 ENDLESS_TX	21	endless transmit ring When this flag is cleared, endless transmit ring option is enabled. When this flag is set, endless transmit ring is considered malicious event.
Bad LSO packet length	8 BAD_LSO_LEN	16	TSO Total Length not equal sum of buffers or equals to zero
Bad LSO MSS	9 BAD_LSO_MSS	18	LSO with MSS is smaller than 64 or larger than 9668.
More than seven context descriptors	12 M_CONTEXTS	21	7 or more consecutive non-data descriptors are fetched in a transmit queue.
Bad descriptor sequence	13 BAD_DESC_SEQUENSE	18	Bad descriptors sequence. Include: MSS min/max; Max number of non-data descriptors; DIF/DIX descriptors (enabled by bit 16); Flex descriptors (enabled by bit 17).
Descriptor type	14 BAD_DESC_TYPE	21	Illegal descriptor type used
No Packet	15 NO_PACKET	21	Tail update that does not contain at least one full packet.
Disable DIF / DIX descriptors	16 DIS_DIF_DIX	11	DIF/DIX descriptors are considered malicious descriptors.
Disable Flexible Descriptors	17 DIS_FLEX	20	Flexible descriptors are considered malicious descriptors.
Zero Bsize	18 ZERO_BSIZE	23	A descriptor with a zero BSIZE is found

38.23.2.2.4 RX Checks (GL_MDCK_RX register)

The table below describes the checks that are done by the 10 GbE controller on data fetches for RX.

Table 38-287.Rx Data Fetch Checks

Check type	GL_MDET_RX bit	Event ID on MDET_RX register	Description
RX descriptor address	0 DESC_ADDR	1	descriptor fetch failed

38.23.2.3 Hardware Resources not Assigned to VFs

Certain device capabilities are not exposed to VFs, neither directly nor via a PF. The following features are available only to PFs or controlled solely by the PF:

- Power management and WoL are PF resources and are not supported per VF.
- Link Control - The link is a shared resource and as such is controllable only by the PF. This includes PHY settings, speed and duplex settings, flow control settings, etc. Flow control packets are sent using the station MAC address stored in the EEPROM. The watermarks of the flow control process and the time-out value are also controllable by the PF only. In a DCB environment, the parameters of per-TC-flow control and the ETS settings are also PF responsibilities.
- Configuration of Control Domains and Profiles is done solely by the PFs and is not exposed to VFs.
- DCB policy and configuration of the device (either via DCBx or otherwise) is not open to VFs' control. A VF may still associate its Queues with specific TCs, may request (via its PF) for Tx Scheduler nodes to be added under specific VFs, and to set the appropriate QoS fields in its transmitted packets.

- Special Filtering Options - Save Bad Packets is a debug feature. As such, Save Bad Packets is available only to the PF. Bad packets are forwarded to a control VSI and thus should not be seen by a VF in regular operation.
- Reception of long packets is controlled separately per queue. As this impacts flow control thresholds, the PF should be made aware of the decisions of all VMs. Because of this, the setup of large send packets is centralized by the PF and each VF might request this setting.

38.23.2.4 Hardware Resources Assignment to VFs

Table 38-288 lists how the 10 GbE controller shared resources are distributed between different VFs. Details for each type of resource can be found in the relevant section of this document.

Table 38-288.VF Resource Allocation (Sheet 1 of 2)

Resource	Allocation method
General Resources	
Tx and Rx Queues	Dynamic allocation. Each VF can have a different number of queues (up to 256). Each PF allocates the queues to its VFs and their VSIs. The allocation is done using the *Add VSI* or *Update VSI* Admin commands. Queue initialization is done by the PF. Following initialization, the VF manages its queues for Tx/Rx operation.
Admin Queues	An admin queue is allocated to each VF to communicate with its PF. The queue accesses a shared mailbox in the device.
Interrupt Causes and Vectors	Allocated according to total number of exposed VFs.The interrupt causes and vectors are allocated to VFs only and not to VMs that are controlled by the PF. These VMs use the PF interrupts. 512 vectors allocated evenly among VFs. Assignment of interrupt causes: • Causes for Tx queues, Rx queues and PE queues to interrupt vectors are done by each VF. • Other causes are mapped to vector 0. • VFs operate with MSI-X interrupts only.
Transmit Scheduling	A VF is represented in the scheduling tree through its VSI(s). Nodes associated with such a VSI might be configured with all supported attributes, such as guaranteed bandwidth, rate limiting, and arbitration scheme. Configuration is done by the PF and not directly by the VF.
Stateless Offloads	Tx — All the regular transmit offloads like checksum and TSO are available to VFs. Enabling these offloads is done by the PF as part of the queue initialization process. Rx — All the regular receive offloads like checksum and header split are available to VFs. Enabling these offloads is done by the PF as part of the queue initialization process.
Statistics	The VF is not directly exposed to statistics counters. If a VF needs to get statistics for its traffic, it is done via its PF.
IEEE 1588	IEEE 1588 is a per link function and thus is controlled by the PF driver. VMs have access to the real time clock register via CSRs.
RDMA Resources	
RDMA capabilities	32 VFs might have RDMA capabilities. The *GLPE_VFPFMAP* table is used to map RDMA enabled VFs to the RDMA register sets.
QPs/CQs/CQEs/SDs	According to the profile of the device, the QP/CQ/CQE/SD resources are distributed evenly between the PFs supporting iWARP. The resources of a PF might be evenly distributed between the VFs supporting RDMA.
CSRs	All VFs have a set of registers to control RDMA functionality. However, only 32 of these sets are active. The RDMA register set contains registers in regular VF CSR space. These registers are accessible to the VF driver and provide a common doorbell page accessible to all the user space processes in the VF.
Switching Resources	

Table 38-288.VF Resource Allocation (Sheet 2 of 2)

Resource	Allocation method
Switch Resources	Switch configuration and resource allocation are not done by a VF directly, but through its PF.
VSIs	Up to 256 VSIs can be directly supported by the 10 GbE controller. These VSI resources are distributed between the different PFs dynamically. Each VF is guaranteed to receive at least one VSI. The PF might allocate multiple VSIs to a VF. The allocation is done using the using the *Add VSI* Admin command. There is no limit on the number of VSIs that can be assigned to a VF up to the number of Tx/Rx queue pairs the VF is allocated.
Unicast MAC Addresses, Multicast Addresses, VLAN tags	The PF driver is responsible for the resource allocation to its VFs. The 10 GbE controller does not manage the per-VF resources of the switch. The PF assigns filters to VFs VSI using Admin commands.
Filtering Resources	
RSS	Directly controlled by each VF. RSS per VSI with either small or medium RSS table.
Flow Director	Flexible population of FD entries with VF rules. Programming is done through the PF.
Quad Hash Filtering	Each PF allocates a private memory region for itself and its VFs. Each PF populates its private memory region with its VFs' entries. The on-die quad-hash filter caches entries for both PFs and VFs.

38.24 Data Center Bridging (DCB)

This chapter assumes the reader is familiar with the following specifications:

- IEEE P802.1Qbb-2011 — Priority-based Flow Control (PFC) specification
- IEEE P802.1Qaz-2011 — Enhanced Transmission Selection for Bandwidth Sharing Between Traffic Classes (ETS) specification
  - — DCB Center Bridging Exchange Protocol (DCBX) specification refers to Clause 38 in the ETS specification
- IEEE Std 802.1AB-2009 — Link Layer Discovery Protocol (LLDP) specification

38.24.1 Receive Path DCB

38.24.1.1 Receive Path Enhanced Transmission Selection (ETS)

38.24.1.1.1 Identifying Low Latency (LL) Traffic in Receive

Only two types of traffic are identified along the receive data path, LL and Bulk (B). This approach requires a priority differentiation between low latency and bulk traffic. TC indexes are used for that purpose according to a setting made in PRTDCB_RETSC.LLTC bitmap.

The entity that runs DCBX must configure all non-ETS TCs as LL traffic and only these TCs.

38.24.1.1.2 UP-to-TC in Receive

Mapping of UP-to-TC in Receive

Register PRTDCB_RUP2TC controls the mapping of incoming packets to TCs according to the UP field they carry. The same mapping is used for packets received from the wires and for those looped back internally. It defines on the account of which TC a packet is stored in the Rx packet buffer, and which UPs bits are set in the PFC XOFF/XON frames issued to the link partner when the filling state of a TC requires it. See Section 38.24.1.1.6.

Packets received with no 802.1p tag are also mapped to a TC according the setting made in NOVLANUP field of PRTDCB_RUP register that is applied as an input to the UP to TC mapping table of PRTDCB_RUP2TC register. To ensure that LLDP and other MAC Control packets are not dropped internally by the device before they reach EMP or the host, it is recommended that the PRTDCB_RUP.NOVLANUP field be set to the no-drop UP with the lowest index.

The *GL_SWT_L2TAGCTRL.HAS_UP* bit indicates per tag type if its UP is candidate for DCB usage. The UP for DCB is taken from the first tag encountered in the packet that has this bit set. The same method is used both for receive and loopback traffic. This bit should be set for S-tags and VLAN (internal and external) EtherTypes.

Remapping of the UP Field in Receive

The remapping scheme applies also to the traffic destined to EMP (or MC), which is represented in the tables by its own four VSI numbers.

38.24.1.1.3 Receive Flow for ETS

Receive Linked Lists

The total available PCIe bandwidth allocated for traffic reception is *initially* allocated among the LAN ports, and *secondly* allocated among TCs (and among the different UPs attached to it) for each LAN port separately. Bandwidth allocated to a TC) over a LAN port might differ to the traffic allocated to the same TC index over another LAN port. Since the number of TCs to be supported over a port might vary from 1 to 8 as per DCBX exchange, the Rx packet buffer is organized in a fixed manner into 32 receive linked lists, one for each UP over each LAN port.

Receive Arbitration Levels

The two levels of bandwidth allocation previously described, one across LAN ports and one across the TCs of a LAN port, induce two levels of arbitration. One Port Round Robin (PRR) arbiter that is used to select the Rx LAN port to be handled and one ETS arbiter that is used to select the TC to be handled within the selected LAN port. Since both arbitration schemes do not deal with absolute throughput allocation, no PCIe bandwidth should be wasted in case for some time some LAN ports or TCs offer less workload than allocated to them. Unused bandwidth by a TC is proposed first to other TCs over the LAN port, and secondly to other LAN ports.

38.24.1.1.4 Receive ETS Arbiter

The 10 GbE controller's receive ETS arbiters determine the order in which the per UP linked lists of a port are serviced at the Rx packet buffer’s exit. Note that within each linked list, packets are drained in the order they arrived, indifferently whether they arrived from the Rx port or from the Tx loopback path of the port.

The arbitration algorithm between the linked lists is either strict priority or packet-based round robin.

Two operating modes are supported according to setting made in using the *NON_ETS_MODE* bit in the PRTDCB_RETSC register:

1. **Strict Priority (SP) Mode** — TCs are served in a strict priority order between them starting from the TC with the higher index until it has no workload, and so forth down to the TC with the lowest index.
2. **Round Robin (RR) Mode** — TCs are served in a packet-based round-robin manner between them until no workload is left to any of them.

When several UPs are mapped (by DCBX) to the same TC index in PRTDCB_RUP2TC register, two operating modes are supported:

1. **Strict Priority (SP) Mode** — This mode is selected by setting *UPINTC_MODE* field to 0b for the corresponding TC index in PRTDCB_RETSTCC register array. UPs are served in a strict priority order between them within the total bandwidth allocated to the TC. Each time the TC is selected by the ETS arbiter, the highest UP is served first until it offers no traffic, and so forth down to the lowest UP of the TC. This is the default operating mode.
2. **Round Robin (RR) Mode** — This mode is selected by setting *UPINTC_MODE* field to 1b for the corresponding TC index in PRTDCB_RETSTCC register array. UPs are served in a packet-based round-robin manner between them within the total bandwidth allocated to the TC. Each time the TC is selected by the ETS arbiter, a different UP offering workload is served among the UPs mapped to the TC, and so forth cyclically.

According to the total number of enabled ports and to the number of TCs of the port, these fields are configured by the DCBX agent as follows:

- Quad port configuration
  - Ports with 1 TC:
    - PRT_SWR_PM_THR.THRESHOLD = 0xA
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x1E
  - Ports with 2 to 4 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0xA
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0xA
  - Ports with 5 to 8 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0xA
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x5
- Dual port configuration
  - Ports with 1 TC:
    - PRT_SWR_PM_THR.THRESHOLD = 0x14
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x3C
  - Ports with 2 to 4 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0x14
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x14
  - Ports with 5 to 8 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0x14
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0xA

- Single port configuration
  - 1 TC:
    - PRT_SWR_PM_THR.THRESHOLD = 0x28
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x78
  - 2 to 4 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0x28
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x28
  - 5 to 8 TCs:
    - PRT_SWR_PM_THR.THRESHOLD = 0x28
    - PRTDCB_RPPMC.RX_FIFO_SIZE = 0x14

Depending on the locality of Rx traffic, while in quad port configuration, ports with 5 to 8 TCs do not achieve the Rx performance goals.

38.24.1.1.5 Receive Low Latency Prioritization (Rx-LLP) Arbiter

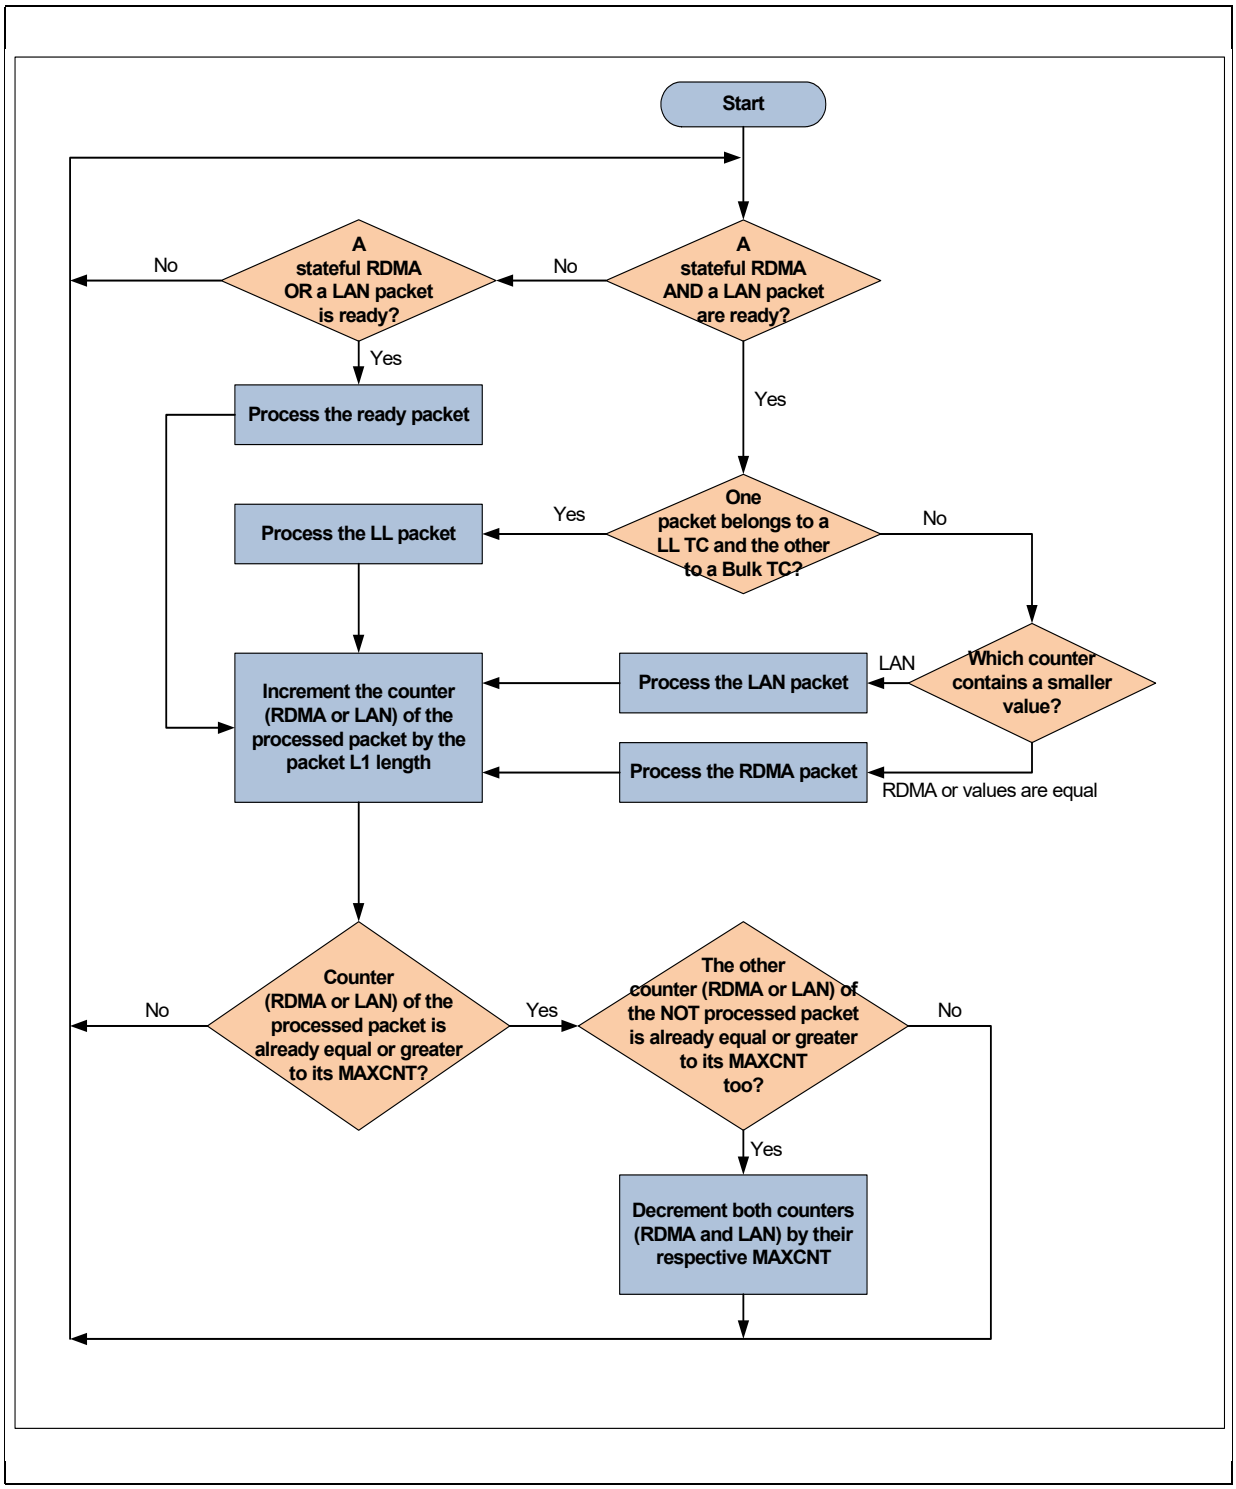
Without this last level DCB arbitration, the simplest low latency benchmark test would fail: a single LAN low latency packet is received while a number of RDMA packets that were under processing get ready to be sent to host. In such a situation the low latency packet suffers from longer delays than usual, even if it get prioritized by the PRR/WSP arbiters.

The following algorithm is run to decide which packet should be sent to host between the two: a packet that is ready at the head of the RDMA pipe or that at the head of the LAN pipe. It requires handling a 1-byte counter per each pipe RDMA and LAN (read accessible via GLDCB_RLLPSRDMA / GLDCB_RLLPSLAN register, respectively) to ensure the following:

1. Packets from either pipe (RDMA or LAN) that belong to a LL TC are always strictly prioritized each time they compete with bulk packets on the other pipe.
2. Each time the competing RDMA/LAN head of pipe packets belong to the same type, either both LL or both bulk, they are serviced in a 50%/50% round-robin ratio relatively to the amount of bytes already serviced per RDMA/LAN type.

Note: Byte counts can overflow the configured limit (MAXCNT) up to one MFS (minus one byte) to get aligned with packets boundary. From then, they saturate until the other counter reaches its upper limit as well.

Figure 38-61.Operation of the Rx Low Latency Prioritization Arbiter



b. Delay of one MFS Ethernet frame due to the last minute decision made at Rx-LLP arbiter.

Note that different latency delays are measured for LL LAN traffic depending if RDMA pipe is enabled or not. This is due to the extension of LAN pipe monitor

required when operating with two separate pipe monitors. Also, in case low latency and bulk TCs are mixed over RDMA traffic, low latency RDMA traffic suffers from the deep RDMA Rx processing path that is shared between them. Ideally, RDMA Rx processing path should have made possible for low latency flows to bypass other flows, but this is not supported by the 10 GbE controller.

3. Low latency prioritization — When one pipe (RDMA/LAN) is fed only with LL traffic, and the other only with bulk traffic, then LL traffic is served (first). When both pipes (RDMA and LAN) are fed with traffic from the same type, either both LL or both bulk, then both pipes must be equally served in bytes amount, in a round robin manner.
4. Impact of packet size — if PCIe bandwidth is much lower than LAN bandwidth (TC buffers are full), and TCs have similar bandwidth allocation, but asymmetric.

38.24.1.1.6 Rx ETS Configuration Rules

PRTDCB_RPRRC are dynamic registers that are auto-programmed by the device. The device retrieves different default values from NVM, one for each the link speed. Each time a port changes its link speed, the corresponding default value is loaded by hardware.

PRTDCB_RUP2TC, PRTDCB_GENC,PRTDCB_RPPMC.RX_FIFO_SIZE, and PRT_SWR_PM_THR are also dynamic registers. Refer to the flow described in Section 38.24.3.3.1 for the way they are modified.

All other Rx-ETS settings described in Section 38.24.1.1 are static. They must not be modified at run time. They are loaded from the NVM only at initialization/reset time.

38.24.1.2 Receive Path Priority Flow Control (PFC) and Rx Packet Buffer (RPB)

This section describes the guaranteeing of no packet loss inside the 10 GbE controller for the PFC-enabled traffic, whether it is received from the LAN wires or from the internal switch. Since this feature is tightly related to the allocation of receive packet buffer to the TCs, the partitioning scheme of the Rx packet buffer is described first.

RPB has a maximum byte capacity of 968 KB and a maximum packet capacity of 7744 packets (968 KB / 128B).

TCs are classified in two types relatively to PFC: no-drop (loss less) TCs, and drop TCs (best effort delivery). PRTDCB_TC2PFC bitmap controls the use of PFC by a TC over a link. The setting applies for both Tx and Rx directions.

Refer to Ethernet flow control basic operation section, which is relevant whether or not the device can operate in DCB mode.

38.24.1.2.1 Requirements on Rx Packet Buffer

DCB requires that separate queuing resources be allocated to each TC along the entire path from the source to the destination node. This guarantees the good functioning of the ETS scheme, and mainly when it comes to prioritize LL TCs over others.

- Handle one linked list of packets per each UP, per port. The list maintains arriving order of packets inside a flow. UPs are attached to TCs in Rx according to settings made in PRTDCB_RUP2TC register.
- No crosstalk be sensed between the LAN ports, at least on regular basis and if the average incoming packet size is greater or equal to 128 bytes.

- Be capable to allocate fully independent buffers for up to five basic TCs per port, as follows:
  - 2 no-drop TCs, one for any other traffic type that requires PFC-enabled and 9.5 KB Jumbo frames (such as iSCSI traffic).
  - 3 best effort delivery TCs (drop TCs) for which PFC is disabled and which carry 9.5 KB jumbo frames.
- Be capable to allocate fully independent buffers for up to 8 best effort TCs per port.
- Three extra TCs beyond the five basic TCs previously described or any other TC settings up to eight TCs per port are supported. It can however be handled via some level of buffer sharing between them.
- Partitioning of Rx packet buffers across the enabled LAN ports is set equally at init time, according to NVM settings.
- Partitioning of the amount of Rx packet buffers allocated to a port is done dynamically according to the following parameters:
  - Number of TCs supported by the port, as per DCBX
  - Number of PFC-enabled TCs over the port, as per DCBX
- Support LPI, and especially the worst case Tx LPI exit time of 17.38 µs while Rx is not in LPI state.

38.24.1.2.2 Normal Partitioning of Rx Packet Buffer

- Eight dedicated pools per port, one per TC. The size of each dedicated buffer is set by PRTRPB_DPS array of registers. Setting a null size to a dedicated packet buffer is allowed (such as for non-used TCs or for the extra TCs), it is equivalent to state that no dedicated buffer is allocated to the TC.
  - Normal partitioning assumes at least the five basic TCs per port get dedicated buffers.
  - Eight dedicated filling counters per port, one per TC.
  - Eight high watermarks per port, one per TC. It is set by PRTRPB_DHW array of registers.
  - Eight low watermark per port, one per TC. It is set by PRTRPB_DLW array of registers. At any time, it must be set to a lower value than the corresponding high watermark. Setting a null low watermark is allowed.
- One shared pool per port. The size of the shared buffer is set by PRTRPB_SPS register. Setting a null size to the shared buffer of a port is allowed, it is equivalent to state that no shared buffer is allocated to the port. This might be the case when only the five basic TCs are supported on a port.
  - One shared pool filling counter per port.
  - One high watermark per shared buffer. It is set by PRTRPB_SHW register.
  - One low watermark per shared buffer. It is set by PRTRPB_SLW register. At any time, it must be set to a lower value than the corresponding high watermark. Setting a null low watermark is allowed.
  - Eight occupancy counters per port, one per TC, to track the amount of bytes of the TC stored on the account of the shared buffer of the port.
  - Eight high thresholds per port, one per TC. It is set by PRTRPB_SHT register. The threshold is relative to the corresponding occupancy counter.
  - Eight low thresholds per port, one per TC. It is set by PRTRPB_SLT register. At any time, it must be set to a lower value than the corresponding high threshold. Setting a null low threshold is allowed. The threshold is relative to the corresponding occupancy counter.

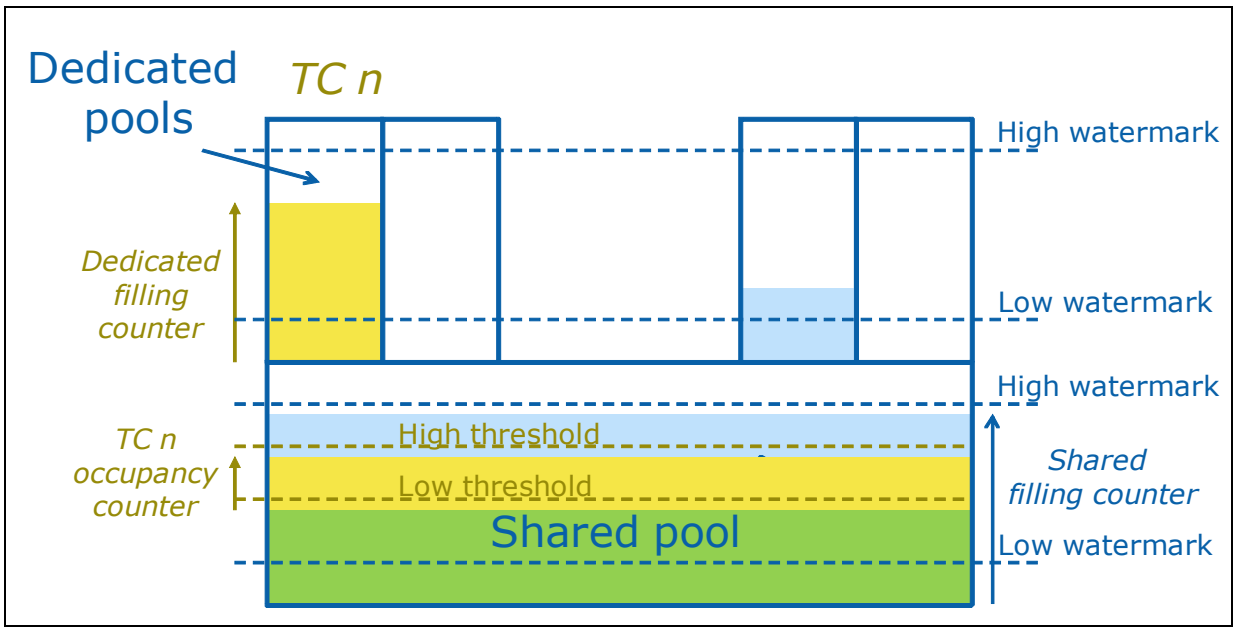
- One packet buffer is allocated per port. Setting a null size to the port packet buffer is allowed (like for disabled ports), it is equivalent to state that no packet buffer is allocated to the port.
  - Normal partitioning assumes the sum of the four per-port buffer sizes equals to the total size of the Rx packet buffer in the 10 GbE controller. For example, 968 KB.
  - The size of the per -ort packet buffer is computed internally as the shared pool size plus the sum over all the dedicated pools size of the port.
  - One per port filling counter.
- One global filling counter for the entire Product Name's receive packet buffer.
  - One global high watermark for the entire device, relative to the global filling counter. It is set by GLRPB_GHW register.
  - One global low watermark for the entire device, relative to the global filling counter. It is set by GLRPB_GLW register. Normal partitioning assumes it is set to zero.

Note: The receive packet buffer accounting granularity is 16 bytes, a physical memory line. To all buffer sizes, threshold, and watermarks registers defined in bytes, the device discards the four LS bits written by software.

The maximum capacity in bytes of the receive packet buffer is 968 KB, provided that the average size of the packets stored is equal or greater than 128 bytes.

- One global packet counter for the entire Product Name's receive packet buffer.
  - One packet high watermark for the entire device, relative to the global packet counter. It is set by GLRPB_PHW register. It is used to reflect the implementation limit, and must normally be set equal or lower than full Rx packet buffer size (968 KB) divided by 128 bytes.
  - One packet low watermark for the entire device, relative to the global packet counter. It is set by GLRPB_PLW register.

Figure 38-62.Normal Partitioning of the Per-port Rx Packet Buffer



38.24.1.2.3 Receive Drop Policy

When receiving a packet attached to a drop TC, either from the LAN wire or from the internal loopback path, the packet is dropped if ANY of the following conditions occur when storing it into the Rx packet buffer:

a. The dedicated pool (PRTRPB_DFC) is filled above or equal to its high watermark (PRTRPB_DHW), and the TC occupancy counter has reached its high threshold.

b. The dedicated pool (if any, PRTRPB_DFC) is filled above or equal to its high watermark (PRTRPB_DHW), and the shared pool filling counter has reached its high watermark and has not returned to the low watermark yet.

c. The dedicated pool (if any, PRTRPB_DFC) is filled above or equal to its high watermark, and the global filling counter has passed above its global high watermark (GLRPB_GHW) and has not returned to the global low watermark yet.

d. The global packet counter has passed above its packet high watermark.

Note: The hysteresis between high and low watermarks is required to avoid starving the no-drop TCs, which can use only the shared pool account with drop TC traffic.

When receiving a packet, even for a no-drop TC, either from the LAN wire or from the internal loopback path, the packet is dropped if there would be no place for storing it entirely in the global Rx packet buffer.

38.24.1.2.4 Policy for Issuing XOFF

When receiving a packet attached to a no-drop TC, either from the LAN wire or from the internal loopback path, a PFC XOFF notification is issued onto the wire and internally to the loopback path for all the UPs mapped to the TC if ANY if the following condition occurs:

a. The dedicated pool (if any, PRTRPB_DFC) is filled above or equal to its high watermark (PRTRPB_DHW).

b. No dedicated pool for the TC (PRTRPB_DPS=0b), and the TC occupancy counter (which is relative the shared pool only) has reached its high threshold (PRTRPB_SHT).

c. No dedicated pool for the TC (PRTRPB_DPS=0b), and shared pool filling counter is above its high watermark (PRTRPB_SHW). In this case XOFF is only concerned with all the no-drop TCs of the port that do not have a dedicated pool.

d. Global filling counter has reached its global high watermark (GLRPB_GHW). In this case XOFF is only concerned with all the no-drop TCs of all ports.

e. The global packet counter has passed above its packet high watermark (GLRPB_PHW). In this case XOFF is only concerned with all the no-drop TCs of all ports.

Next time such a condition occurs, no XOFF is issued until the congested condition disappeared (such as XON sent) or until the XOFF timer expired.

38.24.1.2.5 Accounting Packet Reception

When a packet is stored into the receive packet buffer (the packet has not been dropped), the global filling counter is increased by the number of bytes required to store the packet. Also increment the FIRST counter for which the condition is satisfied when checking it in the following order:

1. Shared pool filling counter — Unless one of the following conditions is met:
   a. No shared pool for the port (null shared pool size, PRTRPB_SPS=0b).

b. Shared pool filling counter has reached its high watermark (PRTRPB_SHW) and there is a dedicated pool for the TC (PRTRPB_DPS>0).

c. TC occupancy counter (relative to the shared pool only) has reached its high threshold (PRTRPB_SHT) and there is a dedicated pool for the TC (PRTRPB_DPS>0).

2. Dedicated pool filling counter — Unless there is no dedicated pool for the TC (PRTRPB_DPS>0).

38.24.1.2.6 Accounting the Servicing of a Receive Packet

When a packet is fetched from the receive packet buffer (packet sent to the host), the global filling counter is decremented by the number of bytes used to store the packet in the receive packet buffer. Also decrement the counter(s) for which the condition is satisfied when checking them in the following order until the amount of served bytes has been reached:

1. Dedicated pool filling counter — If both conditions are fulfilled:

   a. There is a (non-null) dedicated buffer attached to the TC (PRTRPB_DPS>0).

   b. The dedicated pool filling counter has still not reached zero (non-empty). Note that the shared pool is no longer full. However, there is no hurry to send XON for a TC that has still not been served internally by Rx-ETS since it gets into XOFF state. This approach might encounter some tolerable fairness issues across the TCs.

2. Shared pool filling counter — When no or empty dedicated pool and as long as shared pool filling has not reached zero.

Note: When a port is disabled or disconnected, its Rx packet buffer is drained in such a way that all its associated filling counters get down to zero within a short and bounded time.

Note: When a packet is served, it may that 2 x 48 bytes = 96 bytes are not decremented from the dedicated pool filling counter and from the shared pool occupancy counter. This happens if the packet is not aligned with 64-byte memory blocks and if packets in the TC are not served as per their insertion order.

38.24.1.2.7 Policy for Issuing XON

When servicing a packet attached to a no-drop TC (packet sent to the host), a PFC XON notification is issued onto the wire and internally to the loopback path if ALL the following conditions are satisfied:

1. XOFF was issued for this UP.
2. TC occupancy counter is below or equal to its low threshold.
3. The global packet counter is below or equal its packet low watermark (GLRPB_PLW) AND the relevant condition is met:

   a. If there is a dedicated pool for the TC and it has a non-null low watermark (PRTRPB_DLW>0): when the dedicated pool filling is below or equal its low watermark.

   b. If there is a dedicated pool for the TC (PRTRPB_DPS>0) and it has a null low watermark (PRTRPB_DLW=0b) when the shared pool filling is below or equal its low watermark.

   c. If there is no dedicated pool for the TC when the shared pool filling is below or equal its low watermark.

38.24.1.2.8 Prevention of PFC crosstalk Between PCIe Functions

Though Rx queues are allocated per TC in RSS mode (in the 10 GbE controller), no TC index is stored in the Rx queue context. Intel recommends to avoid mixing drop and no-drop traffic over the same Rx queue, as the no-drop traffic might cause head of line blocking of the drop traffic.

There is a need to prevent a malfunctioning function, a paused function, or a non-trusted VM from blocking an entire PFC-enabled TC if it does not provide Rx descriptors. For this purpose, a per UP timer is started each time a packet located at the head of the per UP linked list is waiting for software to free Rx descriptors in the Rx queue to which the packet is destined. A timer starts counting on if the UP is associated with a TC of type No Drop (if the TC is of type Drop, head-of-line packets are dropped when descriptors are not available).

The timer is reset when Rx descriptors are freed.

The ports/UPs for which the timer timed out can be read via GLDCB_RUPTI bitmap register. Writing 1b to a bit in the bitmap restarts the corresponding timer. The Rx queue that blocked the UP is reported to the PRTDCB_RUPTQ array of registers. The queue index reported in this register is the absolute queue index in the device space, which is different than the queue index used for the Tx and Rx queue registers.

When a timer expires, the EMP is interrupted and takes the following steps:

1. EMP identifies the port and UP of the offending queue by reading the GLDCB_RUPTI register.
2. EMP reads the PRTDCB_RUPTQ register to identify the offending queue.
3. EMP clears the timer by writing a 1b to the corresponding bit in GLDCB_RUPTI.
4. EMP reads the QTX_CTL[Q] register, where Q is the index of the offending RX queue. QTX_CTL identifies the following:

Note: This flow is based on the assumption that the software programs the QTX_CTL register for any matched transmit queues of all enabled receive queues. If this rule is not addressed by the software, a reported LAN Queue Overflow Event admin command is sent to PF0.

   a. Whether the queue belongs to a PF or VF (the PFVF_Q field).
      - A VM queue is considered to be a PF queue for this section.
   b. The PF that owns the queue (or the parent PF in case the queue belongs to a VF) (the PF_INDX field).
   c. The VF that owns the queue (for the case that the queue belongs to a VF) (the VFVM_INDX field).

5. If the queue belongs to a PF:
   a. If the NVM bit *PF reset on queue overflow* is set.
      - The EMP issues a PFR to the function. Note that the PFR also resets the PF's VFs.
   b. If the NVM bit *PF reset on queue overflow* is cleared.
      - The EMP sends a LAN Queue Overflow AQ event to the PF, notifying the event.
6. The EMP indicates to the MC that the PF driver is not present, if the queue belongs to a VF.
   a. The EMP sends a LAN Queue Overflow AQ event to the respective PF that owns the VF, notifying the event.

b. The PF issues a VFR to the function.

Note: It is advisable to assign manageability traffic to UPs associated with Drop TCs, therefore avoiding the risk of stalling due to host queue that overflows.

38.24.1.2.9 Rx Packet Buffer Configuration Flow

All RPB registers are dynamic registers. They can be loaded from the NVM at initialization/reset time, and/or they can be modified at run time further to a change in DCBX resolution. Re-configuring RPB while working might lead to the issuing of XOFF/XON notifications to several TCs at once.

When a change has been made to one of the input parameters described in Section 38.24.1.2.10, the RPB settings have to be updated.

The modified Rx-PB setting must be loaded to the device according to the following order:

1. Low thresholds and low watermarks that require to be decreased — registers PRTRPB_SLT, PRTRPB_SLW, PRTRPB_DLW.
2. High thresholds and high watermarks that require to be decreased — registers PRTRPB_SHT, PRTRPB_SHW, PRTRPB_DHW.
3. Dedicated pools size that require to be decreased.
4. Shared pool size — register PRTRPB_SPS.
5. Dedicated pools size that require to be increased.
6. High thresholds and high watermarks that require to be increased — registers PRTRPB_SHT, PRTRPB_SHW, PRTRPB_DHW.
7. Low thresholds and low watermarks that require to be increased — registers PRTRPB_SLT, PRTRPB_SLW, PRTRPB_DLW.

38.24.1.2.10 Configuration Rules for RPB Partitioning

The computing flow described in this section is run by the entity responsible to run DCBX (see Section 38.24.3). The flow is run for each port independently over the amount of memory allocated to the port, as part of the Rx-PB configuration flow described in Section 38.24.1.2.9.

It makes use of the following parameters as input:

- Number of enabled ports (static parameter after initialization time), used to determine the amount of memory allocated to a port. It is set to 968 KB divided by the number of enabled ports.
- Tx LPI enabled/disabled over the port (as per PRTPM_EEER.TX_LPI_EN register bit). When Tx LPI is enabled over the port, the amount of memory usable for PFC by the port is reduced by [Tx LPI Exit Time - Max MFS over all the TCs of the port]. This reduced effective packet buffer size of the port will be referred as RPB_ESize(Port). For simplicity, worst case Tx LPI Exit Time value is taken regardless of the port type or speed, which corresponds to Tw_phy of 10GBASE-KR Case-2: 14.25 us @ 10G, equivalent to 17.4 KB.
- Number of supported TCs in receive (PRTDCB_GENC.NUMTC).
- Number of PFC-enabled TCs (TC2PFC field in PRTDCB_TC2PFC and for 40 GbE links PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE and PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE).

- MFS per TC table (see Section 38.24.3.3.3, it is maintained by the DCBX handling entity, and can be also loaded from the NVM). MFS over a TC is referred as MFS(TC), while maximum MFS over all TCs of a port is referred as MFS(max).
- PCIe round trip time (see PCIRTT).
- PFCLinkDelayAllowance — Delay Value (DV) over the port. Since MFS is a per-TC value, there is a different DV value per TC, referred as DV(TC). See PFCLinkDelayAllowance.

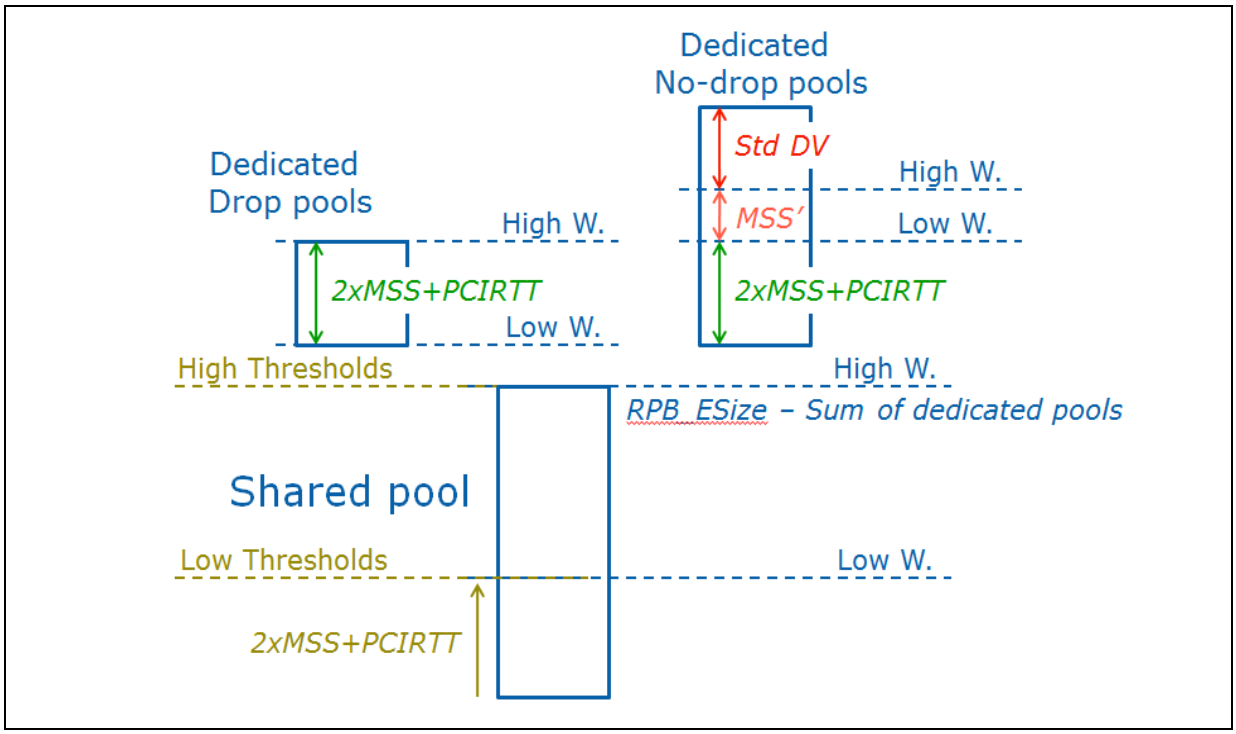
The flow makes use of DV(TC) extended by one MFS(TC) because of a last minute packet from the same TC that can be looped back into the RPB. It is noted as **Std DV(TC) = DV(TC) + MFS(TC)**.

1. **Allocate fully independent buffers to all TCs** and allocate the remaining buffer space (if any) to the shared pool of the port.
   a. Step 1 dedicated no-drop TC:
      - Dedicated no-drop low watermark = 2 x MFS(TC) + PCIRTT
      - Dedicated no-drop high watermark = Dedicated no-drop low watermark + MAX{MFS(max), 4.5KB}; the last term is referred as MFS'
      - Dedicated no-drop pool size = Dedicated no-drop high watermark + Std DV(TC)

   b. Step 1 dedicated drop TC:
      - Dedicated drop low watermark = 0
      - Dedicated drop high watermark = Dedicated drop pool size
      - Dedicated drop pool size = 2 x MFS(TC) + PCIRTT

   c. Step 1 shared:
      - Shared pool size = RPB_ESize(Port) – Sum of Dedicated pools' sizes
      - Shared high watermark = Shared pool size
      - Shared low watermark = 0
      - Shared low threshold = 0
      - Shared high threshold = Shared pool size
      - Exit condition: If shared pool size is not negative, then exit the flow

Figure 38-63.Normal Configuration at Step 1



2. **Downgrade TCs to semi independent TCs** — Downgrade a TC to a semi independent PB. Try a drop TC first, but if it is not enough to fulfill the following exit condition, then downgrade a no-drop TC instead, and so forth starting from lowest TCID and up.

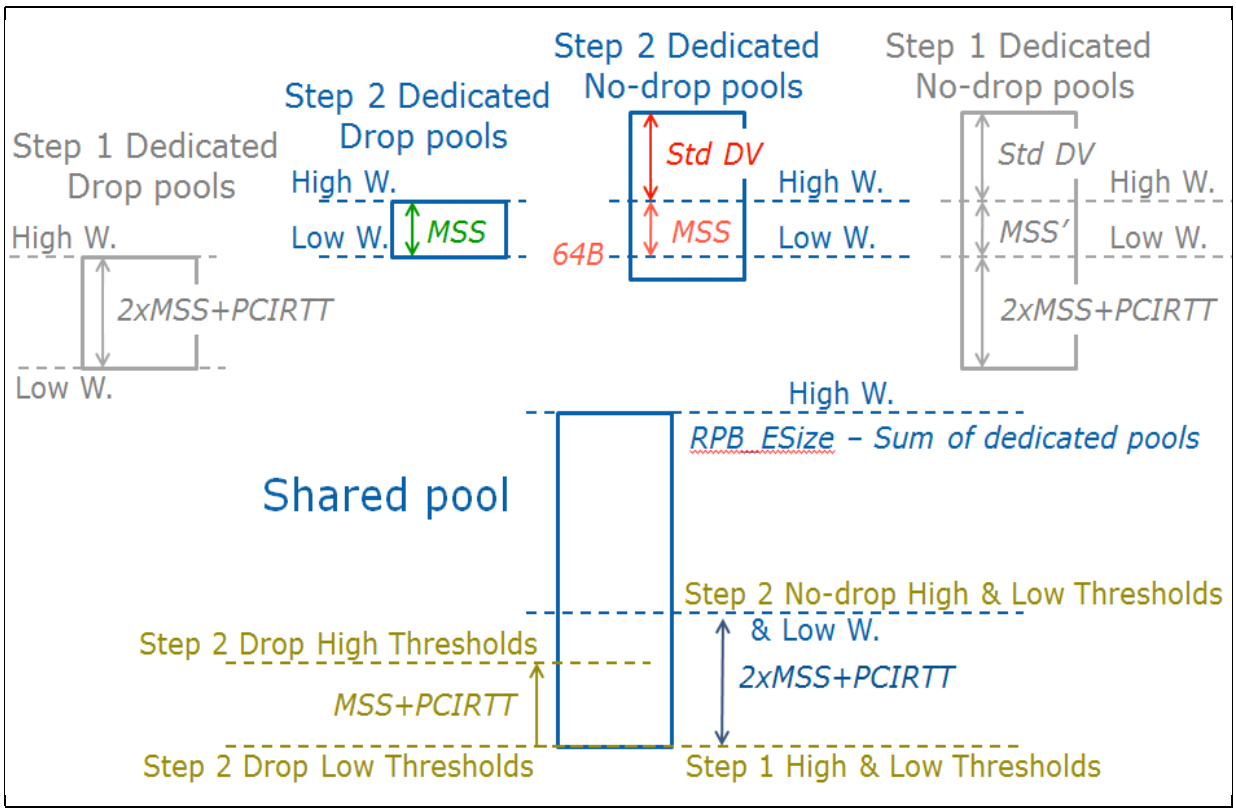
   a. Step 2 no-drop TC:
      - Dedicated no-drop low watermark = 64 bytes
      - Dedicated no-drop high watermark = MFS(TC) + 64 bytes
      - Dedicated no-drop pool size = Dedicated no-drop high watermark + Std DV(TC)
      - Shared no-drop low threshold = 2 x MFS(TC) + PCIRTT
      - Shared no-drop high threshold = 2 x MFS(TC) + PCIRTT

   b. Step 2 drop TC:
      - Dedicated drop low watermark = 0
      - Dedicated drop high watermark = MFS(TC)
      - Dedicated drop pool size = Dedicated drop high watermark
      - Shared drop low threshold = 0
      - Shared drop high threshold = MFS(TC) + PCIRTT

   c. Step 2 shared:
      - Shared pool size = RPB_ESize(Port) - Sum of dedicated pools' size of TCs left unchanged from Step 1 - Sum of Dedicated pools' size of TCs downgraded at Step 2.
      - Shared low watermark = 2 x MFS(max) + PCIRTT
      - Shared high watermark = Shared pool size
      - For TCs left unchanged from Step 1: Shared low threshold = Shared high threshold =0

- Exit condition: If Shared pool size > Sum over n1 of MFS(TC) + Sum over n2 of (MFS(TC)/2) + PCIRTT + MFS(max), where n1 = # of Step 2 no-drop TCs, n2 = # of Step 2 drop TCs; then exit the flow with no new iteration of Step 2

Figure 38-64.Normal Configuration at Step 2



3. **Downgrade TCs to shared pool only** — Downgrade a TC to shared pool only, meaning it does not have a dedicated pool. Try a drop TC first, but if it is not enough to fulfill the following exit condition, then downgrade a no-drop TC instead, and so forth starting from lowest TCID and up.

   a. Step 3 no-drop TC:
      - No dedicated pool
      - Shared no-drop low threshold = 2 x MFS(TC) + PCIRTT
      - Shared no-drop high threshold = Shared no-drop low threshold + MFS(TC)

   b. Step 3 drop TC:
      - No Dedicated pool
      - Dedicated drop low watermark = 0
      - Dedicated drop high watermark = 64 bytes
      - Dedicated drop pool size = Dedicated drop high watermark
      - Shared drop low threshold = 0
      - Shared drop high threshold = 2 x MFS(TC) + PCIRTT

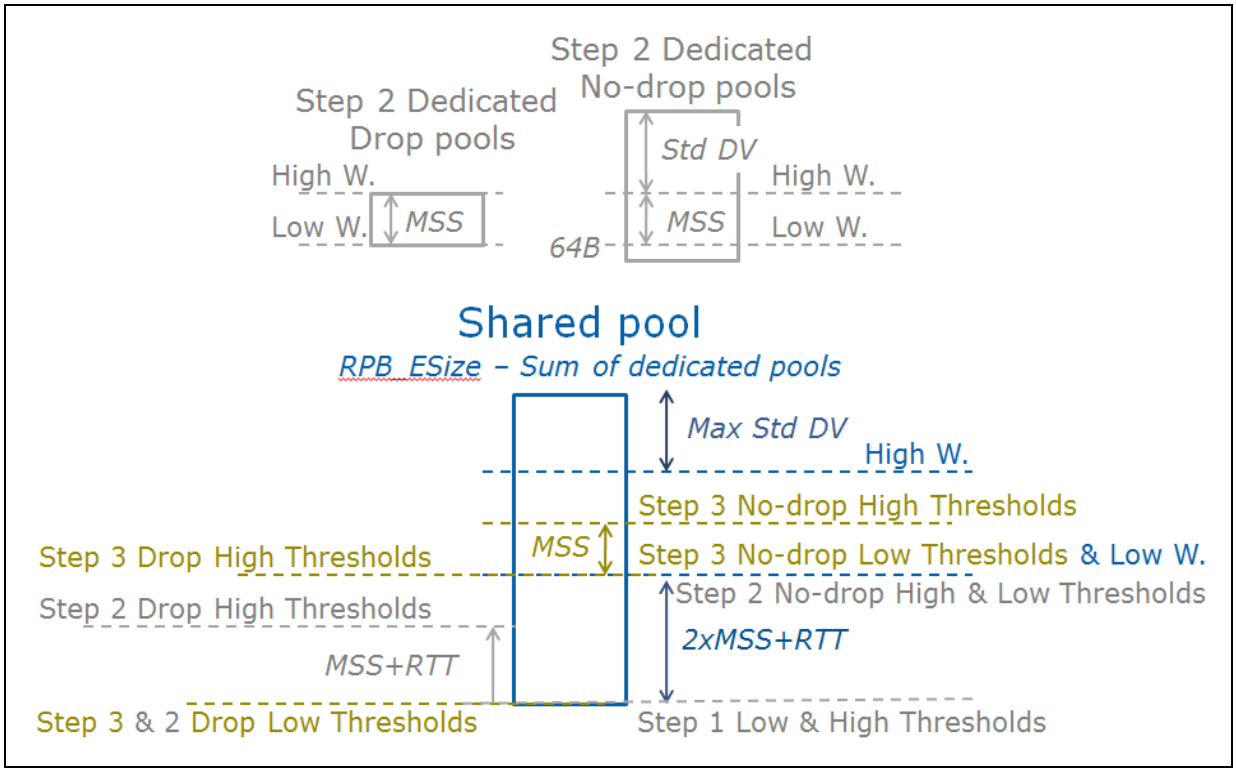
c. Step 3 shared:
   - Shared pool size = RPB_ESize(Port) - Sum of dedicated pools' size of TCs left unchanged from Step 2
   - Shared low watermark = 2 x MFS(max) + PCIRTT
   - Shared high watermark = Shared pool size – Max Std DV across no-drop TCs downgraded at step 3 (if any)

   Exit conditions:

   If Shared pool size > Sum over all no-drop TCs of MFS(TC) + Sum over all drop TCs of (MFS(TC)/2) + PCIRTT + MFS(max), AND

   If Shared pool size > Max {Std DV + 3 x MFS(TC) + PCIRTT} across no-drop TCs downgraded at step 3 (if any), then exit the flow with no new iteration of Step 3.

Figure 38-65.Normal Configuration at Step 3



38.24.1.2.11 Configuration Rules for Global Watermarks

See Section 38.24.1.2.10 for the definition of Std DV(TC).

- The global high watermark (GLRPB_GHW) = [968 KB — Sum over the 4 ports of (Max Std DV(TC) over all no-drop TCs of a port).
- The global low watermark (GLRPB_GLW) = [968 KB — 2 x (Sum over the 4 ports of (Max Std DV(TC) over all no-drop TCs of a port).
- The packet high watermark (GLRPB_PHW) = (968 KB / 128 B) — [(Sum over the 4 ports of (Max Std DV(TC) over all no-drop TCs of a port) / 64 B].
- The packet low watermark (GLRPB_PLW) = (968 KB / 128 B) — 2 x [(Sum over the 4 ports of (Max Std DV(TC) over all drop TCs of a port) / 64 B].

38.24.1.2.12 Examples of RPB Configuration Flows

- 10GBASE-T PHY is assumed, which includes the following interface delay contributors:
  - — XGMII MAC/RS interface: 8 192 + 2 * 2 048 = 12 288 bit times
  - — 10GBASE-T Delay: 25 600 bit times
- All MFS must be rounded up to 16 bytes
- All pool sizes or watermarks must be rounded up to 64 bytes

38.24.2 Transmit Path DCB

38.24.2.1 Transmit Path ETS

Transmit path ETS is basically handled in the Tx-scheduler.

This section describes the requirements on the Tx data path to avoid distortions on the ETS scheme performed by Tx-scheduler.

The approach relies on two principles:

1. Maintain the order of requests issued by the Tx-scheduler, as most as possible.
2. Avoid misleading the scheduler decisions by inexact reports.

Other ETS requirements on Tx data path:

1. Serve low latency traffic as fast as possible in any condition, as long as it is not overtaking its allocated bandwidth.
2. Guarantee that best effort TCs can be served at full blown, regardless to the XOFF/XON events history over loss less TCs.
3. Achieve the per port throughput performance goals.
4. Avoid starvation of one ETS TC by another, even in the case it is dripping packets while the other TCs offer sustained workload.

38.24.2.1.1 Identifying LL Traffic in Transmit

In order to handle sudden PFC XOFF notifications received from the link, the transmit data path is provided with buffers in its different stages. To reduce impact on die size, provision is made for only two types of traffic, LL and Bulk (B). This approach requires a priority differentiation between LL and B traffic in order to decide in which buffer a Tx data or request for data has to be stored. TC indexes are used for that purpose according to a setting made in LLTC bitmap in PRTDCB_TETSC_TCB and PRTDCB_TETSC_TPB registers.

The entity that runs DCBX configures all non-ETS TCs as LL traffic, and only those TCs.

38.24.2.1.2 UP-to-TCs in Transmit

Mapping of UP-to-TC in transmit

Register PRTDCB_TUP2TC controls the mapping of UPs-to-TCs in the transmit path with respect to PFC XOFF/XON notifications received from the link partner or internally from the loopback path. It defines which transmit TC is paused/released when a UP bit is set in a PFC XOFF/XON frame received (or in internal notification).

Note: PRT_TCTUPR, PRTDCB_TUP2TC, and PRTDCB_RUP2TC registers must be programmed identically.

Tx manageability traffic issued by the MC is bound to the lowest indexed drop TC, or to TC0 if all TCs are no-drop.

Remapping of the UP field in transmit

The remapping scheme also applies to the traffic issued by EMP (or MC), which is represented in the tables by its own four VSI numbers.

38.24.2.2 Transmit Path PFC

This section describes the guarantee of no packet loss at the link partner and inside the 10 GbE controller further to receiving PFC pause frames from the link partner or further to PFC notifications received from the internal switch.

TCs are classified in two types relatively to PFC: no-drop (loss less) TCs, and drop TCs (best effort delivery). PRTDCB_TC2PFC and PRTDCB_MFLCN.RPFCE bitmaps (and PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE for 40 GbE links) control the use of PFC by a TC over a link.

38.24.2.2.1 Performance Goals for Transmit Path PFC

Basic assumptions

1. The 10 GbE controller must support optimally up to 2 TCs per port which are PFC-enabled. It might support more, but under sub-optimal performing concerning throughput.
2. One PFC-enable TC supports 9.5 KB jumbo packets.

XOFF performance goal

Once an internal/external XOFF notification is received on a TC:

1. Transmission from the TC is stopped on the wires within the DV specified in Annex O of the PFC specification. See Section 38.24.1.2.10 for more detail.
2. Other TCs (PFC-enabled or not) can be served at full blown. Some limitations can be tolerated for other PFC-enabled TCs if 2 PFC-enabled TCs are already paused for the port, depending on the history of PFC XOFF events. Worst case is when the accumulated amount of traffic (commands or data) that was in the data path at the moment XOFF events were received on a port has reached twice the Tx command/data path depth. In this case, all PFC-enabled TCs of the port are paused.
3. PFC XOFF events received on one port must not impact performance of other PFC-enabled TCs on other ports.

XON performance goal

1. **Over the wires** — Once an external XON notification is received for a TC or once the XOFF timer has ended for it, resuming transmission over the wires for this TC must be made possible within the *Higher Layer Delay* plus the *Interface Delay* specified in Annex O of the PFC specification. This corresponds to half of the DV used for XOFF performance goal above minus the cable delay.
2. **On the internal switch** — Once an internal XON notification is received for a TC, resuming transmission at the internal switch ingress port for this TC must be made possible within only the *Higher Layer Delay* specified in Annex O of the PFC specification. Internal switch ingress port is located at the entry of the Rx packet buffer.

Note: Interface delay must take in account the layers present and active inside the 10 GbE controller and those present in an external PHY connected to it on the board (if any).

38.24.2.2.2 Transmit PFC

The TC(s) concerned by an XOFF/XON notification, which is per UP, are identified by the setting made in PRTDCB_TUP2TC register.

38.24.2.2.3 PFC Dead-lock Prevention

Tx traffic that belongs to PFC-enabled TCs can be halted in the Tx pipe due to endless XOFF received either from the line or from the internal loopback path. Flushing out this traffic is a gating condition for the completion of the following operations: Tx queue disable, PFR, VFR, disabling the PFC of a TC or DCBX UP to TC remapping.

The device implements a mechanism that automatically flushes out Tx traffic that belongs to a port for which the link goes down. However, there is no similar mechanism for flushing out traffic halted in the Tx data pipe due to endless XOFF conditions. In the case of PFR, an endless XOFF condition is detected autonomously by the device and handled as described in the text that follows. For the other cases (previously listed), it is the PF(s) responsibility to detect that the Tx data-path is halted for a long time by periodically monitoring the eight Tx PFC timers attached to a port, one per TC (PRTDCB_TPFCTS.PFCTIMER). Each timer (per TC) is restarted by the device every time the TC is halted by an XOFF notification (received from the link). If any of these counters crosses a threshold defined by the ENDLESS_XOFF_THRESH parameter (in offset 0x15 of EMP setting module in the NVM), the PF(s) software should take the following actions:

- Post a PFC Ignore admin command (see Section 38.24.5.1) for the TC, requesting EMP to set IGNORE_FC bit(s) (32 bits - 1 per TC and per port) in the GLDCB_TFPFCI register. It causes the entire Tx data path to ignore PFC indications for the concerned TC/port, whether they were received from the line or from the internal loopback path. When in this state, the device flushes out the concerned frames without issuing them over the line or into the internal loopback path.
- When the endless XOFF condition disappeared, and/or when the Tx pipe is checked to have been cleaned up (read PRTDCB_TCWSTC and PRTDCB_TCMSTC arrays of registers), the PF clears the *IGNORE_FC* bit by posting a PFC Ignore admin command with *Ignore Flag* cleared.

Note: In case the port is operated in LFC, the functionality is controlled by the bit corresponding to TC0.

The eight Tx PFC timers of a port must be always operative, even if a TC has no more UP mapped to it (further to a UP to TC mapping change driven via DCBX).

38.24.2.3 Tx Path DCB Configuration Rules

Tx-scheduler registers are dynamic registers. They can be loaded from the NVM at initialization/reset time, and/or they can be modified at run time further to a change in DCBX resolution.

PRTDCB_TUP2TC and PRTDCB_GENC are also dynamic registers. Refer to the flow described in Section 38.24.3.3.1 for the way they are modified.

All other Tx DCB settings described in Section 38.24.2.1 and in Section 38.24.2.2 are static. They must not be modified at run time. They are loaded from the NVM only at initialization/reset time.

38.24.3 DCBX

DCBX protocol relies on the exchange with the peer of untagged LLDP packets over the physical link.

38.24.3.1 DCBX / LLDP Ownership

By default DCBX is handled by EMP, though when the device is operated in SFP mode, the host can decide to take the DCBX ownership once system boot has been completed. SFP mode software initiates the transition on a per port basis, by posting the Stop LLDP Agent command.

When software owns DCBX, it might give DCBX ownership back to EMP using the Start LLDP Agent AQ command. Each time the host which handles DCBX goes to sleep mode, DCBX is un-covered (EMP does not cover for DCBX). It is the host's responsibility to reset DCB configuration to its default settings (such as single TC, PFC disabled, etc.) prior to entering the sleep state. When software handles DCBX, it is also responsible to configure the DCB settings of the port, via setting the DCB registers. It must use the relevant flow described in Section 38.24.4. In such case, the end-station might be made by software as the DCBX master. For example, the entity that propagates its DCB settings to the peer.

When LLDP/DCB is handled by EMP, the 10 GbE controller behaves always as a DCBX slave, retrieving its DCB settings from recommendations or configurations received from the peer.

The LLDP agent embedded in EMP (including its DCBX agent) is reset by GLOBR. Further to such reset events, EMP restarts LLDP Agent and DCBX resolution for the ports on which LLDP was handled by EMP.

When LLDP is handled by EMP, following to a CORER event, EMP must reconfigure the Tx/Rx paths (and any relevant hardware that was reset) with the DCB configuration that prevailed before the reset occurred.

38.24.3.2 DCBX Version

There are two known versions of DCBX standard. IEEE and CEE. The 10 GbE controller supports both and can adopt at runtime its peer's mode of operation or to determine the mode of operation based on NVM configuration word: DCBX Mode.

The NVM configuration selects one of the three options; CEE, IEEE or adopt peer's mode of operation.

When it configured to adopt peer's mode of operation, it is done based on DCBX TLV's received from the link peer using the following detailed flow.

- Upon initialization (linkup, GLOBR or LLDP ownership hand-off from software to EMP, TLV counters expire) EMP runs IEEE/DCBX as default mode.
- Upon receiving a DCBX TLV's from the partner:
  - EMP determines the actual DCBX mode it runs. This is done based on the OUI field in the DCBX TLV. in IEEE the OUI TLV value is 00 80 C2. in CEE, this value is 00 1B 21.
  - If the message contains IEEE/DCBX TLV's, then
    - DCBX mode == IEEE
    - Ignore and CEE/DCBX TLV in the message
  - End if

  - Else If the message contains only CEE/DCBX TLV's, then
    - DCBX mode == CEE
  - End if
- When DCBX mode is changed between CEE and IEEE, the entire DCB configuration is re-initialized to the default DCB setting.

Method used by software to find which version EMP runs

Software sends down the GET_CEE_DCBX_OPER_CFG AQ command and waits for its completion.

```
If retval == success

    DCB Mode = CEE.

    Negotiated DCB arbitration available in response buffer for this command.

End if

If retval == ENOENT

    DCBX Mode = IEEE.

    SW sends down "GET_LLDP_MIB" AQ command to find out the DCB arbitration
negotiated using DCBX protocol.

End if

If retval == EPERM

    Software has taken control of DCBX. Query SW DCB agent for any DCBX
configuration

End if
```

38.24.3.2.1 CEE Vs. IEEE DCBX

This section highlights the main difference between CEE and IEEE modes that affects the DCBX resolution. Refer to the two standard specifications for more details.

Operational configuration

IEEE DCBX TLV's always advertise the operational setting of the feature. CEE DCBX on the other hand, computes the operational configuration based on local DesiredCfg and peer's DesiredCfg. If software wants to determine the OperCfg, it cannot use the GET_LLDP_MIB AQ command for CEE as OperCfg is not the wire in case of CEE. Software has to GET_CEE_DCBX_OPER_CFG AQ command for obtaining the OperCfg in CEE.

Priority groups

CEE DCBX has a concept of priority group that is not present in IEEE DCBX. EMP is required to equate the priority group and TC concepts. That is, treat the priority-to-priority group mapping received in the CEE DCBX TLV as the priority-to-TC mapping as well.

PFC

For CEE DCBX, if the PFC does not become operational via CEE DCBX state machine, then CEE DCBX disables PFC and enables link level flow control. When EMP runs the DCBX agent in IEEE mode this recommendation is irrelevant since it behave in slave mode and align itself to the peer.

38.24.3.3 DCBX Offload Flow

DCBX TLVs embedded in the LLDP packets are identified by a TLV type value of 127 followed by the IEEE 802.1 OUI field value of 0x0080C2 for IEE and 0x001B21 for CEE.

There are four types of IEEE/DCBX TLVs that are handled by the 10 GbE controller, and they are classified into three categories as follow:

- ETS TLV's — ETS configuration TLV and ETS recommendation TLV.
- Priority-based FC configuration TLV.
- Application priority configuration TLV.

CEE/DCBX defines the following sub-TLV's:

- Control TLV — Contains fields controlling the operation of CEE DCBX.
- Priority Groups TLV — Similar to IEEE ETS feature.
- Priority Flow Control TLV — Similar to IEEE PFC feature.
- Application Protocol TLV — Similar to IEEE application priority feature.

CEE/DCBX transmits all DCB TLV's packed inside a single LLDP TLV. IEEE/DCBX uses a separate LLDP TLV for each of the DCB features.

LLDP packets are periodically issued with DCBX TLV's inside. The following steps represent the specific handling required from the EMP-based DCBX agent, after receiving DCBX TLVs from the peer:

1. **Wait until the first DCBX TLV is received or for a change in the received DCBX TLV**.
2. **EMP identifies LLDP/DCBX peer** — The LLDP peer identifier is made by the concatenation of its chassis ID and port ID fields. Compare these fields to a saved copy of the previous LLDP peer identifier received (if there is any and if it is not aged out).
   a. If the LLDP peer identifier is not the same, then store the new LLDP peer identifier into the Remote DCBX parameters saved in firmware data RAM, and start a timer with the longest 802.1AB TTL value of any of the peers. Go to next step even before waiting for timer's end.
   b. If the number of LLDP peers that run DCBX is greater than one at the timer ends, then a multiple peer condition is detected and reported via the *PRTDCB_GENS.DCBX_STATUS* field set to MULTIPLE_PEERS (as well as via a LLDP MIB change event if configured for). Restart the timer with the longest 802.1AB TTL value of any of the peers and exit the flow with updating the LLDP DCBX peer and treating DCBX parameters as NULL (no DCBX peer).
3. **If for some reason, the DesireCFG received from the peer does not match the DesiredCfg issued to it, the CEE/DCBX agent re-sends the DCB TLV's for the concerned feature(s) with the DesiredCfg copied from the peer and with the LocalParmaterCahnge bit set.**
   a. Refer to CEE DCBX specification for the way CEE/DCBX agent must handle the CEE control and feature state machines.

4. **EMP resolves DCBX and reconfigures DCB** — Update the RPB settings according to the flow described in Section 38.24.1.2.9 and to the rules described in Section 38.24.1.2.10 for the normal RPB settings. Update the Local DCB management objects of Section 38.24.3.4 according to the flows described in Section 38.24.3.3.1 and Section 38.24.3.3.3.

   a. If LLDP TLVs were aged out, EMP reconfigures the device with the default DCB settings, excepted for LFC which should be reverted to the previously known LFC mode that prevailed before DCBX was resolved.

   b. If some DCBX TLVs are missing or malformed, the concerned DCB settings are returned to their default configuration.

38.24.3.3.1 ETS TLVs Resolution

IEEE/DCBX ETS TLV's

Figure 38-66.ETS Recommendation FLV Format

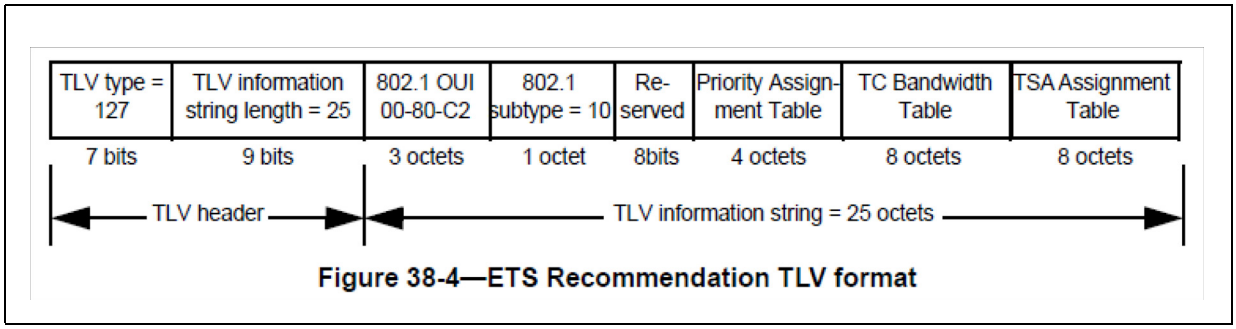

Figure 38-4—ETS Recommendation TLV format

Figure 38-67.ETS Configuration FLV Format

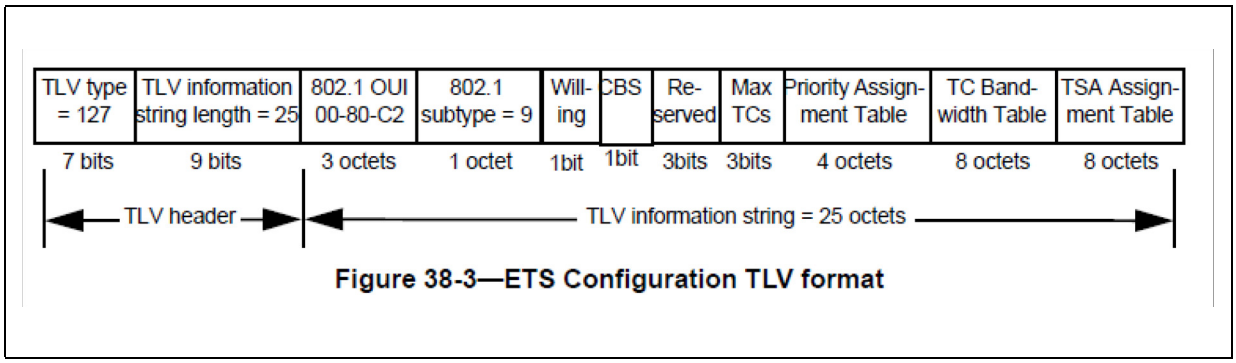

Figure 38-3—ETS Configuration TLV format

The ETS TLV sent by a node concerns its ETS setting in transmit direction. ETS parameters resolution uses the asymmetric attribute passing state machine described in Section 38.4.1 of DCBX standard. It allows a different setting for each Tx direction between two peers. When DCBX is handled by EMP, the 10 GbE controller acts as a DCBX slave and therefore the local *Willing* bit issued to the peer is always set.

If no ETS TLV is received from the peer, or if they are aged out, the default ETS setting is recovered, which assumes all the UPs are mapped to a single non-ETS TC, TC 0.

Otherwise, two scenarios whether or not an ETS recommendation TLV has been received from the peer:

1. If the ETS recommendation TLV is present in peer's TLVs, local Tx ETS settings are extracted from the ETS recommendation TLV received. It ise referred to as the

remote ETS TLV. Local Rx ETS settings are extracted from ETS configuration TLV of the peer.

2. If no ETS recommendation TLV or if it is aged out, local ETS settings (both Tx and Rx) are extracted from the ETS configuration TLV of the peer. It is referred as the remote ETS TLV.

CEE/DCBX ETS TLV's

Refer to corresponding section in the CEE ETS specification.

ETS Configuration Change Flow

EMP extracts the number of TCs from the ETS TLV. For IEEE/DCBX, it corresponds to the number of different TC indexes identified in the priority assignment table. It then performs the following tasks sequentially, according to the case:

1. If a there is a change in a PFC policy or in UP-to-TC mapping, go to the port draining flow.
   a. Reconfigure the DCB settings according to the following order: Load the number of TCs into PRTDCB_GENC.NUMTC.
   b. Configure the Rx commands FIFOs as described in Section 38.24.1.1.4.
   c. Update the PFC settings to TCs according to the new priority assignment table (if it was modified), using the flow described in Section 38.24.3.3.2.
   d. Load the priority assignment table extracted from the remote ETS TLV into PRTDCB_RUP2TC.
   e. Load the priority assignment table extracted from the remote ETS TLV into PRT_TCTUPR.
   f. Mark non-ETS TCs as LL TCs in the *LLTC* field of PRTDCB_TETSC_TCB and PRTDCB_TETSC_TPB registers.
   g. Assign MC pass-through traffic to the lowest indexed drop TC, or to TC0 if all TCs are no-drop.
2. Go to the Tx-scheduler configuration flow where TC bandwidth table and TSA assignment table extracted from the remote ETS TLV is loaded there into Tx-Scheduler.

Note: When changing the UP-to-TC mapping and/or PFC policy, it might be that PFC and ETS behaviors be perturbed during the transition time until traffic in the pipes are emptied.

The 10 GbE controller always advertises support to eight TC's, but in CEE/DCBX it locally operates with a number of TC's that equal to the number of priority groups received from the peer. It is a one-to-one device's TC-to-priority group assignment made locally by the EMP. So, from TC index 0 and up, from PG index 0 and up: TC0 to PG0, TC1 to PG1 etc. Excepted PGID 15,which is a special value dedicated to the strict priority group, such as the priority group with unlimited bandwidth allocation. PGID 15 must be mapped to the lowest free TC index once all other priority groups have been mapped

38.24.3.3.2 PFC Configuration TLV Resolution

IEEE/DCBX PFC TLV

Figure 38-68.Priority-based Flow Control TLV Format

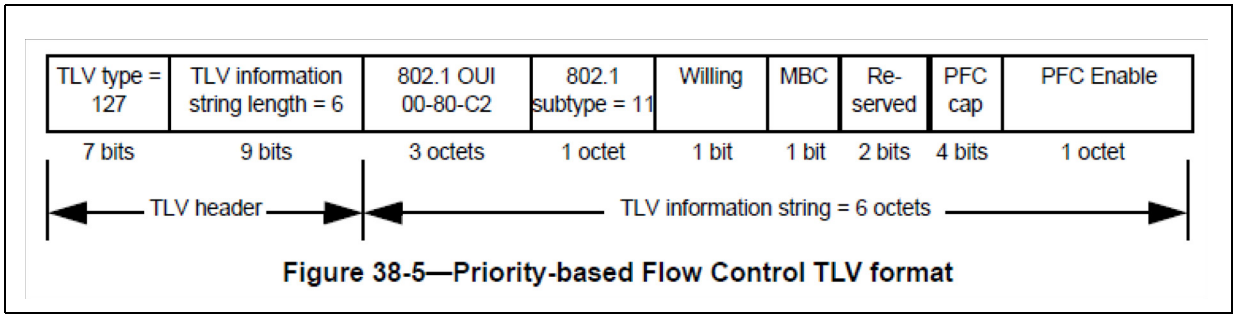

Figure 38-5—Priority-based Flow Control TLV format

PFC parameters resolution uses the symmetric attribute passing state machine described in Section 38.4.2 of DCBX standard. It means that the same setting is expected in both directions Tx/Rx, up to the edge of the DCB network.

Two scenarios follows, assuming the local *Willing* bit is always set:

1. Remote *Willing* bit is cleared. The local PFC configuration is copied from the peer.
2. Remote *Willing* bit is set as well. The local PFC configuration is taken from the link partner with the lower numerical MAC address.

With scenario 1 and scenario 2, if the peer has the lower numerical MAC address, the PFC configuration change flow described in PFC Configuration Change Flow is performed by the EMP.

Note: Since PFC is disabled by default on all UPs, Intel recommends that the remote *Willing* bit not be set, so that the device for sure inherits the PFC setting from the peer.

CEE/DCBX PFC TLV

Refer to the corresponding section in the CEE specification.

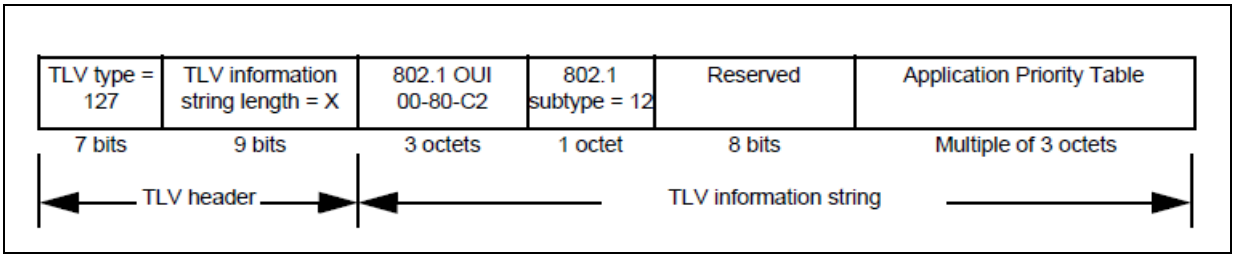
PFC Configuration Change Flow

- Load the PFC *Enable* bit vector of the peer into *TC2PFC* field of PRTDCB_TC2PFC and into *RPFCE* field in PRTDCB_MFLCN (and into PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE and PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE for 40 GbE links), making use of the PRTDCB_RUP2TC.UP2TC settings as follows:
  a. If one of the UPs attached to a TC has its bit set in the PFC *Enable* bit vector, then set to 1b the TC2PFC bit that corresponds to the TC.
  b. If all the UPs attached to a TC have their bit cleared in the PFC *Enable* bit vector, then clear to 0b the TC2PFC bit that corresponds to the TC.
- Set the *PRTDCB_RUP.NOVLANUP* field with the lowest indexed no-drop UP. If there is not a no-drop UP, use the lowest indexed drop UP instead.

38.24.3.3.3 Application Priority TLV

IEEE/DCBX Application Priority TLV

Figure 38-69.Application Priority Table TLV Format

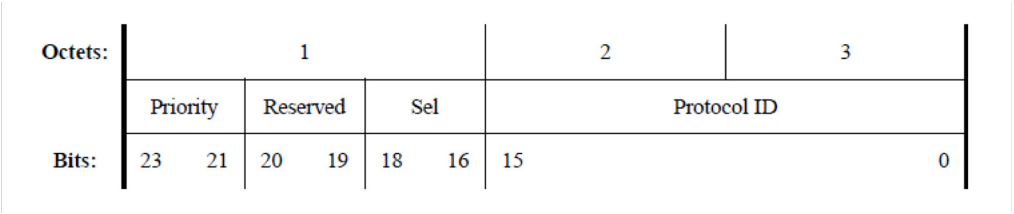


Content of this TLV is mainly informational. Two sets are stored by firmware in the DCBX database: one local set and one remote set received from the peer.

It is assumed that the peer always sends the application TLV and that the local set is copied from the remote set.

The local/remote tables stored by firmware are accessible to software via the Get LLDP MIB command (see PFCLinkDelayAllowance).

Figure 38-70.Application Priority Table



The UP attached to iSCSI traffic is the priority field in the application priority table row for which:

- Sel = 2 or 4
- Protocol ID = iSCSI TCP port (3260)

CEE/DCBX application protocol TLV

Refer to the corresponding section in the CEE specification.

38.24.3.4 DCB Managed Objects

38.24.3.4.1 DCBX Managed Objects

When a DCBX port is handled by the EMP, the DCBX managed objects are the DCBX parameters stored internally in EMP data RAM and/or in device registers. All DCBX objects are per-LAN port. Two instances are stored per port, one issued by the device to the link partner referred as Local DCBX parameters, and one received from the link partner referred as remote DCBX parameters.

When DCBX is handled by the EMP, the PFs must be restrained from any write access to the DCB registers listed in Table 38-293. Note that RW in the table refers to the EMP capability to write the object.

Table 38-293.Local DCBX Managed Objects

IEEE Object Name *CEE Object Name	Data Type	Width In Bits	Admin	Default	Related Local Configuration Register
ETS Configuration TLV					
Willing	Boolean	1	RO	1	Firmware only
Credit-based Shaper (CBS)	Boolean	1	RO	0	Firmware only
Max TCs *Num TCs Supported	Unsigned integer	3	RW	0[1]	PRTDCB_GENC.NUMTC
Priority Assignment Table *Priority Allocation Table	Unsigned integer [0..7]	8x4	RW	0	PRTDCB_TUP2TC, PRT_TCTUPR, PRTDCB_RUP2TC
TC Bandwidth Table *Priority Group Allocation Table	Unsigned integer [0..7]	8x7	RW	0	
TSA Assignment Table	Unsigned integer [0..7]	8x8	RW	0[2]	
PFC Configuration TLV					
Willing	Boolean	1	RO	1	Firmware only
MBC	Boolean	1	RO	0	Hardcoded
PFC Cap *Num TC PFC Supported	Unsigned integer	4	RO	0x8[3]	Firmware only
PFC Enable *PFC Config Table	Boolean [0..7]	8x1	RW	0	TC2PFC in PRTDCB_TC2PFC RPFCE in PRTDCB_MFLCN PRTMAC_HSEC_CTL_RX_PAUSE_ENABLE PRTMAC_HSEC_CTL_TX_PAUSE_ENABLE PRTMAC_HSEC_CTL_RX_ENABLE_GPP PRTMAC_HSEC_CTL_RX_ENABLE_PPP
Application Priority Configuration TLV					
Application Priority Table *App Protocol Config Table	Unsigned integer	32x24	RW	0	Firmware only
MFS per TC Table	Unsigned integer	8x15[4]	RW	1536	Firmware only

Notes:

1. 0 is the encoding for 8.
2. Strict priority algorithm is assumed by default (indicated by a zero value) on each user priority. Setting the value of 2 selects ETS bandwidth allocation scheme.
3. The 10 GbE controller is always able to support up to eight PFC-enabled TCs though in some cases (when jumbo frames are enabled) fully independent PFC behavior is partially achieved.
4. Max frame size is defined in bytes.

38.24.3.4.2 PFC Managed Objects

The PFC managed objects are PFC parameters that do not concern DCBX. Note that RW in Table 38-294 refers to the software capability to write the object.

Table 38-294.PFC Managed Objects

Object Name	Data Type	Width In Bits	Admin	Default	Specification Reference	Related Local Configuration Register
PFC Control Objects					Table 12.1	
PFCLinkDelayAllowance[1]	Unsigned integer	16[2]	RW	0	12.18	PRTDCB_GENC.PFCLDA
PCIRTT[a]	unsigned integer	16	RW	0	N/A	GLDCB_GENC.PCIRTT
PFCRequests	unsigned integer	16	RO	0	12.18	GLPRT_PXOFFTXCNT
PFCIndications	unsigned integer	16	RO	0	12.18	GLPRT_PXOFFRXCNT

Notes:

1. These parameters are relevant only when DCBX is handled by EMP. Any modification made by the PF driver to these register fields take effect on the RPB settings only once a DCB Updated admin command is posted.
2. In PFC specification the parameter is expressed in link bits, but in the 10 GbE controller it is expressed in 16-byte units. SNMP agent handled in the operating system is responsible to convert the parameter in bits units when returning it in the corresponding MIB object.

PFCLinkDelayAllowance

The value of PFCLinkDelayAllowance is configurable by software per port via the PRTDCB_GENC.PFCLDA register field. It is expressed in 16-byte time units. It might be more accurate if the EMP selects by itself the PFCLinkDelayAllowance value that corresponds to the PHY, without referring to this register field.

Firmware uses this parameter to compute the Rx packet buffer settings. See Section 38.24.1.2.10 for more detail.

Referring to Annex O in PFC Std, PFCLinkDelayAllowance is also referred as the DV, which is computed per TC as follows:

DV= 2*(Max Frame) + (PFC Frame) + 2*(Cable Delay) + 2*(Interface Delay) + (Higher Layer Delay)

- *2*(Max Frame) = MFS (TC) + MFS (max)* is in fact formed by the sum of the MFS (TC) over the TC for which DV is computed and the maximum MFS (max) over all TCs. See Section 38.24.3.3.3 for the MFS per TC table to be used. The PFCLinkDelayAllowance loaded to the PFCDLA register field must assume MFS is 9.5 KB for both. Firmware is responsible for handling a different PFCLinkDelayAllowance per each TC according to the MFS per TC table it handles; referred to as DV(TC).
- *(PFC Frame)* duration is equal to 672 bit times.
- *2*(Cable Delay)* is proportional to the cable length and inversely proportional to the bit time duration (like link speed). A 100 m Cat6 cable operating at 10 GbE link speed is the worst case for all the supported cable length, medium type, and link speeds across 10 GbE, 1 GbE, and 100 Mb/s. Under this worst case conditions the term equals to 2*(5,556) bit times. Firmware is not responsible for optimizing the term contribution if the link speed is below 10 GbE. However, it is firmware's responsibility to multiply this value internally by 4 for 40 GbE link.

- *2* (Interface Delay) + (Higher Layer Delay)* must take in account the interface delay at each side of the link, and higher layer delay at the peer side. The PFCLinkDelayAllowance value loaded to the PFCLDA register field must be computed assuming at the peer the worst case values tolerated by the standard over the medium type. Table O-1 in Annex O of the PFC standard gives the interface delay contributors for the different layers that might be present between the 10 GbE controller and the physical medium.

Figure 38-71.IEEE 802.3 Interface Delays

Sublayer	Maximum RTT (bit times)	Maximum RTT (pause quanta)	Reference (subclause of 802.3)
10G MAC Control, MAC, and RS	8 192	16	46.1.4
XGXS and XAUI	2 048	4	48.5
10GBASE-X PCS	2 048	4	49.2.15
10GBASE-R PCS	3 584	7	50.3.7
LX4 PMD	512	1	53.2
CX4 PMD	512	1	54.3
Serial PMA and PMD	512	1	52.2
10GBASE-T	25 600	50	55.11

The *higher layer delay* at 10 GbE is 614.4 ns, which is equivalent to 6,144 bit times. As before, firmware is not responsible for optimizing the contribution of this term if the link speed is below 10 GbE.

PCIRTT

The value of PCIRTT is configurable by software for the entire device via the GLDCB_GENC.PCIRTT register field. It is expressed in 16-byte time units.

Firmware uses this parameter to compute the Rx packet buffer settings. See Section 38.24.1.2.10 for more detail.

It represents the maximum PCIe round trip time supported with no performance penalty (2 µs by default. A 10 GbE link speed is the worst case for all the supported link speeds across 10 GbE, 1 GbE, and 100 Mb/s. At 10 GbE speed the term is equal to 20,000 bit times. Firmware is not responsible for optimizing the term contribution if the link speed is below 10 GbE.

38.24.4 Initialization of DCB Functionality

38.24.4.1 DCB Initialization Flow

DCB initialization flow is always handled by the EMP, starting from pre-boot time, further to any of the following events: GLOBR, PCIR, PERST, EMPR, and POR.

1. **Auto-load** — The device auto loads the default configuration of the ports from the NVM, which might include some changes to the DCB/RPB registers'. See Table 38-295 for the default DCB/RPB settings, since the registers hardware default are tuned to four ports enabled at 10 GbE (or lower) link speed. In any case, DCB/RPB defaults loaded to registers at this stage must guarantee basic connectivity for the enabled ports.

It must equally partition RPB across the enabled ports by setting an identical value into their shared pool buffer (PRTRPB_SPS register) so that their sum equals 968 KB. For disabled ports, zero is expected to be loaded from the NVM into PRTRPB_SPS. DCB defaults must assume one single (non-ETS) TC for the port (like TC0) to which all UPs are mapped. No dedicated pools are used at this stage. PFC is disabled for all UPs. The control port of the internal switch must (by default) be addressed to EMP. It guarantees untagged LLDP packets are forwarded to the EMP in Rx, and in Tx, untagged LLDP packets (wrongly) issued by the host are filtered out by the device before reaching the wire.

2. **Auto-negotiation** — If auto-negotiation is enabled by default, the device performs auto-negotiation with the peer, which might result in a link speed change and/or in a LFC status change. Any DCB/RPB configuration change that requires further to auto-negotiation is handled by the device at pre-boot stage, as follows:

   a. *Further to a link speed change* — Update receive port arbiter. The device updates the credits allocated to the port in the Rx port arbiter. Other link speed registers settings are handled by the EMP. Firmware is responsible to multiply internally the value of PFCLinkDelayAllowance by 4 for 40 GbE link.

   b. *Further to a LFC state change* — Update RPB and LFC registers. The EMP computes and loads the high/low watermark of the shared pool allocated to the port as if it was a single fully independent buffer. See Section 38.24.1.2.10. Other LFC registers settings are handled by the EMP.

3. **EMP runs DCBX** — Once EMP has re-loaded, the LLDP filters in the internal switch, and if the LLDP agent was not disabled via NVM settings or via the Stop LLDP Agent admin command (the later case is not relevant for POR triggering events), the EMP performs a DCBX exchange with the link partner from scratch, and updates the device registers related to DCB managed objects as per the flows described in Section 38.24.3.2.

   a. This step starts as soon as the link is up (auto-negotiation has completed) and any time the link goes up again later on.

4. **PFs read the DCB configuration** — PFs issue a Get LLDP MIB command to the device. From the response posted by the EMP, it identifies the UP used for storage as well as the UP to TC mapping used at the link level.

5. **PFs configure VEBs and VSIs according to the flow.**

   a. If there are several UPs attached to a TC, and if there is at least one Rx queue for each, the EMP might attach one corresponding Tx queue set per each UP under the TC. This is done upon availability of the Tx queue set resources. In this case, a Tx queue set belongs to a single UP and to a single TC. Otherwise, it belongs to a single TC. In any case, an Rx queue might not carry traffic from a single UP or a single TC, as Rx filters assign traffic to Rx queues according to many decision parameters that might not take in account only UP/TC.

   b. The EMP sets the per VSI UP translation tables used in Tx and Rx, VSI_TUPR and VSI_RUPR tables, respectively.

Note: On CORER events, the EMP must reconfigure the core blocks with the DCB settings saved from the last DCBX resolution.

38.24.4.2 Transfer of DCB Ownership Between EMP and Operating System

38.24.4.2.1 Transfer of DCB Ownership to Operating System

In SFP mode, it might be that the operating system decides to take ownership over DCBX from the EMP. This is done per port according to the following flow:

1. **Operating system disables DCBX offload** — The operating system posts a Stop LLDP Agent command. This notifies the EMP to stop handling DCBX.
   a. If the Shutdown LLDP Agent command variant is used, the EMP LLDP agent issues a last LLDP packet to the peer with TTL=0 before returning the port to its default DCB setting; one single non-ETS TC (like TC 0). This variant is used by the PF when it does not plan to take LLDP ownership. It has the advantage to gracefully shutdown the LLDP with the peer without requiring the host to get involved in the last LLDP packet transmission.
2. **EMP completes the Stop LLDP Agent command**.
3. **Operating system redirects LLDP to the host** — Operating system moves the LLDP forwarding rules of the internal switch to the control VSI.
4. **Operating system runs DCBX** - Operating system performs a DCBX exchange with the link partner, and updates the device registers related to DCB managed objects as per the flows described in Section 38.24.3.2. It might be that the operating system re-runs DCBX in master mode, propagating to the peer the local DCB settings, which were made to its DCBX agent via some DCB application.
5. **When the operating system detects a DCBX change**, it posts a DCB updated event in the admin command queue to notify the EMP that the untagged traffic mapping must be modified.

Note: If the Stop LLDP Agent command is issued when the LLDP agent is already off, the command is silently dropped.

The LLDP agent might be disabled by default via clearing the Factory LLDP Admin Status word in the NVM LLDP configuration module. This mode can be useful on nodes that provide NAT and other network edge services.

On any reset event other than POR, the EMP does not retake LLDP ownership on ports where ownership has been moved to the PF. It means that the PF must not perform the transfer of DCB ownership to the operating system again further to such reset events.

38.24.4.2.2 Return of DCB Ownership to EMP

At operating system reboot, it is possible that the system goes through a complete initialization cycle, including a BIOS pre-boot phase. In such a case, it is required that LLDP ownership returns to the EMP so that it supports pre-boot activities such as operating system boot over the network. Pre-boot software has to first initiate a GLOBR to re-initiate the device hardware, and then to signal the EMP to take over the LLDP agent. The later is done by posting a Start LLDP Agent command.

Further to receiving the Start LLDP agent, the EMP starts the LLDP agent from scratch, making use of the hardware defaults of registers.

38.24.4.3 Initial DCB Settings

Table 38-295 lists the changes in DCB registers that must be made via NVM settings. Hardware default settings for DCB registers correspond to ports are operated at 10 GbE or lower speeds.

Table 38-295.Changes in DCB Registers Made via NVM Settings When Port Operated at Different Link Speed

Register	Field	1x10 GbE	2x10 GbE	4x10 GbE
PRTDCB_GENC	PFCLDA	0x079D [1]	0x079D [1]	0x079D [1]
GLDCB_GENC	PCIRTT	0x009C	0x009C	0x009C
PRTDCB_RPPMC	RX_FIFO_SIZE	0x10	0x10	0x08
PRT_SWR_PM_THR	THRESHOLD	0x0F	0x0F	0x09
GLRPB_PHW	PHW	0x1246	0x1246	0x1246
GLRPB_PLW	PLW	0x0846	0x0846	0x0846
PRTRPB_SPS	SPS	0x3C800	0x3C800	0x3C800
GLDCB_TGENC_RLPM	TCPM_DIS	0x0	0x0	0x0
	CWLB_MODE	0x0	0x0	0x0
PRTDCB_TCPFCPC_RLPM	PORTOFFTH	0xC64	0x65C	0x34A

PRTDCB_TCPFCTCC_RLPM	LL_PRI_EN	0x0	0x0	0x0
	LL_PRI_TRESH	0x608	0x304	0x182

Note:
1. *The value put in the NVM image must be optimized to reflect the PHY type and the internal delays in the 10 GbE controller.

38.24.5 DCB Admin Commands

All parameters in the admin commands are defined in little endian.

38.24.5.1 PFC Ignore

This command is used to request the device to ignore a PFC condition present on a Tx path for a TC. The same command is used to release PFC ignore request. When PFC packets are ignored they are considered as regular packets and might be forwarded to the host.

Table 38-296.PFC Ignore Response (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0301	Command opcode.
Datalen	4-5		Must be zeroed.
Return Value	6-7		Return value. 0x0 - No error (success).
Cookie High	8-11	Cookie	Opaque value, is copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by the EMP into the completion of this command.

Table 38-296.PFC Ignore Response (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Completion_flags	16		Bits 7:0 = TC status bitmap. Returns the TCs for which PFC is currently ignored. Bit n set to 1b means a PFC condition on Tx path for TC n is ignored by the device.
Reserved	17-19		Reserved, must be zeroed.
Reserved	20-23		
Reserved	24-27		
Reserved	28-31		

Table 38-297.PFC Ignore Command

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0301	Command opcode.
Datalen	4-5		Must be zeroed by driver.
Return Value/ VFID	6-7		Must be zeroed by driver.
Cookie High	8-11	Cookie	Opaque value, is copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by the EMP into the completion of this command.
Command_flags	16-17		Byte 16, bits 7:0 = TC bitmap. A bitmap of the TCs concerned by the command. Bit n set to 1b means TC n is concerned by the request. When LFC is used instead of PFC, TC index 0 is used to request ignoring LFC. Byte 17, bits 6:0 = Reserved, must be zeroed. Byte 17, bit 7 = Ignore flag. When set to 1b, the PF requests to ignore PFC conditions on the TC indexes set to 1b in the TC bitmap. When cleared to 0b, the PF requests to release any ignore PFC condition request issued for the TC indexes set to 1b in the TC bitmap.
Reserved	18-19		Reserved, must be zeroed.
Reserved	20-23		
Reserved	24-27		
Reserved	28-31		

38.24.5.2 LLDP/DCBX Admin Commands

Refer to the LLDP Protocol commands section for more details.

38.24.5.3 DCB Updated Command

When LLDP is handled by the PF, this command is used to notify the EMP that a DCB setting has been modified.

When LLDP is handled by the EMP, it is used by PF to notify the EMP that one of the following parameters has been modified:

- PFCLinkDelayAllowance set by PRTDCB_GENC.PFCLDA
- PCIRTT set by PRTDCB_GENC.PCIRTT

In return, the EMP might modify the mapping of untagged traffic (via PRTDCB_RUP). A command completion is posted once the mapping has been changed.

Table 38-298.DCB Updated Response

Name	Bytes.Bits	Value	Remarks
Flags	0-1	0	
Opcode	2-3	0x0302	Command opcode.
Datalen	4-5		Must be zeroed.
Return Value	6-7		Return value. 0x0 = if needed, RPB or untagged traffic mapping was modified accordingly.
Cookie High	8-11	Cookie	Opaque value, is copied by the EMP into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by the EMP into the completion of this command.

Name	Bytes.Bits	Value	Remarks
Reserved	24-31		Reserved, must be zeroed.

38.25 Transmit Scheduling

38.25.1 Bandwidth Management Hierarchy

38.25.1.1 Hierarchy of Switching Elements

The 10 GbE controller contains a number of switching elements that might be arranged in a hierarchical manner. Depending on how the 10 GbE controller is configured, the hierarchy might consist of zero, one or two layers. Each switching element contains a single uplink (egress) port and one or more virtual (ingress) ports. The egress port of the switching element can be connected to physical port or to the virtual ingress port of another switching element. For a detailed description of the switching components, terminology and hierarchy rules supported by the 10 GbE controller see Section 38.21.7.2.1.

Figure 38-72.Hierarchy of Switching Elements

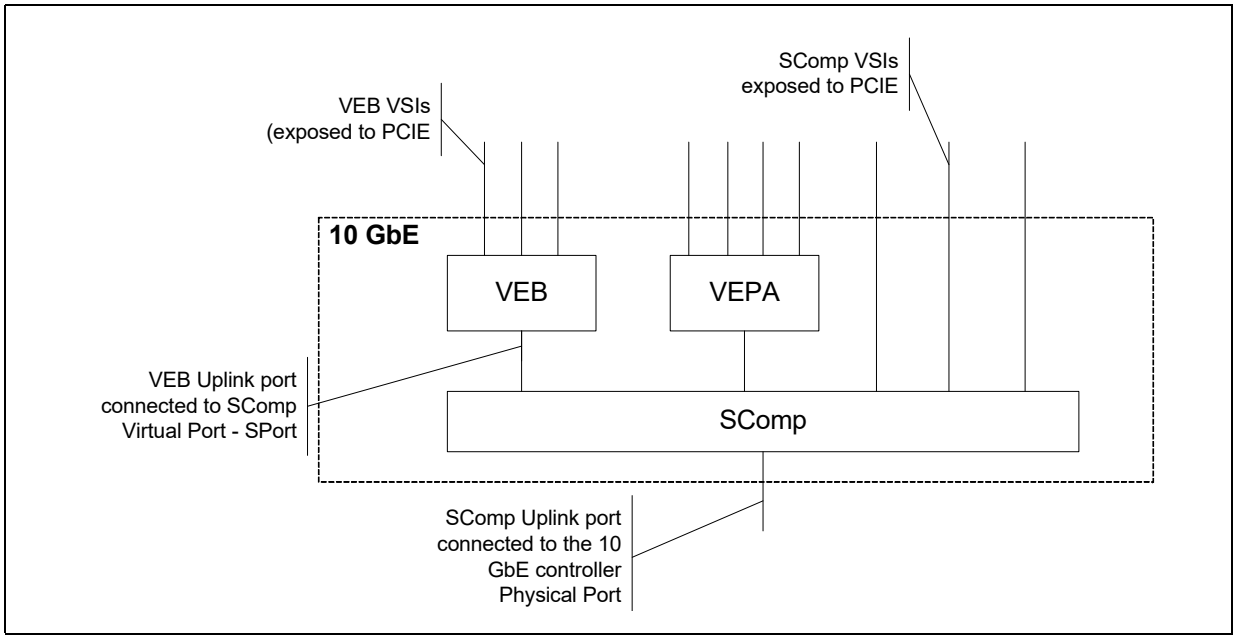

Figure 38-72 shows an example of a two level switching hierarchy. The S-comp's ingress port is connected to the physical port. Several of the S-comp's virtual ports (S-channels) are exposed as PCIe functions. Two of the S-comp's egress ports are connected to VEB and VEPA switching elements. Both the VEB and VEPA switching elements expose multiple virtual ports as PCIe functions or VSIs.

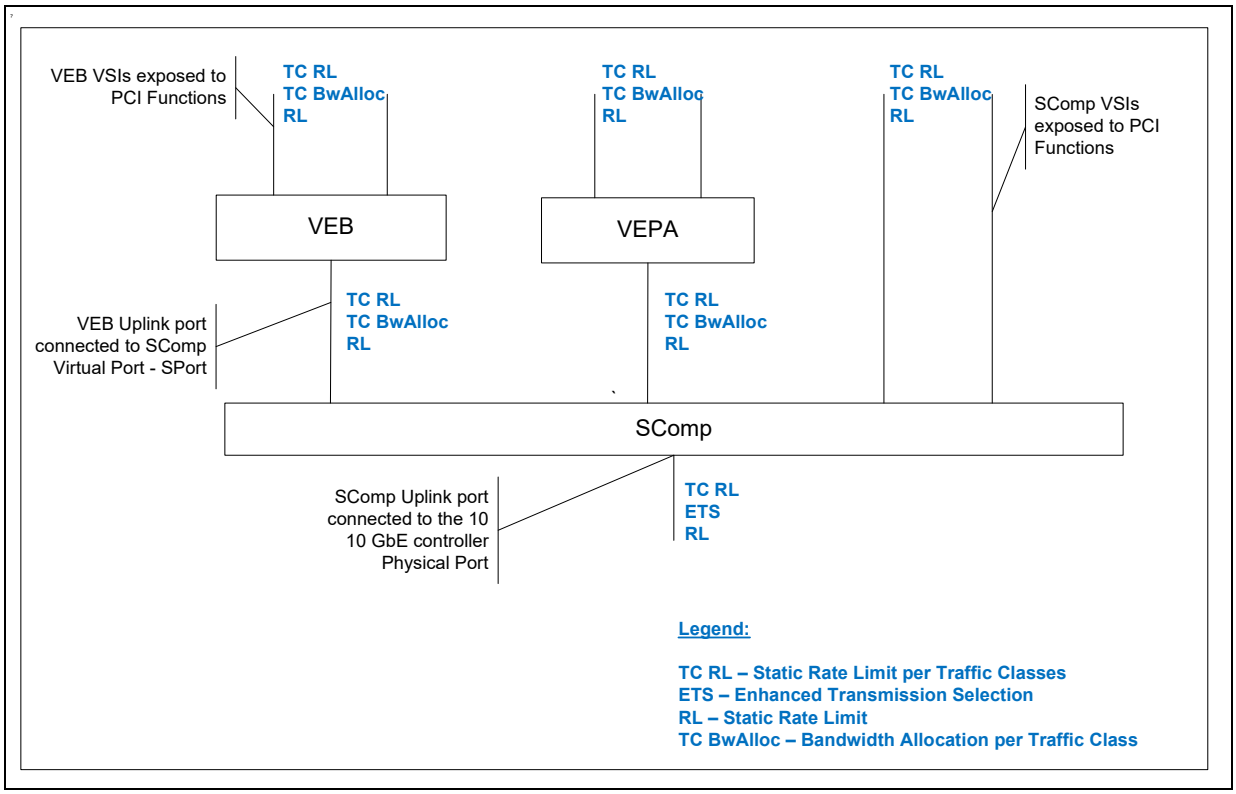
A virtual port that is not connected to the egress of a switching element is exposed as a virtual port to the PCIe interface and called a VSI. In this chapter, the term virtual port is used to refer to all ports of a switching component, and the term VSI is used for virtual ports that are exposed as PCIe functions. Each of the VSIs is assigned to either

the PF or VF and connected to the virtual egress port of the respective PCIe function. A VSI can be owned by a single PCIe function at any one time, but might transition from one PCIe function to another. A single PCIe function can own multiple VSIs.

By default, a VF owns a single VSI. A VM that needs connectivity to multiple virtual ports or switching elements can either use an emulated path through a VMM (using VSIs owned by the physical function) or use multiple VFs, one for each VSI.

Figure 38-73.10 GbE Ethernet Controller Bandwidth Management Attributes



The 10 GbE controller transmit scheduler configuration follows topology of the internal switching components. Figure 38-73 shows various bandwidth management attributes and their association with the switching components. A subset of bandwidth management controls shown on this diagram is available depending on the transmit scheduler configuration scheme. See Section 38.25.2 for description of supported transmit scheduler configuration schemes.

- VSI/Switching Component Bandwidth Limit — Each VSI and switching component can be configured to limit maximum bandwidth used by that VSI and switching component. Limiting bandwidth of the switching component effectively limits bandwidth all VSIs associated with that switching component. For details, see Section 38.25.1.3. Bandwidth limit of VSIs and switching components can be configured in all supported transmit scheduler configuration schemes. See Section 38.25.2.
- ETS Configuration of Physical Port — The 10 GbE controller physical port can be configured with ETS configuration.This enables designers to specify distribution of bandwidth among TCs enabled for the physical port. Each physical port can be configured with independent ETS. TCs configured to the physical port can be enabled for the switching components and VSIs allocated for the port. Allocation, association and bandwidth distribution within each one of the TCs must be

consistent with the physical port ETS configuration and bandwidth distribution within the switching hierarchy. For example, TCs enabled for VSI must be enabled for respective switching components and physical ports, and a total bandwidth allocated to all VSIs for particular TC must be equal to the bandwidth allocated for that TC on the switching component. For details on ETS configuration, see Section 38.25.1.4.

- Per Traffic Type Bandwidth Allocation — Each VSI and switching component can have relative bandwidth allocated per TC. Such bandwidth allocation is hierarchical, similar to the VSI/switching component bandwidth allocation previously described. But it is done within a particular TC. For example, each VSI of the switching component can be configured with bandwidth share with respect to other VSIs of the same switching component for the particular TC. Such bandwidth allocation is mutually exclusive with the VSI bandwidth allocation previously described and depends on the transmit scheduler configuration scheme. See Section 38.25.2 for more detail. The bandwidth allocation principles are described in Section 38.25.1.2.
- Per Traffic Type Bandwidth Limit — Each VSI that has an ETS enabled can be configured to limit the maximum bandwidth available for one or more TCs configured for that port. For details, see Section 38.25.1.4.

Configuring the 10 GbE controller scheduler is done by firmware. Software can use the Admin Queue interface to modify a default allocation of bandwidth attributes. See Section 38.25.3.1 for more detail.

Table 38-301 lists bandwidth management attributes supported for each switching component and VSI depending on the transmit scheduler configuration scheme. For a description of both transmit scheduler configuration schemes, see Section 38.25.2.

Table 38-301.10 GbE Ethernet Controller bandwidth Management Attributes

Configuration Scheme	Switching Element Name	Bandwidth Attribute	Description
ETS-Based Scheme	SComp	Bandwidth Limit	This applies to any switching component or VSI directly attached to the physical port. Bandwidth limit for entire physical port regardless type of TC.
		ETS	Relative bandwidth allocation between TCs within switching component.
		Traffic Type Bandwidth Limit	Bandwidth limit for individual TC.
	VEB/PA	Bandwidth Limit	Bandwidth limit for entire switching component regardless type of TC.
		Traffic Type Bandwidth Allocation	Relative bandwidth allocation of switching component within each TC type.
		Traffic Type Bandwidth Limit	Bandwidth limit for switching component per TC type.
	VSI	Bandwidth Limit	Bandwidth limit for the entire VSI regardless of TC type.
		Traffic Type Bandwidth Allocation	Relative bandwidth allocation of VSI within each UP type.
		Traffic Type Bandwidth Limit	Bandwidth limit for VSI per traffic type (TC or UP).

38.25.1.2 Bandwidth Allocation

The 10 GbE controller supports configurable allocation of bandwidth to the switching elements and their virtual (ingress) ports. Each switching element gets certain portion of bandwidth allocated to its uplink port. The total bandwidth available for the switching component is shared across its ingress virtual ports. This effectively enables distribution of the egress switch port bandwidth between ingress ports (VSIs in case of virtual port exposed to PCIe functions). Each virtual port is configured with its share of the switching element bandwidth.

The default configuration assumes equal bandwidth distribution between ingress ports. This default configuration can be changed using admin queue commands defined in Chapter 38.25.4. By default, bandwidth distribution between switch virtual ports is relative, and if some of virtual ports did not use their bandwidth allocation, the remaining bandwidth can be used by other virtual ports relatively to their original bandwidth share. For example, if bandwidth allocation of three VSIs is configured to 10%, 30% and 60% respectively; and if VSI_2 (configured to 60%) does not use its bandwidth; then VSI_0 and VSI_1 can share the remaining 60% of wire bandwidth relative to their original bandwidth allocation (which was 10% for VSI_0 and 30% for VSI_1). The new bandwidth distribution would be 25% for VSI_0 and 75% for Port1.

Note that bandwidth ratio between two VSIs remains the same (1:3). In the relative bandwidth allocation mode, all entities that can be scheduled are assigned non-zero bandwidth share, see Figure 38-74 for an example of bandwidth distribution.

Bandwidth allocation is not accumulative. If a virtual port did not use its bandwidth share, for any reason (such as no work available, bandwidth limit, priority flow control, etc.), it does not accumulate any additional bandwidth and next time it becomes active, it is allowed to consume its allocated bandwidth share, regardless a period of staying idle and not using bandwidth.

Granularity of the bandwidth allocation per virtual link is 1% of the bandwidth available for that virtual link.The virtual port propagates its bandwidth allocation to the uplink egress port of the switching element, or to the PCIe function owning this virtual port. This bandwidth allocation can be in turn shared by virtual ports/VSIs of the switching element or by transmit queues of respective PCIe function.

Figure 38-74.Example of Bandwidth Distribution

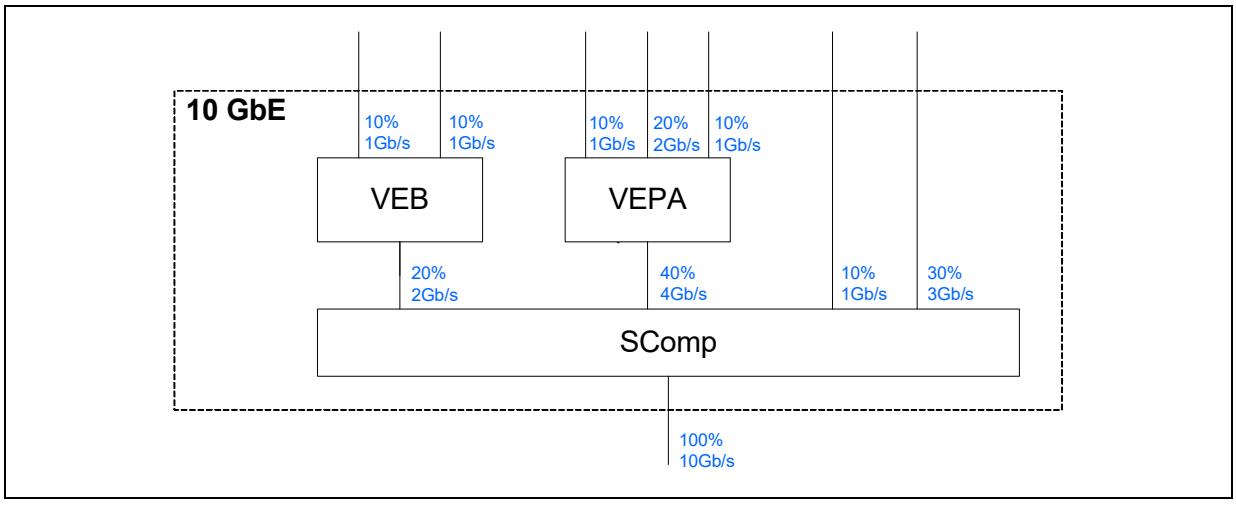


Figure 38-74 shows an example of bandwidth distribution within switching hierarchy. S-comp uplink port is connected to the 10 GbE physical port of the device, and owns all the bandwidth available on the wire. S-comp has four virtual ports: two VSIs is two S-channels connected to the VEB/VEPA switching components and bandwidth allocation for each port is as shown in Figure 38-74. Note that bandwidth distribution is relative, and each virtual port gets a percentage of the bandwidth available for the S-comp. For example if the total amount of bandwidth available for S-comp is decreased to half, then bandwidth available for each virtual port is effectively halved, or if some virtual ports will not use a bandwidth allocated for them, other virtual ports can use the remaining bandwidth. VEB switching component is configured to get 20% of the bandwidth available for the S-comp. Bandwidth available for the VEB in turn is equally distributed between VEB VSIs.

38.25.1.2.1 Arbitration Schemes

The 10 GbE controller supports three types of arbitration schemes: weighted strict priority, weighted round robin and combination of both. The arbitration scheme can be specified by software as a part of the bandwidth distribution definition.

A weighted strict priority scheme enables software to assign different bandwidth share priorities to scheduled entities. Multiple entities can be configured with weighted strict priority. Entity with higher priority is allowed to fully consume its bandwidth share before virtual port with lower priority can use a bandwidth share allocated to it. This scheme enables one or more lightly loaded ingress virtual ports with high bandwidth share priority to use its bandwidth as soon as data becomes available on those ports independent of the ports with lower priority. If a virtual port is configured to weighted strict priority, software can specify its bandwidth share to be unlimited by allocating 127 bandwidth share credits to the virtual port. Strict priority arbitration scheme is a weighted strict priority with an unlimited bandwidth allocation credits.

A weighted round robin scheme enables virtual ports to use allocated portions of bandwidth in round robin fashion. In this configuration, all virtual ports are assumed to have the same bandwidth allocation priority and ports are interleaving in round robin sequence while using a portion of the bandwidth allocated to the port.

A combined configuration enables software to specify per switching component two sets of ingress virtual ports: one sharing bandwidth using weighted strict priority scheme and another sharing bandwidth using weighted round robin scheme. Virtual ports belonging to the weighted round robin group can use their bandwidth share only if all virtual ports in weighted strict priority group either fully used their bandwidth share or cannot use their share due to other restrictions (such as no data available for the port, or the port exceeded its static rate limit).

Software is allowed to modify bandwidth allocation of the virtual port on the fly using the Admin Queue commands described in Section 38.25.4. New bandwidth allocation can take effect after a few scheduling cycles.

38.25.1.3 Static Rate Limiting

The 10 GbE controller enables the configuration of a maximum bandwidth limit for each virtual port of switching element (both ingress and egress ports) and for the TCs/UPs on ETS/SLA enabled ports. This limit specifies the maximum amount of bandwidth that can be consumed by the virtual port. Limiting maximum bandwidth of the uplink (egress) port of the switching element effectively limits the total bandwidth that can be used by all virtual (ingress) ports of that switching element. This causes propagation of the maximal bandwidth limit through the switching hierarchy. Maximum bandwidth allocated for a virtual port should not exceed the maximum bandwidth of the respective uplink port (if configured). The sum of the bandwidth limits of all virtual ports of the switching element can exceed a bandwidth limit of uplink port to enable efficient bandwidth utilization.

Maximum bandwidth limit can be configured for the ETS TC groups and TCs. See Section 38.25.1.4 for more detail.

Maximum bandwidth limits can be used to share bandwidth between VSIs. This is not the most efficient method, but it is still a supported bandwidth distribution scheme. In this case, relative bandwidth allocation should match a maximum bandwidth limit for each port, and the sum of bandwidth limits should add up to the total bandwidth available for the switching element.

Figure 38-75.Example of Limiting Maximum Bandwidth

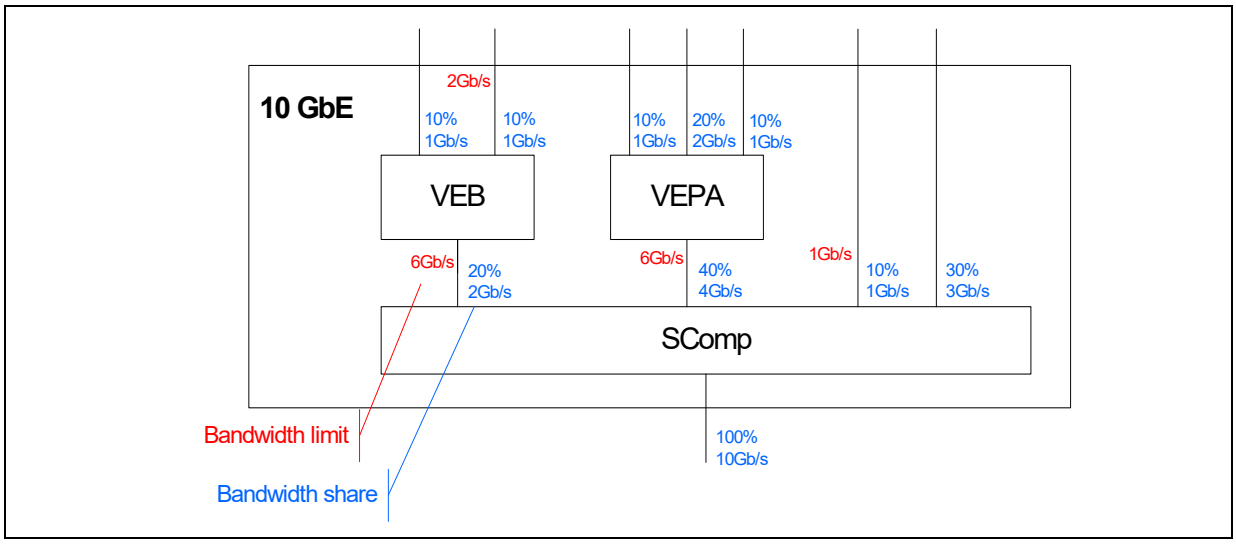

Figure 38-75 shows an example of bandwidth distribution between switching elements and their virtual ports in conjunction with limiting the maximum bandwidth available for some of virtual ports. Bandwidth limit on the uplink port of VEB limits total bandwidth available for that switching element (such as 6 Gb/s for the VEB uplink port on Figure 38-75). Some virtual ports of the switching element might be bandwidth limited as well (like the right side VSI of VEB is limited to 2 Gb/s). Bandwidth limit of an individual virtual port should be less or equal to the bandwidth limit of the switching element or its uplink port. However, the sum of bandwidth limits of the virtual ports should (for the efficient bandwidth use) exceed a bandwidth limit of the switching element. For example, the sum of bandwidth limits of S-comp virtual ports is 13 Gb/s, while the total available bandwidth is
10 Gb/s.

The 10 GbE controller enables configurable accumulation of the bandwidth limit credits. If a virtual port, with static rate limit enabled, does not use allowed bandwidth, the port can accumulate rate limiting credits and use more bandwidth than allowed by static rate limiter up to the configurable limit for the burst of quanta bytes. The 10 GbE controller maintains single quanta for the entire device; this is configured via the TSCDQUANTA register.

The 10 GbE controller static rate limiters can be configured to the minimal rate limit of 50 Mb/s with a granularity of 50 Mb/s. The maximum rate limit supported by the 10 GbE controller is 40 Gb/s.

Static bandwidth limits can be configured to VSIs and switching components in all supported configuration schemes. See Section 38.25.2 for more detail.

38.25.1.4 ETS

In a DCB enabled environment, a single physical port or VSI can be shared by multiple traffic types. The ETS standard defines sharing of the virtual or physical link bandwidth by multiple types of traffic. Different types of traffic are segregated in TCs based on UPs. Each TC is mapped to one or more UPs. Mapping of UPs to the TCs and sharing of bandwidth of VSI by TCs is defined by the ETS specification. Though ETS bandwidth allocation is defined for the egress ports of the networking devices, it also might apply to the ingress port configuration of adjacent devices sharing the same physical or virtual link.

The 10 GbE controller enables ETS to be enabled and independently configured for the uplink ports and VSIs. When enabled, ETS defines the number of TCs allocated per port, UP-to-TC mapping and distribution of port bandwidth between TCs. Due to limited amount of scheduling resources, the 10 GbE controller limits the number of TCs/UPs that can be installed to average of two per VSI.

Per-traffic type bandwidth allocation of VSIs and physical port ETS are independent, each VSI or switching component can be configured with different number of TCs and different bandwidth distribution. However, ETS configuration of the entire internal switching fabric must be consistent. For example, TCs enabled for VSI, must be enabled for respective switching components and physical port, and a total bandwidth allocated to all VSIs for particular TC must be equal to the bandwidth allocated for that TC on switching component.

The 10 GbE controller supports a mixed bandwidth allocation for the TCs, when some TCs are configured as strict priority TCs and others are configured as ETS TCs. Strict priority TCs have a scheduling priority over ETS TCs and can consume unlimited amount of bandwidth. Strict priority TCs are intended to be lightly loaded TCs carrying high priority traffic that does not consume much bandwidth. ETS TCs are sharing bandwidth unused by strict priority TCs relatively to their bandwidth share allocation. See Section 38.25.1.2.1 for the description of arbitration schemes.

38.25.1.5 Transmit Queues and Queue Sets Assignment

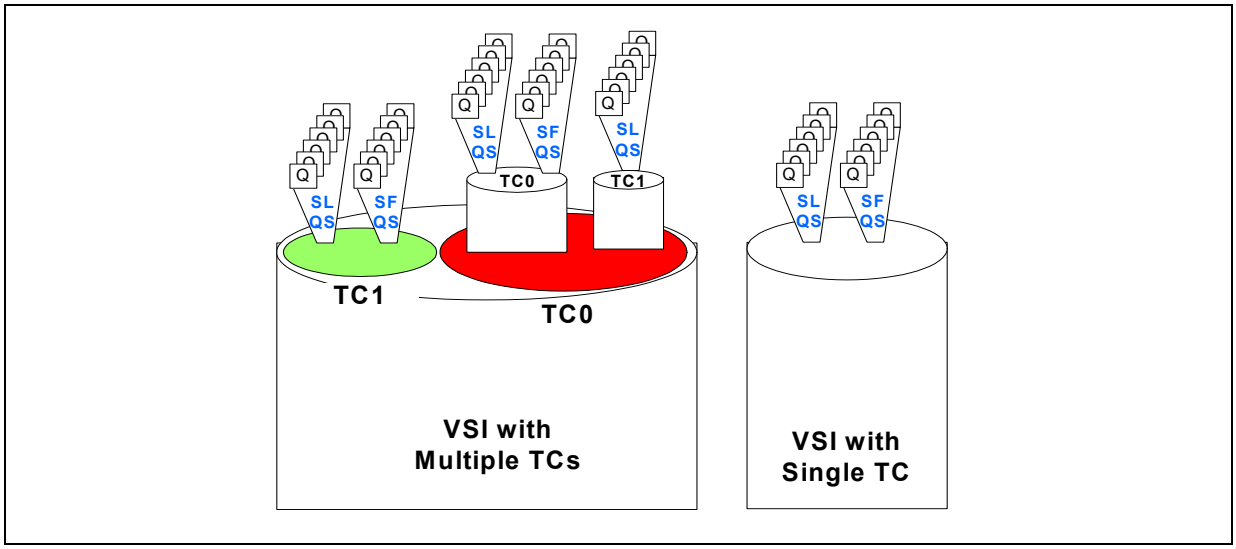
The 10 GbE controller supports two types of queue sets: stateful and stateless queue sets. Each queue set can be associated with multiple transmit queues. A stateful queue set is a set of transmit queues carrying accelerated RDMA or User-space Direct Access (UDA) traffic. A stateless queue set is a set of transmit queues carrying unaccelerated traffic generated by the networking stack.

A VSI can have multiple sets of transmit queues associated with it.

A VSI configured to the carry single type of traffic (one TC) has a one pair of transmit queue sets assigned to it: one stateful queue set and one stateless queue set.

A VSI configured to carry multiple types of traffics has one pair of queue sets allocated for each TC configured for the port.

Figure 38-76.Queue Qet Assignment Diagram



Allocation of queue sets to VSIs is managed by firmware. This is done either at VSI creation time, or when ETS/SLA configuration of the VSI is enabled or modified by software. See Section 38.25.4.8 and Section 38.25.4.17.

Bandwidth allocation between queue sets in the pair is configured separately in addition to bandwidth distribution between VSIs and ETS bandwidth distribution within VSI.

All queues assigned to the same queue set belong to the same TC, and have even bandwidth allocation.

Assignment of the queues to queue sets is performed by software.

To comply with function-level reset requirement, all queues associated with the same queue set must belong to the same PCIe function.

38.25.1.5.1 Queue Set Reassignment

Certain modifications of scheduler configuration such as changing number of TCs enabled for VSI (Section 38.25.4.8) can result in reassignment of active transmit queues from one queue set to another. Transmit queue reassignment involves changing of the transmit queue context to carry a new queue set handle.

If both queue sets remain active after configuration change, then software can perform transmit queue reassignment lazily in the background in parallel with the regular scheduling operation. Transmit queues might get scheduled once via old queue set before switching to the scheduling using a new queue set.

If an old queue set should be deallocated, then software should:

- Upon completion of the configuration change, start reassigning transmit queues to the new queue set.

- Meanwhile hardware might keep scheduling transmit queues using old queue set. The re-assigned transmit queue might be scheduled using an old queue set at most once.
- When the transmit queue reassignment completes, software should notify firmware using the Release Queue Set AQ command (Section 38.25.4.9) that it has completed its part of transition and that firmware can proceed with queue set deallocation.

Software should not request release of the queue set, if it still has transmit queues assigned to it.

38.25.2 Transmit Scheduler Configuration Schemes

The 10 GbE Ethernet Controller scheduler supports wide variety of configuration schemes. Programming interfaces described in Section 38.25.4 enable software to configure ETS-based configuration schemes described in Section 38.25.2.1.

38.25.2.1 ETS-based Scheduler Configuration Scheme

Figure 38-77 shows a logical diagram of ETS-based configuration scheme.

Figure 38-77.ETS-based Scheduler Configuration Scheme

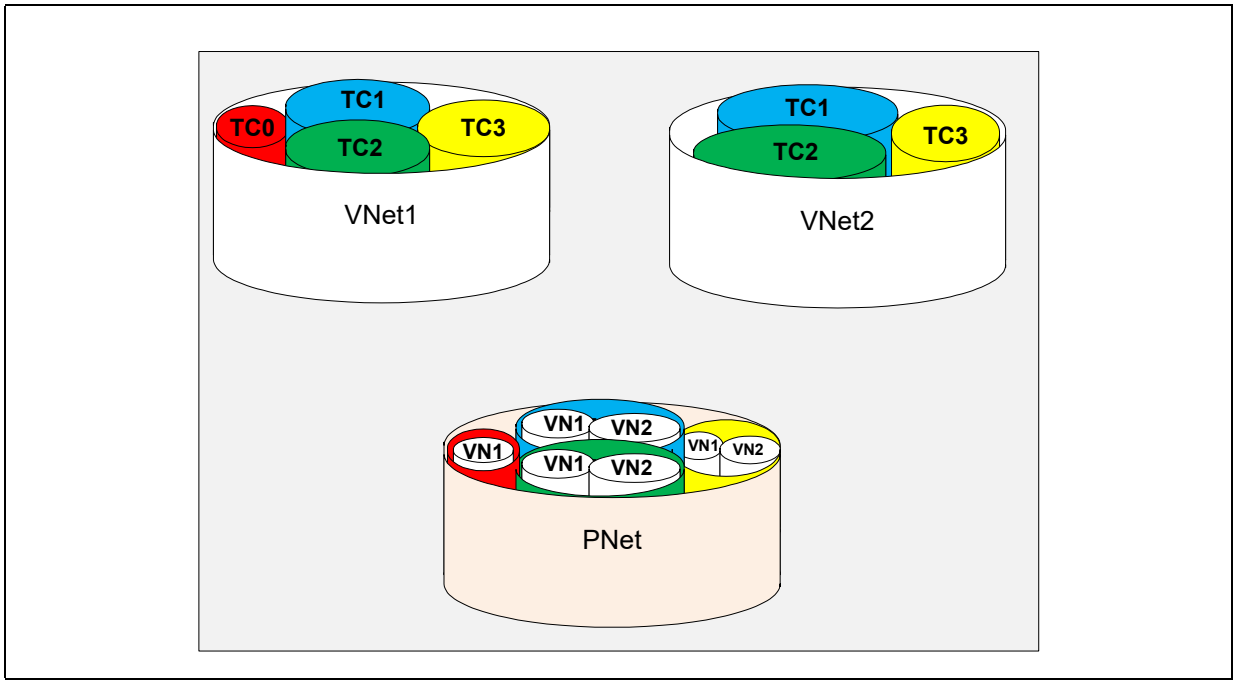


Figure 38-77 shows two virtual vetworks. Each virtual network carries multiple types of traffic. Each traffic type can be identified by its TC or UP. Virtual networks are merging to the physical network. Physical network shows a bandwidth distribution between virtual networks and their traffic types in an ETS-based scheduler configuration scheme.

In the ETS-based configuration, bandwidth is first distributed between types of traffic on the wire and then between virtual networks within each traffic type. Note that traffic type bandwidth distribution might be more complex than shown in Figure 38-77 and might include multiple bandwidth distribution layers. These might include bandwidth

distribution between TCs and then between UPs within a TC. Similarly, bandwidth distribution between virtual networks might involve multiple bandwidth distribution levels (such as virtual switches and their virtual ports).

If a virtual network does not have traffic currently available of a particular traffic type (like VNet2.TC3), then the physical network attempts to preserve ratio of bandwidth allocated for that traffic type and the remaining bandwidth is distributed between other virtual networks having the same traffic type available (like VNet1.TC3).

Such per-traffic type bandwidth distribution does not guarantee any bandwidth allocation for the virtual network, but does allow full control over traffic distribution on the wire per traffic type (ETS). This scheme does guarantee virtual network bandwidth allocation per type of traffic (TC or UP).

This configuration is very suitable for the DCB-enabled fabric. As long as traffic is available for each traffic type enabled on the virtual network the bandwidth distribution on the physical wire matches the ETS configuration of the physical port.

The ETS-based configuration scheme enables designers to configure an ETS for the switching component or VSI connected to the physical port, and hierarchically distribute per-traffic type bandwidth between all other switching components (VEB/PA and port extender) and VSIs.

Figure 38-78 shows an example of bandwidth distribution in an ETS-based scheduler configuration scheme.

Figure 38-78.ETS-based Bandwidth Configuration Example

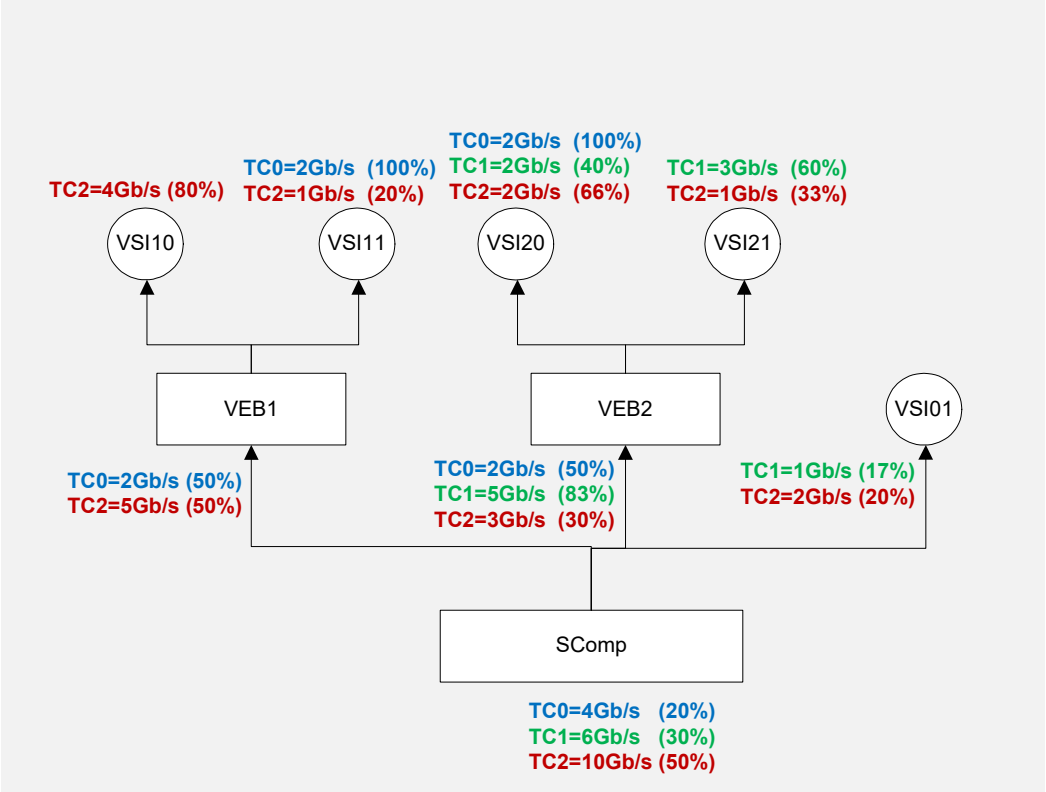

Figure 38-78 shows a single port configuration with S-comp. Two VEB switching components are connected to S-comp (VEB1 and VEB2), along with VSI (VSI01). Each VEB has two VSIs (VSI10 and VSI11, and VSI20 and VSI21, respectively). Each one of the switching components is configured with bandwidth allocation per traffic type. The physical port is configured with ETS, showing one level of bandwidth distribution (per TC). The physical port can be configured with two level ETS including bandwidth allocation per TC, and bandwidth allocation per UP within respective TC.

Bandwidth allocation between switching components and VSIs on each level of switching topology is relative within same TC and hierarchical. Figure 38-78 shows an example bandwidth allocation in Gb/s and relative percentage. Color coding helps to visualize bandwidth distribution between switching components and VSIs within TC.

- S-comp level.
- Physical wire bandwidth is 20 Gb/s. This bandwidth is distributed between three TCs enabled for S-comp (TC0, TC1 and TC2) accordingly with wire ETS configuration.
- TC0=20%, TC1=30% and TC2=50%, total of 100% bandwidth available on the wire
- VEB Level (VEB1, VEB2 VSI01).
- Per TC bandwidth is distributed between VEBs and VSI. Bandwidth distribution is relative. Total of 100% of bandwidth per TC.
  - TC0: VEB1=50%, VEB2=50%
  - TC1: VEB2=83%, VSI01=17%
  - TC2: VEB1=50%, VEB2=30%, VSI01=20%

Total effective bandwidth (in Gb/s) allocated for TCs on VEB level equals to the bandwidth allocated per TC for S-comp. (such as VEB1.TC0 + VEB2.TC0 = SComp.TC0, VEB2.TC1 + VSI01.TC1 = SComp.TC1, and VEB1.TC2 + VEB2.TC2 + VSI01.TC2 = SComp.TC2).

- VSI Level (VSI10, VSI11) and (VSI20, VSI21).
- Per TC bandwidth is distributed between VSIs within respective VEB. Bandwidth allocation for each TC is relative within VEB.
- VEB1 VSIs:
  - TC0: VSI11=100%
  - TC1: 0%
  - TC2: VSI10=80%, VSI11=20%
- Total effective bandwidth (in Gb/s) allocated for TCs on VEB1 VSI level (VSI10 and VSI11) equals to the bandwidth allocated per TC for VEB1. (such as VSI10.TC0 + VSI11.TC0 = VEB1.TC0, and VSI11.TC2 = VEB1.TC2)
- VEB2 VSIs:
  - TC0: VSI20=100%
  - TC1: VSI20=40%, VSI21=60%
  - TC2: VSI20=66%, VSI21=33%

Total effective bandwidth (in Gb/s) allocated for TCs on VEB2 VSI level (VSI20 and VSI21) equals to the bandwidth allocated per TC for VEB2. (such as VSI20.TC0 = VEB2.TC0, VSI20.TC1 + VSI21.TC1 = VEB2.TC1, and VSI20.TC2 + VSI21.TC2 = VEB2.TC2).

Bandwidth allocation must be consistent. Bandwidth allocated to the TC on the S-comp level, must be equal to the total bandwidth allocated for the same TC on the level of VEBs and VSIs connected directly to the S-comp (VEB1, VEB2 and VSI01). Bandwidth allocated to the TC on VEB (VEB1) level must be equal to the total bandwidth allocated to that TC on VSI level (VSI10 and VSI11).

The ETS-based scheduler configuration scheme does not support bandwidth allocation per switching component or VSI. It supports only bandwidth allocation for switching component or VSI within particular TC.

ETS-based scheduler configuration scheme enables software to instantiate bandwidth limits for each of the switching components and VSIs. Bandwidth limit can be programmed to restrict total bandwidth available for switching component and VSI, or limit bandwidth available for the switching component or VSI for the particular type of traffic, identified by UP or TC.

38.25.3 Scheduling

The The 10 GbE controller scheduler operates with queue sets. Every scheduling cycle scheduler selects a next queue set to be served. The amount of traffic that can be generated on the wire by transmit queues associated with the selected queue set is limited to the configurable value (Quanta). Selection of the queue set is based on the bandwidth share, bandwidth limit and ETS configuration of the VSI and uplink ports of the internal switching components. The scheduler fairly distributes available bandwidth among queue sets that have transmit queues with work available staying within limits of the bandwidth allocation dictated by bandwidth limit, bandwidth share and ETS constraints. Bandwidth distribution between queues within same queue set is intended to be even.

The scheduler limits amount of data that can be transmitted by selected queue set to the configurable value (Quanta). Single quanta might enable transmission of multiple Ethernet frames. Quanta constrains the amount of burst of the traffic generated by the 10 GbE controller. Independent of the rate limit implied on the queue set, the 10 GbE controller transmits a Quanta worth of data with the wire speed of the associated physical port.The default Quanta value is 4 KB.

Scheduler configuration is derived from the configuration of internal switching elements, and in most cases follows hierarchy of the switching elements.

The 10 GbE controller does not schedule individual packets. All packets belonging to the same transmit queue follow same route within internal switching hierarchy and are subject to the same set of bandwidth constraints.

When the 10 GbE controller transmits packet from one of the transmit queues of the selected queue set, it effectively uses bandwidth of all switching components in internal switching hierarchy leading from the virtual port that queue set is associated with to the physical port of the device. Bandwidth constraints applied to the switching component on the route from the queue set to physical port of the device automatically apply to the queue set. This means that a particular queue set can be scheduled only if there is enough bandwidth available in all switching components on the transmission route.

The scheduler is aware of the PFC, and stops scheduling queue sets associated with a paused TC to avoid head of line blocking in pipeline.

38.25.3.1 Scheduler Configuration Process

The scheduler implements one set of configuration tables shared by all PCIe functions. To synchronize access to the shared configuration table and keep configuration consistent, direct access to the internal scheduler configuration is restricted to firmware.

The scheduler does not expose its internal configuration tables to the standard deployment software. A set of registers enabling a direct access to the internal scheduler structures is exposed to firmware to enable programming of the scheduler configuration tables. Those registers are exposed in debug mode to bring up and other privileged software. A default configuration of the scheduling tables is done by firmware and based on the internal switch and scheduling configuration profiles kept in NVRAM. Software is allowed to modify the default configuration by proxying its requests through firmware using Admin Queue commands. Software should use an admin queue interface to communicate its scheduler configuration requests with firmware. Firmware is responsible to constrain access to the scheduling configuration tables based on the software privilege level.

The 10 GbE controller maintains single Quanta for entire device, configured via the TSCDQUANTA register. Quanta accounts for payload and headers generated by software for the LAN traffic and payload and headers generated by PE for RDMA traffic. Quanta does not account for the L2 tags, Ethernet, MPA, CRCs, MPA markers and RDMA padding inserted by hardware on the fly.

The scheduler is intended to be configured by a PF driver using the Admin Queue commands described in Section 38.25.4. A PF driver is considered to be a trusted software, and firmware should accept requested configuration changes. Most of the switching components are owned either by single PF or by one of the VFs associated with same PFs. If a switching component is shared among physical functions, this component is either configured by an EVB agent running in firmware, or by service running in one of the PFs. In the later case, firmware relies on software to coordinate scheduler configuration among different PFs.

Most of the scheduler configuration is fully controlled by a PF driver in the standard deployment environment. If a VF driver or configuration software running in VFs is granted control over one of the scheduling configuration parameters (such as the ETS/SLA configuration of the virtual port, scheduler configuration commands should be proxied via PF driver).

The scheduler supports up to 768 pairs of queue sets, regardless of the number of queue sets populated in each pair.

38.25.4 Admin Queue Commands

The internal structure of the scheduler configuration tables is not exposed to software. Firmware is responsible for the scheduler configuration and provides software with admin queue interface enabling alter scheduler configuration. In some configurations, a privileged software is allowed to perform direct programming of the scheduler configuration tables bypassing firmware. Firmware or privileged software should maintain a mapping table of the scheduling resources assigned to each PCIe function.

This section defines admin queue commands that should be used by software to program scheduler configuration attributes.

A standard Product Name scheduler configuration is based on the configuration of the internal switch and its components including instantiated switching components, their VSIs, S-channels, and connectivity between internal switching component. Scheduler configuration adds bandwidth management attributes to the configured switching components, including allocation of bandwidth for the switching components, and their VSIs, enablement and configuring ETS or bandwidth allocation per TC, and instantiation of rate limiters.

The AQ commands described in this section are intended to be used by PF driver only. A VF driver is not allowed to directly participate in scheduler configuration. The PF driver is considered to be a trusted software component within this PF. Firmware validates that AQ commands impacting configuration of the components owned by the PF driver issuing those commands. This is done using association of the AQ with particular PF and information kept in the switch configuration tables. When PF performs configuration on behalf of VF, corresponding VF must be provided within an AQ command.

Table 38-302 lists the AQ commands enabling configuration of internal scheduler structures.

Firmware must avoid partial command execution. All command validation and resource availability checks must be done prior to updating scheduler configuration tables. Note that aborting a command with a partially updated scheduler configuration table might lead to unpredictable hardware behavior.

Table 38-302.Scheduler Configuration Admin Queue Commands (Sheet 1 of 2)

Command	Opcode	Brief Description	Detailed Description
Configure VSI Bandwidth Limit	0x0400	This command enables software to configure bandwidth limit to the specified VSI of the specified switch component. This is a global bandwidth limit that applies to all TCs enabled for VSI.	Section 38.25.4.6
Configure VSI Bandwidth Limit Per Traffic Type	0x0406	This command enables configuration bandwidth limits assigned to TCs of the specified VSI exposed to PCIe interface.	Section 38.25.4.7
Configure VSI Bandwidth Allocation Pper Traffic Type	0x0407	This command enables specifying traffic types enabled for VSI and configure relative bandwidth allocation of VSI within each TC type. This command is valid for ETS-based configuration only.	Section 38.25.4.8
Query VSI Bandwidth Configuration	0x0408	This command enables retrieving configuration of the specified VSI of the specified switching component. This configuration should include bandwidth limit and bandwidth allocation.	Section 38.25.4.15
Query VSI Bandwidth Configuration Per Traffic Type	0x040A	This command enables retrieving current bandwidth configuration of VSI within each TC type. This command is valid for ETS-based configuration only.	Section 38.25.4.16
Configure Switching Component Bandwidth Limit	0x0410	This command enables software to enable, disable or modify bandwidth limit of the egress port of specified switching component. This is a global bandwidth limit that applies to all TCs enabled for a switching component.	Section 38.25.4.9
Enable Physical Port ETS	0x0413	This command enables ETS configuration of the egress port of the specified switching component or VSI directly connected to the physical port. It carries full specification of ETS configuration for the port, including number of TCs. user priority to TC mapping, TC bandwidth allocation, TC arbitration scheme, and bandwidth allocation. This command is valid for switching components directly connected to the physical port only. This command is valid in ETS-Based configuration only.	Section 38.25.4.10

Table 38-302.Scheduler Configuration Admin Queue Commands (Sheet 2 of 2)

Command	Opcode	Brief Description	Detailed Description
Modify Physical Port ETS	0x0414	This command enables modifying ETS configuration of the egress port of the specified switching component or VSI directly connected to the physical port. It carries full specification of ETS configuration for the port, including number of TCs. UP to TC mapping, TC bandwidth allocation, TC arbitration scheme, and bandwidth allocation. This command is valid for switching components directly connected to the physical port only. This command is valid in ETS-Based configuration only.	Section 38.25.4.10
Disable Physical Port ETS	0x0415	This command enables disabled ETS configuration of the egress port of the specified switching component or VSI directly connected to the physical port. It carries full specification of ETS configuration for the port, including number of TCs. user priority to TC mapping, TC bandwidth allocation, TC arbitration scheme, and bandwidth allocation. This command is valid for switching components directly connected to the physical port only. This command is valid in ETS-based configuration only.	Section 38.25.4.10
Configure Switching Component Bandwidth Limit Per Traffic Type	0x0416	This command enables enabling, disabling or modifying bandwidth limits assigned to TCs of the egress port of the specified switching component. This command is valid in ETS-based configuration only.	Section 38.25.4.13
Configure Switching Component Bandwidth Allocation Per Traffic Type	0x0417	This command enables specifying traffic types enabled for switching components and configure relative bandwidth allocation of switching components within each TC type. This command is valid for ETS-Based configuration only.	Section 38.25.4.14
Suspend Port's TX Traffic	0x041B	This command enables PF to suspend a port's transmit traffic. The command is completed after all Qsets belonging to the port are suspended and the Tx pipe of the port is drained. This enable software to modify a port's configuration like DCB setting. This command is valid only under SFP mode.	Section 38.25.4.11
Resume PF Traffic	0x041C	This command is used to resume suspended Qsets. It resumes all Qsets belonging to the PF.	Section 38.25.4.12
Query Switching Component Bandwidth Configuration	0x0418	This command enables retrieving current configuration of the switching component.	Section 38.25.4.17
Query Physical Port ETS Configuration	0x0419	This command enables retrieving current ETS configuration of the switching component. This should include number of valid TCs bandwidth allocation and bandwidth limit for TCs. This command is valid for switching components directly connected to the physical port only. This command is valid in ETS-based configuration only.	Section 38.25.4.18
Query Switching Component Bandwidth Configuration per Traffic Type	0x041A	This command enables retrieving current bandwidth configuration of a switching component within each TC type. This command is valid for ETS-Based configuration only. This command is valid only under SFP mode.	Section 38.25.4.19
Add VSI	0x0210	This is a switch configuration command. Execution of this command affects scheduler configuration. This command allocates VSI and returns a VSI SEID that should be used to modify VSI bandwidth configuration.	Section 38.25.4.2
Add VEB, Add_PE	0x0210	This is a switch configuration command. Execution of this command affects scheduler configuration. This command allocates switching component, and returns SEID that should be used to modify switching component bandwidth configuration.	Section 38.25.4.2
Delete Element	0x0210	This is a switch configuration command. Execution of this command affects scheduler configuration.This command deallocates switching elements including VSIs. Deallocation of the switching element results in deallocation of he scheduling resources associated with this switching element, and cleanup of scheduler configuration tables.	Section 38.25.4.2

38.25.4.1 Scheduler Initialization Flow

Main scheduler configuration and initialization flows are initiated by software and performed by firmware using AQ interface. The sections that follow define various AQ commands that can be used by software to configure the transmit scheduler.

Prior to initialization of AQ command interface, firmware can use information available in NVRAM to perform default configuration of the scheduler. Similar to the standard configuration, default scheduler configuration follows a default configuration of the switching components.

38.25.4.2 Allocation of Switching Elements

A default configuration of the scheduler tables is performed as a part of the internal switch configuration. Each time software adds a new switching component or VSI to the internal switch, the configuration tables of the scheduler are updated respectively by firmware. A new added switching component or VSI is configured with a default bandwidth allocation and bandwidth limit disabled. The allocated switching component or VSI is created with single TC enabled (TC0). Software can enable TCs either by using the bitmask in the Add VSI or Add VEB/PA commands, or by using the AQ command described in Section 38.25.4.7 and Section 38.25.4.14. Along with default bandwidth, distribution firmware allocates a pair of queue sets for each configured TC of the new allocated VSI.

With completion of a switching element allocation request, software is provided with a handle per allocated queue set. The queue set handle should be used to associate a queue with a queue set.

A default bandwidth allocation provides a new instantiated switching component and VSI with a minimal bandwidth share with respect to other switching components or ports sharing same virtual link. Software can modify the default bandwidth allocations using the Admin Queue command described in Section 38.25.4.8 and Section 38.25.4.14.

Initial configuration of the scheduler tables is done as a part of the initial configuration of the internal switch and is based on the device profiles. No software involvement is required to perform initial scheduler configuration. As soon as firmware completes initial configuration, scheduler is enabled and ready to schedule transmit work.

Software is allowed to change internal switch configuration or modify scheduler configuration by adding/removing internal switching components and/or VSIs, or by changing bandwidth distribution, bandwidth limits and ETS configuration of physical port, switching components or VSIs. Some configuration changes, causing modification of the internal switching structure, might require firmware to partially or fully suspend scheduler operation until it completes a local or global modification of the internal scheduler tables. Certain scheduler configuration changes, such as bandwidth redistribution, or modification of the bandwidth limit, can be done without suspending normal scheduler operation.

Firmware is responsible to track allocated resources and their configuration, and manage configuration of internal scheduler tables. If software performs incremental modification of the internal switching structure, it should rely on firmware to maintain consistency of internal scheduler tables, and fit requested modifications to the existing configuration. Each allocated switching element, including instance of internal switch or VSI is assigned a unique within the device identification number (SEID). SEID should be used by software when referencing to the switching component during scheduler configuration.

38.25.4.2.1 Queue Set Assignment

As a part of the default scheduler configuration, each instantiated VSI is supplied with a pair of queue sets per configured TC: one for stateless and one for the stateful queues. Firmware manages the shared pool of the queue sets. Allocation and deallocation of queue sets is hidden from software, and done based on the software resource allocation/deallocation requests. Handles of allocated queue sets are returned to software as a part of completion of Admin Queue command and should be used by software to associate transmit queues and queue sets. Firmware allocates a single queue set handle to the LAN/PE queue sets pair.

Software can change a default configuration of the VSI. (like change the number of configured TCs). A change in VSI configuration results in changing the number of TCs allocated for the port, causing firmware to reallocate queue sets assigned to the VSI to match number of TCs.

Allocated queue set handles are provided in completion of respective AQ command. Firmware always returns eight queue set handles. Order of handles returned matching an order of TCs enabled for VSI (from 0 to 7). Invalid queue set handles carry value of 0xFFFF. Queue set handles are returned for all AQ commands that can be result in allocation or change of allocation of queue sets (create VSI, configure VSI bandwidth allocation per traffic type, configure VSI bandwidth limit per traffic type). For more detail see Section 38.25.4.7 and Section 38.25.4.8. Software can also use AQ command to query queue sets allocated for particular VSI, see Section 38.25.4.16.

Queue set assignment is completely hidden from software. Software should use a queue set handle when referring to the particular queue set.

Assignment of queues to queue sets is not described here, and outside of the scope of the scheduler configuration definition. If software changes configuration of the VSI and this change results in reallocation of queue sets, as long as TC remains assigned to the VSI, all queues associated with the queue set identified by the VSI and TC remain associated with the queue set. If software modifies the VSI configuration and eliminates the TC, which has an active queue associated with, software must resolve contention and reassign queues.

38.25.4.3 Release of the Switching Elements

Software can use the AQ Commands Delete Element and the Configure Bandwidth Allocation/Limit of the VSI/Switching Component per Traffic Type to remove switching components and VSIs or change their configuration per traffic type. Removal of the switching component or VSI is allowed only if the respective uplink switching element has been previously removed or a traffic type configuration has been previously adjusted to the uplink switching element. For example, if software decides to change VEB configuration per traffic type and reduce number of traffic types enabled for VEB, it must first respectively adjust traffic types for all VSIs allocated for that VEB. Software might request to remove VEB, only after it removed all VSIs allocated for that VEB.

Software might also request to remove VSI only if the queue set associated with that VSI has all transmit queues removed, see Section 38.25.4.3.1.

38.25.4.3.1 Queue Set Release

Certain modifications to the scheduler configuration, such as change in number of TCs enabled for the VSI, or change in TC mapping or VSI deallocation, might lead to release of the queue set previously allocated for VSI.

Prior to performing any operation that might require release of the queue set, software must remove from the queue set all queues that were previously associated with the queue set. Operation of the queue removal depends on the queue type. For the LAN, this operation requires Q disable. For the PE Qs, Q might have transmission suspended. In any case, software must either suspend or disable all Qs that were previously associated with the queue set. Completion of Q suspend or Q disable operation must be confirmed by hardware.

Scheduler configuration firmware validates that a queue set subject to release does not have Qs associated with, and fails the requested operation, reporting EBUSY error, if it does.

38.25.4.4 Common Processing and Error Handling

All Transmit Scheduler Admin Queue Commands described in the sections that follow are derived from the generic Admin Queue commands, and using a generic Admin Queue Command structure as a baseline.

Sections describing Transmit Scheduler Admin Queue commands are relating to the Admin Queue command fields that are specific to the particular command.

The transmit scheduler uses various types of Admin Queue commands. Some of them Direct Admin Queue commands (all command information is provided within the body of command) and some indirect (additional data is provided within the buffer referred by Admin Queue command). Some commands report completion within Admin Queue command body and others carry completion information within buffer provided by original command. Each Transmit Scheduler Admin Queue command indicates its type in the command description.

Table 38-303 lists errors specific to Transmit Scheduler Admin Queue commands and reported in Admin Queue Completions, providing their cause and a reported error code.

Table 38-303.Transmit Scheduler Admin Queue Completion Errors

Error Name	Error Code	Description
Invalid Handle	ENOENT	Upon allocation of the transmit scheduler resources software is provided with various handles, such as TC handle, UP handle, QS handle. Those handles must be used by software for the future reference to the allocated resources. This error indicates that handle provided by software is not valid.
Invalid SEID	ENOENT	SEID provided within Admin Queue command is not valid.
Parameter Out Of Range	ERANGE	Provided argument does not match definition (not within allowed range).
Resource Allocation Failure	ENOSPC	Failed to allocate transmit scheduler resource.
Operation Not Permitted	EPERM	Depending on the scheduler configuration scheme, certain AQ commands should not be used by software (like in ETS-based configuration software should not attempt configure bandwidth allocation to VSI or switching component). This error indicates that software attempted AQ command that is not valid in the current operation.
Resource Is Busy	EBUSY	Software attempted to release a queue set that had Qs associated with it.

38.25.4.5 Function-level Reset

Transmit scheduler configuration tables are updated by firmware as a part of the function-level reset processing by the 10 GbE controller. All scheduling resources allocated for a particular function are released during this process, including VSIs and Queue Sets. Respective resources can be later on allocated to the different PCI Functions.

Scheduler operation is not suspended during function-level reset but its performance and bandwidth distribution might be intermittently affected. Upon completion of function-level reset processing, the transmit scheduler completes its normal operation.

38.25.4.6 Configure VSI Bandwidth Limit

This command enables software to configure a bandwidth limit for the specified VSI of the switch component that is exposed to PCIe interface. To configure bandwidth limit of the egress port, software should use the command described in Section 38.25.4.9. The 10 GbE controller provides hierarchical bandwidth limit, that apply to VSI and all associated TCs and UPs. See Section 38.25.1.3.

Software cannot have both a bandwidth limit and bandwidth limit per traffic type enabled for the same VSI. A request to enable bandwidth limit for VSI that has bandwidth limit per traffic type enabled should fail and report an EPERM error.

In that case, the PF uses more than one TC (such as an iSCSI PF that must be opened for Storage TC and LAN TC as well).

- PF is allowed to enable more than one TC. According enabled UP's and UP to TC mapping.
- Bandwidth relative allocation defined for this PF and the Alt RAM is configured for each one of the used TC's.
- Max bandwidth for the PF is declared as shared rate limiter.

This is a Direct Admin Queue command with completion reported within the completion descriptor structure. Table 38-304 lists the command format and defines command specific fields.

Table 38-304.Configure VSI Bandwidth Limit Command Fields (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0400	Command opcode.
Datalen	4-5	0	Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
VSI SEID	16-17		Unique identifier of the VSI.
Reserved1	18-19	0	Reserved. Must be set to 0.
Bandwidth Limit Credits	20-21		Bandwidth limit in Mb/s. Supported range is 50 Mb/s - 40 Gb/s, in increments of 50 Mb/s. 0 indicates that bandwidth limit is disabled. One credit corresponds to bandwidth limit of 50 Mb/s.

Table 38-304.Configure VSI Bandwidth Limit Command Fields (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Bandwidth Limit Max	24.0-24.2		Maximum bandwidth limit indicates how much bandwidth limit credits can be accumulated due to inactivity. Single scheduling Quanta consumes multiple bandwidth limit credits. The 10 GbE controller enables accumulating of following discrete values of Quanta-worth credits: 0,1, 2, and 4 Quanta worth credits. This field is valid, only if bandwidth limit is enabled.
Reserved2	24.3-31	0	Reserved. Must be set to 0.

38.25.4.7 Configure VSI Bandwidth Limit per Traffic Type

This command enables software to specify TCs enabled for VSI and configure a bandwidth limits of TCs enabled for the specified VSI of the switching component.

In an ETS-based configuration scheme, software can configure either VSI bandwidth limit or VSI bandwidth limit per traffic type.

Software should keep track of already configured bandwidth limits and provide complete bandwidth limit configuration, and not just do incremental modifications.

Software is allowed to change the bandwidth limit per traffic type and TCs enabled for VSI that has a VSI bandwidth allocation configured. A new TCs enabled for VSI has a default bandwidth allocated. Software should use a Configure VSI Bandwidth Allocation per VSI AQ command to modify a default bandwidth allocation.

Software should not request change of TC configuration of VSI leading to release or remapping of TCs, prior to disassociating Qs with affected queue sets. Operation fails with EBUSY error, if software requested to release queue sets having Qs associated with.

The only exception for the previous rule is when remapping of only one TC is required. In this case, software is allowed to use this command when this queue set is suspended and the 10 GbE controller transmit pipeline is drained from packets belongs to this queue set. After the TC remapping takes place, software can resume its transmit activity using the command Resume PF Traffic Section 38.25.4.12. EMP firmware is required to keep remapped TCs queue set handles for its new location. If TC re-configuration is needed while the VSI is suspended then new generated TC nodes of this VSI is suspended too.

Software cannot have both bandwidth limit and bandwidth limit per traffic type enabled for the same VSI. Request to enable bandwidth limit per traffic type for VSI that has bandwidth limit enabled should fail and EPERM error reported in completion.

This is an Indirect Admin Queue command. Software should provide a valid buffer carrying additional command attributes as listed in Table 38-306.

Table 38-305 lists the command format, and defines fields specific to the command.

Table 38-305.Configure VSI Bandwidth Limits per Traffic Type Command Fields (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0406	Command opcode.
Datalen	4-5		Length of response buffer.

Table 38-305.Configure VSI Bandwidth Limits per Traffic Type Command Fields (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
VSI SEID	16-17		Unique identifier of the VSI.
Reserved1	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-306 lists the format of the command buffer and additional command attributes.

Table 38-306.Configure VSI Bandwidth Limit per Traffic Type Command Buffer (Sheet 1 of 2)

Category	Byte/Bit	Field	Description
TC Valid	0.0-0.7	TC0-TC7 Valid	Valid bit per TC. Should list all TCs enabled for VSI. Must be consistent with physical port and uplink switching component.
Reserved1	1-15	0	Reserved. Must be set to 0.
TC Bandwidth Limit Credits	16-17	TC0 BW Limit Credits	This field specifies a bandwidth limit per TC in Mb/s. Supported bandwidth limit range is 50 Mb/s-40 Gb/s, with increments of 50 Mb/s. Bandwidth limit of 0 Mb/s indicates that bandwidth limit is disabled. Bandwidth limit should be provided for the valid TC handles only. One credit corresponds to bandwidth limit of 50 Mb/s.
	18-19	TC1 BW Limit Credits	
	20-21	TC2 BW Limit Credits	
	22-23	TC3 BW Limit Credits	
	24-25	TC4 BW Limit Credits	
	26-27	TC5 BW Limit Credits	
	28-29	TC6 BW Limit Credits	
	30-31	TC7 BW Limit Credits	
TC Max Bandwidth Limit	32.0-32.2	TC0 Max BW Limit	Maximum bandwidth limit indicates how much bandwidth limit credits can be accumulated due to inactivity. Single scheduling Quanta consumes multiple bandwidth limit credits. The 10 GbE controller enables accumulating of following discrete values of Quanta-worth credits: 0,1, 2, 4, 8,16 32 and 64 Quanta worth credits.
	32.3	Reserved	
	32.4-32.6	TC1 Max BW Limit

	33.0-33.2	TC2 Max BW Limit	
	33.3	Reserved	
	33.4-33.6	TC3 Max BW Limit	
	33.7	Reserved	
	34.0-34.2	TC4 Max BW Limit	
	34.3	Reserved	
	34.4-34.6	TC5 Max BW Limit	
	34.7	Reserved	
	35.0-35.2	TC6 Max BW Limit	
	35.3	Reserved	
	35.4-35.6	TC7 Max BW Limit	
	35.7	Reserved	

Table 38-306.Configure VSI Bandwidth Limit per Traffic Type Command Buffer (Sheet 2 of 2)

Category	Byte/Bit	Field	Description
Reserved2	36-63	0	Reserved. Must be set to 0.

Table 38-307 lists the format of completion returned in response buffer.

Table 38-307.Configure VSI Bandwidth Limit per Traffic Type Completion Buffer

Category	Byte/ Bit	Field	Description
QueueSet Handles	16-17	QS0 Handle	Handle per queue set. Completion always carries eight queue set handles. Only TCs that were marked as a valid TCs in the command have valid queue set handles returned in completion. Invalid handles are marked by 0xFFFF. Order of queue set handles matches order of TCs. Queue set handles must be used by software to associated transmit Q with queue set.
	18-19	QS1 Handle	
	20-21	QS2 Handle	
	22-23	QS3 Handle	
	24-25	QS4 Handle	
	26-27	QS5 Handle	
	28-29	QS6 Handle	
	30-31	QS7 Handle	

38.25.4.8 Configure VSI Bandwidth Allocation per Traffic Type

This command enables software to specify TCs enabled for VSI, and configure relative bandwidth allocation of VSIs within each TC.

This command can be used for VSI configured in ETS-based mode only. Otherwise the command is ignored and error is reported.

To configure VSI bandwidth allocation per traffic type, software should provide complete relative bandwidth allocation for all TCs enabled for VSI.

This is an Indirect Admin Queue command. Software should provide a buffer that would be used both to provide additional command attributes and for the command completion.

Software is allowed to change bandwidth allocation per traffic type and TCs enabled for VSI that has a VSI bandwidth limit enabled. It is responsibility of firmware to adjust hardware configuration to reflect this change.

Software should not request a TC configuration change of a VSI leading to release or remapping of TCs, prior to disassociating Qs with affected queue sets. Operation fails with a EBUSY error, if software requested to release queue sets having Qs associated with.

The only exception for the previous rule is when remapping of only one TC is required. In this case, software is allowed to use this command when this queue set is suspended and the 10 GbE controller transmit pipeline is drained from packets belongs to this queue set. After the TC remapping takes place, software can resume its transmit activity using the command Resume PF Traffic described in Section 38.25.4.12. EMP firmware is required to keep remapped TCs queue set handle for its new location. Currently the 10 GbE controller supports transmit pipe draining in port's granularity. This is used by DCBX flows described in Section 38.25.5.6.1.

In that case, the PF uses more than one TC (such as an iSCSI PF that must be opened for Storage TC and LAN TC as well).

- PF is allowed to enable more than one TC. According to enabled UP's and UP to TC mapping.
- Bandwidth relative allocation defined for this PF in the Alt RAM is configured for each one of the used TC's.
- Maximum bandwidth for the PF is declared as a shared rate limiter.

If TC re-configuration is needed while the VSI is suspended then new generated TC nodes of this VSI is also suspended.

Table 38-308 lists the command format and defines a command specific fields.

Table 38-308.Configure VSI Bandwidth Allocation per Traffic Type Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0407	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by fFirmware.

	26-27	QS5 Handle	
	28-29	QS6 Handle	
	30-31	QS7 Handle	

38.25.4.9 Configure Switching Component Bandwidth Limit

This command allows software to enable, disable or modify a bandwidth limit for the specified switch component. By enabling bandwidth limit of switching component, software effectively enables a bandwidth limit on the egress port of the switching component.

This command allows software to enable a global bandwidth limit regardless the traffic type. to enable a bandwidth limit per traffic type, software should use command described in Section 38.25.4.13.

Software cannot have both bandwidth limit and bandwidth limit per traffic type enabled for the same switching component. Request to enable bandwidth limit for a switching component that has bandwidth limit per traffic type enabled fails.

In that case, the PF uses more than one TC (such as an iSCSI PF that must be opened for Storage TC and LAN TC as well).

- PF is allowed to enable more than one TC. According enabled UP's and UP to TC mapping.
- Bandwidth relative allocation defined for this PF in the Alt RAM is configured for each one of the used TC's.
- Maximum bandwidth for the PF is declared as a shared rate limiter.

The 10 GbE controller provides a hierarchical bandwidth limit. Configuring a bandwidth limit to the switching component, software automatically limits the total bandwidth available for all VSI allocated for that switching component. See Section 38.25.1.3.

This is a Direct Admin Queue command with completion reported within the completion descriptor structure. Table 38-311 lists the command format and defines command specific fields.

Table 38-311.Configure Switching Component Bandwidth Limit Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0410	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switching Component SEID	16-17		Unique identifier of the switching component.
Reserved1	18-19	0	Reserved. Must be set to 0.
Bandwidth Limit Credits	20-21		Bandwidth limit in Mb/s. Supported range is 50 Mb/s - 40 Gb/s, in increments of 50 Mb/s. 0 indicates that bandwidth limit is disabled. One credit corresponds to bandwidth limit of 50Mb/s.
Bandwidth Limit Max	24.0-24.2		Maximum bandwidth limit indicates how much bandwidth limit credits can be accumulated due to inactivity. Single scheduling Quanta consumes multiple bandwidth limit credits. The 10 GbE controller enables accumulating of following discrete values of Quanta-worth credits: 0, 1, 2, and 4 Quanta worth credits.
Reserved2	24.3-31	0	Reserved. Must be set to 0.

38.25.4.10 Enable, Disable, or Modify Physical Port ETS

This command allows software to enable, disable or modify ETS configuration of the specified switching component connected directly to the physical port. Configuring ETS for the switching component effectively results in configuring ETS for the switching component egress port.

This command can be used only for switching components directly connected to the physical port configured to ETS-based scheduler configuration. Otherwise, the command is ignored and an error is reported.

Software is expected to store a current ETS configuration of the switching component and fully specify the ETS configuration every time it requests its modification. Software cannot provide incremental changes to the ETS configuration.

Firmware configures TC arbitration to be a weighted round robin arbitration scheme. Software can chose to specify a different arbitration scheme (strict priority or a combination of WRR and WSP), it also has an option to provide an infinite number of credits to strict priority TCs.

This is an Indirect Admin Queue command with additional command attributes and completion attributes are provided within the data buffer. Table 38-312 lists the command format and defines command specific fields.

Table 38-312.Configure Physical Port ETS Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0413 0x0414 0x0415	Command opcode. 0x0413 = Enable ETS. 0x0414 = Modify ETS. 0x0415 = Disable ETS.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Physical Port SEID	16-17		Unique identifier of the physical port.
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-17		Address of buffer.
Data Address Low	28-31		

Table 38-313 lists the format of the data buffer carrying additional command attributes. The majority of the fields in this table are valid for ETS enable and modify operations only. ETS disable operation should refer to the switching component SEID only.

Table 38-313.Configure Physical Port ETS Command Buffer

Category	Byte/Bit	Field	Description
Reserved1	0-3		Reserved to match VSI configuration format.
TC Valid	4.0-4.7	TC0-TC7 Valid	Valid bit per TC. Should list all TCs enabled for physical port. At list one TC must be enabled.
Reserved1	5.0-5.7		Reserved. Must be set to 0.
TC Strict Priority	6.0-6.7	TC0-TC7 Strict Priority Flag	Strict priority flag per TC. If set then TC should be arbitrated based on its priority. If software decides to configure one or more TCs to be a strict priority TC, then TC with higher TC number has a higher priority.
Reserved2	7.0-7.7		Reserved. Must be set to 0.
Reserved3	8-23	0	Reserved to match VSI configuration format.
TC Bandwidth Share Credits	24	TC0 Bandwidth Credits	Relative credits per TC. Valid range of credits is 1-127 credits, in increments of the single credit. 127 (indicates infinite credits if TC is configured to strict priority).
	25	TC1 Bandwidth Credits	
	26	TC2 Bandwidth Credits	
	27	TC3 Bandwidth Credits	
	28	TC4 Bandwidth Credits	
	29	TC5 Bandwidth Credits	
	30	TC6 Bandwidth Credits	
	31	TC7 Bandwidth Credits	
Reserved4	32-127		Reserved to match VSI configuration format.

38.25.4.11 Suspend Port's Tx Traffic

This command enables a PF to suspend a port's transmit traffic. Note that this command is completes immediately. After all queue sets belonging to the port are suspended and the TX pipe of the port is drained, EMP firmware uses a Send Link Status Event notification to update the PF. During the time period between processing this command and getting the event notification about port draining, the AQ commands Set PHY Config, MAC Config, and Set Link and Restart AN for this port, are not allowed and are rejected with an error code EAGAIN (8).

Prior to calling this Admin command, a PF must use Set Event Mask to register itself to link events notifications.

This command enables software to modify a port's configuration like DCB setting when it owns the LLDP agent.

Port draining is part of DCB configuration flow. This command is used to verify that the Tx pipe is drained from any Tx packet belong to the port. This is a pre-condition to some configuration changes of the port TC or DCB. This command is valid only under SFP mode. See Section 38.25.5.6.1 for more detail.

This is a Direct Admin Queue command with completion reported within the direct command completion structure. Table 38-314 lists the command format and defines its specific fields.

Table 38-314.Suspend Port's Tx Traffic

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x041B	Command opcode.
Datalen	4-5	0	Length of response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Physical Port SEID	16-17		Unique identifier of the physical port.
Reserved	18-31	0	Reserved. Must be set to 0.

38.25.4.12 Resume PF Traffic

This command is used to resume suspended Tx traffic for the PF. It resumes all queue sets belonging to the PF (all its VEBs and VSIs for all their TCs). This command is called by the PF driver after the completion of a configuration flow, which requires a port's Tx pipe to be suspended. See Section 38.25.5.6.1 for more detail.

This is a Direct Admin Queue command with completion reported within the direct command completion structure. Table 38-315 lists the command format and defines its specific fields.

Table 38-315.Resume PF Traffic

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x041C	Command opcode.
Datalen	4-5	0	Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Reserved	16-31	0	Reserved. Must be set to 0.

38.25.4.13 Configure Switching Component Bandwidth Limit per Traffic Type

This command enables software to specify TCs enabled for a switching component and configures bandwidth limits of TCs enabled for the specified switch component.

Software should keep track of already configured bandwidth limits and provide complete bandwidth limit configuration, and not just incremental modifications.

This command can be used only for switching components belonging to the physical port configured to ETS-based scheduler configuration. Otherwise, the command is ignored and an error is reported.

Software is allowed to change bandwidth limit per traffic type and TCs enabled for a switching component that has a bandwidth allocation configured. New TCs enabled for a switching component has a default bandwidth allocated. Software should use a configure switching component bandwidth allocation per VSI AQ command to modify a default bandwidth allocation.

This command can be used to enable bandwidth limit per TC for the physical port.

Software cannot have both bandwidth limit and bandwidth limit per traffic type enabled for the same switching component. A request to enable bandwidth limit per traffic type for the switching component that has bandwidth limit enabled should fails and an EPERM error is reported in completion.

Software can configure either the switching component bandwidth limit or switching component TC bandwidth limit.

In that case, the PF uses more than one TC (such as an iSCSI PF that must be opened for Storage TC and LAN TC as well).

- PF is allowed to enable more than one TC. According enabled UP's and UP to TC mapping.

- Bandwidth relative allocation defined for this PF in the Alt RAM is configured for each one of the used TC's.
- Maximum bandwidth for the PF is declared as a shared rate limiter.

If TC re-configuration is needed while the VSI is suspended then new generated TC nodes of this VSI is also suspended.

This is an Indirect Admin Queue command. Software should provide a valid buffer carrying additional command attributes as listed in Table 38-316. Command completion does not provide any additional information beyond status, and does not use a data buffer provided by software for command attributes.

Table 38-316 lists the command format and defines command specific fields.

Table 38-316.Configure Switching Component Bandwidth Limits per Traffic Type Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0416	Command opcode.

38.25.4.14 Configure Switching Component Bandwidth Allocation per Traffic Type

This command enables software to specify TCs enabled for a switching component and configure relative bandwidth allocation of switching components within each TC.

This command can be used for switching components configured in ETS-based mode only. Otherwise, the command is ignored and an error is reported.

To configure switching component bandwidth allocation per traffic type, software should provide complete relative bandwidth allocation for all TCs enabled for the switching component.

Software is allowed to change bandwidth allocation per traffic type and TCs enabled for a switching component that has a switching component bandwidth limit enabled. It is responsibility of firmware to adjust hardware configuration to reflect this change.

In that case, the PF uses more than one TC (such as an iSCSI PF that must be opened for Storage TC and LAN TC as well).

- PF is allowed to enable more than one TC. According enabled UP's and UP to TC mapping.
- Bandwidth relative allocation defined for this PF in the Alt RAM is configured for each one of the used TC's.
- Maximum bandwidth for the PF is declared as a shared rate limiter.

If TC re-configuration is needed while the VSI is suspended then new generated TC nodes of this VSI is also suspended.

This is an Indirect Admin Queue command. Software should provide a buffer that would be used both to provide additional command attributes and for the command completion.

Table 38-318 lists the command format and defines a command specific fields.

Table 38-318.Configure Switching Component Bandwidth Allocation per Traffic Type Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0417	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switching Component SEID	16-17		Unique identifier of the VSI.

38.25.4.15 Query VSI Bandwidth Configuration

This command enables software retrieve current bandwidth configuration of the specified VSI of the specified switching component.

This is an Indirect Admin Queue command. Software should provide a buffer for command completion. Command completion carries VSI bandwidth configuration attributes, listed in Table 38-321.

DCB flow might require VEB configuration changing followed by VSI configuration changing. Calling to query VSI bandwidth configuration between the previous two steps is responded with an error code EBUSY (12).

Table 38-320 lists the command format and defines a command specific fields.

Table 38-320.Query VSI Bandwidth Configuration Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0408	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. This should carry a status and an indication whether ETS is enabled or not.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
VSI SEID	16-17		Unique identifier of the VSI.
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-321 lists the format of the completion buffer and defines completion attributes. In addition to the bandwidth characteristics of VSI, this completion carries UP handles and QS handles of UPs and queue sets allocated for VSI.

Table 38-321.Query VSI Configuration Completion Buffer (Sheet 1 of 2)

Category	Byte/Bit	Field	Description
TC Valid	0.0-0.7	TC0-TC7 Valid	Valid bit per TC.
TC Suspended	1.0-1.7	TC0-TC7 Suspended	Marks per TC if this TC transmission is suspended.
Reserved0	2-15	0	Reserved. Must be set to 0.
QueueSet Handles	16-17	QS0 Handle	Queue set handles of configured queue sets. Invalid handles carries the value of 0xfFFFF Order of queue set handles matches order of TCs (0-7).
	18-19	QS1 Handle	
	20-21	QS2 Handle	
	22-23	QS3 Handle

Table 38-321.Query VSI Configuration Completion Buffer (Sheet 2 of 2)

Category	Byte/Bit	Field	Description
Bandwidth Limit	36-37		Bandwidth limit configured for the VSI in Mb/s. 0 indicates that bandwidth limit was not configured for the VSI. One credit corresponds to bandwidth limit of 50 Mb/s.
Reserved2	38-39	0	Reserved. Must be set to 0.
Bandwidth Limit Max	40.0-40.2		Maximum bandwidth limit indicates how much bandwidth limit credits can be accumulated due to inactivity. Single scheduling Quanta consumes multiple bandwidth limit credits. The 10 GbE controller allows accumulating of following discrete values of Quanta-worth credits: 0,1, 2, and 4 Quanta worth credits.
Reserved3	40.3-63	0	Reserved. Must be set to 0.

38.25.4.16 Query VSI Bandwidth Configuration per Traffic Type

This command enables software to retrieve a bandwidth configuration of the specified VSI within each TC.

This command can be used for VSI configured in ETS-based mode only. Otherwise, the command is ignored and an error is reported.

If the physical port ETS is configured to single level ETS, and defines bandwidth distribution between TCs only. Software can assume one-to-one mapping of UPs-to-TCs from the bandwidth allocation perspective, and use this command to retrieve a bandwidth allocation for VSI within each TC.

This is an Indirect Admin Queue command. Software should provide a buffer for additional command attributes and command completion. Command completion carries VSI ETS/SLA configuration attributes, listed in Table 38-322.

DCB flow might require VEB configuration changing followed by VSI configuration changing. Calling to query VSI bandwidth configuration between the previous two steps is responded with error code EBUSY (12).

Table 38-322 lists the command format and defines command specific fields.

Table 38-322.Query VSI Bandwidth Allocation per Traffic Type Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x040A	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. This should carry a status and an indication whether ETS is enabled or not.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
VSI SEID	16-17		Unique identifier of the VSI.
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-323 lists the format of completion buffer and its attributes.

Table 38-323.Query VSI Bandwidth Allocation per Traffic Type Completion Buffer

Category	Byte/Bit	Field	Description
TC Valid	0.0-0.7	TC0-TC7 Valid	Valid bit per TC.
TC Suspended	1.0-1.7	TC0-TC7 Suspended	Marks per TC if this TC transmission is suspended.
Reserved1	2-3	0	Reserved. Must be set to 0.
TC Bandwidth Share Credits	4	TC0 Bandwidth Credits	Relative VSI credits within same TC with respect to other VSIs enabled on the same switching component Valid range of credits is 1-127 credits, in increments of the single credit. 127 (indicates infinite credits).
	5	TC1 Bandwidth Credits	
	6	TC2 Bandwidth Credits	
	7	TC3 Bandwidth Credits	
	8	TC4 Bandwidth Credits	
	9	TC5 Bandwidth Credits	
	10	TC6 Bandwidth Credits	
	11	TC7 Bandwidth Credits	
TC Bandwidth Limit Credits	12-13	TC0 Bandwidth Limit Credits	This fiend specifies a bandwidth limit per TC in Mb/s. Supported bandwidth limit range is 50 Mb/s-40 Gb/s, with increments of 50 Mb/s. Bandwidth limit of 0 Mb/s indicates that bandwidth limit is disabled. Bandwidth limit should be provided for the valid handles only. One credit corresponds to bandwidth limit of 50 Mb/s.
	14-15	TC1 Bandwidth Limit Credits	
	16-17	TC2 Bandwidth Limit Credits	
	18-19	TC3 Bandwidth Limit Credits

	31.7	Reserved	

38.25.4.17 Query Switching Component Configuration

This command enables software retrieve current bandwidth management configuration of the specified switching component.

This is an Indirect Admin Queue command. Software should provide a buffer for command completion. Command completion carries switching component bandwidth configuration attributes, listed in Table 38-325.

Table 38-324 lists the command format, and defines a command specific fields.

Result of this command is returned as a completion to the Admin Queue command.

Table 38-324.Query Switching Component Configuration Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0418	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. This should carry a status and an indication whether ETS is enabled or not.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Switching Component SEID	16-17		Unique identifier of the switching component.
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-325 lists the format of completion buffer and its attributes.

Table 38-325.Query Switching Component Configuration Completion Buffer

Category	Byte/Bit	Field	Description
TC Valid	0.0-0.7	TC0-TC7 Valid	Valid bit per TC.
Reserved1	1-31	0	Reserved. Must be set to 0.
Reserved1	32-35	0	Reserved. Must be set to 0.
Bandwidth Limit	36-37		Bandwidth limit configured for the port in Mb/s. 0 indicates that bandwidth limit was not configured for the switching component. One credit corresponds to bandwidth limit of 50 Mb/s.
Reserved2	38-39	0	Reserved. Must be set to 0.
Bandwidth Limit Max	40.0-40.2		Max bandwidth limit indicates how much bandwidth limit credits can be accumulated due to inactivity. Single scheduling Quanta consumes multiple bandwidth limit credits. The 10 GbE controller allows accumulating of following discrete values of Quanta-worth credits: 0,1, 2, and 4 Quanta worth credits.
Reserved3	40.3-63	0	Reserved. Must be set to 0.

38.25.4.18 Query Physical Port ETS Configuration

This command enables software to retrieve ETS configuration of the specified switching component or VSI directly connected to the physical port.

This is an Indirect Admin Queue command. Software should provide a buffer for additional command attributes and command completion. Command completion carries switching component ETS/SLA configuration attributes, listed in Table 38-327.

This command can be used only for switching components directly connected to the physical port configured to ETS-based scheduler configuration. Otherwise, the command is ignored and an error is reported.

Table 38-326 lists the command format and defines command specific fields.

Table 38-326.Query Physical Port ETS Configuration Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0	
Opcode	2-3	0x0419	Command opcode.
Datalen	4-5		Length of response buffer.
Return Vvalue/ VFID	6-7		Return value. Zeroed by driver. Written by firmware. This should carry a status and an indication whether ETS is enabled or not.
Cookie High	8-11	Cookie	Opaque value, is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value, is copied by firmware into the completion of this command.
Physical Port SEID	16-17		Unique identifier of the physical port.
Reserved	18-23	0	Reserved. Must be set to 0.
Data Address High	24-27		Address of buffer.
Data Address Low	28-31		

Table 38-327 lists the format of completion buffer and its attributes.

Table 38-327.Query Physical Port ETS/SLA Completion Buffer (Sheet 1 of 2)

Category	Byte/Bit	Field	Description
Reserved1	0-3		Reserved to match VSI configuration format.
TC Valid	4.0-4.7	TC0-TC7 Valid	Valid bit per TC. This field is valid for ETS enable operation only. For ETS modify operation TC handles must be used instead. Up to eight TCs can be valid at any time.
TC Strict Priority	6.0-6.7	TC0-TC7 Strict Priority Flag	Strict priority flag per TC. If set then TC should be arbitrated based on its priority. If software decides to configure one or more TCs to be a strict priority TC, then TC with higher TC number has a higher priority. Configuring TCs to the strict priority may be useful for SLA configuration.

Table 38-327.Query Physical Port ETS/SLA Completion Buffer (Sheet 2 of 2)

Category	Byte/Bit	Field	Description
TC Bandwidth Share Credits	8	TC0 Bandwidth Credits	Relative credits per TC. Valid range of credits is 1-127 credits, in increments of the single credit. 127 (indicates infinite credits if TC is configured to strict priority).

	35.7	Reserved	
Reserved3	36-67	0	Reserved to match VSI configuration format. Must be set to 0.

38.25.4.19 Query Switching Component Bandwidth Configuration per Traffic Type

This command enables software to retrieve a bandwidth configuration of the specified switching component within each TC.

This command can be used for a switching component configured in ETS-based mode only. Otherwise, the command is ignored and an error is reported.

This is an Indirect Admin Queue command. Software should provide a buffer for additional command attributes and command completion. Command completion carries VSI ETS/SLA configuration attributes, listed in Table 38-328.

Table 38-328 lists the command format, and defines command specific fields.

Table 38-328.Query Switching Component Bandwidth Allocation per Traffic Type Command Fields

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0

38.25.5 Scheduler Configuration Flows

This section describes use of AQ commands defined in Section 38.25.4 to configure the scheduler. It is not intended to provide a complete coverage of all possible configuration flow, but rather cover a several main stream cases.

Table 38-330 lists all possible configuration changes of the internal switch or bandwidth configuration that have an impact on the transmit scheduler configuration, along with AQ commands that should be used.

Table 38-330.Scheduler Configuration Summary (Sheet 1 of 2)

Configuration Change	Description	AQ Command
Default Port ETS Configuration	Default ETS configuration is ETS disabled, and the only TC enabled is TC0. See Section 38.25.5.3.	NA
Disable Physical Port	Disabling previously configured physical port does not directly impact scheduler configuration. Firmware suspends the disabled port and software is responsible for resource deallocation using Delete Element AQ command.	NA
Change Physical Port ETS Configuration	Driven by agent implementing DCBX protocol. Agent can run in firmware or in software. In case of software AQ command should be used to perform required ETS configuration change. See Section 38.25.5.3.	Enable, Disable, Modify Physical Port ETS. See Section 38.25.4.10.
Add Default VSI	Default VSI is allocated at switch initialization time. SFP configuration - one default VSI per port. Default VSI is configured with default bandwidth configuration (even bandwidth allocation, no bandwidth limits), and with single TC enabled - TC0. See Section 38.25.5.1.	NA
Add VSI	Regular VSI can be added directly connected to the physical port, S-channel of PE, or VEB. Scheduler configuration is done as a part of the internal switch configuration. A new VSI is configured with a default bandwidth configuration (single bandwidth allocation credit, and no bandwidth limit enabled). A new VSI can be configured with an initial set of TCs enabled for VSI. TCs enabled for VSI must be a subset of TCs enabled to the parent switching element or physical port. See Section 38.25.5.3.	Add VSI.
Change TCs Enabled For Default VSI Or Regular VSI.	Default or regular VSI TC configuration can be changed using Configure VSI Bandwidth Allocation per Traffic Type or Configure VSI Bandwidth Limit per Traffic Type AQ commands. In either case TCs enabled for the default VSI must be a subset of TCs enabled for the corresponding physical port/PE. Update VSI CANNOT be used to change TC configuration of transmit scheduler.	Configure VSI Bandwidth Allocation per Traffic Type. See Section 38.25.4.8. Configure VSI Bandwidth Limit per Traffic Type. See Section 38.25.4.7.
Change VSI Bandwidth Configuration	To change VSI bandwidth configuration, software can use one of three AQ commands: Configure VSI Bandwidth Limit to enable/modify/disable bandwidth limit that applies to entire VSI (all enabled TCs) Configure VSI Bandwidth Limit per Traffic Type to enable/modify/disable bandwidth limit for individual TC enabled for VSI. Configure VSI Bandwidth Allocation per Traffic Type to modify bandwidth allocation for the individual TC enabled for VSI.	Configure VSI Bandwidth Limit See Section 38.25.4.5. Configure VSI Bandwidth Allocation per Traffic Type. See Section 38.25.4.8. Configure VSI Bandwidth Limit per Traffic Type. See Section 38.25.4.7.
Delete VSI	Software can remove VSI using Delete Element AQ command. This includes removing all TC nodes enabled for VSI.	Delete Element.
Add VEB to Default VSI	When VEB is added to the default VSI, it is effectively inserted between default VSI and physical port/PE. VEB can be configured with a set of TCs enabled for VEB. TCs enabled for VEB must include all TCs enabled for the default VSI. VEB inherits bandwidth configuration of default VSI. TCs that are enabled for VEB and not enabled for the default VSI must be configured with a default bandwidth configuration. See Section 38.25.5.2.	Add VEB/PA.

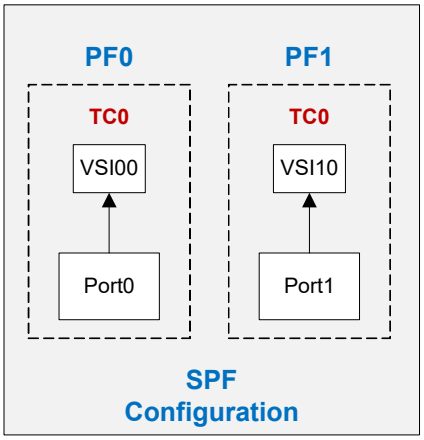
Table 38-330.Scheduler Configuration Summary (Sheet 2 of 2)

Configuration Change	Description	AQ Command
Add Floating VEB	Not supported by current scheduler definition. Transmit scheduler must provide a physical port and TC along with the scheduling request to enable proper device resource allocation by the pipeline. There are several ways how floating VEB can be enabled for the scheduler. All options result in modification of the Scheduler configuration tables.	Add VEB/PA.
Change TCs Enabled For VEB	To change number of TCs enabled for VEB software should use either Configure Switching Component Bandwidth Limit per Traffic Type, or Configure Bandwidth Allocation per Traffic Type AQ commands. TCs enabled for VEB must be a subset of TCs enabled for the parent switching component or physical port. Update VEB CANNOT be used to change TC configuration of transmit scheduler.	Configure Switching Component Bandwidth Limit per Traffic Type. See Section 38.25.4.14. Configure Switching Component Bandwidth Allocation per Traffic Type. See Section 38.25.4.13.
Change VEB Bandwidth Configuration.	To change VEB bandwidth configuration software can use one of three AQ commands: Configure Switching Component Bandwidth Limit to enable/ modify/disable bandwidth limit that applies to entire VEB (all enabled TCs). Configure Switching Component Bandwidth Limit per Traffic Type to enable/modify/disable bandwidth limit for individual TC enabled for VEB. Configure Switching Component Bandwidth Allocation per Traffic Type to modify bandwidth allocation for the individual TC enabled for VEB.	Configure Switching Component Bandwidth Limit. See Section 38.25.4.9. Configure Switching Component Bandwidth Limit per Traffic Type. See Section 38.25.4.14. Configure Switching Component Bandwidth Allocation per Traffic Type. See Section 38.25.4.13.
Delete VEB	Software can remove VEB using Delete Element AQ command. This includes removing all TC Nodes enabled for VEB. Software can remove VEB only after removing all VSIs attached to it after VEB creation. When VEB is removed, a default VSI is attached back to the S-channel or physical port.	Delete Element.

38.25.5.1 Default VSI

Default VSI is automatically created for each PF. In SFP environment single default VSI is allocated per physical port. Default VSI is always associated with TC0. Default VSI owns all bandwidth allocated for the physical port or a PF. Software can change TCs enabled for the default VSI and bandwidth allocation per Traffic Type using AQ command described in Section 38.25.4.8.

Figure 38-79.Default VSI Configuration



Firmware allocates a queue set for the each default VSI. Software can retrieve a queue set handle using Query VSI command. There is no additional configuration of default VSI is required, and once respective queue set handle is associated with transmit queue, that queue can be scheduled for transmission.

ETS is disabled for the default VSI. Software can enable ETS configuration for the physical port and then configure ETS for VSI. See Section 38.25.5.3.

Software can instantiate a switching component using Add VEB or Add PE commands, see Section 38.25.5.2.

38.25.5.2 Adding VEB/PA/Port Extender

Adding S-comp (port extender) does not impact transmit scheduler configuration. S-comp is effectively replacing a physical port in the transmit scheduler configuration hierarchy. All attributes configured for the port automatically apply for the S-comp (like ETS configuration, etc.).

VEB/PA added to the switching hierarchy can be inserted between a default VSI and a physical port or an S-comp, or can be instantiated using its own S-channel.

Regular VEB, attached to physical port, always inserted between port or port extender and VSI. If VSI is not a default VSI automatically allocated by firmware for each physical function or physical port, software is required to allocate VSI prior to adding VEB.

Figure 38-80.Adding VEB/PA

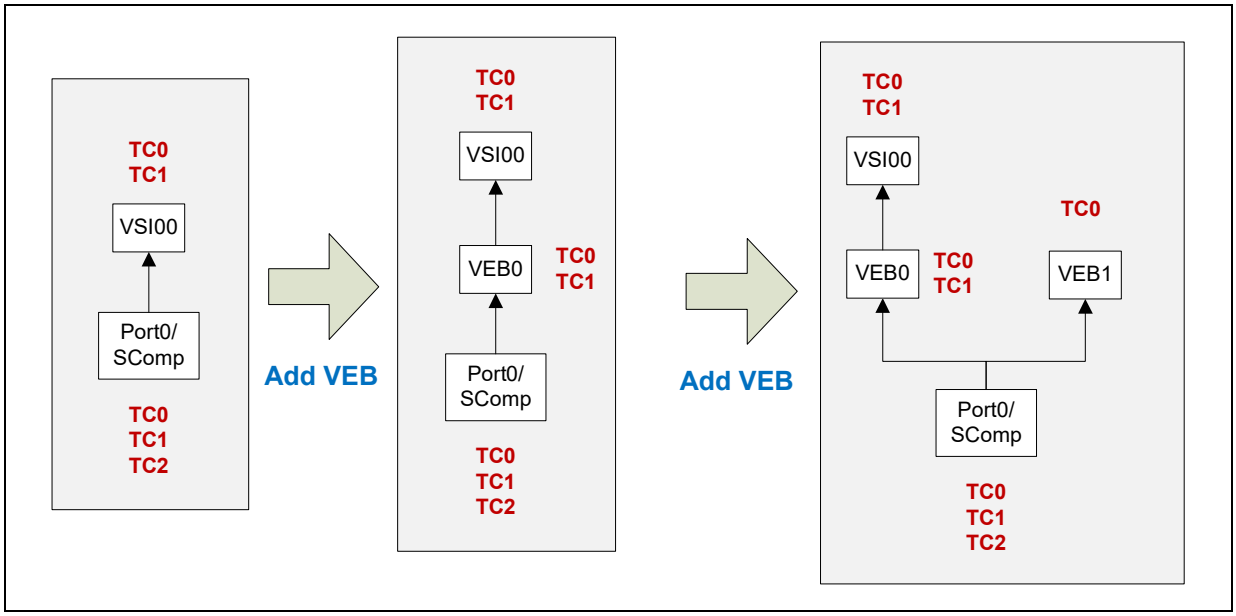


Figure 38-80 shows a transition of adding a VEB/PA switching component.

The first step shows insertion of the VEB between physical port and a default VSI (VSI00). In this example port has an ETS enabled, and a default VSI is configured with multiple TCs. Inserted VEB inherits VSIs configuration (such as TCs enabled for VSI, and bandwidth management attributes). VEB might have more TCs enabled than VSI. Software can change TCs enabled for VEB and relative bandwidth allocation within each Traffic Class using AQ command described in Section 38.25.4.14.

Insertion of VEB between default VSI and S-channel does not impact queue set allocated for VSI. Transmit queues, if any, previously associated with queue sets allocated for default VSI remains operational.

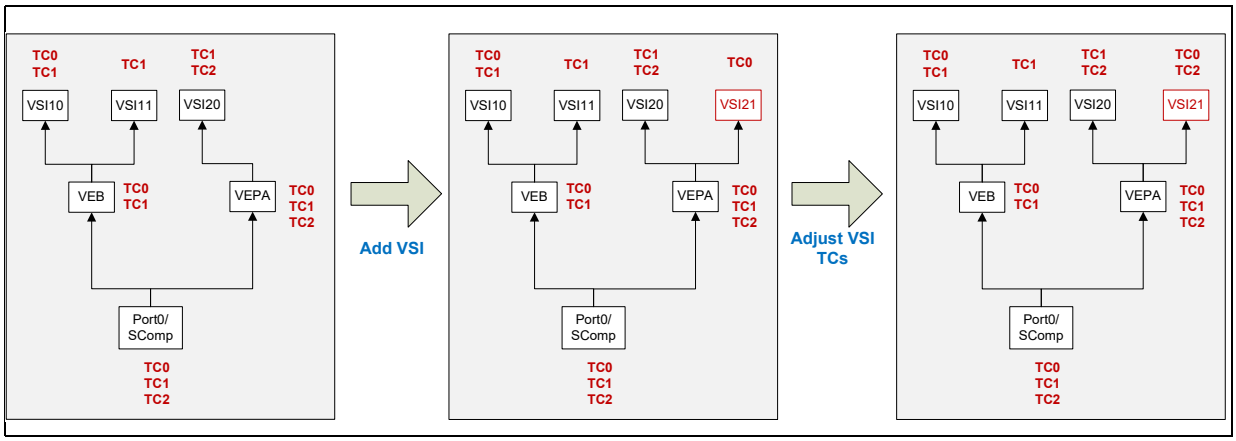
The second step shows a new VSI directly attached to the S-channel. Software is required to add VSI prior to adding a new VEB. In the example shown on the diagram, new VSI has TC0 enabled. Software can specify TCs enabled for VSI using a TC enable bitmap in Add VSI AQ Command, or can change it later using Configure VSI Bandwidth Allocation per Traffic Type, or Configure VSI Bandwidth Limit per Traffic Type AQ commands. Upon allocation of VSI, firmware allocates a queue set for each TC enabled for VSI, and provides it in the AQ command completion.

The third step shows a second VEB/PA inserted between VSI10 and the PE (VEB1). Process of creation and bandwidth configuration is similar to one previously described for the VEB0.

38.25.5.3 Adding VSI

In addition to the default VSI created for each port in SFP mode, software can request adding VSI to the previously allocated switching component. By default VSI is allocated with single TC enabled - TC0. Software can configure TCs enabled for VSI either using a bitmask in Add VSI AQ command, or using scheduler configuration AQ command described in Section 38.25.4.8.

Figure 38-81.Add VSI



Each allocated VSI is allocated a queue set per enabled TC. Queue set handles are returned in completion of Add VSI, or AQ command described in Section 38.25.4.8.

38.25.5.4 Bandwidth Limiting

Each allocated switching component and VSI might have a bandwidth limit configured. The 10 GbE controller supports two kinds of bandwidth limits: global, including traffic generated on all TCs enabled for VSI or switching component and per traffic type bandwidth limit. Global bandwidth limits can be enabled using AQ commands described in Section 38.25.4.9 and Section 38.25.4.5. Per TC bandwidth limits can be enabled using AQ commands described in Section 38.25.4.7.

Bandwidth limits are be default disabled. Software can enable only one kind of bandwidth limit to each switching component and VSI.

Software does not have to modify relative bandwidth allocation for the switching components and VSIs to enable bandwidth limits. The default (even) bandwidth allocation can be used, and bandwidth would be equally distributed between switching components and VSIs as long as they have not reached configured bandwidth limit.

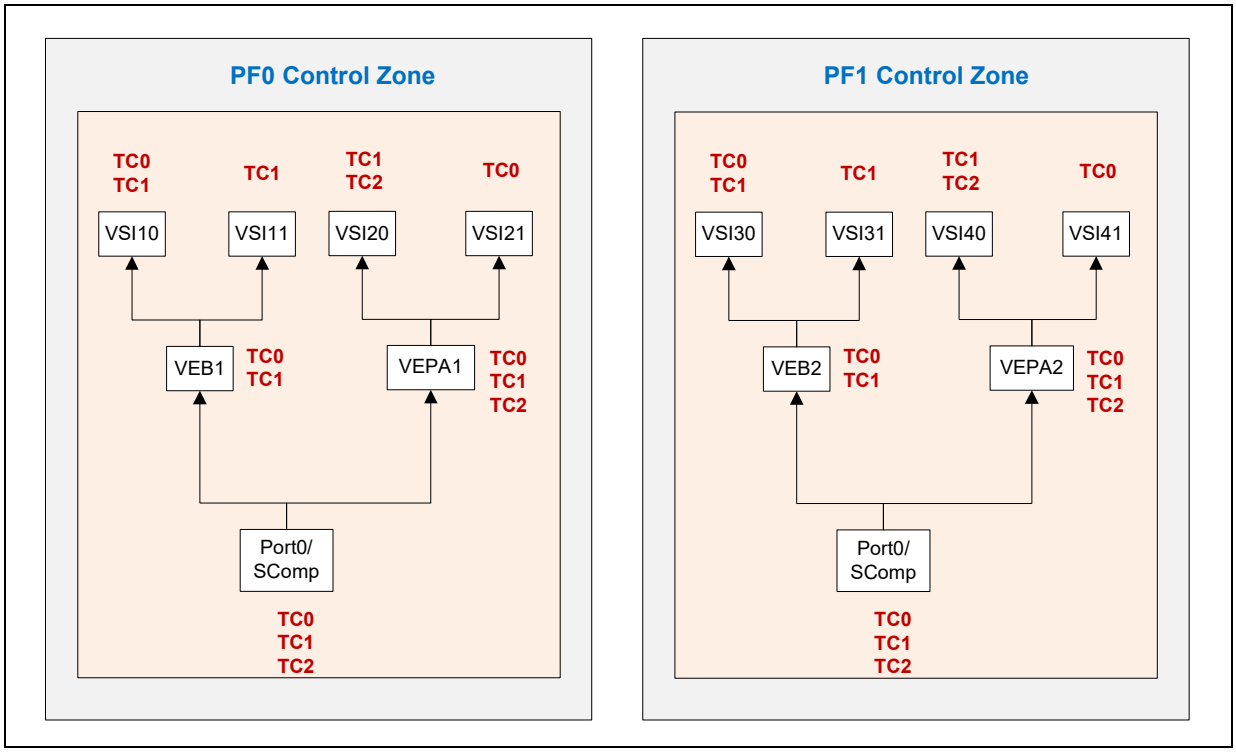
38.25.5.5 Bandwidth Distribution Ownership

38.25.5.5.1 SFP Mode

In SFP configuration one PF owns all resources allocated to the physical port.

ETS configuration of the physical port by default would be performed by firmware based on data provided by DCBX agent running in firmware. Software can take over the role of DCBX agent, and then it controls ETS configuration of the physical port as well. In either case, allocation or bandwidth management of the switching components and VSIs is completely owned by software, and performed using AQ commands described in Section 38.25.4.

Figure 38-82.Software Control Zone in SFP Mode



Bandwidth allocation should be done using relative credits only. The PF driver should have all information available to manage relative credits.

38.25.5.6 Enabling/Changing port DCB Configuration

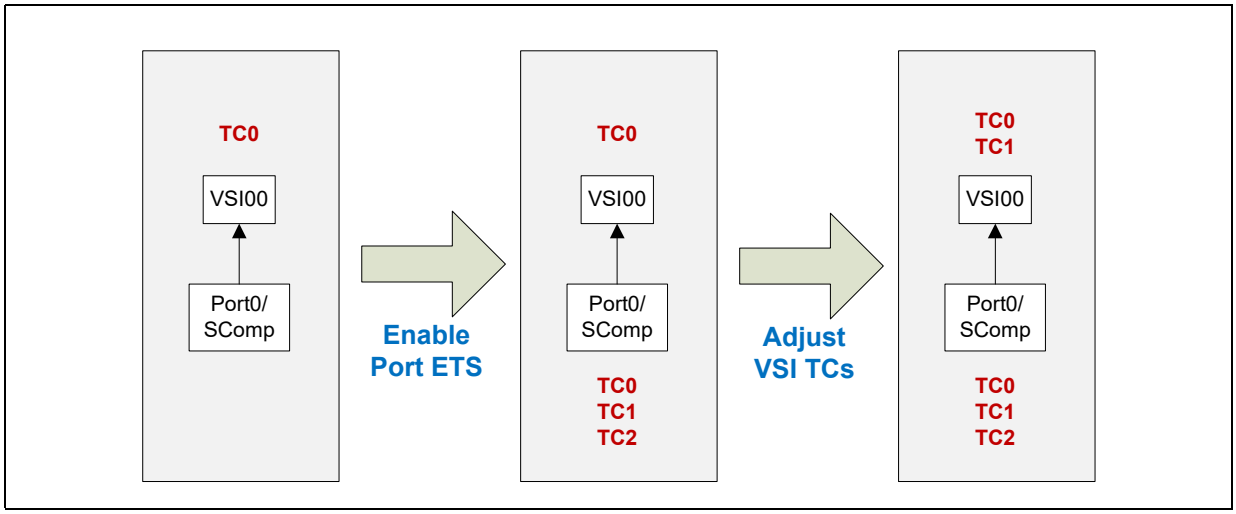
ETS configuration of a physical port can be enabled or modified at any point. This is not expected to be a frequent event, and therefore transition period to adjust scheduler configuration to reflect the change is acceptable.

At least one TC must be enabled. If DCB is disabled for the Port, TC0 should be used.

If port extender (S-comp) is enabled for the physical port, all attributes configured for the port automatically apply for the S-comp (like ETS configuration, etc.)

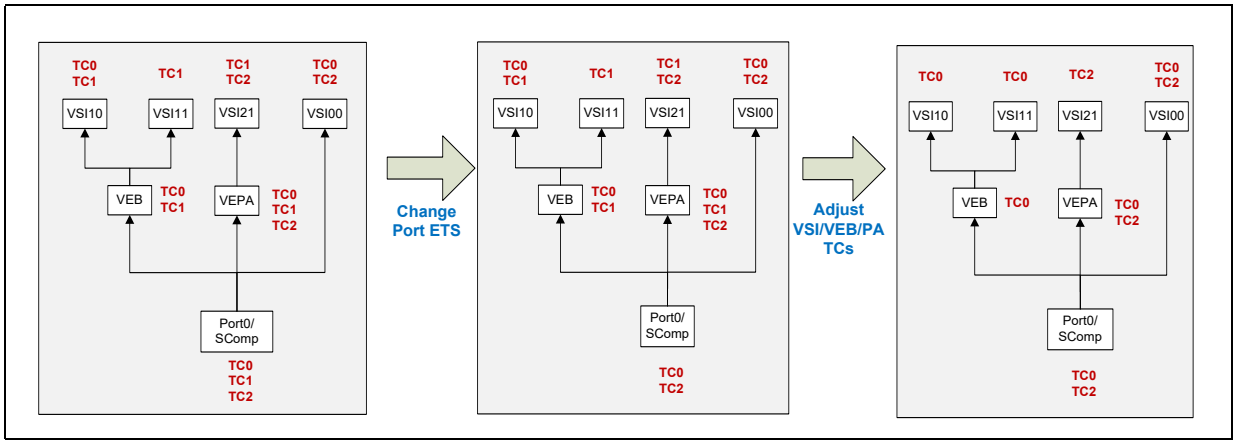
In the default flow, firmware negotiates ETS configuration of the physical port, and configures TCs enabled by ETS for the physical port. Default VSI, previously created for the port or PFs associated with the port, remains associated with TC0 only. Software should use AQ command described in Section 38.25.4.8 to modify TCs enabled for VSI and a relative bandwidth allocation of VSI within each enabled TCs.

Figure 38-83.Enable Physical Port ETS



If software instantiated additional VSIs or switching components prior to ETS is enabled for the port, or if ETS configuration has been changed, firmware is responsible to update ETS configuration of physical port, and add or remove TCs. All previously allocated VSIs and switching components remain associated with TCs previously configured TCs. Software should use AQ commands described in Section 38.25.4.8 and Section 38.25.4.14 to adjust TCs enabled for VSIs and switching components, and modify bandwidth allocation per traffic type as required.

Figure 38-84.Change Physical Port ETS



Scheduler starts scheduling requests for the new TCs added to the physical port configuration, only after this TC is enabled for one or more VSIs. Adding more TCs to VSI leads to allocation of new queue sets, which in turn must be associated with transmit queues.

Once TC is removed from the physical port configuration, transmit scheduler suspends scheduling traffic for all queue sets associated with that TC and then notifies software with an LLDP MIB change event. To resume scheduling traffic on transmit queues associated with such queue sets, software needs to adjust TC configuration of VSIs and switching components, and reassign affected transmit queues to queue sets associated with other TCs.

Port DCB configuration can be directly changed by firmware as a result of the DCBX exchange, this assumes a DCBX agent running in firmware (which is a default configuration). Or it can be configured by software using AQ command described in Section 38.25.4.10 if software took over duty of running DCBX agent. Transmit scheduler configuration does not depend on the location of the DCBX agent.

ETS reconfiguration of VSI might move Tx queues between TCs. Running this configuration flow while Tx pipe is loaded with Tx packets belong to this queue (either in the TCB or in the TPB) might cause out of order completion for this Tx queue.

To prevent this error case, it is required to verify that Tx pipe is drained from any Tx packet belonging to re-configured queue or queue set. There are two ways software can verify this draining.

1. PF can stop feeding the Tx ring and waits until all pending work completes.
2. PF can disable the Tx queue. This provides faster draining mechanism but flushes all pending work.

EMP firmware provides a service which suspends port's queue sets and drains the Tx pipe on the fly. This port draining service is used as part of DCBX change (see Section 38.25.4.11 for more detail).

The general flow DCBX exchange is: If ETS setting of VSI's is required to be changed then the EMP first drains the first the Tx pipe of the port (initiated by LLDP owner, done by EMP and Tx scheduler). After the port is drained, firmware notifies the PF that makes those required ETS changes (via Tx scheduler AQC). After VSI's ETS setting is adjusted, the PF resumes its queue sets using AQC described in Section 38.25.4.7 and in Section 38.25.4.8.

Some other DCB parameters require Tx pipe draining before re-configuration. DCBX owner (EMP firmware or software) uses the Tx scheduler draining service. More details are described in DCBX.

Some of DCBX flows require change of queue context configuration. In those cases, software must disable the queue first.

38.25.5.6.1 Tx Scheduler DCB Control Flows

General

DCBX and Tx scheduler control flows were declared under some assumptions and decisions as followed:

- For DCBX exchange event, software runs the similar flow under SFP.
- Usually DCBX agent runs in the EMP. Under SFP mode, software might take LLDP agent ownership.
- If software did not take LLDP ownership, the difference between DCBX software flows when running under SFP needs to be minimized.

- DCBX event might occur during first connectivity to the network as part of power up flow, as part of link down link up event, or in rare case, the switch had decided to change DCB setting.
- Three typical boot sequences are identified (DCBX runs at a different stage in each case):

Case I - Typical SFP boot sequence

a. EMP sets the initial scheduler configuration — One initial VSI per PF. Detailed flow in Reset/init flow.

b. DCBX runs. Detailed flow in DCBX.

c. Software boot. Detailed flow in Software Boot.

Case II - Late DCBX, DCBX parameters changed by the peer, or Link event.

a. EMP sets the initial scheduler configuration — One initial VSI per PF. Detailed flow in Reset/init flow.

b. Software boot. Detailed flow in Software Boot.

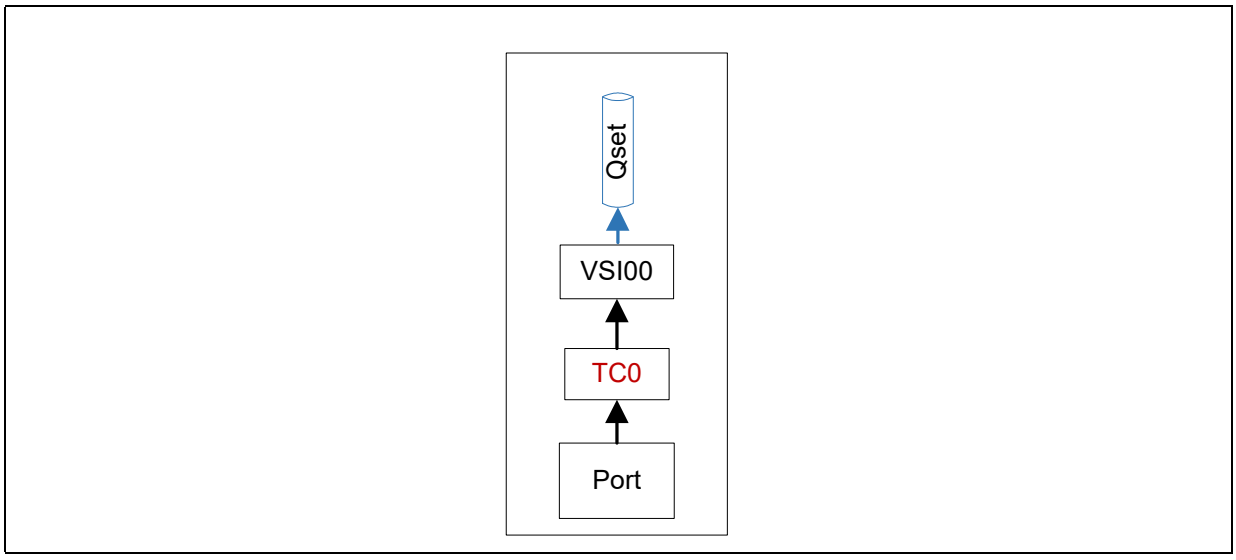
c. DCBX runs or makes changes in DCBX setting. Detailed flow in DCBX.

- When link goes up either while power up flow or while system already runs, all DCBX MIBs are reset to their default values (All TC are in DROP policy, all UPs are mapped to TC#0 and TC#0 is the only active TC for this port). So, after link up, the DCBX flow runs twice, a) Reset MIBs to default. b) New DCBX exchange with the new link partner.

Reset/init flow

- EMP initializes switch and Tx scheduler tables.
- For SFP, EMP builds one initial VSI per active port.
- EMP exposes the Qsets for pre-boot Tx (without active AQ)

Figure 38-85.initial Setting in SFP (One Initial VSI/Port)



DCBX exchange

- When EMP owns LLDP:

  - IF port draining is required (change in drop policy, application TLV, UP to TC mapping or port TC mapping)
    - EMP suspends all port's Tc (all TCs - no credits)
    - EMP drains port's Tx pipeline (waits until all pipe monitor counters are zeroed).
  - EMP re-configures needed DCB settings.
  - IF port is suspended then EMP resumes manageability Tx traffic.
  - EMP re-configures TX scheduler.
    - Port ETS setting (suspend the TC nodes of disabled TCs, resume TC nodes of enabled TCs).
    - TC bandwidth configuration.
  - EMP notifies DCBX event to all PFs that are registered for LLDP MIB notification.
    - This is done via posting LLDP MIB change event, after waking up the host if it was not in D0 state.
    - LLDP MIB change event notification includes *miscellaneous* field, which mark to the PF if the MIB change involved port draining and if per TC pipe flushing was used.
    - PF that is not registered for LLDP event must periodically check for LLDP MIBs update status.

Following is relevant only when software is up and running (case III):

- When software owns LLDP (applies only in SFP mode).
  - IF port draining is required, PF calls Suspend Port’s TX Traffic AQC (See Section 38.25.4.11).
    - EMP suspends all port's TX (all TCs - no credits).
    - EMP stops manageability Tx traffic.
    - EMP drains port's Tx pipeline (waits until all pipe monitor counters are zeroed).
    - EMP drains port's Tx pipeline (waits until all pipe monitor counters are zeroed).
  - PF re-configures needed DCB settings as needed.
  - PF instructs EMP to configure Tx scheduler with port's TC setting (via Configure Physical Port ETS AQC).
- PF computes the needed tree topology changes according the new UP to TC mapping and PFs' UP settings.
- PF marked as an iSCSI service, defined in Alt RAM: PF protocol (Offset 0xB), needs to be opened for both iSCSI TC and LAN TC.
- PF adjusts VEBs and VSIs per TC setting:
  - Done via Configure VSI Bandwidth Limit per Traffic Type, Configure VSI Bandwidth Allocation per Traffic Type, Configure Switching Element Bandwidth Limit per Traffic Type or Configure Switching Element Bandwidth Allocation per Traffic Type commands.
    - If the commands Configure VSI Bandwidth Limit per Traffic Type, Configure VSI Bandwidth Allocation per Traffic Type are called and remapped to only one TC node, EMP gives this TC node its original queue set handle. This enables the PF to skip the step of disabling and enabling all queues.
    - The commands Configure VSI Bandwidth Limit per Traffic Type, Configure VSI Bandwidth Allocation per Traffic Type can be used to expand VSI’s TC

setting. The EMP returns the queue set handle for each one of the enabled TCs including the new used TCs.
    - PF copies the new queue set handles to the contexts of the Tx queues belonging to the new established queue sets. When a queue context needs to change its queue set (moving between queue sets), software must disable the queue, reconfigure and enable back.
- After configuration completes, the PF resumes its suspended Tx traffic using AQC Resume PF Traffic (see Section 38.25.4.12).

Software Boot

- PF reads the DCBX MIBs (including UP-TC mapping).
  — In order to get consistent MIB data, the PF is required to verify that the LLDP owner is not processing LLDP messages right now by polling PRTDCB_GENS.DCBX_STATUS until it is set to DONE.
- Before making any change to VSI settings, the PF reads initial configuration and configures all queue sets.
  — Tree topology reading done via Get Switch Configuration command.
  — For each VSI, the PF needs to call Query VSI Bandwidth Configuration (see Section 38.25.4.15).
    - The response buffer includes:
    - A bitmap, which TCs are enabled in this VSI.
    - A queue set handle for each enabled TC.
    - A bitmap, which of the enabled TCs is suspended due to DCBX event.
    - PF must verify that a queue set is established for each enabled TC.
    - For each enabled TC, PF is required to copy the queue set handle value to all queues belonging to the queue set (before enabling the queue).
- PF determines whether to move/add any VSI to a different TC. Done via Configure VSI Bandwidth Limit per Traffic Type, Configure VSI Bandwidth Allocation per Traffic Type commands.
  — If the commands Configure VSI Bandwidth Limit per Traffic Type, Configure VSI Bandwidth Allocation per Traffic Type are called and moved to only one TC node, the EMP gives this TC node, its original queue set handle. This enables the PF to skip the step of disabling and enabling all queues.
    - PF resumes its suspended VSI's using AQC Resume PF Traffic (see Section 38.25.4.12).
- When the PF needs to change a TC setting of a VSI (not as a response to DCBX event, This VSI is NOT suspended), PF MUST drain all Tx queues belonging to moved TCs (in the VSI) before changing its TC settings. Changing any setting of a queue set while it has packets in the Tx pipe might cause out of order completion.
- Any topology change is done via the Add VSI or Add VEB commands (*Enabled TCs* field) that defines the TCs for the VSI or VEB.
  — EMP adds VEB, VSI, queue sets accordingly.
  — As a response to ADD VSI command, the EMP provides the queue set handles of the enabled TCs.
  — For each enabled TC, the PF is required to copy the queue set handle value to all queues belonging to the queue set.

38.25.5.7 Transmit Scheduler Resource Allocation Control

Each PF is configured with limited number of resources. The 10 GbE controller scheduler enables flexible resource allocation, but due to limited number of queue set supported, it is allowed to allocate an average of two queue sets per VSI.

Number of VSIs dedicated per PF is a switch configuration parameter configured via NVRAM. The remainder of available VSIs are shared on the first-come-first-serve bases.

Scheduler configuration firmware only controls resources allocated for PF, and enables the PF driver to distribute those resources within PF.

Allocation of queue sets per PF is proportional to the allocation of VSIs, assuming average of two queue sets per VSI. Shared queue sets can be allocated to PFs on first-come-first-serves bases, similar to VSIs.

38.25.5.8 Scheduler Configuration Schemes

The ETS-based scheme enables ETS configuration for the switching component or VSI directly connected to the physical port, and bandwidth allocation of other VSIs and switching components within each traffic type that can be either UP or TC enabled for that VSI or switching component. See Section 38.25.2.1.

Software should not attempt to configure bandwidth management attributes that are not supported by configured scheme. Firmware rejects performing invalid operations and returns an EPERM error described in Section 38.25.4.4.

38.25.5.8.1 ETS-based Scheme: Relative Bandwidth Credits Calculation

ETS-based configuration enables the 10 GbE controller's software to configure relative bandwidth allocation for each switching component and VSI within each traffic type (UP or TC). Software should use AQ commands described in Section 38.25.4.8 and Section 38.25.4.14, respectively.

The 10 GbE controller software should be able to configure ETS-based transmit scheduler based on:

- An absolute bandwidth allocation (in GB/s or Mb/s) for VSIs and switching components within each TC or UP enabled for the respective VSI or switching component.
- An absolute bandwidth allocation for VSIs and switching components and ETS configuration for each VSI and switching component.

In either case, configuration provided by system management software needs to be translated to relative bandwidth allocation of VSIs and switching components within TC or UP expressed in relative bandwidth allocation credits.

Figure 38-86 shows an example of ETS-based scheme bandwidth configuration and process of relative bandwidth credits calculation.

Figure 38-86.ETS-Based Scheme: Relative Bandwidth Calculation Example

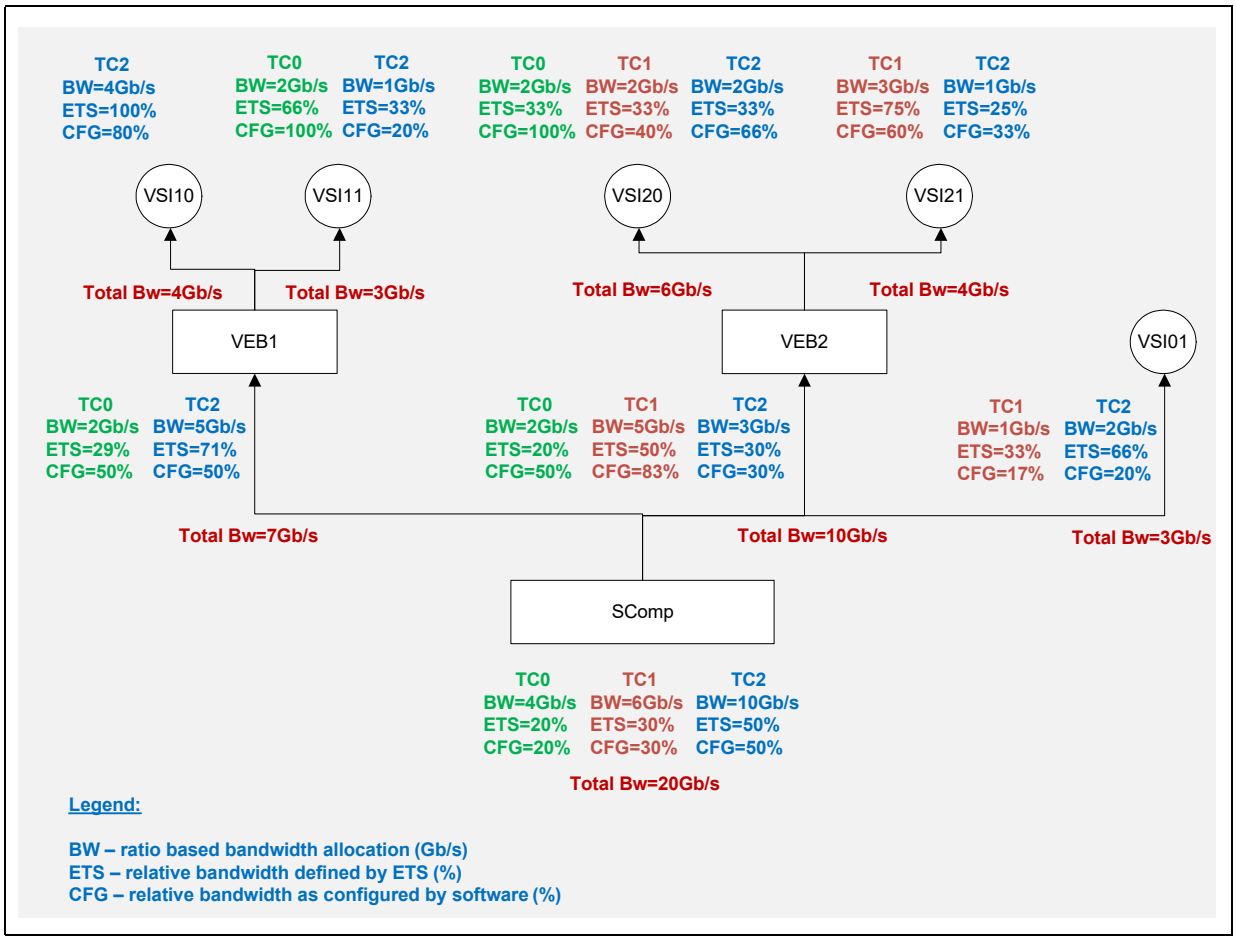


Figure 38-86 shows a single port configuration with S-comp. Two VEB switching components are connected to S-comp (VEB1 and VEB2), along with VSI (VSI01) directly attached to S-comp. Each VEB has two VSIs (VSI10 and VSI11, and VSI20 and VSI21, respectively).

Figure 38-86 for each switching component and VSI shows a per TC bandwidth allocation using three terms:

- ETS — Relative bandwidth allocation per TC within VSI/switching component in percentage with respect to other TCs. can be provided by system software along with total bandwidth allocated for the switching component and VSI.
- BW — Bandwidth allocation per TC in Gb/s, based on the physical wire speed of 20 Gb/s, and hierarchical bandwidth distribution specified by ETS. Can be either provided by system management software, or calculated based on the total bandwidth allocation for the switching component or VSI and ETS configuration.
- CFG — Calculated hierarchical relative bandwidth allocation of VSIs and switching components within each TC, in percentage with respect to other VSIs and switching components on the same hierarchy level.
- Total Bandwidth — Can be provided by system management software along with ETS configuration for the switching components and VSIs.

Note: ETS-based configuration does not guarantee bandwidth allocation for VSIs and switching components in ETS-based configuration, but it can use bandwidth allocation provided by system software to configure VSI and switching components relative bandwidth allocation within each TC or UP.

If a physical port is configured to a two-level ETS (such as bandwidth is allocated for TCs, and then distributed between UPs within same TC), then VSI and switching component bandwidth is allocated per UP.

If a physical port is configured to single-level ETS (bandwidth distribution between TCs only), the 10 GbE controller software can assume a logical one-to-one mapping of UPs to TCs for the bandwidth distribution purpose, and use AQ commands described in Section 38.25.4.8 and Section 38.25.4.14 to configure VSi and switching component bandwidth allocation within TC.

In either case, relative credits calculation should be done following this algorithm:

- If system software provided absolute bandwidth allocation per TC or UP:
  - The 10 GbE controller software should calculate a relative bandwidth allocation with respect to the parent switching entity within each traffic type (TC or UP).
  - Translate relative bandwidth allocation to credits, minimizing number of credits allocated.
- If system software provided an absolute bandwidth allocation for VSI or switching component and ETS:
  - The 10 GbE controller software should calculate an absolute bandwidth allocation per traffic type within VSI or switching component, which would be the same as an absolute bandwidth allocation of VSI or switching component within traffic type (TC or UP). Calculate a relative bandwidth allocation with respect to the parent switching entity within each traffic type (TC or UP).
  - Translate relative bandwidth allocation to credits, minimizing number of credits allocated

Table 38-331 lists an example of relative bandwidth credits calculation for the ETS-based system configuration shown on Figure 38-86. This example assumes that system management software provided a total bandwidth allocated for each VSI and switching component, and ETS.

Table 38-331.ETS-Based Scheme-relative Bandwidth Calculation Example (Sheet 1 of 2)

Switching Element Name	Parent Switching Element Name	Total BW	ETS (TCs)	ETS (%)	ETS (Gb/s)	Relative BW Within TC	Relative Credits within TC	Comments
S-comp	Physical Port	20 Gb/s	TC0	20%	4 Gb/s	100%	NA	No need to configure relative bandwidth allocation within traffic type for switching element attached directly to physical port.
			TC1	30%	6 Gb/s	100%	NA	
			TC2	50%	10 Gb/s	100%	NA	
VEB1	S-comp	7 Gb/s	TC0	29%	2 Gb/s	50%	1	VEB1 shares TC0 bandwidth with VEB2, 50% each, therefore 1 relative credit will correctly reflect a relative bandwidth allocation between VEB1 and VEB2 (1:1).
			TC2	71%	5 Gb/s	50%	5	VEB1 shared TC2 bandwidth with VEB2 and VSI01, with ratio 5:3:2, which is reflected by relative credits.

Table 38-331.ETS-Based Scheme-relative Bandwidth Calculation Example (Sheet 2 of 2)

Switching Element Name	Parent Switching Element Name	Total BW	ETS (TCs)	ETS (%)	ETS (Gb/s)	Relative BW Within TC	Relative Credits within TC	Comments
VEB2	S-comp	10 Gb/s	TC0	20%	2 Gb/s	50%	1	VEB2 shares TC1 bandwidth with VSI01, relative ratio is 5:1, which is reflected in relative credits.
			TC1	50%	5 Gb/s	83%	5	
			TC2	30%	3 Gb/s	30%	3	
VSI01	S-comp	3 Gb/s	TC1	33%	1 Gb/s	17%	1	
			TC2	66%	2 Gb/s	20%	2	
VSI10	VEB1	4 Gb/s	TC2	100%	4 Gb/s	80%	4	VSI10 shared TC2 bandwidth allocated for VEB1 with VSI11, with relative ratio 4:1, which is reflected in allocated relative credits.
VSI11	VEB1	3 Gb/s	TC0	66%	2 Gb/s	100%	1	VSI11 consumes all TC0 bandwidth allocated for VEB1, and therefore can be configured with 1 relative credit.
			TC2	33%	1 Gb/s	20%	1	
VSI20	VEB2	6 Gb/s	TC0	33%	2 Gb/s	100%	1	VSI20 consumes all TC0 bandwidth allocated for VEB2, and therefore can be configured with 1 relative credit.
			TC1	33%	2 Gb/s	40%	2	VSI20 shared TC1 bandwidth allocated to VEB2 with VSI21 with relative ratio 2:3, which is reflected in relative credits
			TC2	33%	2 Gb/s	66%	2	
VSI21	VEB2	4 Gb/s	TC1	75%	3 Gb/s	60%	3	VSI21 shared TC2 bandwidth allocated to VEB2 with VSI20 with relative ratio 1:2, which is reflected in relative credits.
			TC2	25%	1 Gb/s	33%	1	

Note: Table cells with gray background show numbers calculated by the 10 GbE controller software.

38.26 Host Memory Cache (HMC)

The 10 GbE controller uses host memory as a backing store for a number of context objects used to track queue state and iWARP objects. The HMC is the component responsible for managing the LAN and iWARP context objects stored in host memory. The HMC manages host memory on a per-PCI function basis and further breaks down each of the PCI function's HMC memory space into memory used to manage each context object that is in use for a given PCI function. Host software is responsible for allocating the host pages used by the HMC before accessing a specific object. Additionally, the amount of memory that can be used for HMC backing store for a specific function is dictated by the active resource profile that is determined by the software drivers operating environment and the number of PCI functions that are currently active. Resource profiles can be selected at software device driver initialization time.

38.26.1 Host Memory Usage

The HMC requires a backing store for numerous data structures to be resident in host memory to perform its functions. Table 38-332 lists the data structures and the amount of memory that needs to be allocated for each data structure. The HMC Object Location column indicates if the HMC object (and the associated backing store pages) is located only in the PF HMC object space or if it is located in both the PF and the VF HMC object space. In general, all LAN objects for both PFs and VFs are located in the PF HMC object space while PE HMC objects are separated into PF and VF specific HMC object spaces. The resources can be sparsely populated. For example, if a function is allotted 512 QPs and only 8 are used, then only 4 KB of memory needs to be allocated not the entire memory for all 512 QPs. Some HMC objects need to be fully populated at software device driver initialization such as PE hash table entries. Refer to the HMC resource allocation policies for LAN and the PE, respectively.

Table 38-332.HMC Objects

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
LAN Transmit Queue	PFs	128	1536 Per Device	The PF owns the objects for the associated VFs. LAN absolute queue numbers assignment to PFs are determined by the programming of the PFLAN_QALLOC registers. HMC object indexes match the LAN queue indexes.
LAN Receive Queue	PFs	32	1536 Per Device	The PF owns the objects for the associated VFs. See the previous description of LAN transmit queues for details on the relationship between absolute LAN QP numbers and HMC object indexes.
Protocol Engine QP Context	PE Enabled PFs and VFs	512	256 KB	512 bytes are reserved for QP context. There is a maximum of 256 KB QP contexts per device. This number is divided among all PE enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF Requester ID (RID). For a single function device, hardware reserves one of the 256 KB QPs for internal use.
Protocol Engine CQ Context	PE Enabled PFs and VFs	64	128 KB	64 bytes are reserved for CQ Context. There is a maximum of 128 KB CQ contexts per device. This number is divided among all PE enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.

Table 38-332.HMC Objects

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
Protocol Engine Shared RQ	PE Enabled PFs and VFs	64	32 KB Per PCI Function	64 bytes are reserved for shared RQ context. There is a maximum of 32 KB S-RQ contexts per PE enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Protocol Engine TCP Timers	PE Enabled PFs And VFs	64	2^{28} Per PCI Function	This structure is allocated per PCI function. The number of elements allocated for this structure is dependent on the number of QPs associated with the PCI function. The equation for the number of objects is ((ROUNDUP512(number of QPs)/512) + 1) * 4096. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Protocol Engine Hash Table Entry	PE Enabled PFs And VF	64	(#PE QPs Multicast Groups)* 3 Per Function	This structure is allocated per PCI function. The number of elements allocated for this structure needs to be the number of QPs allocated to the function multiplied by 3. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID. The actual number of hash table entries for the PF is programmed using the PFQF_CTL_2 and VFQF_CTL registers.
ARP Table Entry	PE Enabled PFs And VF	16	65536 Per PCI Function	The maximum size of the ARP table is 65536 entries per PE enabled PCI function. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Accelerated Port Bit Vector In-use	PE Enabled PFs And VF	8KB	1 Per PCI Function	This table is used for the 10 GbE controller to track each PCI functions usage of the accelerated port bit vector table and is only required for PE enabled PCI functions. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Memory Region Table Entry (MRTE)	PE Enabled PFs And VF	32	4 MB Per PCI Function	Each PE enabled PCI function can have up to 4 MB MRTE entries allocated. The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Physical Buffer List Entry (PBLE)	PE Enabled PFs And VF	8	256 MB Per PCI Function	Each PE enabled PCI function can have up to 256 MB PBLE entries allocated. The memory for the VF objects is allocated by the VF driver and accessed using the VF RID. PF drivers are also able to (via VF) force PBLEs to be accessed with the PF RID by using the *use_pf_rid* bit in the memory registration associated with the PBLE. Any associated page descriptors are allocated by the PF driver and accessed using the PF RID.
Transmit FIFO	PE Enabled PFs And VFs	32	32 MB Per PCI Function	Each PE enabled PCI function can have up to 32 MB transmit FIFO entries per PCI function. Transmit FIFO entries are used to track un-acknowledged PE send queue work requests (WQEs). The number of transmit FIFO entries to allocate for a given PCI function can be calculated based on expected network performance and workload pattern. Allocating too few transmit FIFO entries results in head of line blocking for PE QPs running on a particular PCI function.The memory for the VF objects is allocated by the PF driver and accessed using the PF RID. Must be specified as a power of two.
Transmit FIFO Free List	PE Enabled PFs And VFs	4	16 MB Per PCI Function	Each PE enabled PCI function can have up to 16 MB transmit FIFO free list entries per PCI function.The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.

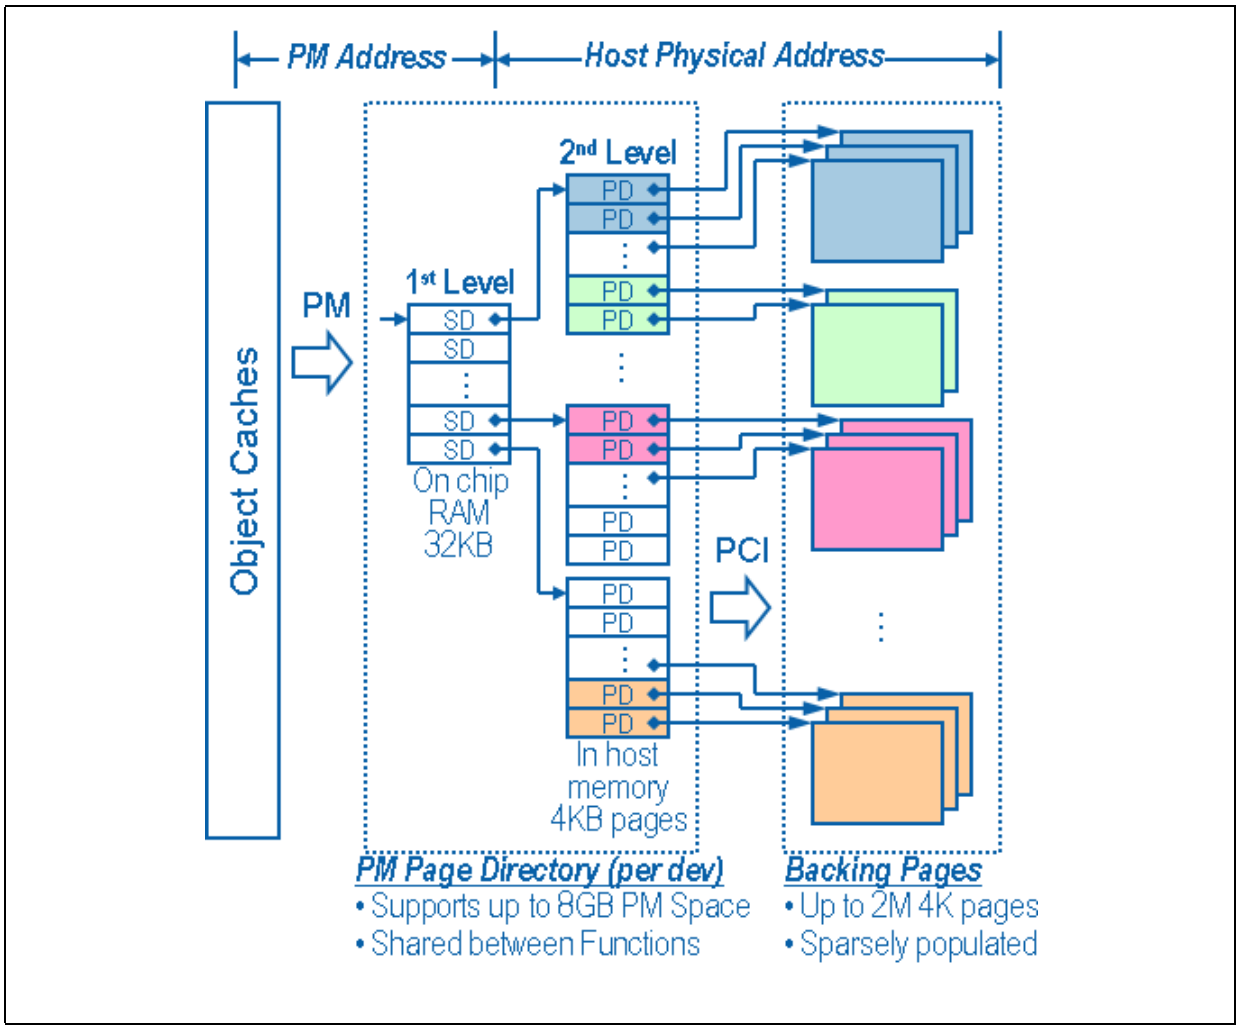
Table 38-332.HMC Objects

HMC Object	HMC Object Location	Size (Bytes)	Max Quantity	Description
Inbound RDMA Read Queue (IRRQ or Q1)	PE Enabled PFs And VF	64	32 MB Per PCI Function	Each PE enabled PCI function can have up to 32 MB IRRQ entries. IRRQ entries are allocated on a per QP basis and in quanta's of the maximum number of outstanding RDMA reads that are allowed multiplied by 2. In other words, if a PE enabled PCI function has 64 KB QPs enabled and each is allowed up to 64 outstanding RDMA reads, space for 8 MB (64K*(64*2))IRRQ entries (512 MB) must be allocated by the software device driver.The memory for the VF objects is allocated by the PF driver and accessed using the PF RID. Must be specified as a power of two.
Inbound RDMA Read Queue (IRRQ or Q1) Free List	PE Enabled PFs And VF	4	32 MB Per PCI Function	Each PE enabled PCI function can have up to 32 MB IRRQ free list entries.The memory for the VF objects is allocated by the PF driver and accessed using the PF RID.
Multicast Group	PE Enabled PFs And VF	64	8192 Per PCI Function	Each PE enabled PCI PF can have up to 8 KB multicast groups. VFs do not have multicast groups.
Address Handles	PE Enabled PFs and VFs	32	65536 per PCI Function	Each PE enabled PCI function might have up to 64 KB address handles.The memory for the VF objects is allocated by the PF driver and accessed using the PF Requestor ID (RID).

In order to access (and cache in on-chip memory) the data structures listed in Table 38-332, the HMC uses the concept of private memory address space. The 10 GbE controller has an 8 GB private memory address space that can be sparsely backed with host memory based on actual context usage. Software device drivers do not need to allocate pages for HMC objects that are not currently being used by the software device driver. The private memory address space is first broken down by PCI function, then by object or data structure type, and finally by object index. The portion of the private memory address space that is allocated to a particular PCI function is termed Function Private Memory (FPM). FPM objects for VF LAN are located in the associated PFs FPM. Also note that the VF FPMs are not programmed directly by the VF drivers. The PF driver uses the HMC function index to select the VF FPM to be programmed.

Figure 38-87 shows how the 10 GbE controller provides the address mapping between private memory and host physical addresses. Private memory address shown on the left side of the diagram indicates the 10 GbE controller private memory address from 0 to 8 GB-1. The 10 GbE controller works with private memory address space internally, which is converted to host physical addresses in order to access host memory.

Figure 38-87.Host Memory Cache Private Memory Address Space



The left portion of Figure 38-87 shows portions of the HMC that are resident on-chip. This portion includes the actual object caches that retain portions of the data from host memory to improve performance and the Segment Descriptors (SD). The SDs reside in a 32 KB on-chip RAM called the segment descriptor table. The segment descriptor table holds 4096 pointers to host memory pages. Unique ranges of sequential SDs in the segment descriptor table are allocated to a each PCI function that is active. The segment descriptor table is the first level of private memory address translation provided by the 10 GbE controller. SDs are programmed using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers. PE CQP operations also can be used to program SDs. Everything to the right of the segment descriptor table in Figure 38-87 resides in host memory. Each PCI function has a set of registers (GLHMC_SDPART[n] and GLHMC_VFSDPART[n]) that define the base and number of SDs that belong to the PCI function. The GLHMC_SDPART[n] and GLHMC_VFSDPART[n] registers are programmed from the NVM. The 10 GbE controller provides range checking for each internal access to ensure that a given PCI function is never allowed to access memory outside of its valid range of SDs. The 10 GbE controller manages the SD base and number registers internally based on the resource profile that is loaded from the NVM.

The second level of private memory address translation provided by the 10 GbE controller are Page Descriptors (PDs). Each SD points to a single host page that is divided into 512 PDs that are 64-bit physical memory addresses. Each PD points to a backing page for the private memory address space. The total 8 GB private memory address space is derived using a fully populated segment descriptor table pointing to 4096, 4 KB host pages that hold the 2 M PDs. Each of the 2 M PDs point to host memory backing pages for a total of 8 GB of address space. As previously mentioned, there is no requirement to populate all SDs or PDs with memory if the portion of private memory address space is not in use by software. The format of the PD structure in host memory is listed in Table 38-333.

Table 38-333.HMC page descriptor format

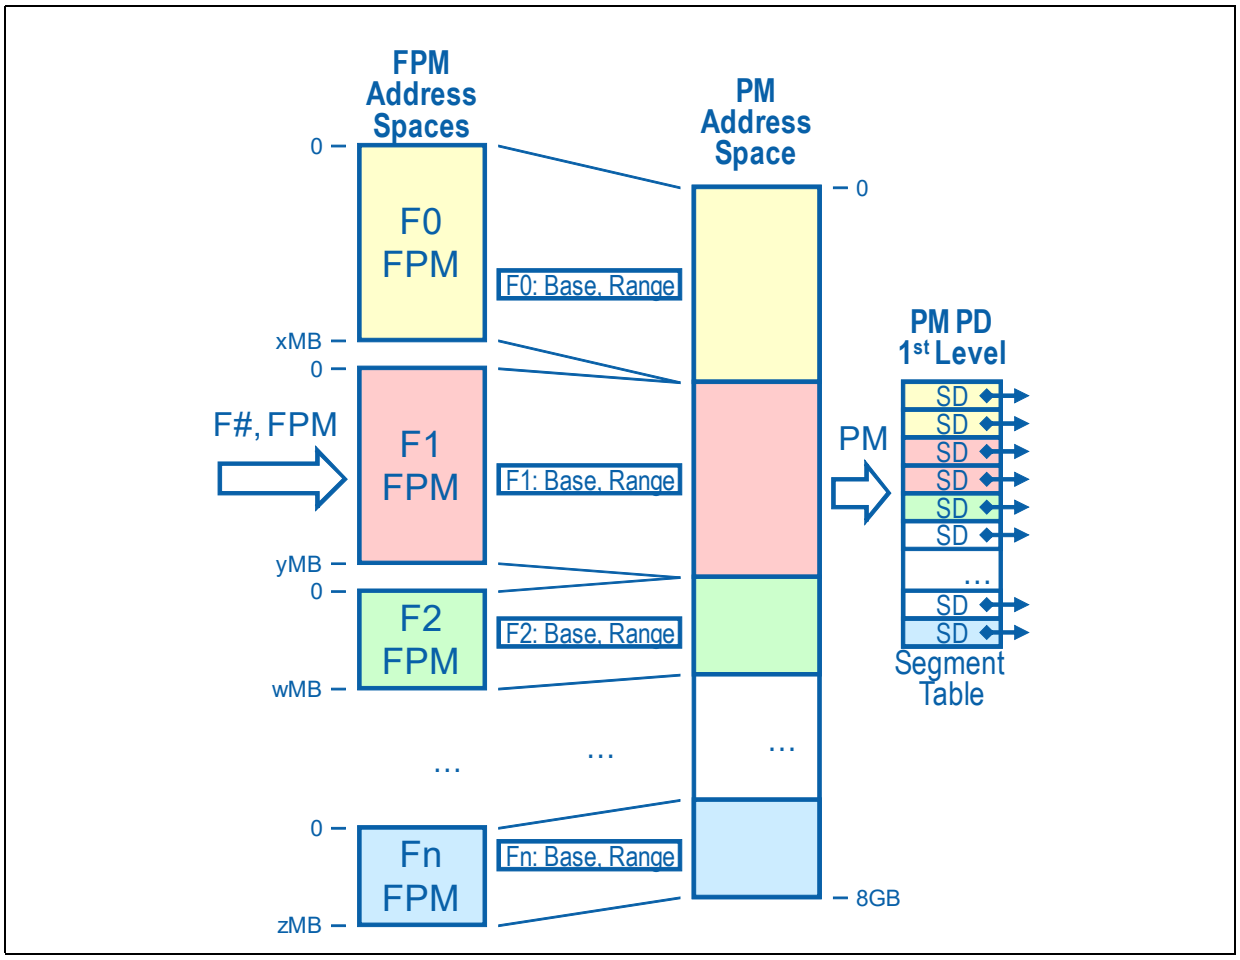
Byte Offset	[Bit Range]Field Name
0	[63:12] HMC Backing Page Physical Address [11:1] Reserved [0] PD Valid

The HMC backing page physical address is the address of a software device driver allocated page that holds HMC object context. This address must be aligned to a 4 KB address in host memory. The PD *Valid* bit enables software to sparsely populate the PD entries on an as needed basis once HMC context objects are needed. Software must allocate host memory pages that hold packed arrays of PDs as shown in Figure 38-87. The physical address of these PD pages are used to populate SD entries by using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers. For more information on how to program SDs using these registers, see Section 38.26.5.

Private memory is further divided into separate PCI FPM addresses. A PCI function can be either a PF or VF. The first 16 FPM address spaces are reserved for Network Interface Cards (NICs) and PFs.The next 16 FPM address spaces are used for PFs that support PE-provided accelerations for iWARP or UDA. The final 32 FPM address spaces are used for VFs that support the PE provided accelerations for iWARP or UDA. NIC objects are located in the PF FPM.

Figure 38-88 shows how the private memory address space is divided up for each PCI function. The smallest amount of private memory that can be allocated to a function is 2 MB (1 SD). The maximum that could be allocated to a function would be the entire segment table in which case no other function can have any private memory resources. Note that the object caches address HMC objects using HMC function number to determine the correct FPM. The FPM identifies the range of private memory address space that belongs to a PCI function. Since each SD represents 2 MB of HMC PM address space, the FPM also identifies the range of SDs that belong to a PCI function.

Figure 38-88.HMC FPM Space



Each PCI function's private memory space is further divided into separate memory spaces for each object in host memory. Each PCI function has a set of registers per function that define the object's base address in FPM space and the bounds (or maximum number of entries) of a particular object. Figure 38-89 shows some of the current objects that reside in the private memory space. See Table 38-332 for a complete list of the objects. The FPM address is calculated based off of the object type, which identifies the object base register and object index (the FPM base has already been calculated). Ultimately, the FPM base address, object base address, object size, and object index are all used to determine the private memory address.

Figure 38-89.HMC FPM Object Access

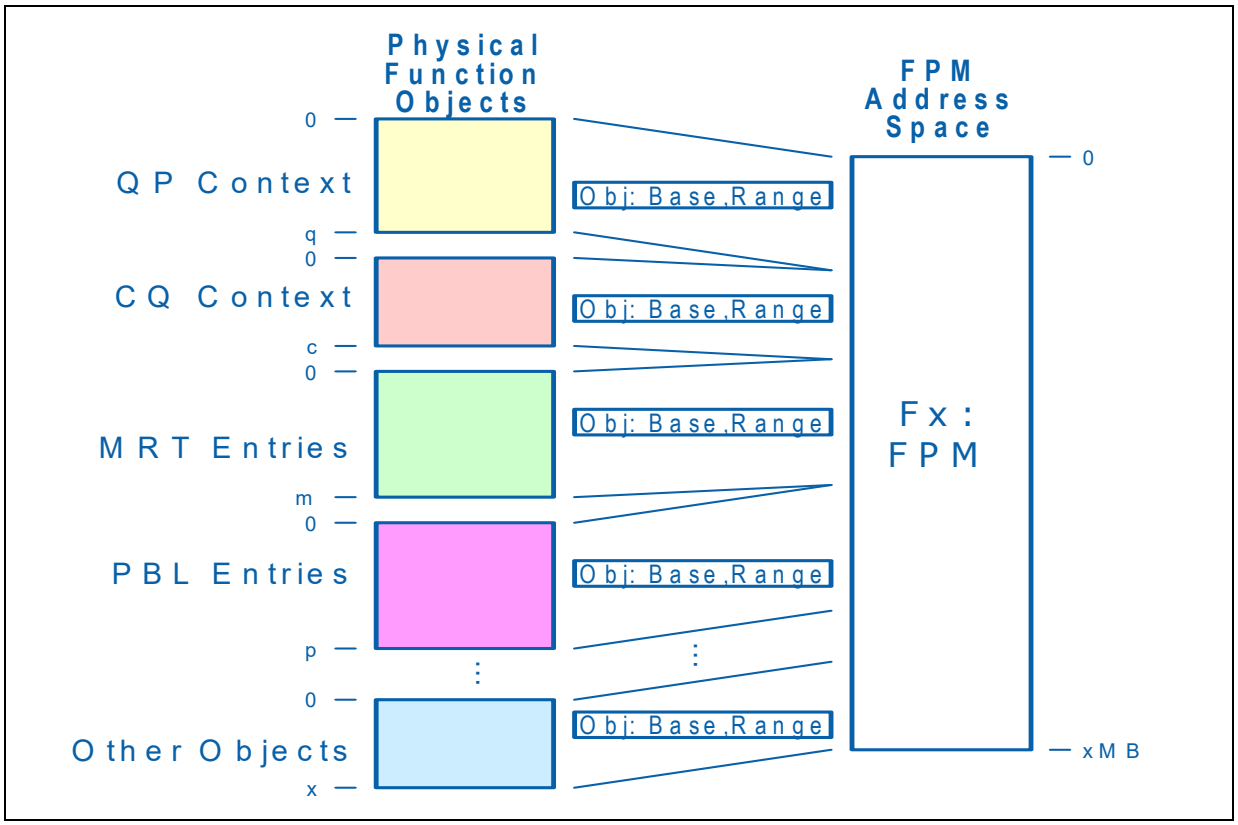


Figure 38-90 shows the decoding of the private memory address into host address. Additionally, Figure 38-90 shows an SD addressing a private memory space backing page directly instead of using the second level of indirect addressing (PD). Each PCI function can set any SD within its range of SDs to be either pointing to a PD or directly to a backing page. The segment type is specified in the PFHMC_SDDATALOW.PMSDTYPE register field. The direct segment approach can be used for PCI functions that do not have a large requirement for FPM space to reduce overhead incurred while accessing HMC objects. Additional usage of the direct segment approach is possible if the software device driver is able to allocate a physically contiguous range of pages large enough to hold the entire PD space needed to support the FPM required by the software device driver loading on a specific PCI function. This mode prevents an additional address lookup and increases the performance if the software device driver happens to allocate a block of physically contiguous memory or the operating system has support for 2 MB pages.

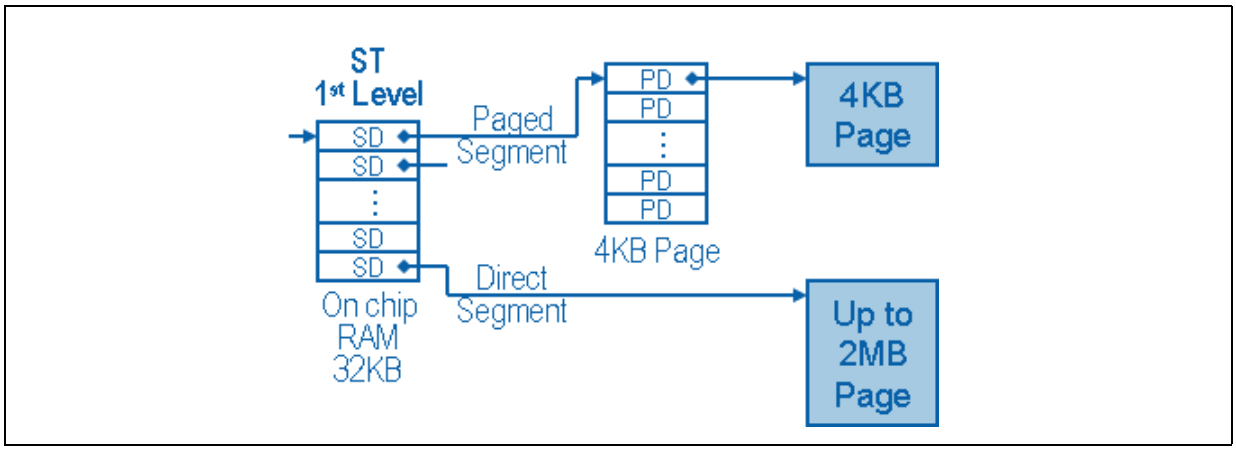
Figure 38-90.HMC Direct Segment



See Section 38.26.4 for more details on the specific formats of the SD entries for paged and direct addressing modes.

38.26.2 Private Memory Space Profiles

The 10 GbE controller's private memory address space configuration is a two step process. The first step is to partition the HMC related resources into per PCI function resources. The second step is to divide the resulting FPM into individual objects. In order to simplify resource allocation, The 10 GbE controller provides a resource profile concept the operating system environment into account to divide HMC private memory space and PE doorbell resources. These HMC resource profiles are used to partition the HMC segment descriptor table and PE doorbell resources. Software performs the FPM division on a per PCI function basis. The currently defined HMC resource profiles are listed in Table 38-334. PE doorbell resources place constraints on the HMC resource profiles since there is a fixed number of these resources on-die. There are enough doorbell resources for 256 KB protocol queue pairs and 128 KB PE completion queues. These resources must be partitioned between PCI functions that require PE functionality. The resource profiles drive the values found in the following registers:

- GLHMC_SDPART — Configures the HMC segment descriptor range per PF
- GLHMC_VFSDPART — Configures the HMC segment descriptor range per PE enabled VF
- GLHMC_DBQPPART — Configures the range of PE QP doorbells per PF
- GLHMC_VFDBQPPART — Configures the range of PE QP doorbells per PE enabled VF
- GLHMC_DBCQPART — Configures the range of PE CQ doorbells per PF
- GLHMC_VFDBCQPART — Configures the range of PE CQ doorbells per PE enabled VF
- GLHMC_CEQPART — Configures the range of PE CEQs per PF
- GLHMC_VFCEQPART — Configures the range of PE CEQs per PE enabled VF

These registers are loaded from the NVM to match the default profile. The admin queue can be used to change the programming of these registers to match any of the following resource profiles.

Table 38-334.10 GbE Controller HMC Resource Profiles

Profile Name	Description
Default	The default profile evenly distributes all HMC segment descriptor table entries and PE doorbell resources among all active PFs. No PE resources are allocated to VFs but LAN objects for VFs are allocated to the PFs associated with VFs as configured from NVM. See Section 38.26.2.2 for more details.
SR-IOV VF Primary	The SR-IOV VF primary HMC resource profile first distributes HMC LAN resources for PFs and VFS to PFs, then distributes a relatively small number of HMC PE resources to the active PFs, and then evenly distributes the remaining HMC PE resources among the PE enabled VFs. This resource profile assumes that the PE functionality primarily used by VFs when running a virtualized operating system. See Section 38.26.2.3 for more details.
SR-IOV Even Distribution	The SR-IOV even distribution HMC resource profile first distributes HMC LAN resources for PFs and VFs to PFs and then evenly distributes the HMC PE resources among the PFs and PE enabled VFs. This resource profile assumes that the PE functionality is used by PFs and VFs when running a virtualized operating system. See Section 38.26.2.4 for more details.

Each of these profiles are a set of equations that the 10 GbE controller uses to configure the HMC. This first phase of the HMC initialization is activated by an NVM reload (all settings revert back to the default profile) or by writing using the AQ commands specified in Section 38.27. Host software only needs to change from the default profile based upon the need for PE functionality in a VF. If this is not the case then the default profile covers all usage models. If PE functionality is required in a VF, the software device driver determines which of the two resource profiles best fit the users needs and selects that profile at software device driver initialization time. Note that all profiles cover the needs of LAN resources for both virtualized and non-virtualized environments.

38.26.2.1 Host HMC Resource Partitioning

The HMC resource profile can be selected by expansion ROM code before the operating system loads and also by the first software device driver that loads within the operating system. It is expected that expansion ROM boot code (PXE and iSCSI) does not need to change the profile, but it can change the profile if needed. Once the operating system software device driver loads, it is also allowed to change the HMC resource profile. The assumption is that all the instances of the operating system software device driver requests the same HMC resource profile. The currently active profile loaded by the 10 GbE controller can be retrieved by issuing the Get HMC Resource Profile AQ command.

38.26.2.2 Default HMC Profile Equations

The default HMC resource profile enables the maximum number of LAN queue objects for each PF and associated VFs and distributes all PE resources evenly among all active PFs (no PE resources are available for VFs). This includes partitioning the SD table, the PE QP and CQ doorbell resources, and the PE completion event queues. The number of active PFs is reported in the GLGEN_PCIFCNCNT registers.

Table 38-335.Default HMC Profile Examples

Number of Active PFs	PF Index	SD Base Index	SD Count	PE QP Doorbell Base Index	PE QP Doorbell Count	PE CQ Doorbell Base Index	PE CQ Doorbell Count	PE CEQ Base Index	PE CEQ Count
1	0	L2:0 PE:10	L2:1	0	256 KB	0	128 KB	0	128
	1-15	L2:0 PE:0	L2:0 PE:0	0	0	0	0	0	0
2	0	L2:0 PE:2	L2:1	0	128 KB	0	64 KB	0	128
	1	L2:1	L2:1	128 KB	128 KB	64 KB	64 KB	128	128
	2-15	L2:0 PE: 0	L2:0 PE:0	0	0	0	0	0	0
4	0	L2:0 PE:4	L2:1	0	64 KB	0	32 KB	0	64
	1	L2:1	L2:1	64 KB	64 KB	32 KB	32 KB	64	64
	2	L2:2	L2:1	128 KB	64 KB	64 KB	32 KB	128	64
	3	L2:3	L2:1	192 KB	64 KB	96 KB	32 KB	192	64
	4-15	L2:0 PE:0	L2:0 PE:0	0	0	0	0	0	0

The calculation used by the 10 GbE controller for the number of SDs should be SDs (4096) divided by the number of PFs, rounded down to the next integer. The calculation for the number of PE QPs is the number of PE QPs (256 KB) divided by the number of PFs, rounded down to the next full page size that would be needed for context. PE QP context size is 512 bytes per QP. The calculation for the number of PE CQs is similar except that the max number of PE CQs is 128 KB and the CQ context size is 64 bytes. The PE CEQ calculation is similar to the segment descriptor calculation except that the number of PE CEQs total is 256 and the maximum number or CEQs for any single PCI function is 128. Table 38-336 lists the resource counts for all possible PF counts in the default HMC resource profile.

Table 38-336.Initial 10 GbE Controller Host Memory Cache Partitioning per PF

PF Count	#SDs	#PE QPs	#PE CQs	#PE CEQs
1	1	262144	131072	128
2	1	131072	65536	128
3	1	87376	43648	85
4	1	65536	32768	64
5	1	52424	26176	51
6	1	43688	21824	42
7	1	37448	18688	36
8	1	32768	16384	32
9	1	29120	14528	28
10	1	26208	13056	25
11	1	23824	11904	23
12	1	21840	10880	21
13	1	20160	10048	19
14	1	18720	9344	18

Table 38-336.Initial 10 GbE Controller Host Memory Cache Partitioning per PF

PF Count	#SDs	#PE QPs	#PE CQs	#PE CEQs
15	1	17472	8704	17
16	1	16384	8192	16

38.26.2.3 SR-IOV VF Primary HMC Profile Equations

The SR-IOV VF primary HMC resource profile allocates PE resources in favor of the VFs. LAN resources are the same as the default profile since the LAN resources are always located in the PF HMC address space. In this case, the FPM spaces are broken down into two sets:

1. PFs
2. PE enabled VFs

The first 16 FPMs are always reserved for PFs even if less than 16 PFs are enabled. If less than 16 PFs are enabled, some of the FPMs will have zero resources allocated to them. The next set of FPMs (16-47) are the PE enabled VFs. The maximum number of VFs in this set is 32 but can be limited to less by setting the PE enabled VF count in the Set HMC Resource Profile AQ command.

In this resource profile, all enabled PFs are allocated the following resources:

- 10 SDs for PF PE
- 1024 PE queue Pairs
- 512 PE completion queues
- 8 PE completion event queues

After allocating the resources for the PFs and the NIC VF resources that reside in the PF, the remaining resources are evenly distributed across all PE enabled VFs. Assuming that there are 2 PFs active and 128 VFs (32 of which can be enabled for PE support), the HMC resources would be distributed as listed in Table 38-337.

Table 38-337.Example SR-IOV VF Primary Profile Resource Partitioning per FPM

Function Type	FPM Index Range	#SDs	#PE QPs	#PE CQs	#PE CEQs
PF (2)	L2: 0-1 PE: 16-17	L2: 10 PE: 10	1024	512	8
Inactive PF (14)	L2: 2-15 PE: 18-31	L2: 0 PE: 0	0	0	0
Protocol Engine Enabled VFs (32)	PE: 32-63		8128	4032	7
Total		4072	262144	130048	240

The equations for distributing PE QPs and CQs are similar to those used to distribute resources among PFs in the default HMC resource profile.

38.26.2.4 SR-IOV Even Distribution HMC Profile Equations

The SR-IOV even distribution HMC profile is used for environments where there is equal need for PE resources in the PFs and all PE enabled VFs in operating systems that support I/O virtualization. Typically the number of PE enabled VFs is reduced in this profile in order to enable sufficient PE resources for a VF to run HPC workloads.

In this resource profile, all enabled PFs are allocated the following resources:

- 1 SD for PF NIC
- Remaining SDs/(active PFs + RDMA enabled VFs) SDs for PE
- 256K/(active PFs + RDMA enabled VFs) PE queue pairs
- 128K/(active PFs + RDMA enabled VFs) PE completion queues
- 256/(active PFs + RDMA enabled VFs) PE completion Event queues

In this resource profile, all enabled VFs are allocated the following resources:

- Remaining SDs/(active PFs + RDMA enabled VFs) SDs for PE
- 256K/(active PFs + RDMA enabled VFs) PE queue pairs
- 128K/(active PFs + RDMA enabled VFs) PE completion queues
- 256/(active PFs + RDMA enabled VFs) PE completion event queues

Assuming the 2 PFs are enabled, 128 VFs are enabled, and 16 PE enabled VFs are configured, Table 38-338 lists the distribution of resources to the HMC FPMs.

Table 38-338.SR-IOV Even Distribution Profile Resource Partitioning Per FPM

Function Type	FPM Index Range	#SDs	#PE QPs	#PE CQs	#PE CEQs
PF (2)	L2: 0-1 PE: 16-17	PE: 22	14560	7232	14
Inactive PF (14)	L2: 2-15 PE: 18-31	L2: 0 PE: 0	0	0	0
PE Enabled VFs (16)	PE: 32-47	22	14560	7232	14
Total		4088	262080	130176	252

38.26.3 FPM Space Configuration

Once the NVM has set the default profile or the Set HMC Resource Profile AQ command has been used to set an appropriate HMC resource profile, the software device driver can then continue on with the second step of HMC configuration, which is to break down the FPM space into individual object regions. In order to do this, the software device driver must perform the following steps:

1. Determine the HMC function index to be configured. In the case of a PF, the HMC function number is equal to the PCI function number. In the case of a VF when the PE resources are configured, the HMC index depends on the programming of the HMC PM function table using the CQP manage HMC PM function table operation. Note that there are two arrays defined for each HMC FPM register (one array for PFs and a second array for the PE enabled VFs).
2. For LAN queue objects, read the PFLAN_QALLOC register associated with the PF to find the base queue index and number of queues associated with the PF.
3. For PE objects, read the current HMC configuration information in order to know how to calculate the numbers of each HMC object that need to be requested.

a. GLHMC_SDPART[n] or GLHMC_VFSDPART[n] — A PE enabled VF register associated with the HMC FPM reports the currently available SDs for a given PCI function, which can be used to calculate the maximum FPM space.

b. GLHMC_DBQPPART[n] or GLHMC_VFDBQPPART[n] — A PE enabled VF reports the maximum number of PE QPs that can be used. The software device driver does not have to allocate maximum FPM space based on PMDBMAXQP if less QPs are needed for the active software device driver deployment model.

c. GLHMC_DBCQPART[n] or GLHMC_VFDBCQPART[n] — A PE enabled VF used to determine the maximum number of PE completion queues that can be used by a given PCI function. Similarly to the maximum QP count, the software device driver is not required to allocate the maximum amount of FPM space for CQs if the software device driver deployment model requires less.

d. GLHMC_CEQPART[n] or GLHMC_VFCEQPART[n] — A PE enabled VF used to determine the maximum number of CEQs that can be used with a given PCI function. Note that PE CEQs do not consume FPM space but are still partitioned as part of the HMC resource profiles.

e. GLHMC_{object}MAX — Other object maximum values are found in these registers.

4. Each FPM object size register is written with the minimum of the values determined in steps 2-4 or the actual software device driver needs.

5. Write the base and count registers for each LAN object based on the maximum object index that would be used for the PCI function (HMC PM LAN objects are indexed with the absolute queue number).

For PE objects, issue the commit FPM values CQP operations to program the object base registers.The HMC resource profiles enable enough FPM space for the maximum number of LAN objects.

Table 38-339 lists all the HMC objects and the registers used to determine the object location within FPM space including the size and limit of each object.

Table 38-339.FPM Object Registers

HMC Object	Base Register Array	Object Count Register Array	Maximum Object Count Register	Object Element Size Register
LAN Transmit Queue	GLHMC_LANTXBASE	GLHMC_LANTXCNT	PFLAN_QALLOC	GLHMC_LANTXOBJSZ
LAN Receive Queue	GLHMC_LANRXBASE	GLHMC_LANRXCNT	PFLAN_QALLOC	GLHMC_LANRXOBJSZ
PE QP Context	GLHMC_PEQPBASE GLHMC_VFPEQPBASE	GLHMC_PEQPCNT GLHMC_VFPEQPCNT	GLHMC_DBQPMAX	GLHMC_PEQPOBJSZ
PE CQ Context	GLHMC_PECQBASE GLHMC_VFPECQBASE	GLHMC_PECQCNT GLHMC_VFPECQCNT	GLHMC_DBCQMAX	GLHMC_PECQOBJSZ
PE Shared Receive Queue	GLHMC_PESRQBASE GLHMC_VFPESRQBASE	GLHMC_PESRQCNT GLHMC_VFPESRQCNT	GLHMC_PESRQMAX	GLHMC_PESRQOBJSZ
PE TCP Timers	GLHMC_PETIMERBASE GLHMC_VFPETIMERBASE	GLHMC_PETIMERCNT GLHMC_VFPETIMERCNT	GLHMC_PETIMERMAX	GLHMC_PETIMEROBJSZ
PE Hash Table Entry	GLHMC_PEHTEBASE GLHMC_VFPEHTEBASE	GLHMC_PEHTCNT[1] GLHMC_VFPEHTCNT	GLHMC_PEHTMAX	GLHMC_PEHTEOBJSZ
ARP Table Entry	GLHMC_PEARPBASE GLHMC_VFPEARPBASE	GLHMC_PEARPCNT GLHMC_VFPEARPCNT	GLHMC_PEARPMAX	GLHMC_PEARPOBJSZ
Accelerated Port Bit Vector In-use	GLHMC_APBINUSEBASE GLHMC_VFAPBINUSEBASE	N/A (1 table per function)	N/A (1 table per function)	N/A (8KB fixed)
Memory Region Table Entry (MRTE)	GLHMC_PEMRBASE GLHMC_VFPEMRBASE	GLHMC_PEMRCNT GLHMC_VFPEMRCNT	GLHMC_PEMRMAX	GLHMC_PEMROBJSZ

Table 38-339.FPM Object Registers

HMC Object	Base Register Array	Object Count Register Array	Maximum Object Count Register	Object Element Size Register
Transmit FIFO	GLHMC_PEXFBASE GLHMC_VFPEXFBASE	GLHMC_PEXFCNT GLHMC_VFPEXFCNT	GLHMC_PEXFMAX	GLHMC_PEXFOBJSZ
Transmit FIFO Free List	GLHMC_PEXFFLBASE GLHMC_VFPEXFFLBASE	GLHMC_PEXFFLCNT GLHMC_VFPEXFFLCNT	GLHMC_PEXFFLMAX	N/A (4-byte fixed)
Inbound RDMA Read Queue (IRRQ or Q1)	GLHMC_PEQ1BASE GLHMC_VFPEQ1BASE	GLHMC_PEQ1CNT GLHMC_VFPEQ1CNT	GLHMC_PEQ1MAX	GLHMC_PEQ1OBJSZ
Inbound RDMA Read Queue (IRRQ or Q1) Free List	GLHMC_PEQ1FLBASE GLHMC_VFPEQ1FLBASE	GLHMC_PEQ1FLCNT GLHMC_VFPEQ1FLCNT	GLHMC_PEQ1FLMAX	N/A (4-byte fixed)
Multicast Group	GLHMC_FSIMCBASE	GLHMC_FSIMCCNT	GLHMC_FSIMCMAX	GLHMC_FSIMCOBJSZ
Address Handles	GLHMC_FSIAVBASE GLHMC_VFFSIAVBASE	GLHMC_FSIAVCNT GLHMC_VFFSIAVCNT	GLHMC_FSIAVMAX	GLHMC_FSIAVOBJSZ
Physical Buffer List Entry (PBLE)	GLHMC_PEPBLBASE GLHMC_VFPEPBLBASE	GLHMC_PEPBLCNT GLHMC_VFPEPBLCNT	GLHMC_PEPBLMAX	N/A (8-byte fixed)
Multicast Group	GLHMC_FSIMCBASE	GLHMC_FSIMCCNT	GLHMC_FSIMCMAX	GLHMC_FSIMCOBJSZ
Address Handles	GLHMC_FSIAVBASE GLHMC_VFFSIAVBASE	GLHMC_FSIAVCNT GLHMC_VFFSIAVCNT	GLHMC_FSIAVMAX	GLHMC_FSIAVOBJSZ

Notes:

1. For PFs, the sum of PFQF_CTL_0.PEHSIZE and PFQF_CTL_0.PEDSIZE must be smaller than or equal to GLHMC_PEHTCNT. For VFs, the sum of VPQF_CTL_PE.PEHSIZE and VPQF_CTL_PE.PEDSIZE must be smaller than GLHMC_VFPEHTCNT.

38.26.3.1 Programming the HMC FPM Base Registers

Host software is responsible for setting up the GLHMC_{object}CNT and GLHMC_{object}BASE registers for LAN objects. All settings of FPM registers impact only the function associated with the registers. The software device driver on a given PCI function must only program the GLHMC_{object}CNT and GLHMC_{object}BASE registers for HMC PMs that are owned by that same PCI function or HMC PMs that are associated with PE enabled VFs that the PF owns. The FPM base of the first HMC object (GLHMC_LANTXBASE) for each PCI function is always zero. The FPM base of subsequent HMC objects increment from previous HMC object base, the number of elements for the previous HMC object, and the size of the previous HMC object element. Additional rounding is necessary to get to the next FPM address that is properly aligned for the HMC object under consideration. Table 38-340 lists the FPM object order that must be maintained for proper HMC operation and the alignment requirements for each object.

Table 38-340.FPM Object Order and Alignment

HMC Object Order	HMC Object	Alignment Requirement
0	LAN Transmit Queue	512 bytes
1	LAN Receive Queue	512 bytes
2	Reserved	512 bytes
3	Reserved	512 bytes
4	PE QP Context	2 MB (must be the start of an SD)
5	PE CQ Context	512 bytes
6	PE Shared Receive Queue	512 bytes
7	PE Hash Table Entry	512 bytes
8	ARP Table Entry	512 bytes

Table 38-340.FPM Object Order and Alignment

HMC Object Order	HMC Object	Alignment Requirement
9	Accelerated Port Bit Vector In-use	512 bytes
10	Memory Region Table Entry (MRTE)	512 bytes
11	Transmit FIFO	512 bytes
12	Transmit FIFO Free List	512 bytes
13	Inbound RDMA Read Queue (IRRQ or Q1)	512 bytes
14	Inbound RDMA Read Queue (IRRQ or Q1) Free List	512 bytes
15	PE TCP Timers	512 bytes
16	Physical Buffer List Entry (PBLE)	512B (4KB for VFs, handled by CQP firmware)
17	Read Response FIFO	512 bytes
18	Read Response FIFO Free List	512 bytes
19	Header Information	512 bytes
20	Metadata	512 bytes
21	Out of Order Send Completion	512 bytes
22	Out of Order Send Completion FIFO Free List	512 bytes

As a partial example of how the 10 GbE controller must program the registers listed in Table 38-340, the following steps should be taken to program the first three HMC objects:

1. Program GLHMC_LANTXBASE = 0
2. Program GLHMC_LANRXBASE = ROUNDUP512((GLHMC_LANTXBASE*512)+(GLHMC_LANTXCNT*$2^{GLHMC\_LANTXOBJSZ}$)) / 512

The special case of PE QPs must be rounded up to the next SD boundary. The base registers for PE objects (indexes 4 and up) can be set using the commit FPM values CQP operation.

Note: The software device driver can choose to set the GLHMC_{obj}CNT register to zero if it does not need to use an object. For example, only the GLHMC_LANTXOBJSZ and GLHMC_LANRXOBJSZ register need to be non-zero if a PE resource is not needed.

38.26.4 Populating HMC Backing Pages

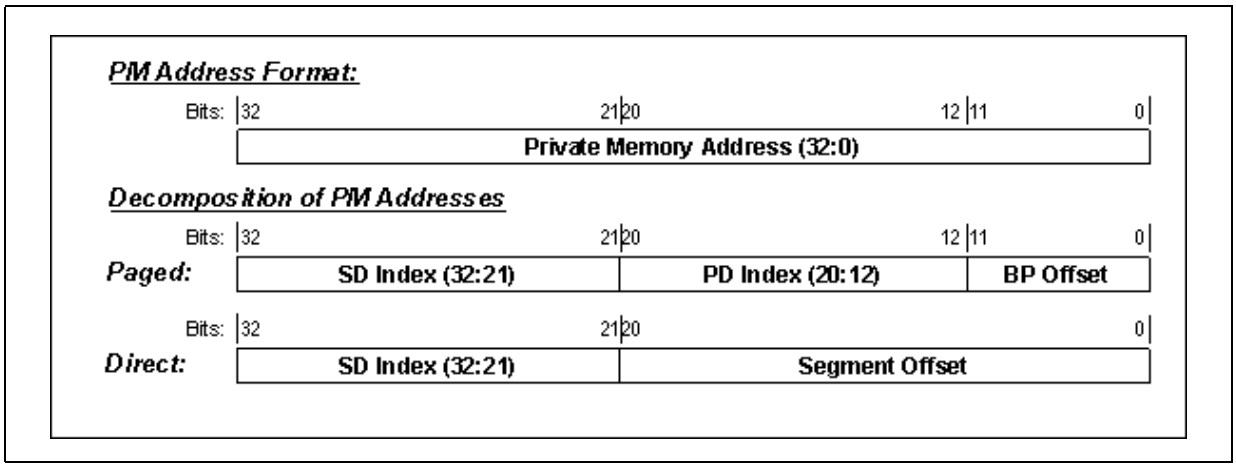
Once the HMC resource profile has been picked (Section 38.26.2) and the FPM space has been programmed (Section 38.26.3), the software device driver must populate the HMC backing pages for the PCI function that it is initializing. The first step in this phase of initialization is to allocate 4 KB pages for the PDs. Each 4 KB PD page holds 512 PDs and occupies a single SD entry. Once a 4 KB page has been allocated, initialized to zero and pinned by software, the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers are used to populate the SD table for the PCI function. PE enabled VFs use the GLHMC_VFSDCMD[n], GLHMC_VFSDDATALOW[n], and GLHMC_SDDATAHIGH[n] where n is the HMC VF index. PE related SDs are programmed using the update PE SDs CQP operation.

A software device driver on a given PCI function must only manipulate SD table entries that are allocated for that PCI function via the SD partitioning process. SDs are addressed on a per PCI function basis starting and zero and is limited by PMSDMAX. Note that software is not aware of the actual portion of the SD table that it is using.

Accesses outside of the SD range configured by the NVM using the PFHMC_SDCMD or GLHMC_VFSDCMD registers are ignored (operation is not performed) by the 10 GbE controller and an error is returned in the completion for the operation that is in error. The second step in this phase of software device driver initialization is to allocate additional host pages for backing HMC FPM objects for use by the 10 GbE controller before the software device driver attempts to access the object. The breakdown of the FPM address into components is listed in Table 38-340. Note that GLHMC_VFSDCMD, GLHMC_VFSDDATALOW, and GLHMC_SDDATAHIGH registers might be written only through CQP operations.

Note: Direct mapped queues in the VF object cache must be fully populated for the entire 2 MB space of the SD.

Figure 38-91.FPM Address Decomposition



The identification of which SDs to populate and which HMC FPM backing pages to populate in the PD pages can be calculated as follows in the paged scenario:

FPM_object_address = (GLHMC_{object}BASE*512) + ($2^{GLHMC\_\{object\}OBJSZ}$ * element_index)

SD_index = INT(FPM_object_address / 2 MB)

PD_index = INT(FPM_object_address / 4 KB) and 0x1FF

HMC_PM_index = PF index or the HMC VF FPM index

An example of populating the backing pages the HMC is shown assuming that a software device driver needs to allocate FPM backing pages for 512 LAN receive queues starting at index 0:

1. Allocate one PD page (capable of holding 512 backing pages of 4 KB each).
2. Identify the first SD necessary:
   a. FPM_object_address = (GLHMC_LANTXBASE[HMC_PM_index]*512) + ($2^{GLHMC\_LANTXOBJSZ}$*GLHMC_LANTXCNT[HMC_PM_index]).
   b. FPM_object_limit = FPM_object_address + ($2^{GLHMC\_LANTXOBJSZ}$*512).
   c. SD_index = FPM_object_address / 2 MB.
   d. Last_SD_index = ((FPM_object_limit - 1) / 2 MB.
3. Allocate, zero and pin a host memory page (PD page) for each SD needed from SD_index to Last_SD_index.
4. Calculate the number of PDs that need to be allocated:

a. FPM_PD_index = (FPM_object_address / 4 KB) and 0x1FF.

b. FPM_PD_limit_index = ((FPM_object_limit - 1) / 4 KB) and 0x1FF.

c. FPM_PD_count = FPM_PD_limit + 1 - FPM_PD_index.

5. Initialize the PDs:

   a. Allocate/zero/pin FPM_PD_count pages (these are the FPM object backing pages).

   b. Initialize each of the PDs with the physical address of a page allocated in step 5a and set the PD valid bit (see Table 38-333 for the format). The PDs are in the PD pages allocated in step 3.

6. Update the SD table using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers for each PD page allocated in step 3 (if the PDs are associated with a PE enabled VF then the GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index] and GLHMC_VFSDDATAHIGH[HMC_PM_index] registers must be used). These registers are programmed via the update PE SDs CQP operation for backing pages related to PE objects.

   a. Write the most significant 32 bits of the physical address of the PD page to the PFHMC_SDDATAHIGH.

   b. Write the last significant 32 bits of the physical address of the PD page to the PFHMC_SDDATALOW ensuring that the lower 12 bits are 0.

   c. Write 512 to PFHMC_SDDATALOW.PMSDBPCOUNT. If this was the last SD of the FPM, the value might be lower than 512, but PE QPs are in the middle of FPM space so the value must be 512. The PMSDBPCOUNT field is used by the 10 GbE controller to calculate the end of the FPM space without having to read the valid bit for each individual PD entry.

   d. Write 0b to PFHMC_SDDATALOW.PMSDTYPE.

   e. Write 1b to PFHMC_SDDATALOW.PMSDVALID.

   f. Write PFHMC_SDCMD with PMSDIDX set to the proper SD index value and PMSDWR=1b.

When this process completes for typical configurations, the second SD is populated with the address of a single PD page, and entries 1-129 are populated with the address of the 128 FPM object backing pages that have been allocated.

If the PDs are associated with a PE enabled VF, registers GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index] and GLHMC_VFSDDATAHIGH[HMC_PM_index] must be used. These registers are programmed via the update PE SDs CQP operation for backing pages related to PE objects, but PE QPs are in the middle of FPM space so the value must be 512.

38.26.5 De-populating HMC Backing Pages

The process of de-populating and freeing HMC object backing pages is as follows:

- Make sure software and hardware are not going to access objects in the pages.
- Calculate the SD range and/or PD range that provides the address mapping to the 10 GbE controller.
- Update the associated PD entries.
- Invalidate the on-die PD cache entries using the PFHMC_PDINV (or GLHMC_VFPDINV[HMC_PM_index]) register.

- Update the SDs using the PFHMC_SDCMD, PFHMC_SDDATALOW, and PFHMC_SDDATAHIGH registers to notify the 10 GbE controller that the pages are no longer valid for use. If the PDs are associated with a PE enabled VF then the GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index] and GLHMC_VFSDDATAHIGH[HMC_PM_index] registers must be used. These registers are programmed via the update PE SDs CQP operation for backing pages related to PE objects.

38.26.5.1 Removing a Backing Page

Once software has determined that a backing page is no longer needed, software must clear the *PD_Valid* bit (see Table 38-333) in the PD entry that references the backing page. After clearing the *PD_Valid* bit in the PD in host memory, software must then write the PFHMC_PDINV register with the SD index and PD index of the newly invalidated PD entry. This is to ensure that references to the invalid PD entry have been removed from any the 10 GbE controller cache. Once this write completes, the backing page can be freed by software. Writing the PFHMC_PDINV register is not required for direct SDs since there is not a PD involved in addressing the HMC backing pages. If the backing pages are associated with a PE enabled VF, register GLHMC_VFPDINV[HMC_PM_index] must be used.

38.26.5.2 Removing a Page Descriptor Page

Once software has determined that an entire PD page is no longer needed, the PFHMC_SDDATALOW register must be written with PFHMC_SDDATALOW.PMSDVALID set to 0b and PFHMC_SDCMD must be written with PMSDIDX set to the proper SD index value and PMSDWR=1b. Once this sequence completes, software is free to de-allocate or re-use the PD page. If the PDs are associated with a PE enabled VF, registers GLHMC_VFSDCMD[HMC_PM_index], GLHMC_VFSDDATALOW[HMC_PM_index] and GLHMC_VFSDDATAHIGH[HMC_PM_index] must be used. These registers are programmed via the update PE SDs CQP operation for backing pages related to PE objects.

38.26.6 Special Cases for PE Objects

There is one instance when LAN objects and PE objects are handled differently.

- LAN objects for VFs exist in the HMC FPM of the PF but PE objects exist in the HMC FPM of up to 32 HMC VFs. Since there are less HMC VF FPM spaces than there are VFs, there is a mapping required that is described in Section 38.26.6.1.

38.26.6.1 VF Support

The HMC supports 16 HMC FPM spaces that are dedicated to PFs (index 0-15) and 32 HMC FPM spaces that are available for VFs. The 32 VF FPM spaces do not have LAN objects since these objects reside in the associated PF FPM space. Since there are less HMC FPM VF spaces available than actual VFs for the 10 GbE controller, a mapping is required. The VF mapping is performed by CQP firmware using the manage HMC PM function table operation.

38.26.7 HMC Error Reporting

HMC related errors are reported through the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. The HMC_ERR interrupt status bit in the PFINT_ICR0 register can also deliver an interrupt for HMC errors if the interrupt is enabled in the PFINT_ICR0_ENA register. When the HMC detects an error, it sets the PFHMC_ERRORINFO.ERROR_DETECTED bit along with the relevant information in the

other fields of the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers. No further notification of subsequent HMC errors associated with any given PF are issued until the current error is acknowledged by writing a 0b to the PFHMC_ERRORINFO.ERROR_DETECTED bit. Table 38-341 lists the errors detected for each HMC object and the behavior associated with each error.

Table 38-341.HMC Errors

HMC Object	Error Type(s)	Error Behavior
LAN Transmit Queue	PMF Invalid, Invalid PMF Index	Not applicable to this object type.
	Invalid LAN Queue Index or HMC Object Index Too Large	Index of LAN queue is reported in the PFHMC_ERRORDATA register. The packets associated with the queue are not transmitted.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the LAN queue object is reported in the PFHMC_ERRORDATA register. Packets associated with the queue are not transmitted.
LAN Receive Queue	PMF Invalid, Invalid PMF Index	Not applicable to this object type.
	Invalid LAN Queue Index or HMC Object Index Too Large	Index of the LAN queue is reported in the PFHMC_ERRORDATA register. Packets associated with the queue are dropped.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the LAN queue object is reported in the PFHMC_ERRORDATA register. Packets associated with the queue are dropped.
Protocol Engine QP Context	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PE QP is reported in the PFHMC_ERRORDATA register. Packets associated with the QP are dropped. PE AEs are not reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the PE QP object is reported in the PFHMC_ERRORDATA register. Packets associated with the QP are dropped. PE AEs are not reported.
Protocol Engine CQ Context	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PE CQ is reported in the PFHMC_ERRORDATA register. Completions for all QPs associated with the CQ are dropped. PE AEs are not reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the PE CQ object is reported in the PFHMC_ERRORDATA register. Completions for all QPs associated with the CQ are dropped. PE AEs are not reported.
Protocol Engine Shared Receive Queue	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PE S-CQ is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the PE S-RQ object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.

Table 38-341.HMC Errors

HMC Object	Error Type(s)	Error Behavior
Protocol Engine TCP Timers	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PE timer object is reported in the PFHMC_ERRORDATA register. Timer operation associated with the function goes idle. Host software is responsible for cleaning up all PE resources associated with the PCI function and reporting a fatal adapter error to the RDMA protocol stack.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The index of the PE timer object is reported in the PFHMC_ERRORDATA register. Timer operation associated with the function goes idle. Host software is responsible for cleaning up all PE resources associated with the PCI function and reporting a fatal adapter error to the RDMA protocol stack.
Protocol Engine Hash Table Entry	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PE hash table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the hash table entry are dropped. PE AEs are not reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the PE hash table entry object is reported in the PFHMC_ERRORDATA register. Packets associated with the hash table entry are dropped. PE AEs are not reported.
ARP Table Entry	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the ARP table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the ARP table entry are dropped. PE AEs are not reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the ARP table entry is reported in the PFHMC_ERRORDATA register. Packets associated with the ARP table entry are dropped. PE AEs are not reported.
Accelerated Port Bit Vector In-use	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the APBVT entry is reported in the PFHMC_ERRORDATA register. Packets associated with the APBVT entry are dropped. PE AEs are not reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the APBVT entry is reported in the PFHMC_ERRORDATA register. Packets associated with the APBVT entry are dropped. PE AEs are not reported.
Memory Region Table Entry (MRTE)	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the MRTE is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the MRTE object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
Transmit FIFO	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the transmit FIFO entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the transmit FIFO entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.

Table 38-341.HMC Errors

HMC Object	Error Type(s)	Error Behavior
Transmit FIFO Free List	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the transmit FIFO free list entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the transmit FIFO free list entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
Inbound RDMA Read Queue (IRRQ or Q1)	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the IRRQ entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the IRRQ entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
Inbound RDMA Read Queue (IRRQ or Q1) Free List	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the IRRQ free list entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the IRRQ free list entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
Physical Buffer List Entry (PBLE)	PMF Invalid, Invalid PMF Index, HMC Object Index Too Large	The index of the PBLE entry is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.
	Invalid LAN Queue Index	Not applicable to this object type.
	HMC Private Memory Address Too Large, Segment Descriptor Invalid, Segment Descriptor Too Small, Page Descriptor Invalid	The private memory address of the PBLE entry object is reported in the PFHMC_ERRORDATA register. The receive data is dropped and the QP is put into the terminate state. A PE AE for the QP is reported.

38.27 AQ

38.27.1 Preface

The AQ is designed with the following goals:

- Abstract firmware interface so that firmware can be changed, whether for added functionality or for firmware updates, without changing the software device driver. Further extension of the firmware enables changing parts of the hardware without modifying the software device driver.
- Remove MMIO access from all non-essential software device driver paths.
- Incorporate the VF-to-PF and function-to-function mailboxes into a single, extensible interface. Shared resources should be accessed through the AQ.
- It is possible to write one software device driver that would work both on a primary function and on a virtual function.
- A low-resource software device driver such as a pre-boot driver or an out-of-box software device driver can use the AQ for limited transmit and receive.

The 10 GbE controller provides one type of admin queue, which is used for communication between the software driver and the 10 GbE controller's firmware engine. When implemented by firmware, this queue is capable of supporting PF driver-to-VF driver communication.

The 10 GbE controller provides the following sets of AQs:

- One firmware AQ per PF, used for software-to-firmware communication, exposed in the PF memory BAR
- One firmware AQ per VF in the VF memory BAR

Assumptions:

- Currently, firmware does not maintain context for any software device driver operation, except for the state of the queue itself.
- Firmware deals with one command at a time and does not start working on a new command before finishing its current task. This might change in a future version of the firmware, so the queue mechanism must allow for it today in order to avoid the need to modify the software device driver if this happens. Firmware does however pipeline descriptor and data fetches to optimize execution latency.

38.27.2 Queue Structure

The AQ is comprised of an Admin Transmit Queue (ATQ) and an Admin Receive Queue (ARQ). Software device river commands are posted on the ATQ. Firmware completes software device driver commands by writing back onto the command descriptor. Events that are not an immediate result of a command are written to the ARQ. The software device driver posts empty buffers to the ARQ and then firmware fills them with events.

Both queues support direct and in-direct commands.An AQ direct command is one that fits entirely in the queue descriptor and while extended or an indirect command is one that uses an additional buffer, which is specified in the descriptor. When a command needs an additional external buffer it marks the BUF flag. If the buffer contains data that firmware needs to read, the RD flag is used, a buffer bigger than 512 bytes (AQ_LARGE_BUF) must have the LB flag set. The maximum buffer size supported in this version of the queues is 4096 bytes.

Both queues use the same descriptor structure. All descriptors and commands are defined using Little endian notation with 32-bit words. Software device drivers using other conventions should take care to do the proper conversions.

Table 38-342.Admin Queue Descriptor Structure (in LE 32 Order)

+3								+2								+1								+0

Data Address Low																															

Table 38-343.Admin Descriptor Field descriptions

Name	Bytes.Bits	Description
Flags.DD	0.0	Set by firmware to mark entry done.
Flags.CMP	0.1	Set by firmware to mark entry as completion.
Flags.ERR	0.2	Set by firmware to mark entry as an error indication.
Flags.VFE	0.3	Set by firmware to mark entry as an event forwarded from a VF driver.
Flags.Reserved	0.4-1.0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Set by software device driver to indicate that indirect buffer is longer than AQ_LARGE_BUF.
Flags.RD	1.2	Set by software device driver to indicate that firmware needs to read indirect buffer.
Flags.VFC	1.3	Set by software device driver to indicate command on behalf of a VF.
Flags.BUF	1.4	This command uses additional data.
Flags.SI	1.5	Do not interrupt when this command completes.
Flags.EI	1.6	Interrupt on error (supersedes Flags.SI in case of an error).
Flags.FE	1.7	If previous command completed in error, flush this one.
Opcode	2-3	Command opcode (see Table 38-354).
Datalen	4-5	Indirect data length (can be used for other uses if Flags.RD is not set).
Return Value/ VFID	6-7	Return value / VF ID for command or event, only sent by firmware or PF driver. See Section 38.27.8 and Table 38-353.
Cookie High	8-11	Opaque data, echoed by receiver, high half.
Cookie Low	12-15	Opaque data, echoed by receiver, low half.
Param0	16-19	First general use parameter.
Param1	20-23	Second general use parameter.
Data Address High	24-27	Indirect data pointer (can be used for other uses if Flags.RD is unset).
Data Address Low	28-31	Indirect data pointer (can be used for other uses if Flags.RD is unset).

See Section 38.27.5 for details on the different command types

38.27.2.1 AQ CSRs

AQs have 32 byte descriptors. They are serviced by the following registers (Table 38-344).

{PFX} denotes the register scope prefix:

- for VFs it is VF_
- for PFs it is PF_

Except for the name prefix the PF and VF registers are exactly the same.

Table 38-344.AQ Registers

Name	Width	Comment
{PFX}ATQBAH	32 bits	High bytes of ATQ base address.
{PFX}ATQBAL	32 bits	Low bytes of ATQ base address, address must be 64-byte aligned.
{PFX}ATQLEN	10+4 bits	ATQ length in descriptors, MSB is set for queue enable, three error bits (critical error, overflow error and VF error) are set by FW to indicate error conditions (see further Section 38.27.9.1).
{PFX}ATQH	10 bits	ATQ head pointer (firmware updates).
{PFX}ATQT	10 bits	ATQ tail pointer (software device driver updates).
{PFX}ARQBAH	32 bits	High bytes of ARQ base address.

Table 38-344.AQ Registers

Name	Width	Comment
{PFX}ARQBAL	32 bits	Low bytes of ARQ base address, address must be 64-byte aligned.
{PFX}ARQLEN	10+4 bits	ATQ length in descriptors, MSB is set for queue enable, three error bits (critical error, overflow error and VF error) are set by firmware to indicate error conditions (see further Section 38.27.9.1).
{PFX}ARQH	10 bits	ARQ head pointer (firmware updates).
{PFX}ARQT	10 bits	ARQ tail pointer (software device driver updates).

38.27.2.2 AQ Interrupts

Firmware triggers an interrupt when it completes descriptors on the transmit queue or when it posts events to the receive queue. The interrupt triggered is the other interrupt and the *ADMINQ* cause bit is set to signals that this was the reason.

38.27.3 Initialization

when initializing the queue, the software device driver must do the following:

- The software device driver allocates and set ups appropriately sized host memory for the queues.
- The software device driver must post initialized buffers to the receive queue before it can use the transmit queue (see Section 38.27.3.1 for receive queue element initialization).
- The software device driver clears the head and tail registers for each queue ({PFX}ATQH and {PFX}ARQH. Tail registers are {PFX}ATQT and {PFX}AROT.
- The software device driver then programs the base, and length registers for each queue ({PFX}ATQBAL, {PFX}ATQBAH, {PFX}ATQLEN, {PFX}ARQBAL, {PFX}ARQBAH and {PFX}ARQLEN) and sets *length.enable* to 1b to signal firmware that the queue is now enabled.
- For a firmware AQ, the software device driver must then issue a Get Version admin command and check the queue and firmware major version numbers before it can use the queue for anything else. If the major versions does not match what the software device driver expects, it reports the mismatch and fails to load. For details and current queue version number (see Section 38.27.11.1).
- For a firmware AQ, after the software device driver has verified the queue version, it sends a Driver Version command to the 10 GbE controller. The 10 GbE controller then sends an indication to the BMC that the PF driver is present.
- A PF driver must have at least one buffer posted to the receive queue for each VF that is currently running. Note that this can never be greater than the number of logical cores in the system. This must be done before enabling VFs.
- A PF might disable a VF transmit and receive admin queues by clearing the matching GL_VF_CTRL_TX[n].AQ_TX_EN bit or GL_VF_CTRL_RX[n].AQ_RX_EN bit for Tx or Rx admin queue commands.

38.27.3.1 Receive Queue Element Initialization by Software Device Driver

The software device driver must clear any unused fields (including unused flags) and set data pointers and data length to a mapped DMA pointer.

The software device driver might set the SI and the EI flags in the receive queue element. The software device driver must not set the FE flag on receive queue elements.

Table 38-345.Receive Queue Element - Initial Values

Name	Bytes.Bits	Value	Remarks
Flags.DD	0.0	0	Software device driver must clear.
Flags.CMP	0.1	0	Software device driver must clear.
Flags.ERR	0.2	0	Software device driver must clear.
Flags.VFE	0.3	0	Software device driver must clear.
Flags.Reserved	0.4 1.0	0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	0 or 1	Set by the software device driver if buffer is longer than AQ_LARGE_BUF (512 bytes).
Flags.RD	1.2	0	Not applicable to receive queue.
Flags.VFC	1.3	0	Software device driver must clear.
Flags.BUF	1.4	1	Receive queue elements always have an additional buffer.
Flags.SI	1.5	Driver Might Set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver Might Set	Interrupt on error - supersedes Flags.SI in case of error.
Flags.FE	1.7	0	Software device driver must clear.
Opcode	2-3		Software device driver must clear.
Datalen	4-5	Buffer Len	Additional data length.
Return Value/ VFID	6-7		Software device driver must clear.
Cookie High	8-11		Software device driver must clear.
Cookie Low	12-15		Software device driver must clear.
Param0	16-19		Software device driver must clear.
Param1	20-23		Software device driver must clear.
Data Address High	24-27	Buffer ADDR	Indirect data pointer (can be used for other uses if Flags.RD is not set).
Data Address Low	28-31	Buffer ADDR	Indirect data pointer (can be used for other uses if Flags.RD is not set).

The values written by firmware when it uses the EAQ element are discussed in the following paragraphs.

38.27.4 Driver Unload and Queue Shutdown

When shutting down the firmware AQ the software device driver (both for PF and VF):

- Posts a Queue Shutdown admin command (0x0003). See Section 38.27.11.3 for more detail. In this command, the software device driver sets the Driver Unloading flag if it intends to unload.
- Software must not send any additional commands on the queue until the flow is completes.

Firmware:

- Waits for any pending DMA transactions from firmware to be acknowledged by hardware.
- Closes the Rx queue by clearing its *Enable* bit.
- Sends a completion to the software device driver as usual, honoring all the interrupt control bits in the descriptor.
- Software then closes the Tx queue by clearing its *Enable* bit.

If the software device driver is unloading, it issues a function reset (PFR or VFR) to the 10 GbE controller.

If the software device driver is unloading, firmware signals the MC.

- Only for a PF driver.

Note that before the firmware AQs are re-enabled, software should clear the head and tail registers of the transmit and receive firmware AQ.

38.27.5 Commands Description

38.27.5.1 Direct Command

38.27.5.1.1 Direct Admin Command

The template for a command that is fully contained in the descriptor and does not need an additional data buffer.

Table 38-346.Direct Admin Command Structure

Name	Bytes.Bits	Value	Remarks
Flags.DD	0.0	0	Software device driver must clear.
Flags.CMP	0.1	0	Software device driver must clear.
Flags.ERR	0.2	0	Software device driver must clear.
Flags.VFE	0.3	0	Software device driver must clear.
Flags.Reserved	0.4-1.0	0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	0	A direct command has no additional buffer.
Flags.RD	1.2	0	A direct command has no additional buffer.
Flags.VFC	1.3	0	Software device driver must clear.
Flags.BUF	1.4	0	A direct command does not have an additional write buffer.
Flags.SI	1.5	Driver Might Set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver Might Set	Interrupt on error (supersedes Flags.SI in case of error).
Flags.FE	1.7	Driver Might Set	If set, the command is flushed if the preceding command resulted in an error.
Opcode	2-3	Opcode	Command opcode (see Table 38-354).
Datalen	4-5	0	
Return Value/ VFID	6-7		
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.
Data Address low	28-31		Can be used for an additional command parameter.

38.27.5.1.2 Direct Command Completion

Table 38-347.Direct Command Completion Event Template

Name	Bytes.Bits	Value	Remarks
Flags.DD	0.0	1	Firmware must set.
Flags.CMP	0.1	1	Firmware must set.
Flags.ERR	0.2	0 or 1	Firmware must set only if it reporting an error.
Flags.VFE	0.3	0	Firmware must set.
Flags.Reserved	0.4 -1.0	0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Echo	Firmware copies the value from the command.
Flags.RD	1.2	Echo	Firmware copies the value from the command.
Flags.VFC	1.3	Echo	Firmware copies the value from the command.
Flags.BUF	1.4	Echo	Firmware copies the value from the command.
Flags.SI	1.5	Echo	Firmware copies the value from the command.
Flags.EI	1.6	Echo	Firmware copies the value from the command.
Flags.FE	1.7	Echo	Firmware copies the value from the command.
Opcode	2-3	Opcode	Command opcode (see Table 38-354).
Datalen	4-5		Can be used for an additional command parameter.
Return Value/ VFID	6-7		Firmware returns value 0 = no error (for error codes see Table 38-353).
Cookie High	8-11	Echo	Opaque value is copied by firmware from the command.
Cookie Low	12-15	Echo	Opaque value is copied by firmware from the command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.
Data Address Low	28-31		Can be used for an additional command parameter.

38.27.5.2 Indirect Command

38.27.5.2.1 Indirect Admin Command

An indirect write command uses an additional DMA buffer specified in the descriptor.

The *BUF* flag must be set by the software device driver. If the buffer is larger than 512 bytes the *LB* flag must be set.

This version of the queue is limited to buffers up to 4096 bytes. If the command uses the buffer to pass data, the *RD* flag needs to be set.

Table 38-348.Indirect Command Template

Name	Bytes.Bits	Value	Remarks
Flags.DD	0.0	0	Software device driver must clear.
Flags.CMP	0.1	0	Software device driver must clear.
Flags.ERR	0.2	0	Software device driver must clear.
Flags.VFE	0.3	0	Software device driver must clear.
Flags.Reserved	0.4-1.0	0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	0 or 1	Set by the software device driver if the buffer is longer than AQ_LARGE_BUF (512).
Flags.RD	1.2	0 or 1	Set if additional buffer has command parameters.

Table 38-348.Indirect Command Template (Continued)

Name	Bytes.Bits	Value	Remarks
Flags.VFC	1.3	0	Software device driver must clear.
Flags.BUF	1.4	0 or 1	Software device driver must set this flag on an indirect command.
Flags.SI	1.5	Driver May set	Do not interrupt when this command completes.
Flags.EI	1.6	Driver May set	Interrupt on error (supersedes Flags.SI in case of error).
Flags.FE	1.7	Driver May set	If set, the command is flushed if the preceding command resulted in an error.
Opcode	2-3	Opcode	Command opcode (see Table 38-354).
Datalen	4-5	Buffer len	Usable length of additional buffer.
Return value/VFID	6-7		
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address high	24-27	Buff Addr	High bits of buffer address.
Data Address low	28-31	Buff Addr	Low bits of buffer address.

38.27.5.2.2 Indirect Command Completion

When completing an indirect command, firmware overwrites the data length with the actual length of data returned by the command.

Table 38-349.Indirect Command Completion

Name	Bytes.Bits	Value	Remarks
Flags.DD	0.0	1	Firmware must set.
Flags.CMP	0.1	1	Firmware must set.
Flags.ERR	0.2	0 or 1	Firmware must set only if it reporting an error.
Flags.VFE	0.3	0	Firmware must clear.
Flags.Reserved	0.4 -1.0	0	Reserved, must be zeroed by sender and ignored by receiver.
Flags.LB	1.1	Echo	Firmware copies value from command.
Flags.RD	1.2	Echo	Firmware copies value from command.
Flags.VFC	1.3	Echo	Firmware copies value from command.
Flags.BUF	1.4	Echo	Firmware copies value from command.
Flags.SI	1.5	Echo	Firmware copies value from command.
Flags.EI	1.6	Echo	Firmware copies value from command.
Flags.FE	1.7	Echo	Firmware copies value from command.
Opcode	2-3	Opcode	Command opcode (see Table 38-354).
Datalen	4-5		Can be used for an additional command parameter.
Return Value/ VFID	6-7		Firmware returns a value of 0 = no error (for error codes see Table 38-353).
Cookie High	8-11	Echo	Opaque value is copied by firmware from the command.
Cookie Low	12-15	Echo	Opaque value is copied by firmware from the command.
Param0	16-19		First command parameter.
Param1	20-23		Second command parameter.
Data Address High	24-27		Can be used for an additional command parameter.

Table 38-349.Indirect Command Completion

Name	Bytes.Bits	Value	Remarks
Data Address Low	28-31		Can be used for an additional command parameter.

38.27.6 Command Fetch and Verification

When a command posts, firmware looks it up in an internal permission table to decide if the request should be honored. Possible actions are:

- Allow — Firmware acts upon the command.
- Forward — Firmware halts the queue and forward the command to the PF driver, a completion for this command is initiated by the PF driver when it finishes it, only then further processing of commands from this queue is allowed. The PF driver needs to re-enable the queue after it deals with it.
- Error — Firmware completes the action by returning the error specified in the table.
- Drop — Firmware behaves as if the command succeeded but does nothing.

A VF driver is only allowed to post the commands listed in Table 38-350. If any other command is posted by a VF, firmware returns the EPERM (operation not permitted) error code.

Table 38-350.Commands Allowed for VF Firmware Admin Queues

Opcode	Command
0x0001	Get version.
0x0801	Send to PF.
0x0B02	Set RSS key.
0x0B03	Set RSS LUT.
0x0B04	Get RSS key.
0x0B05	Get RSS LUT.

38.27.7 Non-Completion Events

Events that are not an immediate result of a command completion, are posted by the FW onto the receive queue.

Table 38-351 lists the currently defined events, note that whenever possible the same number is used for the opcode that generates the event and for the event ID.

Table 38-351.Non-Completion Events

Name	Opcode	Reference	Type
Send to PF	0x0801	Section 38.27.12.1	Indirect/Direct
Send to VF	0x0802	Section 38.27.12.2	Indirect/Direct
Send to Peer PF	0x0803	Section 38.28	Indirect/Direct
Send to Peer Driver	0x804		Indirect/Direct

38.27.8 Error Handling

When firmware encounters an error it uses the return value field to indicate the type of error. The error code is comprised of two bytes: the lower byte is a user-visible code from Table 38-353, the higher byte can be used by firmware to report internal state or debug information. Note that the software device driver must log this information;

however, firmware might change this value from release to release. It is not to be reported to the user and no other action is to be taken upon this data. when the return value is zero (no error) firmware must not set the high byte. In the event that the queue itself is inaccessible, firmware overwrites the queue base addresses with an error code and clears the enable bit of both queues.

Table 38-352.Admin Queue Return Value Fields

Name	Bytes	comment
Code	0:7	Return value from Table 38-353.
Firmware Internal Code	8:15	Firmware internal code, must be zero if the *Code* field is zero.

38.27.9 Error dodes

When firmware completes a command, it must use the following error codes.

Table 38-353.Admin Queue Return Values and Error Codes

Error Code	Value	Meaning
(No Error)	0	No error (success).
EPERM	1	Operation not permitted.
ENOENT	2	No such element.
ESRCH	3	Bad opcode.
EINTR	4	Operation interrupted.
EIO	5	I/O error.
ENXIO	6	No such resource.
E2BIG	7	Arg too long.
EAGAIN	8	Try again.
ENOMEM	9	Out of memory.
EACCES	10	Permission denied.
EFAULT	11	Bad address.
EBUSY	12	Device or resource busy.
EEXIST	13	Attempt to crate something that exists.
EINVAL	14	Invalid argument.
ENOTTY	15	Not a typewriter.
ENOSPC	16	No space left or allocation failure.
ENOSYS	17	Function not implemented.
ERANGE	18	Parameter out of range.
EFLUSHED	19	Command flushed because a previous command completed in error.
BAD_ADDR	20	Internal error, descriptor contains a bad pointer.
EMODE	21	Operation not allowed in current device mode.
EFBIG	22	File too big.

38.27.9.1 Critical Error Indication

- On any error that prevents data placement to a queue ATQLEN.ATQCRIT (or ARQLEN.ARQCRIT) bit are set by firmware and the queue is stopped (by clearing its enable bit), then an interrupt is sent by firmware to the software device driver.
- Software reads and reports the error code and then resets the queue.

- If an overflow occurs and a message to the queue is dropped because the queue is full, firmware sets ARQLEN.ARQOVFL and interrupts the software device driver. Firmware does not stop the queue since, depending on the software device driver mode, this might be a recoverable error.

Note: This error can currently only happen on the receive queue, but to simplify the hardware design, the bit is present on both queues.

- When a VF has an event that causes firmware to set an error bit in its queue, firmware sets ATQLEN.ATQVFE in the corresponding PFs queue and interrupts it. Firmware does not stop the PF queue in this case.

Note: Events and completions that have already been posted before the error are still readable and can be handled by software.

38.27.10 Command Opcodes

Opcodes are 16 bits of which the upper 8 bits designate the group of the opcode and the lower 8 bits are the command in the group. Each group is described in the relevant sections that follow.

Table 38-354.opcode groups

Name	Opcodes
Generic	0x00XX
Mac Address	0x0100
PXE Mode	0x0110
WoL	0x012X
Switch	0x02XX
DCB	0x03XX
Scheduler	0x04XX
HMC	0x05XX
Link	0x06XX
NVM	0x07XX
Virtualization	0x08XX
Alternate Structure	0x09XX
LLDP	0x0AXX
Receive Filters	0x0BXX
Profiles Handling	0x0C40:0x0C5F

38.27.11 Generic Firmware Admin Commands

Table 38-355.Generic Commands

Name	Opcode	Reference	Type
Get Ver	0x0001	Section 38.27.11.1	Direct
Driver Version	0x0002	Section 38.27.11.2	Direct
Queue Shutdown	0x0003	Section 38.27.11.3	Direct

Get Expanded AQ Error Reason	0x0005		Direct
Request Resource Ownership	0x0008	Section 38.27.11.5	Direct

Table 38-355.Generic Commands

Name	Opcode	Reference	Type
Release Resource Ownership	0x0009	Section 38.27.11.6	Direct
Discover Function Capabilities	0x000A	Section 38.27.11.7	Indirect
Discover Device Capabilities	0x000B	Section 38.27.11.7	Indirect
CSR Access	0x0206		Direct

38.27.11.1 Get Version Admin Command

This must be the first command that the software device driver issues before it can use the queue for other purposes. The software device driver must inspect the reply to ensure that the firmware version is compatible. If firmware is still initializing it might delay response until it completes. Both firmware and the API have two unassigned 16-bit values as a minor and major version. The software device driver must not continue loading if the major version is a mismatch. Minor versions are for tracking changes that do not need software device driver modifications.

Table 38-356.Get Version Command (Opcode: 0x0001)

Name	Bytes.Bits	Value	Remarks
Flags	1-0		See AQ section for details.
Opcode	2-3	0x0001	Command opcode.
Datalen	4-5	0	no external response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
ROM Build ID	16-19		Device ROM build version.
Firmware Build ID	20-23		Device Firmware build version.
AQ API Patch Version	31		AQ API patch version (unsigned 8-bit integer).
Firmware Major Version	24-25		Major firmware version (unsigned 16-bit integer).
Firmware minor Version	26-27		Minor firmware version (unsigned 16-bit integer).
API Major Version	28-29	1	Major queue version (unsigned 16-bit integer). One for this version of the queues.
API Minor Version	31-32	1	Minor queue version (unsigned 16-bit integer). One for this version of the queues.

38.27.11.2 Driver Version Indirect Admin Command

Table 38-357.Driver Version Command (Opcode: 0x0002) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	1-0		See AQ section for details.
Opcode	2-3	0x0002	Command opcode
Datalen	4-5		Buffer length. Can be up to 32.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.

Table 38-357.Driver Version Command (Opcode: 0x0002) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Driver Version	16-19	version	byte 16 = major version. byte 17 = minor version. byte 18 = build version. byte 19 = sub-build version.
Reserved	20-23	0x0	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Table 38-358.Driver Version Buffer

Name	Length	Description
Driver Version	Datalen	Driver string (not null terminated) as reported by the software device driver.

38.27.11.3 Queue Shutdown Command

This is the final command posted to the queue, closing the queue as described in Section 38.27.4. When this command completes the software device driver is allowed to free any host resources associated with the firmware AQ.

If the software device driver is going to unload it must set the *Driver Unloading* flag to signal firmware.

Once this command is posted, the software device driver is not allowed to issue any more commands on the queue before a reset is done.

Note: Interrupt generation and the interrupt control flags in this command are handled as usual by firmware. This means that if an interrupt was not inhibited by setting the *SI* flag it happens. If the software device driver is in polling mode and cannot handle an interrupt, it needs to either inhibit the interrupt or have interrupts disabled through the interrupt control registers.

Table 38-359.Queue Shutdown Command (Opcode: 0x0003)

Name	Bytes.Bits	Value	Remarks
Flags	1-0		See AQ section for details.
Opcode	2-3	0x0003	Command opcode.
Datalen	4-5	0	No external data.
Return Value/VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Driver Unloading	16.0		Set to one if the software device driver intends to unload. Zero otherwise.
Reserved	17-31	0x0	Reserved.

38.27.11.4 Set PF Context

This admin command is used to set an explicit PF ID number initiated from the Tools firmware AQ. It is needed for some admin commands that requires control on a specific PF context regardless of the PF from which the admin command is initiated.

Table 38-360.Set PF Context Command (Opcode: 0x0004)

Name	Bytes.Bits	Value	Remarks
Flags	1-0		See AQ section for details.
Opcode	2-3	0x0003	Command opcode.
Datalen	4-5	0	No external data.
Return Value/VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
PF ID	16		PF ID.
Reserved	17-31	0x0	Reserved.

38.27.11.5 Request Resource Ownership Admin Command

This command is used by the software device driver to request ownership of a shared resource. It specifies the resource and the type of access it requests (see Table 38-361). On success, the command returns a value of zero. The completion specifies the maximum time in ms that the software device driver might hold the resource in the *Timeout* field. The software device driver must free the resource before that time. It must also free a resource before asking for it again. A request for a resource that is already held by th software device driver fails with an EACCESS error code. A timeout value of zero means no timeout.

If the resource is held by another resource, the command completes with a busy return value and the *Timeout* field indicates the maximum time the current owner of the resource has to free it.

Firmware implements a timeout mechanism taking back the ownership if the software device driver hangs. Any further commands by this software device driver that attempt to access this resource fails with an EPERM error code until the software device driver frees the resource and requests it again.

Table 38-361.Shared Resources

Resource	ID	Supported Modes	Default Timeout
NVM	0x0001	1 = Read. 2 = Write.	3000ms for read. 180000ms for write.
SDP	0x0002	1 = Read. 2 = Write.	Zero (no timeout).

Table 38-362.Request Resource Ownership Admin Command (Opcode: 0x0008) (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0008	Command opcode.
Datalen	4-5	0	No external buffer for this command.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.

Table 38-362.Request Resource Ownership Admin Command (Opcode: 0x0008) (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Resource ID	16-17	ID	See Table 38-361 for list of IDs.
Access Type	18-19	Type	See Table 38-361 for list.
Timeout	20-23	Timeout	Timeout in ms (written by firmware).
Resource Number	24-27	Number	This is the ID pin for an SDP.
Reserved	28-31		Reserved.

38.27.11.6 Release Shared Resource Admin Command

This command is used to return ownership of a shared resource to firmware. The software device driver specifies the ID of the resource it is releasing in the ID field.

Table 38-363.Release Resource Ownership Admin Command (Opcode: 0x0009)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0009	Command opcode.
Datalen	4-5	0	No external buffer for this command.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Resource ID	16-17	ID	See Table 38-361 for list of IDs.
Reserved	18-23	Reserved	Reserved.
Resource Number	24-27	Number	If a resource number was specified in the request, it needs to be specified here too.
Reserved	28-31	Reserved	Reserved.

38.27.11.7 Discover Device/function Capabilities

This command is used to request the list of capabilities of the device or the function. Firmware fills in the capabilities structure and returns the length to the software device driver. If the buffer size is not big enough for the entire structure, firmware returns ENOMEM and sets the length to the size of the structure (firmware does not fill in a partial structure). This can be used to discover the structure size. Capabilities are described using the structure listed in Table 38-365. This list of resources recognized by this version of the command are listed in Table 38-366. Additional capabilities can be retrieved using the Get PHY Abilities (0x0600) command and the Get Switch Resource Allocation (0x0202) command.

Table 38-364.Discover Device/function Capabilities (Opcode: 0x000A, 0x000B)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3		Command opcode.
Datalen	4-5	0x0	Must be zero. Value is ignored.

Table 38-364.Discover Device/function Capabilities (Opcode: 0x000A, 0x000B)

Name	Bytes.Bits	Value	Remarks
Return Value/VFID	6-7		Return value. Zeroed by software device driver. Written by firmware. 0x0 = Command success. EPERM is returned if the command was called while not in PXE mode.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Operation Mode	16.0		Defines the operation mode of firmware 0b = Normal operation mode. 1b = NVM recovery mode.
Reserved	16.1-19	Reserved	Reserved.
Cap Count	20-23		Number of capability records returned. Zeroed by the software device driver and written by firmware).
Data Address High	24-27	0x0	Address of response buffer.
Data Address Low	28-31	0x0	Address of response buffer.

Table 38-365.Capability Structure

Name	Length	Remarks.
Capability	16 bits	See Table 38-366 for a list of capabilities.
Major Version	8 bits	
Minor Version	8 bits	
Number	32 bits	Number of resources described by this capability.
Logical ID	32 bits	Only meaningful for some types of resources.
Physical ID	32 bits	Only meaningful for some types of resources.
Reserved1	64 bits	Reserved.
Reserved2	64 bits	Reserved.

Table 38-366.Resources Recognized by This Version of the Command

Name	Capability	Ver	Number	Logical ID	Physical ID
Switching Mode	0x0001	1.0	Returns the switching mode supported: 0 = EVB switching (including cloud). Other = Reserved.		
Manageability Mode	0x0002	1.0	Returns the value of the *Manageability Mode* field in the NVM.		
OS2BMC Capable	0x0004	1.0	Returns the value of the *OS2BMC Capable* field in the NVM.		
Functions Valid	0x0005	1.0	Bits 15:0 each corresponds to a PFPCI_STATUS1.FUNC_VALID bit for PFs 0,…,15.		
Alternate RAM Structure	0x0006	1.0	One.		

Table 38-366.Resources Recognized by This Version of the Command

Name	Capability	Ver	Number	Logical ID	Physical ID
WoL and Proxy Support	0x0008	1.0	Number of ACPI supported filters = 8 if supported, 0 otherwise. Same value for all ports and for the device command. For the 10 GbE controller, return the total number of filters across all supporting functions.	SEID of WoL and proxy VSI of the port. N/A if programming method is hardware. N/A for the 10 GbE controller.	Bit0 = APM WoL is supported (based on PFPM_APM.APME bit for device command or of all the PFs bits. Bit 1 = ACPI programming method (relevant only if number of ACPI supported filters is not zero). 1 = AQC. Bit 2: Proxy support. 0 = disabled 1 = enabled for device command or of all the PFs bits. Other bits = reserved
SR-IOV	0x0012	1.0	Set to one if enabled in config space. For the 10 GbE controller, should be set if set in any of the functions.	SR-IOV version (1.1)	
Virtual Function	0x0013	1.0	Function: Number of allocated VFs. Device: Total number of VFs exposed to all functions.	Logical ID of first VF	
VMDq	0x0014	1.0	Set to one.		
802.1Qbg	0x0015	1.0	One if enabled.		
VSI	0x0017	1.0	Function: Number of guaranteed VSI as read from PF allocations structure for PFs. Device: Number of VSIs allocated to the host (not including EMP VSIs).		
DCB	0x0018	1.0	One if enabled.	Device = 0: Bitmap of active TCs.	Max number of TCs 8.
Reserved	0x0021	1.0	Reserved.		
iSCSI	0x0022	1.0	0x1 if iSCSI is enabled. 0x0 if not enabled. For device capability it is always set, and for a function capability it is a reflection of the PFGEN_STATE.PFSCEN flag.		
RSS	0x0040	1.0	Table size 512 for PFs. 64 for VFs.	Entry width in bits: 6 for PFs. 4 for VFs.	
Rx Queues	0x0041	1.0	Function: Number of queues allocated to the PF. Device: Total number of queues available to the device.		ID of first queue.
Tx Queues	0x0042	1.0	Function: Number of queues. Device: Total number of queues available.		ID of first queue.

Table 38-366.Resources Recognized by This Version of the Command

Name	Capability	Ver	Number	Logical ID	Physical ID
MSI-X	0x0043	1.0	Number of vectors.		
VF-MSIX	0x0044	1.0	Number of MSIX Vectors available to VFs of this PF.		
Flow Director	0x0045	1.0	Function: Number of filters guaranteed to this PF. Device: Number of filters available in device (8192).	Function: Number of best effort filters. Device: Number of filters available in device (8192).	
1588	0x0046	1.1	Function: TimeSync is enabled on the port on which this function runs. Device: TimeSync-enabled on any of the ports (IPRTTSYN_CTL.TSYNENA).	Function: N/A. Device: A bitmap of the enabled ports.	
MaxMTU	0x47	1.0	Function: Max MTU of the function. Device: Max MTU of hardware (9728).		
NVM Versions[1]	0x48	1.0	1st word - NVM address. 2nd word - NVM value.	1st word - NVM address. 2nd word - NVM value.	1st word - NVM address. 2nd word - NVM value.
iWARP	0x0051	1.0	One if enabled.		
LED[2]	0x0061	1.0	Always one.	Action.	Pin number (GPIO index).
SDP[3]	0x0062	1.0	Always one.	Action.	Pin number (GPIO index).
MDIO[4]	0x0063	1.0	One if enabled.	Mode: 0x0 = MDIO shared. 0x1 = MDIO dedicated. 0x2 = I^2C.	The interface used to control this port.
WR_CSR_PROT	0x0064	1.0	Bytes 0 … 3 of the WR_CSR_PROT parameter. LS byte is byte 0 of the field.	Bytes 4 … 7 of the WR_CSR_PROT parameter. MS byte is byte 7 of the field.	
Drop/No-drop Policy	0x0065	1.0	Returns the value of the PXE Mode No-Drop Policy Supported NVM bit.	• 0x1, if no-drop policy is enabled on the port used by the current PF. • 0x0, if no-drop policy is not enabled on the port used by the current PF.	
Number of Ports in Switch Mode	0x0072	1.0	Returns the number of ports in switch mode.		

Notes:

1. The NVM versions capability is used to return NVM version data to software in a centralized location. It appears multiple times, reporting three NVM versions per entry. The following NVM words are returned as versions: 0x18-0x2E (inclusive), 0x34 and 0x35.
2. Repeat this entry for each assigned LED. If device = 1, returns an entry for each LED in the device.
3. Repeat this entry for each assigned pin. If device = 1, returns an entry for each SDP in the device.
4. This entry is not relevant for device = 1 and is not returned.

Note: Fields that are not applicable (empty in the table) are set to zero by firmware.

Note: When device capabilities are requested, the total numbers for the entire device should be returned.

Table 38-367.Configure No-drop Policy (Opcode: 0x0112)

Name	Bytes.Bits	Value	Remarks
Flags	1:0	0x0	See Section 38.27.5.2.1 for details.
Opcode	2-3	Opcode	Command opcode.
Datalen	4-5	0x0	Must be 0x0, value is ignored.
Return Value/ VFID	6-7		Return value. Zeroed by device driver. Written by firmware. 0x0 = Command success. EPERM returned if the command was called while not in PXE mode. EPERM returned if software control of the drop/no-drop policy is locked by NVM setting.
Cookie High	8-11	Cookie	Opaque value. Copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value. Copied by firmware into the completion of this command.
Force No-drop	16.0	0x0	Sets the No-drop/Drop Policy. 1b = Force no-drop. 0b = Remove the force and return to normal firmware behavior.
Reserved	16.1-31	0x0	Reserved.

38.27.12 Virtualization Admin Commands

Table 38-368.Virtualization Admin Commands

Name	Opcode	Ref	Type
Send to PF	0x0801	Section 38.27.12.1	Indirect /Direct
Send to VF	0x0802	Section 38.27.12.2	Indirect /Direct
Send to peer	0x0803	Section 38.28	Indirect /Direct

38.27.12.1 Send Message to PF Admin Command

This command, together with the next one, implements a communication channel between PFs and their VFs. The data in the external buffer is copied into an event on the PF receive queue. The command completes once the data is copied. The contents of the messages is defined by software.

Since the value of the cookie is copied to the event, if 8 bytes are enough for needed message, the software device driver might specify a length of zero and not use an external buffer. In this case, it should not set the *BUF* flag.

Note: This version of the queues supports messages of up to 4096 bytes.

Table 38-369.Send to PF Command (Opcode: 0x0801)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0801	Command opcode.
Length	4-5	buffer length	Length of message.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.

Table 38-369.Send to PF Command (Opcode: 0x0801) (Continued)

Name	Bytes.Bits	Value	Remarks
Reserved	16-19		
Reserved	20-23		
Data Address High	24-27	0x0	Address of data buffer.
Data Address Low	28-31	0x0	Address of data buffer.

After posting the event to the PF admin receive queue, firmware completes this command by updating the flags and returning a value of zero for success.

Table 38-370.Message From VF Event (Opcode: 0x0801)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See Section 38.27.5.1.1 for details.
Opcode	2-3	0x0801	Event code.
Length	4-5	Buffer Length	Length of message.
Return Value/ VFID	6-7	VFID	ID of sending VF.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16-19		Reserved.
Reserved	20-23		Reserved.
Data Address High	24-27	0x0	Address of data buffer.
Data Address Low	28-31	0x0	Address of data buffer.

38.27.12.2 Send Message To Vf admin command

This command, together with the previous one, implements a communication channel between PFs and their FVs. The data in the external buffer is copied into an event on the VF receive queue. The command completes once the data is copied. The contents of the messages are defined by software. A PF can only send messages to one of it's VFs.

Since the value of the cookie is copied to the event, if 8 bytes are enough for needed message, the software device driver might specify a length of zero and not use an external buffer. in this case, it should not set the *BUF* flag.

Note: This version of the queues supports messages of up to 4096 bytes.

Table 38-371.Send to VF Command (Opcode: 0x0802)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0802	Command opcode.
Length	4-5	buffer length	Length of message.
Return Value	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
VFID	16-19	VFID	ID of VF.
Reserved	20-23		
Data Address High	24-27	0x0	Address of data buffer.

Table 38-371.Send to VF Command (Opcode: 0x0802) (Continued)

Name	Bytes.Bits	Value	Remarks
Data Address Low	28-31	0x0	Address of data buffer.

After posting the event to the VF admin receive queue, firmware completes this command by updating the flags and returning a value of zero for success.

Table 38-372.Message From PF Event (Opcode: 0x0802)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0802	Event code.
Length	4-5	Buffer Length	Length of message.
Return Value/ VFID	6-7		Reserved.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16-19		Reserved.
Reserved	20-23		Reserved.
Data Address High	24-27	0x0	Address of data buffer.
Data Address Low	28-31	0x0	Address of data buffer.

38.28 Statistics

The 10 GbE controller provides statistics for the following interfaces:

- Physical ports
- Virtual switch elements VEBs, PVs, and VSIs
- PE statistics, some of which are global and some are per VSI
- Flow director statistics
- Host interface statistics

A minimal set of Ethernet interface group statistics (RFC 2863) is provided by the 10 GbE controller at the switch sampling points, a fuller set of statistics is provided for physical ports.

The prefixes for the statistics counter names are listed in Table 38-373.

Table 38-373.Counter Name Prefixes

Element	Register Prefix	Instances	Remark
Port	GLPRT	4	
VEPA or VEB	GLSW	16	
VEB per VLAN	GLVEBVL	128	
VEB per TC	GLVEBTC	16 x 8	Two dimensional array of 8 TCs for 16 VEBs.
VSI	GLV	384	

38.28.1 Counter Implementation

Most of the counters in the 10 GbE controller are used by more than one entity. For example, VSI counters are both a virtual switch port (hence used by a switch monitor agent) and a software device driver interface. The 10 GbE controller does not provide clear-on-read statistics counters, since these need to be duplicated per client.

As a general rule, the 10 GbE controller statistics counters should not be reset by software, because they are shared between more than one owner. Software needs to maintain a delta from the first value seen. If software needs the ability to reset counters, this should be implemented by updating the delta reference value.

To enable firmware to reset counters when a switching element is allocated, or for debug, the counters are implemented as clear-on-write, that means that writing any value clears the counter.

The 10 GbE controller provides 48-bit counters for byte and packet counters, and 32 bit counters for errors and discard events. Software should maintain counters that are appropriate in size for the operating system and MIB requirement.

48-bit counters are implemented as a two registers who’s names end with high and low containing the upper 16 bits and lower 32 bits, respectively.

When accessed using a 64-bit operation from PCI, these accesses are guaranteed by design to be atomic. They are internally converted to two 32-bit accesses that are always consecutive with no interleaving between reads from different software device drivers. A special hardware indication signals the statistics block that this is the case. The statistics block preforms one read of the counter memory to satisfy both requests, thus providing atomicity.

When 32-bit accesses are used to read the counters, they each cause a separate read from the statistics block and therefore care must be taken to properly handle the possibility of one half around between the reads, since atomicity is not guaranteed.

VFs have no access to statistics registers, they should query the PF through the VF to PF virtual channel for their statistics.

38.28.2 Statistics Consistency Rules

- At each switch sample point, a packet is either good or error. That means that when a packet is discarded it is not counted in any of the none-error counters. It is also never counted by any of the next processing stages.
- All drops are counted. A packet with an error is only counted in one counter.
- Ethernet octet counters count the packet as seen on the wire, from the Ethernet header up to and including the CRC (for both Rx and Tx). This means that even though an Rx packet might be stripped of tags before placement the byte counters record the original size. Tx packets are counted after all offloads and insertions.
- Flow control packets are only counted in the flow control counters.
- Statistics specific to DDP/iWARP count packets as they are delivered to the offload engine on Rx, and as they leave the engine on Tx. This applies to both packet lengths and packets that were merged or split. For example packets merged by LRO are counted before the aggregation.
- Maximum lengths are adjusted to accommodate added tags. For example, the highest histogram bin MIB counter GLPRT_PTC9522 also count any packet that would have fit in it without the added STags and VLANs.

38.28.3 Supported MIBs

The 10 GbE controller supports different statistic counters as described in this section. The statistic counters can be used to create statistic reports as required by different standards. The 10 GbE controller statistic counters enable support for the following standards:

- IEEE 802.3 clause 30 management — DTE section.
- NDIS 6.0 OID_GEN_STATISTICS.
- RFC 2819 — RMON Ethernet statistics group for ports and VSIs.
- RFC 2863 — SMON Ethernet statistics group for various switch elements.
- Linux Kernel
- net_device_stats

The following section describes the match between the 10 GbE controller's internal statistic counters and the counters requested by the different standards.

38.28.4 Interface Statistics at VSIs and Logical Interfaces

The 10 GbE controller provides Ethernet interface group statistics per RFC 2863 on each of the VSIs, port aggregators and virtual bridges. Table 38-374 lists the interface counters in the 10 GbE controller and their sizes.

VF and PF VSIs have the same counter set. The only difference between the counter set for VSIs and the one for other switch element is that the RUPP (unknown protocol) counter is replaced by a missed packet counter RMPC.

Note that the counter names repeat themselves with a different prefix for the element type. See Table 38-373 for the list of prefixes. The width of the counters that are provided, is calculated to enable ample time for software to get the statistics before they wrap around. The 48-bit counters are a pair of registers, one ending with an L that holds with the lower 32-bits of the counter, the higher 12 bits rest of the bits are in a register ending with and H (listed in Table 38-374 as {H,L}).

Table 38-374.Ethernet Interface Group Statistics Counters

Register Name	Width	Description
[PFX]GORC{H,L}	48	Incoming packet octets.
[PFX]UPRC{H,L}	48	Incoming number of unicast packets.
[PFX]MPRC{H,L}	48	Incoming number of multicast packets.
[PFX]BPRC{H,L}	48	Incoming number of broadcast packets.
[PFX]RDPC	32	Incoming packet discards.
[PFX]RUPP	32	Incoming unknown protocol packets.
[PFX]GOTC{H,L}	48	Outgoing packet octets.
[PFX]UPTC{H,L}	48	Outgoing number of unicast packets.
[PFX]MPTC{H,L}	48	Outgoing number of multicast packets.
[PFX]BPTC{H,L}	48	Outgoing number of non unicast packets.
[PFX]TDPC	32	Outgoing number of discards.
[PFX]TEPC	32	Outgoing packet errors.

Some error counters are not implemented at specific switch elements because they cannot happen at those elements in the current switch design. If software is queried about the value of these counters it should return zero (see Table 38-375).

Table 38-375.Error Counters Not Implemented in Current Design

Counter Name	Switch element	Description
GLPRT_XEC	Port	Port XSUM error count.
GLPRT_TEPC	Port	Port transmit error packet count.
GLV_TDPC	VSI	VSI transmit packets discarded count.
GLSW_RDPC	PA or VEB	Switch receive packets discarded count.
GLSW_TEPC	PA or VEB	Switch transmit error packet count.
GLPRT_TDPC	Port	Packets that were discarded on transmit while link was down.

38.28.4.1 MAC or Physical Uplink Interface Statistics

The MAC or physical uplink interface statistics counters are accessible to the device management/control entity in VMM or IOVM through the PF. The MAC or physical link interface statistics use the counters listed in Table 38-376. The only exception is the Unknown Protocol Packet (UPP) counter, which has no meaning in the case of the physical port and therefor is absent.

In addition, the 10 GbE controller provides per MAC port some of the statistics out of the IEEE 802.3 clause 30 management counters as well as part of the RMON Ethernet statistics group as defined by IETF RFC 2819. See Table 38-376.

Table 38-376.Additional Per Port Counters

Register Names	Width	Description
GLPRT_PRC64{H,L}	48	Packets Received [64 Bytes] Count.
GLPRT_PRC127{H,L}	48	Packets Received [65–127 Bytes] Count.
GLPRT_PRC255{H,L}	48	Packets Received [128–255 Bytes] Count.
GLPRT_PRC511{H,L}	48	Packets Received [256–511 Bytes] Count.
GLPRT_PRC1023{H,L}	48	Packets Received [512–1023 Bytes] Count.
GLPRT_PRC1522{H,L}	48	Packets Received [1024 to 1522] Count.
GLPRT_PRC9522{H,L}	48	Packets Received [1523 to Max Bytes] Count.
GLPRT_PTC64{H,L}	48	Packets Transmitted (64 Bytes) Count.
GLPRT_PTC127{H,L}	48	Packets Transmitted [65–127 Bytes] Count.
GLPRT_PTC255{H,L}	48	Packets Transmitted [128–255 Bytes] Count.
GLPRT_PTC511{H,L}	48	Packets Transmitted [256–511 Bytes] Count.
GLPRT_PTC1023{H,L}	48	Packets Transmitted [512–1023 Bytes] Count.
GLPRT_PTC1522{H,L}	48	Packets Transmitted [1024 to 1522] Count.
GLPRT_PTC9522{H,L}	48	Packets Transmitted [1523 to Max Bytes] Count.
GLPRT_LXONRXCNT	32	Link XON Received Count.
GLPRT_LXOFFRXCNT	32	Link XOFF Received Count.
GLPRT_LXONTXCNT	32	Link XON Transmitted Count.
GLPRT_LXOFFTXCNT	32	Link XOFF Transmitted Count.
GLPRT_PXONRXCNT[n]	32	Priority XON Received Count.
GLPRT_PXOFFRXCNT[n]	32	Priority XOFF Received Count.
GLPRT_PXONTXCNT[n]	32	Priority XON Transmitted Count.
GLPRT_PXOFFTXCNT[n]	32	Priority XOFF Transmitted Count.
GLPRT_PRRXON2OFFCNT[n]	32	Priority XON to XOFF Count.
GLPRT_CRCERRS	32	CRC Error Count.
GLPRT_ILLERRC	32	Illegal Byte Error Count.
GLPRT_MLFC	32	MAC Local Fault Count.
GLPRT_MRFC	32	MAC Remote Fault Count.
GLPRT_RLEC	32	Receive Length Error Count.
GLPRT_RUC	32	Receive Undersize Count.
GLPRT_RFC	32	Receive Fragment Count.
GLPRT_ROC	32	Receive Oversize Count.
GLPRT_RJC	32	Receive Jabber Count.
GLPRT_MSPDC	32	MAC short Packet Discard Count. Only supported when in 10G mode. note that these packets are also counted as undersized packets
GLPRT_RDPC	32	Received packets from the network that are dropped in the receive packet buffer. The packets are dropped due to possible lack of bandwidth on PCIe or total bandwidth of the internal data path.
GLPRT_LDPC	32	Loopback Dropped Packet Count.
GLPRT_TDOLD	32	Transmit Packets Dropped On Link Down.
GLPRT_RUPP	32	Packets received on this port that were dropped because they did not match any S-tag. Relevant only if a PV is used on this port, should be ignored otherwise.

38.28.4.2 VEB Statistics

The 10 GbE controller supports SMON statistics per RFC 2613 for each instance of the VEB. The 10 GbE controller supports the following set of smonVlanStats counters per 802.1Q VLAN and smonPrioStats counters per priority. See Table 38-377 and Table 38-378.

Table 38-377.VEB Per VLAN Counters

Register Name	Width	Description
GLVEBVL_GORC{H,L}	48	Incoming packet octets.
GLVEBVL_GOTC{H,L}	48	Outgoing packet octets.
GLVEBVL_UPC{H,L}	48	number of unicast packets.
GLVEBVL_MPC{H,L}	48	number of multicast packets.
GLVEBVL_BPC{H,L}	48	number of broadcast packets.

Table 38-378.VEB Per UP Counters

Register Name	Width	Description
GLVEBTC_RPC{H,L}	48	Total number of packets received per priority.
GLVEBTC_RBC{H,L}	48	Total number of octets received per priority.
GLVEBTC_TPC{H,L}	48	Total number of packets transmitted per priority.
GLVEBTC_TBC{H,L}	48	Total number of octets transmitted per priority.

Table 38-379.VEB Per VSI Counters

Register Name	Width	Description
GLV_TEPC	32	Transmit error packet count.
GLV_GOTC{H,L}	48	Transmit octet count. Counts number of bytes transmitted by this VSI.
GLV_GORC{H,L}	48	Receive octet count. Counts number of bytes received by this VSI.
GLV_UPRC{H,L}	48	Receive unicast packet count. Counts number of unicast packets received by this VSI.
GLV_RUPP{_H,}	48	Receive packets dropped because of an unknown protocol or no forward destination.
GLV_BPTC[H,L}	48	Transmit broadcast packet count. Counts number of broadcast packets transmitted by this VSI.
GLV_MPTC{H,L}	48	Transmit multicast packet count. Counts number of multicast packets transmitted by this VSI.
GLV_MPRC{H,L}	48	Receive multicast packet count. Counts number of multicast packets received by this VSI.
GLV_BPRC{H,L}	48	Receive broadcast packet count. Counts number of broadcast packets received by this VSI.
GLV_UPTC{H,L}	48	Transmit unicast packet count. Counts number of unicast packets transmitted by this VSI.
GLV_RDPC	48	Counts (per VSI) packets that were drop due to no descriptors in host queue.
GLV_GORCH	48	Receive octet count. Counts number of bytes received by this VSI.

The 10 GbE controller provides virtual bridge port or interface statistics counters for VSIs and uplinks associated with a VEB instance. See Section 38.28.4 for additional details on VSI and uplink interface statistics.

38.28.4.3 Statistics Resources

Most all statistic counters are statically allocated. This means that for each element type there is a 1:1 ratio between the number of elements and the number of counter sets. The only two exceptions to this are VEB per VLAN statistics. There can be up to 256 VEBs (switch IDs), but only 32 of these might be allocated a statistic block. The total number of VLAN x VEB combinations in the system can exceed the number of counter sets.

For statically allocated counters, the admin command allocating the object returns the offset in the counter array of the counters for this entity. For dynamically allocated counters, the allocator must request statistics counters for the object. If statistical counters are not available, the allocation fails. The allocating software device driver might retry the operation without requesting statistics in that case.

38.28.5 Other Statistics

This section includes statistic counters that are not included in the previous sections.

Table 38-380.Other Statistics

Name	Description	Size	Comment
GL_RXERR1 {H,L}	Receive Error Counter 1	64 Bits	Count dropped packet due to one of the following exceptions: • Packet size is larger than RXMAX of the queue. • Internal receive queue context error (could be a result of a reset in progress). • Receive descriptor unsupported request on the PCI or internal dummy completion (the dummy completion is a result of a reset in progress).
GL_RXERR2 {H,L}	Receive Error Counter 2	64 Bits	Count dropped packet due to one of the following exceptions: • Packets directed to invalid receive queues. • Packets directed to disabled receive queues. • Packets dropped by the switch filters (these packets are counted also by the switch statistics). • Packets dropped due to MAC errors or FC CRC errors. • Packets dropped by the FD filter. • Packets dropped due to VM reset, VF reset or PF reset.

38.28.6 RDMA Statistics

Refer to the PE statistics section for more details. Note that switch VSI statistics are counted for PE VSIs at PE ingress, that is before any PE processing.

38.29 LLDP Protocol

38.29.1 Introduction

The 10 GbE controller supports the IEEE DCB standards such as IEEE 802.1Qaz ETS, IEEE 802.1Qbb PFC, and IEEE 802.1Qbg ECB. Devices that support these standards use IEEE 802.1AB LLDP to exchange configuration information with their network link partner.

LLDP is a link layer protocol that enables a LAN station to advertise capabilities and status of the system. An LLDP agent transmits and receives information to and from the LLDP agents of other stations attached to the same LAN. The information distributed and received in each LLDPDU (LLDP data unit) is stored in two MIBs per physical LAN port, one for nearest bridge and the other for non-TPMR. This information is used to configure the 10 GbE controller DCB features.

38.29.2 Scope

The 10 GbE controller supports an embedded LLDP agent that runs on the EMP.

This section describes implementation of the embedded LLDP agent. It also describes the agents operational modes, supported TLVs, configuration and run time operation of LLDP.

38.29.3 LLDP Agent

The following IEEE standards use LLDP to exchange configuration parameters with the link partner.

- EVB
- DCB

The IEEE 802.Qbg specification enables a service provider to support multi-point LAN services to customers over a single physical link by using multiple virtual channels, known as S-channels.

The DCB features (PFC, ETS, DCBX, App TLV) are defined as requirements for a VLAN aware bridge component. Both C-components and S-components are VLAN-aware bridge components. The 10 GbE controller supports a single instance of DCB logic per physical LAN port. Therefore, the 10 GbE controller DCB logic is associated with the component connected to the physical LAN port, either C or S depending on the use case/configuration.

The 10 GbE controller supports an LLDP agent that exchanges LLDP MIB with its peer.

The LLDP agent is active under the following conditions:

1. During pre-boot operations including S5 (D0u and D0a).
2. During operating system present mode unless software explicitly turns off the agent using the Stop LLDP Agent AQ command.

During DCBX exchange, the LLDP agent sets the willingness bit and accepts recommended setting from its link partner.

The LLDP agent is enabled during power-on by setting the NVM *Factory LLDP Admin Status* field, (enabled separately per Ethernet port). It is disabled when the Stop LLDP Agent AQ command is executed (per Ethernet port). Software might transfer ownership of LLDP processing back to the device by issuing a Start LLDP Agent AQ command.

38.29.4 LLDP Processing

38.29.4.1 LLDPDU Addressing and Forwarding

38.29.4.1.1 Egress Rules

On the egress side, the LLDP agent uses the appropriate group MAC address as the destination MAC along with Ether type 0x88cc:

- DCB — Nearest bridge address
- CDCP — Non-TPMR nearest bridge address

A control port that needs to send control packets overriding these rules should use the *SWTCH* field in the transmit context descriptor of the control packet. Tagged (802.1Qbg or 802.1BR) LLDP packets are forwarded like regular packets. The software device driver might define different rules (forward to control VSI or drop) using the Add Control Packet Filter admin command.

38.29.4.1.2 Ingress Rules

When an LLDP agent is enabled in the device, the following forwarding rules apply for Rx LLDP packets:

Table 38-381.Forwarding Rules for Rx LLDP Packets

Destination MAC address	S-Tagged LLDP Packets	Untagged LLDP Packets
Nearest Bridge	Forward to PF if programmed so by the PF. Drop otherwise.	Forward to EMP.
Non-TPMR	Forward to PF if programmed so by the PF. Drop otherwise.	Forward to EMP.
Nearest Customer Bridge	Forward to PF if programmed so by the PF. Drop otherwise.	SFP mode. Forward to PF if programmed so by the PF. Drop otherwise.

38.29.4.2 Supported TLV

The LLDP agent should include following TLV as part of the LLDPDU.

Chassis ID TLV — Is one of four mandatory TLVs. Uses TLV type value of one and subtype value of four (MAC address). This TLV contains the permanent/factory assigned MAC address of the LAN port.

Port ID TLV — Is one of four mandatory TLVs. Uses TLV type value of two and subtype value of three (MAC address). This TLV contains MAC address of any physical function. If there is none assigned to a physical function, then this TLV contains the permanent/factory assigned MAC address of the LAN port.

TTL TLV — Is one of four mandatory TLVs. Uses TLV type value three. This TLV contains time to live value and is the lower between [(msgTxHold * msgTxInterval) +1] and 65535. Default msgTxHold and msgTxInterval are defined in NVM and are loaded by the agent during initialization. Refer to LLDP configuration section for default values.

End of LLDPDU TLV — Is one of four mandatory TLVs. Uses TLV type value zero. This TLV does not contain any information and sets the TLV information string length to zero.

Note: Although this is a mandatory TLV, there might some implementations that do not send it. The 10 GbE controller therefore does not require that an LLDPDU ends with this TLV.

OEM Device type TLV — Is one of the three OEM required TLVs. This TLV uses TLV type value of 127 with subtype of one. Refer to OEM specific LLDP specifications for OUI and contents of the TLV.

OEM Firmware Version TLV — Is one of the three OEM required TLVs. This TLV uses TLV type value of 127 with subtype of three. Refer to OEM specific LLDP specifications for OUI and contents of the TLV.

OEM Port Capabilities TLV — Is one of the three OEM required TLVs. This TLV uses TLV type value of 127 with subtype of four. Refer to the OEM specific LLDP specifications for OUI and contents of the TLV.

DCBX ETS Configuration TLV — This TLV uses type value of 127 with OUI of IEEE 802.1, which is 0x0080C2. Subtype is 0x09.

This TLV information string uses the following default values:

- *Willing* bit set to 1b indicating that this station is willing to accept a configuration from a remote station.
- CBS bit is set to 0b indicating that this station does not support a credit-based shaper.
- Maximum TCs.
- Priority assignment table is a four octet string with four bits per entry.

- Bandwidth table is an eight octet string with each octet defining the bandwidth percentage for TCs. Octet zero specifies a bandwidth percentage of TC zero, octet one for TC one and so on.
- TSA assignment table is a string of 8 octets with an 8-bit value specifying a transmission selection algorithm per TC.

DCBX PFC Configuration TLV — This TLV uses type value of 127 with OUI of IEEE 802.1, which is 0x0080C2 along with a subtype of 0x0B.

This TLV information string uses the following default values:

- *Willing* bit set to 1b indicating that this station is willing to accept a configuration from a remote station.
- *MBC* bit is set to 0b.
- PFC capability is a 4-bit unsigned integer indicating the number of TCs that simultaneously support PFC. Default value is eight.
- PFC enable is an 8-bit vector that indicates which TCs have PFC enabled. Default value is zero. No traffic call uses have PFC enabled by default.

DCBX Application Priority Configuration TLV — This TLV uses type value of 127 with OUI of IEEE 802.1, which is 0x0080C2 along with a subtype of 0x0C.

By default this optional TLV is not transmitted by the LLDP agent but the agent reflects the table received from a peer network port if the agent receives LLDPDU with a remote link partner.

This TLV uses a type value of 127 with OUI of IEEE 802.3, which is 00-12-0F along with a subtype of five. TLV information string carries timing information following Low Power Idle (LPI) exit.

The first six octets contain TransmitTw, ReceiveTw and FallbackTw. The default values for TransmitTw and Receive Tw values are loaded from the NVM. The value of FallbackTw is the same as ReceiveTw (FallbackTw = ReceiveTw). TransmitTw and ReceiveTw can be changed at runtime by using admin queue commands from a PF.

Note: There is a single LLDP agent for all LAN ports and each LAN port has multiple PFs. Therefore, it is likely that these variables can overwritten by multiple admin queue commands. The last admin command takes precedent.

Echo Transmit Tw and Echo Receive Tw values are of the remote link partner. If the link partner has not transmitted an LLDPDU then hardware is the default value for the resolved PHY type.

CDCP TLV — This TLV is over Ethernet frames with the nearest non-TPMR bridge group address.

38.29.4.3 LLDPDU Transmission and Reception

The first LLDP transmission is immediate after the LLDP agent reaches a ready state and the link is up. This first transmission populates the LLDPDU with default TLV values.

The LLDP agent enters a fast transmission state/period each time the LLDP agent detects a new neighbor. The LLDP agent enters a new neighbor detected state (fast transmission period) when an IEEE 802.1az link layer LLDP frame with a new chassis and port ID is received. The fast transmission state exists after transmitting a txFastInit number of LLDPDUs. The default value of txFastInit is four.

While not in fast transmission mode, the LLDP agent transmits every msgTxInterval unless there is change in local LLDP MIB variables. LLDPDU is transmitted immediately, without waiting for msgTxInterval when there is a change in local MIB variables.

The 10 GbE controller supports a single LLDP neighbor (such as a single remote MSAP). Therefore, if the received LLDPDU is from a new neighbor, the existing information within the current remote systems MIB is discarded in order to make space for the new information received in the LLDPDU.

The transmission and reception flow is interrupted by several events, each causing a disruption in the normal flow. The behavior in such cases is as follows:

- LLDP events are visible to both ends:
  - Aging of the LLDP timer or LLDPDU is received with a TTL value of zero (like a shutdown LLDPDU).
    - Delete all information in the LLDP remote systems MIB associated with the respective MSAP identifier.
    - EMP reconfigures the device based on the local defaults.
  - Missing TLV in a received LLDPDU:
    - Delete all information for the missing TLV in the LLDP remote systems MIB associated with the respective MSAP identifier.
    - EMP reconfigures the device based on the local defaults of this TLV.
- Events that cause a link down:
  - Link down event (only if the LLDP timer has not expired).
    - When the link is back up, delete all information in the remote systems MIB associated with the LLDP agent(s) for this link.
    - EMP reconfigures the device based on the local defaults.
  - Device resets that cause link down (such as EMP reset, global reset, PCI resets that cause link down).
    - Device performs an internal GLOBR that brings the link down momentarily.
    - Continue as in the link down case.
  - LLDP ownership transfer from software to firmware:
    - Software issues a global reset to the device.
    - Software sends a Start LLDP Agent AQ command to start the LLDP agent in firmware.
    - Continue as in the link down case.
- Events not visible to the other end:
  - LLDP ownership transfer from firmware to software.
    - LLDP agent terminated in the device.
    - No automatic change in device configuration.
    - EMP waits for software commands.
  - Device resets that do not cause a link down (like a core reset, PCI resets that do not cause link down or function-level resets):
    - Device performs an internal CORER.
    - EMP reconfigures the core based on the LLDP MIBs.

Note: No change in MAC/PHY state including flow control configuration and operation.

LLDP reception and transmission continues once the previous configuration completes. Configuration is estimated to take milliseconds, which is below the LLDP timeout values (usually in seconds).

38.29.4.4 LLDP Protocol Variables

Unless otherwise specified, the LLDP agent operational state variables are set to values recommended in Section 9.2.2 of the IEEE 802. AB - 2009 standard. However, certain values can be configured via the NVM and are loaded from the NVM when the LLDP agent reaches an operational state; this occurs after a power up or a device reset. See Section 38.29.5.2 for LLDP protocol variables that can be configured via the NVM.

38.29.4.5 LLDP Data Store

The LLDP agent maintains sufficient information to enable a host software based management agent to support basic LLDP MIB and organizationally specific LLDP MIB extensions.

The following basic variables are maintained by the LLDP agent:

msgTxInterval — This variable defines the time interval in timer ticks between transmissions during normal transmission periods.

msgTxHold — This variable is used as a multiplier of msgTxInterval to determine the value of txTTL that is carried in LLDP frames transmitted by the LLDP agent.

reinitDelay — This parameter indicates the amount of delay from when adminStatus becomes disabled until re-initialization is attempted.

txCreditMax — Maximum number of consecutive LLDPDUs that can be transmitted at any time.

msgFastTx — This variable defines the time interval in timer ticks between transmissions during fast transmission periods.

txFastInit — This value determines the number of LLDPDUs that are transmitted during a fast transmission period.

adminStatus — This variable indicates whether or not the LLDP agent is enabled. The defined values for this variable are as follows:

- Integer value of three means the LLDP agent is enabled for reception and transmission of LLDPDUs.
- Integer value of two means the LLDP agent is enabled for transmission of LLDPDUs only.
- Integer value of one means the LLDP agent is enabled for reception of LLDPDUs only.
- Integer value of zero means the LLDP agent is disabled for both reception and transmission.

The following statistics are maintained by LLDP agent per port:

RemTableLastChangeTime, RemTableInserts, RemTableDeletes, RemTbleDrops, RemTableAgeouts, TxPortFramesTotal, RxPortFramesDiscarded, RxPortFrameErrors, RxPortFramesTotal, RxPortTLVsDiscardedTotal, RxPortTLVsUnrecognizedTotal, RemTooManyNeighbors.

The LLDP agent maintains the last received LLDPDU per port. The upper bound for the size of LLDPDU is 1500 bytes. Details about the data structure used for information store is implementation specific and beyond scope of this document.

The 10 GbE controller provides LSAP services to the operating system provided MSAP services that are used by LLDP agents hosted by system processors.

38.29.5 Initialization and Configuration

38.29.5.1 Initialization

As part of EMP initialization, an the LLDP agent is loaded and initialized by the EMP. The LLDP agent loads default values for TLVs from the NVM. LLDP agent transitions to a ready state and waits for LAN link up before transmitting the first LLDPDU.

The DCBX agent operates in slave mode and sets the willingness bit and accepts recommendations from a link partner.

38.29.5.2 LLDP Configuration

38.29.5.2.1 LLDP Protocol Variables

The following LLDP timers can be configured via the NVM:

msgFastTx — This variable defines the time interval in timer ticks between transmissions during fast transmission periods. The default value of msgFastTx is one. This value can be changed by management to any value in the range 1 through 3600.

msgTxInterval — This variable defines the time interval in timer ticks between transmissions during normal transmission. The default value for msgTxInterval is 30 seconds. This value can be changed by management to any value in the range 1 through 3600.

msgTxHold — This variable is used as a multiplier of msgTxInterval to determine the value of txTTL that is carried in LLDP frames transmitted by the LLDP agent. The recommended default value of msgTxHold is four. This value can be changed by management to any value in the range 1 through 100.

txCreditMax — This value determines the maximum number of LLDPDUs that can be sent per second. This value defaults to five. This value can be changed by management to any value in the range 1 through 10.

txFastInit — This value determines the number of LLDPDUs that are transmitted during a fast transmission period. The default value of txFastInit is four. This value can be changed by management to any value in the range one through eight.

reinitDelay — This parameter indicates the amount of delay from when adminStatus becomes disabled until re-initialization is attempted. The default value is two.

38.29.5.2.2 LLDP Admin Queue Commands

The following commands are supported by the 10 GbE controller to manage the LLDP agent and provide information to the software device drivers.

Table 38-382.LLDP Admin Queue Commands (Sheet 1 of 2)

Command	OpCode	Description
Get LLDP MIB	0x0A00	Fetch latest LLDP MIB.
Configure LLDP MIB Change Event	0x0A01	Request and deliver a notification that the peer has sent an updated LLDP MIB.
Add LLDP TLV	0x0A02	Add a new TLV to the local LLDP MIB.
Update LLDP TLV	0x0A03	Update an existing TLV in the local LLDP MIB.
Delete LLDP TLV	0x0A04	Delete a TLV from the local LLDP MIB.
Stop LLDP Agent	0x0A05	Used to stop or shutdown the LLDP agent.
Start LLDP Agent	0x0A06	Start an LLDP agent running.
Get CEE DCBX CFG	0x0A07	Retrieves the CEE configuration.

Table 38-382.LLDP Admin Queue Commands (Sheet 2 of 2)

Command	OpCode	Description
Set Local LLDP MIB	0x0A08	Load the DCBX configuration.
Stop/Start a Specific LLDP Agent	0x0A09	Stop and restart the firmware DCBX agent.

Get LLDP MIB

This command, posted on the ATQ, is an indirect AQ command. The software device driver requests the complete LLDP MIB, providing a response buffer (address/length pair) and the type of LLDP MIB requested. The LLDP MIB is associated with a physical LAN port. Instead of formatting the LLDP MIB in any particular way, firmware should write the entire packet (including headers) that was sent/received on the wire for the particular MIB type specified. The MIB is guaranteed to fit in a 1.5 KB packet, so there is no need to use a large buffer. For a particular bridge type, software might request the local MIB, the remote MIB, or both MIBs.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ. It writes the status of the request in the *Return Value* field. If both MIBs are returned, firmware always writes the local MIB first and the remote MIB immediately following the Local MIB.

Table 38-383.Get LLDP MIB Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A00	Command opcode.
Datalen	4-5		Length of response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Direction. 0 = Local MIB (sent by device). 1 = Remote MIB (received by device). 2 = Both local and remote MIBs. 3 = Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7: Reserved.
Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Table 38-384.Get LLDP MIB Response

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ
Opcode	2-3	0x0A00	Command opcode.
Datalen	4-5		Length of LLDP MIB if status = success. In bytes.
Return Value/ VFID	6-7		Return value. Zeroed by software device driver. Written by firmware. Status of request. A value of success means that the command was performed successfully. Error Codes: ENOENT - Firmware returns this value if any requested LLDP MIB doesn't exist. EPERM - Firmware returns this value if software has taken control of LLDP processing. EFBIG - Firmware returns this value when the size of LLDPDU is larger than size of the response buffer. EINVAL - Firmware returns this value when software requests for a bad request (like an invalid bridge type or direction).
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Direction. 0 = Local MIB (sent by device). 1 = Remote MIB (received by device). 2 = Both local and remote MIBs. 3 = Reserved. Bits 2-3 = Bridge yype. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7 = Reserved.
Reserved	17	Reserved	Reserved.
Local MIB Length	18-19	Len	If the response buffer contains a local MIB, this field reports its length. If no local MIB is present, this field is written with a value of zero.
Remote MIB Length	20-21	Len	If the response buffer contains a remote MIB, this field reports its length. If no remote MIB is present, this field is written with a value of zero.
Reserved	22-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Note: If only one MIB is present, it is written to the response buffer beginning at the first byte of the response buffer (offset=0). If two MIBs are present, the local MIB is always written first (offset=0), and the remote MIB is written immediately following the local MIB (offset=LocalMIBLength).

Configure LLDP MIB Change Event

This command, posted on the ATQ, is a direct AQ command. The software device driver uses this command to request that firmware post an event on the ARQ when the LLDP MIB associated with this interface changes. The software device driver can also use this command to request that firmware stop posting this event to the ARQ.

Firmwasre writes back the status of the request to the *Return Value* field.

Table 38-385.Configure LLDP MIB Change Event Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ
Opcode	2-3	0x0A01	Command opcode.
Datalen	4-5	0	Direct command; no response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Command	16	Cmd	Bit 0 = Command. 0 = Enable event. 1 = Disable event. Bits 1-7 = Reserved.
Reserved	17-31	Reserved	Reserved.

Table 38-386.Configure LLDP MIB Change Event Response

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A01	Command opcode.
Datalen	4-5	0	Direct command; no response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware. Status of request. A value of success means that the command was performed successfully. Error code: EPERM - Firmware returns this value if software has taken control of LLDP processing.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16-31	Reserved	Reserved

LLDP MIB Change Event

This event is posted on the ARQ to indicate to software that any LLDP MIB associated with the physical interface has changed. The LLDP MIB change event must also be posted if a multiple peers condition is detected or if a TLV is aged out.

Firmware provides the status of the event, the length of the LLDP MIB in bytes, the type of LLDP MIB which has changed, and copies the cookie value from the associated configure LLDP MIB change event.

The response buffer includes the entire MIB that changed. The formatting is identical to the response for the Get LLDP MIB command.

Note that the opcode for this event is the same as the opcode for the related command on the ATQ that enabled this event to be sent to software.

Table 38-387.LLDP MIB Change Event

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A01	Event code.
Datalen	4-5		Length of LLDP MIB if status = success. In bytes.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware. Status of request.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Direction. 0 = Local MIB (sent by device). 1 = Remote MIB (received by device). 2 = Reserved. 3 = Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-5 = Miscellaneous. 0 = Port's Tx active. 1 = Port's Tx suspended and drained. 2 = Reserved. 3 = Port's Tx suspended and drained. Blocked TC pipe flushed. Bits 6-7 = Reserved.
Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Add LLDP TLV

This command, posted on the ATQ, is an indirect AQ command. The software device driver provides the type of MIB to be updated, the TLV to be added, and the address/ length of the buffer containing the TLV. Software is responsible for guaranteeing that the TLV to be added does not already exist in the MIB or follows the TLV usage rules for TLVs, which allow multiple instances. Software can only add TLVs to the Local LLDP MIB.

Firmware adds the a new TLV to the Local LLDP MIB just before the End of LLDPDU TLV command. Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 38-388.Add LLDP TLV Command (Sheet 1 of 2)

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A02	Command opcode.
Datalen	4-5	Len	Length of indirect buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.

Table 38-388.Add LLDP TLV Command (Sheet 2 of 2)

Name	Bytes.Bits	Value	Remarks
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1= Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7 = Reserved.
Reserved	17	Reserved	Reserved.
Length	18-19	Len	Length of TLV placed in the indirect buffer by the software device driver.
Reserved	20-23	Reserved	Reserved.
Data Address High	24-27		Address of indirect buffer.
Data Address Low	28-31		Address of indirect buffer.

Table 38-389.Add LLDP TLV Response

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A02	Command opcode.
Datalen	4-5		Length of LLDP MIB if status = success. In bytes.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware. Status of request. Error codes: ENOMEM – Firmware returns this value if there is not enough space available to add the new TLV. EINVAL – Firmware returns this value if the MIB Type associated with this command does not exist. EPERM - Firmware returns this value if software has taken control of LLDP processing.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7 = Reserved.
Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Update LLDP TLV

This command, posted on the ATQ, is an indirect AQ command. The software device driver provides the bridge type of the MIB to be updated, the TLV to be updated (both original and updated versions), the offset/length of both TLVs in the indirect buffer, and

the address/length of the indirect buffer. Software is responsible for guaranteeing that the TLV to be updated does already exist in the MIB. Only a local MIB can be updated by the software device driver.

Firmware must match the entire original TLV in the MIB before performing an update. There are some TLV types that might appear more than once, and so matching based only on type/subtype is not sufficient.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 38-390.Update LLDP TLV Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A03	Command opcode.
Datalen	4-5	Len	Length of indirect buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software driver. Written by firmware.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 =Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7 = Reserved.
Reserved	17	Reserved	Reserved.
Length1	18-19	Len	Length of original TLV in the indirect buffer. Offset is assumed to be zero.
Offset2	20-21	Offset	Offset of updated TLV in the indirect buffer.
Length2	22-23	Len	Length of updated TLV in the indirect buffer.
Data Address High	24-27		Address of indirect buffer.
Data Address Low	28-31		Address of indirect buffer.

Name	Bytes.Bits	Value	Remarks
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Type	16	MIB Type	Bit 0-1 = Reserved. Bits 2-3 = Bridge type. 0 = Nearest bridge. 1 = Non-TPMR bridge. 2 = Reserved. 3 = Reserved. Bits 4-7 = Reserved.
Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Delete LLDP TLV

This command, posted on the ATQ, is an indirect AQ command. The software device driver provides the type of MIB to be updated and a copy of the TLV to be deleted. Software is responsible for guaranteeing that the TLV to be deleted does already exist in the MIB.

Firmware writes back the complete LLDP MIB to the response buffer. It writes the length of the LLDP MIB into the *Datalen* field in the descriptor on the ATQ.

Table 38-392.Delete LLDP TLV Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A04	Command opcode.

Reserved	17-23	Reserved	Reserved.
Data Address High	24-27		Address of response buffer.
Data Address Low	28-31		Address of response buffer.

Stop LLDP Agent

This command, posted on the ATQ, is a direct AQ command. The software device driver uses this command to request that firmware stop or shutdown the LLDP agent on the port.

If stop is specified, the 10 GbE controller stops the LLDP agent on the port and directs all untagged ingress LLDP frames received on the port to the default queue of the control VSI associated with the port aggregator or port extender.

If shutdown is specified, the 10 GbE controller stops the LLDP agent on the port and sends a last LLDP PDU on the wire with TTL = 0 and with nearest bridge and non-TPMR destination address. Firmware then directs all untagged ingress LLDP frames received on the port to the default queue of the S-component control VSI.

Firmware writes back the status of the request.

Any preceding registration to events on the port (via the Configure LLDP MIB Change Event command) is discarded. Software should register for events again once the LLDP agent in the device is active again.

After the response, the software device driver should route the LLDP flows to a control VSI using the Add Control Packet Filter command.

Table 38-394.Stop LLDP Agent Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A05	Command opcode.
Datalen	4-5	0	Direct command; no response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware.

Datalen	4-5	0	Direct command; no response buffer.
Return Value/ VFID	6-7		Return value. Zeroed by the software device driver. Written by firmware. Status of request. A value of success means that command was performed successfully. Error code: EPERM - Firmware this value if software has taken control of LLDP processing or if the firmware LLDP agent is disabled.
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16-31	Reserved	Reserved.

Start LLDP Agent

It is expected that CORER has occurred before this command is issued. CORER causes the EMP to reload LLDP forwarding rules from the NVM and re-initialize per NVM settings.

This command, posted on the ATQ, is a direct AQ command. In response to this command EMP re-enables LLDP agent over all ports enabled by the NVM Factory LLDP Admin Status word. It is expected that only pre-boot software issues this command to start the LLDP agent.

If the software device driver defined LLDP forwarding rules previous to sending this command, these rules should be removed using the Remove Control Packet Filter admin command before sending this command.

Table 38-396.Start LLDP Agent Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.
Opcode	2-3	0x0A06	Command opcode.
Datalen	4-5	0	Direct command; no response buffer.

Restore LLDP Agent Factory Settings

This command, posted on the ATQ, is a direct AQ command. The software device driver uses this command to request that firmware uses the factory default setting for firmware's LLDP agent on the port.

Table 38-398.Restore LLDP Agent Factory Settings Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See Admin Queue section for details.
Opcode	2-3	0x0A0A	Command opcode
Datalen	4-5	0	Direct command; no response buffer.
Return Value	6-7		Return value. Zeroed by driver. Written by Firmware.

Get CEE DCBX OPER CFG

This command, posted on the ATQ, is an indirect AQ command. The software device driver requests the operational configuration of CEE/DCBX. The software device driver then provides a response buffer (address/length pair).

The EMP writes back the CEE/DCBX configuration to the response buffer.

Table 38-400.Get CEE DCBX OPER CFG Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.

Table 38-402.Get CEE DCBX OPER CFG Response Buffer Format (Sheet 1 of 2)

Offset (Bytes)	Description
0	Reserved, return zero.
1	Local Oper Num Traffic Class Supported. Returns a value between 1-8 for the number of TCs supported locally.
2-5	Local Oper Priority Assignment. For each UP, 4-bits for the TCID. Available value is 0-7. Upper bit = 0. Bits 0-3 = Assigned for up 0. Bits 4-7 = Assigned for up 1. : Bits 27-31 = Assigned for up 7.
6	Reserved, return zero.
7-14	Local Oper TCB Bandwidth. An 8-byte field. Each byte represents the relative bandwidth allocation of one enabled TC. Byte 7 assigned for TC 0. Relative bandwidth allocation is a value 0-100 and represents the percentage of the available bandwidth this TC is allocated with. The sum of the bandwidth allocated for all TCs equal to 100%.
15	Local Oper PFC Enable. A bitmap containing a PFC-enable flag for each UP. Bit 0 relative to UP 0.
16	Reserved, return zero.
17-18	Local Oper Application Priority. Indicates the application TLV negotiated for iSCSI and FIP (encoded in three bits). 17.0-2 = Reserved. 17.3-5 = Reserved for iSCSI application priority. 17.6-7 = Reserved. 18.0-2 = Reserved for FIP application priority. 18.3-7 = Reserved.
19	Reserved, return zero.

Table 38-402.Get CEE DCBX OPER CFG Response Buffer Format (Sheet 2 of 2)

Offset (Bytes)	Description
20-21	Status flags for DCBX TLVs. For each TLV indicates the status of the TLV: operational mode, synced, error (1b = true, 0b = false). 20.0-2 = Status bits for PG. 20.3-5 = Status bits for PFC. 20.6-7 = Reserved. 21.0-2 = Status bits for application priority.

Set Local LLDP MIB

This command, posted on the ATQ, is an indirect AQ command. The software device driver configures the complete DCBX MIB, providing a response buffer (address/length pair). The DCBX MIB is associated with a physical LAN port and must be expressed in IEEE format even though firmware sends it as CEE TLVs on the wire if needed. Instead of formatting the DCBX TLVs in any particular way, firmware should send on the wire the entire DCBX MIB (including headers) that was posted by the host. The MIB is guaranteed to fit in a 1.5 KB packet, so there is no need to use a large buffer. Once DCBX negotiation with the peer completes, the local DCBX MIB returned by the Get LLDP MIB command reflects the final resolved values. In the future, the command could be extended to support additional LLDP MIBs.

This command is useful to configure the local DCBX agent into the non-willing mode (master mode) and to set the DCB configuration to be pushed to the peer.

Firmware writes back the status of the request in the *Return Value* field.

If the willing bit is set in a DCBX TLV, the DCBX agent should take it in account when resolving DCBX with the peer, as per the rules defined in the IEEE/CEE standard.

Firmware might change the local configuration twice, once after receiving the AQ command to align the default configuration to what is published in the TLVs sent to the peer, and after receiving the peer's TLV when resolving DCBX. These two steps might be collapsed into one single configuration change in case the peer's TLV is received within short delays. The new default configuration is maintained until the next GLOBR event or until a Stop DCBX Agent AQ command is received.

If the command is received while the firmware DCBX agent is disabled or stopped, the MIB is parsed by firmware and used to configure the local DCB settings of the port, with no DCB TLV exchange with the peer performed by firmware. Firmware drains the Tx pipe if TC or PFC changes were pushed, as if was a result from a regular DCBX negotiation flow.

Table 38-403.Set local LLDP MIB Command

Name	Bytes.Bits	Value	Remarks
Flags	1:0		See AQ section for details.

Reserved	17-31	Reserved	Reserved.

Stop/start a Specific LLDP Agent

This command, posted on the ATQ, is a direct AQ command. The software device driver uses this command to request that firmware stops or restarts the DCBX agent on the port. In the future, the command could be extended to support more specific agents.

Stopping the DCBX agent on the port means the following:

1. When parsing the LLDP TLVs received from the peer, the LLDP agent skips over all DCBX TLVs.
2. LLDP agent does not send DCBX TLVs to the peer.
3. Local DCB configuration is returned to the hardware default (single TC, no PFC).
4. Get LLDP MIB will still return the remote DCBX MIBs if such are received from the peer.

Restarting the DCBX agent on the port means the following:

1. LLDP agent parses and processes the DCBX TLVs received from the peer.
2. LLDP agent sends DCBX TLVs to the peer.
3. Local DCB configuration is modified according to the DCBX negotiation with peer.

Firmware writes back the status of the request.

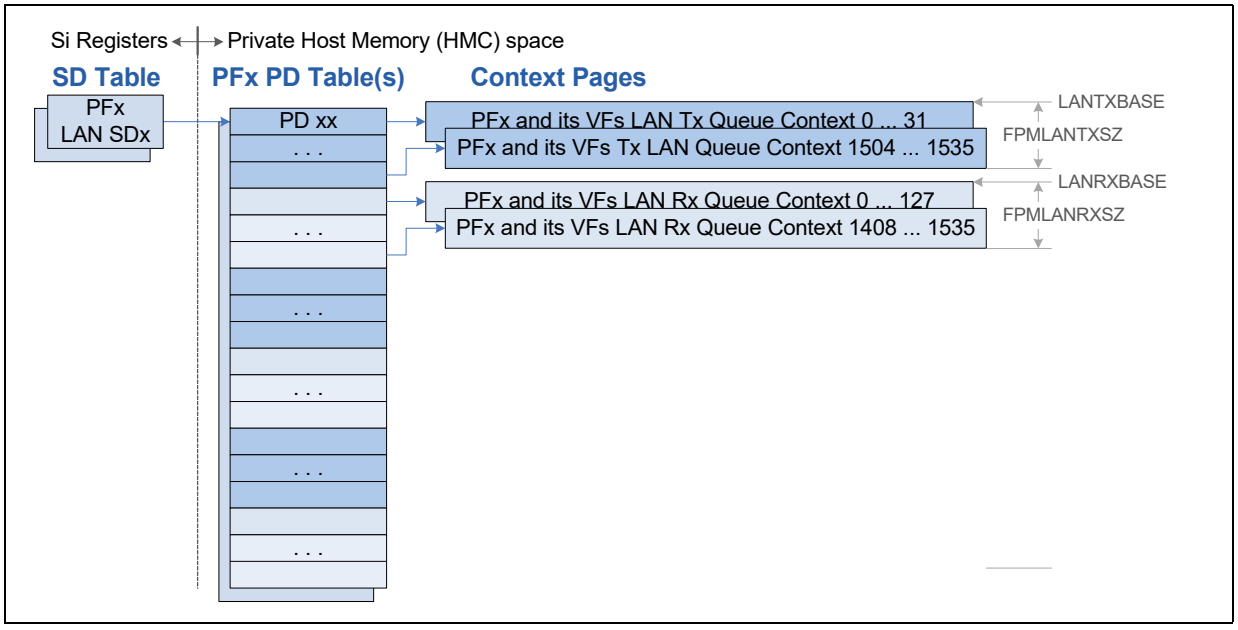
38.30 LAN Engine

38.30.1 LAN Cache and Private Host Memory

The LAN transmit and receive queue contexts are stored in memory pages in the FPM space detailed in Section 38.26. The FPM for the Tx and Rx queue contexts is defined by the GLHMC_LANTXBASE, GLHMC_LANRXBASE, GLHMC_LANTXOBJSZ and GLHMC_LANRXOBJSZ registers. The context of the PF and its VFs reside in the private memory spaces of the PF. A conceptual description of these structures (assuming each object starts at a new PD) is shown in Figure 38-92.

The FPM is considered a private memory of the hardware so software is not expected to access it other than in LAN queue contexts for initial programming (as described in this section). During run time, the hardware fetches the queue context from the FPM to its cache according to internal needs.

Figure 38-92.PF LAN FPM



38.30.2 Shared LAN Data Path

38.30.2.1 LAN Queue Pairs Allocation

38.30.2.1.1 LAN Queue Pairs Allocation to PFs

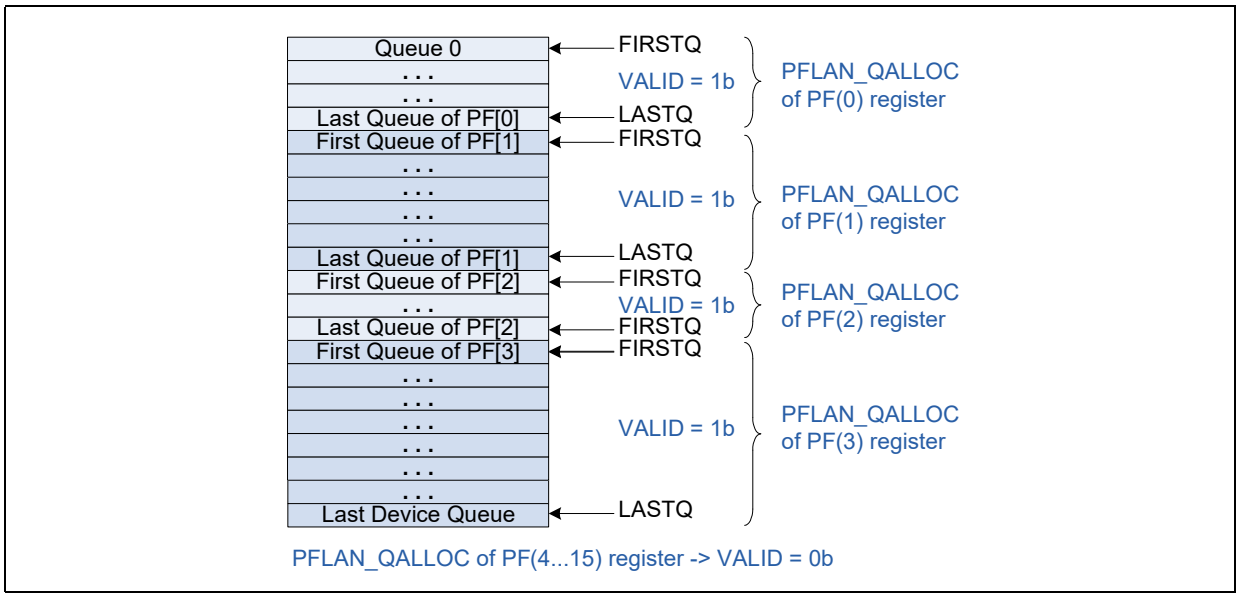
Queues are allocated in pairs of transmit and receive queues, called LAN Queue Pairs (LQP) in this section. LQPs are statically allocated to PFs in a flexible manner according to PFLAN_QALLOC registers (loaded from the NVM):

- Active PFs must have LQPs enabled by the VALID flag.
- LQPs of a PF start at the absolute LQP index defined by the FIRSTQ field and end at the absolute LQP index defined by the LASTQ field.

The allocated LQPs for the PFs must be defined monotonically. This means that LQPs of PF(n) must be allocated after the LQPs of PF(n-1) in the absolute physical device space. Figure 38-93 provides an example of 4 PFs.

Note: Based on the PFLAN_QALLOC values, the PF software allocates the LQPs for its usage and for its VFs as detailed in the following sub-sections.

Figure 38-93.LAN Queue Pairs Allocation Example of 4 PFs



38.30.2.1.2 LAN Queue Pairs Allocation Within a PF

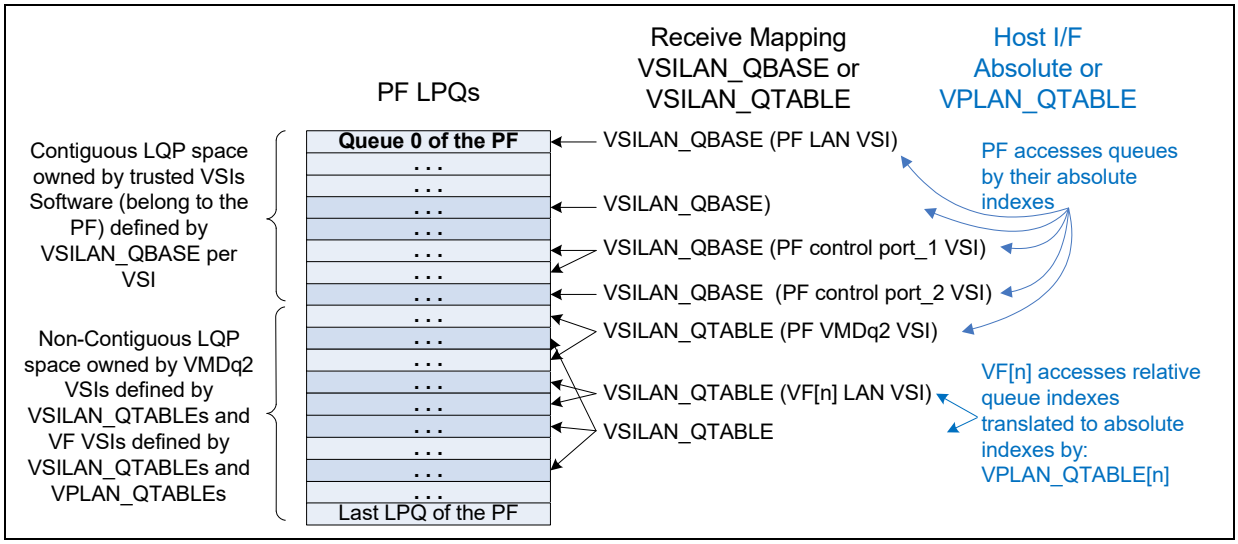
The PF software device driver is expected to read the values of the PFLAN_QALLOC register to determine the LQPs owned. The PF allocates these LQPs by programming the VPLAN_QTABLEs and VPLAN_QBASE registers and by the add VSI AQ command that programs the VSILAN_QBASE and VSILAN_QTABLEs. An example of LQP allocation within a PF to its VSIs is shown in Figure 38-94. Note the following:

- Receive queue zero of the PF is reserved for the flow director filter programming status descriptor. Note that LPQ zero must be a member of a VSI. If it is needed to avoid mixed traffic and flow director status indications on the same receive queue, this VSI should not be the default VSI of the port and should not be a target of any switch filters.
- VFs used by the VMM are expected to be statically allocated and therefore could be contiguous. Contiguous space is defined by the VFFIRSTQ and VFNUMQ field in the

VPLAN_QBASE register. VFs that are allocated contiguous LQPs in the PF space can get up to 256 LQPs.

- Non-statically allocated VFs and VMDq2 VSIs are allocated up to 16 scattered LQPs in the PF space by the VPLAN_QTABLE, and VSILAN_QTABLE registers. The VSILAN_QTABLE registers enable scattered LQPs allocation useful for dynamic VM motion.
  - For VFs, the *VSILAN_QTABLE* registers of all its VSIs must be set to the same indexes assigned to the VF by the *VPLAN_QTABLE* registers.
  - These tables are not readable for the VFs. Instead, the VF is notified by the PF about the number of its allocated LQPs (using a software API or the mailbox). The PF on its side, must allocate the LQPs starting at LQP zero and setting contiguous entries in these tables.
  - Mapping of a *VSILAN_QTABLE*[m] to a VF is the same for all other VSI registers defined by the VSI_VSI2F registers.
- VSIs allocated to nominal PF traffic or PF control ports are expected to be statically allocated and therefore could be contiguous. Contiguous space is defined by the *VSIBASE* field in the VSILAN_QBASE register. VSIs that are allocated contiguous LQPs in the PF space can get any number of LQPs.
  - The size of the contiguous VSI is not enforced by hardware setting so it is software's responsibility to keep within the VSI boundaries.
  - During reception, hardware checks that the queue index generated by the receive classification filters does not exceed the PF queue range. However, it does not check if the queue index exceeds the VSI range. It is PF software's responsibility to define the receive classification filters so that the queues do not exceed the VSI space.
- Contiguous vs. scattered VSI is controlled by the VSIQTABLE_ENA flag in the VSILAN_QBASE register.
- It is PF software's responsibility to define free LQPs that are within the space of the PF.

Figure 38-94.PF Queues (Example)



Software Access to the Queues of the Functions

PF software accesses its LQPs by their index within the PF space. Queue index 'm' of PF 'n' equals to 'm + PFLAN_QALLOC[n].FIRSTQ' in the device space. Accessing LQPs outside the PF space does not impact device functionality. Write accesses are terminated successfully on the PCIe bus with no impact on the hardware while read accesses provide meaningless data.

VF software accesses its LQPs using an index within the VF space. LQPs indexes are translated to indexes in the PF space by the VPLAN_QTABLE and VPLAN_QBASE registers. The VPLAN_QTABLE supports up to 16 LQPs. When using a contiguous allocation via the VPLAN_QBASE, up to 256 queues can be accessed. A VF might get less than the maximum number of LQPs. A VF software attempt to access LQPs above the allocated ones does not impact device functionality (the same as previously described for the PF).

Note that a function (PF or VF) might have multiple VSIs. Still, software accesses all LQPs by their index in the function space rather than index in the VSI spaces.

Associating Received Packets to VSI Queues

The 10 GbE controller associates received packets to VSIs by the embedded switch. It then associates packets to queues using the classification filters.

- As opposed to the software interface, the classification filters assign a queue index in the VSI space. The queue index 'n' is mapped to the PF space as follows:
  - Queue index 'n' of a contiguous VSI is mapped to queue index 'n + VSILAN_QBASE.VSIBASE'
  - Queue index 'n' of a "scattered" VSI is mapped as follows:
    - For an even 'n' it is mapped to VSILAN_QTABLE[n/2].QINDEX_0
    - For an odd 'n' it is mapped to VSILAN_QTABLE[(n-1)/2].QINDEX_1
- Invalid receive queues
  - An invalid queue for contiguous VSI is identified if n + VSILAN_QBASE.VSIBASE exceeds the PF queue space.
  - An invalid queue 'n' for scattered VSI is identified if its QINDEX in the VSILAN_QTABLE equals to 0x3FF or if 'n' is greater or equal than 16.
- Packets received to invalid queues are dropped and counted by the GLV_REPC counter of the VSI.

Dynamic Queue Allocation

The 10 GbE controller supports dynamic queue allocation between VSIs of each PF. Dynamic queue allocation is mainly aimed to support dynamic load balance of VFs according to needs due to VM motion. Queues can be de-allocated from an active VSI during run time. These queues can then be allocated to another VSI of the same VF or to another VF. The entire flow is managed by the PF as described in the text that follows.

The following steps relate to LQPs of VFs while it is similar to LQPs of VMs:

- PF software communicates to the VF that it needs to give up a specific LQP(s).
- The PF removes the queue(s) from the VPLAN_QTABLE, *VPLAN_QBASE* and the VSILAN_QTABLE. As a result, the VF can no longer access the queue(s).
- PF software disables the relevant queues, following the queue disable flow described in Section 38.30.3.3.3 and Section 38.31.3.1.2. As part of the flow, the PF waits for the hardware indication that the queues are disabled with no further activity to host memory.

- The PF notifies the VF that it can release the host memory structures of the removed LQP(s).
- The PF remaps these LQP(s) to another VF as follows:
  - It programs the new queue context parameters in the FPM and then enables these queues (see Section 38.30.3.3.2 and Section 38.31.3.1.2 for receive and transmit queue enablement flows).
  - It maps the LQP(s) to the new VF in the VPLAN_QTABLE, VPLAN_QBASE and VSILAN_QTABLE and informs the VF about this action.
- The queues are ready to be used by the VF.

38.30.2.1.3 LAN Queue Pair Allocation Example

Allocate the LQPs to the VSIs of the PF by setting the VSILAN_QBASE registers, VSILAN_TABLE and VPLAN_TABLE. Table 38-407 lists 5 VSIs while the PF owns 128 LQPs (as configured by PFLAN_QALLOC.FIRSTQ = 128 and PFLAN_QALLOC.LASTQ = 255).

Table 38-407.5 VSIs While the PF Owns 128 LQPs Example

VSI #	VSI Usage	Requirement	Setting
None	N/A	1 LQP	Allocating dedicated receive queue for the flow director filter programming status descriptors. Queue index 0 in the PF space is absolute queue index 128.

0	PF Control Port	1 LQP	VSILAN_QBASE[0].VSIQTABLE_ENA = 0 // contiguous range.
			VSILAN_QBASE[0].VSIBASE = 1.
			Queue index 1 in the PF space is absolute queue index 129.

1	PF LAN and its VMDq1 VMs	64 LQPs	VSILAN_QBASE[1].VSIQTABLE_ENA = 0 // contiguous range.
			VSILAN_QBASE[1].VSIBASE = 2.
			Queue indexes 2...65 in the PF space are absolute queue index 130...193.

2	PF Traffic	16 LQPs	VSILAN_QBASE[2].VSIQTABLE_ENA = 0 // contiguous range
			VSILAN_QBASE[2].VSIBASE = 66.
			Queue indexes 66...81 in the PF space are absolute queue index 194...209.

10	VMDq2	2 LQPs	VSILAN_QBASE[10].VSIQTABLE_ENA = 1 // scattered range.
			VSILAN_QTABLE[10,0].QINDEX_0 and QINDEX_1 = 100, 102 and QINDEX_0 and QINDEX_1 in VSILAN_QTABLE[10,1...7] = 0x7FF.
			Queues 100,102 in the PF space are absolute queues 228,230.

100	VF[20]	4 LQPs	VSILAN_QBASE[100].VSIQTABLE_ENA = 1 // scattered range.
			VSILAN_QTABLE[100,0].QINDEX_0 and QINDEX_1 = 90, 98.
			VSILAN_QTABLE[100,1].QINDEX_0 and QINDEX_1 = 110, 112.
			QINDEX_0 and QINDEX_1 in VSILAN_QTABLE[100,2...7] = 0x7FF.
			VPLAN_QTABLE[20; 0,1,2,3,4:15].QINDEX = 90, 98, 110, 112, 0x7FF.
			Queues 90,98,110,112 in the PF space are absolute queues 218,226,238,240.

38.30.2.2 LAN Initialization Flow

This section describes the LAN engine initialization flow executed by the PF software driver. It is assumed that a PF reset (PFR) was initiated by the software prior to this flow:

- LQPs are allocated to the PF by an NVM setting loaded to the PFLAN_QALLOC registers following a core reset (CORER).
- The statistic counters are cleared only at POR. As part of PF driver initialization, the software should read all the PF and its VF statistic counters. The values of these counters is the baseline for any statistics collected later.

- Operating system driver only step — Transition the device to non-PXE mode by initiating the Clear PXE Mode admin command. See the command description in Section 38.30.2.2.1 and Section 38.30.2.2.2 for more detail.
- Most of the LAN engine logic is cleared by the hardware by core reset signal (CORER). If it is not guaranteed that a CORER was initiated, software should clear the following control registers (listed in the LAN Transmit Receive Registers section) of the PF and its VFs:
  - LQPs mapping:
    - Clear the QTX_ENA, QRX_ENA, QTX_TAIL and QRX_TAIL registers of all the PF and its VFs LAN queue pairs.
    - Initialize LAN port parameters using the Set Port Parameters admin command (setting save bad packet, default VSI and more). In a single VSI per port, the VSI parameters are loaded from the NVM even though software could execute this step only if it requires another setting other than the NVM image.
- Allocate the LQPs to VFs and VSIs of the PF:
  - For each assigned VSI do the following as part of the create VSI procedure:
    - Allocate the LQPs to the VSI (see the programming example in Section 38.30.2.1.3).
    - Program the VSILAN_QBASE and VSILAN_QTABLE (use QBASE option for contiguous LQPs or the QTABLE option for scattered LQPs).
  - Program the VPLAN_QTABLE and VPLAN_QBASE of each assigned VF.
- Enable individual receive and transmit queues of the PF and its VFs following the flow described in Section 38.30.3.3.2 and Section 38.31.3.1.1, respectively.

38.30.2.2.1 Clear PXE Mode Admin Command

The Clear PXE Mode admin command transitions the device from PXE to non-PXE mode. The structure of the admin command and its completion are listed in Table 38-408. The complete software and device response is followed in Section 38.30.2.2.2.

Table 38-408.Clear PXE Mode Admin Command (Opcode: 0x0110)

Name	Bytes.Bits	Value	Remarks
Flags	0-1		See AQ section for details.
Opcode	2-3	0x0110	Command opcodes.
Datalen	4-5	0x00	N/A (reserved zero).
Return Value/ VFID	6-7	0x00	N/A (reserved zero).
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16	0x2	Reserved 0x2.
Reserved	17-31		Reserved.

Table 38-409.Clear PXE Mode Admin Command Completion (Opcode: 0x0110)

Name	Bytes.Bits	Value	Remarks
Flags	0-1		See AQ section for details.
Opcode	2-3	0x0110	Command opcode.
Datalen	4-5	0x00	N/A.
Return Value/ VFID	6-7		Some comments on specific errors: 0x0 = No Error. 0xD = EEXIST (no action, the device is already in non-PXE mode).
Cookie High	8-11	Cookie	Opaque value is copied by firmware into the completion of this command.
Cookie Low	12-15	Cookie	Opaque value is copied by firmware into the completion of this command.
Reserved	16-31		Reserved.

38.30.2.2.2 Transitioning Flow to Non-PXE Mode

Device Response to Clear the PXE Mode Admin Command

1. When the Clear PXE Mode admin command is initiated, the device checks the value of the PXE_MODE flag in the GLLAN_RCTL_0 register.
2. If the PXE_MODE flag is found cleared:
   a. Return a command completion with an EEXIST indication.
3. Else, the PXE_MODE flag is active:
   a. Disable Rx queue 0 and Rx queue 1 of all enabled PFs by clearing the QENA_REQ flag in the QRX_ENA[0] and QRX_ENA[1] registers of the PFs.
   b. Wait until all receive queues are disabled by polling the QENA_STAT flag in the QRX_ENA registers of all previous Rx queues. It is expected that all Rx queues are disabled within a few microseconds.
   c. Clear the PXE_MODE flag in the GLLAN_RCTL_0 register.
   d. Flow is completed by posting a command completion with No Error.

Software Steps Transitioning to Non-PXE Mode

1. The admin queue must be active before the following steps.
2. Software initiates the Clear PXE Mode admin command and waits for its completion.
3. Proceeds with the software initialization flow.

38.30.2.3 Cloud Computing Support

The cloud provides software, storage and compute infrastructure services over the Internet. Cloud platforms should provide isolation among tenants by creating private virtual networks over the physical network infrastructure and should be able to provision services on any physical machine within the data center. The 10 GbE controller provides filtering and pruning functionality that supports these goals.

Cloud providers build virtual network overlays over existing network infrastructure that provide tenant isolation and scaling. Tunneling layers added to the packets carry the virtual networking frames over existing Layer 2 and IP networks. Conceptually, this is similar to creating virtual private networks over the Internet. Processing these tunneling layers by the hardware is a critical element of this solution.

The tunneling packet formats supported by the 10 GbE controller are shown in Figure 38-95. Refer to the transmit and receive descriptor sections for requested offloads on transmission and reported status on reception.

The 10 GbE controller should be set for tunneling mode or non-tunneling mode by an NVM image. NVM images are used to set the VSI filters and receive classification filters. There are three planned NVM images:

1. Non-tunneling.
2. MAC in UDP tunneling.
3. IP in IP, IP in GRE and MAC in GRE tunneling.

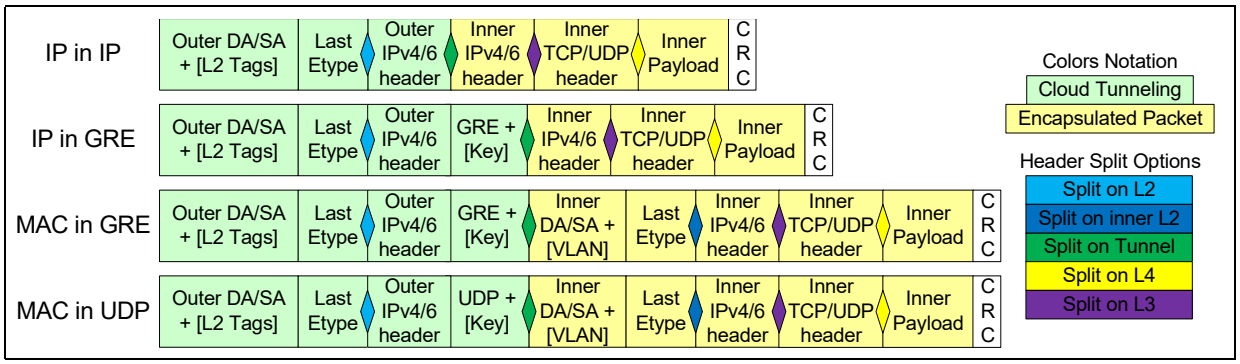
An overview of the packet processing is listed in Table 38-410.

Table 38-410.Tunneled Packet Processing

Packet Type	Accept / Reject Packet	Forward Packet To Specific VSI (Based On...)	Identify, Insert / Strip L2 Tags	L4/IPv4 XSUM	TSO	Tunneling Header Split (On Top Of Non-tunneling Options)	RSS (Hash) And FD Filters
IP in IP	Based on outer L2 MAC and optional L2 Tags (including VLAN, QinQ or S Tag with/without VLAN)	Outer IP	L2 tags in the outer L2 headers Only single VLAN in the inner L2 header	Both inner and outer IP headers, Inner L4 header	Yes	Outer IP header	Yes (same as non-tunneled packets)
IP in GRE		Outer IP with/ without GRE key				GRE header	
MAC in GRE		Inner L2 MAC/VLAN with/without one of the following: GRE key; Outer IP; Outer MAC				GRE header	
MAC in UDP		Inner L2 MAC/VLAN with/without VN Key words				Outer UDP header and its extension header	

The Figure 38-95 shows the supported tunneled packet formats:

Figure 38-95.Tunneled Packet Formats



38.30.2.4 Steering Tag and Processing Hint Support for LAN Engine Traffic (TPH)

Refer to the TLP processing hint support section for more detail. The Table 38-411 lists how a steering tag and processing hints are generated and how TPH operation is enabled for types of DMA traffic associated with the LAN queues.

Table 38-411.Steering Tag and Processing Hint Programming by the LAN Engine

Traffic Access	Steering Tag Value And TPH Enablement	PH Value
Read Receive Descriptor	CPUID and TPHRDesc in the Rx Queue Context	Desc_PH in GLTPH_CTRL register
Write Back Receive Descriptor	CPUID and TPHWDesc in the Rx Queue Context	Desc_PH in GLTPH_CTRL register
Write Receive Packet Payload	CPUID and TPHData in the Rx Queue Context	DATA_PH in GLTPH_CTRL register
Write Receive Packet Header	CPUID and TPHHead in the Rx Queue Context	DATA_PH in GLTPH_CTRL register
Read Transmit Descriptor	CPUID and TPHRDesc in the Tx Queue Context	Desc_PH in GLTPH_CTRL register
Write Back Transmit Descriptor	CPUID and TPHWDesc in the Tx Queue Context	Desc_PH in GLTPH_CTRL register
Transmit Head Write back	CPUID and TPHWDesc in the Tx Queue Context	Desc_PH in GLTPH_CTRL register
Read Transmit Packet	CPUID and TPHRPacket in the Tx Queue Context	DATA_PH in GLTPH_CTRL register

38.30.3 LAN Receive Data Path

The LAN receive data path includes the following major topics:

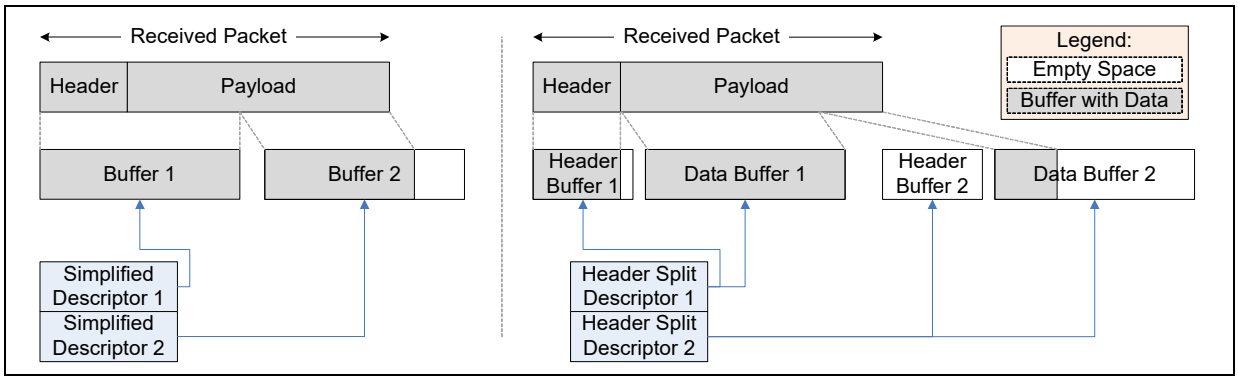
- Receive packets stored in system memory.
- Indicating the free memory structures to hardware and indicating the completed structure back to software.
- Receive descriptor queues, which are also called descriptor ring.
- Receive arbitration.
- Stateless receive offloads.

38.30.3.1 Receive Packet in System Memory

Receive packets are posted to system (host) memory buffers indicated to the hardware by descriptors. There are several types of descriptors that include pointers to the data buffers and status indications of the received packets. Figure 38-96 shows two examples of receive packets in host memory composed of two buffers (indicated by two matched descriptors). The 10 GbE controller fetches the receive descriptors (on demand) to an internal cache. A few rules relating to receive packet posting to host memory are:

- Receive packets might span from one to five buffers (descriptors).
- Receive packets shorter than 64 bytes are never posted to host memory (even in save bad frame mode enabled by the *SBP* flag in the PRT_SBPVSI register). These packets are counted by the GLPRT_MSPDC counter per LAN port.

Figure 38-96.Receive Packet in System Memory



38.30.3.1.1 Receive Descriptor Cache

Descriptor Fetch Policy

The 10 GbE controller fetches multiple receive descriptors at a time in order to minimize PCIe and memory bandwidth overhead (eight or four descriptors when using 16- or 32-byte descriptors, respectively. New descriptors are fetched to the cache, when there are fewer descriptors than incoming packets require or the last free descriptor is used for a received packet.

Note the following rules relating descriptor fetch policy:

- Following a CORE reset, hardware wakes up in PXE mode (the PXE_MODE flag in the GLLAN_RCTL_0 is set). PXE mode functionality and limitations are:
  - The receive queue should not be larger than 16 x 16 byte descriptors.
  - Software can bump the tail at descriptor granularity. Hardware fetches and writes back these descriptor at descriptor granularity as well.
  - Each packet might span only on a single buffer (in a single descriptor). A receive packet that is larger than a single buffer is reported as OVERSIZE in the receive descriptor.
- During normal operating mode, the PXE_MODE flag must be cleared by software. This step is expected to occur during the PF software initialization procedure. In case of multiple active PFs, only the first PF affects the device setting while the others do nothing.
- When the PXE_MODE flag is cleared, software should bump the tail at the entire 8 x descriptors granularity. In this mode, hardware fetches descriptors in the entire cache lines (4 x 32 byte descriptors or 8 x 16 byte descriptors).

38.30.3.2 LAN Receive Descriptors

38.30.3.2.1 Receive Descriptor - Read Format

16-Byte Receive Descriptors Read Format

Table 38-412 lists the 16-byte receive descriptor read format prepared by software.

Table 38-412.16-Byte Receive Descriptors Read Format

Quad Word	63 ... 0
0	Packet Buffer Address
1	Header Buffer Address

Packet buffer address (64) — The physical address of the packet buffer defined in byte units. The packet buffer size is defined by the DBUFF parameter in the receive queue context.

Header buffer address (64) — The physical address of the header buffer defined in byte units. The header address should be set by software to an even number (word-aligned address). The header buffer address is meaningful only for header split queues and split always queues as defined by the DTYPE field in the receive queue context. If a received packet spans across multiple buffers, only the first descriptor's header buffer is used. The header buffer size is defined by the HBUFF parameter in the receive queue context.

Note that the LS bit should be set to zero regardless of header split enablement since it is used for Descriptor Done (DD) indication to software (as described in the descriptor write back format).

32-Byte Receive Descriptors Read Format

Following is the 32-byte receive descriptor read format prepared by software.

Table 38-413.32-Byte Receive Descriptors Read Format

Quad Word	63 ... 0
0	Packet Buffer Address
1	Header Buffer Address
2	Reserved (0x0)
3	Reserved (0x0)

The fields in first 16 bytes — Identical to the 16-byte descriptors previously described.

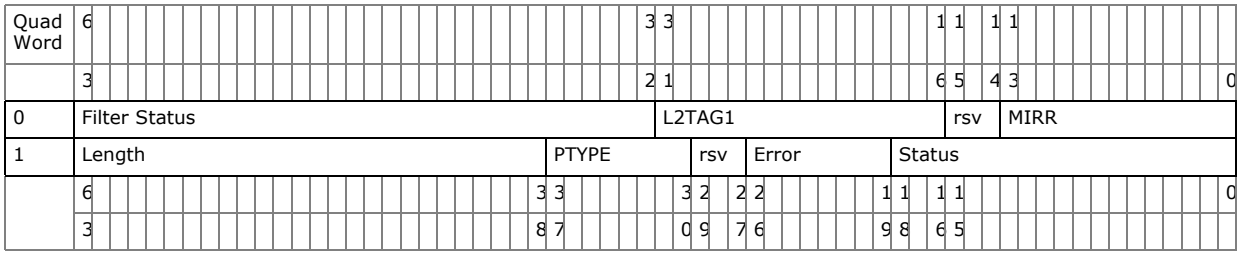
38.30.3.2.2 Receive Descriptor – Write-Back Format

The following sub-sections describe the fields of receive descriptor write back when using 16-byte and 32-byte descriptors. In both cases, a single packet might span on a single buffer or multiple buffers reported by their matched descriptors. If a packet is described by a single descriptor then all the fields are valid. Following are some rules that apply for a packet that is described by multiple descriptors:

- These fields are valid in all descriptors of a packet: Done (DD) flag, End Of Packet (EOP) flag and Packet Content Length (PKTL) field.
- These fields are valid only in the first descriptor of a packet: HDRL (packet content length in the header buffer); SPH (header is identified for header split functionality) and HBO (header buffer overflow).
- All other fields are valid only in the last descriptor of a packet.

16-Byte Receive Descriptors Write-Back Format

Following is the 16-byte receive descriptor write-back format.



RSV (7 bits) — Reserved.

Status field — Quad Word 1, 19 bits.

Table 38-414.Status Bits (Sheet 1 of 2)

Bits	Name	Functionality
0	DD	Descriptor done indication flag.
1	EOP	End of packet flag is set to 1b indicating that this descriptor is the last one of a packet.
2	L2TAG1P	L2 TAG 1 presence indication while the L2 tag is stripped from the packet and reported in the L2TAG1 field in the descriptor. The type of the tag is defined by the L2TSEL flag in the queue context. The L2TSEL flag selects between the first or second active flags in the SHOWTAG field in the VSI_TSR register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAGxxx registers. If the specified L2 tag is not present in the packet the L2TAG1P flag is cleared.
3	L3L4P	For IP packets, this flag indicates that L3 and L4 integrity check is processed by the hardware. For a tunneled packet, the L3L4P relates to the inner IP header. Processing is according to the packet type, which is reported in the PTYPE field. See Section 38.30.4.2 for a description of the supported integrity checks.
4	CRCP	CRCP indicates that the Ethernet CRC is posted with data to the host buffer. Note that strip CRC is enabled by the CRCStrip flag in the queue context. If the RXE error flag is set, the CRC bytes are not stripped regardless of the CRCStrip flag in the queue context. Loopback packets originated by another local VSI for which the HW computes the CRC are never posted with the CRC bytes regardless of the CRCStrip setting in the queue context.
7:5	TSYNINDX	Sampled 1588 timestamp index. bit 7 is the TSYNINDX valid indication. Only when it is set to 1b the lower 2 bits are meaningful. bit 5:6 is the index of the PRTTSYN_RXTIME Register that holds the packet reception timestamp. Note that 1588 packets over UDP can be sampled regardless of a possible checksum error.

Table 38-414.Status Bits (Sheet 2 of 2)

Bits	Name	Functionality
8	EXT_UDP_0	This flag is set for received tunneled packets with outer UDP header on which the outer UDP checksum word equals to zero. Note that UDP checksum zero is an indication that there is no checksum. This option is valid only for IPv4 packets and considered an exception error for IPv6 packets (reported to the stack by the software device driver).
10:9	UMBCAST	Destination address can be one of the following: 00b = Unicast 01b = Multicast 10b = Broadcast 11b = Mirrored packet Non-parsed packets are indicated by PTYPE equals to PAYLOAD (non identified MAC header).
11	FLM	Flow director filter match indication. This flag is set if the received packet matches any of the Flow Director (FD) filters that direct the packet to a specific receive queue. Refer to the RSSSTAT field description for more detail.
13:12	FLTSTAT	The FLTSTAT indicates the reported content in the *Filter Status* field. FLTSTAT has the following encoding (see conditions in the *Filter Status* field): 00b = No Data in the filter status field (The packet does not meet any of the cases below). 01b = FD filter ID (this option is valid only for 16B descriptor while in 32B it is reported elsewhere). 10b = Reserved. 11b = Hash filter signature (RSS).
14	LPBK	Loopback indication that means that the packet is originated from this system rather than the network.
15	IPV6EXADD	Set when an IPv6 packet contains a destination options header or a routing header (See additional details in Section 38.30.4.2.) If the packet contains two IPv6 headers (tunneling), the IPV6EXADD is a logic OR function of the two IP headers.
17:16	Reserved	Reserved.
18	INT_UDP_0	This flag is set for received UDP packets on which the UDP checksum word equals to zero. Note that UDP checksum zero is an indication that there is no checksum. This option is valid only for IPv4 packets and considered an exception error for IPv6 packets (reported to the stack by the software device driver). Note that for tunneled packets with a UDP header, this flag relates to the checksum field in the inner UDP header.

Error field — Qword 1, 8 bits.

Table 38-415.Error Bits

Bits	Name	Functionality
0	RXE	The RXE error bit is an indication for any of the following MAC errors: CRC, alignment, oversize, undersize, or length error. Packets with RXE are posted to host memory to Rx queue 0 of the VSI defined by the PRT_SBPVSI register, if enabled by the SBP flag in the same register. If the RXE flag is set, then any other status fields reporting the content of the packet are meaningless.
1	RSV	Reserved.
2	HBO	Header Buffer Overflow. This flag is set when using header split buffers or split always buffers and the identified packet header is larger than the header buffer. See Table 38-429 for details.
5:3	L3L4E	For IP packets processed by hardware, the L3L4E flag has the following encoding: Bit 3 = IPE: IP checksum error indication (for tunneled packets it is the most inner IP header indication). Bit 4 = L4E: L4 integrity error indication (most inner L4 header in case of UDP tunneling). Bit 5 = EIPE: External (most outer) IP header or UDP checksum error. ***Note:*** For the purpose of these bits, a tunneled packet is a VXLAN?NVGRE/Geneve packet.
6	OVERSIZE	Oversize packet error indicates that the packet is larger than five descriptors in normal operation or larger than one descriptor in PXE mode. In this case, the portions of the packet that exceeds the permitted number of descriptor(s) is not posted to host memory.
7	RSV	Reserved.

MIRR (Qword 0, 14 bits) — Multiplexed field between mirroring parameters as listed in Table 38-416. If the packet is not mirrored then this field equals zero.

Table 38-416.Mirroring Functionality

Bits	Name	Mirroring Functionality (UMBCAST field equals to 11b)
7:0	RSV	Reserved (equals 0x7 for mirrored packets).
13:8	MIRR	Matched mirror rule ID that directed the packet to this queue.

L2TAG1 (Qword 0, 16 bits) — Stripped L2 tag from the receive packet. This field is valid if the L2TAG1P flag in this descriptor is set (see additional description of the L2TAG1P flag).

Filter status (Qword 0, 32 bits) — Multiplexed field between RSS (hash filter) and FD filter ID as indicated by the FLTSTAT field. Note that the FD filter ID is reported in this field only in 16-byte descriptors. In 32-byte descriptors, the data is reported in a different field.

- If the packet matches a FD filter that enables its FD filter ID reporting while using a 16-byte descriptor, then FLTSTAT equals 01b and this field contains the programmed FD filter ID.
- Else, if the packet matches the hash filter, then FLTSTAT equals 11b and this field contains the hash signature (RSS).
- Else, FLTSTAT equals 00b and this field is set to zero.

Length — Qword 1, 26 bits.

Table 38-417.Length Bits

Bits	Name	Functionality
13:0	PKTL	Packet content length in the packet buffer defined in byte units.
24:14	HDRL	Packet content length in the header buffer defined in byte units.
25	SPH	The split header flag is an indication that the device identified the packet header. See Section 38.30.4.1 for a complete description of packet types identified for header split and conditions for usage of the header and data buffers.

PTYPE (Qword 1, 8 bits) — *Packet Type* field encode supported packet types as listed in Table 38-418. Note that in Table 38-418, any UDP tunneling (Teredo, VXLAN) and GRE tunneling are reported as GRENAT.

Table 38-418.Packet Types (Sheet 1 of 4)

Parser Aborted Code		Else	
255	Parser Aborted	Else	Reserved

32-Byte Receive Descriptors Write-Back Format

The 32-byte descriptor is composed of four Qwords. The first two Qwords are identical to the 16-byte descriptor write back other than the FD filter ID that is moved from the *Filter Status* field to the FD Filter ID / *Flexible Bytes High* field.

Quad Word	63:44	43:38	37:32	31:30	29:20	19:0
0	Filter Status		L2TAG1	rsv	MIRR	
1	Length	PTYPE	rsv	Error	Status	
2	L2TAG2 (2nd)	L2TAG2 (1st)	rsv	rsv	Ext_Status	
3	FD Filter ID / Flexible Bytes High		Flexible Bytes Low			

Ext_Status — Qword 2, 12 bits.

Table 38-419.Ext_Status Bits (Sheet 1 of 2)

Bits	Name	Functionality
0	L2TAG2P	L2 TAG 2 presence indication while the L2 Tag is stripped from the packet to the L2TAG2 (1st) field in the descriptor. The type of tag is defined by the L2TSEL bit in the queue context. This flag selects between the first or second active flags in the *SHOWTAG* field in the VSI_TSR register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAGxxx registers. If the stripped tag is larger than one word, then the first word is posted to the L2TAG2 (1st) field and the second word is posted to the L2TAG2 (2nd) field. If the specified L2 tag is not present in the packet the L2TAG2P flag is cleared.
1	RSV	Reserved.
3:2	FLEXBL_STAT	The FLEXBL_STAT indicates the content of the *Flexible Bytes Low* field as follows: 00b = The field is set to zero. 01b = Flexible first four bytes defined by the FD filter are posted in the *Flexible Bytes Low* field. 10b = Reserved. 11b = Reserved.
5:4	FLEXBH_STAT	The FLEXBH_STAT indicates the content of the *FD Filter ID / Flexible Bytes High* field as follows: 00b - The field is set to zero. 01b - FD filter ID is reported in the *FD Filter ID / Flexible Bytes High* field. 10b - Flexible second 4 bytes defined by the FD filter are posted in the *FD Filter ID / Flexible Bytes High* field. 11b - Reserved.

Table 38-419.Ext_Status Bits (Sheet 2 of 2)

Bits	Name	Functionality
8:6	RSV	Reserved.
9	FDLONGB	The FDLONGB flag is set if the matched FD filter's index within its bucket is above the threshold. If the packet is searched in the FD filter and it is not found, the FDLONGB represents the bucket length relative to the same threshold. The threshold is defined by the MAXFDBLEN parameter in the GLQF_CTL register.
10	Reserved	Reserved.
11	RSV	Reserved.

L2 tags — Qword 2, 32 bits.

Table 38-420.L2 Tag Bits

Bits	Name	Functionality
15:0	L2TAG2 (1st)	Extracted L2 Tag 2 from the packet (see L2TAG2P flag).
31:16	L2TAG2 (2nd)	Extracted second word of the L2 tag 2 from the packet (see L2TAG2P flag).

Flexible bytes low (Qword 3, 32 bits) — Flexible bytes as controlled by the FLEXBL_STAT parameter in this descriptor as listed in Table . If the packet matches a FD filter that enables reporting flexible bytes from the packet, then FLEXBL_STAT equals 01b. Otherwise, FLEXBL_STAT equals 00b and this field is set to zero.

Table 38-421.Flexible Bytes Low Bits

Bits	Name	FD Filter Flexible Bytes (FLEXBL_STAT = 01b)
31:0	FLEXBL	This field contains four bytes from the flexible payload in the field vector (extracted from the packet). The word offset (in the field vector) of these bytes are defined by the programmed FLEXOFF parameter of the FD filter. The reported bytes in this field are defined in little endian notation while bits 0:7 are the LS byte, which is the last byte on the wire.

FD filter ID / flexible bytes high (Qword 3, 32 bits) — Multiplexed field between the *FD Filter ID* / *Flexible Bytes High* fields as follows:

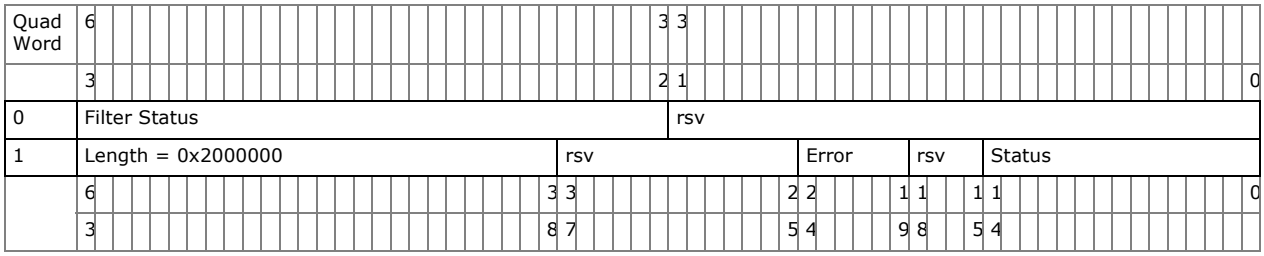
- If the packet matches a FD filter that enables reporting the FD filter ID, then FLEXBH_STAT equals 01b and this field contains the programmed FD filter ID.
- Else, if the packet matches a FD filter that enables reporting eight flexible bytes from the packet, then FLEXBL_STAT equals 10b and this field contains the four bytes from the flexible payload in the field vector (extracted from the packet). The reported bytes in this field are defined in little endian notation while bits 24:31 are the MS byte of the entire 8-byte field, which is the first byte on the wire.
- Else, FLEXBH_STAT equals 00b and this field is set to zero.

Programming Status Descriptor Write-Back Format

The programming status descriptor provides an indication of FD filter programming as listed in Table . Programming status vs. packet's descriptor is identified by the *Length* field set to 0x2000000. The programming status is provided by a 16-byte structure. When using 32-byte descriptors, only the first 16 bytes are meaningful while the last 16 bytes are reserved zeros.

Table 38-422.FD Filter Programming Indications

Context Type	Action	Fail/OK	Programming Indication	Reported Receive Queue
FD Filter	Add Filter	OK	No Reporting	N/A
FD Filter	Add Filter	Fail	Programming Status Descriptor	Queue zero of the PF.
FD Filter	Remove Filter	OK	No Reporting	N/A
FD Filter	remove Filter	Fail	Programming Status Descriptor	Queue zero of the PF.
DDP Context	Add Context	OK	No Reporting	N/A
DDP Context	Add Context	Fail	Programming Status Descriptor	Queue zero of the VSI.
DDP Context	Invalidate Context	OK	Programming Status Descriptor	Queue zero of the VSI.
DDP Context	Invalidate Context	Fail	Programming Status Descriptor	Queue zero of the VSI.



Status field (Qword 1, 15 bits) — status field.

Table 38-423.Status Field Bits

Bits	Name	Functionality
0	DD	Descriptor done indication flag.
1	RSV	Reserved.
4:2	PROG_ID	The PROG_ID indicates the status reported by this descriptor as follows: 001b = FD filter status. 010b = Reserved. 100b = Reserved.
14:5	RSV	Reserved.

Error Field — Qword 1, 6 bits.

Bits	Name	Functionality
0	Failed FD Programming	FD filter programming failed. It could be due to no space in the FD table or since the function exhausted its quota.
1	Failed FD Removal	FD filter removal failed. It could be a result of an attempt to remove non-existent entry.
3:2	Reserved	Reserved.
5:4	RSV	Reserved

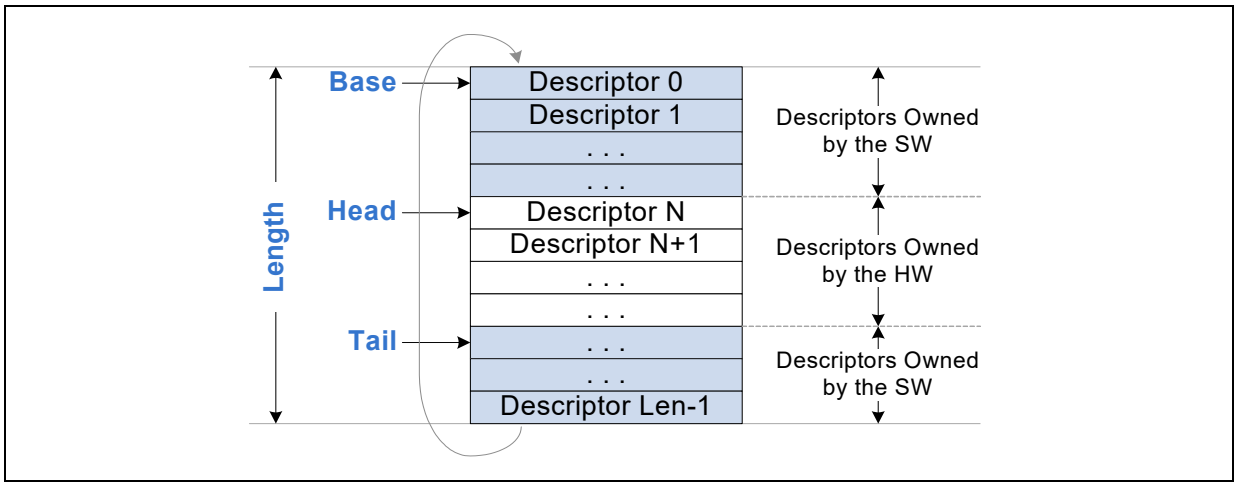
Filter status (Qword 0, 32 bits) — Equals the *FD Filter ID* field for FD filter programming status.

38.30.3.3 LAN Receive Queue (Ring)

Received packets are posted to host memory through a set of queues. Each queue is a cyclic ring made of a sequence of receive descriptors in contiguous memory. These queues are also called descriptor rings. The 10 GbE controller supports up to 1536 receive queues allocated to PFs and VFs (see Section 38.30.2). Receive queues are defined by a set of parameters called the queue context. The main parameters are the queue pointers shown in Figure 38-97. The queue context includes additional parameters that define the queue functionality as detailed in Section 38.30.3.4. Part of these context parameters are kept in hardware (like the Tail register, queue enable / disable flags and interrupt related context). Most of the queue context parameters are stored in FPM, fetched to an internal cache when required.

The software interface to the queue for its initialization, during normal operation as well as queue disable flow, is described in Section 38.30.3.3.1. The 10 GbE controller includes additional global setting option parameters for the entire device or per function that affect multiple queues described in Section 38.30.3.3.1.

Figure 38-97.Receive Descriptor Ring Structure



38.30.3.3.1 Receive Queue Programming

Queue enable and disable flows are described in the following subsection and listed in the Table 38-424.

Table 38-424.Receive Queue Enable / Disable Flags

QRX_ENA[n] Register		Receive Queue State
QENA_REQ	QENA_STAT	
0	0	Queue is not enabled.
1	0	Queue enable request by software.
1	1	Queue is enabled.
0	1	Queue disable request by software.

38.30.3.3.2 Receive Queue Enable Flow

Queue enable flow is executed by the PF software for PF queues as well as for the queues of its VFs. The flow below assumes that the queue is already allocated as detailed in Section 38.30.2.1.2.

- Software steps
- The function that owns the queue (PF or VF) allocates contiguous memory in its own memory space for the receive ring. It then program the receive descriptors in the ring so they are ready for new packet reception.
- If the queue might have been disabled recently, then the software should wait at least 50msec from the completion of the queue disable flow before proceeding to the next step.
- Prepare the queue context in the FPM in the PF memory space. See a examples for queue context setting in Section 38.30.3.4.3. At pre-boot time, memory allocation might be tight and the FPM could exceed the budget. There is a mechanism to program the queue context directly to the device bypassing the FPM as described in the section that follows.
- Clear the tail pointer in the QRX_TAIL[n] register and then set the tail pointer to the end of the descriptor ring (‘n’ is the queue index within the PF space).
- Set the QENA_REQ flag in the QRX_ENA[n] register (‘n’ is the queue index within the PF space).
- As a response, hardware sets the QENA_STAT flag in the QRX_ENA[n] register. The QENA_STAT follows the QENA_REQ almost instantly and not more than 10 µs after that. Once the QENA_STAT flag in the QRX_ENA[n] register is set, software can start using the queue.
- If the queue is targeted for a VF, PF software should also program the matched entry in the VFQ_TABLE. Then it is expected to inform the VF software that the queue is enabled. Note that the VFQ_TABLE is shared for the receive and transmit queues. So the PF software should enable the transmit queue before communicating to the VF.

Direct Queue Context Programming

This section describes direct queue context programming, bypassing the FPM for pre-boot flow.

Context programming flow:

- Write the four PFCM_LANCTXDATA registers with a total of 16 bytes of context data.
- Write the PFCM_LANCTXCTL register identifying the queue and the specific sub-line to be programmed.
- Poll the CTX_DONE flag in the PFCM_LANCTXSTAT register until done is indicated.
- Loop back to the first step until all sub-lines of the queue context are programmed.

Context invalidation flow. Note that this flow is not needed during normal operation.

- Write the following fields in the PFCM_LANCTXCTL register: QUEUE_NUM and QUEUE_TYPE, identify the queue and the OP_CODE fields should be set to Invalidate.
- Poll the CTX_DONE flag in the PFCM_LANCTXSTAT register until done is indicated.

38.30.3.3.3 Receive Queue Disable Flow

Queue disable flow is executed by PF software for PF queues as well as for the queues of its VFs.

- Remove the queue from the interrupt linked list.
- The PF software clears the QENA_REQ flag in the QRX_ENA[n] register, while 'n' is the queue index within the PF space.
- Hardware generates a queue disable marker to the receive pipe.
- Eventually, the queue disable marker gets to the top of the pipe. At this point, it is guaranteed that the pipe does not contain any additional receive packets for the specific queue.
- Hardware waits for completion of all outstanding requests from the specific queue on the PCIe bus.
- The queue context is invalidated from the internal cache without updating the FPM and the QENA_STAT flag in the QRX_ENA[n] register is cleared.
- Once the QENA_STAT flag in the QRX_ENA[n] register is cleared, software can release all memory structures of the queue.

38.30.3.3.4 Fast Receive Queue Disable Flow

Fast queue disable flow should be executed by software only as part of a VF reset flow (or VM reset flow). Following a PFR, the device does all this automatically.

- It is assumed that a VFR was initiated by the PF software and the matched VFRD flag in the VPGEN_VFRSTAT register is already active. Or a VMR was initiated by PF software and the matched VMRD flag in the VSIGEN_RSTAT register is already active.
- The PF software sets the FAST_QDIS flag (and clear the QENA_REQ flag) in the QRX_ENA[n] register where 'n' is the queue indexes in the PF space for all VF or VM queues.
- The queue contexts are invalidated instantly from the internal cache and the QENA_STAT flag in the matched QRX_ENA[n] register is cleared.

38.30.3.3.5 Software Fast Path Programming

During normal operation, the function that owns the queue (PF or VF) accesses the hardware directly.

- Prepare receive descriptors by clearing the *DD* bit and setting the buffer pointer(s). Start at the descriptor indicated by the tail pointer in the relevant QRX_TAIL register.
- Software should never set the tail to a value above the descriptors owned by the hardware minus one. The descriptors considered as owned by the hardware are those ones already indicated to hardware but not yet reported as completed.
- Bump the tail to the last prepared descriptor plus one (the descriptor index incremented the next time).
- The number of free descriptors owned by hardware is defined by the tail minus the head. If the number of free descriptors becomes lower than LRXQTRESH, then an immediate interrupt is triggered. The head and LRXQTRESH are listed in the Table 38-425.

38.30.3.4 Receive Queue Context Parameters

This section describes setting options of LAN receive queue parameters called the queue context. Some queue context parameters reside in dedicated hardware registers and some are stored in host memory (FPM). Active queues are kept in the cache.

38.30.3.4.1 Receive Queue Context in Hardware Registers

The queue context parameters that software accesses during fast past programming as well as its enablement reside in hardware registers:

- Queue enablement flags in the QRX_ENA[n] registers while 'n' is the queue index of the PF. Queue enable and disable flow by the PF are explained in Section 38.30.3.3.1.
- The tail pointer in the QRX_TAIL[n] registers for the PF and VFQRX_TAIL[n] registers for the VFs while 'n' is the queue index of the function (PF or VF). The usage of the Tail register is detailed in Section 38.30.3.3.4.

38.30.3.4.2 Receive Queue Context in FPM

The receive queue context parameters that are stored in host memory (FPM) are fetched for the active queues to the internal cache. These parameters are listed in Table 38-425. The queue context is a contiguous vector of 256 bits (32 bytes).

Table 38-425.LAN Rx Queue Context in the Private Host Memory (174 Bits = 25 Bytes) (Sheet 1 of 2)

Alias	Width [bits]	LS Bit	MS Bit	Type	Software Init	Description
HEAD	13	0	12	Dynamic	0x0	Receive Queue Head. An index relative to the beginning of the queue that defines the next descriptor to be used. During idle time, all descriptors starting by the head up to (excluding) the RTAIL are owned by hardware and the rest are owned by software. During dynamic operation it is not guaranteed that all descriptors below the head complete.
CPUID	8	13	20	Dynamic	0x0	CPU Socket ID for TPH. The CPU socket ID is updated by hardware.
RSV	11	21	31	N/A	0x0	Reserved.
BASE	57	32	88	Static	BASE	Receive Queue Base Address. Indicates the starting address of the descriptor queue defined in 12-byte units.
QLEN	13	89	101	Static	QLEN	Receive Queue Length. Defines the size of the descriptor queue in descriptors units from 8 descriptors (QLEN=0x8) up to 8 KB descriptors minus 32 (QLEN=0x1FE0). QLEN restrictions: When the PXE_MODE flag in the GLLAN_RCTL_0 register is cleared, the QLEN must be a whole number of 32 descriptors. When the PXE_MODE flag is set, the QLEN can be one of the following options: • Up to 4 PFs, QLEN can be set to: 8, 16, 24 or 32 descriptors.
DBUFF	7	102	108	Static	DBUFF	Receive Packet Data Buffer Size. The packet data buffer size is defined in 128-byte units. It must be at least 1 KB bytes and up to 16 KB minus 128 bytes.
HBUFF	5	109	113	Static	HBUFF	Receive Packet Header Buffer Size. The header buffer size is defined in 64-byte units enabling a buffer size up to 2 KB minus 64 bytes.
DType	2	114	115	Static	DType	Descriptor type as listed in Table 38-426.

Table 38-425.LAN Rx Queue Context in the Private Host Memory (174 Bits = 25 Bytes) (Sheet 2 of 2)

Alias	Width [bits]	LS Bit	MS Bit	Type	Software Init	Description
DSize	1	116	116	Static	DSize	Descriptor Size Flag. 0b for 16-byte descriptors and 1b for 32-byte descriptors.
CRCStrip	1	117	117	Static	CRCStrip	CRC Strip. Strip the Ethernet CRC bytes before the packet is posted to host memory. Note that no CRC strip option can only work properly if the entire packet is posted to the data buffer(s) in host memory with no other strip option.
Reserved	1	118	118	Static	Reserved	Reserved.
L2TSEL	1	119	119	Static	0x0	L2TSEL defines the reported L2 tags in the receive descriptor. When the L2TSEL flag is cleared, the second L2 tag defined by the *SHOWTAG* field in the VSI_TSR register of the VSI is posted to the L2TAG1 field. The first tag is reported in the L2TAG2 field. When the L2TSEL flag is set to 1b, the previous L2 tags are switched between the *L2TAG1* and *L2TAG2* fields.
HSPLIT_0	4	120	123	Static	HSPLIT_0	Header split 0 control as listed in Table 38-427.
HSPLIT_1	2	124	125	Static	HSPLIT_1	Header Split 1 control as listed in Table 38-428.
RSV	1	126	126	N/A	0x0	Reserved.
SHOWIV	1	127	127	Static	SHOWIV	The VLAN in the inner L2 header is stripped to the receive descriptor if enabled by this flag.
RSV	46	132	173	Static	0x0	Reserved
RXMAX	14	174	187	Static	RXMAX	Max packet size for this queue defined in byte units. The "rxmax" parameter defines the whole packet size starting at the L2 header up to including the Ethernet CRC. The RXMAX must not be set to a larger value than 5 x DBUFF (since receive packet must never span on more than 5 buffers). Received packet larger than RXMAX is dropped and counted by the GLV_REPC counter of the VSI. Note that packets larger than MFS defined per MAC are dropped by the MAC even before it gets to the receive queue.
TPHRDesc	1	193	193	Static	TPHRDesc	Read Descriptor TPH Ena (descriptor fetch).
TPHWDesc	1	194	194	Static	TPHWDesc	Write Descriptor TPH Ena (descriptor writeback).
TPHData	1	195	195	Static	TPHData	Packet Data TPH Ena.
TPHHead	1	196	196	Static	TPHHead	Packet Header TPH Ena.
RSV	1	197	197	Static	0x0	Reserved
LRXQTRESH	3	198	200	Static	LRXQTRESH	Low receive queue threshold defined in 64 descriptor units. When the number of free descriptors (defined by tail minus head) goes below the LRXQTRESH, an immediate interrupt is triggered.
RSV	1	201	201	Static	RSV	Reserved
RSV	54	202	255	Static	000b	Reserved.

38.30.3.4.3 Receive Queue Context Setting Example

Dword Context Offset	7	6	5	4	3	2	1	0
Context Bit Index	255 ... 224	223 ... 192	191 ... 160	159 ... 128	127 ... 96	95 ... 64	63 ... 32	31 ... 0
Init Hex Value	00000000	0000021E	01800000	00000000	00200301	00000000	001579A0	00000000

38.30.3.4.4 Receive Buffer Size Setting Example

BASE = 0x001579A0	HBUFF = 0	HSPLIT = 0 (no split|)	LRXQTRESH = 2 (no threshold)
QLEN = 0x80 (128 descriptors)	DType = 00b (no split	RXMAX = 0x600 (1536 bytes)	CRCStrip = 1
DBUFF = 12 (1536 bytes)	DSize = 0 (16 bytes)	TPH = 0xF (enable all flags)	FCENA = 0

Operating System	Queue Type	HSPLIT	DBUFF	HBUFF	Notes
Linux*	Standard	0x0	1536	-	
	Standard	enabled	2048	256	
	Jumbo	0x0	Multiple of 1 KB	-	
	Jumbo	enabled	2048	256	
Windows*	Any	0x0	Multiple of 1 KB	-	Up to 10 KB.
	VMQ	enabled	2048	64	L2 header split.
FreeBSD*	Any	0x0	2 KB, 4 KB, 8 KB, or 10K	-	
	Any	enabled	2 KB, 4 KB, 8 KB, or 10 KB	256	
ESX NPA	Any	enabled	4096	1984	max header buffer.
Solaris*	Any	0x0	256, 1 KB, 2 KB	-	
XEN*					Same as Linux.
KVM					Same as Linux.

38.30.4 Stateless Receive Offloads

38.30.4.1 Header Split

This feature consists of splitting a received packet into two separate regions based on the packet content. Splitting is usually between the packet header that can be posted to a dedicated buffer and the packet payload that can be posted to a different buffer (or multiple buffers). The size of these buffers are defined by the DBUFF and HBUFF parameters in the receive queue context. This kind of splitting is useful when different buffer allocation rules might apply to these buffers or different rules for TPH enablement. Header split is enabled per receive queue by the *DTYPE*, *HSPLIT_0* and *HSPLIT_1* fields in the receive queue context as listed in Table 38-426, Table 38-427 and Table 38-428 and shown in Figure 38-98. A split between the header buffer and the payload buffers and the status reporting is listed in Table 38-429. The physical pointers to the header and payload buffers are defined in the receive descriptor.

Some rules regarding header split:

- A packet that has a MAC error (reported by the RXE flag) is posted as a whole to the packet buffers with no split. Note that posting such packets to the host is enabled on in save bad frame mode (enabled by the SBP flag in the PRT_SBPVSI register).
- For tunneled packets, the rules defined by the HSPLIT_1 parameter take precedence on those ones defined by the HSPLIT_0 parameter. This means that if any flag in HSPLIT_1 is enabled and the packet matches that setting, then the packet is split according to HSPLIT_1 regardless of HSPLIT_0 setting.

- In each individual register: HSPLIT_1 or HSPLIT_0, the packets are split according to the lowest matched entry in the tables that follow. If both HSPLIT_0 and HSPLIT_1 are set to zero, then DTYPE in the receive queue context must be set to 00b. Otherwise (any header split is enabled by these registers), DTYPE must be set to one of the header split options: 01b or 10b (explained in the sub-sections that follow).
- If the packet is posted to multiple descriptors, only the header buffer of the first one is used.
- The packet header cannot span across buffers. If the header buffer is smaller than the received header, the header is posted together with the packet payload. See Table 38-429.
- The header of a fragmented IP packet is defined up to including the IP header regardless if the fragment includes the L4 header. For IPv6 header, the IP header is defined up to including the fragmented extension header.
- When a packet is replicated to multiple receive queues, the packet can be split differently on each according to the queues settings.
- Header split is supported for packets received from the network as well as local VM to VM traffic.

Figure 38-98.Header Split Option by Packet Formats

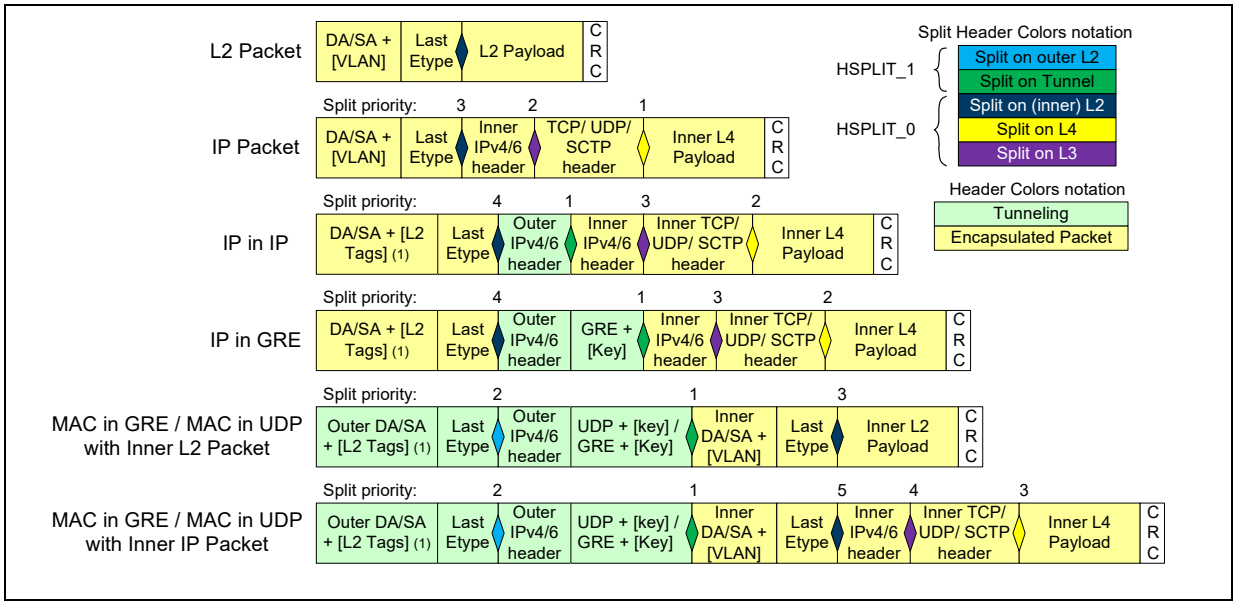


Table 38-426.Header Split Modes Defined by the DTYPE Field (Sheet 1 of 2)

DTYPE	Functionality
00b = Single buffer descriptors.	No header split mode.
01b = Header split descriptors.	Header split is enabled for packets that the hardware identifies their headers as enabled by the HSPLIT field. The packet content up to including the most inner header enabled by the HSPLIT is posted to the header buffer. The rest of the packet is posted to the payload buffer. See Table 38-429 for rules of the header and payload buffers usage.
10b = Split always	Header split always is enabled regardless of the HSPLIT setting. If the packet header is identified as defined by the HSPLIT, the packet content up to including the most inner header enabled by the HSPLIT is posted to the header buffer. See Table 38-429 for rules of the header and payload buffers usage.

Table 38-426.Header Split Modes Defined by the DTYPE Field (Sheet 2 of 2)

DTYPE	Functionality
11b	Reserved.

Table 38-427.Split Headers Enabled by the HSPLIT_0 Field

HSPLIT_0	Functionality
0000b	No header is enabled by HSPLIT_0.
xxx1b	Enable split after L2 header. In case of L2 tunneling it is the second (inner) L2 header.
xx1xb	Enable split after the IP header. In case of tunneling it is the second IP header. In case of option/extension IP headers the split is after these headers.
x1xxb	Enable split after the UDP and TCP header (in case of UDP tunneling it is the second UDP header).
1xxxb	Enable split after the SCTP header.

Table 38-428.Split Headers Enabled by the HSPLIT_1 Field

HSPLIT_1	Functionality
00b	No split on tunneling headers.
x1b	Enable split after the outer (tunneling) L2 header.
1xb	Enable split on the tunneling header as follows: Non-tunneled packet, no impact. IP in IP, enable split after the outer IP header. IP in GRE or MAC in GRE, enable split after the GRE header. MAC in UDP, enable split after the tunneling UDP header (including its private UDP header).

Table 38-429.Header Split vs. Packet and Buffer Sizes

DTYPE	Condition	Header and Payload DMA	SPH	HBO	PKTL[1]	HDRL[a,2]
00b = Single buffer.	None	Post the entire packet to the packet buffer(s).	0	0	Size of the entire packet.	0x0
01b = Header split.	Header is not identified	Post the entire packet to the packet buffer(s).	0	0	Size of the entire packet.	0x0
	Header size ≤ HBUFF[b]	Post the header to header buffer and payload to the packet buffer(s).	1	0	Size of the packet payload.	Header size.
	Header size > HBUFF[b]	Post the entire packet to the packet buffer(s).	1	1	Size of the entire packet.	Header size.
10b = Split always.	Packet length ≤ HBUFF	Post the entire packet to the header buffer(s).	0	0	0x0	Packet length.
	Header is not identified and packet length > HBUFF	Post the entire packet to the header buffer plus packet buffer(s).	0	0	Size of the entire packet minus HBUFF.	HBUFF
	Header size ≤ HBUFF	Post the header to the header buffer and the payload to the packet buffer(s).	1	0	Size of the packet payload.	Header size.
	Header size > HBUFF	Post the entire packet to the header plus packet buffer(s).	1	1	Size of the entire packet minus HBUFF.	Header size.

Notes:

1. If the data posted to the packet buffer is larger than PKTL, multiple buffers (descriptors) are used.
   a. All buffers but the last one are full (PKTL = DBUFF) while the last one contains the rest of the data.
   b. Only the header buffer of the first descriptor is used.

2. For split conditions, the packet and header lengths are taken from the received packets including all L2 tags (VLAN for example) as well as the CRC bytes. Regardless if these tags are posted to the buffers or posted to the receive descriptors or extracted from the packet. Orthogonal to this condition, the reported HDRL parameter represents the actual data posted to the buffer.

38.30.4.2 Receive L3 and L4 Integrity Check Offload

The 10 GbE controller offloads the following L3 and L4 integrity checks: IPv4 header(s) checksum, outer UDP checksum, inner TCP or UDP checksum and SCTP CRC integrity (see Table 38-430). The 10 GbE controller identifies the packet type and then checks the matched integrity scheme. The identified packet type is reported on the *PTYPE* field in the receive descriptor. Processing indication of the L3 and L4 headers is reported on the L3L4P flag in the receive descriptor. Potential IPv4 checksum error, L4 integrity error and outer IPv4/UDP checksum error are reported by the IPE, L4E and the EIPE error flags in the receive descriptor, respectively.

Note: Outer UDP checksum is supported for all supported encapsulation over UDP (VXLAN, Geneve, and Teredo).

Some rules for integrity check offload are listed as follows. If the following rules are not met, integrity offload is not provided and L3L4P is not set.

- IPv4 header is assumed to be at least 20 bytes long (the length of the basic header).
- IPv4 headers might have any IP option headers that fit within the maximum header size (60 bytes).
- IPv6 support — The pseudo header for the L4 checksum takes into account the addresses in the IPv6 header ignoring the optional extension headers. Packets with routing header type 2 and destination options header with home address option contain an alternative IP address in the extension header. Therefore, checksum calculation for such packets most probably results in an erroneous value. The 10 GbE controller indicates the existence of a destination options header or a routing header in the *IPV6EXADD* bit of the Rx descriptor. Software can then do one of the following:
  - — Ignore the checksum done by the device.
  - — Parse the extension header and identify if it contains an IP address. Then ignore the checksum done by the device only in this case.
  - — Tunneled packets without internal IP header — The *L3L4P* bit is cleared for these packets indicating no checksum offload.
  - — Fragmented packets — The 10 GbE controller parses fragmented receive packets up to including the IP header (for IPv4) or up to including the fragmentation extension header (for IPv6).
  - — L4 checksum offload is not supported for IPv6 fragmented packets and the L3L4P flag in the receive descriptor is not set.
  - — Fragmented IPv4 packet is offloaded up to including the IP header.
  - — TCP header is assumed to be at least 20 bytes long (the length of the basic header).
  - — The TCP header might have any option headers that fit within the maximum header size (60 bytes).
  - — VM-to-VM loopback traffic is processed by the hardware for L3/L4 integrity check as any other packet received from the network.

Table 38-430 lists all supported packet formats and the processed integrity. The table uses the following notations:

- IP is a generic term for IPv4 header or IPv6 header. The IPv4 header can have IP option headers and the IPv6 header can have IPv6 extension headers.

- L4 is a generic term for UDP, TCP or SCTP headers.
- IP checksum is meaningful only for IPv4.
- Checksum is a generic term for UDP and TCP checksum as well as SCTP CRC integrity.
- Zero UDP checksum — Zero UDP checksum for IPv4 packet is treated as no checksum and is reported by hardware as no error. Zero UDP checksum for IPv6 packet is illegal and is reported by hardware as L4 checksum error.

Table 38-430.Integrity Offload Check for Receive Packet Types

Packet Type	Supported Integrity Offload	Reported L3L4P
IP ≥ [data / Unknown / fragmented].	IP checksum offload.	1 (for IPv4) / 0 (for IPv6).
IP ≥ L4.	IP and L4 checksum offload.	1.
IP ≥ IP ≥ [data / Unknown / fragmented].	2 x IP checksum offload.	1 if at least one of the IP headers is IPv4.
IP ≥ IP ≥ L4.	IP and L4 checksum offload.[1]	1.
IP ≥ [tunnel header] ≥ IP ≥ data / Unknown / fragmented.	Only IP checksum offload.	1 if at least one of the IP headers is IPv4.
IP ≥ [tunnel header] ≥ IP ≥ L4.	IP and L4 checksum offload.[2]	1.
IP ≥ [tunnel header] ≥ data and IP ≥ [tunnel header] ≥ MAC ≥ data	None.	0
IP ≥ [tunnel header] ≥ MAC ≥ IP ≥ data.	IP checksum (relevant only for IPv4) and outer UDP checksum.	1 if at least one of the IP headers is IPv4.
IP ≥ [tunnel header] ≥ MAC ≥ IP ≥ L4.	IP, outer UDP and L4 checksum offload[a].	1.

Notes:

1. The L4 checksum offload relates to the inner header:
   a. For UDP or TCP protocols, hardware calculates the expected checksum including the pseudo IP header.
   b. For SCTP protocol, hardware calculates the expected SCTP CRC.
2. Tunneling headers could be one of the following: GRE, Teredo, VXLAN UDP header.

38.31 LAN Transmit Data Path

The LAN transmit data path section covers the following major topics:

- Transmit packets stored in system memory and indicated to hardware by descriptors.
- Transmit descriptor queues that are called also descriptor rings and transmit arbitration queue lists.
- Stateless transmit offloads.

38.31.1 Transmit Packet in System Memory

Transmit packets are made up of data buffers in host memory indicated to hardware by descriptors (16-byte structures described in Section 38.31.2.2). These descriptors include pointer and length pairs to the data buffers as well as control fields for the transmit data processing. In some cases additional control parameters that cannot fit within the data descriptors are needed to process the packet(s). In this case, additional context descriptor(s) are needed in front of the data descriptors. A few examples for needed context descriptor(s) are: transmit segmentation (TSO) and FD filter programming. Refer to an example of a transmit packet in host memory composed of two buffers (header buffer and payload buffer), indicated by two matched data descriptors and optional context descriptor previously provided.

A few rules related to the transmit packet in host memory are:

- The total size of a single packet in host memory must be at least 17 bytes and up to the max frame size of the port as configured by the Set MAC Config admin command.
  - — Packets outside this range are considered malicious. The respective queue is stopped and an interrupt is issued to the PF. The relevant event is a bad single send size”
  - — This rule applies for single packet send as well as any packet within a transmit segmentation (TSO).
- A single transmit packet might span up to eight buffers (up to eight data descriptors per packet including both the header and payload buffers).
- The total number of data descriptors for the entire TSO (explained later on in this section) is unlimited as long as each segment within the TSO obeys the previous rule (up to eight data descriptors per segment for both the TSO header and the segment payload buffers).
- If a packet or TSO spans on multiple transmit data descriptors, the fields in all the data descriptors must be valid.

38.31.2 Transmit Descriptors

This section describes the descriptors provided on the LAN transmit queues. The 10 GbE controller supports the following transmit descriptor types.

LAN descriptors: In many cases only the data descriptor is needed to indicate a packet. Multiple descriptors are needed for FD filter programming, for TSO and/or packets that require offloads like tunneling. In those cases, the descriptor’s order must follow the order listed in Table 38-431.

Table 38-431.LAN Descriptor Types

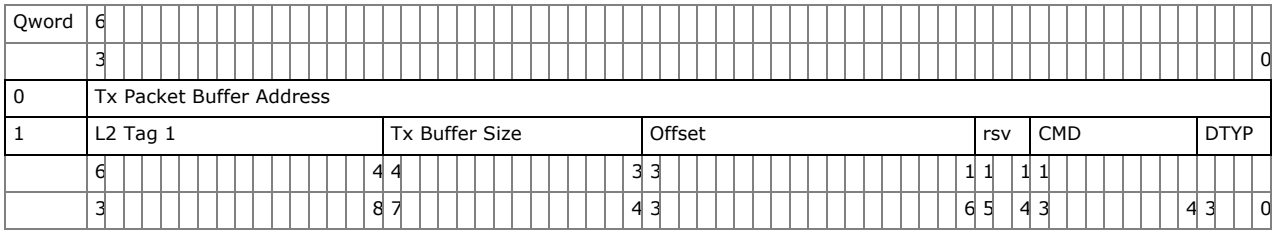
Type	DTYP Value	Description	Reference
Optional NOP Descriptors	0x1	NOP descriptors can be used to align descriptors to cache lines (optional usage)	Section 38.31.2.1.2
LAN Transmit Context Descriptor	0x1	Used as a companion to the transmit data descriptor to provide more information on the packet.	Section 38.31.2.2
FD Filter Programming Descriptor	0x8	Used to program FD filters.	Section 38.31.2.3
Transmit Data Descriptor	0x0	Regular data descriptor used to send LAN packets.	Section 38.31.2.1

The following sections describe these descriptors.

Note: For all descriptors: fields indicated as rsv (reserved) should be set to zero by software at programming time.

38.31.2.1 General Descriptors

38.31.2.1.1 Transmit Data Descriptor



Descriptor type - DTYP (Qword 1, bits 0:3) — 0x0 stands for a transmit data descriptor.

Command field - CMD — Qword 1, bits 4:15.

Bits	Name	Functionality
0	EOP	End Of Packet. The EOP flag is set in the last descriptor of a packet or TSO.
1	RS	Report Status. When set, hardware reports the DMA completion of the transmit descriptor and its data buffer. Completion is reported by setting the *DTYP* field to 0xF or by head write back as configured by the HEAD_WBEN flag in the transmit context. The RS flag can be set only on a last transmit data descriptor of a packet or last transmit data descriptor of a TSO or last transmit data descriptor of a filter.
2	RSV	Reserved
3	IL2TAG1	Insert an L2 tag from the *L2TAG1* field in this descriptor. For MAC in UDP or MAC in GRE tunneling, the *L2TAG1* field is relevant to the outer L2 header. See IL2TAG_IL2H for VLAN tag insertion to the inner L2 header. The type of the tag is defined by the *L2TAG1INSERTID* field in the VSI_L2TAGSTXVALID register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAGxxx registers. If the type of L2 tag requires more than two variable bytes, then additional bytes are taken from the *L2TAG2* field while *L2TAG1* is first on the wire. In this case, the IL2TAG2 flag must be cleared.
4	DUMMY	When the dummy flag is set, the packet is not transmitted (internal and external). The dummy indication can be useful for context programming purposes such as FD filters. Note that when using the dummy option, the packet does not have to have a correct checksum. Software should set all the fields in the data descriptor and context descriptors describing the packet structure as it does for normal packets.
6:5	IIPT	The IP header type and its offload. In case of tunneling, the IIPT relates to the inner IP header. Refer to the *EIPT* field for the outer (external) IP header offload. 00b = non IP packet or packet type is not defined by software. 01b = IPv6 packet. 10b = IPv4 packet with no IP checksum offload. 11b = IPv4 packet with IP checksum offload.
7	Reserved	Reserved.
9:8	L4T	L4T is the L4 packet type: 00b = Unknown / fragmented packet. 01b = TCP. 10b = SCTP. 11b = UDP. When L4T is set to other values than 00b, L4LEN must be defined as well. When set to UDP or TCP, hardware inserts the L4 checksum and when set to SCTP hardware inserts the L4 CRC.

Header offset parameters — OFFSET (Qword 1, bits 16:33).

Bits	Name	Functionality
6:0	MACLEN	MAC header length defined in words. In case of a tunnel packet, MACLEN defines the outer L2 header. MACLEN defines the L2 header length up to including the Ether-type. If L2 tag(s) are provided in the data buffers, then they are included in MACLEN. Any MPLS header should be included in MACLEN.
13:7	IPLEN	IP header length (including IP optional/extended headers) in the Tx buffer defined in Dwords. In case of a tunnel packet, IPLEN defines the most inner IP header length.
17:14	L4LEN	L4LEN is the L4 header length in the Tx buffer defined in Dwords. In case of a tunnel packet, L4LEN defines the most inner L4 header length. L4LEN should obey the following rule: When the *L4T* field is set to 00b, L4LEN must be set to zero. Otherwise, it should be set to 8 / 12 for UDP / SCTP, respectively and should be equal or larger than 20 for TCP.

L2 Tag 1 - L2TAG1 - (Qword 1, 48:63) — A 16-bit tag to be inserted into the packet if the IL2TAG1 flag is set. If IL2TAG1 is cleared, L2TAG1 should be set by software to zero.

Transmit buffer description — BUFF (Qword 0, bits 0:63; Qword 1, bits 34:47).

Table 38-432.Transmit Buffer

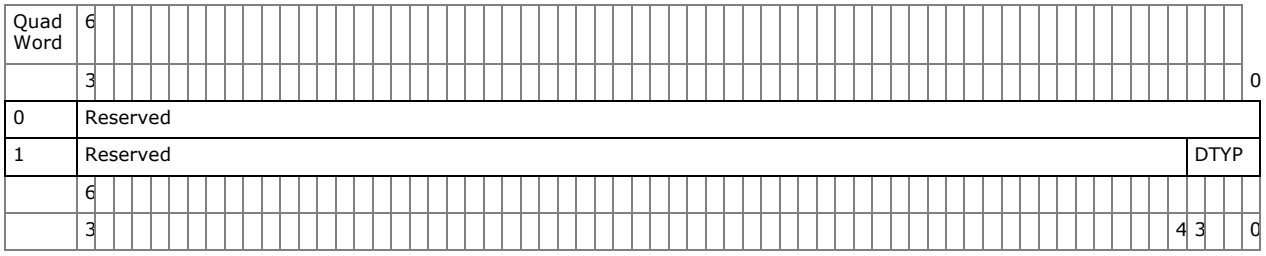
Bits	Name	Functionality
47:34	BSIZE	Buffer size in byte units from 1 byte up to 16 KB minus 1.
63:0	BADDR	Buffer address in byte granularity.

38.31.2.1.2 NOP Descriptor

A NOP descriptor can be used if there is a software need to align descriptors. An NOP descriptor does not cause any activity other then processing the descriptor.

NOP descriptors are is implemented by a null setting of a context descriptor as follows: DTYP should be set to 0x1 (LAN context descriptor) and all other fields should be cleared. Note that NOP descriptors are permitted only between commands.

38.31.2.1.3 Transmit Descriptors Write-Back Format



Descriptor Type - DTYP — Qword 1, bits 0:3.

- Hardware indicates a completed descriptor by setting the *DTYP* field to a value of 0xF. The write-back status is the same for all transmit descriptors used for LAN traffic and filter programming.
- Hardware reports this status in the following two cases:
  - — For descriptors with the *RS* bit set (Report Status) while the HEAD_WBEN flag in the transmit context is set to descriptor write-back mode. Refer to the rules for setting the *RS* flag in the transmit descriptors in Section 38.31.2.1.1.
  - — For the last descriptor of a command that was executed before an interrupt of the queue is initiated.

38.31.2.2 LAN Transmit Context Descriptors

38.31.2.2.1 Transmit Context Descriptor

A context descriptor might have additional setting options for a single packet or TSO defined by the data descriptor(s) that follows. Following the previously described packet or TSO, the context provided by this descriptor is lost.

See Table 38.31.4 for field settings as a function of required offload.

Quad Word	6 3	4 4 8 7	3 3 2 1	2 2 4 3	0
0	rsv	L2TAG2 (STag / VEXT)	rsv	Tunneling Parameters	
1	MSS / TARGET_VSI	rsv	TSO Total Length	rsv	rsv	CMD	DTYP

	6 3	5 4 0 9	4 4 8 7	3 2 0 9	1 1 8 7	1 1 1 0	4 3	0

Descriptor Type - DTYP (Qword 1, bits 0:3) — 0x1 stands for a LAN context descriptor.

Command Field - CMD — Qword 1, bits 4:10.

Bits	Name	Functionality
0	TSO	Transmit segmentation offload is activated when the TSO flag is set.
1	TSYN	1588 Time Stamp. When set, hardware samples the packet transmission time in the PRTTSYN_TXTIME register. The TSYN flag is processed by the device only if TimeSync is enabled by the TSYNENA flag in the transmit queue context. Note that the TSYN flag is aimed only for a single send with no TSO.
2	IL2TAG2	Insert the L2 tag from the *L2TAG2* field in this descriptor. For MAC in UDP or MAC in GRE tunneling, the *L2TAG2* field is relevant to the outer L2 header. See IL2TAG_IL2H for VLAN tag insertion to the inner L2 header. The type of the tag is defined by the *L2TAG2INSERTID* field in the VSI_L2TAGSTXVALID register of the VSI. The structure of this tag is defined by the matched GL_SWT_L2TAGxxx registers. See also IL2TAG1 in the data descriptor for 32-bit tag handling.
3	IL2TAG_IL2H	Insert VLAN to the inner L2 header from the *L2TAG2* field in this descriptor. The VLAN is added after the header defined by L4TUNLEN. *IL2TAG2* and *IL2TAG_IL2H* are mutually exclusive and software might set only one of them. *IL2TAG_IL2H* can be set to 1b only for L4 tunneled packets with non-zero L4TUNLEN.
5:4	SWTCH	Switch Control Tag (Can be set to non-zero only by control VSI as programmed by the *Allow Destination Override* flag per VSI): 00b = No switch control tag. The packet is routed according to hardware filters. 01b = Uplink packet. The packet is transmitted to the network bypassing hardware filters. 10b = Local packet. The packet is transmitted only to local VSIs according to the hardware filters. 11b = Target VSI. The packet is transmitted to a specific VSI defined in the *MSS/VSI* field in this descriptor. TSO is mutually exclusive with this option.
6	Reserved	Reserved.

Segmentation parameters / switching parameter — Qword 1, bits 30:47; bits 50:63.

Bits	Name	Functionality
47:30	TLEN	TSO Total Length. This field defines the L4 payload bytes that should be segmented. Note that the sum of all transmit buffer sizes of the TSO should match exactly the TLEN plus the TSO header size in host memory. If the TSO flag is cleared, the TLEN should be set by software to zero. If the TSO flag is set, the TLEN must be set by software to a larger value than zero.

Bits	Name	Functionality
63:50	MSS / TARGET_VSI	When the TSO flag is set, this field functions as MSS. When the *SWTCH* field is set to 11b, this field function as TARGET_VSI. If the TSO flag is set then the *SWTCH* field should not be set to 11b and vice versa. If both the TSO flag is cleared and the *SWTCH* field is not equal to 11b then this field should be set to zero. When the TSO flag is set, the *MSS* field defines the MSS of the packet's payload in the TSO (excluding the L2, L3 and L4 headers). In case of tunneling, the MSS relates to the inner payload. In this case, the MSS should not be set to a lower value than 64 or larger than 9668 bytes. When the *SWTCH* field equals to 11b, it is the destination VSI of the packet. This option is valid only for control VSIs on which the *Allow Destination Override* flag is set.

Tunneling parameters — Qword 0, bits 0:23.

Bits	Name	Functionality
1:0	EIPT	The external (outer) IP header type and its offload: 00b = No external IP header. 01b = External IPv6. 10b = External IPv4 with no checksum offload. 11b = External IPv4 with checksum offload.
8:2	EIPLEN	External (outer) IP header length (including IP optional/extended headers) defined in Dwords. When the packet has no outer IP header (EIPT equals to zero), this field must be set to zero.
10:9	L4TUNT	L4 tunneling type (Teredo / GRE header / VXLAN header) indication: 00b = No UDP / GRE tunneling (field must be set to zero if EIPT equals to zero). 01b = UDP tunneling header (Any UDP tunneling, VXLAN and Geneve). 10b = GRE tunneling header. Else = Reserved.
11	RSV	Reserved, set to zero.
18:12	L4TUNLEN	L4 tunneling length (Teredo / GRE header / VXLAN header) defined in words (field must be set to zero if L4TUNT equals to zero). For standard Teredo headers with no additional header payload it should be set to four, which equals eight bytes. If the tunneling header includes proprietary content it should be included as well. For IP in GRE it should be set to the length of the GRE header. For MAC in GRE or MAC in UDP it should be set to the length of the GRE or UDP headers plus the inner MAC up to including its last Ether-type. Note that this field represents the length of data provided in host memory buffers. If the L4TUNT is cleared, this field must be set to zero.
22:19	DECTTL	Decrement TTL in the inner IP header by DECTTL and drop the packet if the original TTL was not greater than DECTTL. If the EIPT is cleared, this field must be set to zero.
23	L4T_CS	Calculate the outer L4 checksum. Must be set only if L4TUNT = 01b and EIPT is not zero. Supported only if L4 protocol is UDP.

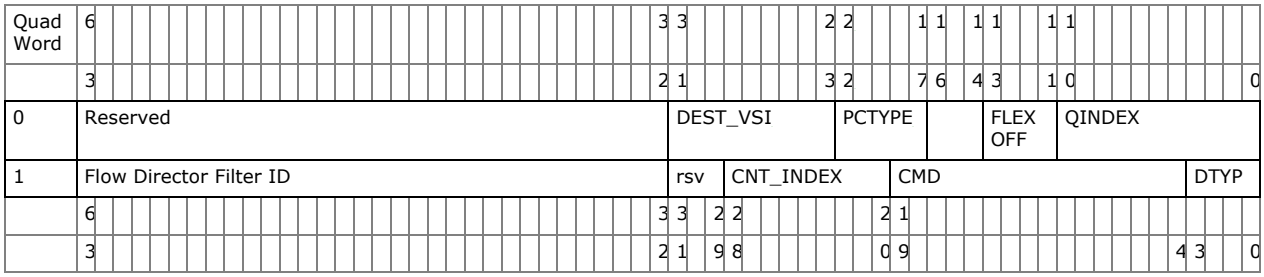
L2 tag 2 — Qword 0, bits 32:47.

Bits	Name	Functionality
47:32	L2TAG2	A 16-bit tag to be inserted to the packet if the IL2TAG2 flag is set or if IL2TAG1 is set while L2 tag 1 include four variable bytes or if the IL2TAG_IL2H flag is set. If the previous conditions are not met, L2TAG2 should be set by software to zero.

Note: RSV, reserved bits that must be set to zero.

38.31.2.3 Filter Programming Descriptor

The filter programming descriptor should be followed by data descriptor(s).



Qword 0.

Bits	Name	Functionality
10:0	QINDEX	Destination queue index for this filter. The queue index is defined in the range of the VSI.
13:11	FLEXOFF	Flexible Offset. This is a word offset in the flexible payload" in the field vector relative to the beginning of the flexible payload space from which bytes are extracted to the 32-byte receive descriptor. The FD_STATUS flag enables either four or eight bytes or none. The (first) four bytes indicated by FLEXOFF are posted to the *Flexible Bytes Low* field in the receive descriptor and the (last) four bytes are posted (if enabled) to the *Flexible Bytes High* field. Note that the FLEX bytes are supported only by 32-byte receive descriptors. FLEXOFF must not be larger than six when four bytes are enabled and must not be larger than four when eight bytes are enabled.
16:14	RSV	Reserved.
22:17	PCTYPE	Matched Packet Type. When the FD_AUTO_PCTYPE flag in the GLQF_CTL register is cleared, this field defines the PCTYPE of the programmed FD filter. When the FD_AUTO_PCTYPE flag in the GLQF_CTL register is set, this field is meaningless and should be set to zero. In this case, the device concludes the PCTYPE by the packet used to program the FD filter.
31:23	DEST_VSI	Expected VSI Index. 0x0 = 0x17F. Matched VSI index of the received packet. Else = Reserved Note that hardware does not check DEST_VSI at programming time while it is software's responsibility to program DEST_VSI, which is owned by the PF.
63:22	RSV	Reserved.

Qword 1.

Bits	Name	Functionality
3:0	DTYPE	0x8 for a FD filter programming descriptor.
19:4	CMD	Described in the table that follows.
28:20	CNT_INDEX	Statistic counter index for packets that match this filter. This field is meaningful only when the CNT_ENA flag is set in this descriptor.
31:29	RSV	Reserved.
63:32	FDID	Flow Director Filter ID. Note that FDID is opaque to hardware. The programmed FDID can be reported back in the received descriptor of a matched received packet (if enabled by the FD_STATUS parameter in this descriptor). If so, it can be used by software to associate the received packet with its matched filter.

Command field - CMD — Qword 1, bits [4:19].

Bits	Name	Functionality
2:0	PCMD	Filter Programming Command: 001b = Add filter[1]. 010b = Remove filter. Else = Reserved.
4:3	DEST	Matched Packet Destination Control. 00b = Drop packet. 01b = Direct packet to LAN queue defined by the QINDEX. 10b = Direct packet to LAN while the queue is defined by other filters. 11b = Reserved.
7	CNT_ENA	Statistic Counter Enable Flag (relevant only for FD filter). This flag enables packet counting by the statistic counter defined by the statistic counter index in this command.
8	RSV	Reserved.
10:9	FD_STATUS	The FD_STATUS flag enables status indication of the FD filter ID and extracting flexible bytes in the receive descriptor as follows: 00b = FD ID and flexible bytes are not enabled. 01b = FD ID is enabled. 10b = FD ID and 4 Flexible bytes are enabled. 11b = Eight flexible bytes are enabled.
13:11	RSV	Reserved.
14	ATR	If set, this filter is candidate for automatic eviction.
15	RSV	Reserved.

Notes:

1. If the filter entry does not exist, the filter is added. If the filter already exists, the filter parameters are updated.

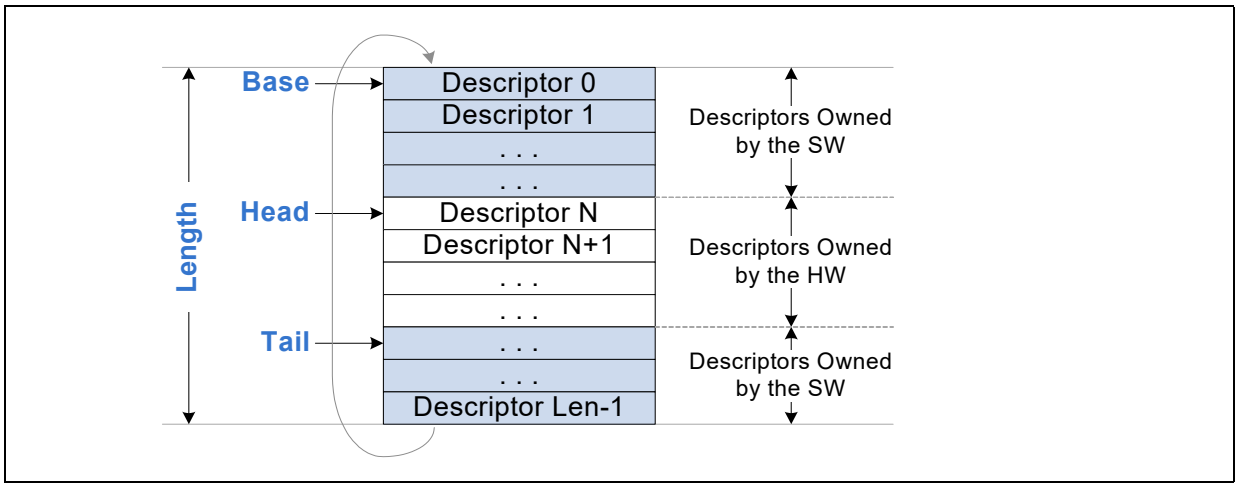
38.31.3 LAN Transmit Queue (Ring)

Software prepares structures for transmission in system memory indicated to hardware by a list of consecutive descriptors. These descriptors are organized in a contiguous memory handled as a cyclic queue, which is also called a descriptor ring. The 10 GbE controller supports up to 1536 transmit queues allocated to PFs and VFs as described in Section 38.30.2.

Transmit queues are defined by a set of parameters called the queue context. The main parameters are the queue pointers shown in the Figure 38-99. The queue context includes additional parameters that define the queue functionality as detailed in Section 38.31.3.4. Part of these context parameters are kept in hardware (like the Tail register, queue enable flag and interrupt related context). Most of the queue context parameters are stored in FPM, fetched to an internal cache when required.

the software interface to the queue (for initialization, normal operation, and queue disable flow) is described in Section 38.31.3.1. The 10 GbE controller has additional global parameters for the entire device or per function parameters that affect multiple queues. See Section 38.30.3.3.1 for more detail.

Figure 38-99.Transmit Descriptor Ring Structure



38.31.3.1 Transmit Queue Programming

Queue enable and disable flows are described in the following section and listed in Table 38-433.

Table 38-433.Transmit Queue Enable / Disable Flags

QTX_ENA[n] Register		Transmit Queue State
QENA_REQ	QENA_STAT	
0	0	Queue is not enabled.
1	0	Queue enable request by software.
1	1	Queue is enabled.
0	1	Queue disable request by software.

38.31.3.1.1 Transmit Queue Enable Flow

Queue enable flow is executed by PF software for PF queues as well as for the queues of its VFs.

- The function that owns the queue (PF or VF) allocates contiguous memory in its own memory space for the transmit ring.
- If the queue might have been disabled recently then software should wait at least 50 ms from the completion of the queue disable flow before proceeding to the next step.
- Software should clear the queue disable flag by setting the CLEAR_QDIS flag in the matched GLLAN_TXPRE_QDIS[n] register. The QINDX field in the GLLAN_TXPRE_QDIS[n] register should be set to the absolute queue index (equals to the queue index within the PF plus the FIRSTQ field in the PFLAN_QALLOC register of the PF).
- Software prepares the queue context in the FPM in PF memory space, clears the QTX_HEAD[n] register and then sets the QENA_REQ flag in the QTX_ENA[n] register, while 'n' is the queue index within PF space. Before that, the PF also defines the function that owns the queue in the PFVF_FUN; PF_INDX; VFVM_INDX parameters in the matched QTX_CTL[n] register. See several examples for queue context settings in Section 38.31.3.4.3. At pre-boot time, memory allocation might be tight and the FPM could exceed the budget.

Note: There is a mechanism to program the queue context directly to the device bypassing the FPM as described in Section , "Direct Queue Context Programming".

- As a response, hardware sets the QENA_STAT flag in the QTX_ENA[n] register. The QENA_STAT follows the QENA_REQ almost instantly and not more than 10 µs after that.
- Once the QENA_STAT flag in the QTX_ENA[n] register is set, software can start using the queue.
- If the queue is targeted for a VF, PF software should also program the matched entry in the VFQ_TABLE. Then it is expected to signal VF software that the queue is enabled. Note that the VFQ_TABLE is shared for the receive and transmit queues. So PF software should also enable the receive queue before communicating it to the VF.

38.31.3.1.2 Transmit Queue Disable Flow

Queue disable flow is executed by PF software for PF queues as well as for the queues of its VFs.

- Remove the queue from the interrupt linked list.
- PF software sets the SET_QDIS flag in the matched GLLAN_TXPRE_QDIS[n] register. The DINDX field in the GLLAN_TXPRE_QDIS[n] register should be set to the absolute queue index (equals to the queue index within the PF plus the *FIRSTQ* field in the PFLAN_QALLOC register of the PF). Software should guarantee a gap of at least 100 µs at 2 x 10 GbE and above or 400 µs at 1 x 10 GbE before the next step executes. Note that software could execute this step for multiple transmit queues and then proceed to the next step for these queues concurrently.
- PF software clears the QENA_REQ flag in the QTX_ENA[n] register, while 'n' is the queue index within the PF space.
- Hardware schedules this event like it does for any other software update of the tail. Further updates of the tail register are ignored by hardware.
- Hardware posts a queue disable marker in the transmit pipe.
- Any preceding commands in the transmit pipe are processed while their buffers are fetched from host memory.
- Eventually, the queue disable marker gets to the end of the pipe. At this point it is guaranteed that the pipe does not contain any additional transmit commands that might require the host memory.
- Hardware invalidates the transmit queue from the internal cache and also clears the QENA_STAT flag in the QTX_ENA[n] register.
- Once the QENA_STAT flag in the QTX_ENA[n] register is cleared, software releases all memory structures of the queue. If the QENA_STAT flag in the QTX_ENA[n] register is not cleared within a reasonable time it might be an indication for too long pause packets from the network.

Note: The progress of the queue disable marker following clearing the QENA_REQ flag is subjected to scheduling in the transmit data path the same as any other packet. This means that processing latency might take longer time if the TC is paused.

38.31.3.1.3 Fast Transmit Queue Disable Flow

Fast queue disable flow is executed by hardware following a PFR, VFR or VMR resets. Once these resets are completed by hardware, all transmit queues of the function or the VM are disabled. All queue contexts of the matched function or the VM are invalidated from the internal cache and their QENA_STAT flag in the matched QTX_ENA[n] register are cleared while the queue context is not updated in the FPM.

38.31.3.1.4 Software Fast Path Programming

During normal operation, the function that owns the queue (PF or VF) accesses the hardware directly.

- Prepare transmit descriptors starting at the descriptor indicated by the TQTAIL pointer in the relevant QTX_TAIL register. Note that software should update the TQTAIL at whole-structured boundaries. For TSO, it is the entire TSO, for a single packet, it is the entire packet and for filter, it is the end of the packet that is associated to the filter programming. Failing to do so might hang the activity of the queue.
- Software should never set the TQTAIL to a value above the descriptors owned by hardware minus one. Descriptors considered as owned by hardware are those already indicated to hardware but are not yet reported as completed.
- Hardware reports completed descriptors only for those ones indicated by an *RS* bit in the CMD field in the descriptor. Completion indication is provided in one of two modes as programmed by the HEAD_WBEN parameter in the queue context as follows:
  - Descriptor write back — Hardware changes the value of the *DTYP* field in the completed descriptor to a 0xF (*DTYP* equals to 0xF is reserved for completed descriptor indication). It also sets the rest of the descriptors to all zero's.
  - Head write back — Hardware indicates the head pointer of the next descriptor that follows a completed descriptor (with active *RS* bit). Hardware post the four bytes of the head pointer at the address defined by the HEAD_WBADDR parameter in the queue context.
- Bump the tail to the last prepared descriptor plus one (the descriptor index to be added in the next time).

38.31.3.2 Transmit During Link Down

In most usage models when the link becomes inactive, it is not required to preserve the transmit packets that were not sent. During link down, hardware continues to fetch transmit descriptors and data regardless of the link status. Packets directed to the network are discarded while packets directed to local VSI port are forwarded successfully.

Note that when the link becomes inactive, PFs on this port get a link status change interrupt. It is expected that the VFs get the link status change indication from their parent PF.

38.31.3.3 Transmit Arbitration Queue Set

Transmit queues are grouped into arbitration queue sets. The 10 GbE controller supports 1024 LAN queue sets (indicated by the RDYList parameter in the transmit queue context). Queue arbitration within the same queue sets is a simple round robin scheme. A queue context is fetched on demand (if not already in the cache) when it is scheduled. Then hardware fetches the transmit descriptors (if not already in the cache) and then it fetches the transmit data.

38.31.3.4 Transmit Queue Context Parameters

This section describes the setting options of the LAN transmit queue parameters named as queue context. Part of the queue context parameters reside in dedicated hardware registers and part of the context is stored in host memory (FPM) while the active queues are kept in cache.

38.31.3.4.1 Transmit Queue Context in Hardware Registers

The queue context parameters that software accesses during fast past programming as well as its enablement reside in hardware registers:

- Queue enablement flags in the QTX_ENA[n] registers while 'n' is the queue index of the PF. Queue enable and disable flow by the PF are explained in the sub-sections of Section 38.31.3.1.
- The tail pointer in the QTX_TAIL[n] registers while 'n' is the relative queue index of the function (PF or VF). The usage of the Tail register is detailed in Section 38.31.3.1.4.
- Association of the queue to a function (PF and its VF or VM) is programmed by the QTX_CTL[n] registers while 'n' is the relative queue index of the PF. The QTX_CTL includes the following parameters that are programmed by the PF:
  - PF_INDX is the absolute index of the PF (between 0 and 15).
  - PFVF_Q flag associate the queue to the PF, the EMP or to one of its VFs or its VMs.
  - VFVM_INDX is the absolute index of the VF (between 0 and 127) if the queue belongs to a VF or the absolute index of the VSI (between 0 and 383) if the queue belongs to a VM. Otherwise, the VFVM_INDX should be set to zero.

38.31.3.4.2 Transmit Queue Context in FPM

The transmit queue context parameters that are stored in host memory (FPM) are fetched for the active queues to the internal cache. These parameters are listed in Table 38-434. The queue context is structured as contiguous lines of 128 bits (16 bytes) each, as follows:

Table 38-434.LAN Tx Queue Context in the Private Host Memory (Sheet 1 of 3)

Alias	Width [Bits]	LS Bit	MS Bit	Type	SW Init	Description
Line 0						
HEAD	13	0	12	Dynamic	0x0	Transmit Queue Head. An index updated by hardware relative to the beginning of the queue that defines the next descriptor to be used. All descriptors starting by the head up to (excluding) the TTAIL are owned by hardware and the rest are owned by software. At idle time the head equals TTAIL.
RSV	16	13	29	Dynamic	0x0	Reserved.
New_Context	1	30	30	Dynamic	0x1	New Context Flag. Should be set to 1b by software at queue context programming.
RSV	1	31	31	N/A	0x0	Reserved.
BASE	57	32	88	Static	BASE	Transmit Queue Base Address. Indicates the starting address of the descriptor queue defined in 128-byte units.
Reserved	1	89	89	Static	Reserved	Reserved.

Table 38-434.LAN Tx Queue Context in the Private Host Memory (Sheet 2 of 3)

Alias	Width [Bits]	LS Bit	MS Bit	Type	SW Init	Description
TSYNENA	1	90	90	Static	TSYNENA	TimeSync Enable. If the TSYNENA flag is set, then setting the TSYN flag in the transmit context descriptor is processed by the hardware sampling the packet timestamp in the PRTTSYN_TXTIME register.
FDENA	1	91	91	Static	FDENA	Enable FD filter programming by this queue.
ALT_VLAN	1	92	92	Static	ALT_VLAN	Alternate VLAN Tag Selects. At 0b the PORT_TAG_ID tag in the VSI_TIR is disabled and at 1b the PORT_TAG_ID tag in the VSI_TAIR register is enabled.
RSV	3	93	95	N/A	0x0	Reserved.
CPUID	8	96	103	Dynamic	CPUID	CPU socket ID for TPH. The CPU socket ID is updated by hardware.
RSV	4	104	127	N/A	0x0	Reserved.
Line 1						
THEAD_WB	13	0	12	Dynamic	0x0	Reflection of the reported head at head write back.
RSV	19	13	31	N/A	0x0	Reserved.
HEAD_WBEN	1	32	32	Static	HEAD_WBEN	This flag selects between head write back and transmit descriptor write back: 0b = Descriptor write back 1b = Head write back
QLEN	13	33	45	Static	QLEN	Transmit Queue Length (QLEN). Defines the size of the descriptor queue in descriptors units from 8 descriptors (QLEN=0x8) up to 8 KB-32 descriptors (QLEN=0x1FE0). QLEN restrictions: At smaller queue size than 32 descriptors the QLEN must be a whole number of 8 descriptors. At a larger size than 32 descriptors, QLEN must be a whole number of 32 descriptors.
TPHRDesc	1	46	46	Static	TPHRDesc	Descriptor Read TPH Ena flag for descriptors fetch.
TPHRPacket	1	47	47	Static	TPHRPacket	Packet Content TPH Ena flag for the packet header and payload.
TPHWDesc	1	48	48	Static	TPHWDesc	Head WB / Descriptor Completion Status Write Back TPH Ena flag.
RSV	15	49	63	N/A	0x0	Reserved
HEAD_WBADDR	64	64	127	Static	HEAD_WBADDR	When HEAD_WBEN is set to 1b, this field defines the HEAD write-back address. Must be set to 0x0 if HEAD_WBEN is cleared.
Line 2						
RSV	128	0	127	N/A	0x0	Reserved.
Line 3						
RSV	128	0	127	Tx_Desc	0x0	Reserved for internal parameters.
Line 4						
RSV	128	0	127	Internal	0x0	Reserved for internal parameters.
Line 5						
RSV	128	0	127	Internal	0x0	Reserved for internal parameters.
Line 6						
RSV	128	0	127	Internal	0x0	Reserved for internal parameters.

Table 38-434.LAN Tx Queue Context in the Private Host Memory (Sheet 3 of 3)

Alias	Width [Bits]	LS Bit	MS Bit	Type	SW Init	Description
Line 7						
RSV	84	0	83	Internal	0x0	Reserved.
RDYList	10	84	93	Static	RDYList	Transmit arbitration queue set. The RDYList index is absolute so it should be set to those RDYList allocated to the function.
RSV	34	94	127	Internal	0x0	Reserved.

38.31.3.4.3 Examples for Transmit Queue Context Setting

Following is an example of a transmit queue context setting:

PF LAN transmit queue context example =

Offset	Even_L.0	Even_L.1	Even_L.2	Even_L.3	Odd_L.0	Odd_L.1	Odd_L.2	Odd_L.3

Line 2, 3:	0x00000000	00000000	00000000	00000000	00000000	00000000	00000000	00000000
Line 4, 5:	0x00000000	00000000	00000000	00000000	00000000	00000000	00000000	00000000
Line 6, 7:	0x00000000	00000000	00000000	00000000	FFFFFFFF	480FFFFF	00000000	00000000

BASE = 0x001579A0 (0x0ABCD000)	HEAD_WBEN = 0
FCENA = 0	QLEN = 512 (0x200)
TSYNENA = 0	TPH = 111b (enable all TPHxxx flags)
FDENA = 1	HEAD_WBADDR = 0x00...0
ALT_VLAN = 0	RDYList = 0x80 (128)

38.31.4 Stateless Transmit Offloads

38.31.4.1 Insert Ethernet CRC Bytes

38.31.4.2 Transmit L3 and L4 Integrity Offload

The 10 GbE controller can offload the following L3 and L4 integrity checks: IPv4 header(s) checksum for simple and tunneled packets, inner TCP or UDP checksum, tunneling UDP checksum, and SCTP CRC integrity. If a checksum is required, software should provide it as well as the inner checksum value(s) that are required for the outer checksum. In order to request L3 and L4 integrity offloads, software should define the packet format and the required offload in the transmit descriptors as shown in Figure 38-100 and Table 38-436.

Some rules for integrity offload are:

- Offloads for inner headers to an IPv6 header with a fragment extension header or fragmented IPv4 packets do not make sense. Note that this rule is not enforced by the 10 GbE controller.
- IPv6 support — The pseudo header for the L4 checksum takes into account the addresses in the IPv6 header ignoring the optional extension headers. Packets with

routing header type 2 and destination options header with home address option contain an alternative IP address in the extension header. Therefore the operating system should not request a checksum nor segmentation offload for packets with a routing extension header type 2.

- IP header length requirements (IPLEN and EIPLEN).
  - In the case of a non-tunneled packet, IPLEN defines the IP header length in Dword units and the IIPT defines the IP header type.
  - In the case of tunneled packets, IPLEN defines the inner IP header length and EIPLEN defines the outer (external) IP header length. IIPT defines the inner IP header type and EIPT defines the outer IP header type.
  - The *Length* field in the IP header is prepared by the software in the packet buffers. This length field includes the payload of the IP header. In MAC tunneling, the inner MAC header (including optional VLAN tag) is part of the outer IP header payload. This optional VLAN tag can be embedded in the packet buffers or by using the IL2TAG_IL2H option in the transmit context descriptor. Regardless of the previous, the optional VLAN tag should be taken into account in the length field of the outer IP header.
  - For IPv4 it should be at least 20 bytes (basic header size), and not more than 60 bytes.
  - For IPv6 it should be at least 40 bytes (basic header size), and up to the maximum size enabled by the parsing fields for basic IPv6 header and its extension headers.
- L4 header length requirements (L4LEN):
  - For TCP, it should be at least 20 bytes (basic header size), and not more than 60 bytes.
  - For SCTP, it should be set to 12 (SCTP common header size).
  - For UDP, it should be set to 8 (UDP header size).

Table 38-436 lists all supported packet formats and the processed integrity. The table uses the following notations:

- IP is a generic term for an IPv4 header or IPv6 header. The IPv4 header can have IP option headers and the IPv6 header can have IPv6 extension headers.
- L4 is a generic term for UDP, TCP or SCTP headers.
- IP checksum is meaningful only for IPv4.
- Checksum is a generic term for UDP and TCP checksum as well as SCTP CRC integrity.

Offload details:

- IPv4 checksum calculation (both inner and outer IP header for tunneled packets).
  - Software should set the IPv4 checksum to zero.
  - Hardware calculates the IPv4 header checksum starting at the beginning of the IPv4 header up to the end of the header.
- Outer UDP checksum calculation (UDP tunneling).
  - Software provides the pseudo IP header checksum in the outer UDP header.
  - Hardware calculates the UDP checksum starting at the beginning of the tunnel header up to the end of the packet, which includes the pseudo header provided by software.
- UDP and TCP checksum calculation (inner L4 header in case of UDP / GRE tunneling).
  - Software provides the pseudo IP header checksum in the L4 header.

  - — Hardware calculates the L4 checksum starting at the beginning of the L4 offset up to the end of the packet, which includes the pseudo header provided by software.
- See Table 38-435 for a list of fields that the software device driver should fill when sending a packet.
- SCTP CRC calculation (inner L4 header in case of UDP / GRE tunneling).
  - — Software should set the CRC in the header to zero.
  - — Hardware calculates the CRC according to SCTP standard starting at the beginning of the SCTP header up to the end of the packet.
- Tunneling UDP / GRE header length requirements.
  - — For UDP / GRE tunneling, the header can be any value in 2-byte granularity from 8 bytes (bare Teredo UDP header) and up to 254 bytes (including optional network key and optional inner L2 header up to including the last Ether-type). Note that the header length includes only those bytes provided in the packet buffers in host memory.

Table 38-435.Pseudo Header Pre-Loaded Values

Field	Single Send Packet (No TSO)	Transmit Segmentation Offload (TSO)
Outer IP Length	IPv4: IP header +payload size IPv6: payload size only, including header extensions Should match the data size stored in host memory (hardware modifies it upon offloads).	Don't care (calculated by hardware).
Outer L4 (UDP) Length	UDP header size + payload size. Should match the data size that stored in host memories (hardware modifies it upon offloads).	Don't care (calculated by hardware).
Outer L4 CS Field	IP header pseudo checksum, calculated on IP header fields: IPv4: Source addr +destination addr +protocol (=0x11) + UDP length. IPv6: Source addr +destination addr + NextHeader(=0x11) + UDP length. UDP Length is the payload that follows the IP header. It includes the size of UDP header and data.	IP header pseudo checksum, calculated on IP header fields. Not including UDP length: IPv4: Source addr +destination addr + protocol (=0x11). IPv6: Source addr +destination addr + NextHeader(=0x11).
Inner/Single IP Length	IPv4: IP header +payload size. IPv6: payload size only, including header extensions. Should match the data size stored in host memory (hardware modifies it upon offloads).	Don't care (calculated by hardware).
Inner/Single L4 (UDP/ TCP) Length	Header size + payload size. Should match the data size that stored in host memories (hardware modifies it upon offloads).	Don't care (calculated by hardware).
Inner/Single L4 CS Field	IP header pseudo checksum, calculated on IP header fields: IPv4: Source addr +destination addr + protocol + L4 Length. IPv6: Source addr +destination addr + NextHeader + L4 length. Protocol or NextHeader values are: 0x11 for UDP and 0x6 for TCP. L4 Length is the payload that follows the IP header. It includes the size of L4 header and data.	IP header pseudo checksum, calculated on IP header fields. Not including L4 length: IPv4: Source addr +destination addr + protocol. IPv6: Source addr +destination addr + NextHeader. Protocol or NextHeader values are: 0x11 for UDP and 0x6 for TCP.

Figure 38-100.Transmit L3 and L4 Header Lengths (in Host Memory) for Integrity Offload

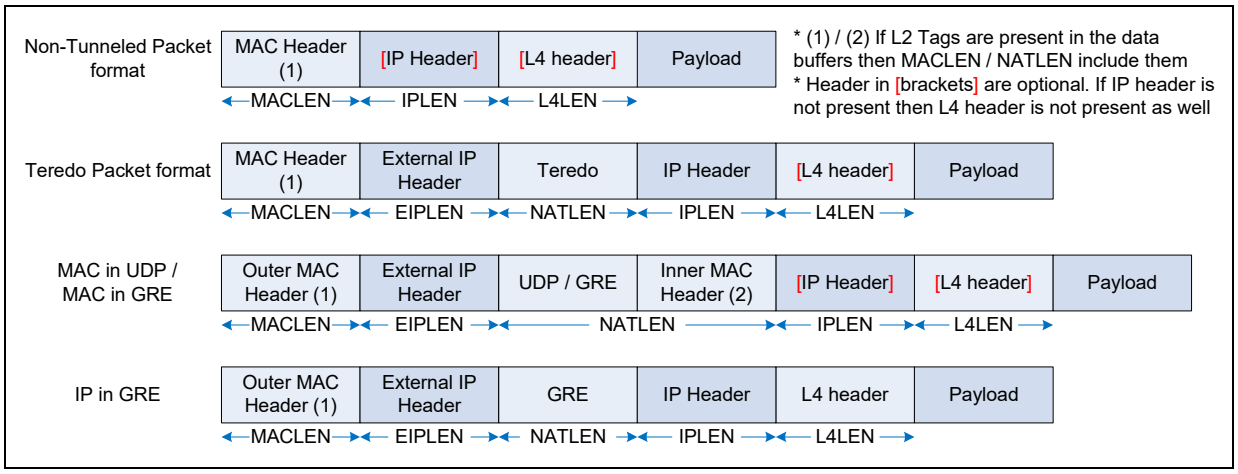

Table 38-436.Transmit Integrity Offload for Packet Types

Packet Type	Parsing Hints and Offload Enablement In The Transmit Descriptors[1,2]	Supported Transmit Checksum Offload
Fragmented IPv4 or IPv4 ≥ Unknown.	IIPT = 10b or 11b. L4T = 00b (unknown).	IPv4 checksum if IIPT = 11b.
Fragmented IPv6 or IPv6 ≥ Unknown.	IIPT = 01b. L4T = 00b (unknown).	None.
IP ≥ L4.	IIPT = 10b or 11b for IPv4. IIPT = 01b for IPv6. IPLEN = the length of the IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). L4LEN = L4 header length. EIPT = EIPLEN = L4TUNT = 0 (no tunneling).	IPv4 checksum if IIPT = 11b. L4 checksum if L4LEN is meaningful (like, L4T <> 0).
IP ≥ (Fragmented IP or IP ≥ Unknown).	IIPT, IPLEN, EIPT, EIPLEN, L4TUNT = same as IP ≥ IP ≥ L4. L4T = 00b (unknown).	Inner IPv4 checksum if IIPT = 11b. Outer IPv4 checksum if EIPT = 11b. No L4 checksum.
IP ≥ IP ≥ L4.	IIPT = 10b or 11b for inner IPv4. IIPT = 01 for inner IPv6. IPLEN = the length of the inner IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). EIPT = 10b or 11b for outer IPv4. EIPT = 01 for outer IPv6. EIPLEN = the length of the outer IP header (including IP optional or extension headers). L4TUNT = 00b (no L4 tunneling).	Inner IPv4 checksum if IIPT = 11b. Outer IPv4 checksum if EIPT = 11b. L4 checksum if L4LEN is meaningful (like, L4T <> 0).
IP ≥ Teredo UDP / GRE ≥ IP ≥ L4.	IIPT = 10b or 11b for inner IPv4. IIPT = 01 for inner IPv6. IPLEN = the length of the inner IP header (including IP optional or extension headers). L4T = 11b, 01b, 10b (UDP, TCP, SCTP). EIPT = 10b or 11b for outer IPv4. EIPT = 01 for outer IPv6. EIPLEN = the length of the outer IP header (including IP optional or extension headers). L4TUNT = 01b for UDP/GRE tunneling. L4TUNLEN = Tunneling header length.	Same as IP ≥ IP ≥ L4.

Table 38-436.Transmit Integrity Offload for Packet Types

Packet Type	Parsing Hints and Offload Enablement In The Transmit Descriptors[1,2]	Supported Transmit Checksum Offload
IP ≥ Teredo UDP / GRE ≥ (fragmented IP or IP ≥ unknown).	IIPT, IPLEN, EIPT, EIPLEN, L4TUNT, L4TUNLEN = same as IP ≥ IP ≥ L4. L4T = 00b (unknown).	Same as IP ≥ (fragmented IP or IP ≥ unknown).
IP ≥ GRE / UDP ≥ MAC (with/ without VLAN) ≥ IP ≥ L4.	IIPT, IPLEN, L4T, EIPT, EIPLEN = same as IP ≥ IP ≥ L4. L4TUNT = 01b for UDP/GRE tunneling. L4TUNLEN = UDP/GRE header length in the packet buffers up to excluding the inner IP header.	Same as IP ≥ IP ≥ L4 plus tunneling UDP checksum.
IP ≥ GRE / UDP ≥ MAC (with/ without VLAN) ≥ (fragmented IP or IP ≥ unknown).	IIPT, IPLEN, L4T, EIPT, EIPLEN = same as IP ≥ (fragmented IP or IP ≥ unknown). L4TUNT, L4TUNLEN = same as IP ≥ GRE / UDP ≥ MAC (with/without VLAN) -> IP -> L4.	Same as IP ≥ (fragmented IP or IP ≥ unknown).

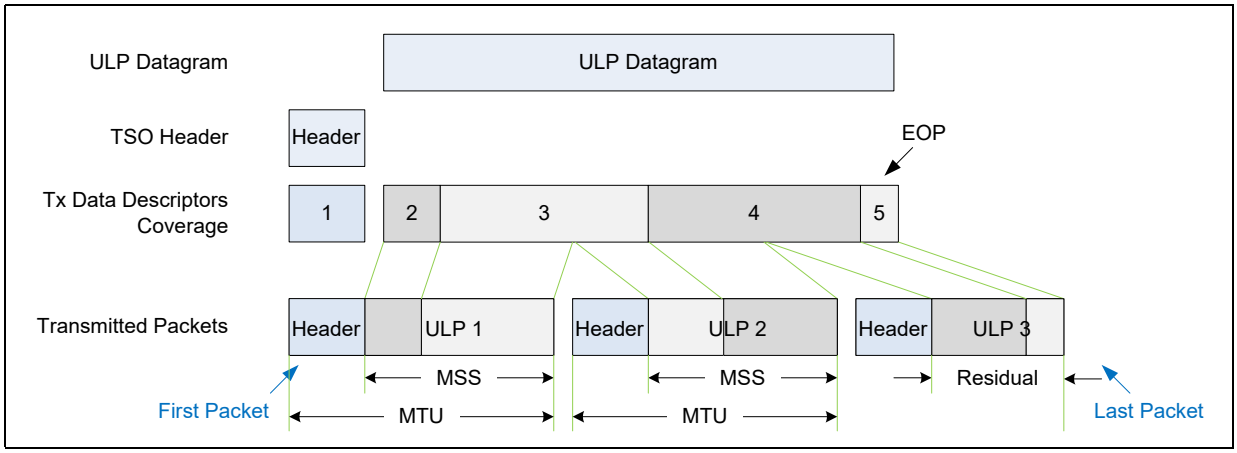
Notes:

1. Common settings to all cases: When context descriptor is used, the TSO flag should be cleared.
2. When IP-IP or other supported tunneling is transmitted, a context descriptor must be used to provide the additional fields types and sizes. For non-tunneled packets the context descriptor might be needed for other offloads than checksum. The values indicated in this table assumes that the context descriptor is used.

38.31.4.3 Transmit Segmentation Offload (TSO)

TSO, also called Large Send offload (LSO) enables the TCP/IP stack to pass to the network device a larger ULP datagram than the Maximum Transmit Unit Size (MTU). The 10 GbE controller divides the large ULP datagram to multiple segments according to the MTU size as shown in the Figure 38-101. The size of the ULP datagram supported for TSO can be as small as a single byte (transmitted on a single segment) and up to 256 KB (2^18) supporting TSO and giant TSO.

Figure 38-101.TSO Functionality (Example)



38.31.4.3.1 Frame Formats and Assumptions

The following packet formats are supported for TSO.

Note: For all the following formats, IP is IPv4 or IPv6 with/without option/extension headers. L4 is TCP.

- IP ≥ L4
- IP ≥ IP ≥ L4
- IP ≥ Teredo ≥ IP ≥ L4

- IP ≥ UDP Tunneling [Key] ≥ MAC ≥ [VLAN] ≥ IP ≥ L4
- IP ≥ GRE [Key] ≥ MAC ≥ [VLAN] ≥ IP ≥ L4
- IP ≥ GRE [Key] ≥ IP ≥ L4

SNAP packet formats are not supported for TSO. The following assumptions apply to the TCP segmentation implementation in the 10 GbE controller:

- TSO is activated by setting the TSO flag in the transmit context descriptor. On top of it, software should follow the data and context descriptor settings for integrity offload as listed in Table 38-436.
- The TSO header (L2, L3 and L4) should be provided by a maximum three descriptors, while still allowed to mix header and data in the last header buffer. The maximum size of the TSO header is 512 bytes.
- The maximum size of a single TSO can be as large as 256 KB minus 1 (defined by the *TLEN* field in the transmit context descriptor).
- The *RS* bit in the data descriptor can be set only on the last data descriptor of the TSO (on which the EOP bit is set).
- It is assumed that the software initializes the pseudo header checksum excluding the TCP length (as opposed to single send on which the pseudo header checksum includes the TCP length).

38.31.4.3.2 Transmit Segmentation Flow

The TSO flow includes the following steps:

- The protocol stack receives from an application a ULP datagram to be transmitted.
- The protocol stack calculates the number of packets required to be transmitted based on the MSS.
- The stack interfaces with the software device driver and passes the block down with the appropriate header information: Ethernet, IP header(s), optional tunneling headers and the L4 header.
- The stack interfaces with the software device driver and commands it to send the entire datagram. The software device driver sets up the interface to the hardware (via descriptors) for segmentation.
- Hardware fetches the segmentation parameters as well as the data and header buffers description by the transmit context and data descriptors.
- Hardware fetches the header and data buffers and then transmits them by segments according to the TSO parameters.
- Dynamic fields set by the software:
  - For IPv4 the IP header checksum should be set to zero.
  - The total *Length* field in the IP header(s) should be set to zero.
  - The IP ID of the first segment to be transmitted.
  - The pseudo header checksum of the TCP header should be calculated and placed as part of the packet data in the TCP or UDP checksum offset.
  - Initial value of the TCP flags (see the sections that follow for its value in the TSO packets).
- Dynamic fields in the IPv4 header(s) that are modified by hardware:
- The total *Length* field should reflect the IP payload size plus the IP header length. The L4 payload size is MSS for all packets but the last one which contains the rest of the data. So for the inner IP header (in case of tunneling), it is the L4 payload +

L4LEN + IPLEN. This is the same rule for the IP header in non tunneling case. For an outer IP header (for tunneling) it equals to: L4 payload + L4LEN + IPLEN + optional L4TUNT length + EIPLEN. Note that for MAC tunneling the length of the outer IP includes the inner L2 header including optional VLAN.

  - The *Identification* field (in the IP header in non-tunneled packets or the inner IP header in tunneled packets) is taken from the TSO header in the first segment and then it is increased by one for each transmitted segment.
  - The *Identification* field (in the external IP header) is taken from the TSO header in the first segment and then it is either increased by one for each transmitted segment or remains constant depending on the EIP_NOINC setting in the transmit context descriptor.
  - The header checksum is calculated after the other parameters in the IP header are updated.

- Dynamic fields in the IPv6 header(s) that are modified by hardware:
  - The payload length should reflect the payload size. It is the MSS for all packets but the last one that contains the rest of the data. The payload length should reflect the IP payload size. So for the inner IP header (in case of tunneling) it is the L4 payload + L4LEN + IP extensions. This is the same rule for the IP header in non-tunneling case. For an outer IP header (in case of tunneling) it equals to: L4 payload + L4LEN + IPLEN + optional L4TUNT length + IP extensions. The IP extensions length equals to IPLEN minus 40 or EIPLEN minus 40 for the inner or external IP headers, respectively. Note that for MAC tunneling, the length of the outer IP includes the inner L2 header including optional VLAN.
- Dynamic fields in the TCP header that are modified by the hardware:
  - The sequence number in the TCP header is taken from the TSO header in the first segment. It is then incremented by MSS for each transmitted segment.
  - The TCP flags are taken from the TSO header. The header is then masked (logic AND) by the *TCPMSKF*, *TCPMSKM* and *TCPMSKL* fields in the GLLAN_TSOMSK_F/M/L global registers. *TCPMSKF* is used for the first segment of the TSO; *TCPMSKL* is used for the last segment of the TSO, and *TCPMSKM* is used for all other segments of the TSO. If the TSO is composed of a single segment, then it is processed the same as the last segment of a multiple segment TSO.
  - The TCP checksum is calculated starting by the initial value (of the pseudo header). The checksum includes the updated TCP header, TCP payload and the calculated TCP length (equals to the payload size plus the TCP header size).
- Dynamic fields in a tunneling UDP header (Teredo or MAC in UDP) that are modified by the hardware:
  - The UDP length reflects the size of the tunneling UDP payload plus 8, which is the size of the UDP header.

38.31.4.3.3 Transmit Arbitration

The 10 GbE controller arbitrates between transmit queues at packet boundaries while enabling each queue to transmit at least pre-defined quanta (as long as the queue is not empty). TSOs are not an exception to this rule. If the queue exhausts its quanta in the middle of a TSO, the 10 GbE controller switches to the next queue in line at the end of the transmitted segment of the TSO. See the Transmit scheduling section for a description of transmit arbitration.

38.31.4.3.4 Segmentation Indication to Hardware

Software indicates a TCP segmentation by a transmit context descriptor just before the data descriptor with the following parameters:

- TSO flag is set, indicating a TSO is requested.
- Insert STag or external VLAN can be set only by the PF (the same as a single send).
- Switch control fields must not be enabled for TSO.
- MSS should be set to the required size of the L4 payload on each segment (MTU minus the size of the headers).
  - MSS outside the range (256 bytes to 9674 bytes) are considered malicious. The respective queue is stopped and an interrupt is issued to the PF. The relevant event is bad LSO MSS.
- TLEN is the total ULP datagram length.
- Other parameters in the data descriptor(s) and the context descriptor are defined the same as a single send.

The data descriptors indicate the TSO header as well as the ULP datagram while following the frame formats and assumptions described in Section 38.31.4.3.1.

38.32 TimeSync (IEEE 1588 and 802.1AS)

38.32.1 Overview

Measurement and control applications are increasingly using distributed system technologies such as network communication, local computing, and distributed objects. The 1588 standard enables accurate synchronization between clocks on distributed systems.

The 10 GbE controller includes 1588 logic per LAN port; the logic is enabled by the TSYNENA flag in the PRTTSYN_CTL registers per port. The PFs can access only the 1588 registers of a port. All PFs on a given port can access the 1588 registers while only one PF is expected to control the logic. The PF ID that owns the 1588 logic of the port is reflected by the PF_ID in the PRTTSYN_CTL0 registers per port. All PFs are permitted to read the 1588 timer registers (on the port they belong).

Software Note: The PF_ID field has no impact on the hardware; it is used only by the software. The field is expected to be loaded from the NVM or set by a management agent. During normal operation the PF software driver is not expected to change the field's setting.

The synchronized clock (PRTTSYN_TIME) is a 96-bit register (per LAN port). Out of it, the upper 64 bits are used for timestamp sampling and synchronized events described later in this section. Tune this register so that the upper 64 bits are defined in ns units. The register then can define the absolute time relative to PTP epoch, which is January 1st 1970 00:00:00 International Atomic Time (TAI).

38.32.1.1 1588 Registers

All 1588 registers are supported per port.

Many 1588 registers are 64 bits wide. The 10 GbE controller provides a 32-bit interface. Therefore, accessing these registers require multiple slave accesses.

- Reading any 64-bit register, software should access the LS register first and then the MS register. Specifically relating to dynamic registers: reading the LS register, the hardware latches internally the value of the MS register until it is fetched as

well. Included in this category are: PRTTSYN_TIME; PRTTSYN_RXTIME; PRTTSYN_TXTIME; PRTTSYN_INC; PRTTSYN_TGT and PRTTSYN_EVNT registers.

- Writing to any 64-bit registers. Software should write the LS register first and then the MS register. Only after writing the MS register is the value latched internally. Included in this category are: the PRTTSYN_TIME, PRTTSYN_INC, PRTTSYN_TGT, and PRTTSYN_EVNT registers. Writing to the PRTTSYN_TIME (*_L and *_H) registers, the device also clears the additional internal lowest 32 bits (usually used for sub ns units). Note that this sub ns register is internal, and not exposed to the software.

38.32.2 Time Synchronization Flow

The operation of a 1588 logic is based on Precision Time Protocol (PTP). This protocol is composed of two stages: initialization and time synchronization. These stages are described in the sections that follow emphasizing hardware and software roles.

38.32.2.1 Initialization Phase

If enabled as a potential master (by a software setting), software transmits sync packets that include the master's clock parameters periodically. Upon receipt of a sync packet, software on any potential master compares the received clock parameters to its own parameters. If the received parameters are better, software transitions to a slave state and stops sending sync packets.

While in a slave state, software selects a particular master. Software continuously compares the received sync packet to its selected master. If the received sync packet belongs to a different master with better clock parameters, software switches to the new master. Eventually only one master (with the best clock parameters) remains active while all other nodes act as slaves listening to the single master.

Every node has a defined time-out interval. If no sync packets are received from the selected master each slave, software switches back to the initialization phase until a new master is chosen. Note that there are more than one option for the previous flow while there are other flows that are based on static master setting. The node can be set statically to a master or slave modes. While in slave mode, the node can be tuned statically to a specific master.

38.32.2.2 Time Synchronization Phase

There are two phases to the synchronization flow:

1. The slave calibrates its clock to the master.
2. The master performs complete synchronization.

38.32.2.2.1 Clocks Calibration

The master sends sync packets periodically (about of 10 packets per second). These packets are followed by Follow_UP packets that indicate the transmission time. The slave captures the reception time of the sync packet so it holds the packet transmission time at the master and its reception time at the slave. Receiving consecutive sync packets, the slave gets the delta T of the master and can calibrate its timer to get the same delta T. During this phase, the slave starts with an initial time calibration that can be used as the transmission delay between the master and the slave.

In order to minimize sampling inaccuracy, both master and slave sample the packets transmission and reception time at a location in the hardware that has as much as possible deterministic delay from the PHY interface.

- Software hardware flow in the master — Sending the sync packet by the master, software indicates this packet to the hardware by setting the TSYN flag in the transmit context descriptor. Setting this flag, hardware samples its transmission time using the PRTTSYN_TXTIME register. After transmission, software should read the PRTTSYN_TXTIME register and sent the transmission time in a Follow_Up packet (according to a two-step flow). Note that software is responsible to read the PRTTSYN_TXTIME register before initiating another packet with an active TSYN flag.
- Software hardware flow in the slave — The sync packet is received by the slave and its reception time is sampled using one of four PRTTSYN_RXTIME registers. The index of the register that sampled the reception time is reported in the *TSYNINDX* field in the receive descriptor. The PRTTSYN_RXTIME register holds the reception timestamp until software reads it. It is then released for sampling another packet reception.

38.32.2.2.2 Time Synchronization Phase

The complete synchronization scheme is shown in Figure 38-102. It relies on measured time stamp of sync packets transmission and reception by the master and the slave. The scheme is based on two assumptions:

- The clocks at both nodes are almost identical (achieved in the first step).
- Transmission delays between the master to the slave and backward are symmetric.

  The master's software sends periodic sync packets to each slave followed by a Follow_Up packet, as explained in the software hardware flow in the master for the clocks calibration phase). The slave samples the TSYN packet reception time in one of the PRTTSYN_RXTIME registers.

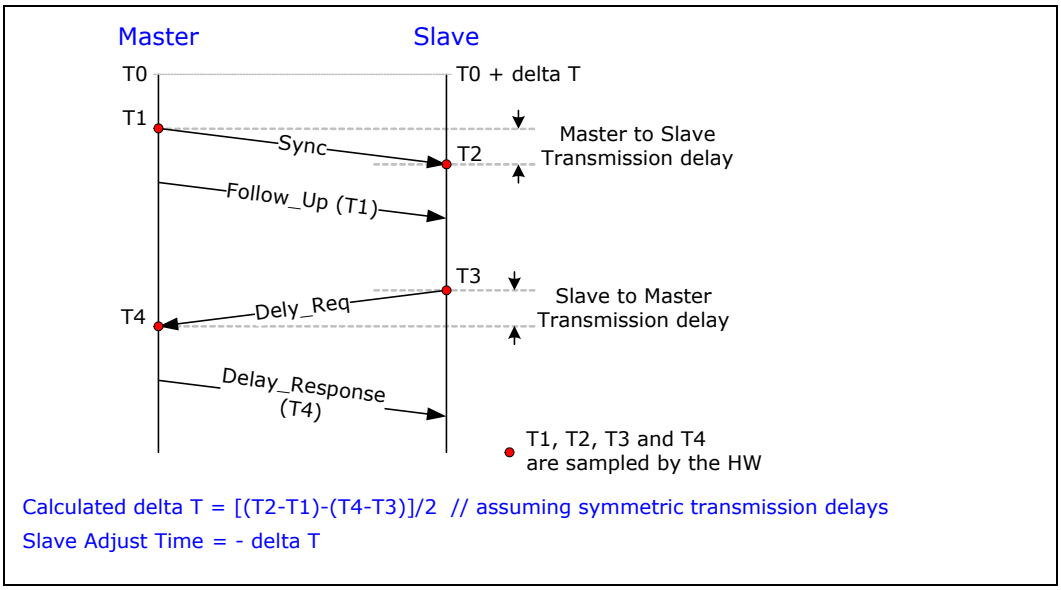
The slave responds, sending a Delay_Request packet to the master. Hardware in the slave samples its transmission time in the PRTTSYN_TXTIME register and hardware in the master samples its reception time in one of the PRTTSYN_RXTIME registers. Software in the slave checks the Delay_Request packet transmission time (reading the PRTTSYN_TXTIME register) and could optionally send a Follow_Up packet that includes the captured transmission time. The master responds back with the Delay_Response packet reporting the reception time of the Delay_Response to the slave. At this point, the slave has all the following parameters (the following notations match the notations used in Figure 38-102):

- T1 — Sync packet transmission time in the master (based on master clock).
- T2 — Sync packet reception time in the slave (based on slave clock).
- T3 — Delay_Request transmission time in the slave (based on slave clock).
- T4 — Delay_Request reception time in the master (based on master clock).

The Slave can adjust its clock using the following equation:

- Slave adjust time = - [(T2-T1) - (T4-T3)] / 2.

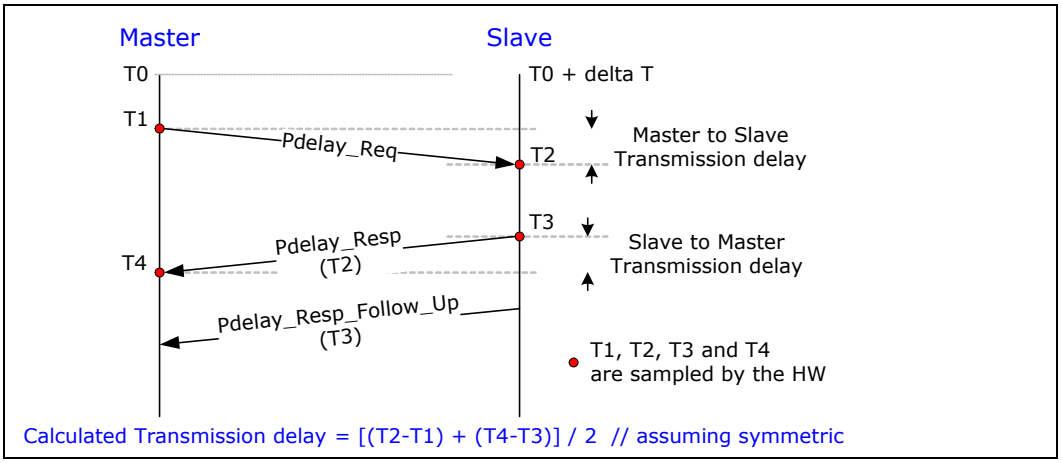
Figure 38-102.Sync Flow and Offset Calculation



PDelay Flow for Dynamic Master Selection

The master sends a Pdelay_Req packet to the slave and the slave response by sending back a Pdelay_Resp packet followed by a Pdelay_Resp_Follow_Up packet. The master uses these packets to calculate the link delay. This process is also used for fast recovery when the master is changed. The process is usually enabled when dynamic master selection is enabled. It can operate asynchronous to the time synchronization flow previously described. Figure 38-103 shows the PDelay flow.

Figure 38-103.PDelay Flow



38.32.3 Time Stamp Indication

Relevant packet transmission time (as sync and Delay_Request) are sampled by hardware at a deterministic as possible affinity to the PHY interface. The sampled time is taken at the beginning of the packet (packet size does not matter) as shown. The latency between packet time sampling and packet on the Ethernet interface pins is listed in Table 38-437.

Figure 38-104.Time Stamp Point

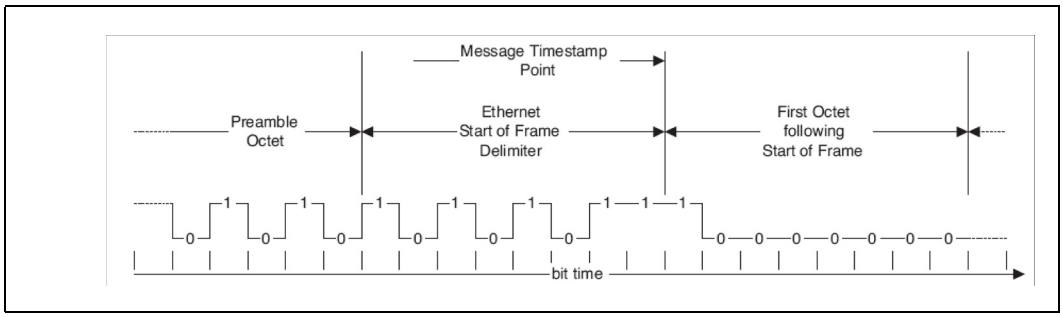


Table 38-437.Packet Time Stamp Latency

Link Speed	Interface	Time Stamp to Packet Transmission Latency	Packet Reception to Time Stamp Latency
10 GbE	KR / SFI		
1 GbE	KX		

38.32.3.1 Transmit Time Stamp

Software indicates to hardware the packets to be sampled by setting the *TSYN* bit in the transmit context descriptor. Hardware samples the transmission time of packets with an active *TSYN* bit, enabled for the queue by the TSYNENA flag in the transmit queue context. The transmission time stamp is sampled in the PRTTSYN_TXTIME register. It is software's responsibility to read the PRTTSYN_TXTIME_L and PRTTSYN_TXTIME_H registers before sending another packet with an active *TSYN* bit.

Note that in order to use the TSYN flag in the transmit descriptor, the TSYNENA flag should be set in the transmit queue context. Software should set the TSYNENA flag only for PF queues so VFs cannot interfere with TimeSync functionality. Software should limit this enablement on a single PF per port that is assigned to control the 1588 logic.

38.32.3.2 Receive Time Stamp

The 10 GbE controller identifies received PTP event packets as described in Section 38.32.9. PTP packet reception time is sampled by one of four PRTTSYN_RXTIME[n] registers per port, which is found free. Such packets are posted to LAN queues with active an 1588 TS Index (TSYNINDX) field in the receive descriptor.

TSYNINDX is the index of the PRTTSYN_RXTIME register that contains the packet reception time stamp. Once a PRTTSYN_RXTIME register samples a packet reception time, the register is locked until software reads its value. When accessing this register software should read first the PRTTSYN_RXTIME_L[n] register and then the PRTTSYN_RXTIME_H[n] register. Following read accesses to the PRTTSYN_RXTIME register, the lock is released and the register becomes free again.

Note that PRTTSYN_RXTIME registers are not accessible to any of the VFs (so they cannot interfere with the proper functionality). PRTTSYN_RXTIME are 64-bit registers that capture the upper 64 bits of the PRTTSYN_TIME register that belong to the LAN port on which the PTP packet was received (accessible to software by 2 x 32-bit accesses).

38.32.4 1588 Clock Registers

The clock driving the time sync elements is the MAC clock on the port. The MAC clock frequency depends on the link speed (Table 38-438). After a change in link speed the PRTTSYN_INC register should change accordingly. Note that software is responsible for this setting.

Table 38-438.PRTTSYN_INC as a Function of MAC Clock Frequency

Link Speed	MAC Clock Frequency	Sampling Clock Precision	Recommended PRTTSYN_INC Defining The 64 MS Bits Of PRTTSYN_TIME In ns Units
40 Gb/s	625 MHz	± 0.8 ns	6871947673 (0x199999999)
10 Gb/s	312.5 MHz	± 1.6 ns	13743895347 (0x333333333)
1 Gb/s	31.25 MHz	± 16 ns	137438953472 (0x2000000000)

The PRTTSYN_TIME is a 96-bit register holding the synchronized clock while its upper 64 bits are meaningful to software accessible by 2 x 32-bit accesses. Each MAC clock, the PRTTSYN_TIME is increment by PRTTSYN_INC. The lower 32 bits of the PRTTSYN_TIME register are internal, not accessible to software.

PRTTSYN_INC is a programmable 38-bit register accessible to software by 2 x 32-bit accesses (the upper 26 bits of this register are reserved and set to zero). When updating this register, software should set first the PRTTSYN_INC_L register and then the PRTTSYN_INC_H register. Hardware updates the internal value of the PRTTSYN_INC only after these two write cycles.

Software in slave mode adjusts PRTTSYN_TIME in order to track the 1588 timer of the master using one of two methods:

- Direct write access to the upper 64 bits of the PRTTSYN_TIME register. This step can be useful for an initial setting of the time during the clocks calibration phase.
- Fine adjustment during the 1588 time synchronization phase using the PRTTSYN_ADJ register. The PRTTSYN_ADJ register is composed of a SIGN flag and *TSYNADJ* field that defines the absolute value of the adjustment. The *TSYNADJ* value is defined in the units of the PRTTSYN_TIME_L. The PRTTSYN_TIME is updated iteratively by the PRTTSYN_ADJ together with the nominal INC value on each MAC clock as shown:

```
If (TSYNADJ = 0) then:

PRTTSYN_TIME += PRTTSYN_INC

Else then:     // TSYNADJ is not equal to zero

If positive adjust (SIGN=0) then: PRTTSYN_TIME += PRTTSYN_INC + 2^32

Else : PRTTSYN_TIME += PRTTSYN_INC - 2^32

TSYNADJ -= 1
```

38.32.5 Synchronized Auxiliary Events

The 10 GbE controller supports the following global auxiliary events for all ports:

- Synchronized events to global I/O signals are described in Section 38.32.5.1.
- Synchronized events to PCI slave access are described in Section 38.32.6.1

38.32.5.1 Auxiliary 1588 I/O Signals

The 10 GbE controller supports 30 global GPIO signals that are controlled by 2 PRTTSYN_AUX[n] registers (n = 0,1). GPIO 'n' functionality is controlled by the GLGEN_GPIO_CTL[n] register (expected to be loaded from the NVM). GPIOs can be assigned to 1588 of a specific LAN port by the PRT_NUM and PIN_FUNC fields in the GLGEN_GPIO_CTL register. Setting the PIN_FUNC field to *Timesync 0* or *Timesync 1* assigns the GPIO to PRTTSYN_AUX[0] or PRTTSYN_AUX[1], respectively.

GPIO signals are set to input or output by the PIN_DIR field in the GLGEN_GPIO_CTL registers. When set to input signal the sampling event is sampled by the PRTTSYN_EVNT[n] registers ('n' is the matched index to the PIN_FUNC field). When set to output signal, the output event time is defined by the PRTTSYN_TGT[n] register ('n' is the matched index to the PIN_FUNC field).

There are several output modes of operation as described in the sections that follow. In any of them, the initial state of the GPIO output level can be controlled by setting the INSTNT and the OUTLVL flags in the PRTTSYN_AUX[n] register. All the output modes are enabled by the OUT_ENA flag in the PRTTSYN_AUX[n] register. There are also several input modes of operation controlled by the *EVNTLVL* field in the PRTTSYN_AUX[n] register.

Synchronized level output — This mode is selected by setting the PRTTSYN_AUX[n].OUT_ENA, setting the PRTTSYN_AUX[n].OUTMOD field to output level mode and the event time is defined by the matched PRTTSYN_TGT[n] register. When the upper 64 bits of the PRTTSYN_TIME crosses the value of the PRTTSYN_TGT[n], the assigned GPIO transits to the requested level defined by the PRTTSYN_AUX[n].OUTLVL.

Synchronized flipped output signal — Defined by the PRTTSYN_TGT[n] and PRTTSYN_AUX[n] registers similar to the synchronized level output mode. The only difference is that for flipped output, the *OUTMOD* field should be set to flipped output mode. In this case, each time the upper 64 bits of the PRTTSYN_TIME crosses the value of the PRTTSYN_TGT[n] the I/O signal flips its output level.

Synchronized output pulse — Defined by the PRTTSYN_TGT[n] and PRTTSYN_AUX[n] registers similar to the synchronized level output mode. The only difference is that the *OUTMOD* field should be set to output pulse mode. In this case, each time the upper 64 bits of PRTTSYN_TIME crosses the value of PRTTSYN_TGT the GPIO signal flips its output state for 16 x PRTTSYN_AUX.PULSEW plus 1 MAC clock and then reverts back to its previous level.

Synchronized clock output — Defined by the PRTTSYN_TGT[n] and PRTTSYN_AUX[n] registers similar to the synchronized level output mode with the following changes: The *OUTMOD* field should be set to output clock mode and the matched PRTTSYN_CLKO[n] register should be set to 50% of the required output clock duration. Each time the upper 64 bits of the PRTTSYN_TIME crosses the value of PRTTSYN_TGT the GPIO signal flips its output level. Then, the PRTTSYN_TGT register is reloaded by hardware to PRTTSYN_TGT[n] plus PRTTSYN_CLKO[n] (while PRTTSYN_CLKO is padded by 32 MS bit zero's). Note that for proper operation the PRTTSYN_CLKO must be larger than PRTTSYN_INC + 2^{32} and for reasonable accuracy the PRTTSYN_CLKO should be significantly larger than PRTTSYN_INC + 2^{32}.

Sampling input event — The 10 GbE controller can capture the time on which an event is sensed on any of the 1588 auxiliary signals. The event time is captured by one of two matched 64-bit event time registers named PRTTSYN_EVNT[n]. The sampled input event type is defined by the *EVNTLVL* field in the PRTTSYN_AUX[n] register, equals to one of the following options: disable, rising edge, falling edge, or any transition. When

the defined transition is sampled by hardware (synchronized to the MAC clock), the upper 64 bits of PRTTSYN_TIME are latched by the matched PRTTSYN_EVNT[n] register. Once the event is sampled, the PRTTSYN_EVNT register is locked, keeping the event time until software reads it.

38.32.6 Synchronization with Host Timer

The time relationship between the CPU time and devices within the system is a key element in many applications. Specifically, the relationship with the 1588 clock is critical. The following sub-section describes the mechanism to measure this relationship.

38.32.6.1 1588 PCI Slave Access

Following a write access to PRTTSYN_AUX[n] while setting the SAMPLE_TIME flag, hardware samples PRTTSYN_TIME to the matched PRTTSYN_EVNT[n] register (the upper 64 bits of the PRTTSYN_TIME). This functionality can be useful to synchronize between a system timer accessible to the CPU and PRTTSYN_TIME.

38.32.7 Interrupts

The 10 GbE controller can trigger an interrupt on any GPIO regardless of whether it is enabled for 1588 functionality. In addition, the 10 GbE controller can generate a 1588 interrupt for one of the following events (if enabled by the TIMESYNC flag in the PFINT_ICR0_ENA register):

- Packet transmission time is latched by the PRTTSYN_TXTIME registers while this interrupt is enabled by the TXTIME_INT_ENA flag in the PRTTSYN_CTL0 register.
- Input event is latched by one of the PRTTSYN_EVNT registers while this interrupt is enabled by the EVENT_INT_ENA flag in the PRTTSYN_CTL0 register.
- One of the time registers has expired while this interrupt is enabled by the TGT_INT_ENA flag in the PRTTSYN_CTL0 register (a target time register expires when the PRTSYN_TIME register is larger or equal than the target time register).

Regardless of interrupt enablement, the previous events are reported in the PRTTSYN_STAT_0 and PRTTSYN_STAT_1 registers. Following an interrupt assertion, software should read these registers to identify the cause. The registers are cleared on read, so they report an updated status since the last time they were read by software.

38.32.8 1588 Initialization Flow

This section describes the PF software initialization flow required to activate the 1588 logic.

- Check the PF_ID in the PRTTSYN_CTL0 register if the PF is expected to control the 1588 logic.
- The 1588 CSRs are initialized by global reset that might not be triggered by a PCI reset. Therefore, PF software is required to initialize most of the 1588 registers listed in the TimeSync (IEEE 1588) registers section:
  - Set PRTTSYN_CTL0 and PRTTSYN_CTL1 to the required 1588 packet type as well as required interrupt functionality.
  - Clear any optional residuals reported in the PRTTSYN_STAT register.
  - Read all receive time stamps releasing them for normal operation (PRTTSYN_RXTIME registers).

  - — Set the PRTTSYN_AUX register as required for the AUX functionality.
  - — The timer and the increment values are expected to be programmed as part of normal operation (PRTTSYN_TIME and PRTTSYN_INC registers).
- Assign a transmit queue for 1588 transmission and enable the TSYNENA flag in its queue context.
- Optionally assign a receive queue. The Ether-type classification filter can be used to direct layer 2 or UDP 1588 packets to a specific LAN receive queue.

38.32.9 PTP Packet Recognition

The time sync implementation supports both the 1588 Version 1 (V1) and Version 2 PTP frame formats (V2). The V1 structure is expected only as UDP payload over IPv4 while the V2 is expected over L2 with its Ether-type or as a UDP payload over IPv4 or IPv6. Note that the 10 GbE controller accepts the expected packet formats but does not enforce these UDP/IP rules.

The 802.1AS uses only the layer 2 V2 format. Note that PTP frame structure is not supported in the 10 GbE controller for tunneled packets. The layer 2 packet format and UDP packet format are shown in Figure 38-105. The PTP message V1 and V2 formats are shown in Figure 38-440. The packet format supported by the 10 GbE controller for receive time stamp is controlled by the parameters shown in Figure 38-439.

Note: Correct UDP checksum is not a criteria for PTP packets recognition by the 10 GbE controller. Still, such a packet is reported to software with a checksum error. Software can ignore the packet, but should read the register that carries the time stamp to release it for upcoming packets.

Note: The 10 GbE controller does not recognize tunneled PTP packets.

Table 38-439.Receive Time Stamp Control Parameters

Parameter	Register	Functionality
TSYNTYPE	PRTTSYN_CTL1	Controls which packets are sampled by the 1588 logic. It can be one of the following: • L2 version 2 packets while message type is defined by the PRTTSYN_CTL1 register. • UDP version 1 packets while the UDP ports are defined by UDP_ENA and message type is defined by the PRTTSYN_CTL1 register. • L2 and UDP version 2 packets while UDP ports and message type are defined as previously detailed. • L2 and UDP version 2 event packets while UDP ports are defined by the UDP_ENA and the message type < 8.
UDP_ENA	PRTTSYN_CTL1	Enable the UDP port numbers that are recognized as 1588 packets. It could be one of the following options: • No UDP packet recognition. • UDP port number equals 0x013F. • UDP port number equals 0x0140. • UDP port numbers equals either 0x013F or 0x0140.
V1MESSTYPE0, V1MESSTYPE1	PRTTSYN_CTL1	Controls the PTP V1 message type for sampled time stamp.
V2MESSTYPE0, V2MESSTYPE1	PRTTSYN_CTL1	Controls the PTP V2 message type for sampled time stamp.

38.33 Software Timer

The 10 GbE controller includes a 32-bit counter in the GLVFGEN_TIMER register that is based on a free running 1 µs clock. The counter is cleared by Core Reset (CORER) and increments after being cleared. The timer wraps around in about 70 minutes.

38.34 Protocol Engine (PE)

38.34.1 PE Overview

The Protocol Engine (PE) adds Remote Direct Memory Access (RDMA) capabilities to the traditional LAN functionality found in standard NICs. RDMA is a networking performance optimization that enables servers to communicate across a network using high-performance, low-latency, zero-copy DMA semantics. It is designed to reduce host CPU use, host memory bandwidth used for network traffic, and network latency when compared to traditional networking stacks such as sockets with TCP/ IP. Following are some of the RDMA capabilities provided by PE:

- Secure, direct access to PE hardware for user space or kernel applications
  - — Supported in VM environments using SR-IOV
- Translation Protection Table (TPT)
  - — Similar to a CPU Memory Management Unit (MMU)
  - — Enables definition of > 1 M memory regions
  - — A memory region is a virtually or logically contiguous area of application address space registered with the operating system. An enabled memory region enables the PE to perform DMA access for local and (optional) remote requests, and enables user space applications to specify buffers in virtual address space.
  - — 100 M+ virtual-to-physical page translations
- Reliable Connection Transport
  - — 100 K+ connections, analogous to a DMA engine with 100 K+ channels
  - — Sequence number checks
  - — Acknowledgment
  - — Dynamic congestion control
  - — Retransmission
  - — Timers
- IP routable RDMA

38.35 Features

Table 38-442 lists the PE feature set.

Table 38-442.PE features

Category	Description
General	**RDMA Protocol Support (Baseline)** Support for either iWARP or RoCE v2 (both protocols are not simultaneously available). Configure either iWARP or RoCE v2 from the NVM.
General	**RDMA Protocol Support (Enhanced)** Simultaneous support for both iWARP and RoCE v2.
General	**Ethernet Ports Supported** Support for 4 Ethernet ports with 8 TCs, or 8 Ethernet ports with 4 TCs.
General	**IP Version** Support both IPv4 and IPv6 offloaded RDMA connections.
General	**ARP Table** Supports a unique ARP table instance with up to 65536 entries per PCI function (PF or VF). Each entry contains a six byte Ethernet address, plus control/status information for neighbor reachability detection. The ARP table supplies a destination Ethernet address for all transmitted RDMA packets.
General	**IP Datagrams / Fragmentation** RDMA IP datagrams are never transmitted with fragmentation. RDMA IPv4 datagrams are always transmitted with the *Don't Fragment* flag set and the *Fragment Offset* field set to 0b. Received RDMA IP datagram fragments are sent to the LAN stack and not processed by the RDMA offload engine.
General	**Per vPort RDMA Statistics** Implement one set of RDMA statistics for each RDMA-enabled VSI. For example, if the IP supports 8 PCIe PFs and 32 PCIe VFs, then it must implement 40 sets of RDMA statistics.
QP	**Max QP Count** Supports 256 K queue pairs for RDMA that are dynamically assigned to PCI functions at runtime by PE firmware.
QP	**Work Queue Elements (WQEs) - Baseline** These WQE properties are supported: Similar WQE format for SQs and RQs. Each iWARP WQE can vary in size from 1 to 7 fragments, with these corresponding sizes: 32 bytes, 48 bytes, 64 bytes, 80 bytes, 96 bytes, 112 bytes, 128 bytes. Each RoCE WQE can vary in size from 1 to 5 fragments, with these corresponding sizes: 64 bytes, 80 bytes, 96 bytes, 112 bytes, 128 bytes. Fragments are specified with virtual addresses and are virtually contiguous. The PE performs virtual-to-physical translation using its built-in Memory Management Unit (MMU). An iWARP SQ WQE can optionally directly convey 112 bytes of in-line data for small message latency optimization. A RoCE SQ WQE can optionally directly convey 80 bytes or more of in-line data for small message latency optimization.
QP	**Work Queue Elements (WQEs) - Enhanced** Support the features defined by Work Queue Elements (WQEs) - Baseline plus increase the max WQE size from 128 bytes to 256 bytes. This could enable a larger number of fragments per WQE, or a larger amount of in-line data for small message latency optimization. This enhancement appears more valuable on the SQ than the RQ, and might be implemented only on the SQ side. Send queue push mode support is required.
QP	**Work Queues (WQs)** RDMA WQs are mapped into host memory as physically or virtually contiguous ring buffers. Maximum WQ size is 16 K entries x 32 bytes = 512 KB. Maximum WQ depth is configurable on a per-WQ basis. Supported values range from 4 to 16 K 32 bytes WQEs, in power-of-two increments. Dynamic WQ resizing is not supported.
QP	**SQ Operations (baseline)** Support for these baseline SQ operations: Send, Send with Invalidate, Send with Solicited Event, Send with Solicited Event and Invalidate, RDMA Write, RDMA Read (iWARP-style single local SGE), RDMA Read with Local Invalidate (iWARP-style single local SGE), Bind Memory Window, Fast-Register Memory Region, Invalidate Local STag. These operations operate with either iWARP or RoCE v2, except the iWARP-style RDMA Reads, which are iWARP-only.
QP	**SQ Operations (RDMA Write with Immediate Data)** Support for RDMA write with immediate fata. CQE and SQ WQE formats enable 8 bytes of immediate data for both iWARP and RoCE. For iWARP, 8 bytes of immediate data is conveyed on the network. For RoCE, only 4 bytes of immediate data is conveyed on the network.

Table 38-442.PE features

Category	Description
QP	**SQ Operations (RDMA Read special)** Support RDMA read (IB-style with multiple local SGEs). For RoCE v2, this is the only form of RDMA read. iWARP must support all three RDMA read operation types simultaneously on a given QP: RDMA read (iWARP-style single local SGE), RDMA read with local invalidate (iWARP-style single local SGE), RDMA read (IB-style with multiple local SGEs).
QP	**SQ Operations (Send with Immediate)** Support Send with Imm, Send with Inv and Imm, Send with SE and Imm, Send with Inv and SE and Imm
QP	**Number of RDMA Reads** The number of outstanding inbound RDMA reads, defined by Inbound RDMA Read Queue Depth (IRD) is configured independently per QP. These IRD settings are supported: 2, 8, 32, 64, 128, 256. IRD cannot be modified after the QP has been created. The number of outstanding outbound RDMA reads, defined by Outbound RDMA Read Queue Depth (ORD), is also configured independently per QP. These ORD settings are supported: 0 to 127255, in single-step increments. ORD can be modified after the QP has been created, if the proper quiesce conditions are met.
QP	**Send Queue Push Mode** This device supports send queue *Push Mode*. In this mode, the host CPU writes or pushes SQ WQEs with *inline data* to the device memory-mapped address space using CPU write-combining buffers. Each of the device's PCIe PFs must support up to 1024 separate 4 KB push pages. Each of the device's RDMA-enabled VFs must support 16 4 KB push pages. The push pages are typically exposed through an extension of the memory BAR that contains the CSRs. PF push pages must be assignable to VMs via device firmware in para-virtualized driver models.
CQ	**Completion Queues** Supports up to 131072524288 CQs that are dynamically assigned to PCI functions at runtime by device firmware. A CQ/ring buffer can be either virtually or physically contiguous. Each CQE is 32 bytes, and can optionally be padded to a 64-byte cache-line boundary to avoid memory conflicts. Max CQ size is 1 M entries x 32 bytes = 32 MB (or 64 MB if optional 64 byte CQE size is used). Supports user-defined mapping of WQs to CQs. Supports CQ resizing, CQ size can be increased or decreased while the CQ is active. Supports CQ overflow detection.
EQ	**Completion Event Queues (CEQs)** Supports 256 CEQs for RDMA that are dynamically assigned to PCI functions at runtime by device firmware.
EQ	**Asynchronous Event Queues (AEQs)** Supports 48 AEQs for RDMA that are dynamically assigned to PCI functions at runtime by PE firmware.
MMU	**Protection Domains** Each PCIe PF or VF enabled to use RDMA can define up to 32256 K protection domains.
MMU	**Memory Regions and Windows** Each PF or VF enabled to use the PE can allocate up to 4 M (like 2^{22}) memory regions or memory windows. The maximum size of a single memory region or memory window matches the maximum virtually mapped memory supported per PF or VF.
MMU	**Wide Memory Windows** Support wide memory windows for both iWARP and RoCE. Wide memory windows have protection domain scope, whereas standard iWARP memory windows have QP scope.
MMU	**Host Memory Page sizes (baseline)** Host memory page sizes supported: 4 KB, 2 MB. Each memory region can be independently configured for either page size.
MMU	**Host Memory Page sizes (enhanced)** Includes everything in baseline, plus support for 1 GB host memory page size.
MMU	**Physical Buffer List (PBL)** Each RDMA memory region can be physically mapped (such as the region is physically contiguous in host memory) or virtually mapped with a one- or two-level PBL. Each RDMA-enabled PF or VF can allocate up to 256 M (like 2^{28}) PBL entries. A single PBL entry maps a single host memory page.
MMU	**Maximum Virtually Mapped Memory (baseline)** The maximum virtually mapped memory a single PF or VF can register for RDMA is implementation limited to 2^{45} bytes = 32 TB. The maximum might be further reduced depending on host page sizes used. For example, if a PF or VF allocates it's maximum limit of 256 M PBL Entries, then... ...its maximum virtually mapped memory using 100% 2 MB host memory pages is: MIN(2^{45}, 2^{21} x 2^{28}) = 2^{45} bytes = 32 TB ...its maximum virtually mapped memory using 100% 4 KB host memory pages is: MIN(2^{45}, 2^{12} x 2^{28}) = 2^{40} bytes = 1 TB

Table 38-442.PE features

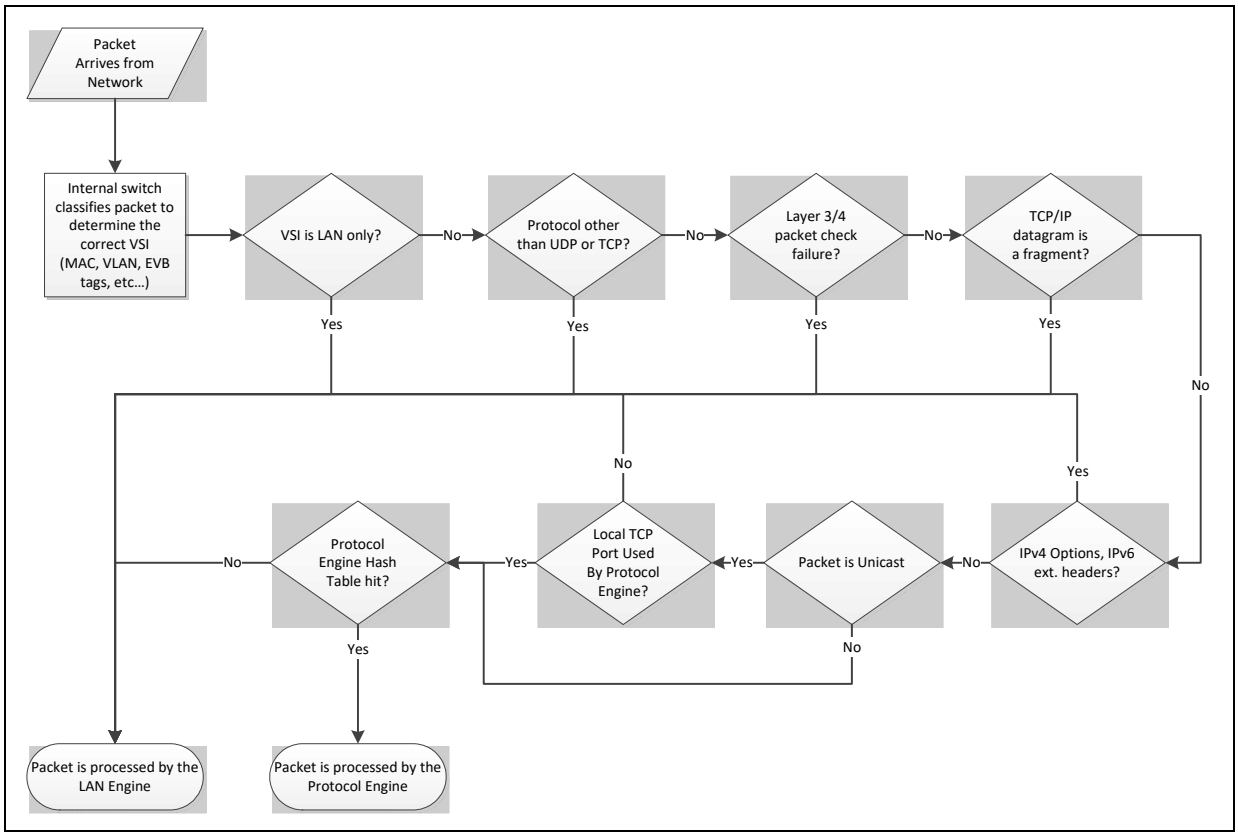
Category	Description
MMU	**Maximum Virtually Mapped Memory (enhanced)** The maximum virtually mapped memory a single PF or VF can register for RDMA depends on host page sizes used. The following examples show this for different page sizes. Supported page sizes are defined elsewhere, and some of these examples might not be relevant. If a PF or VF allocates it's maximum limit of 256 M PBL entries, then... ...its maximum virtually mapped memory using 100% 1 GB host memory pages is: 2^{30} x 2^{28} = 2^{58} bytes = 256 PB ...its maximum virtually mapped memory using 100% 2 MB host memory pages is: 2^{21} x 2^{28} = 2^{49} bytes = 512 TB ...its maximum virtually mapped memory using 100% 4 KB host memory pages is: 2^{12} x 2^{28} = 2^{40} bytes = 1 TB
UD	**Address Handles** Supports {minimum 64K, target 256K} Address Handles per PCIe function.
iWARP	**Standards Compliance** IETF RFC 5040, 5041, 5042, 5044, 6580, 6581, 7306 RDMA Consortium Verbs
iWARP	**Receive Window Size** Each RDMA connection has a configurable Receive Window with maximum size of 1GB-1B.
iWARP	**Non-permissive IETF RNIC** Using a term coined in IETF RFC 5044, this device is a Non-permissive IETF RNIC (an RNIC that implements the IETF protocols but not the RDMAC protocols)
iWARP	**MPA - Baseline support** Support all of the following: Insertion of Transmit markers (can be enabled/disabled per QP). MPA CRC generation for outbound iWARP packets. Transmit up to four FPDUs in a single Ethernet packet. Able to transmit partial FPDUs when there is outstanding (un-acknowledged) data and an MSS change occurs. MPA CRC checking on inbound packets (can be enabled/disabled per QP). Process received Ethernet packets with any number of iWARP FPDUs (bounded by max packet size). Support for detection/handling of received partial FPDUs. Drop out-of-order received FPDUs without ACKing the TCP segment containing them.
iWARP	**MPA - place out-of-order received FPDUs** Support a per-QP setting to configure either 1 or 2 below: 1. Drop out-of-order received FPDUs without ACKing the TCP segment containing them 2. Placement of out-of-order received MPA FPDUs, with one restriction: An out-of-order received MPA FPDU with Send opcode will only be placed if it targets a non-shared RQ with dedicated CQ.
RoCE	**Standards Compliance** InfiniBand Architecture Specification Volume 1 Release 1.3 (support the subset of this specification that applies to RoCE v2) InfiniBand Architecture Specification Annex A17: RoCE v2 Sept 2014

38.36 Functional Description

38.36.1 Packet Classification and the PE

The 10 GbE controller provides several filtering checks that can be used to distinguish LAN traffic that should be handled by the PE from other LAN traffic. The first mechanism that can be used to direct a packet to be processed by the PE is to set the PETCP_ENA bit in the VSIQF_CTL register. Additionally all unicast or multicast UDP traffic might be forwarded to the PE by setting the PEUUDP_ENA and/or PEMUDP_ENA bits in the VSIQF_CTL register. The internal switching components including this special setting are used to identify a Virtual Station Interface (VSI). Once the VSI has been identified, the checks shown in Figure 38-107 determine if a packet is processed by the PE.

Figure 38-106.PE Packet Classification



Once the internal switch packet classification has been performed, the following checks must be passed before a packet is processed by the PE:

1. The VSI configuration option that enables traffic to be routed to the PE must be enabled.
2. The packet must be a protocol that is supported by the PE. The current protocols that the PE is capable of handling are TCP/IP and UDP/IP. Multicast and unicast packets are supported for UDP/IP.
3. Additional checks to validate the IP and TCP or UDP headers must succeed.
4. If the packet is an IP packet it must not be a fragmented IP datagram.
5. The destination port of the TCP or unicast UDP packet header must have its associated bit set in the Accelerated Port Bit Vector Table (APBVT). APBVT is described in Section 38.36.3.5.5.
6. The packet is then sent through a hash table lookup and must be found. The fields from the packet that are used for the lookup vary based on the packet contents. TCP/IP packets that do not have the SYN bit set or have the SYN bit set and ACK bit set use the combination of destination MAC address, VLAN tag if present, source and destination IP addresses and the source and destination port fields. TCP/IP packets with the SYN bit set and ACK bit clear or unicast UDP/IP packets use the destination MAC address, VLAN tag if present, destination IP address and destination port. See Section 38.36.3.5.7 for more details on the PE hash filter. If this check fails, a bit indicating that a hit in the APBVT was found, the IP table index from check number #5 and destination TCP port number are reported in the receive descriptor as status.

7. Finally, the packet must not have IPv4 options or IPv6 extension headers.

If any of the previous checks fail, the packet is processed by the LAN engine.

The PE has some limitations regarding the packet formats that are supported with RDMA and UDA traffic. The PE supports all packet formats that are configured using the internal switch and configured for the VSI. Additional headers (such as an extra inserted IP header, IP and NAT tunneling headers, or IP and Teredo headers) that are inserted for L2 traffic on a per packet basis are not supported for PE traffic. When the VSI is not configured for handling specific header formats, the PE is capable of handling packets with up to one extra packet headers to match the L2 VLAN capability. The VLAN tag specified in QP context matches the definition for L2TAG1 for LAN descriptors.

38.36.2 Verbs Programming Model

The verbs programming model is specified for iWARP from the RDMA Consortium(http://www.rdmaconsortium.org/home/draft-hilland-iwarp-verbs-v1.0-RDMAC.pdf). The 10 GbE controller supports the verbs constructs of QPs, Q (CQs), Shared-Receive Queues (S-RQs), and events. The 10 GbE controller supports verbs events by implementing CEQs and AEQs. Further description of each of these constructs in provided in the following sections. Additional information on the verbs programming model can be found in the link to the RDMA consortium website previously provided.

38.36.2.1 Verbs from a System View

The following sections provide an overview of each verbs construct supported by the 10 GbE controller from a system view. It is expected that the user is generally familiar with the verbs programming interface.

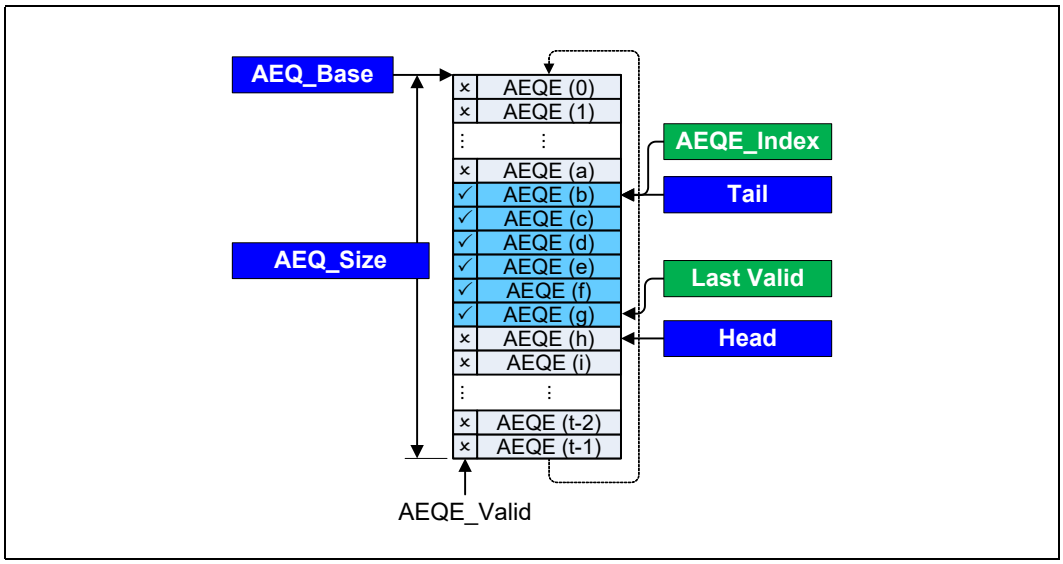
38.36.2.1.1 Asynchronous Event Queue (AEQ)

The 10 GbE controller supports a single AEQ per PE enabled PCI function. AEQs are used to report status and errors associated with PE QPs, CQs, and ARP table entries. AEQs are a packed array of AEQ entries (see Section 38.36.2.5 for the format of an AEQ entry) located in a virtually contiguous buffer in host memory (see Figure 38-107). AEQs should be sized to enable a single entry for every QP, CQ and ARP table entry that is active for the PCI function. Each QP, CQ and ARP table entry ensures that it generates only a single AEQ entry at a time. Software interaction is required for each resource to enable subsequent AEQ entries. If the AEQ is not sized appropriately, AEQ overflows can result [(Head+2)%AEQ_Size=Tail] in which case AEQ entries are lost and the AEQE_Overflow bit in the AEQE is set to notify software that the overflow condition occurred. Once the AEQ has overflowed, no new AEs are delivered to that queue. The AEQ must be discarded and then recreated to resume AE processing.

The initial condition for software shown in Figure 38-107 is AEQE_Index set to 0b. The last valid is shown strictly for discussion purposes. the 10 GbE controller first writes to the AEQE index specified by head. After an AEQE is written, an interrupt is generated if AEQ interrupts are not masked. Once an interrupt has been received that indicate that a new AEQ element (AEQE) is available, software reads the AEQE at AEQE_Index and increments AEQE_Index. Software processes all valid AEQEs until it encounters an invalid entry and stores the index of the invalid entry in the AEQE_Index variable. Subsequent AEQ entries might be generated by the 10 GbE controller after the entry that caused the interrupt while interrupts are masked. For each valid AEQ entry found, the PFPE_AEQALLOC register must be written to notify the 10 GbE controller that the AEQ entry is available for use by hardware. Writing the PFPE_AEQALLOC register causes the 10 GbE controller to increment the on-chip tail context variable. The PFPE_AEQALLOC register supports batching of AEQ entry acknowledgment into a single

write to enable software to minimize the number of register writes necessary to complete AEQ interrupt processing. PE enabled VF must use the VFPE_AEQALLOC registers instead of the PFPE_AEQALLOC.

Figure 38-107.AEQ



If software stops processing the AEQ before it has consumed all valid AEQEs, software must use a software initiated interrupt to return to processing AEQEs. Otherwise, no further interrupts are generated until a new AE is generated. Once the 10 GbE controller has run through the AEQ and wrapped back to AEQ0, the polarity of the AEQE_Valid bit is switched to avoid the need for software to go back and clear the AEQE_Valid bit for each AEQE processed.

38.36.2.1.2 Completion Event Queue (CEQ)

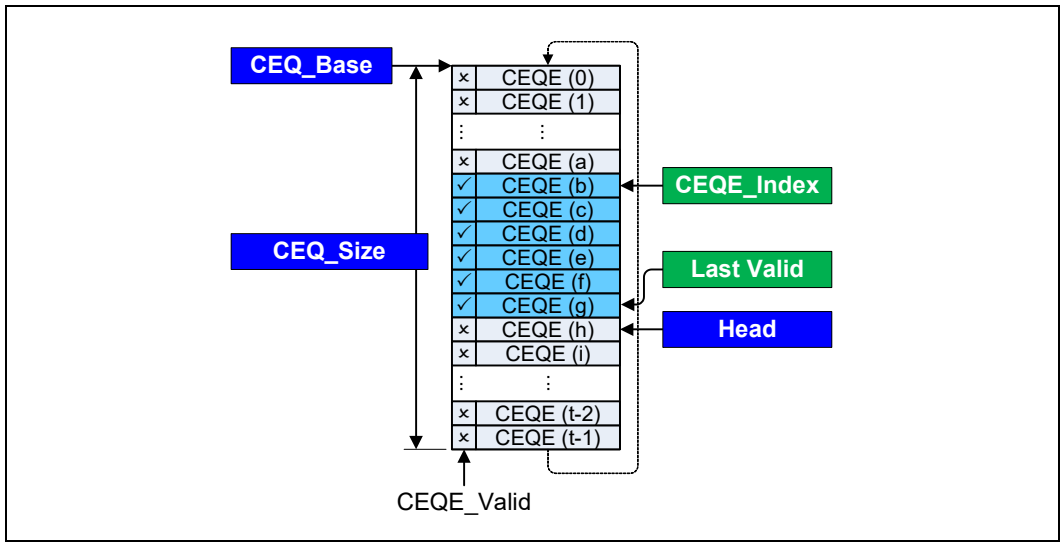
The 10 GbE controller supports one CEQ per MSI-X vector per PE enabled PCI function and a maximum of 256 CEQs total. HMC resource profiles are used to distribute the number of CEQs across the PE enabled PCI functions. Software can determine the number of CEQs and the specific instances assigned to a particular PCI function by reading the GLHMC_CEQPART[n] or GLHMC_VFCEQPART[n] registers after the HMC profile has been selected. Each CEQ is associated with a separate interrupt cause. It is expected that the number of CEQs that software uses is the minimum of the number of MSI-X vectors available, the number of CPU cores, and the value reported from the GLHMC_CEQPART[n].PMCEQSIZE. Software uses multiple CEQs to distribute the completion process workload across multiple CPUs. Each CQ is individually assigned a CEQ via the CreateCQ or ModifyCQ operations defined in Section 38.36.3.3.3.

Figure 38-108 shows that CEQs are a packed array of CEQ elements (see Section 38.36.2.4 for the CEQ element definition) located in a virtually contiguous buffer in host memory. CEQs should be sized according to the maximum number of active CQs that are assigned to the CEQ. Each CQ guarantees that it generates a maximum of one CEQ entry without having software acknowledge that the CEQ entry has been consumed. CEQs are not checked for overflow conditions so it is important that they are sized correctly or completion events are lost.

The initial conditions for software shown in Figure 38-108 is CEQE_Index is set to 0b. The last valid is shown strictly for discussion purposes. When the 10 GbE controller generates a new CE, a CEQE is written to the CEQ at index value of head with the CEQE_Valid bit indicating that a new event is available and an interrupt is generated.

The 10 GbE controller bumps head as part of the CEQE generation process and when the head reaches the end of the CEQ it wraps back to 0b. Software management of CEQE_Index must match the 10 GbE controller's head algorithm. Subsequent CEQEs might be written after the entry that caused the interrupt while CEQ interrupts are masked. Software is required to process all valid CEQEs up to the point where the first invalid entry is found. If software stops processing CEQEs before it has found an invalid entry, software must force the 10 GbE controller to generate a new interrupt using the SWINT_TRIG bit in the interrupt control registers. This is necessary since the 10 GbE controller does not track a tail value for CEQs and therefore cannot determine if a new interrupt is required to process CEQEs that have already been written and not processed by software. Once software has processed a valid CEQ entry, software writes the PFPE_CQACK register to enable the CE to generate new events.

Figure 38-108.CEQ



Once the 10 GbE controller has wrapped back to CEQE0, the polarity of the CEQE_Valid bit is switched to avoid the need for software to go back and clear the CEQE_Valid bit for each CEQE processed.

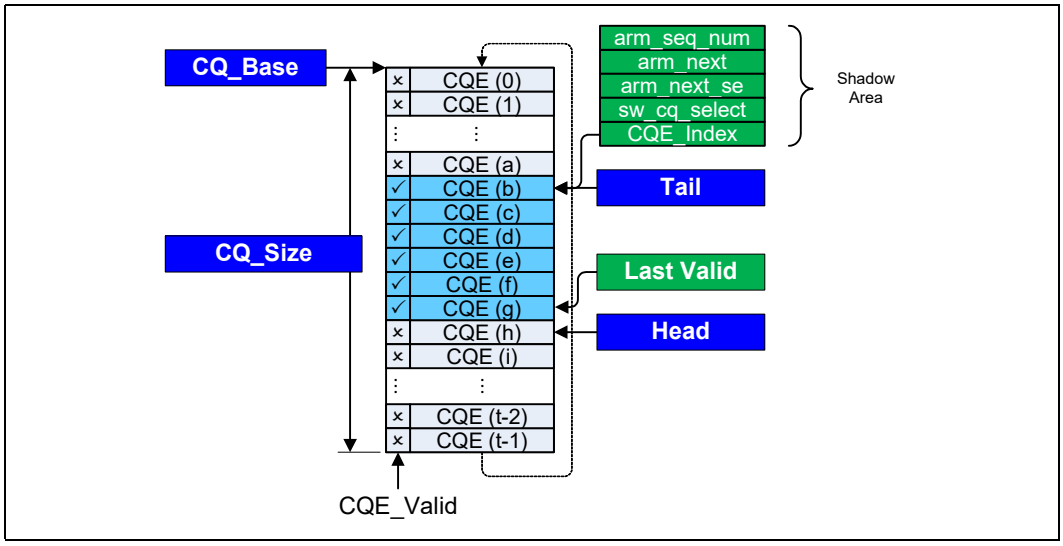
38.36.2.1.3 CE

When work requests submitted to Work Queues (WQs) complete, the 10 GbE controller might post CQEs to associated CQs. QPQP WQs might be SQs(SQs) or Receive Queues (RQs). SQs and RQs are associated with their CQs at QP creation time. This association remains (and cannot be changed) until the QP is destroyed. Each SQ and RQ (or Shared Receive Queue) can be bound to same or separate CQs. CQs can also be shared by multiple s from different QPs.

The 10 GbE controller supports up to 128 KB CQs that are distributed among that active PCI functions using HMC resource profiles. Refer to the section about the resource distribution mechanism used with CQs. The 10 GbE controller maintains the context of each completion queue in CQ context data structures in the HMC's FPM space. The storage elements of CQs reside in system memory. Refer to the section about the 10 GbE controller's usage of host memory for CQ context. As shown in Figure 38-109, CQs are organized as circular array of CQEs. Each CQE is 32 or 64 bytes in length and the format is dependent on the type of the WQ that is associated with the CQE. CQP, RDMA, and UDA WQs all can be related to CQs. CQs are managed using the Create/Modify/DestroyCQ operations defined in Section 38.36.3.3.3.

In addition to the CQ itself, software maintains a shadow area that the 10 GbE controller reads when the CQ is getting low on CQEs for hardware to write or when the CQ has been armed for event generation. The 10 GbE controller supports the verbs interface calls for requesting completion notification based on the next completion or based on the next completion that is associated with an operation that is a solicited event. The shadow area contains variables that must maintained by software in a atomic fashion since the 10 GbE controller could read that area at anytime. Specifically the two 32-bit words in the completion queue doorbell shadow area must be access using atomic 32-bit processor instructions. The arm_seq_num, arm_next and arm_next_se fields are ignored if an arm request has not been made by writing to the PFPE_CQARM register. The PFPE_CQARM register exists in CSR space for kernel mode drivers to access and also in the doorbell page area of the PCI function's BAR space that can be mapped directly to a user space application's memory space for kernel bypass operation. The format of the shadow area for CQs is listed in Table 38-465.

Figure 38-109.CQ



The CQ is organized as a circular queue, written by the 10 GbE controller and read by the driver software. Initially, both the 10 GbE controller and the driver software point to the first entry in the queue. The 10 GbE controller advances the Head context field after it writes a CQE to the CQ. Similarly, when the driver picks up a CQE, it advances the CQE_Index context field in shadow area in host memory. When head approaches tail, the 10 GbE controller reads the CQ shadow area and writes the CQE_Index value from the shadow area to the tail context variable. If head reaches tail-1 when the 10 GbE controller attempts to write a CQE, then an overflow condition is reported and the CQ is put into the error state. CQs generate a single asynchronous AE_CQ_OPERATION_ERROR event at this point and any further CQEs that are attempted to be generated by the 10 GbE controller are lost.

Completion events are generated if the CQ is armed for the appropriate event. The 10 GbE controller generates completion events under the following conditions assuming the tail does not equal head:

1. Any CQE is written (or has been written since the last event) and the CQ is armed for the next completion.
2. CQE is written (or has been written since the last event) that is associated with a solicited event operation and the CQ is armed for next solicited event.
3. CQ is armed on a recently re-sized CQ and software has not moved over to the new CQ yet based on the sw_cq_select value in the shadow area.

Completion events might be deferred if a completion event has been generated for a CQ and the PFPE_CQACK register has not been written by software.

The 10 GbE controller differs slightly from the verbs specification definition of generating completion events in two ways. First, the 10 GbE controller generates a completion event for a CQ that is armed for next completion without waiting for a new completion to be generated if it appears that CQEs have not been processed by software (Head != tail after reading the doorbell shadow area). Secondly, the 10 GbE controller does not track the exact location of the solicited events that have been generated since the last completion event. The 10 GbE controller generates an completion event for a solicited event operation if any solicited event completion has been generated since the last completion event was generated and it appears that CQEs have not been processed by software.

The 10 GbE controller process for arming CQs for event generation is simply to first write to the appropriate bit in the CQ shadow area to enable either next or next solicited completion notification events, increment arm_seq_num, and then write to the PFPE_CQARM register. The 10 GbE controller then reads the shadow area and the CQ context is used to either immediately generate a new completion event if the CQ has unprocessed CQEs remaining or arm the CQ to generate a new event once a subsequent CQE is written. As previously described, completion events can be deferred under certain circumstances. The 10 GbE controller maintains a copy of the last arm_seq_num value that was read during the last arm request in CQ context. The 10 GbE controller compares the value of arm_seq_num in CQ shadow area with the value in CQ context during arm requests and drops arm requests that have the same value in the shadow area and in CQ context. This comparison prevents CQ arm requests from rogue applications from changing the arm state of a CQ unless the application also has access to the CQ shadow area.

CQ resize operations with the 10 GbE controller involve four steps. The first is to allocate a new CQ in host memory based on the new size requested by an application. The second is to issue a ModifyCQ operation to the 10 GbE controller. ModifyCQ operations notify the 10 GbE controller to start using the new CQ for new CQEs. The third step is to completely process CQEs from the old CQ. The final step is to start to process CQEs from the new CQ after freeing the buffer for the old CQ. The old CQ can be considered to be completely processed when an invalid CQE has been found in the old CQ and at least a single valid CQE has been encountered on the new CQ. When the transition to updating CQE_index based on the new CQ occurs, sw_cq_select must be incremented. During the ModifyCQ operation, the 10 GbE controller incremented its cq_select value and switched over to writing CQEs to the new CQ. Since there could be pending CQEs still on the old CQ, the 10 GbE controller compares the CQ shadow area sw_cq_select to the hardware cq_select value during any reads of the CQ shadow area due to arms or CQ tail updates. If hardware cq_select does not match sw_cq_select, the 10 GbE controller ignores CQE_index and does not update CQ tail, assuming that software is still working with the old CQ. Arm requests generate new events immediately since the 10 GbE controller is no longer aware of the state of the old CQ. Once software has properly set CQE_index to reflect progress on the new CQ it must also increment sw_cq_select so the 10 GbE controller starts processing arm requests and CQ tail updates based on the new CQ.

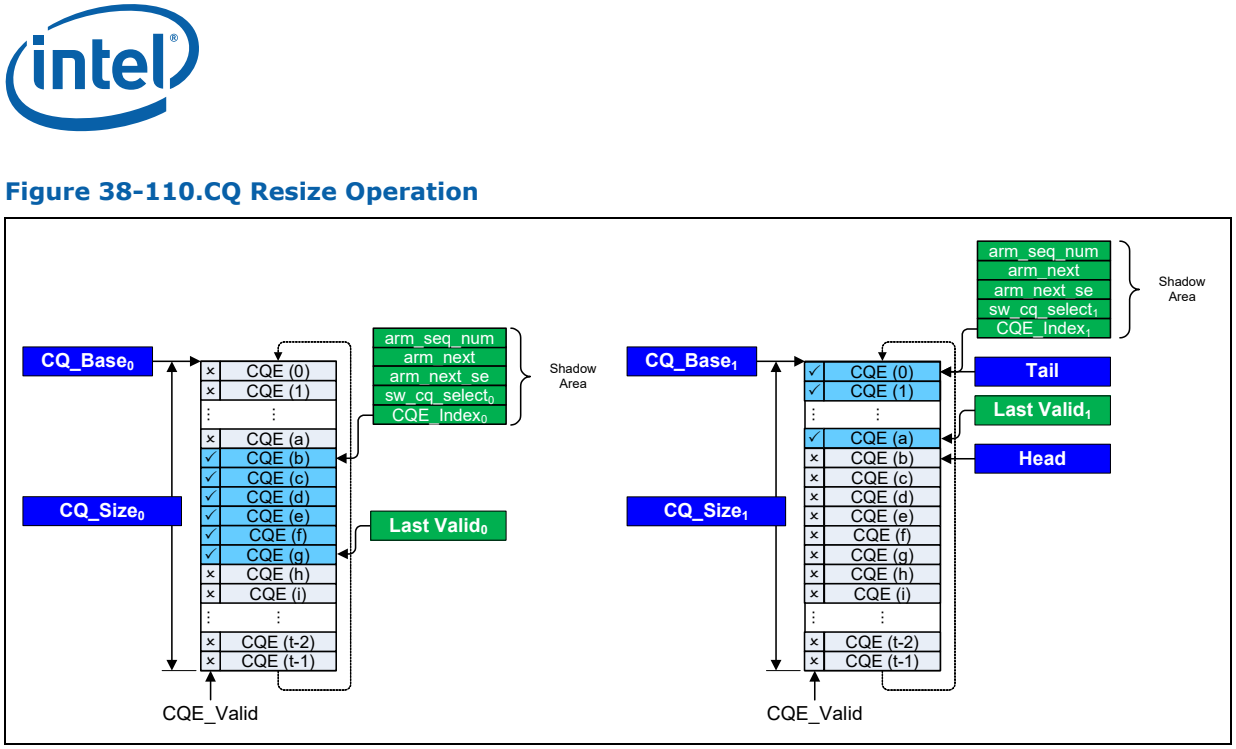


Figure 38-110.CQ Resize Operation

Figure 38-110 shows a CQ during a resize operation. The original CQ is shown on the left side of the diagram. At the time that the ModifyCQ operation occurred for the resize, the CQ had valid CQEs that had not been processed by software. The 10 GbE controller switched over to the new CQ shown on the right side of the diagram at the time of the ModifyCQ and incremented its cq_select value. New CQEs are shown as generated on the new CQ in Figure 38-110. Any arm requests immediately generate new CEs while sw_cq_select does no match the hardware cq_select value. If the doorbell region is read during this time, the CQE_Index$_0$ value is ignored because sw_cq_select0 does not match cq_select. Once software has found an invalid entry in the original CQ and CQE0 from the new CQ is valid, software can reset CQE_Index to 0, increment sw_cq_select, and start processing CQEs on the new CQ. At this time it is safe to free the memory used for the original CQ since the 10 GbE controller no longer writes to the old CQ. While two CQ shadow areas are shown in Figure 38-110, there is really only one. Two are shown to indicated that values of sw_cq_select and CQE_index have changed to signal the change over to the new CQ.

38.36.2.1.4 Memory Registration (Translation/protection)

In today's modern operating systems, applications running at user protection level use virtual addresses and they are not aware of their data buffers' physical addresses. However, traditional I/O devices require physical addresses to transfer data to/from system memory. This gap is typically bridged by the software device driver, which runs in the kernel protection level. Transitioning from user to kernel protection level, and than back to user protection level is not only quite expensive (in terms of MIPs) but also contributes to increased latency. The iWARP architecture solves this inefficiency by:

- Using virtual data buffer addresses in the RNIC programming model.
- Servicing latency critical functions through libraries running at the user protection level.

This approach requires RNICs to implement robust address translation and protection techniques. This section provides in depth descriptions of the address translation and protection mechanism used by the 10 GbE controller. However, designers are assumed to be familiar with the memory management concepts, operations and related terms described by iWARP Verbs specification.

The 10 GbE controller uses a Memory Region Table (MRT) and Physical Buffer Lists (PBLs) to represent virtually contiguous system memory locations that are accessible for iWARP operations. The data structures in MRT are used to describe these memory locations and their protection attributes. PBLs provide the page lists that back each MRT entry. These concepts, supporting data structures and related operations are described in Section , "Address Translation and Protection Overview". In these sections, the actual MRT and PBL construction details through the HMC are intentionally omitted and a virtually contiguous HMC FPM space is assumed.

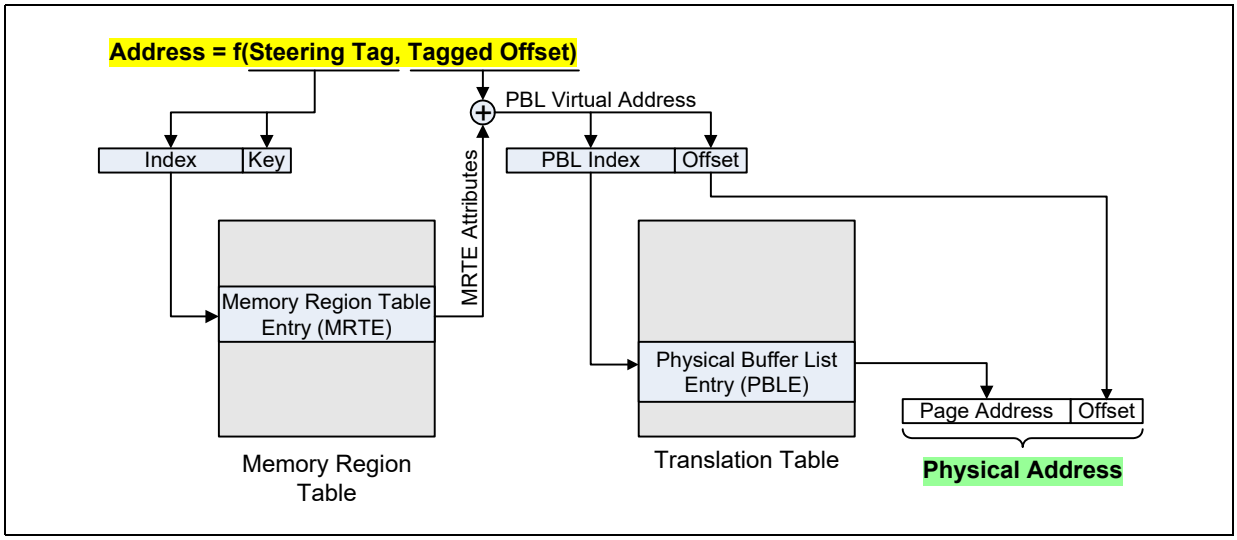
Address Translation and Protection Overview

As shown in Figure 38-111, the 10 GbE controller supports a two level protection and translation flow. The STag and tagged offset pair define the protection attributes and physical address of the system memory being accessed.

The STag portion of the address is used to locate the Memory Region Table Entry (MRTE) in the MRT. This data structure provides the protection attributes (Type, Access Control, Protection Domain and Key), the bounds check attributes (Base Tagged Offset, Length and First Byte Offset), and the address translation attributes (Page Size, and Base PBL Index). These attributes are described in detail later in this section.

After the protection attributes are checked and the address bounds checks are performed, the address translation attributes, along with tagged offset are used to calculate the PBL virtual address. The translation flow is explained in detail later in this section. The PBL Index portion of the PBL virtual address is used to locate the Physical Buffer List Entry (PBLE), which provides the physical page address. Finally, the page address is concatenated with the offset portion of the PBL virtual address to form the physical system address.

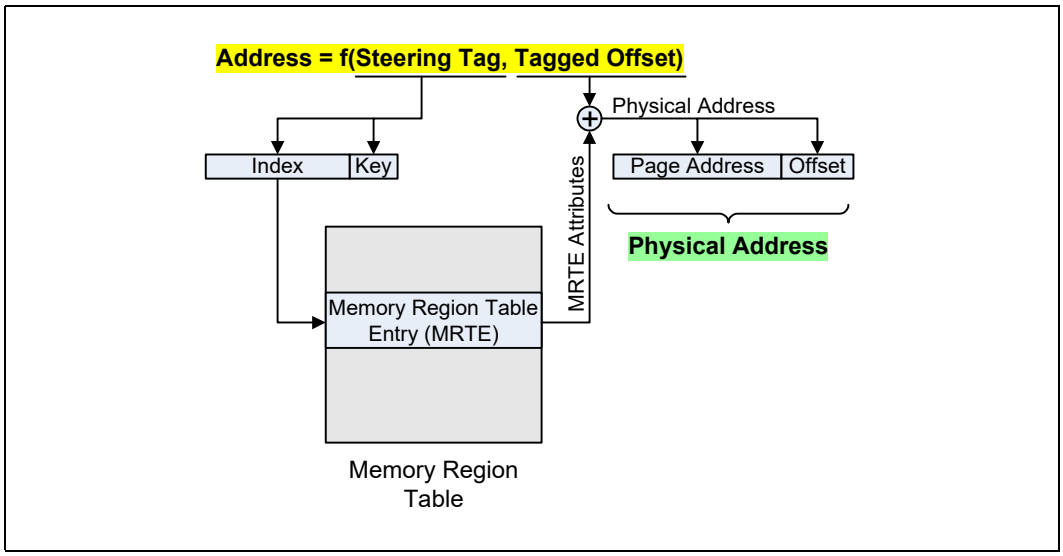
Figure 38-111.STag Decomposition to Physical Address



Depending on its size, each MRTE might be associated with multiple PBLEs. In this case, the PBLEs must be allocated consecutively to form the PBL. The PBLs can also be shared between multiple MRTEs when memory windows or shared memory regions are used. This enables efficient representation of a section of the system memory that is registered multiple times; potentially with different protection attributes.

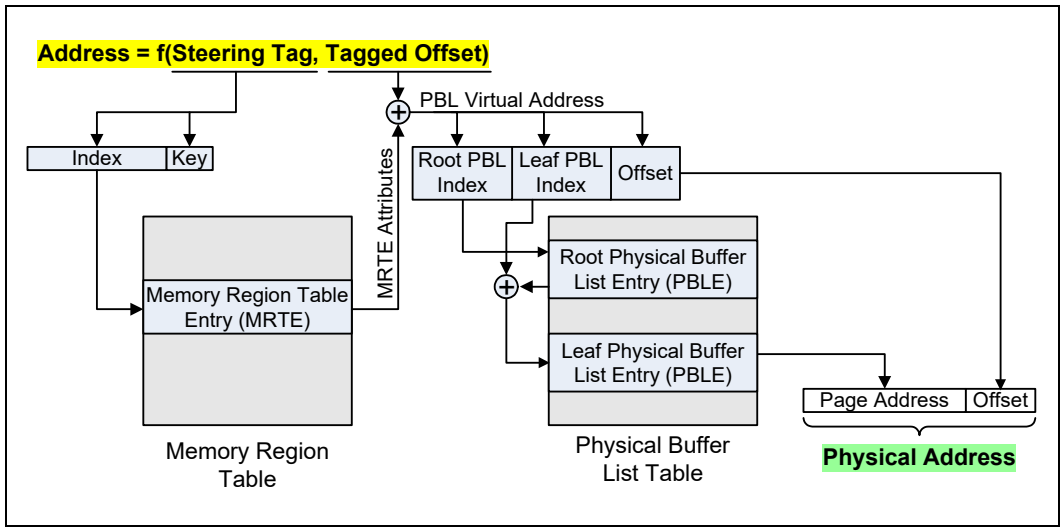
The 10 GbE controller also supports two other modes of address translation. The first is termed direct page translation that can be used when the STag is backed by a physically contiguous buffer is depicted in Figure 38-112. In this case the PBL translation step is skipped, which enables more efficient calculation of the physical address accessed for a given STag.

Figure 38-112.Direct Page Translation



The second additional mode of address translation is designed to enable software to make more efficient use of PBL address space when large numbers of large buffers are used for an application at the expense of additional accesses to host memory in order to calculate the ultimate physical address. Figure 38-113 shows a mode where PBLs are accessed twice by breaking the PBL virtual address into three pieces instead of two. The root PBLE is first accessed in order to find the PBLE associated with the leaf PBL. Once the leaf PBL is identified, the leaf PBL index is used to identify the leaf PBLE address that contains the page address portion of the physical address. In this mode, the leaf PBLs must be either 256 (64 root PBLEs or 32 leaf PBLEs) or 4096 (1024 root PBLEs or 512 leaf PBLEs) bytes in size. The root PBLs can be any size. This mode enables software to slice up the PBL space into fixed size PBLs for large memory regions of up to 2 Gb/s instead of having to reserve large contiguous regions of PBL space for a single STag.

Figure 38-113.Two-Level Page Translation



Each root PBLE is just a 28-bit object index of the starting PBLE object for the associated leaf PBLE. In other words, each root PBLE points to a another PBLE HMC object that is the start of the leaf PBL. Each leaf PBL is an array of 32 or 512 PBLEs. The size of the root PBL is determined from the region size specified in the MRTE. Each leaf PBLE is a 64-bit pointer to a host memory page that can be a 4 KB or a 2 MB page. For 4 KB pages the lower 12 bits of the host memory page pointer are ignored and for 2 MB pages the lower 21 bits are ignored.

Following is a brief overview of commonly used terms that are provided in the sections that follow.

STag

All local and remote memory accesses require use of an STag. The STag, along with a tagged offset is used to identify a memory location within a specific memory region or memory window. STags are found in RQ and SQ WQEs and in tagged iWARP messages received from the wire. As shown in Figure 38-114, 32-bit wide STag is further divided into two fields.

Figure 38-114.STag Format

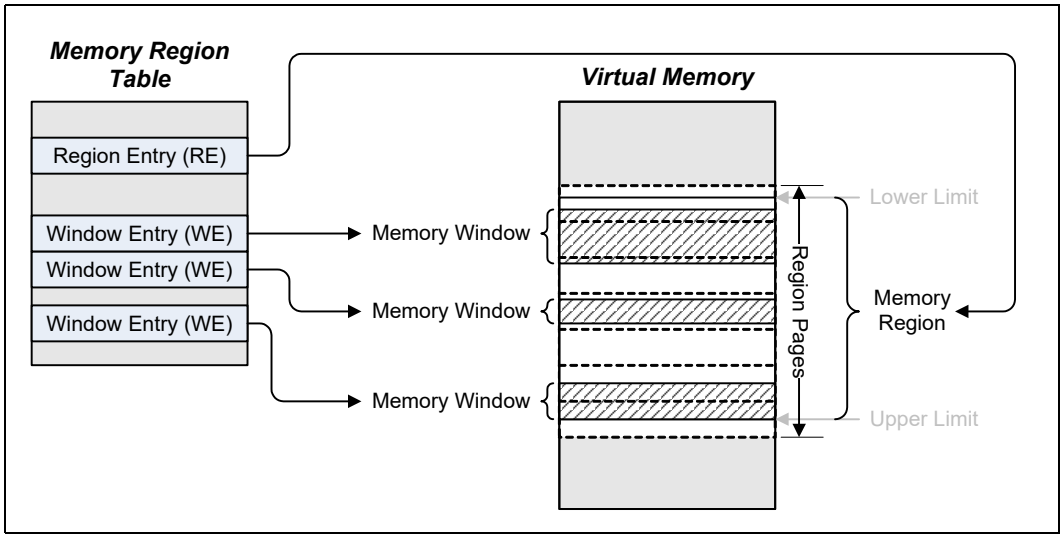
- STag index — The most significant 24-bits of STag is called the STag index. Since this field is used as an index into the MRT, it is also known as the memory region table index or MRT index in short. The 10 GbE controller supports up to 4 MB protection entries. Note that the unused most significant bits of the STag index can be randomized by software to provided reduced predictability for any MRT attacks.
- STag key — The least significant 8-bits of the STag is called the STag key. The STag *Key* field is a user or driver provided key that provides an additional level of security for the STag protection check.

Memory Region and Memory Window

Applications must register memory regions prior to accessing the system memory either locally or remotely. Memory regions, and their translation and protection attributes are represented by properly formatted MRT entries. MRT entries of this type are also called region entries or RE in short. Memory region registration and de-registration requests are communicated to the 10 GbE controller by:

1. Using CQP commands (like: register memory region and de-register memory region).
2. Working a request through a SQ (like: fast register non-shared memory region and invalidate STag).

Figure 38-115.Memory Region to Memory Window Relationship



The Verbs specification also defines the memory windows concept. Memory windows can be placed anywhere within a valid memory region. Multiple memory windows are allowed within a memory region. Memory windows are allowed to overlap, or completely included within another memory window. However, memory windows are not allowed to cross memory region boundaries. The 10 GbE controller supports memory windows through another type of protection entry. These protection entries are also referred as Window Entry (WE). Figure 38-115 shows the relations between memory regions and memory windows.

Memory windows can only be bound to memory regions that can be binded. A memory window's protection attributes are constrained by the protection attributes of the memory region. The 10 GbE controller supports byte-level lower and upper address limits for both memory regions and memory windows.

Tagged Offset (TO)

The 64-bit wide *TO* field specifies the first byte of the buffer being addressed in a memory region or memory window. Memory regions and memory windows have a base attribute as either zero-based TO or Virtual Address (VA) based TO. For a VA based TO, the TO of the first memory location associated with the memory region equals the base virtual address value specified when the memory region is registered. For a zero-based TO, the TO of the first memory location associated with the memory region equals zero.

Page Size

Each memory region and memory window has a page size attribute. Memory windows inherit the page size attribute of their associated memory regions. The 10 GbE controller supports two different page sizes: 4 KB and 2 MB. All system memory pages that are part of a memory region or memory window must be of the same size.

38.36.2.1.5 QP

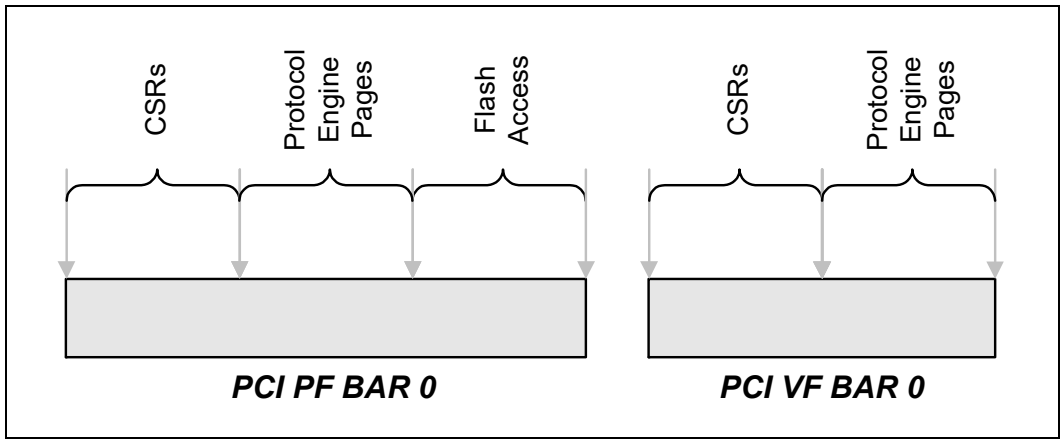
The PE in the 10 GbE controller supports the verbs QP. QPs are made up of a pair of WQs.

QP WQs are either SQs or RQs. SQs and RQs are associated with their CQs at QP creation time. The 10 GbE controller supports QPs for PE administrative commands (control QP or CQP), RDMA supported by iWARP, and UDA. Each QP type has unique operation types that are described in Section 38.36.3.3, Section 38.36.4.5, and Section 38.36.5.8, respectively. Note that CQP does not implement a RQ. The 10 GbE controller supports a maximum of 256 KB QPs that are distributed among that active PCI functions using HMC resource profiles. Refer to the section describing the resource distribution mechanism used with QPs. The 10 GbE controller maintains the context of each QP in QP Context data structures in the HMC's FPM space. The storage elements of QP context reside in system memory. Refer to the section about the 10 GbE controller's usage of host memory for QP context.

38.36.2.1.6 Doorbell Pages

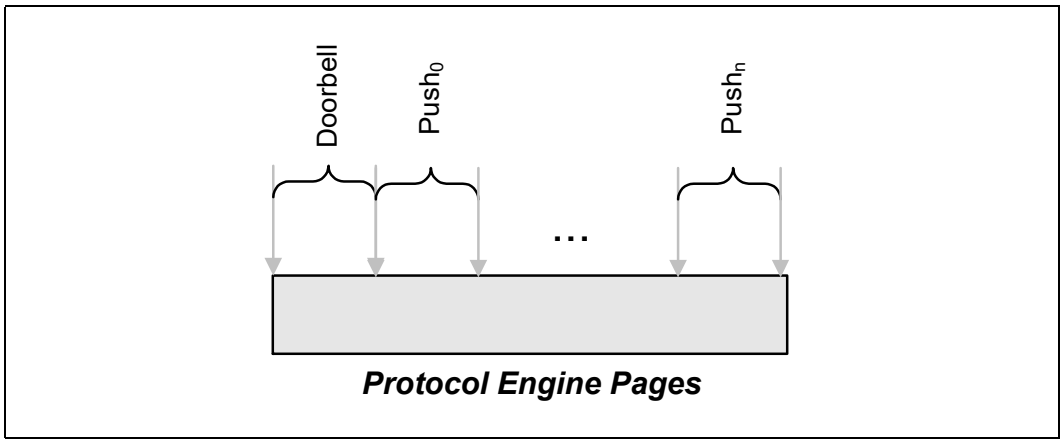
In order to support direct access to the 10 GbE controller hardware for PE functionality, the 10 GbE controller implements adapter memory that can be mapped to a user-space process. The memory is exposed to the system through the PCI BAR registers in a similar manner to the CSRs. Each PCI function optionally has a number of PE pages as shown in Figure 38-116.

Figure 38-116.PE Page Location in BARs



As shown in Figure 38-117, the first PE page is used for submitting work to PE SQs and also for arming CQs from user space. The remaining pages are used to support low latency push mode operation.

Figure 38-117.PE Pages



The format of the doorbell portion of the PE pages is listed in Table 38-443. The details of each register found in the PE pages are documented in the programming interface section.

Table 38-443.Doorbell Page Register Summary

Offset / Alias Offset	Abbreviation	Name	Block	RW
PE Registers				
0x00000000	PFPE_WQEALLOC	PE WQE Allocate Register	PE	RW
0x00000040	PFPE_CQARM	PE CQ Arm	PE	RW

38.36.2.1.7 SQ

As shown in Figure 38-118, SQs are organized as circular array of SQ Elements (SQEs). The host memory used for SQs might be physically contiguous or discontiguous. Each SQE is 32 bytes in size and can have up to 6 additional fragments for a total of 7. This approach enables Work Requests (WR) to consume a variable amount of SQ space that enables software to advertise 7 fragments as the maximum supported but opportunistically pack multiple WRs into a smaller space if the application needed fewer fragments for a given WR. The 10 GbE controller takes advantage of variable size WRs by reading 128 bytes at a time from the SQ when processing work. If a WR used all 7 fragments, it would consume the 128 bytes and would transmitted by itself. If instead the application happened to be using 4 consecutive single fragments WRs, all 4 WRs would be fetched (assuming software posted the WRs before the 10 GbE controller managed to read the first WR) with a single read of the SQ which boosts bus efficiency. The minimum size of a SQ is four maximum sized WQEs for proper operations. For example, this means that if a WR can ever use 7 fragments, then the SQ must be 512 bytes. An additional optimization (iWARP only) that the 10 GbE controller provides is that WRs that are small enough to fit into a single Ethernet packet and fetched as part of the same read of the SQ are sent as a single Ethernet packet for efficiency on the Ethernet fabric.

Figure 38-118.PE SQ

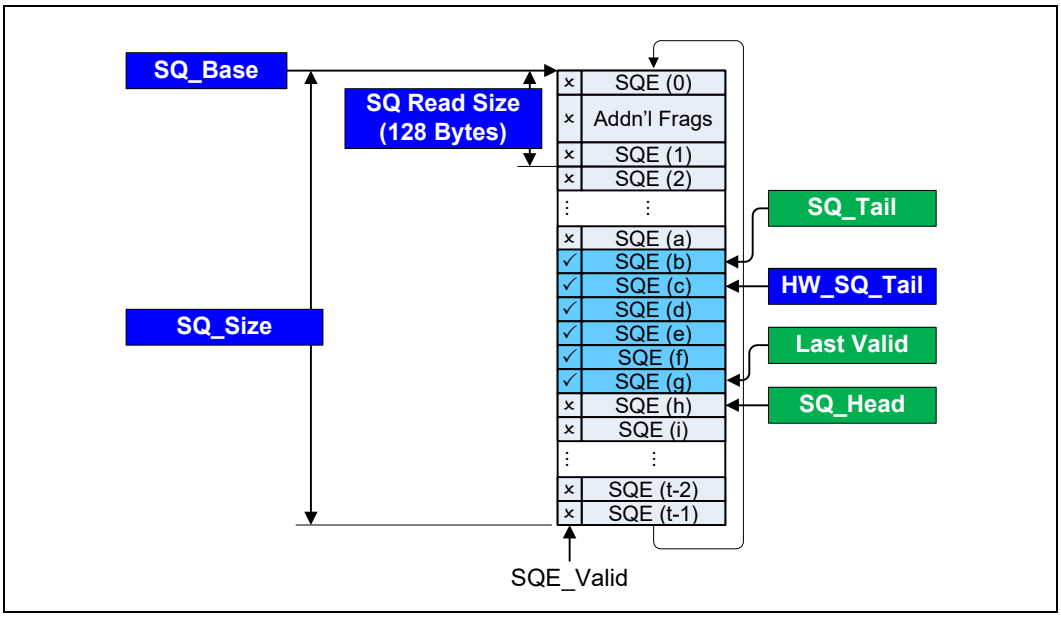


Figure 38-118 shows a typical SQ where software is tracking SQ_head and SQ_Tail and the 10 GbE controller tracks HW_SQ_tail in QP context. Software must size the SQ large enough to support every SQE with the maximum number of additional fragments. The amount of space required per work request is listed in Table 38-444. Essentially the WR space requirements on the SQ end up rounding up to the next multiple of 32 bytes. SQE 0 is shown using four additional fragments and there for takes up 96 bytes. Every SQE must start on an offset that is a multiple of 32 bytes within the SQ and an SQE and all of related additional fragments must fit into a single 128 byte SQ read block. NOP SQEs can be added if necessary to pad SQEs out when necessary to satisfy this requirement. The 32-byte boundary requirements for SQEs means that there is no difference in SQ size between a WR with 4 fragments and a WR with 5 fragments. If SQE 1 required any additional fragments, a single NOP SQE would need to be added in place of SQE 1 and all subsequent SQEs would move down in the SQ so that the SQE 1 and all related additional fragments would fit in the same 128 byte SQ read block.

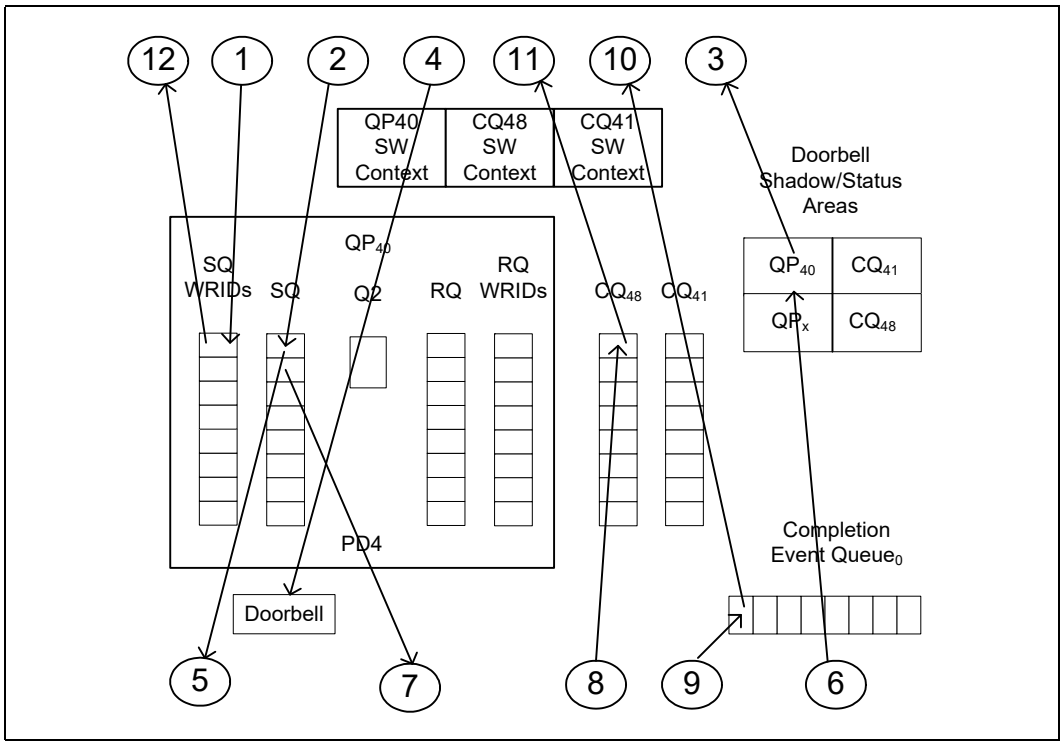
Table 38-444.QP WR Size Requirements

Number of Fragments Requested at QP Creation	Size Required per Work Request
1	32 bytes (one SQE)
2-3	64 bytes (one SQE + two additional fragments)
4-5 (SQ only)	96 bytes (one SQE + four additional fragments)
6-7	128 bytes (one SQE + six additional fragments)

Figure 38-119 shows a system view of how the 10 GbE controller processes PE QP SQs. Before describing the flow in Figure 38-119, software must perform a fair amount of initialization. Software starts by populating all QP related HMC objects necessary for CQs, QPs as well as related memory regions. Next software allocates buffers for software QP and CQ context, SQ and RQ WRID tracking arrays (software context and WRID tracking arrays do not need to be pinned, QP40, CQ48, and CQ41 in Figure 38-119), QP and CQ doorbell shadow/status areas, Q2 areas, and finally the SQ, RQ, and CQ buffers themselves. The doorbell shadow/status areas, Q2 and WQs all

need to be pinned and if they are physically dis-contiguous, the page list for each of the pinned buffers must be collected. CQP operations are used to create the CQs (if they do not already exist) and QPs.

Figure 38-119.PE Operation: SQ



Now that all structures have been created and defined to the 10 GbE controller, the steps shown in Figure 38-119 to process a post-send verbs request are the following:

1. Software stores the WRID supplied by the application on the post send request to the SQ WRID.
2. Software creates a SQE along with any additional fragments necessary to represent the WR.
   a. The valid bit in the SQE must only be set once all fields are valid since the 10 GbE controller can read SQEs at any time. Note that the valid bit is a generational valid bit, which means that the first (and all subsequent odd) iteration through the SQ, 1 means valid on all even iterations through the SQ, 0 indicates that the SQE is valid.

- Software reads HW_SQ_Tail from the doorbell status area for the QP.
- Software then compares the SQE_Head with HW_SQ_Tail.
  a. if the two are equal, the PFPE_WQEALLOC register is written to notify the 10 GbE controller that SQ work is available.
  b. SQE_Head is incremented by the number of SQEs consumed work requests (WR size in bytes/32 bytes).

3. The 10 GbE controller reads the 128-byte SQ read block that contains the SQE indicated by QP context value of HW_SQ_Tail.
   a. The 10 GbE controller processes all valid SQEs contained in the 128 byte SQ read block. In this example it's assumed that only SQE 0 is valid, if no SQEs are valid, proceed to step 6.

b. The 10 GbE controller processes SQE 0,which likely includes fetching data from host memory, sending packets through the Ethernet port, and waiting for TCP acknowledgments.

c. The 10 GbE controller increments the HW_SQ_Tail in the doorbell shadow/status area.

d. If the last SQE in the 128-byte SQ read block is valid, step 5 is repeated, which reads the next 128-byte SQ read bock.

4. The 10 GbE controller writes the doorbell status area for the QP with the current value of HW_SQ_Tail.
5. The 10 GbE controller reads the 128-byte SQ read block one more time to ensure that software has not posted new work.

   a. If a new valid SQE is found, proceed back to step 5a.

6. The 10 GbE controller optionally writes to the CQ associated with the SQ.
7. The 10 GbE controller optionally writes to the CEQ if the CQ was written and generates an interrupt.
8. Software then fields the interrupt if one was generated and reads the CEQ to determine the CQ that generated the event (an application might be polling the CQ directly in which case steps 9 and 10 are skipped). Typically the CEQE contains the most significant 63 bits of the virtual address of CQ context to make CE processing efficient.
9. Software then reads the CQ to determine the QP and WQ that generated the work completion, the SQE index of the WR is reported in the CQE along with a 64-bit pointer that is typically set to the software QP context address at QP creation time.
10. Software then reads the SQ WRID array for the SQE index from the completion, the resulting WRID is returned to the application as an indication that the original work request completed.

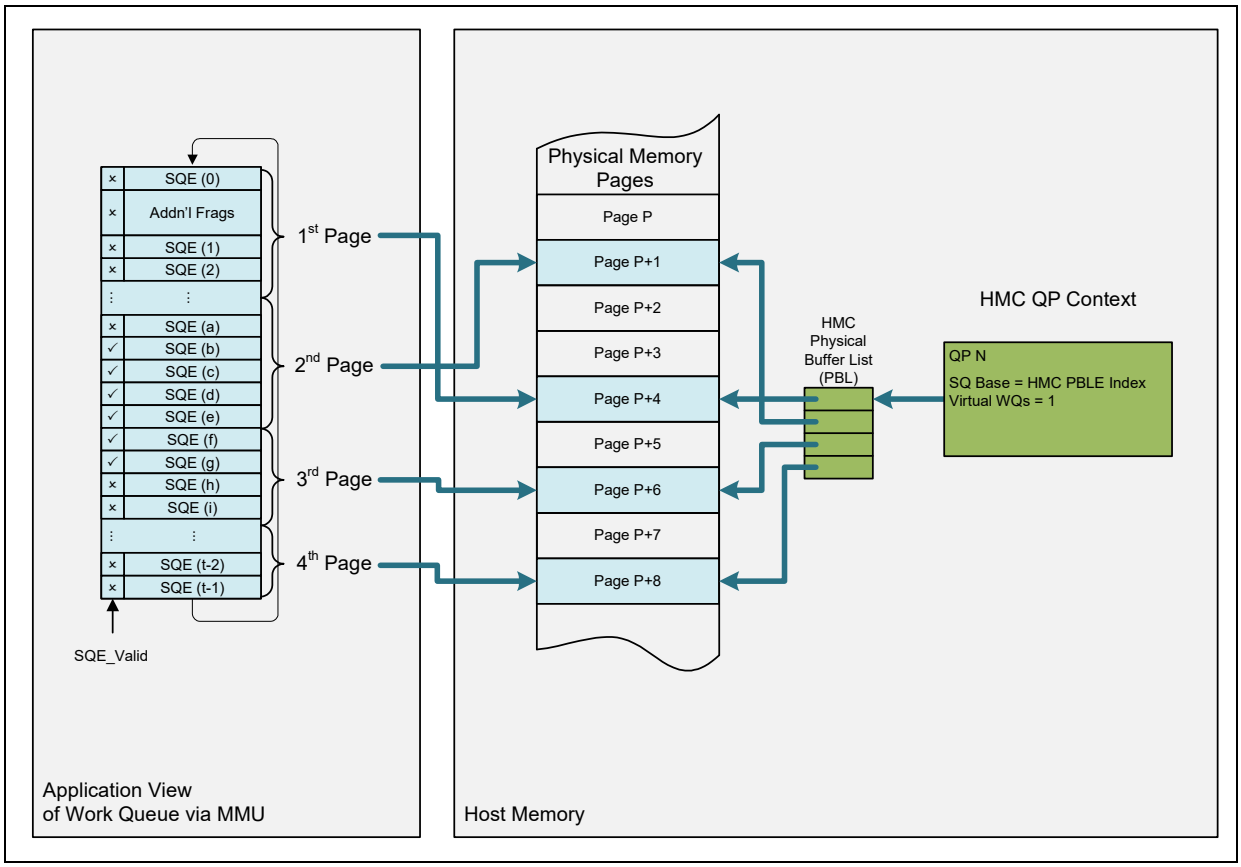
Note: While steps 6 and 8 are shown as sequential, the 10 GbE controller starts both steps simultaneously. Also step 1 can be initiated by software at any time as well.

Virtual Queues

The 10 GbE controller supports physically contiguous and physically dis-contiguous WQs for PE QPs. CQs, and CEQs, and shared receive queues also support both physically contiguous and dis-contiguous buffers. In the case of QPs, the support for physically dis-contiguous WQs is referred to a virtual WQ support. This section describes an example of a SQ.

Figure 38-120 shows a virtually contiguous but physically dis-contiguous SQ. The left side of the figure shows the applications view of the SQ. This particular SQ is composed of four host memory physical pages that are not contiguous. In this scenario, the virtual buffer is pinned and the 1 level page list is retrieved from the operating system. Then an unused page list must be allocated from the HMC PBLE object space with 4 contiguous PBLEs. This PBL is now populated with the page list retrieved from the operating system. When the QP is created, the Virtual_WQs bit is set in CQP Create QP WQE and the SQ Base in QP context is set to the starting PBLE HMC object index instead of a host physical address of the SQ. The RQ for a QP with the Virtual_WQs bit set must also use a PBL even if it happens to be physically contiguous. Note that the SQ and RQ in this case must be allocated a host page boundary.

Figure 38-120.PE Operation: Virtual SQ



SQ Push Mode

Push mode reduces processing latency of the short message posted for transmission on the low-latency QP by eliminating a read of WQE or WQE with inline data from the host memory. This is achieved by software writing WQEs to the adapter memory mapped address space using processor write-combining buffers. Processor write-combined buffers allow combine writes and make transactions on the bus more efficient. Software is not expected to use this mode to stream high rate of the short messages or use this mode to post a large messages. The size of the message posted using push mode should not exceed a configured scheduling Quanta. This feature can be either exposed to the application and have an application responsible for the potential QP bandwidth degradation caused by overuse of this feature, or a verb layer can be instrumented to use information provided by hardware and opportunistically take advantage of push mode messages for the given connection based on true low-latency messaging requirements.

In modern systems, a memory type can be specified within an operating system page structure using an index in the PAT register. This way an individual page of adapter memory can be mapped to the application address space as a write-combined memory. Writes to such page would be combined in the processor write combining buffers. These buffers are flushed on PCI bus in cache lines. In some systems, the same page can be mapped as an uncached memory page that enables software to use uncached write (or doorbell ring) to flush push mode WQEs from processor write-combining buffers to the PCIe bus. Adapter memory mapped pages used to for push mode WQEs are called push pages. The number of push pages exposed to the driver depends on the chip configuration and PCIe function. In most systems, it is not possible to map the same

page as both uncached (non-write-combined) and write-combined. In this case the GLPE_PSHCFG.PSHCFG_DB_SPLIT must be set, which forces the doorbell pages to be treated separately from the page used to push the WQEs and data. When GLPE_PSHCFG.PSHCFG_DB_SPLIT is set, two push pages are mapped to the application address space where the odd number push page is mapped as uncached (used as the push doorbell page) and the even numbered push page is mapped as write-combined. This reduces the amount of push pages available to applications by half since a single application requires two separate push pages for proper operation.

Combining writes using dedicated write-combining buffers is a very old feature of the processors. This feature was mainly used for the ancient graphic adapters. Now days all graphics adapters use their own DMA engines to pull the data from the host memory, rather than having it pushed with CPU.

Processors specify a write combining memory region using several mechanisms.

- The MTRR register specifies a memory type per region. Granularity of memory region sizes does not allow the use of MTRR for wide deployment of write-combining for the 10 GbE controller.
- Page Attribute Table (PAT) in conjunction with flags in Page Table Entry (PTE) enables write-combining on a per-page base, which makes it feasible for the 10 GbE controller deployment. Relatively recent distribution of Linux added an interface allowing change page attributes to write-combined page.

Processors have a set of buffers for write-combined accesses. Each buffer has a size of several cache lines. Writes to write-combined memory are intended to be delayed to enable better memory access efficiency and reduced overhead.

Write-combined buffers are evicted or flushed by serialization events, such as SFENCE, LOCK, interrupt, etc. and read/write to uncached memory. Partial write-combined buffer eviction can be a result of the serialization event. Eviction of a full write-combined buffer is implementation dependent. Intel assumes that serialization events are evicting/flushing both full and partially filled write-combined buffers. Intention is to use door bell ring (write to uncached memory) as a serialization event to evict write combined buffers.

All types of the PE SQ WQEs can posted using a push mechanism. The maximum size of data that can be pushed together with WQE as an inline data is limited to the 112-byte matching the maximum size of data that can be posted using WQE with inline data. Larger messages can be pushed using regular WQE, eliminating a need to read a WQE from the host memory. If an application requested post send, verb layer can decide whether to push the message to adapter based on the message size, configurable threshold and outstanding WQEs previously posted to SQ. In any case, verb layer should always first post WQE to the SQ (without ringing the door bell) and only then write WQE push mode page, followed by uncached write to the associated push mode page. Posting WQE to the SQ required for the proper re-transmission process, and enable hardware opportunistically discard push mode messages and transmit those using regular SQ processing mechanism.

To avoid security implications, a push mode page cannot be shared by different processes. If it was allowed to be shared, then ProcessA could guess the QP number of ProcessB and other QP attributes, like the push mode page, and make ProcessB send a message pushed by ProcessA as its own. This can lead to severe security violation. Multiple threads residing in the same process share a process virtual space and belong to the same security domain. The number of push pages for VFs is limited to 15 to reduce the amount of BAR space that the operating system is required to allocate for the 10 GbE controller. In order to overcome this restriction, a para-virtualized driver is allowed to map PF push pages to the VF for use.

Push mode is an opportunistic latency optimization that supposed to be used on lightly loaded QPs. If adapter runs out of resources or software attempts to use push mode WQEs too aggressively, adapter can discard a push mode WQE, and transmit it later as a regular WQE with inline data posted to SQ.

Software is allowed to post any SQ message using push mechanism. The size of the message should not exceed a configurable Quanta value (default of 4 KB). Messages specified as inline operations by application can be pushed together with data. A total of 112 bytes of the message with inline data can be pushed to the 10 GbE controller to avoid overhead of the SQE and data fetches. Larger messages would avoid a fetch of the SQE element, but still requires a data fetch. Software can post multiple messages with single push operation, as long as all messages are continuously located and do not cross a boundary of the push page SQE element, shown on Figure 38-121 or Figure 38-122. Push mode does not require any change in WQE format, except for setting a push bit in the SQ WQE. A process is enabled for push mode by allocating a push page shown in Figure 38-121 or a pair of push pages as shown in Figure 38-122 (see Section 38.36.3.3.10 for the CQP WQE format) from the 10 GbE controller's BAR to a QP and including the push page Index in QP context when the QP is created. Each PCI function has a number of push mode pages that must be assigned. See Figure 38-116 and Figure 38-117 for more details on how the 10 GbE controller exposes push pages to the system. The 10 GbE controller validates that the push operation is associated with the correct push page and push SQE index as well as PCI function before acting on the operation.

Figure 38-121.Combined Push Page Detail

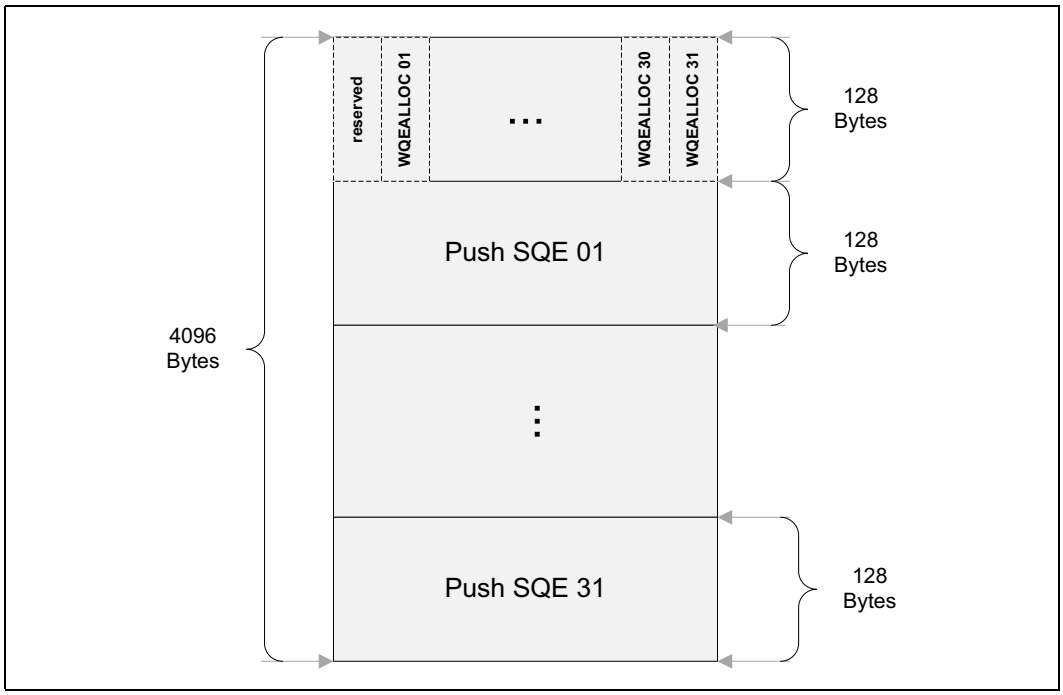


Figure 38-122.Split Push Page Detail

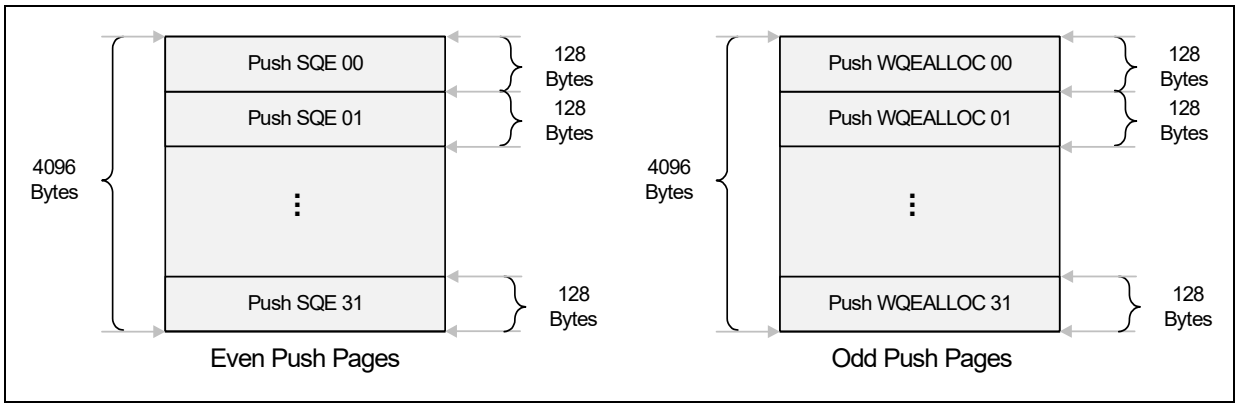
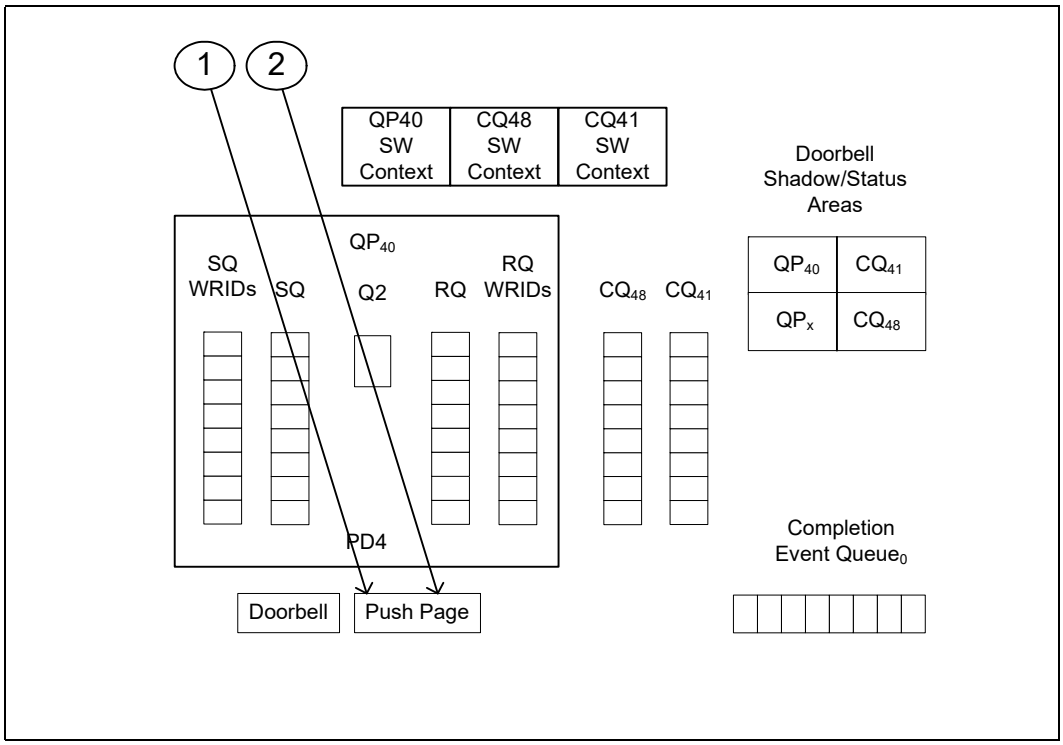


The push doorbell area is located at first 128 byte region of the push page. Push doorbell area for PFs contains 31 instances of the PFPE_WQEALLOC register. PFPE_WQEALLOC instances are continuously located within the push doorbell area starting at offset 4 bytes into the 128 byte region. Push doorbell area for VFs contains 31 instances of the VFPE_WQEALLOC register. VFPE_WQEALLOC instances are continuously located within the push doorbell area starting at offset 4 bytes into the 128 byte region. All QPs associated with a given push page use the same push doorbell area. Each instance of the PFPE_WQEALLOC and VFPE_WQEALLOC corresponds to the respective push SQE. The push SQE index matches an index of the respective PFPE_WQEALLOC or VFPE_WQEALLOC registers. When GLPE_PSHCFG.PSHCFG_DB_SPLIT is set, the WQEALLOC instances are located in odd numbered push pages and the push SQEs are located in even numbered push pages. Additionally, the stride of the doorbell array to 128 bytes instead of the packed array of doorbells shown in Figure 38-121. In other words, each odd numbered push page has WQEALLOC instances at offsets 0, 128, 256, ... instead of 0, 4, 8, ... in order to allow for write-combine avoidance on uncached writes to the push doorbells.

Figure 38-123 shows the mechanism for pushing a WQE to the 10 GbE controller.

Figure 38-123.PE Operation: SQ Push Mode



Push mode operation builds on the typical SQ operation shown in Figure 38-119. The following two steps replace step 4 from the procedure defined in Section 38.36.2.1.7.

1. Instead of the usual doorbell page write, a copy of the SQE is written to one of the push page SQEs from Figure 38-121. This page is configured with write combine attributes for this step. If less than 128 bytes WQEs are written to the 128-byte push WQE and the WQE did not start on a 128-byte boundary within the SQ, then the WQE data from the SQ must be written to the matching offset in the push WQE from the start of the most recent 128-byte boundary in the SQ. For example, if WQE index 5 from the SQ happens to be 32 bytes long and needs to be pushed, 32 bytes need to be written 32 bytes past the start of the Push WQE instead of at offset 0 in the push WQE. This is because WQE index 5 start 32 bytes past the previous 128-byte boundary in the SQ. Two additional requirements place on the writing of the push WQE are:
   a. 32-bit access are the minimum size data that is allowed to be written.
   b. Data must be rounded up to the next 32-byte length when written to the push WQE.
2. After writing the SQE to the push page SQE, the push page doorbell is written to indicate that the push is complete. Note that the doorbell written for non-push operations is not written for push operations.

Step 7 from the procedure described in Section 38.36.2.1.7 is typically skipped for push mode operations unless the 10 GbE controller is low on resources, the TC associated with the push page has insufficient bandwidth allocation to complete the operation. Push mode operations are also ignored if the TC associated with the push page is flow controlled. In the cases where the 10 GbE controller ignores the SQE pushed in Step 2, the WQE is re-fetched normally and processing continues. The only side effects of the dropped push operation is wasted bandwidth on the PCI bus and wasted CPU cycles.

In order to keep the wasted bandwidth and CPU cycles to a minimum, the next CQE generated after the dropped push operation indicates that the drop occurred and software should stop issuing push operations until it reaches an empty SQ condition.

SQ Suspend and Resume

Software is provided with CQP Commands allowing a suspend and resume operation of the SQ. Commands are defined in Section 38.36.3.5.8 and Section 38.36.3.5.9, respectively. Those commands are primarily used to migrate QP from one QS to another QS. This migration might be triggered by a system configuration change. For example, a change in number of TCs configured for the particular physical port, which in turn requires reassignment of QPs to the QSs associated with the TCs.

Software is required to reassign all QPs associated with particular QS prior posting an AQ Command that might result in QS removal. Such reassignment of the QP to the new QS should be performed using Suspend and Resume CQP commands, Section 38.36.3.5.8 and Section 38.36.3.5.9, respectively. Both Suspend and Resume CQP commands are asynchronous requests, and their completion does not indicate completion of a requested operation. Completion of a resume operation is never reported to software. Completion of a suspend operation is reported using AE_QP_SUSPEND_COMPLETE. Software is allowed to request multiple suspend and resume operations for different QPs accelerating transfer of multiple QPs from one QS to another.

RQ

As shown in Figure 38-118, RQs are organized as circular array of RQ Elements (RQEs). The host memory used for RQs can be physically contiguous or dis-contiguous. Each RQE is 32 bytes in size and can have up to 6 additional fragments for a total of 7. Unlike SQs, RQs all have fixed size Work Requests (WR) even if the application uses a smaller number of fragments that could be used to represent a WR. The minimum size of a RQ is four maximum sized WQEs for proper operations. For example, this means that if a WR can ever use 7 fragments, then the RQ must be 512 bytes. This is necessary to allow out of order placement of inbound RDMA send operations for iWARP QPs. All RQEs must start on an offset that is a multiple of RQ WQE size and an RQE along with its associated additional fragments must be contained in a single 128 bytes RQ read size buffer. This leads to the same RQ buffering requirements per WR as those listed for the SQ in Table 38-444.

Figure 38-124.PE RQ

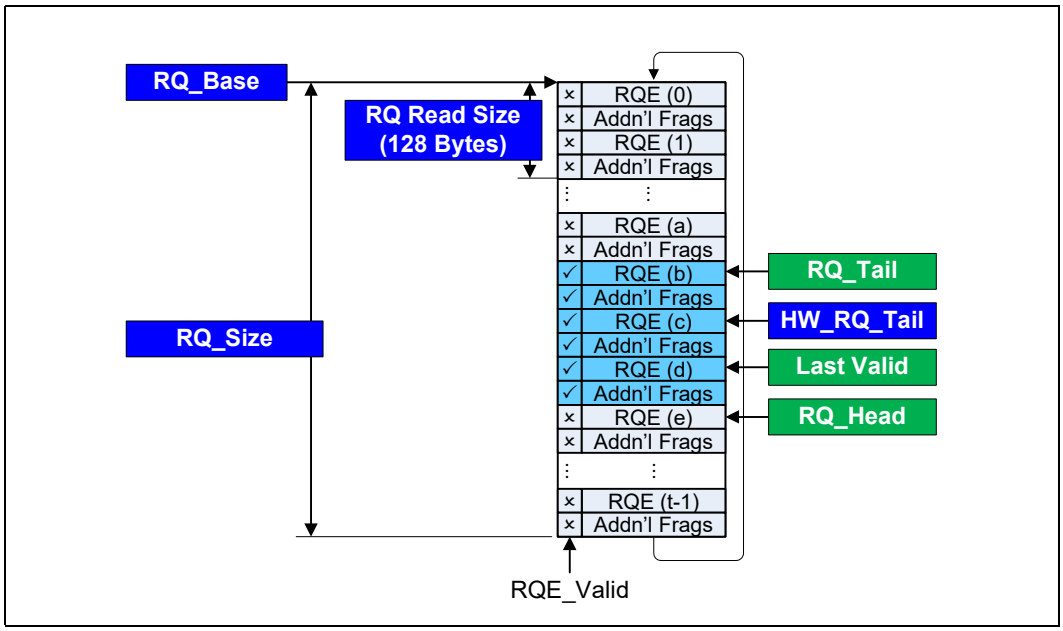


Figure 38-124 shows a typical RQ where software is tracking RQ_head and RQ_Tail and the 10 GbE controller tracks HW_RQ_tail in QP context. Software must size the RQ large enough to support every RQE with the maximum number of additional fragments. All RQEs are shown using two additional fragments and therefore takes 64 bytes. NOP RQEs can be added if necessary to pad RQEs out when necessary to satisfy the RQE alignment requirements. The 32-byte boundary requirements for RQEs means that there is no difference in RQE size between a WR with 2 fragments and a WR with 3 fragments.

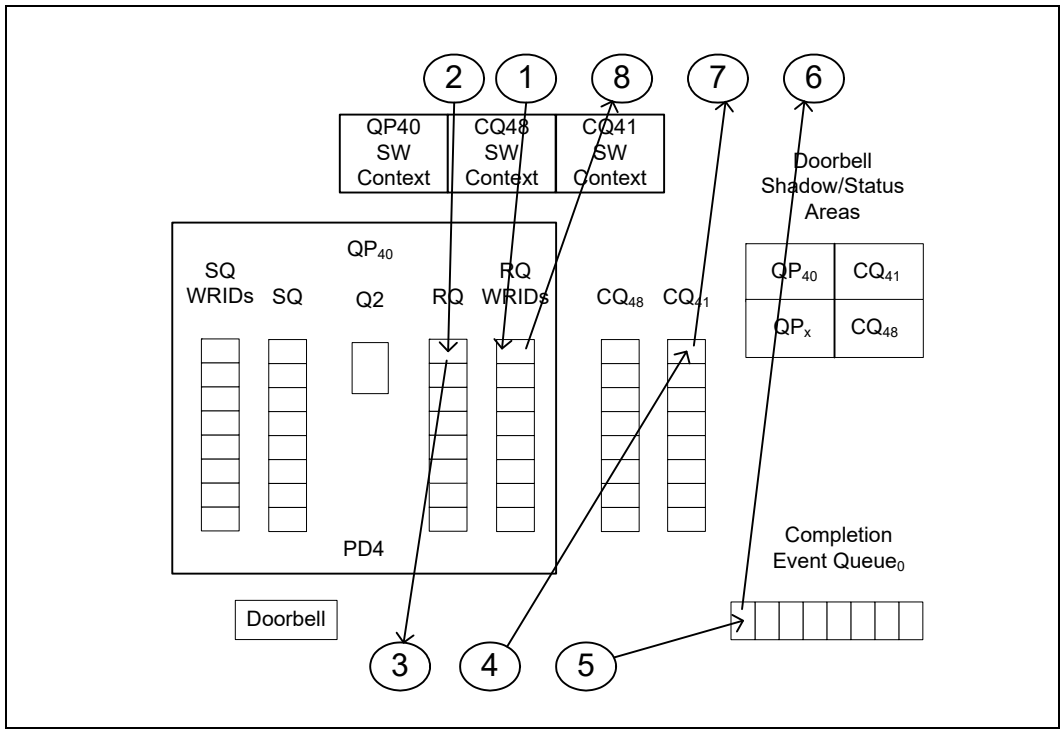
Figure 38-125.PE Operation: RQ



The initialization required to bring a QP to an operation state was generally described in Section 38.36.2.1.7. Once this initialization has been performed, the steps in Figure 38-125 show how software and the 10 GbE controller interact for RQ operations.

1. Software saves the Work Request ID (WRID) passed in on the post receive verbs call.
2. Software builds a RQE using the fields that passed in on the post receive verbs call.
   a. The valid bit in the RQE must only be set once all fields are valid since the 10 GbE controller might read RQEs at any time. Note that the valid bit is a generational valid bit, which means that the first (and all subsequent odd) iterations through the RQ, 1 means valid, on all even iterations through the RQ, 0 indicates that the RQE is valid.
3. Once an operation targeting a QPs RQ is received, the 10 GbE controller reads QP context to determine the location of the RQE to be read.
   a. The RQE is read from host memory and the valid bit is checked. If the RQE is invalid, the packet associated with RQE is dropped or the QP is put into the error state and an AE is generated.
4. The 10 GbE controller reads the 128 byte RQ read block that contains the RQE indicated by the QP context value of HW_RQ_Tail
   a. The 10 GbE controller potentially processes all valid RQEs contained in the 128 byte RQ read block if more than one inbound operation targeted this QP's RQ. For this example it is assumed that a single inbound operation has been received.
   b. The 10 GbE controller processes RQE 0 which likely includes writing data from host memory and sending TCP acknowledgments.
   c. The 10 GbE controller increments the HW_RQ_Tail.

5. The 10 GbE controller writes to the CQ associated with the RQ.
6. The 10 GbE controller optionally writes to the CEQ if the CQ was written and generates an interrupt.
7. Software then fields the interrupt if one was generated and reads the CEQ to determine the CQ that generated the event (an application might be polling the CQ direction in which case steps 6 and 7 are skipped). Typically the CEQE contains the most significant 63 bits of the virtual address of CQ context to make CE processing efficient.
8. Software then reads the CQ to determine the QP and WQ that generated the work completion, the RQE index of the WR is reported in the CQE along with a 64-bit pointer that is typically set to the software QP context address at QP creation time.
9. Software then reads the RQ WRID array for the RQE index from the completion, the resulting WRID is returned to the application as an indication that the original WR has completed.

38.36.2.2 iWARP State Management

iWARP QP state is controlled by the application to a large extent. The verbs interface enables the application to manage QP transitions and provides rules for what the RNIC Interface (RI) must enforce. This section is not intended to repeat all information from the verbs specification. It is intended to be an overview of the expected usage model to be used with the 10 GbE controller. In the end, it is a combination of hardware support from the 10 GbE controller and supporting software that provides a verbs-compliant interface. Table 38-445 lists the operations performed by the 10 GbE controller based on the iWARP QP state.

Table 38-445.iWARP QP State Behavior

QP State	QP Activities
Non-existent	• Doorbell rings are dropped silently. • No transmit (because doorbell rings are dropped). • No receive processing (no hash entry).
Idle	• SQ/RQ WQEs can be posted. • No SQ WQEs are processed. • No receive processing (no hash entry).
RTS	• Normal SQ/RQ/CQ/CEQ processing (hash entry added on transition to RTS by firmware).
Closing	• No new SQ work is expected, but if a door bell rings while in this state, Product Name schedules work and reports an AE BAD_CLOSE (note this is not LLP_BAD_CLOSE) and transitions to an error state. • No new RQ work is expected; however, if a packet arrives with data it is treated as an error (BAD_CLOSE) and the QP transitions to error state.
Terminate	• No RQ processing (discarding received data). • No new SQ WQEs processed. • SQ WQEs might be retransmitted. • Terminate/FIN might be transmitted.
Error	• No SQ WQEs processed. • No RQ WQEs processed. • Host software eventually requests CQP to remove the hash entry.

QP state transitions and the associated software and hardware/firmware actions driven from software interactions with the application are listed in Table 38-446.

Table 38-446.iWARP QP State Transition (Sheet 1 of 2)

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
Nonexistent ≥ Idle (CreateQP)	• Initialize the HMC backing pages necessary to support the QP. • Allocate/Initialize all software tracking structures for the PD, CQ, QP. • Assign QP to a PD. • Create CQ. • Allocate SQ and RQ. • Allocate terminate message buffer (Q2). • Allocate the doorbell shadow area. • Perform parameter checks specified by the verbs specification. • Issue CreateQP WQE to CQP.	• Update QP context.
Idle ≥ Idle	• Perform parameter checks specified by the verbs specification. • Issue Modify QP to CQP, next state = Idle.	• QP state parameters are updated.
Idle ≥ RTS	• Create a TCP socket and ensure that it is in the established state. • Allocate and initialize a local MAC table entry. • If a streaming mode message is desired, ensure that it has been placed on the SQ immediately following any unacknowledged TCP send data. • Perform parameter checks specified by the verbs specification. • Issue Modify QP to CQP, next state = RTS.	• Set the TCP state to established and iWARP state to RTS. • Insert the QP's hash table entry to receive accelerated data. • Start scheduling work for the QP.
Idle ≥ Error	• Perform parameter checks specified by the verbs specification. • Issue modify QP WQE to CQP with the next state set to error, reset connection (if connection not already reset) and remove quad hash (if quad hash entry has not been previously removed) by setting appropriate bits in the bits set. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs. • Handle poll for completion requests for flushed WQEs, the CQ has one CQE for each WQ that had pending WQEs, software must report all pending WQEs as flushed once it gets the single flushed CQE (per WQ with pending WQEs), the number of WQEs flushed can be determined from software's head and tail for the SQ and RQ at the point in time that the poll for completion call is made that returns a flushed CQE.	• Set iWARP state to error. • When the flush WQEs operation is issued and any WQEs are outstanding on the SQ and/or RQ as requested by host software, complete the first pending WQE for each WQ (flushed completion status).
RTS ≥ Closing	• Perform parameter checks specified by the verbs specification. • Stop processing new PostSQ/RQ requests. • Ensure that no outstanding SQ or outbound RDMA read responses are pending (this is really up to the application). • Start a timer to put a bound on how long a connection is allowed to stay in the closing state. • Submit a Modify QP WQE to CQP the next state = Closing. • If the completion error is a bad close, generate an AE, QP state is already error • If any RQ WQEs are still pending, issue Flush WQEs operation to CQP.	• If there is pending SQ or Q1 work, generate a completion error (bad close), software needs to translate into an AE. • Else, update iWARP state to closing. • When the flush WQEs operation is issued and any RQ WQEs are outstanding, complete the first pending WQE for each WQ (flushed completion status).

Table 38-446.iWARP QP State Transition (Sheet 2 of 2)

Initial and Next QP State	Software Actions During State Transition	Hardware Actions During State Transition
RTS ≥ RTS	• Perform parameter checks specified by the verbs specification. • Ensure that the number of currently pending outbound RDMA read requests is less than or equal to the new ORD value. • Ensure the only parameter that is changed is ORD size, it is only allowed to shrink or remain the same.	• Update the ORD value.
RTS ≥ Terminate or Terminate ≥ Terminate	• Perform parameter checks specified by the verbs specification for the RTS -> Terminate case. • Set terminate action (usually send FIN and terminate). • Start a timer to put a bound on how long the QP is allowed to stay in the terminate state in the case of an abortive tear down. • If completion error indicates tcp_state = error: • a. issue Modify QP WQE to CQP with next state = error. • Generate LLP connection reset AE. • If terminate sent AE is received, issue an additional Modify QP with next state = Terminate and terminate action set to 3 (do not sent FIN or terminate). • If completion code indicates LLP closed then a the TCP state has transitioned to closed or time wait so an LLP close complete AE should be generated by software.	• If the TPC state = Closed, generate completion error indicating tcp_state was closed (indicates a reset was received). • Update iWARP state to terminate. • Once all outstanding TCP segments have been acknowledged, send the terminate message and/or FIN. • Generate a terminate sent AE.
RTS ≥ Error or Closing ≥ Error or Terminate ≥ Error	• Perform parameter checks specified by the verbs specification. • See IDLE ≥ Error case for CQP and completion processing. • Block until the RST sent AE has been seen (probably want to start a timer, and upload QP context if it expires to see what has happened). • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs.	• If host software requested the connection to be reset, send a TCP RST segment. • Remove the QP's HTE if the Remove_Hash_Entry field is set. • Update iWARP state to error. • Wait for all packets to clear the pipeline. • Clean up QP context (prevent future scheduling). • Generate a RST sent AE. • Set the TCP state to closed.
Error ≥ Idle	• Software issues discard and create QP operations to CQP.	
Error ≥ Error	• Submit a Modify QP WQE to CQP with next state = Error and the reset_connection bit set. • If any WQEs are still pending, issue flush WQEs operation to CQP after the Modify QP operation completes, if the QP has been setup with a last streaming mode message, the first WQE on the SQ is the streaming mode message, not an iWARP message, a unique completion context should be put in the LSSM WQE in order to correctly distinguish it from iWARP WQEs.	• See RTS ≥ error.

QP state transitions and the associated software and hardware/firmware actions driven from wire interactions with remote peer are listed in Table 38-447.

Table 38-447.iWARP QP State Transition Driven from the Wire

Row #	Wire Activity	Initial QP State (TCP, iWARP)	10 GbE Controller	Software
0	FIN Received	EST, RTS	Set the TCP state to close wait (note that iWARP state is not changed). If no work was outstanding on the SQ or Q1: Issue AE_LLP_FIN_RECEIVED. Else Issue AE_RDMAP_ROE_BAD_LLP_CLOSE. Send ACK to the FIN. Continue processing SQ WQEs.	Stop processing new post RQ operations if not already stopped. Issue appropriate AEs. If system software does not automatically generate closing, start the closing process based on the received event by issuing Modify QP with the next state set to closing.
1	FIN Received	FW1, Closing	Send ACK to the FIN. If the ACK receive with the inbound FIN ACKs the transmitted FIN: Set the TCP state to Time Wait. Issue AE_LLP_CLOSE_COMPLETE. Else Set the TCP state to Closing (note that iWARP state is not changed).	If the AE_LLP_CLOSE_COMPLETE is received: Cancel the pending disconnect fail safe timer. Stop processing new post RQ operations if not already stopped. SQ operation processing should have been stopped on the Modify QP with the next state set to closing. Issue appropriate AEs. Issue Flush WQE CQP operation. The application or system software starts the QP cleanup process.
2	FIN Received	FW2, Closing	Send ACK to the FIN. Set the TCP state to time wait (note that iWARP state is not changed). Issue AE_LLP_CLOSE_COMPLETE.	See row 1 software actions.
3	FIN Received	EST, Terminate	See Row 0 10 GbE Controller actions.	See row 1 software actions.
4	FIN Received	FW1, Terminate	See Row 1 10 GbE Controller. actions.	See row 1 software actions.
5	FIN Received	FW2, Terminate	See Row 2 10 GbE Controller actions.	See row 1 software actions.
7	ACK Received	FW1, Closing or Terminate	Set the TCP state to FW2.	N/A
8	ACK Received	FW2, Closing or Terminate	Send ACK to the FIN. Set the TCP state to time wait (note that iWARP state is not changed). Issue AE_LLP_CLOSE_COMPLETE.	See row 1 software actions.
9	ACK Received	Closing, Closing or Terminate	Set the TCP state to time wait (note that iWARP state is not changed). Issue AE_LLP_CLOSE_COMPLETE.	See row 1 Software actions.

38.36.2.3 Partial FPDU Support

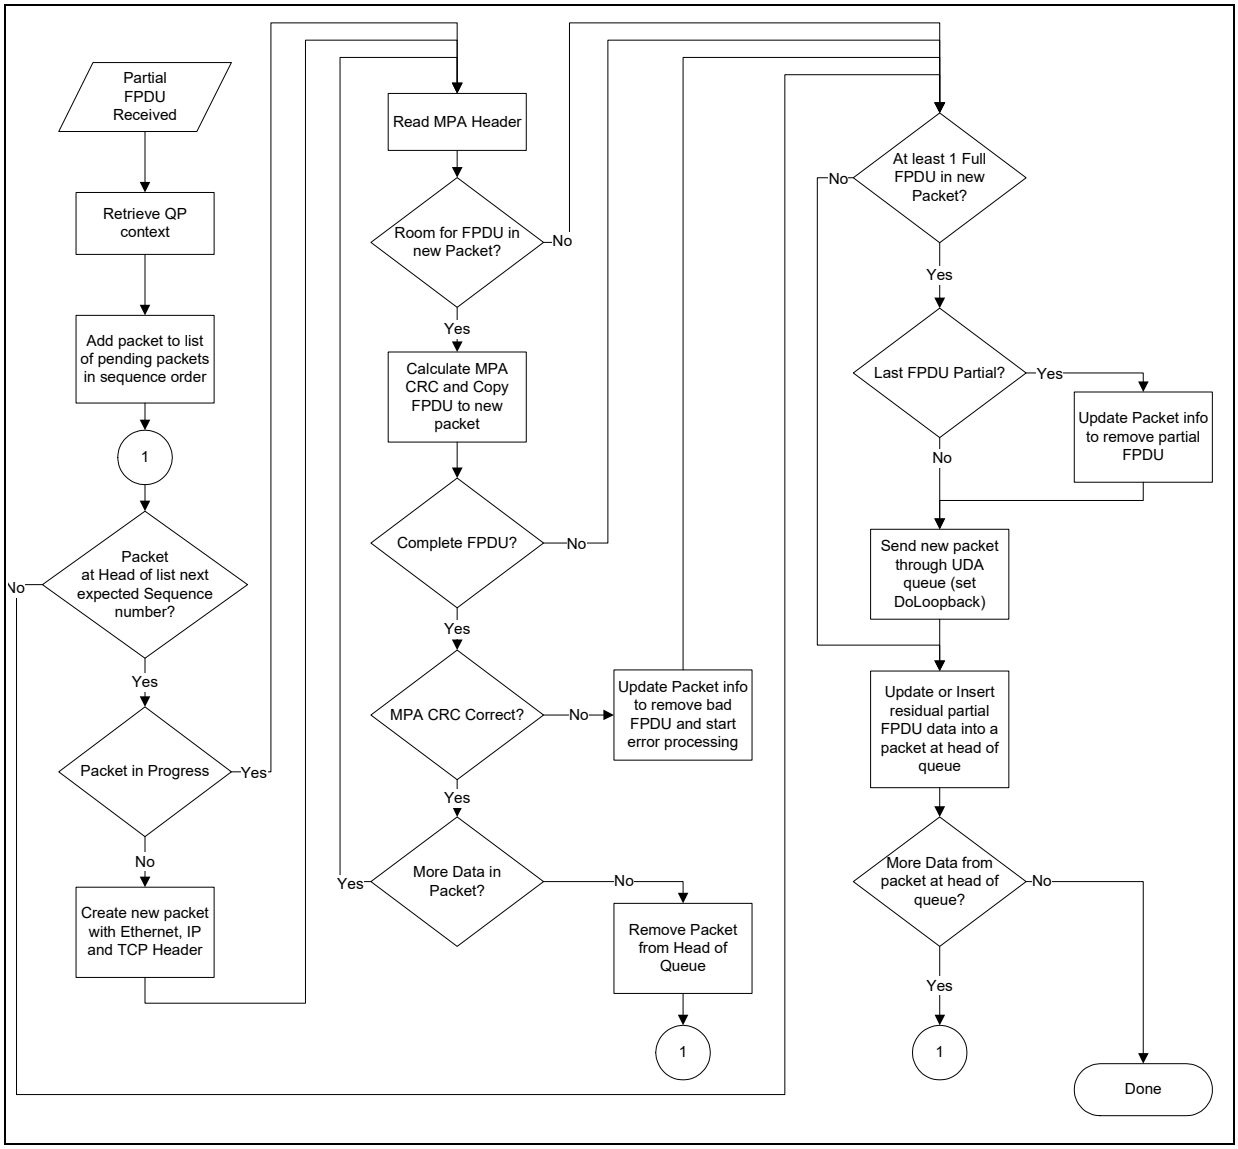
The 10 GbE controller supports partial iWARP FPDUs using software assist. High performance iWARP implementations pay attention to the underlying network MTU and form iWARP FPDUs that do not span Ethernet segments. In the case where software iWARP implementations (or other RNICs) form iWARP FPDUs that span Ethernet segments, the 10 GbE controller reports these Ethernet packets to the UDA queues. Additionally, the PE writes the first_partial_sequence_number field in the Q2 area of the associated QP context. See Section 38.36.4.1 for the definition of the Q2 area. Once a partial FPDU has been received, all subsequent packets for that QP are also forwarded to the UDA queue until software has been able to process the packets and send them back to the 10 GbE controller. Host software must process the packets and break them into full FPDUs and send them back to the 10 GbE controller through a UDA SQ with the *SWPE* bit set. The 10 GbE controller then processes the packets as if they

had come from the wire as full FPDUs. Once all the packets have been sent back to the 10 GbE controller, the QP is automatically set back to normal operation and no further packets are sent to the UDA queues until a new partial FPDU is received. Each time the Q2 area has an updated expected sequence number, the Sequence_Update_Toggle field is toggled. Software must keep track of the last value that it has seen in the Q2 area. If the value does not match, software should update its expected sequence number.

Note: Software must perform the MPA CRC check on all packets that are sent back through to the PE using the *SWPE* bit in addition to reforming full iWARP FPDUs. The 10 GbE controller does not support checking the MPA CRC in hardware on this pass-through chip.

The high-level software algorithm used to handle partial FPDUs is shown in Figure 38-126.

Figure 38-126.Partial FPDU Software Algorithm



38.36.2.4 CEQ Entry Format

A CEQ is a circular ring of CEQEs in host memory. CEQs can be virtually or physically contiguous and are managed using the control QP (see Section 38.36.3.4.2).

Table 38-448.PE CEQ Entry Format

Byte Offset	[Bit Range]Field Name	
0	[63]CEQE_Valid	[62:0]CQ_Context_Value

CEQE_Valid (1)

The CEQE_Valid bit for CEQE is a bit that indicates that a CEQE is ready to be processed by software. The polarity of the valid bit changes each time the CEQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid CEQE. Software is responsible to clear (set to 0b) all memory in a CEQ initially at CEQ creation. The first iteration (and subsequent odd numbered iterations) through the CEQ, the 10 GbE controller sets the *Valid* bit to 1b when it writes a new CEQE. For the second iteration (and all even numbered iterations) through the CEQ, the 10 GbE controller sets the *Valid* bit to 0b when it writes a new CEQE.

CQ_Context_Value (63)

CQ_Context_Value is the value of CQ_Context_Value specified at CQ creation (see Section 38.36.3.3.3). Typically this value is the low 63 bits of a pointer to a software CQ object to enable software to quickly process new CEs.

38.36.2.5 AEQ Entry Format

An AEQ is a circular ring of Asynchronous Event Queue Entries (AEQEs) in host memory. AEQs can be virtually or physically contiguous and are managed using the Control QP (see Section 38.36.3.5).

Table 38-449.PE AEQ Entry Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Completion_Context_Value		
8	[63]	AEQE_Valid	[49:34]	AE_Code
	[62:61]	Q2_data_written	[33]	AEQE_Overflow
	[60:57]	TCP_State	[32]	Reserved
	[56:54]	iWARP_State	[31:18]	WQ_Desc_Index
	[53:50]	AE_Source	[17:0]	QP_CQ_ID

Completion_Context_Value (64)

Completion_Context_Value is a software supplied token that can be used to efficiently locate the necessary software resources necessary to process an AE. The token that is reported can be the QP_Completion_Context from the QP that caused the AE or can be the CQ_Context_Value supplied during CQ creation depending upon the AE_ID and AE_Source fields of the AE.

WQ_Desc_Index (14)

WQ_Desc_Index value is valid only if the source of the event is a WQ (SQ or RQ) and the AE_Code indicates that the WQ_Desc_Index field is valid. See Section 38.36.2.6 for more details on how to determine if WQ_Desc_Index is valid.

QP_CQ_ID (18)

This field carries either the QP ID that is associated with the AE or the CQ ID that is associated with the AE. The AE_Source field (defined later) or the AE_ID field are used to determine if the AE is associated with a QP or a CQ.

AE_Code (16)

AE_Code is the AE code the caused the AE. See Section 38.36.2.6 for more details.

AE_Source (4)

AE_Source defines the source of the AE. The following table lists the values and the related source of the problem.

AE_Source	Description
0000b	Reserved.
00x1b	The AE is associated with the RQ of a QP. QP_CQ_ID is the QP ID. Completion_Context_Value is set to the value of QP_Completion_Context from the associated QP and WQ_Desc_Index is valid.
xx10b	The AE is associated with a CQ. QP_CQ_ID is the CQ ID and Completion_Context_Value is the CQ_Context_Value specified at CQ creation. WQ_Desc_Index not valid.
01x1b	QP_CQ_ID is the QP ID. Completion_Context_Value is set to the value of QP_Completion_Context from the associated QP and WQ_Desc_Index is valid. The event is associated with the SQ of a QP.
10x1b	The AE is associated with an inbound RDMA write or inbound RDMA read response operation related to a QP. QP_CQ_ID is the QP ID. Completion_Context_Value is set to the value of QP_Completion_Context from the associated QP and WQ_Desc_Index is not valid.
11x1b	The AE is associated with an outbound RDMA read response operation related to a QP. This value can also be returned is other cases in which the WQ_Desc_Index value cannot be retrieved by the 10 GbE controller. Completion_Context_Value is set to the value of QP_Completion_Context from the associated QP and WQ_Desc_Index is not valid.

Note that some AE_ID values uniquely define the source of the AE. For these events, AE_Source should be ignored. See Section 38.36.2.6 for more details.

iWARP_State (3)

iWARP_State reflects the iWARP state of the connection at the time the AE occurred according to the 10 GbE controller hardware.

iWARP_State	Description
0	Nonexistent
1	Idle
2	Ready To Send (RTS)
3	Closing
4	Reserved
5	Terminate
6	Error
7	Reserved

TCP_State (4)

TCP_State reflects the TCP state of the connection at the time the AE occurred according to the 10 GbE controller hardware.

TCP_State	Description
0	Nonexistent
1	Closed
2	Listen

TCP_State	Description
3	Syn_Sent
4	Syn_Received
5	Established
6	Close_Wait
7	Fin_Wait_1
8	Closing
9	Last_Ack
10	Fin_Wait_2
11	Time_Wait
12-15	Reserved

AEQE_Valid (1)

The AEQE_Valid bit for AEQE is a bit that indicates that a AEQE is ready to be processed. The polarity of the valid bit changes each time the AEQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the *Valid* bit once software has processed a valid AEQE. Software is responsible to clear (set to 0b) all memory in a AEQ initially at AEQ creation. The first iteration (and subsequent odd numbered iterations) through the AEQ, the 10 GbE controller sets the *Valid* bit to 1b when it writes a new AEQE. For the second iteration (and all even numbered iterations) through the AEQ, the 10 GbE controller sets the *Valid* bit to a 0b when it writes an new AEQE.

AEQE_Overflow (1)

The AEQE_Overflow bit for AEQE is a bit that indicates that a AEQE has been completely filled and that there might have been a loss of subsequent AEQEs. No further AEQEs are generated until additional space is allocated to the AEQ using the PFPE_AEQALLOC or VFPE_AEQALLOC register.

Q2_data_written (2)

Q2_data_written provides status regarding error information that is reported for errors detected for iWARP connections when an AE is generated. The Q2 data area is configured as part of QP setup. See Table 38.36.3.3.2 for more information. This values for this field are:

0 = No data associated with this AE has been written to Q2.

1 = Data written to Q2 starts at the Ethernet header of the offending packet.

2 = Data written to Q2 starts at the MPA header of the offending PDU.

3 = Reserved.

38.36.2.6 AE Codes

Table 38-450 lists the values that can be returned in the AE_ID field of an AEQ entry. The column titled Source defines if the source of the AE is pre-determined based on the AE code or the AE_Source field of the AE field must be used to determine the source. Note that the source of the AE effects the Completion_Context_Value, WQ_Desc_Index, and QP_CQ_ID fields in the AE queue entry defined in section Table 38.36.2.5. The WQ_Desc_Index field is not valid for AE codes that have a source designated as QP or CQ.

Table 38-450.PE AE codes (AE_ID) (Sheet 1 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_AMP_UNALLOCATED_STAG	0x0102	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window that is in an un-allocated state.	Terminate	AE_Source
AE_AMP_INVALID_STAG	0x0103	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window that is in an invalid state.	Terminate	AE_Source
AE_AMP_BAD_QP	0x0104	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory window from a different QP than the QP to which the memory window was bound.	Terminate	AE_Source
AE_AMP_BAD_PD	0x0105	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window from a QP with a different PD than the PD associated memory region or window.	Terminate	AE_Source
AE_AMP_BAD_STAG_KEY	0x0106	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window when the key portion of the STag did not match the key associated with the memory region or window.	Terminate	AE_Source
AE_AMP_BAD_STAG_INDEX	0x0107	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window with an STag index larger than the largest index allowed for the PCI function.	Terminate	AE_Source
AE_AMP_BOUNDS_VIOLATION	0x0108	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access memory outside of the memory area defined by the memory region or memory window.	Terminate	AE_Source
AE_AMP_RIGHTS_VIOLATION	0x0109	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window and a rights violation occurred.	Terminate	AE_Source
AE_AMP_TO_WRAP	0x010A	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to access a memory region or memory window and the tagged-offset plus the ULPDU length caused the address generated for the memory region or window to wrap.	Terminate	AE_Source
AE_AMP_FASTREG_VALID_STAG	0x010C	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to issue a registration operation to a valid memory region.	Terminate	AE_Source

Table 38-450.PE AE codes (AE_ID) (Sheet 2 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_AMP_FASTREG_MW_STAG	0x010D	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to issue a registration operation to a memory window.	Terminate	AE_Source
AE_AMP_FASTREG_INVALID_RIGHTS	0x010E	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that a rights mismatch was detected during a registration operation.	Terminate	AE_Source
AE_AMP_FASTREG_INVALID_LENGTH	0x0110	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to issue a registration operation with an invalid length.	Terminate	AE_Source
AE_AMP_INVALIDATE_SHARED	0x0111	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to invalidate a shared memory region.	Terminate	AE_Source
AE_AMP_INVALIDATE_NO_REMOTE_ ACCESS_RIGHTS	0x0112	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to remotely invalidate a memory region or memory window that did not have remote access rights specified.	Terminate	AE_Source
AE_AMP_INVALIDATE_MR_WITH_BOU ND_WINDOWS	0x0113	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that attempt was made to invalidate a memory region that still had one or more memory windows bound to it.	Terminate	AE_Source
AE_AMP_MWBIND_VALID_STAG	0x0114	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that the STag used on a bind operation was a memory window that was already valid.	Terminate	AE_Source
AE_AMP_MWBIND_OF_MR_STAG	0x0115	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that the STag used on a bind operation was a memory region instead of a memory window.	Terminate	AE_Source
AE_AMP_MWBIND_TO_ZERO_BASED_ STAG	0x0116	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that an attempt was made to bind a memory window to a zero-based memory region.	Terminate	AE_Source
AE_AMP_MWBIND_TO_MW_STAG	0x0117	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that the STag specified for the memory window to be bound to was a memory window instead of a memory region.	Terminate	AE_Source
AE_AMP_MWBIND_INVALID_RIGHTS	0x0118	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that a rights violation was detected during a memory window bind operation.	Terminate	AE_Source

Table 38-450.PE AE codes (AE_ID) (Sheet 3 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_AMP_MWBIND_INVALID_BOUNDS	0x0119	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that a bounds violation was detected during a memory window bind operation.	Terminate	AE_Source
AE_AMP_MWBIND_TO_INVALID_ PARENT	0x011A	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that the memory region that a memory window attempted to bind to was invalid.	Terminate	AE_Source
AE_AMP_MWBIND_BIND_DISABLED	0x011B	This AE is generated when an memory protection error has been detected by the 10 GbE controller. This error indicates that a memory window Bind operation was attempted on a memory region that had bind support disabled.	Terminate	AE_Source
AE_PRIV_OPERATION_DENIED	0x011C	This AE is generated when a privileged operation is attempted on a non-privileged QP, this includes bind operations without bind enabled, fast register without fast register enabled, and STag zero without privilege is not enabled.	Terminate	QP
AE_AMP_MWBIND_WRONG_TYPE	0X120	A memory window bind specified a non-matching window type.	Terminate/ Error	QP
AE_AMP_FASTREG_PBLE_MISMATCH	0X121	Invalid VM fast register request to change a physical MR to a virtually mapped MR or vice versa.	Terminate/ Error	QP
AE_UDA_XMIT_DGRAM_TOO_LONG	0x0132	This AE is generated by the 10 GbE controller when a total length of packet exceeds MSS configured for QP.	Terminate	QP
AE_UDA_XMIT_DGRAM_TOO_SHORT	0x0134	This AE is generated by the 10 GbE controller when a total length of packet is smaller than 16 bytes.	Terminate	QP
AE_BAD_CLOSE	0x0201	This AE is generated when in iWARP state = closing and an iWARP PDU is received. If the 10 GbE controller detects SQ or Q1 work during a Modify QP RTS ≥ closing then a completion error is returned to the Modify QP request instead of an AE.	Error	QP
AE_RDMAP_ROE_BAD_LLP_CLOSE	0x0202	This AE indicates that there was either SQ or Q1 work pending when a FIN was received or data was received with the FIN.	Terminate~~- or Error~~	QP
AE_CQ_OPERATION_ERROR	0x0203	Product Name attempted to generate a CQ entry on an empty CQ that has overflow detection enabled.	N/A	AE_Source
AE_RDMA_READ_WHILE_ORD_ZERO	0x0205	This AE is generated when an RDMA read request is issued to a QP that has the Outbound RDMA Read Queue Depth (ORD) set to 0b.	Terminate	QP
AE_STAG_ZERO_INVALID	0x0206	Detected on an inbound RDMA write, RDMA read response, or RDMA read request (either source or sink). Outbound check is also performed for SQ and RQ operations when a QP is not privileged. Inbound 0 byte RDMA read and RDMA write operations are not indicated as errors since no host data is accessed.	Terminate	QP
AE_IB_RREQ_AND_Q1_FULL	0x0207	This AE is generated if an inbound RDMA read is received and the target QP's inbound RDMA RQ (Q1) is full.	Terminate	QP

Table 38-450.PE AE codes (AE_ID) (Sheet 4 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_WQE_UNEXPECTED_OPCODE	0x020A	This AE is generated if QP encounters a WQE with an invalid OP code on a SQ.	Transmit Suspended	QP
AE_WQE_INVALID_PARAMETER	0x020B	This AE is generated if QP encounters a WQE with invalid parameters.	Terminate	AE_Source
AE_WQE_LSMM_TOO_LONG	0x0220	This AE is generated if the Last streaming mode message specified on the Modify QP operation from the iWARP IDLE state to RTS state is longer than the MSS.	Terminate	AE_Source
AE_DDP_INVALID_MSN_GAP_IN_MSN	0x0301	The AE is generated with a gap is detected in the MSN used to index the RQ or Q1 when data is in order with respect to TCP sequence space.	Terminate	AE_Source
AE_DDP_UBE_DDP_MESSAGE_TOO_LONG_FOR_AVAILABLE_BUFFER	0x0303	This AE is generated on inbound iWARP PDUs if the message offset plus the size of the PDU data is larger than the number of bytes in the RQ WQE targeted by the PDU.	Terminate	AE_Source
AE_DDP_UBE_INVALID_DDP_VERSION	0x0304	This AE is generated when an inbound iWARP PDU has an incorrect DDP version number.	Terminate	QP
AE_DDP_UBE_INVALID_MO	0x0305	This AE is generated if the message offset is larger than the number of bytes in the RQ WQE targeted by the PDU on inbound iWARP PDUs.	Terminate	QP
AE_DDP_UBE_INVALID_MSN_NO_BUFFER_AVAILABLE	0x0306	This AE is generated if and inbound send operation targets an unallocated RQ WQE and the 10 GbE controller is configured to drop the connection for this condition.	Terminate	AE_Source
AE_DDP_UBE_INVALID_QN	0x0307	This AE is generated when an inbound untagged iWARP PDU has an incorrect queue number.	Terminate	QP
AE_DDP_NO_L_BIT	0x0308	Detected when there is no L bit on an inbound RDMA read request.	Terminate	QP
AE_RDMAP_ROE_INVALID_RDMAP_VERSION	0x0311	This AE is generated when an inbound iWARP PDU has an incorrect RDMAP version number.	Terminate	QP
AE_RDMAP_ROE_UNEXPECTED_OPCODE	0x0312	This AE is generated when an inbound iWARP PDU has an incorrect opcode number.	Terminate	QP
AE_ROE_INVALID_RDMA_READ_REQUEST	0x0313	This AE is generated when an inbound RDMA read iWARP PDU is received but the QP is not enabled for inbound RDMA read support.	Terminate	QP
AE_ROE_INVALID_RDMA_WRITE_OR_READ_RESP	0x0314	This AE is generated when an inbound RDMA read response or RDMA write iWARP PDU is received but the QP is not enabled for inbound RDMA read responses or RDMA writes.	Terminate	QP
AE_INVALID_ARP_ENTRY	0x0401	This AE is reported when a connection attempts to transmit a packet using an invalid ARP entry. Host software will either enable the QP for transmitting after updating the ARP entry or upload/discard the connection because the ARP entry is no longer valid.	Transmit Suspended	QP
AE_INVALID_TCP_OPTION_RCVD	0x0402	This AE is generated when the 10 GbE controller encounters an unsupported TCP option and the 10 GbE controller is not configured to ignore unsupported TCP options via the ignore_tcp_uns_options QP context bit. The packet with invalid TCP options are dropped if this AE is generated.	No change	QP
AE_STALE_ARP_ENTRY	0x0403	This AE is reported by the first connection that attempts to transmit a packet using a stale ARP entry.	No change	QP

Table 38-450.PE AE codes (AE_ID) (Sheet 5 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_INVALID_MAC_ENTRY	0x0405	This AE indicates that an invalid MAC table entry was referenced from a QP transmit operation.	Terminate	AE_Source
AE_LLP_CLOSE_COMPLETE	0x0501	This AE indicates that the TCP state of an iWARP QP has transitioned to either closed or time wait in a graceful fashion.	No change	QP
AE_LLP_CONNECTION_RESET	0x0502	This AE indicates that a TCP packet with the *RST* bit set has been received on a TCP connection that is associated.	Error	QP
AE_LLP_FIN_RECEIVED	0x0503	This AE indicates that a TCP packet with the FIN bit set has been received without data and the iWARP state is RTS (implies TCP state is established), host software is responsible for issuing a Modify QP ≥ closing to complete the QP transition to the closing the state.	No change	QP
AE_LLP_RECEIVED_MPA_CRC_ERROR	0x0505	This AE is reported when an MPA CRC error is detected.	Terminate	QP
AE_LLP_SEGMENT_TOO_SMALL	0x0507	This AE is reported when an iWARP segment is received that is too small to contain a DDP or RDMAP header.	Terminate	QP
AE_LLP_SYN_RECEIVED	0x0508	This AE indicates that a TCP packet with the SYN bit set is received on a connection that is associated with an iWARP connection.	Error	QP
AE_LLP_TERMINATE_RECEIVED	0x0509	This AE indicates that a terminate message has been received for an iWARP QP. The received terminate data is placed in the Q2 area associated with the QP in host memory.	Terminate	QP
AE_LLP_TOO_MANY_RETRIES	0x050A	This AE is used to report too many retransmission retries.	Transmit Suspended	QP
AE_LLP_TOO_MANY_KEEPALIVE_ RETRIES	0x050B	This AE is used to report too many keep alive attempts.	Transmit Suspended	QP
AE_LLP_DOUBT_REACHABILITY	0x050C	This AE is used to report that it has reached the threshold for the given connection. This is used in dead gateway detection or black holes.	No change	QP
AE_RESOURCE_EXHAUSTION	0x0520	This AE is used to report that a QP attempted to allocate Q1 or XMIT FIFO resource and no resource was available.	No change	AE_Source
AE_RESET_SENT	0x0601	This AE is generated when the 10 GbE controller sends a reset after host software has requested the connection to be reset via a Modify QP operation.	No change	QP
AE_TERMINATE_SENT	0x0602	This AE is generated when the 10 GbE controller sends a terminate message after host software has requested a terminate to be sent on a connection via a Modify QP operation.	No change	QP
AE_RESET_NOT_SENT	0x0603	This AE is generated when the 10 GbE controller did not send a reset after host software has requested the connection to be reset via a Modify QP operation. The reset will not be sent due to TCP state already having been transitioned to time wait or closed.	No change	QP
AE_LCE_QP_CATASTROPHIC	0x0700	This AE is generated by the 10 GbE controller when it receives an error on a hardware transaction.	Terminate	QP

Table 38-450.PE AE codes (AE_ID) (Sheet 6 of 6)

Asynchronous Event Code	Value	Description	iWARP State After AE	Source
AE_LCE_FUNCTION_CATASTROPHIC	0x0701	This AE is generated by the 10 GbE controller when it receives an error on a hardware transaction that impacts the entire PCI function. QP_CQ_ID is not reliable for this AE and should be ignored.	Terminate	N/A
AE_LCE_CQ_CATASTROPHIC	0x0702	This AE is generated by the 10 GbE controller when it receives a local catastrophic error on a hardware transaction that impacts a CQ.	Terminate	CQ
AE_QP_SUSPEND_COMPLETE	0x0900	This AE is generated upon completion of the requested QP Suspend operation	Transmit Suspended	QP

38.36.2.7 Steering Tag (STag) and Processing Hint Support for PE Traffic (TPH)

Refer to the section for information about how to enable TLP processing hint support.

The following table lists how the STag and processing hints are generated and how TPH operation is enabled for different types of DMA traffic associated with the PE.

Table 38-451.STag and Processing Hint Programming

Traffic Access	STag Location	PH Value[1]	Enable
CQ Element Writes	CQ Context TPH_value	GL_TPH_CTRL.Data_PH	CQ context TPH_en
CQ Doorbell Shadow Area Reads	CQ Context TPH_value	GL_TPH_CTRL.Data_PH	CQ context TPH_en
CEQ Element Writes	CEQ Context TPH_value	GL_TPH_CTRL.Data_PH	CEQ context TPH_en
SQ WQ Element Reads	QP Context SQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context SQ_TPH_en
SQ Work Doorbell Shadow Area Reads	QP Context SQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context SQ_TPH_en
RQ WQ Element Reads	QP Context RQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context RQ_TPH_en
Data Payload Writes	QP Context RQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context RCV_TPH_en
Data Payload Reads	QP Context SQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context XMIT_TPH_en
UDA Packet Header Read	QP Context SQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context SQ_HDR_TPH_en
UDA Packet Header Write	QP Context RQ_TPH_value	GL_TPH_CTRL.Data_PH	QP context RQ_HDR_TPH_en

Notes:

1. Default is 10b (target).

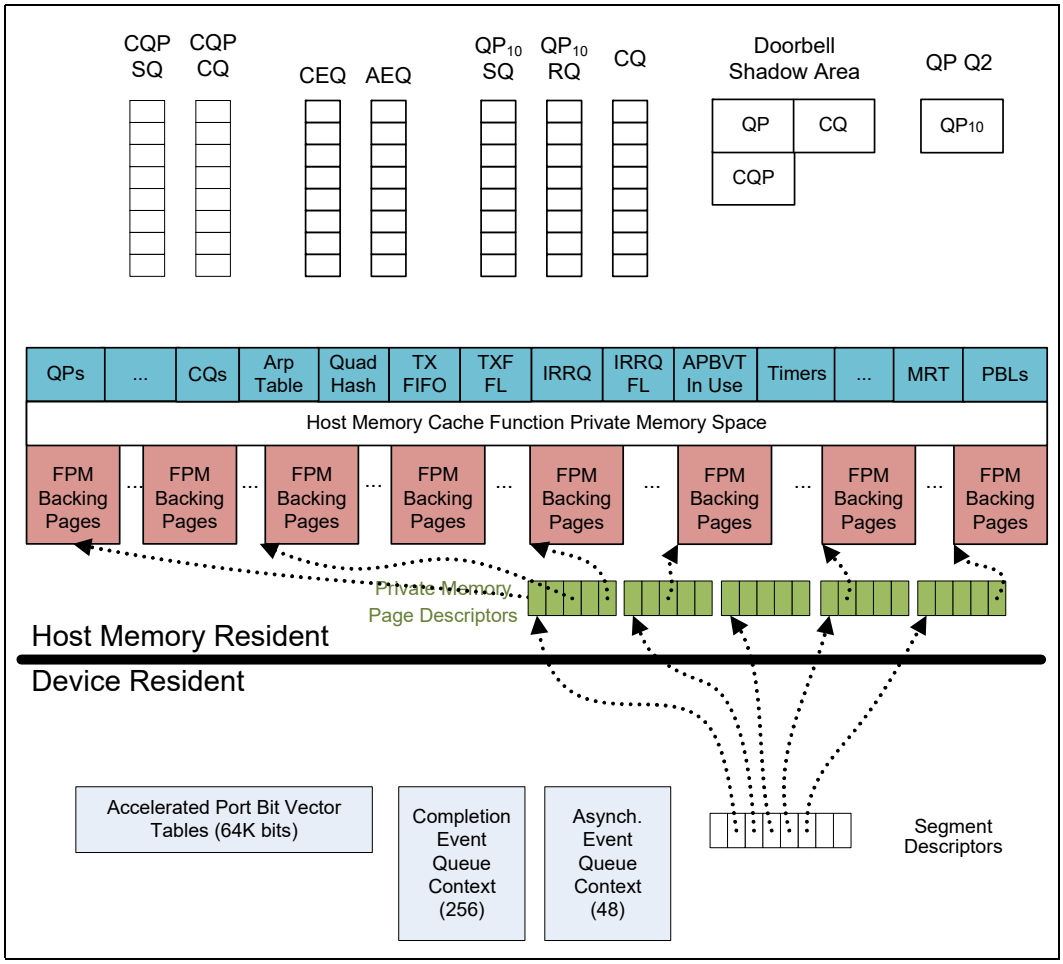
The 10 GbE controller has TPH values for CQ and CEQ in each of the various contexts. When a read is done (such as reading the CQ shadow area) the 10 GbE controller updates the context with the current TPH hint that is returned in the completion (CQ:TPH_value). If the enable bit is set in the particular context, then the 10 GbE controller should provide the TPH information on all subsequent PCI transactions associated with CQ or CEQ transactions. There is no TPH value used on AEQE writes because they are so infrequent that it is unlikely to ever get them on the correct CPU.

QP context has two values for TPH, SQ_TPH and RQ_TPH. They are independent of each other because the SQ and RQ could be on different processors in PE accelerations. They also have separate enable bits.

38.36.3 Resource Management

PE resources are managed through a combination of the HMC FPM space and Control QP operations (described in the following sections). Figure 38-127 shows the PE related data structures that are located in host memory and that reside on-die for the 10 GbE controller. Before any QP or CQ operation is attempted with CQP, the associated HMC pages must be initialized and allocated. Once all FPM page descriptor pages and backing pages have been properly allocated, initialized, and allocated to the 10 GbE controller, CQP can be used to create/modify/discard various objects necessary for PE operations. Note that Figure 38-127 only depicts memory that is visible to the 10 GbE controller. Many other software allocated data structures are allocated to track progress of QPs, CQs, etc., as shown in previous sections (Section 38.36.2.1). All of the host memory shown in Figure 38-127 must be pinned memory. QP and CQ memory including the doorbell shadow areas might be allocated from kernel or user-space virtual memory; however, all other memory shown must be allocated from the kernel in order to provide the proper level of protection between different processes accessing the 10 GbE controller concurrently. Note that any reset that affects a single PCI function also resets the HMC and require reprogramming of all HMC resources. Global resets also reset the segment descriptor programming that require re-selecting the HMC resource profile if the default profile was not in use.

Figure 38-127.10 GbE Controller and Host Memory Data Structures



Since FPM page descriptors and backing pages can be allocated on the fly in order to reduce the kernel drivers memory footprint but certain objects must be allocated at driver initialization. Table 38-452 lists the dependencies between various PE objects.

Table 38-452.PE Objects Dependencies

PE HMC Object	HMC Object Page Population Algorithm	Object Dependencies	Non-HMC Object Dependences
QP Context	Dynamic	ARP Table Entries Quad Hash Entries TX FIFO Entries APBVT In-Use Table CQ Physical Buffer List Entries if Virtually Mapped	VSI Local MAC Address L2 Tag Configuration
CQ Context	Dynamic	Physical Buffer List Entries if Virtually Mapped	
ARP Table Entries	Dynamic	None	
Quad Hash Entries	Static	None	
TX FIFO Entry Free List	Static	None	
TX FIFO Entries	Static	TX FIFO Entry Free List	
Inbound Read Request Queue Entry Free List	Static	None	
Inbound Read Request Queue Entries	Static	IRRQ Entry Free List	
Accelerated Port Bit Vector Table In-Use Table	Static	None	
Memory Registration Table	Dynamic	None	
Physical Buffer List Entries	Dynamic	None	

All PE objects marked as static in Table 38-452 must be allocated at driver initialization time. Entries marked as dynamic may be allocated and de-allocated on an as needed basis. Objects shown as dependencies must be populated and allocated via CQP (along with the HMC FPM memory for the object itself) prior to issuing a CQP operation to manipulate the PE object. More information regarding the object dependencies is available in the individual CQP operations in following sections.

Note that PF resets clears the PE state including any HMC configuration settings for the PF and all associated VFs. VF resets clear all PE state and HMC configuration settings only for the VF if the VF is enabled for PE accelerations.

Dynamic objects of the same type might share a cache line. However, a dynamic object must not share any cache lines with another object that has a different type.

38.36.3.1 PE Initialization

Table 38-453 lists the high-level steps required to initialize a PE. Table 38-454 and Table 38-455 list the high-level steps required to bring an RDMA or UDA QP to the operational state for the 10 GbE controller. This list is not meant to be exhaustive but more as a guide to show one ordered list of a typical initialization flow. It is assumed that the LAN initialization of the VSI has enabled PE operation and has the LAN queues operational for the PF.

Table 38-453.PE Resource Initialization

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Determine if the PE is enabled	Product Name driver.	Read the GLGEN_PE_ENA.PE_ENA CSR bit.	
2	Determine the IP and MAC address for the associated LAN queue pool	Product Name driver.	Each PE interface is associated with a specific LAN interface, The mechanism to find the interface information is operating system specific.	
3	Enable RDMA/UDA for the corresponding VSI	Product Name driver	Each PE interface is associated with a specific VSI. Set PETCP_ENA, PEUUDP_ENA and PEMUDP_ENA bits in VSIQFCTL VSI register.	
4	Enable Local VSI Loopback	Product Name driver.	PE enables communication between QPs associated with the same VSI. Set ALLOWLOOPBACK and ALLOWLOCALLOOPBACK bits in VSISWID register.	This step is not required. The PE uses SWPE to perform loopback.
5	Setup the PE portion of the HMC	Product Name driver.	Wait for PE firmware to be initialized by polling GLPE_CPUSTATUS0 is set to 0x80. First the HMC base and size registers must be programmed for this PF. Subsequently appropriate backing pages must be initialized.	Refer to the details on initializing the HMC.
6	Acquire one or more MSI-X vectors for the PE	Product Name driver.	MSI-X vectors can be shared between LAN and protocol operation or can be partitioned to enable independent operation	See the previous section on LAN initialization for more information on MSI-X vector initialization
7	Initialize the PE control QP	Product Name driver.	Allocate memory for the CQP SQ and CQP context and write to the PECCQPHIGH and PECCQPLOW registers.	See Section 38.36.3.2.1 for more details.
8	Initialize the PE CQ 0	Product Name driver.	Allocate memory for the CQ and issue a create CQ operation to CQP.	See Section 38.36.3.3.3 for details on the Create CQ CQP operation.
9	Initialize the PE CEQ 0	Product Name driver.	Allocate memory for the CEQ and issue a create CEQ operation to CQP, The CEQ is associated with a Product Name interrupt.	See Section 38.36.3.4.2 for details on the create CEQ CQP operation.
10	Initialize the PE AEQ	Product Name driver.	Allocate memory for the AEQ and issue a create CEQ operation to CQP,.	See Section 38.36.3.5 for details on the create AEQ CQP operation.
11	Allocate a local MAC address table entry for the PE	Product Name driver.	Request and initialize a PE MAC address table entry and initialize the entry.	See Section 38.36.3.3.6 and Section 38.36.3.3.7 for the allocate and manage local MAC address table entry CQP operations.

The following table lists steps required to bring RDMA QP to the operational state. The majority of steps are similar to initialization of RDMA QP. PE initialization steps are common for RDMA and UDA traffic and should be done only once.

Table 38-454.RDMA Resource Initialization

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Create a Protection Domain	Product Name driver on behalf of a verbs application.	Reserve a doorbell page from the PE doorbell pages in the Product Name BAR.	See Section 38.36.2.1.6 for more information on doorbell pages.
2	Allocate a CQ	Product Name driver on behalf of a verbs application.	Allocate memory for the CQ and issue a create CQ operation to CQP, The CQ will be associated with the CEQ from step 7.	See Section 38.36.3.3.3 for details on the create CQ CQP operation.
3	Allocate a QP	Product Name driver on behalf of a verbs application.	Allocate memory for the QPs SQ and RQ and issue a Create QP operation to CQP.	See Section 38.36.3.3.2 for details on the create QP CQP operation.
4	Allocate Memory Regions	Product Name driver on behalf of a verbs application.	Allocate physical buffer list entry ranges for the page list that backs the memory provided by the application and then issue register memory region CQP operation.	See Section 38.36.3.3.4 for more information on the register memory region operation and also Section 38.36.2.1.4 for an overview of the 10 GbE controller's memory registration capabilities.
5	Post Work Requests to the QPs RQ	Product Name driver on behalf of a verbs application.	Fill in a RQ work request with the information supplied by the application and submit the work.	See Section 38.36.2.1.4 for more information on RQ operation.
6	Post Work Requests to the QPs RQ	Product Name driver on behalf of a verbs application.	Fill in a SQ work request with the information supplied by the application and submit the work.	See Section 38.36.4.5.1 for information about the RQ work request format and Section 38.36.2.1.7 for more information on RQ operation.
7	Process Interrupts and the CEQ (optional)	Product Name driver.	Once an interrupt occurs for a CEQ, the CQ can be determined from the CEQ Entry. Events are generated to that application to let the application know that an event for a specific CQ has been received.	See Section 38.36.2.1.2 for more information on processing CEQ entries.
8	Process the CQ (optional)	Product Name driver on behalf of a verbs application.	One the application has either receive a completion event or is constantly polling the CQ, CQ entries are processed by the application.	See Section 38.36.2.1.3 for more information on processing CQ entries.

The following table lists steps required to bring UDA QP to the operational state. PE initialization steps are common for RDMA and UDA traffic and should be done only once.

Table 38-455.UDA Resource Initialization (Sheet 1 of 2)

Step	Resource	Responsible Software Component	Action(s)	Notes
1	Create a Protection Domain	Product Name driver on behalf of a verbs application.	Reserve a doorbell page from the PE doorbell pages in the Product Name BAR.	See Section 38.36.2.1.6 for more information on doorbell pages.
2	Allocate a CQ	Product Name driver on behalf of a verbs application.	Allocate memory for the CQ and issue a create CQ operation to CQP. The CQ is associated with the CEQ from step 7.	See Section 38.36.3.3.3 for details on the create CQ CQP operation.
3	Allocate a QP	Product Name driver on behalf of a verbs application.	Allocate memory for the QPs SQ and RQ and issue a create QP operation to CQP.	See Section 38.36.3.3.2 for details on the create QP CQP operation.
4	Allocate Memory Regions	Product Name driver on behalf of a verbs application.	Allocate PBL entry ranges for the page list that backs the memory provided by the application and then issue register memory region CQP operation.	See Section 38.36.3.3.4 for more information on the register memory region operation and alsoSection 38.36.2.1.4 for an overview of the 10 GbE controller's memory registration capabilities.
5	Allocate Address Vector (optional)	Product Name driver on behalf of a verbs application.	For each destination Node issue a create address vector operation to CQP. Allocated address vector is used to generate Ethernet/IP headers.	See Section 38.36.3.5.3 for more information on the create address vector operation as well as an overview of the 10 GbE controller's address vector capabilities.
6	Bind to Local Port (optional)	Product Name driver on behalf of a verbs application.	For each local port allocated for UDP traffic issue a management quad hash entry operation to CQP. This operation will enable forwarding of unicast packet to the QP.	See Section 38.36.3.5.7 for more information on the manage quad hash operation.
7	Post Work Requests to the QPs RQ	Product Name driver on behalf of a verbs application.	Fill in a RQ work request with the information supplied by the application and submit the work.	See Section 38.36.2.1.4 for more information on RQ operation.
8	Post Work Requests to the QPs RQ	Product Name driver on behalf of a verbs application.	Fill in a SQ work request with the information supplied by the application and submit the work.	See Section 38.36.4.5.1 for information about the RQ work request format and Section 38.36.2.1.7 for more information on RQ operation.
9	Process Interrupts and the CEQ (optional)	Product Name driver.	Once an interrupt occurs for a CEQ, the CQ can be determined from the CEQ Entry. Events are generated to that application to let the application know that an event for a specific CQ has been received	See Section 38.36.2.1.2 for more information on processing CEQ entries.

Table 38-455.UDA Resource Initialization (Sheet 2 of 2)

Step	Resource	Responsible Software Component	Action(s)	Notes
10	Process the CQ (optional)	Product Name driver on behalf of a verbs application.	One the application has either receive a completion event or is constantly polling the CQ, CQ entries are processed by the application.	See Section 38.36.2.1.3 for more information on processing CQ entries.

38.36.3.2 Control CQP Operation

CQP operations are modeled after verbs SQ operations as far as the work submission process. Some differences exist for CQP when compared to a typical PE QP:

- CQP QP context is located on-die instead of in the HMC.
- The doorbell register used for work submission is PFPE_CQPDB instead of PFPE_WQEALLOC.
- PFPE_CQPDB take SQ head as input and there is no QP ID specified since each PE enabled PCI function has a dedicated CQP.
- There is no doorbell shadow area associated with CQP.
- Hardware tail can be read from the PFPE_CQPTAIL, but in general software can just track SQ tail based on completion processing from CQ0.

The operations defined for CQP are listed in Table 38-459. CQ0 is the CQ associated with the CQP for each function. All other CQs are available for accelerated PE use.

38.36.3.2.1 Creating the CQP

CQP is created by first allocating memory for CQP context shown in Section 38.36.3.2.3 and initializing context. The HMC resource profile is also able to be selected during the CQP creation process. Note that HMC resource profile is selected during first CQP creation on a device and is then locked. Subsequent attempts to change the HMC resource profile are ignored until all CQPs created on the device have been destroyed. The resource profile that has been selected is reported in the PFPE_CCQPSTATUS register after CQP has been successfully created. Additionally the SQ memory and FPM configuration buffer must also be allocated. This memory must be pinned and the physical address must be determined. Once software has filled in the CQP context properly, the physical address of CQP context is written to the PFPE_CCQPHIGH and PFPE_CCQPLOW registers to notify the 10 GbE controller of the create CQP operation. Both registers must be written and the PFPE_CCQPLOW register must be written last. Product Name then fetches the context and create CQP for the current PCI function. Once CQP has be successfully created, the CCQP_DONE bit in the PFPE_CCQPSTATUS register is set to 1b. If an error was encountered while attempting to create CQP, the CCQP_ERR bit is set instead of the CCQP_DONE bit. The major and minor error codes are available in the PFPE_CQPERRCODES register. The next six operations necessary to get CQP to a functional state are to:

1. Query FPM values.
2. Commit FPM values.
3. Initialize the HMC resources for CQ0.
4. Create CQ 0.
5. Create CEQ.
6. Create the AEQ.

The operations must be done in this order or unexpected results might be observed. In addition to the CQ0 HMC backing pages initialized in step 3, if either the CQ or CEQ need to be virtually mapped, the PBLE HMC object backing pages must also be populated before creating the CQ and/or CEQ. Protocol enabled VFs use the VFPE_* versions of the registers previously mentioned. These steps involve issuing standard CQP operations with the following exceptions:

- PFPE_CQPTAIL must be polled until the create CQ operation has been submitted to CQP and only a single CQP operation must be submitted at a time to CQP while polling CQP Tail. Any errors encountered via CQP is reported via the CQP_ERR bit in the PFPE_CQPTAIL register. The major and minor error codes are available in the PFPE_CQPERRCODES register.
- CQ0 can be polled for the completion of the create CQ operation. No events can be generated since there is no CEQ created at the point when CQ0 is created.

One additional CQP operation must be issued anytime after step 3 but before any iWARP QPs can be created. The static HMC pages allocated operation must be submitted after all static HMC objects have been allocated and configured for the PCI function. See Table 38-452 for the list of statically configured HMC objects.

38.36.3.2.2 Destroying the CQP

Once all PE resources have been destroyed and deallocated, the control QP related resources much also be destroyed. The flow is the following:

1. Issue a CQP operation to discard the AEQ.
2. Issue a CQP operation to discard the CEQ(s).
3. Poll CQ0 to verify these operations completed.
4. Discard CQP by writing the PFPE_CCQPHIGH and PFPE_CCQPLOW registers with 0b.
5. Poll the PFPE_CCQPSTATUS register until it changes to 0b.
6. Discard the CQ0 HMC resources to ensure that no further accesses to host memory is performed.

Once CQP has been destroyed, CQ0 will also have been destroyed as well.

38.36.3.2.3 CQP Context

CQP context describes the SQ for the control QP.

Table 38-456.CQP Context Format

Byte Offset	[Bit Range]Field Name			
0	[63:40] [39:32] [31:24] [23:12]	Reserved num_CEQs_per_VF StructVersion Reserved	[11:08] [7:2] [1] [0]	SQ_Size Reserved Disable_FPDU_Packing Enable_Fine_Grained_Timers
8	[63:9]	SQ_base	[8:0]	Reserved
16	[63:38] [37:32]	RSVD PEEnabledVfCount	[31:3] [2:0]	RSVD HMCProfileType
24	[63:0]	QP_Completion_Context		
32	[63:0]	Reserved		
40	[63:0]	Reserved		
48	[63:0]	Reserved		
56	[63:0]	Reserved		

StructVersion (8)

Used to specify changes in CQP context format. The only value defined is 0.

Enable_Fine_Grained_Timers (1)

This bit enables fine grained TCP timer mode for the PCI function associated with the CQP to be created. Fine grained TCP timer mode changes the PE TCP timers from normal values (2 minutes to ~100 ms) to a more aggressive set of values (~1s to ~100 µs). Fine grained TCP timer mode is useful for environments with low packet congestion and/or low packet loss.

SQ_Size (4)

This field encodes the maximum number of work requests for each WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. Since each CQP WQE takes 64 bytes (as if it consumed an additional fragment descriptor) only the following settings are valid for CQP (all other settings are reserved and might cause unexpected results):

1 = 4 WQEs
2 = 8 WQEs
3 = 16 WQEs
4 = 32 WQEs
5 = 64 WQEs
6 = 128 WQEs
7 = 256 WQEs
8 = 512 WQEs
9 = 1024 WQEs
10 = 2048 WQEs

Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow. WQ overflow results in indeterministic behavior for the affected WQ.

SQ_base (55)

SQ_base is the most significant bits of the physical address of the SQ for the control QP. The WQ base address must be evenly divisible by 512 for proper behavior.

HMCProfileType (3)

This field specifies the HMC resource profile to be activated.

0: Reserved

1: Default

2: SR-IOV VF Primary

3: SR-IOV Even Distribution

7: Reserved

Specifying a reserved HMC resource profile causes the current HMC resource profile to remain active. This field is ignored for VFs.

PEEnabledVfCount (6)

Only valid when HMCProfileType is one of the SR-IOV profile types. Specifies the number of PE enabled VFs to be allocated. Values larger than 32 are rounded down to 32. A value of zero forces the default profile to be selected. This field is ignored for VFs.

QP_Completion_Context

QP_Completion_Context is reported in every CQ Entry related to the CQP.

Disable_FPDU_Packing (1)

num_CEQs_per_VF (8)

This specifies the max CEQs needed for each VF. The purpose of this field is to limit the number of CEQs a VF uses in the even distribution profile in order to leave enough CEQs for the PF. A value of zero preserves the behavior of evenly allocating the CEQs across all functions. This field is valid only if SRIOV is enabled and the balanced profile is in use.

38.36.3.2.4 CQP Error Codes

CQP can return a number of error and status code the operations that it performs. Table 38-457 lists these error and status codes that can be returned in the CQ entry listed in Table 38-458.

Table 38-457.CQP Error Codes (Sheet 1 of 2)

Major Error Code	Minor Error Code	Completion Reason	Description
0x0000	0xKK00	STag Valid	The STag queried is in the valid state, KK is the STag key.
0x0000	0x0001	STag Invalid	The STag queried is in the invalid state.
0x0000	0x0002	RQ WQE Flushed	A RQ WQE was flushed as a result of the flush WQEs operation.
0x0000	0x0003	SQ WQE Flushed	A SQ WQE was flushed as a result of the flush WQEs operation.
0x0000	0x0004	SQ and RQ WQEs Flushed	Both a RQ WQE and a SQ WQE were flushed as a result of the flush WQEs operation.
0x0000	0x0005	Suspend Pending	A suspend QP WQE was issued referencing a busy QP. An AE_QP_SUSPEND_COMPLETE AE is generated when the QP has been successfully suspended.
0xFFFF	0x3000	Packet Count Error	A packet count issue has been detected on a QP that is either being destroyed or uploaded. The state of the QP is indeterminate once this completion code has been observed.
0xFFFF	0x3001	Scratchpad Flush Error	CQP has timed out waiting for TEP to flush scratch pads for a QP that is getting destroyed or uploaded. This error has never been observed and is not expected.
0xFFFF	0x4000	Memory Window Bound	The discard QP operation failed because there are still MWs bound to the QP.
0xFFFF	0x6000	Insufficient Resources (General)	There is an insufficient amount of the resources needed to complete this operation.
0xFFFF	0x6001	Insufficient FLM Resources	A create QP was attempted but there were no available transmit of Q1 FIFO entries.
0xFFFF	0x6002	Insufficient Doorbell Resources	Returned by commit FPM (if requested number of QPs or CQs is greater than count allotted in partition registers).
0xFFFF	0x7000	Bad IP/MAC Table Index	The MAC_IP table index given is either invalid or is not owned by this function.
0xFFFF	0x8000	QPID Too Big	The QPID specified on the operation is too large for the on board memory configuration.
0xFFFF	0x8002	Invalid State	The operation requested is not valid for this resource based upon its current state.
0xFFFF	0x8003	Invalid Next QP State	The next state specified on the Modify QP operation is not valid based on the QP's current state.
0xFFFF	0x8004	Invalid Queue Size	The SQ, RQ, or Q1 is too large or to small.
0xFFFF	0x8005	Invalid QP Type	The operation is not valid for this type of QP.

Table 38-457.CQP Error Codes (Sheet 2 of 2)

Major Error Code	Minor Error Code	Completion Reason	Description
0xFFFF	0x8006	No WQE Pending	A flush operation was attempted but there was not a WQE pending.
0xFFFF	0x8007	Bad Close	A Modify QP from RTS->Closing was attempted while there was SQ and/or Q1 activity in progress.
0xFFFF	0x8009	LLP Closed	Returned by Modify QP (next iWARP state = Terminate if the TCP state is already closed or time wait).
0xFFFF	0x800A	Reset Not Sent	Returned by Modify QP (if the TCP state is already closed).
0xFFFF	0x800C	SD Index Out of Range	An attempt has been made to update a VF's page descriptor using an SD that does not reference a PBLE object.
0xFFFF	0x800D	PD Index Out of Range	An attempt has been made to update a VF's page descriptor using a SD and PD index that does not reference a PBLE object
0xFFFF	0x800E	PD Page Boundary Exceeded	An attempt has been made to update a VF's page descriptor but the request has crossed from one PD page to the next PD page.
0xFFFF	0x800F	SD Boundary Exceeded	Returned by commit FPM (if requested number of HMC objects crosses SD boundary for that function).
0xFFFF	0x8010	Invalid Function Type	The operation is not valid for the PCI function type that attempted to issue the operation.
0xFFFF	0x8011	FLM Not Initialized	Returned by create QP if an attempt to create a QP has been attempted before the static resources allocated WQE has been issued.
0xFFFF	0x8012	Invalid ECN Codepoint	An attempt was made to create a QP with an invalid initial ECN code-point value.
0xFFFF	0x8013	Invalid VF Number	A PF attempted to access resources associated with a VF that it does not own.
0xFFFF	0x8014	Invalid MRTE Index	An attempt was made to access a reserved STag.
0xFFFF	0x8015	Invalid Terminate Message Size	A terminate was requested with a Term_length value that is too small.
0xFFFF	0x8016	Bad Send MSS value	The value given for SndMSS is invalid.
0xFFFF	0x80EE	Unsupported Opcode	The opcode given is unsupported.
0xFFFF	0x80EF	WQE Not Valid	The WQE fetched due to a CQP doorbell ring is not valid.
0xFFFF	0xFFFF	Error	CQP encountered an error during the processing of this WQE.

38.36.3.2.5 CQP CQE Format

The CQP CQ entry is listed in Table 38-458. Every work request processed by the control QP returns a completion on CQ 0 (CQ_ID 0). If CQ0 is created with the Avoid_Memory_Conflicts bit set, then an additional 32 bytes of padding is added to each CQE for a total of 64 bytes per CQE. This doubles the size of the CQ in host memory.

Table 38-458.CQP CQ Entry Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	QP_Completion_Context		
16	[63:32]	RSVD	[31:0]	Operation_Return_Value
24	[63] [62] [61:56] [55]	CQE_Valid SQ RSVD Error	[54:46] [45:32] [31:16] [15:0]	RSVD WQ_Desc_Index Major Error Code Minor Error Code

Op (6)

This field reports the opcode from the operation associated with the CQE.

QP_Completion_Context (64)

This field is transferred to the CQE from CQP QP context listed in Table 38-456.

WQ_Desc_Index (14)

WQ are sliced up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. WQ_Desc_Index reports the 32-byte quanta index of the WQE associated with the completion.

QP_ID (18)

QP associated with the completed message.

Operation_Return_Value (32)

This field is filled in by CiP with operation dependent return values such as the reachability time stamp or the MAC and IP table Index.

CQE_Valid (1)

The CQE_Valid bit for CQE is a bit that indicates that a CQE is ready to be processed. The polarity of the valid bit changes each time the CQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the valid bit once software has processed a valid CQE. Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the 10 GbE controller sets the Valid bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the 10 GbE controller sets the valid bit to a 0b when it writes an new CQE.

Error (1)

The *Error* bit indicates if there was a problem with the operation specified by the WQE associated with the WR that is associated with completion.

0 = No error is being reported with this completion.

1 = An error occurred when processing the WQE associated with this CQE and that the *Error Code* field is valid

SQ (1)

The SQ bits is used to determine if the completion is associated with a SQ (SQ) or a RQ (RQ).

0 = RQ

1 = SQ

Major error code (16) and minor error code (16)

The *Error Code* fields are valid if the *Error* bit is set or if the operation submitted was query STag. See Table 38-457 for the values that are returned for CQP operations.

38.36.3.3 CQP SQ Descriptor Formats

The following WQE formats are used in conjunction with the Control QP (CQP) to manage internal PE structures that the 10 GbE controller uses to communicate with host software. Operations that are supported for CQPs are the following.

Table 38-459.CQP Operations

Operation Code	Operation Name	Page	Operation Code	Operation Name	Page
0x00	Create QP	3196	0x17	RSVD	
0x01	Modify QP	3196	0x18	Discard CEQ	3214
0x02	Discard QP	3196	0x19	Create AEQ	3216
0x03	Create CQ	3200	0x1A	RSVD	
0x04	Modify CQ	3200	0x1B	Discard AEQ	3216
0x05	Discard CQ	3200	0x1C		
0x06			0x1D		
0x07			0x1E		
0x08			0x1F	Update PE SDs	3217
0x09	Allocate STag	3203	0x20	Query FPM Values	3218
0x0A	Register MR	3203	0x21	Commit FPM Values	3221
0x0B	Query STag	3206	0x22	Flush WQEs	3222
0x0C	Register Shared MR	3203	0x23	Manage APBV Table Entry	3224
0x0D	Deallocate STag	3203	0x24	NOP	3224
0x0E	Manage Local MAC Table	3208	0x25	Manage Quad Hash Table Entry	3225
0x0F	Manage ARP Cache		0x26		
0x10	Manage VF PBLE Backing Pages	3210	0x27		
0x11	Manage Push Page	3211	0x28		
0x12	RSVD		0x29	Suspend QP	3228
0x13	Upload context	3212	0x2A	Resume QP	3228
0x14	Allocate Local MAC Entry	3207	0x2B	Static HMC Pages Allocated	3229
0x15	Manage HMC PM Function Table	3214	0x2C	RSVD	
0x16	Create CEQ	3214	0x2D	RSVD	
			0x2C - 0x3F	RSVD	

38.36.3.3.1 Common CQP Descriptor Format Fields

The basic CQP WQE is a 64 byte structure that is broken up into 64 bit (8-byte) words. The placement of these fields within the WQE are common among all CQP WQEs and also iWARP WQEs. Table 38-460 lists the basic structure of a CQP WQE including the common fields. The definition of fields marked as operation code dependent vary from operation-to-operation and are detailed in subsequent sections.

Table 38-460.CQP Common WQE Fields

Byte Offset	[Bit Range]Field Name		
0	[63:0]	Operation Code Dependent	
8	[63:0]	Operation Code Dependent	
16	[63:0]	Operation Code Dependent	
24	[63] [62:41] [40:38]	WQE_Valid Operation Code Dependent RSVD (AdditionalFragmentCount)	[37:32] OP [31:0] Operation Code Dependent
32	[63:0]	Operation Code Dependent	
40	[63:0]	Operation Code Dependent	
48	[63:0]	Operation Code Dependent	
56	[63:0]	Operation Code Dependent	

OP (6)

CQP operation code for create QP, modify QP, or discard QP. See Table 38-459 for the specific values.

WQE_Valid (1)

The WQE_Valid bit for WQ Entries (WQE) is a bit that indicates that a WQE is ready to be processed by the 10 GbE controller. The polarity of the valid bit changes each time the WQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead associated with the need to clear a valid bit and also to enable the 10 GbE controller to read ahead in the WQ to reduce the need for doorbell rings. See Section 38.36.2.1.5 for more information on submitting work to a QP with the 10 GbE controller. Software is responsible to clear (set to 0b) all memory in a WQ initially at QP creation. The first iteration (and subsequent odd numbered iterations) through the WQ, software sets the Valid bit to 1b when it writes a new WQE. For the second iteration (and all even numbered iterations) through the WQ, software sets the valid bit to a 0b when it writes an new WQE.

38.36.3.3.2 Create/Modify/Discard QP Descriptor Format

This WQE format is used by host software to manage QPs. The various valid bits in this format are designed to reduce the load on CQP for determining what has changed. If a valid bit is set for a particular field, then CQP updates the value in the 10 GbE controller's context, else it does not. The only valid operation for QP type CQP is the discard operation. See Section 38.36.3.2.1 for more details on created CQP.

Note that software is responsible for populating the appropriate HMC objects and have having created objects for the HMC and through CQP that the QP depends on.

Table 38-461.CQP Create/Modify/Discard QP WQE Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:52] [51:48] [47:46]	RSVD Term_Length[1] RSVD	[45:32] [31:00]	RSVD RSVD
16	[63:0]	QP Context Address[1]		

Table 38-461.CQP Create/Modify/Discard QP WQE Format (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
24	[63]	WQE_Valid	[46]	Force_Loopback[3]
	[62:60]	Next iWARP State[1]	[45]	Virtual_WQs[3]
	[59]	ARP Table Index Valid[1]	[44]	Cached_Variables_Valid[1]
	[58]	Reset Connection[1]	[43]	TOE_Context_Valid[3]
	[57:56]	Terminate_Actions[1]	[42]	ORD_Valid[1]
	[55]	Remove_Hash_Entry	[41]	RSVD
	[54]	Ignore MW Bound[2]	[40:38]	RSVD
	[53]	RSVD	(AdditionalFragmentCount)	
	[52]	RSVD	[37:32]	OP
	[51]	RSVD	[31:18]	Reserved
	[50:48]	QP_Type	[17:0]	QP_ID
	[47]	CQ_Numbers_Valid[1]		
32	[63:0]	RSVD		
40	[63:7]	Doorbell Shadow Address[3]	[6:0]	RSVD
48	[63:0]	RSVD		
56	[63:0]	RSVD		

Notes:

1. Not used for discard QP operations.
2. Only used for discard QP operations.
3. Valid for create and modify QP operations as long as the iWARP state is not already RTS, error, or terminate.

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

ARP table index valid (1)

If set (1b) ARP cache index has been updated in the QP context. Else (0b) CQP must ignore ARP *Cache Index* field in QP context.

TOE_Context_Valid (1)

If set (1b) the TOE portion of QP context is valid, Else (0b) ignore the TOE portion of QP context. This bit is useful if an iWARP QP is created that does not yet have a TOE connection associated with it. Host software can create the SQ/RQ etc, and then later issue a modify QP to update the TOE context, updating TOE context is only allowed prior to setting the QP iWARP state to RTS for iWARP QPs and prior to setting the QP TOE state to established for TOE QPs.

ORD_Valid (1)

If set (1b) ORD has been updated in QP context. Else (0b) CQP must ignore ORD field in QP context.

Virtual_WQs (1)

If set (1b) the SQ and RQ for this QP are virtually mapped, if clear the SQ and RQ are physically mapped. When a QP is using virtual WQs, the RQ and SQ base address in QP context point to the first HMC FPM space PBLE index for the page table for each WQ. Host software is responsible for populating the PBLEs with the page list associated with each WQ before making the QP active (Modify QP with next state of RTS). Both the SQ and the RQ buffers must be aligned to a multiple of 4 KB in host memory when Virtual_WQs is set. This field is only valid for QPs in the IDLE state or during the IDLE to RTS transition.

Remove_Hash_Entry (1)

Only valid with modify and discard QP opcodes. If set (1b) then the hash table entry associated with this QP is removed from the hash list. This bit has no effect when clear (0b).

CQ_Numbers_Valid (1)

If set (1b) the values for RxCmpQueueNum and TxCmpQueueNum in QP context is used to update internal context, else RxCmpQueueNum and TxCmpQueueNum in QP context are ignored.

Force_Loopback (1)

If set (1b) the traffic for the QP is internally looped back within the VSI associated with the QP. If clear (0b), the traffic is switched normally unless the source and destination IP addresses and MAC addresses match. This field is used to enable loopback traffic for different IP addresses with a single VSI.

QP_Type (3)

QP_Type indicates the type of QP for CQP to create. The valid QP types are CQP (0, only valid for DestroyQP), iWarp (1), or UDA (2).

MSS_Change (1)

If set (1b) the MSS value for the connection has changed. The 10 GbE controller starts using the new MSS value (found in the New MSS Value) immediately which might temporarily cause partial FPDUs to be generated for any RDMA messages that need re-transmission. Only valid for Modify QP operations on QPs with the TCP state = ESTABLISHED.

New MSS value (14)

If MSS_Change is set (1b) this MSS value is used for subsequent outbound packets on this QP. Note that reduction in the MSS might cause fragmentation for retransmitted packets. Only valid for Modify QP operations on QPs with the TCP state = ESTABLISHED.

Ignore MW bound (1) - This field is ignored

This field is only meaningful for discard QP for iWARP QPs. If set (1b) the QP is destroyed even if memory windows are still bound to the QP. If clear (0b) then the discard fails with a major/minor code of 0xFFFF/0x4000 when memory windows are still bound to the QP.

Terminate_Actions (2)

Only valid for Modify QP for iWARP QPs with Next iWARP State set to terminate. Values for this field are:

0 = Send both Terminate and FIN

1 = Send Terminate Only

2 = Send FIN only

3 = Do not send Terminate or FIN

Term_Length (4)

Only valid with modify opcodes when the next iWARP state is set to 5 (terminate) and Terminate_Actions is set to 0b or 1b. This field is ignored in all other cases. This field specifies the number of 4-byte Dwords to transfer from the Q2 outbound terminate data area when a terminate message is requested. The Q2 area starts with a Dword specifying the *Terminate Control* field as specified in the RDMAP RFC. A maximum of 13 Dwords is transmitted (terminate control Dword plus 48 bytes of data for an RDMA read header). Values greater than 13 results in 13 Dwords being transmitted.

Cached_Variables_Valid (1)

Only valid with modify opcodes, If set (1b) then only the cached variables associated with this QP is updated on the modify operation. This bit has no effect when clear (0b). See Table 38-493 for the list of variable that are cached. Each cached variable is marked with a table footnote.

Next iWARP state (3)

Only valid on Modify QP opcodes for iWARP QPs. The iWARP state definitions are:

0 = NON EXISTANT

1 = IDLE

2 = RTS

3 = CLOSING

4= reserved

5 = TERMINATE (iWARP only)

6 = ERROR

7 = Reserved

Reset connection (1)

Only valid with Modify QP opcodes. If set (1b) then a TCP reset is sent out if the TCP state for the QP has already been ESTABLISHED is not TIME_WAIT or CLOSED. If the QP TCP state is already TIME_WAIT or CLOSED, an AE_RESET_NOT_SENT AE is generated.

QP_ID (18)

QP_ID identifies the QP that is to be acted upon by the 10 GbE controller.

QP context address (64)

A physically mapped pointer in host memory that contains QP context. The format of the QP context structures are define in Section 38.36.4.2, Section 38.36.3.2.3. This buffer must be aligned to a multiple of 4 bytes.

Doorbell shadow address (58)

A physically mapped pointer in host memory that hardware writes to when forward progress has been made on SQ work. The format of the doorbell shadow area is listed in Table 38-463. This buffer must be aligned to a multiple of cache-line size bytes.

Modify QP processing performed by CQP for the 10 GbE controller is not designed to be verbs compliant from the point of view of which iWARP state transitions are allowed. The 10 GbE controller enables invalid state transitions to enable host hardware to make state transitions to ERROR or TERMINATE autonomously in order to prevent subsequent work from being processed, but still enable host software the ability to provide verbs compliant behavior to the application.

Additionally, the 10 GbE controller is not providing support for the transition back to IDLE. It is expected that host software destroys QPs and recreate them when the transition from non-IDLE to IDLE is desired. Table 38-462 describes the transitions allowed by the 10 GbE controller.

Table 38-462.Product Name iWARP QP State Transitions

Current iWARP State	Next iWARP State				
	Idle	RTS	Closing	Terminate	Error
Idle	Yes	Yes	No	No	Yes
RTS	No	Yes	Yes	Yes	Yes
Closing	No	No	No	No	Yes
Terminate	No	No	No	Yes	Yes
Error	No (No error reported)	No	No	No	Yes

Table 38-463.QP Doorbell Shadow Area

Byte Offset	[Bit Range]Field Name			
0	[63:14]	RSVD	[13:0]	HW_SQ_Tail
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63:0]	RSVD		
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

For information on the doorbell ringing algorithm and usage of the QP doorbell shadow area, see Section 38.36.2.1.7.

38.36.3.3.3 Create/Modify/Discard CQ Descriptor Format

Host software uses the following structure to manage CQs through the control QP. CQs are comprised of a packed array of CQEs, which are WQ type specific that are managed as a circular queue. They can be either virtually or physically contiguous memory buffers. Further discussion of CQ operation is found in Section 38.36.2.1.3.

Table 38-464.CQP Create/Modify/Discard CQ WQE Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:20]	RSVD	[19:00]	cq_size[1]
8	[63]	RSVD	[62:0]	CQ_Context_Value
16	[63:18]	RSVD	[17:00]	cq_shadow_read_threshold[2]
24	[63] [62] [61] [60] [59:50] [49] [48] [47] [46]	WQE_Valid RSVD Avoid_Memory_Conflicts[2] TPH_en RSVD CEQ_ID_Valid enable_ceqe_mask[2] Virtually Mapped[1] Check_Overflow[2]	[45:44] [43] [42:38] [37:32] [31] [30:24] [23:17] [16:0]	Leaf_PBL_Size[1] CQ_Resize RSVD OP RSVD CEQ_ID RSVD CQ_ID
32	[63:8]	Physical_Buffer_Address[1]	[7:0]	RSVD
40	[63:6]	Doorbell Shadow Address	[5:0]	RSVD

Table 38-464.CQP Create/Modify/Discard CQ WQE Format (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index[1]
56	[63:8]	RSVD	[7:0]	TPH_Value

Notes:

1. Valid on modify operations with the CQ_Resize bit set or on create operations.
2. Only valid on create operations.

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

enable_ceqe_mask (1)

If clear (0b), the 10 GbE controller potentially generates multiple CEQEs per CQ if a request for completion notification is generated by software before a CEQE is consumed by software. This behavior can lead to CEQ overflows. If set (1b), the 10 GbE controller only allows one CEQE to be generated per CQ. Subsequent CEQE generation is enabled by writing the CQ ACK register.

CEQ_ID (7)

CEQ_ID specifies the CEQ to associated with the CQ specified by CQ_ID. This field is only meaningful when CEQ_ID_Valid is set (1b).

CEQ_ID_Valid (1)

If set (1b), the 10 GbE controller updates the CEQ for the CQ; else the CEQ_ID field is ignored. Changing the CEQ_ID for an active CQ is allowed to enable software to redistribute CQ event processing between different processors. Each CEQ for a given function must be assigned to independent MSI-X vectors in order to take advantage of this capability.

CQ_Resize (1)

If set (1b), CQ_Resize a resize operation is being requested; else (0b) ignore CQ_Resize. If a resize operation is performed, the cq_resize_count CQ context variable (known as hw_cq_select in the description of CQ resizing) is incremented by the 10 GbE controller. See the description of CQ resizing in Section 38.36.2.1.3 for more information on the CQ resizing operation.

Avoid_Memory_Conflicts (1)

If set (1b), the size of each CQE is padded with 0's to a total of 64 bytes and the size of the CQ doubles; else (0b) each CQE is 32 bytes in size.

TPH_en (1)

If set (1b), TPH is enabled for this resource. If clear (0b), TPH is not used for this resource.

TPH_value (8)

If TPH_en is set (1b), TPH STag is initialized with TPH_value. If TPH_en is clear (0b), this field is ignored.

Leaf_PBL_Size (2)

See Section , "Address Translation and Protection Overview" for more details on usage of two level PBLs.

0 = Reserved

1 = Variable (one level)

2 = 256 bytes (two level)

3 = 4 KB (two level)

Check_Overflow (1)

If set (1b), the 10 GbE controller checks for CQ overflow conditions; else it is host software's responsibility to ensure that a CQ cannot overflow.

Virtually mapped (1)

If clear (0b), Physical_Buffer_Address is the physical address of the physically contiguous CQ ring buffer; else the CQ is virtually mapped and first_pm_pbl_index is the index of the PBLE HMC object to use for mapping the virtually contiguous CQ. The CQ buffer must be aligned to a multiple of 4 KB in host memory when virtually mapped is set.

first_pm_pbl_index (28)

Points to the first HMC FPM space PBLE index for the page table for the CQ. Host software is responsible for populating the PBLEs with the page list associated with the CQ before issuing the create CQ operation and the page table is not allowed to be changed.

Physical_Buffer_Address (56)

This field specifies the physical buffer address associated with the queue in host memory if virtually mapped is set to zero. If virtually mapped is set to one, this field is ignored by the 10 GbE controller. This address must be aligned to a 256-byte boundary.

cq_size (20)

The number of CQEs allowed on the CQ. Note that the actual number of concurrent CQEs that might be allocated to the CQ is cq_size -1. 0 and 1 are invalid sizes for a CQ.

cq_shadow_read_threshold (18)

Controls when the CQ shadow area is read to in order to update hardware's copy of CQE_Index. When the CQ drops below the number for CQEs specified by cq_shadow_read_threshold, the CQ shadow area is read to find out which CQEs have been processed by software. The value of 0 indicates that the CQ shadow area is only read when the CQ has no more available entries to use for a new CQE that needs to be generated.

CQ_ID (17)

Identifies the CQ index associated with the current CQP operation.

CQ_Context_Value (63)

This value is returned in the CEQE when an event is generated for the CQ specified by CQ_ID. This value is intended to be used by host software to quickly locate host software's CQ context (virtual pointer to CQ context).

Doorbell shadow address (58)

A physically mapped pointer in host memory that hardware reads to determine the CQEs that are owned by hardware. The format of the doorbell shadow area is listed in Table 38-465. This buffer must be aligned to a multiple of cache-line size bytes or 64 bytes, whichever is greater.

Table 38-465.CQ Doorbell Shadow Area

Byte Offset	[Bit Range]Field Name			
0	[63:20]	RSVD	[19:0]	CQE_Index
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63:0]	RSVD		
32	[63:18] [17:16] [15]	RSVD arm_seq_num arm_next_se	[14] [13:0]	arm_next sw_cq_select
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

CQE_Index (20)

Indicates the next CQE that software are polling through verbs. This field is used to update the hardware's version of context to detect CQ overrun conditions.

arm_next (1)

Indicates that software wants a CEQE generated for the next CQ entry posted to the CQ.

arm_next_se (1)

Indicates that software wants a CEQE generated for the next CQ entry posted to the CQ that is associated with a solicited event operation.

arm_seq_num (2)

Arm Sequence Number (arm_seq_num) is a valued incremented by software each time an arm request is issued. It is expected that no more than two arm requests are issued per CE received. If more than 3 arm requests are issued without waiting for a CE, arm request might be lost.

sw_cq_select (14)

This field is used for CQ resize operations. See Section 38.36.2.1.3 for more details on the usage of this field.

38.36.3.3.4 Allocate/Register/Register Shared/De-Allocate STag Descriptor Format

This WQE format is used by host software to manage memory regions and windows. See **Address Translation and Protection Overview** for more details on memory registration concepts with the 10 GbE controller.

Table 38-466.CQP Allocate/Register/Register Shared/De-Allocate STag WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0] Buffer Offset	Virtual Address or First		
8	[63] [62:48]	RSVD PD_ID	[47:46] [45:00]	RSVD STag Length
16	[63:54] [53:32]	RSVD Parent_STag_Index	[31:08] [07:00]	Driver_Key_STag_Index Consumer_Key

Table 38-466.CQP Allocate/Register/Register Shared/De-Allocate STag WQE Format

Byte Offset	[Bit Range]Field Name			
24	[63] [62:61] [60] [59] RSVD [57:54] [53]	WQE_Valid RSVD use_hmc_fcn_index[1] VA_Based_TO RSVD RemoteAccessEnabled	[52:48] [47] [46] [45:44] [43] [42:38] [37:32] [31:0]	Access_Rights RSVD Host_Page_Size Leaf_PBL_Size Memory_Region RSVD OP RSVD
32	[63:0]	Physical_Buffer_Address		
40	[63:6]	RSVD	[5:0]	hmc_fcn_index
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:0]	RSVD		

Notes:

1. This field is only valid for PF operation and will be treated as 0 for VFs.

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

Virtual address or first buffer offset (64)

Indicates the base VA for this region/window for VA-based entries and indicates the first buffer offset for zero-based entries. For VA-based entries, the least significant bits (12 bits for entries based on 4 KB pages, 21 bits for entries based on 2 MB pages) of the VA indicate the offset in bytes from the beginning of the first page where the entry begins.

Physical_Buffer_Address (64)

This field specifies the physical buffer address associated with the virtual address if Leaf_PBL_Size is set to 0b. If Leaf_PBL_Size is not set to zero, this field is ignored by the 10 GbE controller. This address must be aligned to the page size specified in Host_Page_Size. Any offset into the page will be ignored by the 10 GbE controller.

PD_ID (15)

Indicates the protection domain ID associated with the memory region or window.

STag length (46)

Length of the memory region or memory windows specified by the STag index specified by Driver_Key_Stag_Index. A value of 0b indicates that the length is not checked. This is typically used for systems that want to address all of RAM with a single STag. The maximum size that can be registered with a single STag with 4 KB pages and 1 level PBLs is 1TB (2^{28} 4KB pages).

Parent_STag_Index (22)

Index of the STag associated with the memory window (Memory_Region = 0) or linked memory region (OP = Register Shared MR).

Driver_Key_STag_Index (24)

Index and *Driver Key* fields of the STag associated with the memory window (Memory_Region = 0b) or linked memory region (OP = register shared MR). The 10 GbE controller supports a variable size STag index. This means that the number of bits used for *Driver Key* and for STag_Index are dependent on the maximum number of STag supported for a given PCI function. For example, if a PCI function read the

FPMPEMRSZ field and found that the maximum number of MRTEs was 64 KB, the lower 16 bits of this field would be the STag *Index* and the upper 8 bits would be a driver key that the driver can randomize to make guessing the MRTE layout more difficult to guess. STag index 4 M-1 (4,194,303) is reserved for hardware use. The completion returns an error if this reserved STag index is specified.

Consumer key (8)

Consumer key is the least significant 8-bit portion of the STag. This field is supplied by the user application or the driver.

use_hmc_fcn_index (1)

When set to 0b, the HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation. When set to 1b, hmc_fcn_index can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command. Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0) for VF CQP instances.

hmc_fcn_index (6)

Only valid when issued to a PF CQP instance and use_hmc_fcn_index is set to 1b. Ignored otherwise.

VA_Based_TO (1)

VA_Based_TO specifies if the STag is zero-based or Virtual Address (VA) based. Zero-based STags carry only the first buffer offset in the VA or *First Buffer Offset* field. VA-based STags carry the full base VA including first buffer offset in the VA or *First Buffer Offset* field. The STag is VA based if VA_Based_TO is set (1b); else the STag is zero based.

RemoteAccessEnabled (1)

If set, the entry is enabled for remote access. See the remote access flag in verbs for more details.

Access_Rights (5)

Indicates the rights assigned to this STag. The values for this field are 1 (enable local read), 2 (enable local write), 4 (enable remote read), 8 (enable remote write), and 16 (enable window bind).

Host_Page_Size (1)

Host_Page_Size specifies the page size of the backing pages for the STag. The values for this field are:

0b = 4 KB pages

1b = 2 MB pages

Leaf_PBL_Size (2)

The 10 GbE controller support physically contiguous STags and two forms of virtually contiguous STags. Physically contiguous STag do not require any PBLs and store physical address of the first page of the STag directly with the STag (No leaf PBL). Virtually contiguous STags that can be represented with a single HMC virtually contiguous address range require a single level PBL of Variable size. Virtually contiguous STags that are large (or in cases where the HMC address space for PBLs becomes fragmented) might require two level PBLs. In this case, the 10 GbE controller needs to know the length of the leaf PBLs in order to properly manage access to the PBLs. The valid settings for Leaf_PBL_Size are the following:

0 = No leaf PBL

1 = Variable (one level)

2 = 256 bytes (two level)

3 = 4 KB (two level)

Memory_Region (1)

If Memory_Region is set (1b) then the entry describes a memory region; If cleared (0b) the entry describes a memory window.

first_pm_pbl_index (64)

first_pm_pbl_index designates the HMC base address for the PBLs for this STag.

Table 38-467.WQE Fields Valid for Allocate/Register/Register Shared/De-Allocate STAG

WQE Field	Allocate	Register	Register Shared	Deallocate	Comments
Memory_Region	Valid	Valid	Not Valid	Valid	
VA_based_TO	Not Valid	Valid	Valid	Not Valid	
Leaf_PBL_Size	Valid if MR=1	Valid	Not Valid	Not Valid	
Access_Rights	Not Valid	Valid	Valid	Not Valid	
RemoteAccessEnabled	Valid	Valid	Valid	Not Valid	
PD_ID	Valid	Valid	Valid	Valid	
Driver Key STAG Index	Valid	Valid	Valid	Valid	
Parent STAG Index	Not Valid	Not Valid	Valid	Not Valid	
Consumer_Key	Not Valid	Valid	Valid	Not Valid	Host software is expected to validate the consumer key on a de-allocate and on register shared.
Base_VA or First_Buffer_Offset	Not Valid	Valid	Valid	Not Valid	
Physical_Buffer_Address	Not Valid	Valid	Not Valid	Not Valid	
first_pm_pbl_index	Valid	Valid	Not Valid	Not Valid	
STag Length	Valid if MR=1	Valid	Not Valid	Not Valid	
Host_Page_Size	Valid	Valid	Not Valid	Not Valid	
use_hmc_fcn_index	Valid	Valid	Valid	Valid	This field is ignored (assumed to be 0b) for VFs.
hmc_fcn_index	Valid	Valid	Valid	Valid	Only used when use_hmc_fcn_index is set to 1b.

Table 38-467 lists the WQE fields that are valid for the STag management WQEs. Fields that are marked as not valid are ignored by the 10 GbE controller.

38.36.3.3.5 Query STag Descriptor Format

WQE returns the STag value and current state of an STag (valid or invalid) and the consumer key in the completion for the WQE. See Table 38-457 for information on CQP completion codes that indicate the STag state. The full STag value is returned in the Operation_Return_Value. Note that the error bit in the CQE should be ignored for query STag operations.

Table 38-468.CQP Query STag WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:30] [29:08]	RSVD STag_Index	[7:0] RSVD	
24	[63] [62:61] [60] [59:41]	WQE_Valid RSVD use_hmc_fcn_index[1] RSVD	[40:38] RSVD (AdditionalFragmentCount) [37:32] [31:0]	 OP RSVD

40	[63:6]	RSVD	[5:0]	hmc_fcn_index[a]
48	[63:0]	RSVD		
56	[63:0]	RSVD		

Notes:

1. This field is only valid for PF operations and is treated as 0b for VFs.

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

STag_Index (22)

STag_Index specifies the index of the STag to be queried.

use_hmc_fcn_index (1)

When set to 0b, the HMC function index is determined by the PCI function associated with the PCI function that issues the CQP operation. When set to 1b, hmc_fcn_index can be set to a HMC function index that is a VF associated with the PF associated with the CQP instance used to issue the command. Only valid when issued to a PF CQP instance. Ignored (treated as if set to 0b) for VF CQP instances.

hmc_fcn_index (6)

Only valid when issued to a PF CQP instance and use_hmc_fcn_index is set to 1b. Ignored otherwise.

38.36.3.3.6 Allocate Local MAC Entry

This WQE format is used to request an entry from the 10 GbE controller's MAC address table. The MAC table entry index is reported in the Operation_Return_Value field of the CQE associated with this WQE if the operation is successful.

Table 38-469.Allocate Local MAC and IP Address Entry WQE Format

Byte Offset	[Bit Range]Field Name		
0	[63:0]	RSVD	
8	[63:0]	RSVD	
16	[63:0]	RSVD

32	[63:0]	RSVD	

Table 38-469.Allocate Local MAC and IP Address Entry WQE Format

Byte Offset	[Bit Range]Field Name	
40	[63:0]	RSVD
48	[63:0]	RSVD
56	[63:0]	RSVD

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

38.36.3.3.7 Manage Local MAC Descriptor Format

This WQE format is used to manage the 10 GbE controller's local MAC table. A MAC table entry must be created before TCP/IP connection setup can be started and before a QP can be transitioned to RTS since the QP context references an local MAC entry.

Note that the PE has a separate MAC address table from the L2 filters. The reason for this is that the MAC address table is somewhat fluid for L2 but fixed for PE. Note that it is expected that CQP firmware will program both the PE MAC table and the L2 MAC IP table filter to either match indexes or will keep a mapping between L2 filters and PE MAC address. Host software is responsible for keeping the MAC addresses in sync between L2 and the PE table but there is no relationship required between the MAC tables required other than both MAC address filters contain the same values. If there is a change in the local MAC address, it is acceptable for a limited amount of time to go by when L2 and PE are using different local addresses since the network has been disrupted during the transition time anyway.

Table 38-470.Manage Local MAC WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:32]	RSVD	[31:0] RSVD	
24	[63] [62] [61:41]	WQE_Valid Free_Table_Entry RSVD	[40:38] (AdditionalFragmentCount) [37:32] [31:6] [5:0]	RSVD OP RSVD MAC_Table_Index
32	[63:48] [47:40] [39:32] [31:24]	RSVD Local_MAC_Address[5] Local_MAC_Address[4] Local_MAC_Address[3]	[23:16] [15:8] [7:0]	Local_MAC_Address[2] Local_MAC_Address[1] Local_MAC_Address[0]
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

MAC_Table_Index (6)

MAC_IP_Table_Index specifies the index of the local IP table to be manipulated. IP table entries might be shared between members of a PE team.

Free_Table_Entry (1)

When this bit is set (1b), the table entry specified by MAC_IP_Table_Index is freed and available for allocation through the allocate local MAC and IP address table entry CQP operation. When this bit is set, the values for MAC and IP address are ignored. When this bit is clear (0b), this operation configures the MAC and IP addresses for the table entry specified by MAC_IP_Table_Index.

Local_MAC_Address[5-0] (8 bits each)

Specifies the MAC address associated with the local IP address(es) specified in Local_IPv6_IP_Address and Local_IPv4_Address. Index 0 is the LSB and byte 5 is the MSB.

38.36.3.3.8 Manage ARP Table Descriptor Format

This WQE format is used to manage the 10 GbE controller's ARP table. An ARP table entry must be created before a QP can be transitioned to RTS or established since the QP context references an ARP table entry.

Table 38-471.Manage ARP Table WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:32]	RSVD	[31:0]	Reachability_Max
16	[63:48]	RSVD	[47:0]	MAC_Address
24	[63] [62:45] [44] [43] [42]	WQE_Valid RSVD Query Permanent Entry_Valid	[41] [40:38] [37:32] [31:16] [15:0]	RSVD RSVD (AdditionalFragmentCount) OP RSVD ARP_Entry_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

ARP_Entry_Index (16)

ARP_Entry_Index specifies the index of the ARP table entry to be manipulated.

Permanent (1)

When this bit is set (1b), the ARP entry is marked as permanent and is not aged; when this bit is clear (0b), the entry is created in the reachable state and is aged.

Query (1)

When this bit set (1b), the ARP entry is not written instead the entry is read and the reachability timestamp from the ARP entry is returned in the Operation_Return_Value field of the CQE. When this bit is clear (0b), the ARP entry is written according to the specified parameters.

Entry valid (1)

When this bit is set (1b), the ARP entry is set to the valid state; else the ARP entry is set to the invalid state.

Note that the lower 32 bits of the AE generated when an ARP entry is stale contain the timestamp value from the ARP table entry.

Reachability_Max (32 bit):

The maximum number of microseconds that should be allowed to expire before generating a doubt neighbor reachability AEQE. Doubt neighbor reachability AEs indicate that there has been TCP/IP transmits outstanding for Reachability_Max without receiving any inbound traffic from the associated neighbor. In order to receive subsequent doubt neighbor reachability AEs, a manage ARP table WQE must be re-submitted to CQP with query clear (0b) and all original information supplied when the ARP entry was last updated.

MAC address (48 bits):

MAC address to be placed in the ARP cache table.

38.36.3.3.9 Manage VF PBLE Backing Pages Descriptor Format

The manage VF PBLE backing pages descriptor is used to populate and depopulate VF related HMC page descriptor content. A VF that allocates the PBLE HMC object backing pages can request CQP to copy the page list associated with the backing pages to the PF driver allocated page descriptor pages. A VF might also request CQP to invalidate VF related page descriptor entries. This operation reduces the number of VF to PF messages required to populate the VF related HMC PBLE object backing pages.

Table 38-472.CQP Manage VF PBLE Backing Pages WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:44] [43:32] [31:25]	RSVD SD_Index RSVD	[24:16] [15:10] [9:0]	First_PD_Index RSVD PD_Entry_Count
24	[63] [62] [61:41] [40:38]	WQE_Valid Invalidate_PD_Entries RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:3]	PD_Pagelist_Physical_Buffer_Address	[2:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

Invalidate_PD_Entries (1)

When clear (0b), VF PD entries is copied from VF address space to the PF allocated PDs. When set (1b), the PF allocated PDs are invalidated.

PD_Entry_Count (10)

This field indicates the number of PD entries to be populated or invalidated. Valid values for this field are 1 through 512. Other values generate completion errors for the CQP operation. PD_Entry_Count + First_PD_Index must not exceed 512 or a completion error is generated.

First_PD_Index (9)

This field indicates the starting index of the PD page. SD_Index identifies the PD page and First_PD_Index provides the offset into the PD page that is the destination of the CQP operation. If the PD entries associated with the SD_Index and First_PD_Index is not related to a PBLE object, an completion error is generated by CQP for this operation.

SD_Index (12)

This field indicates the SD index that identifies the PD page. The SD entries are in no way modified. If the SD is not related to a PBLE object, then CQP returns a completion error.

PD_Pagelist_Physical_Buffer_Address (61)

This field indicates the 8-byte aligned physical address of the packing page list to be copied to the PD page if Invalidate_PD_Entries is clear. This address is a guest physical address. Host software is responsible to properly set the fields of the PD page list entries previous to issuing the request to CQP.

38.36.3.3.10 Manage Push Page Descriptor Format

The manage push page descriptor is used to assign a push page from BAR0 to a VSI and TC. For an allocate operation, the push page index assigned by CQP is returned in the Operation_Return_Value of the CQE associated with the WQE. For VFs, the push page index is function relative. When GLPE_PSHCFG.PSHCFG_DB_SPLIT is set, two pages (one for doorbells and one for push WQEs) are represented by push page index instead of one.

Table 38-473.CQP Manage Push Page WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:10]	RSVD	[09:0]	QS_Handle
24	[63] [62] [61:41] [40:38]	WQE_Valid Free_Page RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:10] [9:0]	OP RSVD Push_Page_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

Free_Page (1)

When clear (0b) a push page is allocated for the VSI and TC specified by QS_Handle. When set (1b), the push page specified by Push_Page_Index is freed.

Push_Page_Index (10)

Only valid when free page is set (1b). Identifies the push page to be freed. For VFs, the push page index is function relative.

QS_Handle (10)

Identifies the QS handle associated with the push page.

38.36.3.4 Upload Context Descriptor Format

Upload context is used by host software to freeze a QPs state and upload the context to the host.

Table 38-474.CQP Upload Context WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	QP_Context_Address		
24	[63] [62] [61] [60:52] [51:48]	WQE_Valid Freeze_QP RSVD RSVD QP_Type	[47:41] [40:38] [37:32] [31:18] [17:0]	RSVD RSVD (AdditionalFragmentCount) OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

QP_ID (18)

Identifies the QP number be uploaded to host memory.

QP_Type (3)

iWarp=1, UDA=2,all other values are reserved.

Freeze_QP (1)

When set, the QP is frozen before the context is retrieved, else the QP continues processing normally after the snapshot of the context has been returned.

Raw_Format

When set, the QP context is reported in its raw form. This bit should only be set for debug context operations.

QP Context Address

A physically mapped pointer in host memory that contains uploaded context structure format listed in the following table. This buffer must be aligned to a multiple of 4 bytes.

Table 38-475.Uploaded Context Structure Format

Byte Offset	[Bit Range]Field Name			
0	[63:56] [55:48]	RSVD kalive_timer_probes	[47:8] [7:4] [3:0]	RSVD iwarp_state TCP_state
8	[63:32]	timestamp_age	[31:0]	timestamp_recent
16	[63:32]	snd_wnd	[31:0]	snd_nxt
24	[63:32]	rcv_wnd	[31:0]	rcv_nxt
32	[63:32]	snd_una	[31:0]	snd_max
40	[63:32]	rtt_var	[31:0]	srtt
48	[63:32]	cwnd	[31:0]	ss_thresh

104	[63:0]	RSVD		
112	[63:0]	RSVD		
120	[63:0]	RSVD		

hw_sq_tail

This is the 32-byte WQE quanta index of the first unacknowledged WQE for the SQ. There is not a CQE generated for this WQE.

hw_rq_tail

This is the 32-byte WQE quanta index of the first incomplete WQE for the RQ. There is not a CQE generated for this WQE.

q1_wa

This value is set (1b) if Q1 (or inbound RDMA read queue) work is pending when the context was uploaded. The value is clear (0b) if no Q1 work was pending when the context was uploaded.

kalive_timer_probes

The number of retransmits that have been sent (RFC 1122).

Note: See Section 38.36.4.2 for more on context variable definitions.

38.36.3.4.1 Manage HMC PM Function Table

The manage HMC PM function table is used to allocate and free HMC private memory functions for VFs associated with a PF. This WQE is only supported for PF CQPs. For allocate operations (Free_PM_FCN=0b), the HMC function index is reported in the Operation_Return_Value field of the CQE associated with this WQE if the operation is successful.

Table 38-476.CQP Manage HMC PM Function Table WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD

24	[63] [62] [61:38]	WQE_Valid Free_PM_FCN RSVD	[37:32] [31:7] [6:0]	OP RSVD VF_Index
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

Free_PM_FCN (1)

If clear (0b), the 10 GbE controller attempts to allocate a PM function for the VF specified in VF_Index. If set (1b), then the 10 GbE controller frees the PM function specified in VF_index.

VF_Index (7)

VF_Index indicates the PCI VF index to be used for the allocation or free request.

38.36.3.4.2 Create/Discard CEQ Descriptor Format

Host software uses the following structure to manage CEQs through the control QP. CEQs are comprised of a packed array of CEQ entries (see Section 38.36.2.4) that are managed as a circular queue. They can be either virtually or physically contiguous memory buffers. When MSI-X is enabled, each CEQ might be assigned to independent MSI-X vectors to enable distribution of completion event processing across multiple CPUs. Application's process and MSI-X vector assignment capabilities and mechanisms are specific to each operating system.

Table 38-477.CQP Create/Discard CEQ WQE Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:18]	RSVD	[17:0]	ceq_size

Table 38-477.CQP Create/Discard CEQ WQE Format (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
24	[63] [62:61] [60] [59:48] [47] [46] [45:44]	WQE_Valid RSVD TPH_en RSVD Virtually Mapped RSVD Leaf_PBL_Size	[43:41] [40:38] (AdditionalFragmentCount) [37:32] [31:16] [15:7] [6:0]	RSVD RSVD OP RSVD RSVD CEQ_ID

40	[63:0]	RSVD		
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:8]	RSVD	[7:0]	TPH_Value

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

CEQ_ID (7)

CEQ_ID specifies the CEQ to manipulated.

TPH_en (1)

If set (1b), TPH is enabled for this resource. If clear (0b), THP is not used for this resource.

TPH_value (8)

If TPH_en is set (1b), TPH STag is initialized with TPH_value. If TPH_en is clear (0b), this field is ignored.

first_pm_pbl_index (28)

Points to the first HMC FPM space PBLE index for the page table. Host software is responsible for populating the PBLEs with the page list associated with the object before using the object.

Leaf_PBL_Size (2)

See Section , “Address Translation and Protection Overview” for more details on usage of two level PBLs.

0 = Reserved

1 = Variable (one level)

2 = 256 bytes (two level)

3 = 4 KB (two level)

Virtually mapped (1)

If clear (0b), Physical_Buffer_Address is the physical address of the physically contiguous CEQ ring buffer; else the CEQ is virtually mapped and the first_pm_pbl_index is the index of the PBLE HMC object of the PBL to use for mapping the virtually contiguous CEQ. The CEQ buffer must be aligned to a multiple of 4 KB in host memory when virtually mapped is set.

Physical_Buffer_Address (56)

This field specifies the physical buffer address associated with the queue in host memory if virtually mapped is set to zero. If virtually mapped is set to one, this field is ignored by the 10 GbE controller. This address must be aligned to a 256-byte boundary.

ceq_size (18)

The number of CEQEs allowed on the CEQ. Note that the actual number of concurrent CEQEs that can be allocated to the CEQ is ceq_size -1. 0 and 1 are invalid sizes for a CEQ.

38.36.3.5 Create/Discard AEQ Descriptor Format

Host software uses the following structure to manage AEQs through the control QP. AEQs are comprised of a packed array of AEQ entries (see Section 38.36.2.5) that are managed as a circular queue. They can be either virtually or physically contiguous memory buffers.

Table 38-478.CQP Create/Discard AEQ WQE Format

Byte Offset	[Bit Range]Field Name

40	[63:0]	RSVD		
48	[63:28]	RSVD	[27:0]	first_pm_pbl_index
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

first_pm_pbl_index (28)

Points to the first HMC FPM space PBLE index for the page table. Host software is responsible for populating the PBLEs with the page list associated with the object before using the object.

Leaf_PBL_Size (2)

See Section , “Address Translation and Protection Overview” for more details on usage of two level PBLs.

0 = Reserved

1 = Variable (one level)

2 = 256 bytes (two level)

3 = 4 KB (two level)

Virtually mapped (1)

If clear (0b), Physical_Buffer_Address is the physical address of the physically contiguous AEQ ring buffer; else the AEQ is virtually mapped and first_pm_pbl_index is the index of the PBLE HMC object of the PBL to use for mapping the virtually contiguous AEQ. The AEQ buffer must be aligned to a multiple of 4 KB in host memory when virtually mapped is set.

Physical_Buffer_Address (56)

This field specifies the physical buffer address associated with the queue in host memory if virtually mapped is set to zero. If virtually mapped is set to one, this field is ignored by the 10 GbE controller. This address must be aligned to a 256-byte boundary.

AEQE Count (19)

The number of AEQEs allowed on the AEQ. Note that the actual number of concurrent AEQEs that can be allocated to the AEQ is AEQE Count -1. 0 and 1 are invalid sizes for an AEQ.

38.36.3.5.1 Update PE SDs Descriptor Format

This WQE is used to program HMC segment descriptors (SDs) associated with PE enabled PCI functions. CQP ensures that PFs only access HMC functions that belong to the PF at the time of issues the CQP request. PFs can access its own SDs or SDs of protocol enabled VFs that belong to the PF. Accesses to other HMC functions are denied and generate a completion error. This operation is restricted to PF CQP operations.

Table 38-479.CQP Update PE SDs WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:32]	RSVD	[31:0]	SDCMD0
8	[63:32]	SDDATAHIGH0	[31:0]	SDDATALOW0
16	[63:7]	SD_Buffer_Address	[6] [5:0]	RSVD HMC_FCN_ID (PF only)
24	[63] [62:41] [40:38] (AdditionalFragmentCount)	WQE_Valid RSVD RSVD	[37:32] [31:8] [7] [6:4] [3:0]	OP Reserved SKIP_SD_ENTRY_0 Reserved SD_ENTRY_COUNT
32	[63] [62:0]	SD_ENTRY_VALID1 RSVD	[31:0]	SDCMD1
40	[63:32]	SDDATAHIGH1	[31:0]	SDDATALOW1
48	[63] [62:0]	SD_ENTRY_VALID2 RSVD	[31:0]	SDCMD2
56	[63:32]	SDDATAHIGH2	[31:0]	SDDATALOW2

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

HMC_FCN_ID (6)

This field specifies the HMC function ID for the FPM settings to be queried. For PFs, the HMC_FCN_ID is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation.

SD_CMDn (32)

The SD_CMD field definition is the same as the PFHMC_SDCMD register.

SD_DATA_LOWn (32)

The SD_DATA_LOW field definition is the same as the PFHMC_SDDATALOW register.

SD_DATA_HIGHn (32)

The SD_DATA_HIGH field definition is the same as the PFHMC_SDDATAHIGH register.

SD_ENTRY_VALIDn (1)

Indicates of the SDCMD and DATA information is used to update additional SD entries.

SKIP_SD_ENTRY_0 (1)

Indicates SD_CMD0, SD_DATA_LOW/HIGH0 are to be ignored. This is typically useful only if all the SD updates are specified in the update SD host memory structure instead of this WQE.

SD_Buffer_Address (58)

Most significant address bits of the physical address of the update SD host memory structure (listed in Table 38-480). This structure is used to provide additional SD updates. This host memory is only accessed if SD_ENTRY_COUNT is not equal to 0b. The number of entries used from the update SD host memory structure is indicated by SD_ENTRY_COUNT.

SD_ENTRY_COUNT (4)

Indicates the number of contiguous (starting with SDCMD3) SD updates found in the update SD host memory structure.

Table 38-480.Update SD Host Memory Structure

Byte Offset	[Bit Range]Field Name			
0	[63:32]	RSVD	[31:0]	SDCMD3
8	[63:32]	SDDATAHIGH3	[31:0]	SDDATALOW3
16	[63:32]	RSVD	[31:0]	SDCMD4

40	[63:32]	SDDATAHIGH5	[31:0]	SDDATALOW5
48	[63:32]	RSVD	[31:0]	SDCMD6
56	[63:32]	SDDATAHIGH6	[31:0]	SDDATALOW6
64	[63:32]	RSVD	[31:0]	SDCMD7
72	[63:32]	SDDATAHIGH7	[31:0]	SDDATALOW7
80	[63:32]	RSVD	[31:0]	SDCMD8
88	[63:32]	SDDATAHIGH8	[31:0]	SDDATALOW8
96	[63:32]	RSVD	[31:0]	SDCMD9
104	[63:32]	SDDATAHIGH9	[31:0]	SDDATALOW9
112	[63:32]	RSVD	[31:0]	SDCMD10
120	[63:32]	SDDATAHIGH10	[31:0]	SDDATALOW10

38.36.3.5.2 Query FPM Values Descriptor Format

This WQE is used to query the FPM configuration for the PE portion of the HMC objects. The query FPM values command is used to trigger firmware to return the FPM base registers based on the previous software settings or default values.

Table 38-481.CQP Query FPM Values WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:41] [40:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP Reserved
32	[63:2]	Physical_Buffer_Address	[1:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

HMC_FCN_ID (6)

This field specifies the HMC function ID for the FPM settings to be queried. For PFs, the HMC_FCN_ID is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the HMC_FCN_ID is determined by firmware.

Physical_Buffer_Address (62)

This field specifies the physical address of the buffer that firmware fills with the object maximum counts and the object size values.

Table 38-482.FPM Query Configuration Structure Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:45] [44:32]	RSVD max_pe_sds	[31:14] [13:0]	RSVD first_pe_sd_index

40	[63:32]	GLHMC_PEARPOBJSZ	[31:0]	GLHMC_PEARPMAX
48	[63:32]	GLHMC_PEMROBJSZ	[31:0]	GLHMC_PEMRMAX
56	[63:32]	GLHMC_PEXFOBJSZ	[31:0]	GLHMC_PEXFMAX
64	[63:32]	XFBLOCKSIZE	[31:0]	GLHMC_PEXFFLMAX
72	[63:32]	GLHMC_PEQ1OBJSZ	[31:0]	GLHMC_PEQ1MAX
80	[63:32]	Q1BLOCKSIZE	[31:0]	GLHMC_PEQ1FLMAX
88	[63:32]	GLHMC_PETIMEROBJSZ	[31:0]	GLHMC_PETIMERMAX
96	[63:32]		[31:0]	

Table 38-482.FPM Query Configuration Structure Format (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
104	[63:32]		[31:0]	
112	[63:32]	RSVD	[31:0]	GLHMC_PEPBLMAX
120	[63:48] [47:32] [31:20]	RSVD TIMERBUCKETCNT RSVD	[19:16] [15:8] [7:0]	HTMULTIPLIER RSVD max_ceqs

first_pe_sd_index (14)

This field specifies the function relative starting HMC segment descriptor index for PE resources.

max_pe_sds (13)

This field specifies the maximum number of PE SDs allowed for the HMC function.

max_qps (19)

This field specifies the maximum number of PE QPs allowed for the HMC function.

max_cqs (18)

This field specifies the maximum number of PE CQs allowed for the HMC function.

max_ceqs (8)

This field specifies the maximum number of PE CEQs allowed for the HMC function.

XFBLOCKSIZE (32)

This field specifies the number of transmit FIFO entries per transmit FIFO free list entry. This field is used to determine how much space is consumed for transmit FIFO free list entries. The number of transmit FIFO free list entries is calculated with the equation number of transmit FIFO entries / XFBLOCKSIZE.

Q1BLOCKSIZE (32)

This field specifies the number of Q1 FIFO entries per Q1 FIFO free list entry. This field is used to determine how much space is consumed for Q1 free list entries. The number of Q1 free list entries is calculated with the equation number of Q1 entries / Q1BLOCKSIZE.

HTMULTIPLIER (4)

This field specifies the number of hash filter bucket entries per QP. This field is used to determine how much space is consumed for hash filter entries. The number of hash entries is calculated with the equation (round_up_512(number of QPs) rounded up to the next power of two) * HTMULTIPLIER.

TIMERBUCKETCNT (16)

This field specifies the number of timer buckets. This field is used to determine how much space is consumed for timers. The number of timer entries is calculated with the equation (round_up_512(number of QPs)/512 + 1) * TIMERBUCKETCNT.

The remaining fields are register values from the HMC function specified by HMC_FCN_ID or the VF index.

38.36.3.5.3 Commit FPM Values Descriptor Format

This WQE is used to commit the FPM configuration for the PE portion of the HMC objects. The commit FPM values command is used to trigger firmware to calculate the FPM base registers based on the software settings.

Table 38-483.CQP commit FPM Values WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:41] [40:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP Reserved
32	[63:2]	Physical_Buffer_Address	[1:0]	RSVD
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

HMC_FCN_ID (6)

This field specifies the HMC function ID for the FPM settings to be programmed. For PFs, the HMC_FCN_ID is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the HMC_FCN_ID is determined by firmware.

Physical_Buffer_Address (62)

This field specifies the most significant bits of the physical address of the buffer that firmware uses to configure the object maximum counts and the object size values. The buffer described must be aligned to a four byte aligned boundary.

Table 38-484.FPM Commit Configuration Structure Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:32]	GLHMC_PEQPBASE	[31:19] [18:0]	RSVD GLHMC_PEQPCNT

48	[63:32]	GLHMC_PEMRBASE	[31:0]	GLHMC_PEMRCNT
56	[63:32]	GLHMC_PEXFBASE	[31:0]	GLHMC_PEXFCNT
64	[63:32]	GLHMC_PEXFFLBASE	[31:0]	GLHMC_PEXFFLCNT[1]

Table 38-484.FPM Commit Configuration Structure Format (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
72	[63:32]	GLHMC_PEQ1BASE	[31:0]	GLHMC_PEQ1CNT
80	[63:32]	GLHMC_PEQ1FLBASE	[31:0]	GLHMC_PEQ1FLCNT[1]
88	[63:32]	GLHMC_PETIMERBASE	[31:0]	GLHMC_PETIMERCNT[1]
96	[63:32]		[31:0]	
104	[63:32]		[31:0]	
112	[63:32]	GLHMC_PEPBLBASE	[31:0]	GLHMC_PEPBLCNT
120	[63:0]	RSVD		

Notes:

1. These fields are calculated by CQP and returned on completion. On submission, these fields are ignored.

These fields are register values from the HMC function specified by HMC_FCN_ID or the VF index. On request submission, the GLHMC_{obj}CNT fields must be filled in the software. Upon completion of the request, all fields are filled in with the updated values that were actually committed.

38.36.3.5.4 Flush WQEs Descriptor Format

This WQE is used to flush pending WQEs to a CQ. The initial usage for the WQE is to support Winsock Direct socket handoff from one process to another. This WQE is now also used for all WQE flushing. Host software uses this after the quad hash has been deleted for a QP in order to comply with verbs requirements. Note that only a single unprocessed WQE is flushed from the WQ(s) specified by the *FlushRQ*/*FlushSQ* bits. Host software must generate additional completions if more than one outstanding WQE is pending on a WQ that has been flushed.

This WQE can be used to flush pending transmit and receive WQEs for UDA and iWARP QPs. For UDA all filters forwarding to the specified UDA QP must be disabled, prior to flushing WQEs.

Table 38-485.CQP Flush WQEs WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:20] [19:16]	RSVD AE_Source	[15:0]	AE_Code
16	[63:48] [47:32]	SQ_Major_Code SQ_Minor_Code	[31:16] [15:0]	RQ_Major_Code RQ_Minor_Code
24	[63] [62] [61] [60] [59]	WQE_Valid FlushRQ FlushSQ UserFlushCode GenerateAE	[58:41] [40:38] (AdditionalFragmentCount) [37:32] [31:18] [17:0]	RSVD RSVD OP Reserved QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

FlushRQ (1)

0b = Do not flush any pending WQEs from the RQ.

1b = Generate a completion for the first pending RQ with a flushed return code.

FlushSQ (1)

0b = Do not flush any pending WQEs from the SQ.

1b = Generate a completion for the first pending SQ with a flushed return code.

UserFlushCode (1)

UserFlushCode indicates that the WQEs flushed should carry the values specified by SQ/RQ major and minor codes.

0b = Any flushed WQEs carry the flushed completion major and minor codes

1b = Flushed WQEs for the SQ carry SQ_Major_Code and SQ_Minor_Codes, flushed WQEs on the RQ carry RQ_Major_Code and RQ_Minor_Code.

SQ_Major_Code (16)

Valid only when UserFlushCode=1b. SQ_Major_Code is reported in *Major Error Code* field of the CQE for the first flushed WQE for the SQ of the QP specified by QP_ID.

SQ_Minor_Code (16)

Valid only when UserFlushCode=1b. SQ_Minor_Code is reported in *Minor Error Code* field of the CQE for the first flushed WQE for the SQ of the QP specified by QP_ID.

RQ_Major_Code (16)

Valid only when UserFlushCode=1b. RQ_Major_Code is reported in *Major Error Code* field of the CQE for the first flushed WQE for the RQ of the QP specified by QP_ID.

RQ_Minor_Code (16)

Valid only when UserFlushCode=1. RQ_Minor_Code is reported in *Minor Error Code* field of the CQE for the first flushed WQE for the RQ of the QP specified by QP_ID.

GenerateAE (1)

GenerateAE indicates that an AE should be generated after the CQEs have been generated for the flushed WQEs.

AE_Code (16)

Valid only when GenerateAE=1. See Table 38-450 for the values that should be used for this field.

AE_Source (4)

Valid only when GenerateAE=1. See Section 38.36.2.5 for the values that should be used for this field.

QP_ID

Identifies the QP number targeted for the flush operation. This must be an accelerated QP (UDA or iWARP).

38.36.3.5.5 Manage Accelerated Port Bit Vector (APBV)

This WQE sets or clear the bit in the APBV table for the host NIC, IP address and TCP or UDP port number specified in the WQE. The APBV table is used to filter TCP segments belonging to accelerated iWARP connections, TCP segments, UDP multicast and unicast fragments and datagrams belonging to accelerated UDA QPs. Host software also uses the APBV table to flag inbound TCP packets used for connection setup of accelerated connections.

Table 38-486.CQP Manage Accelerated Port Table WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:16]	RSVD	[15:0]	Local TCP/UDP Port
24	[63] [62] [61:41] [40:38]	WQE_Valid Add Port RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

Add Port (1)

When this bit is set to 0b, the port is deleted from the table, when this bit is set to 1b, the port is added to the table.

Local TCP/UDP port (16)

The local (destination port for inbound packets) TCP/IP or UDP/IP port that is used for accelerated iWARP connections and accelerated UDA UDP unicast and multicast first fragments and datagrams, and UDA TCP streams. Any inbound TCP packet and UDP datagram or UDP/IP first fragment who's destination IP address matches that IP address table and destination TCP/UDP port matches Local TCP/UDP port is filtered through quad hash table. If missed, TCP packet and UDP datagram/fragment is passed to the host NIC, and TCP packet has the apbvt_hit bit set in the CQE.

38.36.3.5.6 NOP Descriptor Format

This WQE can be used to generate a CQE that can be used to trigger subsequent processing in a completion handler or as a synchronization mechanism to indicate when all previously issued CQP requests have completed.

Table 38-487.CQP NOP WQE Format (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name	
0	[63:0]	RSVD
8	[63:0]	RSVD
16	[63:0]	RSVD

56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

38.36.3.5.7 Manage Quad Hash Table Descriptor Format

The quad hash table entry can be configured to forward packets to the user-space direct access QP. Multiple entries of the quad hash table can refer to the same QP or multicast group. This CQP operation should be used to program quad hash tables associated with the user-space direct access QPs only.

The same quad hash table is intended to be shared by iWARP QPs and UDA QPs and UDA multicast groups. The quad hash table must be properly sized to allow a good hit rate. It also must be properly sized with respect to the maximum number of entries that are intended to be allocated. One approach is to limit the total number of resources that can be allowed to use quad hash for the given function. This would enable the best use of the shared table. In any case, since allocation of entries in the quad hash table is controlled by PCI function driver, sizing of the table, and allocation policy should be controlled there.

UDA TCP traffic should be using quad hash tables associated with respective PCI function (PF or VF). The manage quad hash table CQP command is allowed to be used on CQP belonging to PF only.

The quad hash table index is calculated by hardware. All hash functions include destination MAC address and VLAN (if valid) in addition to the description provided later. Hash function inputs and a kind of hash function depends on a hash table entry type:

- TCP SYN (ACK Clear) — For the TCP packets with the *SYN* bit set, a hash function should be used as an input a destination IP address and destination TCP port. A hash table entry should match both destination IP address and destination TCP port, and should be of TCP SYN (ACK clear) entry type. Matching entry should carry a destination QP number.
- Established TCP — For the TCP packets with the *SYN* bit clear or the *SYN* bit set and ACK bit set, the hash function should be used as an input source and destination IP addresses, and source and destination TCP ports. The hash table should match both source and destination IP addresses, and source and destination TCP ports. Matching entry should carry a destination QP number.

Table 38-488.CQP Manage Quad Hash Table WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:48] [47:40] [39:32] [31:24]	RSVD Dest_MAC_Address[5] Dest_MAC_Address[4] Dest_MAC_Address[3]	[23:16] Dest_MAC_Address[2] [15:8] Dest_MAC_Address[1] [7:0] Dest_MAC_Address[0]

40	[63:32]	Src_IP_Address_0	[31:00]	Src_IP_Address_1
48	[63:32]	Dest_IP_Address_2	[31:00]	Dest_IP_Address_3
56	[63:32]	Dest_IP_Address_0	[31:00]	Dest_IP_Address_1

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

QS_Handle (10)

Identifies the queue set handle associated with the hash entry.

Dest IP address 0 (32)

This field specifies bits 127 through 96 of the IPv6 IP addresses. Reserved when IPv4 is set (1b). The MSB of this field (bits 31:24) is the first byte on the wire for this field.

Dest IP address 1 (32)

This field specifies bits 95 through 64 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Dest IP address 2 (32)

This field specifies bits 63 through 32 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Dest IP address 3 (32)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP address. The LSB of this field (bits 7:0) is the last byte on the wire for this field.

Src IP address 0 (32)

This field specifies bits 127 through 96 of the IPv6 IP addresses. Reserved when IPv4 is set (1b). The MSB of this field (bits 31:24) is the first byte on the wire for this field.

Src IP address 1 (32)

This field specifies bits 95 through 64 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Src IP address 2 (32)

This field specifies bits 63 through 32 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Src IP address 3 (32)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP address. The LSB of this field (bits 7:0) is the last byte on the wire for this field.

src_port(16)

Source TCP port.

dest_port (16)

Destination TCP port.

QPN (18)

Index of the QP context associated with the entry.

EntryType (3)

The quad hash table is used as a perfect filter for multiple types of accelerated traffic. Depending on the traffic type different hardware accelerations might apply.

0 = iWARP hardware acceleration — not allowed to be used by this WQE. Allocation of a hash table entry with accelerated iWARP QP should be done using Modify QP WQE.

1 = Userspace TCP Established

2 = Userspace TCP SYN (ACK clear)

IPv4_Valid (1)

When set (1b) indicates that both source and destination IP addresses are IPv4. When clear (0b) indicates that both source and destination IP addresses are IPv6.

ManageEntry (2)

0 = Delete entry from the table

1 = Add entry to the table

2 = Modify entry

3 = Reserved

Dest_MAC_Address[5-0] (8 bits each)

Specifies the MAC address associated with the destination IP address. Index 0 is the LSB and byte 5 is the MSB.

VLAN_ID (12 bits)

Specifies the VLAN ID associated with the hash entry. This field is ignored unless VLAN_Valid is set (1b).

VLAN_Valid (1 bit)

Specifies if the hash entry has a VLAN associated with it. If this field is clear (0b), then the hash entry is not associated with a VLAN. If set (1b), then the VLAN associated with the hash entry is specified in the VLAN ID field.

38.36.3.5.8 Suspend QP Descriptor Format

This WQE can be used to suspend a QP that is to be moved to a different QS that the one to which it is currently assigned. QP suspension is required before changing the QS. This WQE might return suspend pending in which case an AE_QP_SUSPEND_COMPLETE AE is issued when the suspend operation completed.

Table 38-489.CQP Suspend QP WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62:41] [40:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:18] [17:0]	OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

QP_ID (18)

Index of the QP to be suspended.

38.36.3.5.9 Resume QP Descriptor Format

This WQE can be used to resume a QP that had been previous suspended in order to be moved to a different QS that the one to which it was assigned. QP suspension is required before changing the QS.

Table 38-490.CQP Resume QP WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:10]	RSVD	[9:0]	QS_Handle
24	[63] [62:41] [40:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:18] [17:0]	OP RSVD QP_ID
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

QP_ID (18)

Index of the QP to be suspended.

QS_Handle (10)

This field specifies Tx scheduler QS handle associated with the TC for this QP. For VFs, the QS_Handle is checked to ensure that the VF issuing the CQP command is associated with the QS_Handle.

38.36.3.5.10 Static HMC Resources Allocated Descriptor Format

This WQE must be used after the commit FPM values operation is complete and all of the static HMC resources from Table 38-452 have HMC backing pages allocated and configured. CQP then completes initializing the function for PE operation.

Table 38-491. Static HMC Resources Allocated WQE Format

Byte Offset	[Bit Range]	Field Name		
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:6]	RSVD	[5:0]	HMC_FCN_ID (PF only)
24	[63] [62:41] [40:38]	WQE_Valid RSVD RSVD (AdditionalFragmentCount)	[37:32] [31:0]	OP RSVD
32	[63:0]	RSVD		
40	[63:0]	RSVD		
48	[63:0]	RSVD		
56	[63:0]	RSVD		

OP (6) and WQE_Valid

See Section 38.36.3.3.1.

HMC_FCN_ID (6)

This field specifies the HMC function ID that software has completed the allocation and configuration of the static HMC backing pages. For PFs, the HMC_FCN_ID is strictly the PF index. For VFs, the HMC function ID was returned from the manage HMC PM function CQP operation. If a CQP instance associated with a VF submits this operation, this field is ignored and the HMC_FCN_ID is determined by firmware.

38.36.4 iWARP Functionality

The operations for RDMA via iWARP are implemented using the context and WQE formats described in the following sections. QP operation, the verbs interface, and system view of the 10 GbE controller are described in Section 38.36.2.1. The CQP operations and HMC structures necessary to bring the 10 GbE controller to a functional state for iWARP are described in Section 38.36.3.

38.36.4.1 iWARP Q2 Area

iWARP QPs have a memory area that is written under error conditions. The format of this area is listed in Table 38-492. This memory area is reference from the Q2_Address variable from the QP context listed in Table 38-493.

Table 38-492.iWARP Q2 Structure Format

Byte Offset	[Bit Range]Field Name			
0 - 55	Outbound_Terminate_Header			
64	[63] Sequence_Update_Toggle [62:32]	RSVD	[31:0]	First_Partial_Sequence_Number
72 -255	Inbound_Q2_Data			

Outbound_Terminate_Header (56 bytes)

This field contains the outbound terminate header used for Modify QP CQP operations when Terminate_Actions is set to send terminate only or send fin and terminate.

First_Partial_Sequence_Number(32 bits)

This field contains the sequence number of the first partial FPDU receive by the 10 GbE controller. See Section 38.36.2.3 for more details on partial FPDU support.

Sequence_Update_Toggle(1 bit)

This field toggles each time the First_Partial_Sequence_Number is updated by the 10 GbE controller. See Section 38.36.2.3 for more details on partial FPDU support.

Inbound_Q2_Data(184 bytes)

This field contains the first 184 bytes of the packet that caused an AE. This could either be an inbound terminate message or the Ethernet packet that had an error.

38.36.4.2 iWARP QP Context Format

iWARP QP context is used by software to initialize or update the 10 GbE controller QP context. Create and Modify QP CQP operations (see Section 38.36.3.3.2) reference this structure.

Table 38-493.iWARP QP Context Structure Format (Sheet 1 of 3)

Byte Offset	[Bit Range]Field Name			
0	[63:62]	iwarp_rdmap_ver	[13:12]	limit

192	[63:32]	Local_IP_Address_0	[31:0]	Local_IP_Address_1
200-248	[63:0]	RSVD		

Notes:

1. This variable is a cached variable. See Cached_Variables_Valid in Modify QP operations for more details on cached context variables.
2. Only valid for QPs.

Push page index (10)

This field identifies the push page associated with the QP. For VFs, the push page index is function relative.

Push mode enable (1)

This field indicates if push mode is enabled for the QP.

ignore_tcp_options (1)

Specifies that the TCP options should be ignored when processing received TCP headers.

ignore_tcp_uns_options (1)

Specifies that the unsupported TCP options should be ignored when processing received TCP headers.

NoNagle (1)

This field indicates if nagle algorithm is in use on this connection. If this field is set, then the nagle algorithm is disabled on this connection (RFC 896).

PrivilegedEnable (1)

This bit is used to enable privilege mode on STag's. If this bit is set, then a local STag of zero (STag 0) is allowed on this connection and the *TO* field should be treated as a physical address. If this bit is cleared, then STag 0 is NOT allowed for a local STag and an AEQE is generated with privilege error indicated. STag 0 is never allowed in an inbound RDMA packet.

FastRegisterEnable (1)

This bit is used to enable fast register opcodes on privilege mode QP's. If this bit is set, then a fast register is allowed on this connection. If this bit is cleared, then fast register is NOT allowed for this connection and an AEQE is generated with privilege error indicated.

BindEnable (1)

This bit is used to enable memory window bind operations on this QP. If this bit is set, then memory window bind operations are allowed on this connection. If this bit is cleared, then memory window bind operations are NOT allowed on this connection and an AEQE is generated with privilege error indicated.

ReceiveMarkers (1)

This field specifies if we are to receive MPA markers in the receive stream. If set to 0b, then no markers are expected in the receive stream; if set to 1b, then markers are expected every 512 bytes.

SendMarkers (1)

This field specifies if generating MPA markers in the transmit stream. If set to 1b, then markers are expected every 512 bytes; if set to 0b, then markers are not included in the transmit stream.

rdmard_ok (1)

This field enables inbound iWARP RDMA read requests when set. If cleared then this field disables inbound iWARP RDMA read requests and an AEQE is generated.

rdmawr_rdresp_ok (1)

This field enables inbound iWARP RDMA write requests and inbound RDMA read responses when set. When cleared, this field disables inbound iWARP RDMA write responses and inbound iWARP RDMA read requests and an AEQE is generated.

timestamp (1)

This field indicates if time stamp option is in use on this connection. If this field is set, then the time stamp option is enabled on this connection (RFC 1323); if cleared, the time stamp option is not present.

keepalive (1)

This field indicates if the keep alive option is in use on this connection. If this field is set, then the keep-alive option is enabled on this connection (RFC 1122).

wscale (1)

This field indicates if window scale option is in use on this connection. If this field is set, then the window scale option is enabled on this connection in both directions (RFC 1323). The window is scaled by the snd_wscale and rcv_wscale variables described later. If clear then both windows are not scaled.

dupack_thresh (3)

Specifies the number of dupacks received before starting fast retransmit (1-7). A value of 0 is remapped to a default value of 3.

err_RQ_index_valid (1)

Indicates that the err_RQ_index is valid. This setting is allowed only for a modify QP-to-terminate or a modify QP-to-error operation.

err_RQ_index (14)

Software uses err_RQ_index to override the index in the RQ during a FlushWQEs CQP operation. This is only valid if err_RQ_index_valid is on and it is a modify QP-to-terminate or modify QP-to-error operation.

drop_out_of_order_seg (1)

If this bit is set and a segment is received that is out-of-order, TRX drops the segment and sends an acknowledgment as required by TCP. If this bit is zero, the out-of-order segment is processed.

ECN_enable (1)

When this bit is clear (0b), ECN is disabled. When this bit is set (1b), then the TOS field of the IPv4 header or IP TC field of the IPv6 header contains the ECN code point (bits 6 and 7 - least significant bits) and the code point in the IP TC or TOS context field must be set to 01b (normal) or code point 10b (optional).

XMIT_TPH_en (1)

If set (1b), TPH is enabled for data reads associated with this QP. If clear (0b), THP is not used for data reads associated with this QP.

SQ_TPH_en (1)

If set (1b), TPH is enabled for the SQ of this QP. If clear (0b), THP is not used for this resource.

SQ_TPH_value (8)

If SQ_TPH_en is set (1b), TPH STag associated with SQ operations is initialized with SQ_TPH_value. If SQ_TPH_en is clear (0b), this field is ignored.

SQ_Size (4)

This field encodes the maximum size for the WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for SQ_Size:

0 = 128 bytes
1 = 256 bytes
2 = 512 bytes
3 = 1024 bytes
4 = 2048 bytes
5 = 4096 bytes
6 = 8192 bytes
7 = 16384 bytes
8 = 32768 bytes
9 = 65536 bytes
10 = 131072 bytes
11 = 262144 bytes
12 = 524288 bytes

Software can only allocate N-1 WQEs on the SQ. Each WQE is variable in size and can consume up to 128 bytes of memory. For more information see Section 38.36.2.1.7. The minimum size for an SQ is four WQEs of the maximum size that will be used.

RCV_TPH_en (1)

If set (1b), TPH is enabled for data placement associated with this QP. If clear (0b), THP is not be used for data placement associated with this QP.

RQ_TPH_en (1)

If set (1b), TPH is enabled for the RQ of this QP. If clear (0b), THP is not be used for this resource.

RQ_TPH_value (8)

If RQ_TPH_en is set (1b), TPH STag associated with RQ operations is initialized with RQ_TPH_value. If RQ_TPH_en is clear (0b), this field is ignored.

RQ_Size (4)

This field encodes the maximum size for the WQ. The encoding of the RQ sizes are $4*2^{RQ\_Size}$ in terms of 32-byte quanta of memory. The following value are allowed for RQ_Size:

- 0 = 128 bytes
- 1 = 256 bytes
- 2 = 512 bytes
- 3 = 1024 bytes
- 4 = 2048 bytes
- 5 = 4096 bytes
- 6 = 8192 bytes
- 7 = 16384 bytes
- 8 = 32768 bytes
- 9 = 65536 bytes
- 10 = 131072 bytes
- 11 = 262144 bytes
- 12 = 524288 bytes

The actual number or WQEs that can be posted to the RQ is the size of the WQ divided by the WQE size determined from RQ_WQE_Size. Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow. WQ overflow results in indeterministic behavior for the affected WQ. The minimum size for an RQ is four WQEs.

RQ_WQE_Size (2)

Specifies the number of 32 byte chunks of memory included with each RQ WQE. The maximum number of additional fragments allowed for an RQ WQE is 6 for a total of 7 fragments and a maximum WQE size of 128 bytes. Valid values are:

- 0 = 32 bytes per WQE (no additional fragments)
- 1 = 64 bytes per WQE (1 or 2 additional fragments)
- 2 = 128 bytes per WQE (3 to 6 additional fragments)
- 3 = Reserved

Insert VLAN tag (1)

This bit is set to enable VLAN processing on a connection. The tag configured in the VLAN_Tag field is used for all processing. If this bit is clear then there is no VLAN insertion or removal performed by the PE. Additional VLAN and priority setting can be configured through the VSI associated with the QP. The most significant portion of the VLAN tag carry the user specified priority. When this bit is set, received packets destined for the QP with mis-matched VLAN or no VLAN tag is sent to LAN queues. When this bit is clear, received packets destined for the QP with VLAN tags are sent to LAN queues.

Insert L2TAG2 (1)

This bit is set to enable L2TAG2 processing for this connection.

IPv4 (1)

This field indicates if the QP is IPv4 or IPv6. 1b indicates IPv4 and 0b indicates IPv6.

iwarp_ddp_ver (2)

These bits are used to set and check the DV fields of DDP PDUs for this connection.

iwarp_rdmap_ver (2)

These bits are used to set and check the RV fields of RDMAP PDUs for this connection.

RxCmpQueueNum (17)

This field specifies which of the 128 K CQs is used for receive completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

TxCmpQueueNum (17)

This field specifies which of the 128 K CQs is used for transmit completion notification.The Rx and Tx completions can be mapped to the same CQ or different queues.

SQ address(64)

If VirtualWQ bit is clear, then this field holds SQ base physical address. It must be aligned to an address divisible by 128 bytes. If VirtualWQ bit is set, then this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first first_pm_pbl_index).

RQ address (64)

If VirtualWQ bit is clear or the QP is associated with a shared RQ, then this field holds RQ base physical address. It must be aligned to an address divisible by 128 bytes. This is the RQ base pointer when this is an iWARP accelerated connection. If VirtualWQ bit is set and the QP is not associated with a shared RQ, then this field specifies the first HMC PBLE index of the 1-level page list for the SQ (first first_pm_pbl_index).

IP TC or TOS (8)

This field specifies the IPv4 type of service bits (RFC 2474). If these bits represent the IPv4 TOS bits, then only the lower 4-bits are valid. These bits are set by software when the connection is created and transmitted in the IP header of all sent datagrams for this connection.

rexmit_thresh (6)

Specifies the number of re-transmissions on this connection that can occur before the AE_LLP_TOO_MANY_RETRIES AE is generated. A value of 0b disables generation of the AE and allows infinite retries.

avoid_stretch_ack (1)

When this bit is set, an ACK is generated ever 2*MSS sequence numbers from cur_ack_seq_num up to current rcv_nxt value. When this bit is off, then ACKs can be coalesced if the 10 GbE controller is busy. In the 10 GbE controller, this works for all cases except when an immediate ACK needs to be generated in which case the ACK sequence number my advance by more than 2*MSS segments. This field is normally clear for iWARP connections.

Source MAC address index (6)

This field specifies an index into one of the 64 possible source MAC addresses. This is used to specify the outbound MAC address in the Ethernet header.

QS_Handle (10)

This field specifies Tx scheduler Queue Set handle associated with the TC for this QP. For VFs, the QS_Handle is checked to ensure that the VF issuing the CQP command is associated with the QS_Handle.

Exception_UDA_Queue (18)

This field specifies UDA queue that receives partial iWARP FPDUs and TCP/IP packets with the *URG* bit set.

Limit (2)

This field specifies a limit value for the number of bytes that increase cwnd for each received acknowledgment - as per RFC3465. If an acknowledgment is for less than limit, then cwnd is advanced by that number of bytes. Generally, this field should be set to 3 for iWARP connections; other values are for interoperation with various TCP offload engines:

0 = cwnd updated by at most 1*SMSS bytes.

1 = cwnd updated by at most 2*SMSS bytes.

2 = cwnd updated by at most 4*SMSS bytes (experimentation).

3 = cwnd updated by the number of bytes Acknowledged (experimentation).

if limit = 3 (cwnd += ACK_SEQ - snd_una)

else cwnd += min(ACK_SEQ - snd_una, SMSS<<limit)

Hop limit or TTL (8)

This field specifies the IPv4 Time-To-Live (TTL) parameter in the IP header (RFC 791). It is initialized by software.

Dest port number (16)

This field specifies the destination TCP port number for the TCP header (RFC 793).

Source port number (16)

This field specifies the source TCP port number for the TCP header (RFC 793).

Dest IP address 0 (32)

This field specifies bits 127 through 96 of the IPv6 IP addresses. Reserved when IPv4 is set (1b). The MSB of this field (bits 31:24) is the first byte on the wire for this field.

Dest IP address 1 (32)

This field specifies bits 95 through 64 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Dest IP address 2 (32)

This field specifies bits 63 through 32 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Dest IP address 3 (32)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP address. The LSB of this field (bits 7:0) is the last byte on the wire for this field. For IPv4 addresses, the MSB (bits 31:24) of this field is the first byte of the destination IP address on the Ethernet wire.

Local IP address 0 (32)

This field specifies bits 127 through 96 of the IPv6 IP addresses. Reserved when IPv4 is set (1b). The MSB of this field (bits 31:24) is the first byte on the wire for this field.

Local IP address 1 (32)

This field specifies bits 95 through 64 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Local IP address 2 (32)

This field specifies bits 63 through 32 of the IPv6 IP addresses. Reserved when IPv4 is set (1b).

Local IP address 3 (32)

This field specifies the 32-bit IPv4 (see RFC 791) or the least significant 32-bits of the IPv6 IP address. The LSB of this field (bits 7:0) is the last byte on the wire for this field. For IPv4 addresses, the MSB (bits 31:24) of this field is the first byte of the destination IP address on the Ethernet wire.

snd_mss (14)

Maximum segment size the sender is allowed to transmit. The 10 GbE controller snd_mss is often set to values smaller than the maximum based on the capabilities of the fabric or connection partner. It can change based on the minimum of the rcv_mss, PathMTU or Ethernet MTU. This field needs to be set to a value less any TCP options so rather than setting the value to 1460 if the time stamp option is enabled it would be set to 1448.

ARP index (16)

Index into the ARP cache to specify the Ethernet MAC address to use for this connection. Initialized by software during connection establishment. Allows access to 65536 entry ARP table.

VLAN tag (16)

Specifies one of the 4096 VLAN tags for this connection, 3-bits of priority and 1-bit canonical format. All bits are valid. The VLAN is in the lower 12-bits of the VLAN *Tag* field. The upper 3 bits are priority.

L2TAG2 (16)

This 16 bit tag will be inserted into outbound packets based on the rules define for LAN if Insert_L2TAG2 is set.

TCP_state (4)

Here are the state definitions (RFC 793):

0 = NON EXISTANT (Software state)
1 = CLOSED
2 = LISTEN (Software state)
3 = SYN_SENT (Software state)
4 = SYN_RECEIVED (Software state)
5 = ESTABLISHED
6 = CLOSE_WAIT
7 = FIN_WAIT_1
8 = CLOSING (Software state)
9 = LAST_ACK (Software state)
10 = FIN_WAIT_2
11 = TIME_WAIT (Software state)
15-12 = Reserved

Flow label (20)

This field specifies the IPv6 *Flow Label* field contents (RFC 2460). This field is set by software when a connection is offloaded and can be changed during operation.

pd_index (15)

Protection domain for this context. This specifies which one of the 32 BK iWARP protection domains this connection context belongs too. There are no reserved index values.

Snd_wscale (4)

This field specifies the shift count used on the advertised window size received from the other end to obtain the real 32-bit advertised window size (AWS). A value of 0 selects no window scaling. A value of 14 supports a maximum window of 1,073,725,440 bytes [(65536 x 16384) - 1) (RFC 1323]. Software initializes this field from the value supplied on the during connection establishment (such as SYN segment). Valid values are: 0-14 supporting windows up to 1 GB -1. A value of 15 is rolled back to a value of 14.

Rcv_wscale (4)

This field specifies the shift count used every time TCP sends a segment to determine the window size to report. The internal 32-bit window size is right shifted by this field to give the value to place in the TCP header. A value of 0 selects no window scaling. A value of 15 supports a maximum window of 1,073,725,440 bytes ((65536 x 16384) - 1) (RFC 1323). Software initializes this field from the value it supplied during connection establishment (like on the SYN segment) based on the receive buffer size. Valid values are: 0-14 supporting a receive window up to 1 GB -1. A value of 15 is rolled back to a value of 14.

Keepalive interval (8 bits):

This field specifies the keep-alive interval in terms of timer ticks of the keep-alive timer.

kalive_timer_max_probes (8)

This field specifies the maximum number of keep-alive probes that are allowed before declaring issuing the AE_LLP_TOO_MANY_KEEPALIVE_RETRIES AE.

timestamp_recent (32)

This field is updated when a segment arrives that includes the expected segment number (RFC 1323). This field is returned in the *Echo Reply* field of a timestamp.

timestamp_age (32)

This field records the value from tcp_now (500 ms timer) the last time ts_recent was copied from a receive segment (RFC 1323). This field is required for TCP to perform PAWS.

snd_nxt (32)

The next sequence number that TCP sends in a transmitted packet (RFC 793).

snd_wnd (32)

This field specifies the senders Advertised Window Size (AWS). This field is the 16-bit receive window shifted by snd_wscale to come up with the AWS (RFC 793). This is a window our partner advertised that limits our transmit operations.

rcv_nxt (32)

This is the next expected receive sequence number. It is also referred to as the left hand receive pointer (RFC 793).

rcv_wnd (32)

This field specifies the receivers AWS. The AWS is flow control imposed by the receiver. This field is used to generate the 16-bit window size reported in the TCP header, shifted by the receive window scale (rcv_wscale). This is the value advertised to the sender (RFC 793).

snd_max (32)

This sequence number points to the maximum send sequence number that has been transmitted. This field sets the upper bound of valid ACK when processing a re-transmission timeout (RFC 793). On connection offload this field is normally set to the same sequence number as snd_nxt unless a retransmission was in progress when the connection was offloaded.

snd_una (32)

This sequence number points to the oldest unacknowledged sequence number for this connection (RFC 793).

srtt (32)

This field is the smoothed round trip time (rtt) << 3 (RFC 793 and RFC 2988) in ms. If this field is set to 0b on connection offload then the hardware calculates the value.

rtt_var (32)

Round trip variation (RTTVAR in RFC 2988) in ms. This field MUST never be set to 0b if srtt is also set to 0b. Make this a non-zero value if srtt is 0b.

ss_thresh (32)

Slow start threshold (RFC 2581).

cwnd (32)

This field is the sender congestion widow. It gets incremented by MSS when an ACK arrives. Software should initialize this field to 1b segment size (in bytes). If a duplicate ACK arrives, this is set to min(cwnd, rcv_wnd) but at least 2 segments. On a transport timeout this is set to 1b segment (RFC 2581).

snd_wl1 (32)

Segment sequence number used for last send window update (RFC 793).

snd_wl2 (32)

Segment acknowledgment used for last send window update (RFC 793).

max_snd_window (32)

Indicates the largest send window advertised by the remote peer. Used in step 3 of the sender side SWS algorithm. If at least ½ of the largest window seen so far is available, then send a segment.

retransmitCount (6)

The number of re-transmits that have been sent when the connection is offloaded (RFC 2581).

Q2 Address (56)

This field points to a buffer in host memory that is used to report a terminate message received on this QP. The field can be located at a fixed offset based on some other pointer (receive base pointer); it only points to a one entry queue to handle errors (terminate requests).

last_byte_sent (8)

This is the last byte transmitted on the wire. It is only used during window probes. During modified iWARP only window probes, the 10 GbE controller transmits the last acknowledged data byte on the wire. This corresponds to the last byte sent because a zero window condition is defined as all bytes acknowledged but no window to continue transmitting. Software should initialize it to the last byte sent before the connect was

offloaded the connection to the hardware, so if a streaming mode message had been sent, it's the last byte sent of the last MPA message sent. If after a SYN/ACK handshake then initialize this field to 0b.

rcv_no_mpa_crc (1)

This field specifies if we are to check MPA CRCs in the receive stream. If set to 1b, then no MPA CRC checks are performed on FPDUs in the receive stream; if set to 0b, then all inbound FPDUs are checked by the 10 GbE controller.

assume_aligned_headers (1)

This field is set by software during connection setup if it knows the other adapter is a the 10 GbE controller that does not generate unaligned headers. This enables the 10 GbE controller to place all segments that arrive if it passes basic header checks even if the packet was received out of order. Markers are not examined.

iWARP mode (1)

This field sets the mode of operation when RQ empty conditions are encountered. When this field is clear (0b) the connections is placed in the terminate state and an AE is generated. When this field is set (1b) the offending packet is dropped and the peer re-transmits the packet in the hope that the empty condition is resolved by the time the re-transmission occurs.

IRD_Size (2)

This field specifies the number of inbound RDMA resources available for this connection (Q1). Valid settings are:

00b = 4 WQE

01b = 16 WQE

10b = 64 WQE

11b = 128 WQE

When advertising resources to the other side only 1/2 the queue is available. For example, if IRD_Size is set to 64 entries, then the ORD size for the connection partner should be set to 32 or less.

ORD_Size (7)

This field specifies the number of outbound RDMA resources available for this connection. Up to 127 outbound RDMA read requests are supported. This field is not encoded because a partner might support a different number of RDMA read requests than on transmit (such as 1, or 10, or 64, etc.).

snd_mrk_offset (9)

This field specifies the offset to the MPA marker in the transmit stream of bytes. Subsequent markers are located every 512 bytes from this location. So modulo math can be used to place the markers in the transmitted byte stream. Software initializes this field upon connection setup.

rcv_mrk_offset (9)

This field specifies the offset to the MPA marker in the receive stream of bytes. Subsequent markers are located every 512 bytes from this location. So modulo math can be used to extract the markers in the receive byte stream. Software initializes this field upon connection setup.

QP_Completion Context (64)

This field is reported in CQEs and also in AEQEs.

Use_Statistics_Instance (1)

This field indicates if the default per PMF statistics are used or if one of the additional RDMA statistics instances are used for this QP. When this field is zero, the default statistics are used. When this field is one, the statistics instance indicated by the Statistics_Instance_Index field is used.

Statistics_Instance_Index (5)

This field specifies which of the additional RDMA statistics indexes are used if Use_Statistics_Instance is one. This field is ignored if Use_Statistics_Instance is zero.

t_high

The high RTT threshold in ms for TIMELY If the current RTT is higher than this threshold then the congestion window is multiplicatively decreased. If zero, the default value of 500 ms is used. This value applies only if TimelyEnable is set (1b).

t_low

The low RTT threshold in ms for TIMELY If the current RTT is less than this threshold then the congestion window is additively increased. If zero, the default value of 50 ms is used. This value applies only if TimelyEnable is set (1b).

38.36.4.3 iWARP QP Completion Codes

iWARP QP errors are typically reported via AEs with the 10 GbE controller. After fielding the AEs, software might issue the flush WQES CQP operation (see Section 38.36.3.5.4) to complete any pending operations. Table 38-494 lists the completion codes reported by the 10 GbE controller in a CQ entry (Table 38-495). Also note that host software can report any completion code necessary using the flush WQEs operation instead of the codes listed in Table 38-494.

Table 38-494.iWARP QP Error Codes

Major Error Code	Minor Error Code	Completion Reason	Description
0x0001	0x0001	WQE Flushed	The WQE has been flushed due to a modify QP state transition.

38.36.4.4 iWARP CQ entry formats

CQ operation for iWARP is described in Section 38.36.2.1.3. CQs are manipulated through CQP operations. See Section 38.36.3.3.3 for further details. Note that an extra 32 bytes of 0's are added to each CQE if the Avoid_Memory_Conflicts is set during the CreateCQ CQP operation.

Table 38-495.iWARP CQ Entry Format Without Immediate Data (Sheet 1 of 2)

Byte Offset	[Bit Range]Field Name			
0	[63:32]	TCP Sequence Number	[31:0]	Payload Length

Table 38-495.iWARP CQ Entry Format Without Immediate Data (Sheet 2 of 2)

Byte Offset	[Bit Range]Field Name			
8	[63:0]	QP Completion Context		
16	[63:50] [49:32]	RSVD QP_ID	[31:0]	Invalidated STag
24	[63] [62] [61:56] [55] [54] [53]	CQE_Valid SQ OP Error Solicited Event (iWARP RQ Only) STag (iWARP RQ Only)	[52] [51] [50:46] [45:32] [31:16] [15:0]	 Push Dropped (iWARP SQ Only) RSVD WQ_Desc_Index Major Error Code Minor Error Code

OP (6)

This field reports the opcode from the operation associated with the CQE.

WQ_Desc_Index (14)

WQ is sliced up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. WQ_Desc_Index reports the 32-byte quanta index of the WQE associated with the completion.

CQE_Valid (1)

The CQE_Valid bit for CQE is a bit that indicates that a CQE is ready to be processed. The polarity of the valid bit changes each time the CQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead by avoiding the need to clear the valid bit once software has processed a valid CQE. Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the 10 GbE controller sets the *Valid* bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the 10 GbE controller sets the valid bit to 0b when it writes an new CQE.

Error (1)

0b = No Error.

1b = An error occurred when processing the WQE associated with this CQE and that the *Error Code* field is valid.

Stag (1)

Indicates if the Invalidated_STag field has valid contents.

0b = Ignore Invalidated_Stag.

1b = An STAG was invalidated and Invalidated_Stag field is valid.

Solicited_Event (1)

Valid for receive only. Value for SQ completions is undefined.

0b = SE bit not set in received packet.

1b = SE bit set in received packet.

SQ (1)

0b = RQ.

1b = SQ.

Push dropped (1)

Valid only when SQ is set.

0b = Push operations are being processed successfully.

1b = A recent push mode operation has been dropped by the 10 GbE controller, software should refrain from submitting additional push mode operations until the SQ has encountered an empty condition.

Payload_Length (31)

Total payload length of the completed message. This field is only valid for RQ WQE completions.

TCP sequence number

For iWARP, this field reports the TCP sequence number associated with the work request specified by the completion.

QP completion context (64)

Completion context pointer. This field is transferred to the CQE from QP context.

QP_ID (18)

QP associated with the completed message.

Invalidated_Stag (32)

Any stag that was invalidated by the completed message. Only valid if the *Stag* bit is also set. If the *Stag* bit is clear, then Invalidated_Stag must be ignored.

Major Error_Code (16)

Valid if error is set (1b). See Table 38-494 for defined values. Software can also report any value via the flush WQEs CQP operation (see Section 38.36.3.5.4).

Minor Error_Code (16)

Valid if error is set (1b). See Table 38-494 for defined values. Software can also report any value via the flush WQEs CQP operation (see Section 38.36.3.5.4).

38.36.4.5 iWARP Descriptor Formats

38.36.4.5.1 iWARP SQ Descriptors

The following WQE formats are used in conjunction with iWARP QPs. Operations that are supported for iWARP QPs are the listed in Table 38-496.

Table 38-496.iWARP QP Operations (Sheet 1 of 2)

Operation Code	Operation Name	Page	Operation Code	Operation Name	Page
0x00	RDMA Write	3249	0x0A	Local Invalidate STag	3252
0x01	RDMA Read	3250	0x0B	RDMA Read with Local Invalidate	3252
0x02			0x0C	NOP	3246
0x03	Send	3247	0x0D		
0x04	Send with Invalidate	3247	0x0E	RSVD	
0x05	Send with Solicited Event	3247	0x0F		
0x06	Send with Solicited Event and Invalidate	3247	0X10		
0x07	RSVD		0x11		
0x08	Memory Window Bind	3251	0x12		
			0x13		

Table 38-496.iWARP QP Operations (Sheet 2 of 2)

Operation Code	Operation Name	Page	Operation Code	Operation Name	Page
			0x14		
			0x15		
0x09	Fast Register memory region	3217	0x12 - 0x3F	RSVD	

Common iWARP SQ Descriptor Format Fields

The basic iWARP WQE is a 32-byte structure that is broken up into 64 bit (8-byte) words. The placement of these fields with WQE are common among all CQP WQEs and also iWARP WQEs. Table 38-497 lists the basic structure of a CQP WQE including the common fields. The definition of fields marked as operation code dependent vary from operation to operation and are detailed in subsequent sections. Fields marked as RSVD (reserved) must be set to 0b or undesired behavior related to the specific QP associated with the WQE might occur. Additionally, iWARP WQEs can optionally include additional descriptors to enable larger WQEs to be created. The additional descriptor format is listed in Table 38-498.

Table 38-497.iWARP Common WQE Fields

Byte Offset	[Bit Range]Field Name		
0	[63:0]	Operation Code Dependent	
8	[63:0]	Operation Code Dependent	
16	[63:0]	Operation Code Dependent	
24	[63] WQE_Valid [62] Signaled Completion [61] Local Fence [60] Read Fence [59] (wait_for_rcvFPDU) Operation Code Dependent [58] Mode) Operation Code Dependent (Streaming [57] Flag) Operation Code Dependent (Inline Data		[56] Push WQE [55 RSVD [54:48] Operation Code Dependent(Inline Data Length) [47] RSVD [46] RSVD [45:41] RSVD [40:38] AdditionalFragmentCount [37:32] OP [31:0] Operation Code Dependent

OP (6)

iWARP operation code. See Table 38-496 for the specific values.

WQE_Valid (1)

The WQE_Valid bit for Work Queue Entries (WQE) is a bit that indicates that a WQE is ready to be processed by the 10 GbE controller. The polarity of the valid bit changes each time the WQ wraps from the last entry back to the first entry. This change in polarity reduces software overhead associated with the need to clear a valid bit and also to enable the 10 GbE controller to read ahead in the WQ to reduce the need for doorbell rings. See Section 38.36.2.1.7 for more information on submitting work to a QP with the 10 GbE controller. Software is responsible to clear (set to 0b) all memory in a WQ initially at QP creation. The first iteration (and subsequent odd numbered iterations) through the WQ, software sets the *Valid* bit to 1b when it writes a new WQE. For the second iteration (and all even numbered iterations) through the WQ, software sets the valid bit to 0b when it writes an new WQE.

AdditionalFragmentCount (3)

AdditionalFragmentCount specifies the number of additional fragment descriptors that are valid for this WQE. Up to 6 additional fragment descriptors (listed in Table 38-498) can be added to a WQE for a maximum total of 7 fragments.

Push WQE (1)

Indicates that the WQE was pushed to the push page associated with the QP. If this bit is set and the 10 GbE controller dropped the push operation the *Push Dropped* bit is set in the next CQE following this WQE to indicate that software to stop pushing WQEs until an empty SQ condition has been observed. Using this rule prevents additional CPU and PCI bus bandwidth from being consumed when the Ethernet fabric is congested or the 10 GbE controller is unable to process push mode operations temporarily.

Signaled_Completion (1)

0b = Do not generate a CQE for this message unless there is an error associated with the WQE.

1b = Generate a CQE for this WQE, a CEQE might or might not be generated depending on the state of the CQ.

Local_Fence (1)

This bit if = 1b signifies that the current WQE MUST NOT start until all prior SQ WQEs on the QP completed.

Read_Fence (1)

This bit if = 1b signifies that the current WQE MUST NOT start until any outstanding RDMA read requests on the SQ complete.

Table 38-498.iWARP Additional Fragment Descriptor Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged Offset		
8	[63:32]	STag	[31:0]	Fragment Length

Tagged offset

The tagged offset (relative to the STag) associated with the data described by the additional fragment descriptor.

STag

STag associated with the data described by the additional fragment descriptor.

Fragment Length

Length in bytes of the data described by the additional fragment descriptor.

SQ WQE Format - NOP

Table 38-499.iWARP SQ NOP WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:0]	RSVD		
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59] [58] [57]	WQE_Valid Signaled_Completion Local_Fence Read_Fence RSVD RSVD RSVD	[56] [55:48] [47] [46] [45:38] [37:32] [31:0]	Push WQE RSVD RSVD RSVD RSVD OP RSVD

OP (6)

This WQE format is valid for the NOP operation. See Section "Common iWARP SQ Descriptor Format Fields" for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), Push_WQE(1),

See Section "Common iWARP SQ Descriptor Format Fields" for more detail.

SQ WQE Format - Send

Table 38-500.iWARP SQ Send WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged_Offset		
8	[63:32]	STag	[31:0]	Fragment_Length
16	[63:0]	RSVD		
24	[63] [62] [61] [60] [59] [58] [57]	WQE_Valid Signaled_Completion Local_Fence Read_Fence wait_for_rcvFPDU Streaming_Mode Inline_Data_Flag	[56] [55:41] [40:38] [37:32] [31:0]	Push WQE RSVD AdditionalFragmentCount OP Remote_Invalidate_STag

OP (6)

This WQE format is valid for the send, send with invalidate, send with solicited event, and send with solicited event and invalidate, as well as the versions of these operations that include immediate data. See Section "Common iWARP SQ Descriptor Format Fields" for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), wait_for_rcvFPDU (1), Push_WQE(1), and AdditionalFragmentCount (3)

See Section "Common iWARP SQ Descriptor Format Fields".

Streaming mode (1)

This bit indicates that this WQE contains data that is to be sent in streaming mode (normal TOE, not iWARP); the only valid OP value with this bit is send, the total length of the message must be less than or equal to MSS or an AE (AE_WQE_LSMM_TOO_LONG) is generated and the QP state is transitioned to terminate.

wait_for_rcvFPDU (1)

Only valid if Streaming Mode = 1b. When this bit is set, the 10 GbE controller does not process the WQE following this one until a valid inbound iWARP ULPDU is received. This is useful for the last WQE of the IETF response frame.

Inline_Data_Flag (1)

Set to 0b for no inline data.

Remote_Invalidate_STag (32)

The STag on the remote peer that is to be invalidated by the message. This field is only valid if the operation type indicates an invalidate operations.

Tagged_Offset (64), STag (32), Length (32)

These fields describe the first fragment of the message to be sent. Additional fragments can be added to the WQE by setting AdditionalFragmentCount to a non-zero value.

SQ WQE Format - Send With Inline Data

Table 38-501.iWARP SQ Send With Inline Data WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Data		
8	[63:0]	Data		
16				
24	[63]	WQE_Valid	[55]	RSVD
	[62]	Signaled Completion	[54:48]	Inline Data Length
	[61]	Local Fence	[47]	RSVD
	[60]	Read Fence	[46]	RSVD
	[59]	RSVD	[45:41]	RSVD
	[58]	RSVD	[40:38]	RSVD
	[57]	Inline_Data_Flag	[37:32]	OP
	[56]	Push WQE	[31:0]	Remote Invalidate STag

OP (6)

This WQE format is valid for the send, send with invalidate, send with solicited event, and send with solicited event and invalidate operations. See Section "Common iWARP SQ Descriptor Format Fields" for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), and Push_WQE(1)

See Section "Common iWARP SQ Descriptor Format Fields".

Inline_Data_Flag (1)

The Inline_Data_Flag must be set to 1b. This bit specifies that the data is contained inline with the WQE. If Inline_Data_Flag = 0b, the WQE is using descriptors and the WQE format is listed in Table 38-500. If Inline_Data_Flag = 1b the WQE has inline data and the WQE format is listed in Table 38-501.

Inline_Data_Length (7)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

Remote_Invalidate_STag (32)

See Section "SQ WQE Format - Send".

Data (up to 16 bytes)

The first 16 bytes of data are included in this field.

SQ WQE Format - RDMA Write

Table 38-502.iWARP SQ RDMA write WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged_Offset		
8	[63:32]	STag	[31:0]	Fragment_Length

24	[63] [62] [61] [60] [59] [58] [57]	WQE_Valid Signaled Completion Local Fence Read Fence RSVD RSVD RSVD	[56] [55:48] [47] [46] [45:41] [40:38] [37:32] [31:0]	Push WQE RSVD RSVD RSVD RSVD AdditionalFragmentCount OP Remote STag

OP (6)

See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), Push_WQE(1), and AdditionalFragmentCount (3)

See Section "Address Translation and Protection Overview."

Tagged_Offset (64), STag (32), length (32)

These fields describe the first fragment (data source) of the message to be sent. Additional fragments can be added to the WQE by setting AdditionalFragmentCount to a non-zero value.

Remote Tagged_Offset (64), Remote_STag (32)

These fields describe the remote buffer (data sink).

SQ WQE Format - RDMA Write With Inline Data

Table 38-503.iWARP SQ RDMA Write With Inline Data WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Data		
8	[63:0]	Data		
16	[63:0]	Remote Tagged Offset		
24	[63] [62] [61] [60] [59] [58] [57] [56]	WQE_Valid Signaled Completion Local Fence Read Fence RSVD RSVD Inline_Data_Flag Push WQE	[55] [54:48] [47] [46] [45:41] [40:38] [37:32] [31:0]	RSVD Inline Data Length RSVD RSVD RSVD RSVD OP Remote STag

OP (6)

See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), and Push_WQE(1)

See Section "Address Translation and Protection Overview."

Inline_Data_Flag (1)

The Inline_Data_Flag must be set to 1b for inline data operations. This bit specifies that the data is contained inline with the WQE. If Inline_Data_Flag = 0b, the WQE is using descriptors and the WQE format is listed in Table 38-502. If Inline_Data_Flag =1b, the WQE has inline data and the WQE format is listed in Table 38-503.

Inline_Data_Length (7)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

Remote Tagged_Offset (64), Remote_STag (32)

These fields describe the remote buffer (data sink).

Data (up to 16 bytes)

The first 16 bytes of data are included in this field.

SQ WQE Format - RDMA Read

Table 38-504.iWARP RDMA Read WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged Offset		
8	[63:32]	STag	[31:0]	Fragment Length

OP (6)

This WQE format is valid for the RDMA read and RDMA read with local invalidate operations. See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), and Push_WQE(1)

See Section "Address Translation and Protection Overview."

Tagged_Offset (64), STag (32), Length (32)

These fields describe the local target (data sink) of the RDMA read operation. STag also specifies the local STag to be invalidated for RDMA read with local invalidate operations.

Remote Tagged_Offset (64), Remote_STag (32)

These fields describe the remote buffer (data source).

SQ WQE Format - Memory Window Bind

Table 38-505.iWARP SQ Bind Memory Window WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Memory Window Base VA		
8	[63:32]	Memory Window STag	[31:0]	Parent Memory Region STag
16	[63:46]	RSVD	[45:0]	Memory Window Length

OP (6)

See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), and Push_WQE(1)

See Section "Address Translation and Protection Overview."

Memory window base virtual address (64)

This field specifies the starting point of the memory window within the parent memory region's virtual address range for the memory window.

Memory window length (46)

This field specifies the size of the memory window. Specifying 0b as a length results in an AE code of AE_AMP_MWBIND_INVALID_BOUNDS.

Memory window STag (32)

This field specifies STag of the memory window including the index and additional keys.

Parent memory region STag (32)

This field specifies STag of the parent memory region to which this memory window is bound including the index and additional keys.

VA_Based_TO (1)

VA_Based_TO specifies if the memory window is zero based or VA based. The memory window is VA based if VA_Based_TO is set (1b); else the memory window is zero based.

STag_Rights (5)

Indicates the rights assigned to this STag. The valid bits for this field are:

4 = Enable remote read.

8 = Enable remote write.

All other bits are unused.

SQ WQE Format - Local Invalidate

Table 38-506.iWARP Local Invalidate WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD

OP (6)

See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), and Push_WQE(1)

See Section “Address Translation and Protection Overview.”

AdditionalFragmentCount (3)

Must be set to 0b for local invalidate operations.

STag (32)

STag specifies the STag to be invalidated.

SQ WQE Format - Fast Register

Fast register support for the 10 GbE controller has two modes of operation that depend on the number of available PBL resources. The prerequisite for issuing a fast register operation is to allocate an invalid memory region with a specific number of page list entries (or PBLEs for the 10 GbE controller). Since the 10 GbE controller enables host software to directly populate PBLs for memory registration, it is desirable to keep the same approach for fast register operations. The issue with allowing only the mode where host software directly populates the PBLs for fast register is apparent if an application issues fast register, send, local invalidate, fast register operations using the same memory region without waiting for completions for the local invalidate operation. If the 10 GbE controller only allowed the mode where software directly populated PBLs for fast register operations in these cases, memory corruption would be highly likely to occur. Software mechanisms to resolve the races end up with extremely inefficient fast register operations if they could be made to work at all. In order to not penalize every application for the previous behaviors but still provide proper handling of these behaviors, the following algorithm should be used for fast register operations:

1. During the allocate memory region operation, software must reserve the full number of PBL resources necessary to satisfy the allocate memory region request.
2. Software must keep an reference count per allocated memory region to track the number of outstanding fast register operations that are outstanding against the memory region that used the PBL resources allocated during the allocate memory region operation.
3. On fast register operation, if there are enough free PBL resources to satisfy the new request, software should populate a new area of PBLEs and issue the fast register operation without setting the Copy_Host_PBLs flag.
4. If there are not enough free PBL resources to satisfy the new request but the reference count of the users of the PBLs allocated during the allocate memory region operation is zero, software can use the PBL resources but must increment the reference count for the memory region.
5. If there are not enough free PBL resources to satisfy the new request but the reference count is one or more, host software must allocate a pinned buffer large enough to hold the page list specified on the fast register operation, populate that buffer with the page list specified by the fast register operation, and set the Copy_Host_PBLs bit and increment the reference count.
6. When the memory region associated with the fast register has been invalidated, the reference count for the memory region must be decremented.

This algorithm minimizes that cases where the page list associated with a fast register operation must be copied across the PCI bus while maintaining safe access to the memory region state and page list.

Table 38-507.iWARP SQ Fast Register WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0] Buffer Offset	Virtual Address or First		
8	[63:12]	PBL_Address	[11:0]	first_pm_pbl_index_high
16	[63:48] [47:46]	first_pm_pbl_index_low RSVD	[45:0]	STag_Length

OP (6)

See Section "Address Translation and Protection Overview" for the associated opcode value.

WQE_Valid (1), Signaled_Completion (1), Local_Fence (1), Read_Fence(1), Push_WQE(1)

See Section "Address Translation and Protection Overview."

AdditionalFragmentCount (3)

Must be 0b for fast register operations.

VA_Based_TO (1)

VA_Based_TO specifies if the STag is zero based or VA based. Zero based STags carry only the first buffer offset in the virtual address or *First Buffer Offset* field. VA-based STags carry the full base VA including first buffer offset in the VA or *First Buffer Offset* field. The STag is VA based if VA_Based_TO is set (1b); else the STag is zero based.

Virtual Address or first buffer offset (64)

Indicates the base VA for this region/window for VA-based entries and indicates the first buffer offset for zero-based entries.

STag length (46)

Length of the memory region or memory windows specified by the STag index specified by Driver_Key_Stag_Index. Specifying 0 as a length results in an AE code of AE_AMP_FASTREG_INVALID_LENGTH. If Leaf_PBL_Size is set to 1b and Host_Page_Size = 0b then AE_AMP_FASTREG_INVALD_LENGTH is also generated if the size exceeds 2^{28} x 4096.

Access_Rights (5)

Indicates the rights assigned to this STag. The values for this field are 1 (enable local read), 2 (enable local write), 4 (enable remote read), 8 (enable remote write), and 16 (enable window bind).

Host_Page_Size (1)

Host_Page_Size specifies the page size of the backing pages for the STag. The values for this field are:

0b = 4 KB pages.

1b = 2 MB pages.

Driver_Key_STag_Index (24)

Index and *Driver Key* fields of the STag associated with the memory region. The 10 GbE controller supports a variable size STag index. This means that the number of bits used for *Driver Key* and for STag_Index are dependent on the maximum number of STags supported for a given PCI function. For example, if a PCI function read the FPMPEMRSZ field and found that the maximum number of MRTEs was 64 KB, the lower 16 bits of this field would be the STag index and the upper 8 bits would be a driver key that the driver can randomize to make guessing the MRTE layout more difficult to guess.

Consumer key (8)

Consumer key is the least significant 8-bit portion of the STag. This field is supplied by the user application or the driver.

Copy_Host_PBLs (1)

PBLs for an STag are located in host memory for the 10 GbE controller in the pages allocated for the Product Name HMC. In most situations, software copies backing pages for an STag directly to the HMC pages to optimize performance. If software needs the 10 GbE controller to populate the HMC pages, then Copy_Host_PBLs must be set to 1b and PBL_Address must point to the physical address of the backing pages in host memory.

Note: If the Copy_Host_PBLs bit is set, the number of PBLEs must be rounded up to an even number. That is, if the number of PBLEs is odd, software must allocate space for one more. The buffer must be a multiple of 16 bytes and it must be aligned on a 16-byte boundary.

Leaf_PBL_Size (2)

The 10 GbE controller supports physically contiguous STags and two forms of virtually contiguous STags. Physically contiguous STag do not require any PBLs and store physical address of the first page of the STag directly with the STag (no leaf PBL). Virtually contiguous STags that can be represented with a single HMC virtually contiguous address range require a single level PBL of Variable size. Virtually contiguous STags that are large (or in cases where the HMC address space for PBLs becomes fragmented) might require two level PBLs. In this case, the 10 GbE controller needs to know the length of the leaf PBLs in order to properly manage access to the PBLs. The valid settings for Leaf_PBL_Size are the following:

0 = No leaf PBL.

1 = Variable (one level).

2 = 256 bytes (two level).

3 = 4 KB (two level).

PBL Address (52)

Only valid if Copy_Host_PBLs is set (1b) or if Leaf_PBL_Size is set to 0b. If Copy_Host_PBLs is set and Leaf_PBL_Size is not set to 0b, PBL address is the physical address of the PBLs in host memory if they were not copied to HMC pages by software. If Leaf_PBL_Size is 256 or 4 KB, PBL address contains the physical address of a packed array of Root PBLEs. The format of the Root PBLEs is listed in Table 38-507. If Leaf_PBL_Size is variable, then PBL_Address contains the physical address of the page

list in host memory to be copied to first_pm_pbl_index. if Copy_Host_PBLs is clear and Leaf_PBL_Size is set to 0b, then the physical address of the physically contiguous memory is contained in this field.

first_pm_pbl_index (28)

This field defines the HMC PBLE object index used for the memory region page list. If Copy_Host_PBLs is set (1b), the 10 GbE controller copies the page list from the host address specified by PBL Address to the HMC object specified by first_pm_pbl_index. If Copy_Host_PBLs is clear (0b), first_pm_pbl_index designates the HMC base address for the PBLs for this STag that software has already initialized with PBL information.

38.36.4.5.2 SQ WQE Format - Connection Established

Table 38-508.iWARP SQ Established WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD		
8	[63:32]	RSVD		
16	[63:00]	RSVD		
24	[63] [62] [61:60] [59] [58] [57]	WQE_Valid RSVD (Signaled_Completion)	[56] [55:48] [47] [46] [45:41] [40:38] RSVD [37:32] [31:0]	RSVD RSVD RSVD RSVD OP RSVD

OP (6)

This WQE tells the chip to notify software when the connection is established. An AE (AE_LLP_CONNECTION_ESTABLISHED) will inform software that the connection is complete. This WQE is not valid forUDA QPs. See Section 38.38 for the associated opcode values.

WQE_Valid (1)

See Section 38.38.

38.36.4.5.3 RQ WQE Format

Table 38-509.iWARP RQ WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged Offset		
8	[63:32]	STag	[31:0]	Fragment Length
16	[63:00]			
24	[63] [62:41] [40:38]	WQE_Valid RSVD AdditionalFragmentCount	[37:32] [31:0]	RSVD (OP) RSVD

WQE_Valid (1) and AdditionalFragmentCount (3)

See Section "Address Translation and Protection Overview."

Tagged_Offset (64), STag (32), Length (32)

These fields describe the first fragment of the byte stream to be sent. Additional fragments can be added to the WQE by setting AdditionalFragmentCount to a non-zero value.

38.36.5 UDA Functionality

The UDA feature expands a user-space networking communication to a wide scope of Ethernet-based protocols beyond iWARP.

The UDA host interface and semantics are very similar to one exposed by iWARP.

- Sending and receiving data
- Application uses UDA QPs and CQs to send and receive data, see Section 38.36.3.3.2 and Section 38.36.3.3.3 for UDA QP and CQ management requests. UDA QPs and CQs resources are shared with iWARP.
- Completion and AE management
- CE notification mechanism is identical to one used for iWARP, see Section 38.36.3.4.2 and Section 38.36.3.5 for CEQ and AEQ allocation description. UDA probably shares event and completion notification structures with iWARP.
- Application buffer memory management
- An application should register its buffers (see Section 38.36.3.3.4) to enable direct placement to and from application buffers. Memory registration used for UDA buffers is identical to the memory registration of iWARP, and uses resources from the same pool of memory regions available for PCI function.
- UDA enables send and receive Ethernet frames by posting frame payload and ULP protocol headers to UDA QP using post send and post receive operations described in Section 38.36.5.8.1 and Section 38.36.5.8.2. Separate SQ/RQ WQE is used to send and receive single Ethernet frame.

UDA provides a protocol agnostic interface with limited stateless accelerations for the well known protocols. To enable secure userspace networking for non-privileged consumers UDA limits scope of supported protocols to IP-based protocol only, by offloading Ethernet and IP header generation to hardware. For the privileged consumer in the trusted environment it enables application fully control of header generation without limiting protocols to be IP-based or having any headers generated by hardware.

Hardware provides partial stateless acceleration for the limited scope of protocols, discussed in Section 38.36.5.1 and Section 38.36.5.2 later.

UDA acceleration enables a wide scope of applications to take advantage of direct communication with hardware bypassing system overhead. UDA brings a variety of benefits, including deterministic and low latency, low-latency deviation and jitter, high-message processing rate with a very low network communication overhead, lock free networking and linear scalability with number of cores in the system without compromising system security.

38.36.5.1 Transmit User-space Direct Access Hardware Acceleration

Transmit UDA hardware provides a limited number of partial stateless accelerations.

UDA traffic is not expected to use a dedicated internal switching resources (VSIs). It shares an internal switch virtual port with iWARP traffic. Depending on the assignment of the user priority, UDA traffic might share a QS with iWARP QPs, or use a dedicated QS. Assignment of UDA traffic to the QS is done at QP creation time, and is similar to assignment of iWARP QP.

The 10 GbE controller generates Ethernet and IP headers based on information provided in address vector for IP-based user-space protocols (see Section 38.36.3.3.2). Offloading Ethernet and IP headers generation does not bring much performance improvement, but does improve security of UDA for IP-based protocols. In the standard deployment configuration, UDA supports only IP-based protocols, with an option available for the privileged software running in trusted environment allowing to generate all headers by software. Privileged mode can be enabled by setting *Privileged Header Generation Enable* bit in the UDA QP context, see Section 38.37.5.4.

The 10 GbE controller supports header generation for non-fragmented datagrams. Hardware is responsible for the *IP Identification* field. Hardware maintains one instance of the *IP Identification* field per UDA QP.

Software is responsible for generating upper protocol headers (TCP, etc.). Those headers can be provided as a part of the payload WQE fragment or as a separate WQE fragment. In privileged mode, software can provide headers in the same WQE fragment with payload or using one or more dedicated WQE fragments. The 10 GbE controller also supports an option of inline data, when both upper layer protocol headers and a frame payload are copied directly to the WQE. See Section 38.36.5.8.2 for more details. push mode, described in Section , can be used to transmit UDA WQEs with inline data. See Section 38.36.5.8.3 for more details.

The 10 GbE controller offloads checksum generation for non-fragmented TCP packets.

UDA traffic uses standard internal switching capabilities provided by the 10 GbE controller to internally switch unicast and multicast traffic between different VSIs. Unlike traffic generated by standard operating system stack, UDA QPs also require additional internal switching capabilities within VSI, similar to iWARP. This enables internal switching between user-space processes directly communicating with hardware using UDA QPs.

UDA and the host operating system networking stack independently generates the *IP Identification* field. To avoid collision of the IP identification space, the 10 GbE controller has a configurable option to override I*P Identification* fields generated by the host networking stack and UDA and forces the MSB of the IP identification to different values. The *IP Identification* field override can be enabled per VSI using the USEENTIREIDRANGE bit in the IPCONFIG register.

38.36.5.2 Receive User-space Direct Access Hardware Filtering and Acceleration

Receive UDA acceleration is focusing on identifying UDA frames and delivering those frames to the associated UDA RQ. This section describes how UDA frames can be identified using various Product Name filters, lists the 10 GbE controller filters that can be programmed for UDA traffic identification and refers to the sections describing programming of each filter in details. UDA Product Name filtering descriptions are organized by the traffic types.

38.36.5.2.1 TCP UDA Filtering and Acceleration

TCP UDA acceleration enables taking advantage of UDA QPs to send and receive unfragmented TCP segments directly from the application address space or from the kernel. iWARP connection management and exception handling is the usage model for this capability.

On the transmit side, TCP UDA acceleration can take advantage of the generic UDA acceleration capabilities described in Section 38.36.5.1.

This section describes receive filtering capabilities and hardware accelerations that can be used to accelerate TCP segments.

UDA TCP acceleration is enabled as soon as iWARP capabilities are enabled for the 10 GbE controller. Similar to iWARP, PCI function for the inbound TCP segments are identified using destination MAC address.

UDA TCP acceleration does not support fragmented IP datagrams. All fragments are processed by stateless filters and delivered to the standard host stack.

UDA TCP acceleration uses an accelerated port table to filter out accelerated traffic based on the destination TCP port. Software should allocate a port to be used for UDA TCP accelerated traffic using the CQP operation described in Section 38.36.3.3.2.

TCP packets that hits an accelerated port table are filtered through the quad hash table.

The quad hash table is a perfect filter that carries an entry for each accelerated TCP connection that is offloaded to the 10 GbE controller's PE. the quad hash table has two kinds of entries used for TCP traffic.

- Quad-touple entries carrying and using as input to hash function a quad of source and destination IP addresses and source and destination TCP ports.
- Du-touple entries carrying and using as an input to the hash functions a pair of destination IP address and destination TCP port.

The du-entries are allocated to filter out connection establishment packets that are targeting accelerated connections. Those entries are used to filter out TCP packets with a *SYN* bit set and *ACK* bit clear.

The quad-touple entries are allocated to filter out packets targeting already established accelerated QPs.

The passive side connection establishment flow:

- Listen.
  - — Allocate du-touple entry with local IP address and local port socket is bound to.
- SYN is received on QP associated with du-touple.
  - — Allocate quad-touple entry with local/remote IP addresses and local/remote TCP ports.
  - — Send SYN-ACK
- ACK is received on the QP associated with quad-touple.

The active side connection establishment flow:

- Connect.
  - — Allocate quad-touple entry with local/remote IP addresses and local/remote TCP ports
  - — Allocate quad-touple entry with local/remote IP addresses and local/remote TCP ports

  - Send SYN
- SYN-ACK is received on QP associated with quad-touple.
  - Send ACK.

UDA TCP uses the quad hash table in the same way this table is used for iWARP traffic. A hit in the table resolves a number of destination QPs. The 10 GbE controller uses information in QP context to identify iWARP and UDA TCP traffic. If a packet misses the quad hash table, it is forwarded for the further processing to the stateless filters.

TCP UDA software should program the quad hash table with du-touple entry to establish UDA accelerated TCP connection (such as listen or connect socket calls) and to add a quad-touple entry once connection has been established. To avoid race and loss of data, the quad-touble entry can be allocated before the connection establishment handshake completed.

The 10 GbE controller does not terminate TCP connections for UDA traffic. It forwards identified UDA TCP segments to the corresponding RQ. Multiple TCP tuples can be configured to be delivered to the same RQ. Each WQE in UDA TCP RQ is consumed by single TCP segment.

In addition to forwarding UDA TCP segments, the 10 GbE controller provides several hardware accelerations.

- Header and data separation. The 10 GbE controller enables an option to configure UDA TCP QP to separate Ethernet/IP and TCP protocol headers from the payload, and deliver it to the separate WQE fragments or to the private header ring buffer. See Section 38.36.5.8.1 and Section 38.37.5.4 for more details.
- TCP checksum calculation and validation. The 10 GbE controller supports calculation and validation of TCP checksum for UDA TCP segments. TCP packets with invalid a checksum is dropped and not delivered to RQ.

38.36.5.3 User-space Direct Access Programming Interface

The UDA programming interface is based on the verb semantics described in Section 38.36.2.1. It uses same basic constructs as iWARP: QP, CQ, CEQ, AEQ and memory regions. Those constructs are described in detail in Section 38.36.2.1. In addition to those constructs, UDA introduces address vectors and multicast groups described later in this section.

38.36.5.3.1 CEQ

CEQ construct enables hardware to provide software with asynchronous completion notifications. Application has a full control over requesting asynchronous completion event for the particular CQ. UDA uses CEQ construct defined for iWARP described in Section 38.36.2.1.2.

CEQs are allocated per MSI-X vector per PCI function and if UDA and iWARP applications are deployed by the same PCI functions or the same application uses both types of traffic, it shares the same CEQ. Each entry in CEQ indicates that a requested CE was received by specified CQ and the application should poll CQ and retrieve completion of transmit or receive operation.

38.36.5.3.2 AEQ

AEQ construct enables hardware to report AE and error notifications. UDA uses AEQ defined for iWARP described in Section 38.36.2.1.1. AEQ is allocated per PCI function and shared by iWARP and UDA if application(s) using both types of traffic are deployed in the same PCI function.

38.36.5.3.3 CQ

CQ is a construct that enables an application to receive notification about completed transmit and receive operations directly in the application address space. UDA uses CQ construct defined for iWARP and described in Section 38.36.2.1.3. CQ is associated with RQ and SQ to report completion of transmit and receive operations. The same CQ can be configured to report completion of transmit and receive operations on the same and different QPs. Application is allowed to use same CQ to report completion of UDA and iWARP traffic.

CQ entry indicates what operation has been completed, and depending on the completed operation, it carries additional information. The format of a UDA CQ entry is described in Section 38.36.5.5. Among other fields, CQ entry carries a 64-bit pointer to the QP completion information. This field can be used to identify a QP that posted completed operation.

Completion of receive operation is always reported in associated CQ. Completion of transmit operation is not necessarily reported and the application can control whether it wants to be notified about a completed transmit operation. Application MUST request completion of transmit operation at least once per SQ size worth of transmit requests.

38.36.5.3.4 QP

QP is a construct that enables an application to post transmit and receive operations directly from the application address space. QP consists of the pair of queues: SQ and RQ. UDA uses QP construct defined for iWARP described in Section 38.36.2.1.5.

Unlike iWARP QP, UDA QP does not have to be associated with any particular connection or connection oriented service and enables mixing of various ULPs on the same QP.

User-space QP is associated with a particular local IP address. Non-privileged UDA consumers need to allocate multiple UDA QPs to send UDA packets using different local IP addresses. Local IP address in QP context is used for UDA IP header generation only. The 10 GbE controller filters can be configured to receive packets targeting different local IP addresses on the same QP.

Software should use WQEs described in Section 38.36.5.6 to post new transmit and receive work to the UDA QP.

UDA QP is associated with a particular TC, and VLAN. If the application needs to use multiple TCs and VLANs, it must create multiple QPs and spread traffic, respectively.

All software errors such as invalid WQE format, invalid STag and memory region boundary violation are considered to be critical errors and result in a transition of QP to the error state and immediately suspend transmit and receive operations of that QP. Respective AE would be reported via AEQ associated with QP. See Section 38.36.2.6.

38.36.5.3.5 Send Operation

The structure of SQ is a process of posting WRs to UDA SQ and flow is similar to one described for iWARP SQs in Section 38.36.2.1.7.

UDA QP enables the application to transmit individual Ethernet frames per posted SQ WQE. Each transmit WQE must refer to a single Ethernet frame. Software is responsible to limit the frame size to the configured MSS. If frame size exceeds MSS, frame would be discarded and error reported in CQE.

Software is allowed to post Ethernet frames shorter than a minimum Ethernet frame length. Hardware pads Ethernet frames to the minimal Ethernet frame length.

Hardware is responsible for Ethernet FCS and IP checksum generation. Software might request hardware to generate TCP checksum for non-fragmented datagrams.

In default operation mode, Ethernet and IP headers are generated by hardware using information provided in the address vector. Software can provide additional ULP header either as a part of the application buffer referred by SQ WQE fragments or using a private header ring buffer (if enabled for the QP). If size of the extended header exceeds the size of the private header ring buffer entry, the packet is discarded and the error is reported in CQE.

Privileged consumers are allowed to post Ethernet frames with all headers. To enable privileged SQ operation mode, the *Privileged Header Generation* bit should be set at QP creation (see Section 38.37.5.4).

Software can selectively request completion of WQEs by setting the *Signaled* bit. Completions with errors are returned regardless of the *Signaled* bit setting. UDA WQE is completed as soon as hardware finished processing WQE and validated lengths and fragments. Completion of UDA SQ WQE does not indicate that respective Ethernet frames are transmitted or received by the destination.

38.36.5.3.6 Receive Operation

The structure of RQ is a process of posting WRs to UDA RQ and flow is similar to one described for iWARP RQs in sub-section Section , "RQ".

UDA QPs can be configured to use SRQ. The structure of SRQ is a process of posting WRs to UDA SRQ and flow is similar to one described for iWARP SRQs in sub-section Section , "RQ".

UDA QP enables an application to receive an individual Ethernet frame in pre-posted RQ WQEs. Each inbound Ethernet frame consumes one RQ WQE. Software needs to make sure that buffers posted to RQ WQE are large enough. If size of the Ethernet frame exceeds the size of RQ WQE, the frame is truncated and an error is reported in CQE.

Ethernet frames failing CRC or checksum checks (IP/TCP) are dropped and not delivered to UDA QPs.

If an Ethernet frame is received while UDA RQ is empty, such frame is dropped and the GLPES_PFIP4RXDISCARD statistics counter is incremented.

Software can enable header/data split feature per RQ. If header/data split is enabled, then hardware splits the frame header and payload and places those separately to the designated locations. Payload of the received Ethernet frame is always placed in the buffers referred to by RQ WQE fragments. Depending on the RQ configuration, a frame header can placed either to the first fragment of the RQ WQE and then the frame payload is placed in RQ WQE starting with second fragment. Or, the frame header can be placed in the private header ring buffer and then the frame payload is placed in the RQ WQE starting with first fragment.

If SRQ and header/data split are enabled, the header can be placed to the first fragment only. The dedicated header ring buffer can be enabled for RQ only.

If RQ is configured with a header/data split option and the size of the frame header exceeds the size of the first fragment of the size of the private ring buffer entry, the frame is dropped and an error is reported in CQE.

RQ completion is delivered with each completed RQ WQE. If a packet carries one or more VLAN tags, the most inner VLAN tag is reported by RQ CQE. Note that VLAN tag is not stripped from the packet header.

38.36.5.3.7 Memory Registration

Memory region is a construct that enables hardware to access data directly from the application buffers. To enable direct hardware access, an application must register application buffers using the register memory region operation. UDA uses memory regions defined for iWARP described in Section 38.36.2.1.4.

Memory region construct is not associated with any particular traffic type and registered memory region can be accessed both by iWARP and UDA traffic. This enables an application to have the same application buffer be directly accessed by iWARP and UDA traffic. For example, data received via one of UDA QPs can be then accessed via iWARP QP without requiring copy operation.

UDA application must register application buffers to be used to send and receive UDA packets.

UDA supports only basic memory registration capabilities and does not support fast memory registration, bind and invalidate operations.

38.36.5.3.8 Push Mode Support

Push mode enables software to reduce processing latency of the short messages by pushing corresponding WQE with inline data to the memory mapped adapter address space. Pushed WQE with inline data can be immediately processed by the adapter and transmitted to eliminate the need to read WQE and data from the host memory. See Section "SQ Push Mode" for a detailed description of push mode concept and constructs.

UDA QPs take advantage of push mode defined for iWARP. Software can use push mode WQEs, described in Section 38.36.5.8.3 to reduce processing latency of the short UDA messages. Similar to iWARP, the size of the UDA push mode message is limited to 96 bytes. The UDA push mode message cannot use private ULP header buffers and the entire message with ULP headers must fit the push mode message size restrictions and posted as inline data. The remainder of push mode message software processing flow is identical to one described for iWARP messages in sub-section Section "SQ Push Mode".

38.36.5.4 User-Space Direct Access QP Context Format

Users-pace direct access QP context is used by software to initialize or update the 10 GbE controller's QP context. Create and Modify QP CQP operations (see Section 38.36.3.3.2) reference this structure.

User-space QP is associated with a particular local IP address. Non-privileged UDA consumers need to allocate multiple UDA QPs to send UDA packets using different local IP addresses. The local IP address in QP context is used for UDA IP header generation only. The 10 GbE controller filters can be configured to receive packets targeting different local IP Addresses on the same QP.

Table 38-510.UDA QP Context Structure Format (Sheet 1 of 2)

Byte Offset	[Bit Range]	Field Name	[Bit Range]	Field Name
0	[63:62] [61:48] [47] [46:42] [41:32] [31] [30] [29] [28] [27] [26] [25:20] [19] [18:16] [15] RSVD(drop_out_of_order_seg) [14]	RSVD RSVD Push Mode Enable RSVD Push Page Index SQ_TPH_en RQ_TPH_en XMIT_TPH_en RCV_TPH_en RSVD RSVD RSVD RSVD RSVD(dupack_thresh) RSVD	[13:12] [11] [10] [9:8] [7] [6] [5] [4] [3] [2] [1:0]	RSVD(limit) RSVD RSVD RQ_WQE_Size RSVD(timestamp) RSVD(Insert VLAN Tag) RSVD(NoNagle[1]) RSVD RSVD(iwarp_ddp_ver[2])

Notes:

1. This variable is a cached variable. See Cached_Variables_Valid in Modify QP operations for more details on cached context variables.
2. Only Valid for iWARP QPs.

This bit is used to enable privilege mode on STag's. If this bit is set, then a local STag of zero (STag 0) is allowed on this connection and the *TO* field should be treated as a physical address. If this bit is cleared, then STag 0 is NOT allowed for a local STag and an AEQE is generated with a privilege error indicated.

PrivilegedHdrGenEnable (1)

This bit is used to enable privilege mode on SQ and enabling software to generate all Ethernet frame headers. When set, hardware assumes that software provides all headers for the Ethernet frame to transmit and does not generate Ethernet/IP headers. Standard anti-spoofing still apply, based on VSI configuration. This mode usually can be enabled for consumers operating in privileged mode (root).

1b = Application is allowed to generate all header, including Ethernet and IP, and hardware does not apply any security checks beyond standard anti-spoofing checks done by internal switch.

0b = Hardware generates Ethernet and IP headers for all packets using information provided in address handle. Upper layer protocol headers can be supplied by application or verb library.

Default mode has this bit clear (0b) to ensure secure Ethernet and IP header generation by hardware. Insecure header generation is allowed for privileged applications operating in trusted environments.

XMIT_TPH_en (1)

If set (1b), TPH is enabled for data reads associated with this QP. If clear (0b), THP is not used for data reads associated with this QP.

SQ_TPH_en (1)

If set (1b), TPH is enabled for the SQ of this QP. If clear (0b), THP is not used for this resource.

SQ_TPH_value (8)

If *SQ_TPH_en* is set (1b), TPH STag associated with SQ operations is initialized with *SQ_TPH_value*. If *SQ_TPH_en* is clear (0b), this field is ignored.

SQ_HDR_TPH_en (1)

If set (1b), TPH is enabled for ULP header read associated with this QP. If clear (0b), THP is not used for ULP header read associated with this QP. Takes effect only if *SQ_Hdr_Ring_Buffer_En* is set (1b).

SQ_Size (4)

This field encodes the maximum size for the WQ. The encoding of the SQ sizes are $4*2^{SQ\_Size}$ in terms of 32-byte quanta of memory. The following values are allowed for *SQ_Size*:

0 = 128 bytes
1 = 256 bytes
2 = 512 bytes
3 = 1024 bytes
4 = 2048 bytes
5 = 4096 bytes
6 = 8192 bytes
7 = 16384 bytes
8 = 32768 bytes
9 = 65536 bytes
10 = 131072 bytes
11 = 262144 bytes
12 = 524288 bytes

Software can only allocate N-1 WQEs on the SQ, where N is a SQ size previously defined. Each WQE is variable in size and can consume up to 128 bytes of memory. For more information see Section 38.36.2.1.7. The minimum size for a SQ is four WQEs of the maximum size that is used for the SQ.

RCV_TPH_en (1)

If set (1b), TPH is enabled for data placement associated with this QP. If clear (0b), THP is not used for data placement associated with this QP.

RQ_TPH_en (1)

If set (1b), TPH is enabled for the RQ of this QP. If clear (0b), THP is not used for this resource.

RQ_TPH_value (8)

If RQ_TPH_en is set (1b), TPH STag associated with RQ operations is initialized with *RQ_TPH_value*. If RQ_TPH_en is clear (0b), this field is ignored.

RQ_HDR_TPH_en (1)

If set (1b), TPH is enabled for packet header placement associated with this QP. If clear (0b), THP is not used for packet header placement associated with this QP. Takes effect only if *RQ_Hdr_Split_En* is set (1b).

RQ_Size (4)

This field encodes the maximum size for the WQ. The encoding of the RQ sizes are $4*2^{RQ\_Size}$ in terms of 32-byte quanta of memory. The following values are allowed for *RQ_Size*:

0 = 128 bytes
1 = 256 bytes
2 = 512 bytes
3 = 1024 bytes
4 = 2048 bytes
5 = 4096 bytes
6 = 8192 bytes
7 = 16384 bytes
8 = 32768 bytes
9 = 65536 bytes
10 = 131072 bytes
11 = 262144 bytes
12 = 524288 bytes

The actual number or WQEs that can be posted to the RQ is the size of the WQ divided by the WQE size determined from RQ_WQE_Size. Software can only submit N-1 WQEs to a WQ without processing completions for the WQ without exposing the possibility of a WQ overflow. Where N is an RQ size previously defined. WQ overflow results in indeterministic behavior for the affected WQ. The minimum size for an RQ is four WQEs.

RQ_WQE_Size (2)

Specifies the number of 32 byte chunks of memory included with each RQ WQE. The maximum number of additional fragments allowed for an RQ WQE is 6 for a total of 7 fragments and a maximum WQE size of 128 bytes. Valid values are:

0 = 32 bytes per WQE (no additional fragments)
1 = 64 bytes per WQE (1 or 2 additional fragments)
2 = 128 bytes per WQE (3 to 6 additional fragments)
3 = Reserved

RxCmpQueueNum (17)

This field specifies which of the 128 K CQs is used for receive completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

TxCmpQueueNum (17)

This field specifies which of the 128 K CQs is used for transmit completion notification. The Rx and Tx completions can be mapped to the same CQ or different queues.

SQ Address (57)

If the *VirtualWQ* bit is clear, then this field holds the SQ base physical address. It must be aligned to an address divisible by 128 bytes. If the *VirtualWQ* bit is set, then this field specifies the first HMC PBLE index of the 1 level page list for the SQ (first first_pm_pbl_index).

RQ Address (57)

If the *VirtualWQ* bit is clear, then this field holds the RQ base physical address. It must be aligned to an address divisible by 128 bytes. This is the RQ base pointer when this is an iWARP accelerated connection. If the *VirtualWQ* bit is set, then this field specifies the first HMC PBLE index of the 1 level page list for the SQ (first first_pm_pbl_index).

QS_Handle (10)

This field specifies the Tx scheduler queue set handle associated with the TC for this QP. For VFs, the *QS_Handle* is checked to ensure that the VF issuing the CQP command is associated with the *QS_Handle*.

pd_index (15)

Protection domain for this context. This specifies which one of the 32 KB UDA protection domains this connection context belongs too. There are no reserved index values.

QP_Completion Context (64)

This field is reported in CQEs and also in AEQEs.

Push Page Index (10)

This field identifies the push page associated with the QP. For VFs, the push page index is function relative.

Push Mode Enable (1)

This field indicates if push mode is enabled for the QP.

snd_mss (14)

This field specifies a maximum MSS size allowed on that QP. MSS includes all headers and payload of Ethernet frame, both generated by hardware and provided by software. If software posts a SQ WQE that exceeds this value, the frame is dropped, AE_UDA_XMIT_DGRAM_TOO_LONG AE is reported and QP transitions to the error state.

Use_Statistics_Instance (1)

This field indicates if the default per PMF statistics are used or if one of the additional RDMA statistics instances are used for this QP. When this field is zero, the default statistics are used. When this field is one, the statistics instance indicated by the Statistics_Instance_Index field are used.

Statistics_Instance_Index (5)

This field specifies which of the additional RDMA statistics indexes are used if Use_Statistics_Instance is one. This field is ignored if Use_Statistics_Instance is zero.

38.36.5.5 User-Space Direct Access CQ Entry Formats

Table 38-511.UDA CQ Entry Format

Byte Offset	[Bit Range]Field Name			
0	[63:48] [47:32]	VLAN Tag RSVD(Partial_Checksum)	[31:25] [24:16] [15:14] [13:0]	RSVD Header_Length RSVD Payload Length
8	[63:0]	QP Completion Context		
16	[63:50] [49:32]	RSVD QP_ID	[31:18] [17:16] [15:2] [1:0]	RSVD L4Protocol RSVD L3Protocol
24	[63] [62] [61:56] [55] [54] [53]	CQE_Valid SQ RSVD (OP) Error RSVD (Solicited Event) RSVD (STag)	[52] [51] [50] [49:46] [45:32] [31:16] [15:0]	 Push Dropped(UDA SQ only) VLAN Tag Valid RSVD WQ_Desc_Index Major Error Code Minor Error Code

CQE_Valid (1)

The *CQE_Valid* bit for CQE is a bit that indicates that a CQE is ready to be processed. The polarity of the valid bit changes each time the (CQ wraps from the last entry back to the first entry). This change in polarity reduces software overhead by avoiding the need to clear the valid bit once software has processed a valid CQE. Software is responsible to clear (set to 0b) all memory in a CQ initially at CQ creation. The first iteration (and subsequent odd numbered iterations) through the CQ, the 10 GbE controller sets the *Valid* bit to 1b when it writes a new CQE. For the second iteration (and all even numbered iterations) through the CQ, the 10 GbE controller sets the *Valid* bit to a 0b when it writes an new CQE.

Error (1)

0b = No error.

1b = An error occurred when processing the WQE associated with this CQE and that the Error Code field is valid.

SQ (1)

0b = RQ.

1b = SQ.

Push Dropped (1)

Valid only when SQ is set.

0b = Push operations are being processed successfully.

1b = A recent push mode operation has been dropped by the 10 GbE controller, software should refrain from submitting additional push mode operations until the SQ has encountered an empty condition.

WQ_Desc_Index (14)

WQ are split up into 32-byte descriptor quanta. Every WQE must start with a 32-byte descriptor on a 32-byte boundary. WQ_Desc_Index reports the 32-byte quanta index of the WQE associated with the completion.

Payload_Length (14)

Total payload length of the completed packet (up to a jumbo frame). This field is only valid for RQ WQE completions.

Header_Length (9)

Length of the packet header placed to the private header ring buffer. if zero, then the header was placed to the payload buffer per *Header_Split_En* bit in QP context. This field is only valid for RQ WQE completion.

QP_ID (18)

QP associated with the completed message.

Major Error_Code (16)

Valid if Error is set (1b). See Table 38-494 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 38.36.3.5.4).

Minor Error_Code (16)

Valid if Error is set (1b). See Table 38-494 for defined values. Software can also report any value via the Flush WQEs CQP operation (see Section 38.36.3.5.4).

L3Protocol (2)

This field carries an indication of a L3 type of the received packet.

- (00b) = IPv4 packet
- (01b) = IPv6 packet
- (1xb) = other type of packet.

This field is only valid for RQ WQE completions (when SQ is clear).

L4Protocol (2)

This field is valid for IPv4/IPv6 packets only. Indicates the L4 protocol of the packet.

- (00b) = TCP
- (01b) = RSVD
- (10b) = RSVD
- (11b) = other.

This field is only valid for RQ WQE completions (when SQ is clear).

VLAN Tag (16)

A most inner VLAN Tag detected in the packet. Note that VLAN Tag is not stripped from the packet. This field is only valid for RQ WQE completions (when SQ is clear).

VLAN Tag Valid (1)

Indication that CQE carries a valid most inner VLAN Tag detected in the packet. This field is always 0 when SQ is set.

QP Completion Context (64)

Completion context pointer. This field is transferred to the CQE from QP Context.

38.36.5.6 UDA QP Completion Error Codes

UDA QP completion errors are typically reported via AEs with the 10 GbE controller. After fielding the AEs, software might issue the Flush WQES CQP operation (see Section 38.36.3.5.4) to complete any pending operations. Table 38-512 lists the

completion codes reported by the 10 GbE controller in a CQ entry (Table 38-511). Received packets that failed checksum validation are dropped by the chip and not delivered to RQ.

Table 38-512.UDA QP Error Codes

Major Error Code	Minor Error Code	Completion Reason	Description
0x0001	0x0001	WQE Flushed	The WQE has been flushed due to a ModifyQP state transition.
0x0002	0x0001	RQ WQE Too Short	The RQ WQE length was shorter than a length of received Ethernet frame. Frame was truncated, and error reported.
0x0002	0x0002	RQ WQE Hdr Too Short	The Header of RQ WQE was shorter than a header of received Ethernet frame. This error can be reported only if header/data split option has been enabled for RQ. Depending on the RQ configuration, Ethernet frame header exceeded either the size of the private receive header buffer, or a size of the first fragment.
0x0002	0x0003	SQ WQE Too Long	The SQ WQE length exceeded an MSS configured for the QP. SQ WQE length should include size of the payload, hardware generated Ethernet and IP headers, and extended header provided by software.
0x0002	0x0004	SQ WQE Hdr Too Long	The SQ WQE extended header size exceeded size of the private header buffer entry.

38.36.5.7 UDA QP Asynchronous Error Codes

UDA uses asynchronous errors to report unrecoverable critical errors. Those errors mostly used to identify invalid use of UDA host interface. UDA uses asynchronous error notification mechanism described in Section 38.36.5.3.2. UDA shares asynchronous error codes with iWARP, see Section 38.36.2.6.

As a rule, once unrecoverable critical error is detected on QP. QP is transitions to the error state, and suspends all transmit and receive operations. Any incoming packet targeting a QP in an error state is silently discarded. To release buffers posted to a SQ and a RQ, software has to use the Flush WQE CQP operation described in Section 38.36.3.5.4.

Following is a list of few UDA specific errors and their mapping to iWARP asynchronous error codes described in Section 38.36.2.6.

- Software attempted to post SQ WQE on non-privileged QP without specifying a valid address handle index. Reported AE is AE_PRIV_OPERATION_DENIED.
- Software attempts to transmit UDA packet using address handle with IPv4 destination IP address, via QP with IPv6 local IP address, or vise versa. Reported asynchronous error is AE_UDA_XMIT_IPADDR_MISMATCH.

38.36.5.8 User-Space Direct Access Descriptor Formats

38.36.5.8.1 UDA SQ WQE Format - Send

Table 38-513.UDA SQ Send WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Tagged_Offset		
8	[63:32]	STag	[31:0]	Fragment_Length
16	[63] [62:56] [55] [54:48] [47:41] [40:32]	 MACLEN RSVD IPLEN RSVD	[31:30] [29:28] [27:24] [23:16] [15:0]	L4T IIPT L4LEN
24	[63] [62] [61] [60] [59] [58] [57] [56]	WQE_Valid Signaled_Completion RSVD (local fence must be 0) RSVD (Read_Fence, must be 0) RSVD (wait_for_rcvFPDU, must be 0) RSVD (Streaming_Mode, must be 0) RSVD(Inline_Data_Flag) Push WQE	[55:4] [45] [44] [43:42] [41] [40:38] [37:32] [31:0]	RSVD RSVD DoLoopback RSVD AdditionalFragmentCount OP RSVD

OP (6)

This WQE format is valid for the send operations. See Section 38.38 for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), PUSH WQE (1) and AdditionalFragmentCount (3)

See Section 38.38.

Tagged_Offset (64), STag (32), Fragment_Length (32)

These fields describe the first fragment of the byte stream to be sent. Additional fragments can be added to the WQE by setting *AdditionalFragmentCount* to a non-zero value. Note that the total length of the packet posted to UDA SQ WQE should not exceed MSS configured for that QP.

DoLoopback(1)

Valid only if *PrivilegedHdrGenEn* bit is set in QP context.

If the *DoLoopback* bit is set (1b) hardware should internally switch this packet within same VSI. Multicast packet should be both internally switched and transmitted via external port.

L4T (2)

For use by privileged consumer only. Required to enable hardware checksum generation offload when all packet headers are generated by software.

L4 packet type.

- 00b = RSVD
- 01b = TCP
- 10b = RSVD

- 11b = RSVD

When the *L4T* field is set to the type other than RSVD the L4LEN must be set as well. If L4T is set to TCP, the respective TCP checksum is generated by hardware. When the L4T value is set to 00b (RSVD), the checksum (TCP or UDP) is not generated by hardware.

IIPT (2)

For privileged consumers. Required to enable hardware checksum generation offload when all packet headers are generated by software.

For non-privileged consumers, this field strictly determines the statistic that is incremented.

Inner IP header type.

- 00b = Non-IP packet, or packet type is not defined by software
- 01b = IPv6 packet
- 10b = RSVD
- 11b = IPv4 with IP checksum offload.

This field is not used for IP fragments.

MACLEN (7)

For use by privileged consumer only. Required to enable hardware checksum generation offload when all packet headers are generated by software.

MAC header length defined in words.

IPLEN (7)

For use by privileged consumer only. Required to enable hardware checksum generation offload when all packet headers are generated by software.

IP header length (including IP optional/extended headers) defined in Dwords.

L4LEN (4)

For use by privileged consumer only. Required to enable hardware checksum generation offload when all packet headers are generated by software.

The L4 header length in Dwords. It should be equal or larger than 5 (or 20 bytes) for TCP.

38.36.5.8.2 UDA SQ WQE Format - Send With Inline Data

Table 38-514.UDA SQ Send With Inline Data WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	Data		
8	[63:0]	Data		
16	[63] [62:56] [55] [54:48] [47]	 MACLEN RSVD IPLEN RSVD	[31:30] [29:28] [27:24] [23]	L4T IIPT L4LEN
24	[63] [62] [61] [60] [59] be 0) [58] 0) [57] [56]	WQE_Valid Signaled_Completion RSVD (Local_Fence must be 0) RSVD (Read_Fence, must be 0) RSVD (wait_for_rcvFPDU, must RSVD (Streaming_Mode, must be Inline_Data_Flag Push WQE	[55] [54:48] [47] [46] [45] [44] [43:42] [41] [40:38] [37:32] [31:0]	RSVD Inline Data Length RSVD RSVD DoLoopback RSVD FwdProgConfirm OP RSVD

OP (6)

This WQE format is valid for the send operations. See Section "Common iWARP SQ Descriptor Format Fields" for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), Push_WQE(1))

See Section "Common iWARP SQ Descriptor Format Fields."

Inline_Data_Flag (1)

The Inline_Data_Flag is not valid for NOP operations. It specifies whether the data is contained inline with the WQE or if the descriptors point to the data. If Inline_Data_Flag == 0b, the WQE is using descriptors and the WQE format is listed in Table 38-500. If Inline_Data_Flag == 1b the WQE has inline data and the WQE format is listed in Table 38-501.

If the Inline_Data_Flag is set, all upper layer protocol headers must be provided as an inline data together with the payload, and cannot be provided as a separate WQE fragment, or inside private header ring buffer.

Inline_Data_Length (7)

Inline_Data_Length indicates the number of bytes included in the WQE and all subsequent additional fragment descriptors.

AdditionalFragmentCount (3)

Must be 0b for the send with inline data.

Inline data length is used to determine the number of additional fragments consumed by the inline data.

DoLoopback(1)

Valid only if the *PrivilegedHdrGenEn* bit is set in QP context.

If the *DoLoopback* bit is set (1b) hardware should internally switch this packet within the same VSI. Multicast packets should be both internally switched and transmitted via an external port.

No_Checksum(1)

0b = Upper protocol checksum for the supported protocols (TCP) should be generated by hardware.

1b = Hardware should not generate an upper protocol checksum, regardless of the protocol type. Software is expected to perform a checksum calculation and provide a valid checksum. This option must be used for IP fragments.

IIPT(2)

See Section 38.36.5.8.1.

L4T(2), L4LEN(4), IPLEN(7), MACLEN(7)

For use by privileged consumers only. Valid only if *Address_Vector_Valid* is clear (0b). Required to enable hardware checksum generation offload when all packet headers are generated by software. See Section 38.36.5.8.1.

38.36.5.8.3 UDA SQ WQE Format - NOP

Table 38-515.UDA SQ Send WQE Format

Byte Offset	[Bit Range]Field Name			
0	[63:0]	RSVD((Tagged_Offset)		
8	[63:32]	RSVD(STag)	[31:0]	RSVD(Fragment_Length)
16	[63:41] [40:32] (Extended_Header_Length	RSVD RSVD	[31:24] [23:16] Next_Header) [15:0] Index)	RSVD RSVD(Protocol/ RSVD(Address Handle
24	[63] [62] [61] [60] [59] [58] [57] [56]	WQE_Valid Signaled_Completion RSVD (Local_Fence must be 0) RSVD (Read_Fence must be 0) RSVD (wait_for_rcvFPDU, must be 0) RSVD (Streaming_Mode, must be 0) RSVD(Inline_Data_Flag) Push WQE	[55:47] [46] [45] [44] [43:42] [41] [40:38] [37:32] [31:0]	RSVD RSVD(Address_Vector_Valid) RSVD RSVD(DoLoopback) RSVD RSVD(FwdProgConfirm) AdditionalFragmentCount OP RSVD

OP (6)

This WQE format is valid for the NOP operations. See Section "Common iWARP SQ Descriptor Format Fields" for the associated opcode values.

WQE_Valid (1), Signaled_Completion (1), Push_WQE(1), and AdditionalFragmentCount (3)

See Section "Common iWARP SQ Descriptor Format Fields".

AdditionalFragmentCount (3)

Must be zero.

38.36.5.8.4 UDA RQ WQE Format

One RQ WQE provides application buffers for a single received Ethernet frame. The application should provide sufficient buffers to include the entire Ethernet frame, both headers and payload. If RQ is configured with a header/data separation option, then both payload and header buffers should be large enough to include the biggest header

and payload supported by the application. If either payload or header size exceeds the buffers provided by RQ WQE, hardware truncates the header or payload respectively, and reports an error in CQE.

Entire packet (both header and data), are placed in the buffers provided by RQ WQE, starting with the first WQE fragment.

Table 38-516.UDA RQ WQE Format

Byte Offset	[Bit Range]	Field Name		
0	[63:0]	Tagged Offset		
8	[63:32]	STag	[31:0]	Fragment Length
16	[63:0]			
24	[63] [62:54] [53:41]	WQE_Valid RSVD RSVD	[40:38] AdditionalFragmentCount [37:32] [31:0]	 RSVD (OP) RSVD

WQE_Valid (1) and AdditionalFragmentCount (3)

See Section "Common iWARP SQ Descriptor Format Fields."

Tagged_Offset (64), STag (32), Length (32)

These fields describe the first fragment of the byte stream to be sent. Additional fragments might be added to the WQE by setting *AdditionalFragmentCount* to a non-zero value.

38.36.6 PE Statistics

38.36.6.1 Summary

Table 38-517 lists the RFCs relevant to the definition of PE statistics.

Table 38-517.Summary of MIBs Supported With Product Name Hardware Statistics Counters

RFC	Description
1213	Title: Management Information Base for Network Management of TCP/IP-Based Internets: MIB-II. Status: RFC1213 obsoletes RFC1158. RFC1213 is updated by RFC 2011(IP), 2012(TCP), 2013(UDP), 2863(Interfaces). There are MIB groups in RFC1213 that will be implemented by the 10 GbE controller SNMP agent (such as the System group) but these do not require the 10 GbE controller hardware accelerations.
2011	Title: SNMPv2 MIB for the Internet Protocol using SMIv2. Description: Defines objects for managing implementations of IPv4 and ICMP. Status: Updates RFC1213, Obsoleted by RFC4293.
2012	Title: SNMPv2 MIB for the Transmission Control Protocol using SMIv2. Description: Defines objects for managing implementations of TCP. Status: Updates RFC1213, Obsoleted by RFC4022.
2013	Title: SNMPv2 MIB for the User Datagram Protocol using SMIv2. Description: Defines objects for managing implementations of UDP. Status: Updates RFC1213, Obsoleted by RFC4113.
4293	Title: MIB for the Internet Protocol (IP). Description: Defines objects for managing implementations of IPv4 and ICMP. Status: Obsoletes RFC2011, PROPOSED STANDARD.
4022	Title: MIB for the Transmission Control Protocol (TCP). Description: Defines objects for managing implementations of TCP. Status: Obsoletes RFC2012, PROPOSED STANDARD.

Table 38-517.Summary of MIBs Supported With Product Name Hardware Statistics Counters

RFC	Description
4113	Title: MIB for the User Datagram Protocol (UDP). Description: Defines objects for managing implementations of UDP. Status: Obsoletes RFC2013, PROPOSED STANDARD.

There is a set of PE statistics instantiated for each virtual and physical PCI function. The 10 GbE controller supports 16 RDMA enabled PFs and up to 32 RDMA enabled VFs. Mapping of VFs to PFs is not static. PFs have an instance of each PE statistics register. VF PE statistics registers are accessed via PF address space, and indexed by HMC VF index. This means there are 48 instances of the statistics set are listed in Table 38-518. Stats colored pink are new for the 10 GbE controller.

Naming convention for the PE Statistics register is as following:

- Physical function instance starts with GLPES_PF prefix following by the register name.
- Virtual function instance starts with GLPES_VF prefix following by the register name.

Table 38-518 lists PE registers by their physical function names. Virtual function register name can be recovered by substituting prefix.

Table 38-518.PE Statistics Instantiated Per-PCI Function

Name	Size	MIB	Description
GLPES_PFRXVLANERR	24b	private	Ethernet received packets with incorrect VLAN_ID.
GLPES_PFIP4RXOCTS	48b	IP	IPv4 octets received.
GLPES_PFIP4RXPKTS	48b	IP	IPv4 packets received.
GLPES_PFIP4RXDISCARD	32b	IP	IPv4 packets received and discarded.
GLPES_PFIP4RXTRUNC	32b	IP	IPv4 packets received and truncated due to insufficient buffering space in UDA RQ.
GLPES_PFIP4RXFRAGS	48b	IP	IPv4 fragments received.
GLPES_PFIP4RXMCPKTS	48b	IP	IPv4 multicast packets received.
GLPES_PFIP4RXMCOCTS	48b	IP	IPv4 multicast octets received.
GLPES_PFIP6RXOCTS	48b	IP	IPv6 octets received.
GLPES_PFIP6RXPKTS	48b	IP	IPv6 packets received.
GLPES_PFIP6RXDISCARD	32b	IP	IPv6 packets received and discarded.
GLPES_PFIP6RXTRUNC	32b	IP	IPv6 packets received and truncated due to insufficient buffering space in UDA RQ.
GLPES_PFIP6RXFRAGS	48b	IP	IPv6 fragments received.
GLPES_PFIP6RXMCPKTS	48b	IP	IPv6 multicast packets received.
GLPES_PFIP6RXMCOCTS	48b	IP	IPv6 multicast octets received.
GLPES_PFIP4TXOCTS	48b	IP	IPv4 octets supplied by the PE to the lower layers for transmission.
GLPES_PFIP4TXPKTS	48b	IP	IPv4 packets supplied by the PE to the lower layers for transmission.
GLPES_PFIP4TXFRAGS	48b	IP	IPv4 fragments transmitted.
GLPES_PFIP4TXMCPKTS	48b	IP	IPv4 multicast packets transmitted.
GLPES_PFIP4TXMCOCTS	48b	IP	IPv4 multicast octets transmitted.
GLPES_PFIP6TXOCTS	48b	IP	IPv6 octets supplied by the PE to the lower layers for transmission.
GLPES_PFIP6TXPKTS	48b	IP	IPv6 packets supplied by the PE to the lower layers for transmission.

Table 38-518.PE Statistics Instantiated Per-PCI Function

Name	Size	MIB	Description
GLPES_PFIP6TXFRAGS	48b	IP	IPv6 fragments transmitted.
GLPES_PFIP6TXMCPKTS	48b	IP	IPv6 multicast packets transmitted.
GLPES_PFIP6TXMCOCTS	48b	IP	IPv6 multicast octets transmitted.
GLPES_PFIP4TXNOROUTE	24b	IP	IPv4 datagrams discarded due to routing problem (no hit in ARP table).
GLPES_PFIP6TXNOROUTE	24b	IP	IPv6 datagrams discarded due to routing problem (no hit in ARP table).
GLPES_PFTCPRXSEGSLO	48b	TCP	TCP segments received.
GLPES_PFTCPRXOPTERR	24b	Intel	TCP segments received with unsupported TCP options or TCP option length errors.
GLPES_PFTCPRXPROTOERR	24b	Intel	TCP segments received that are dropped by TRX due to TCP protocol errors.
GLPES_PFTCPTXSEG	48b	TCP	TCP segments transmitted.
GLPES_PFTCPRTXSEG	32b	TCP	Total number of TCP segments retransmitted.
GLPES_PFRDMARXWRS	48b	Microsoft	RDMAP total RDMA write messages received.
GLPES_PFRDMARXRDS	48b	Microsoft	RDMAP total RDMA read request messages received.
GLPES_PFRDMARXSNDS	48b	Microsoft	RDMAP total RDMA send-type messages received.
GLPES_PFRDMATXWRS	48b	Microsoft	RDMAP total RDMA write messages sent.
GLPES_PFRDMATXRDS	48b	Microsoft	RDMAP total RDMA read request messages sent.
GLPES_PFRDMATXSNDS	48b	Microsoft	RDMAP total RDMA send-type messages sent.
GLPES_PFRDMAVBND	48b	Microsoft	RDMA verbs total bind operations carried out.
GLPES_PFRDMAVINV	48b	Microsoft	RDMA verbs total invalidate operations carried out.

Note: A simple, conservative estimate for octet counter wrap times at 40 Gb/s

Note: 32-bit counter wraps in 0.859 s.

Note: 36-bit counter wraps in 13.744 s.

Note: 40-bit counter wraps in 3.665 m.

Note: 48-bit counter wraps in 15.64 h.

Note: 56-bit counter wraps in 166.8 d.

There is a set of PE statistics instantiated only once. Table 38-519 lists these statistics, which are all defined by Intel and not part of a MIB.

Table 38-519.PE Intel-Specific Statistics Instantiated Once (Sheet 1 of 2)

Name	Size	Description
GLPES_RDMARXUNALIGN	32b	RDMA stat: TCP segments that probably have unaligned FPDUs.
GLPES_RDMARXMULTFPDUS	56b	RDMA stat: TCP segments that probably have multiple FPDUs.
GLPES_RDMARXOOONOMARK	32b	RDMA stat: FPDUs received out-of-order, with no MPA marker.
GLPES_RDMARXOOODDPLO	56b	RDMA stat: Number of out-of-order placed DDP segments.
GLPES_TCPRXPUREACKS	56b	TCP stat: Number of pure ACKs received.
GLPES_TCPRXONEHOLE	56b	TCP stat: Increments when an accelerated connection opens a first TCP hole.
GLPES_TCPRXTWOHOLE	56b	TCP stat: Increments when an accelerated connection opens a second TCP hole.
GLPES_TCPRXTHREEHOLE	56b	TCP stat: Increments when an accelerated connection opens a third TCP hole.
GLPES_TCPRXFOURHOLE	56b	TCP stat: Increments when an accelerated connection opens a fourth TCP hole.

Table 38-519.PE Intel-Specific Statistics Instantiated Once (Sheet 2 of 2)

Name	Size	Description
GLPES_TCPTXRETRANSFAST	56b	TCP stat: Number of TCP re-transmits.
GLPES_TCPTXTOUTSFAST	56b	TCP stat: Number of TCP retransmission timeouts on connections attempting fast re-transmit.
GLPES_TCPTXTOUTS	56b	TCP stat: Number of TCP retransmission timeouts on connections that are *not* currently attempting fast re-transmit.

38.36.7 SR-IOV PE Functionality

The 10 GbE controller PE features are supported in virtualized operating systems that support SR-IOV direct assignment and IOMMUs. The 10 GbE controller also supports para-virtualized drivers in virtualized operating systems environments. The goal for the 10 GbE controller PE programming model for VFs is to preserve as much of the non-virtualized programming model as possible to maximize the existing software investment. HMC resource profiles provide resource distribution/partitioning required to support this independent programming model in the VF. Backing pages for VF HMC pages for most HMC objects and page descriptor pages are allocated from the PF driver to provide improved security and stability. Backing pages for VF HMC PBL objects are allocated in the guest operating systems address space, the doorbell page from the VF BAR is mapped to guest user-space addresses and CQP operations are issued directly from the guest. The differences are in the programming model for VFs and show up in two areas:

- HMC objects— A HMC PCI function needs to be allocated for the VF and a few HMC objects are owned by the PF instead of the VF (specifically multicast groups and PE quad hash objects), additionally most HMC objects are allocated and managed by the PF driver. The VF driver uses the VF-to-PF mailbox or operating system-specific back channel mechanism to coordinate this activity.
- Interaction with the LAN portion of the software device driver.

In order to enable a VF driver to take advantage of PE functionality, an HMC PCI function must be allocated. There are 32 HMC VF PCI functions available in the 10 GbE controller. Firmware allocates HMC PCI functions on an as needed basis between the PFs on a given adapter. This allocation takes place when the VF is allocated by the PF driver to a given guest operating system. In the case of multicast group HMC objects, these objects are always owned by PFs and require the VF driver to coordinate access to them by using VF-to-PF communication mechanisms. The difference in interaction with the LAN portion of the driver is operating system specific due to the different approaches that are taken on each vendor.

A sample initialization flow is as follows on top of the usual LAN VF initialization of interrupts, etc.:

1. When the PF driver created the PF CQP instance, it selected one of the SR-IOV HMC resource profiles to enable RDMA for VFs.
2. The PF driver (typically in the hypervisor or privileged host VM) allocates an HMC function on behalf of the VF using the PF CQP instance. (see Section 38.36.3.4.1 for the WQE format).
3. The VF driver in the guest creates a new CQP instance. Section 38.36.3.2.1.
4. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a query FPM values operation. Section 38.36.3.5.2.
5. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a commit FPM values operation. Section 38.36.3.5.3.

6. The PF driver allocates backing pages and page descriptors for all static HMC resources required for the VF and programs the SDs for the HMC function assigned to the VF using Update PE SDs operations. Section 38.36.3.5.1. Note that backing pages are not allocated for PBLE HMC objects in the model, but page descriptors are. Also note that direct backing pages are not supported for VF PBLE HMC objects.
7. The VF driver (or optionally the PF driver on the VF drivers behalf) issues a static HMC pages allocated operation. Section 38.36.3.5.10.
8. The PF driver (via communication from the VF driver) allocates backing pages and page descriptors for the initial set of HMC resources required by the VF driver. This step involves issuing one or more Update PE SD operations.
9. The VF driver uses its CQP instance to create CQ0, the CEQ, and AEQ for the VF.
10. During runtime, the VF driver signals the PF driver to allocate and initialize more HMC backing pages and/or PDs on its behalf. When PBLEs are needed during memory registration in the VF, the VF driver issues manage VF PBLE backing pages operations. Section 38.36.3.3.9.

38.36.7.1 SR-IOV Protocol Engine State Migration

Given that the PE uses the HMC's FPM concept, it is theoretically possible to migrate an entire VF's PE state (QPs, CQs, etc) from one adapter to another even if the second adapter is not on the same computer. Enablement of this type of migration is required and substantial.

38.37 System Manageability

Network management is an important requirement in today's networked computer environment.

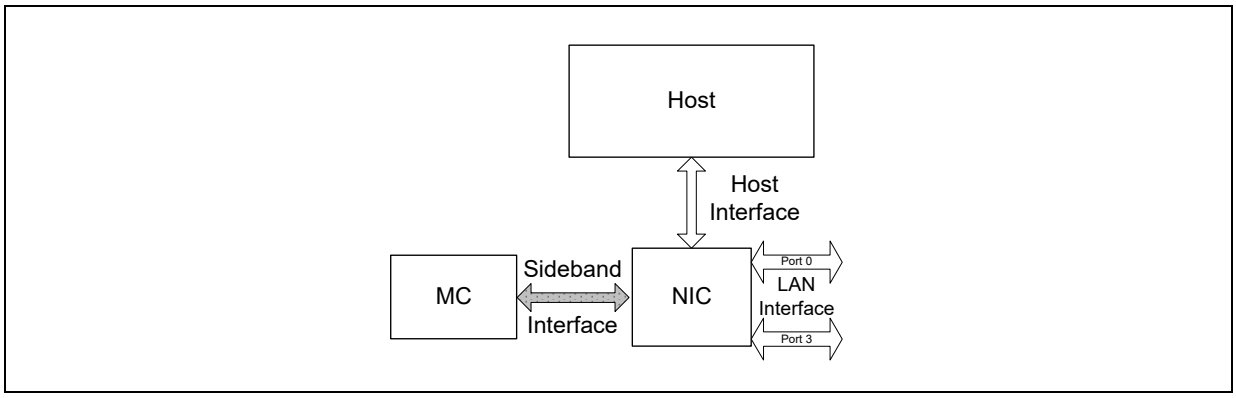
Software-based management applications provide the ability to administer systems while the operating system is functioning in a normal power state (not in a pre-boot state or powered-down state). The Intel® Out of Band Management fills the management void that exists when the operating system is not running or fully functional. This is accomplished by providing mechanisms by which manageability network traffic can be routed to and from a Management Controller (MC).

This section describes the supported management interfaces and hardware configurations for platform system management. It describes the interfaces to an external MC, the partitioning of platform manageability among system components, and the functionality provided by the 10 GbE controller in each platform configuration.

38.37.1 Pass-Through (PT) Functionality

PT is the term used when referring to the process of sending and receiving Ethernet traffic over the sideband interface. The 10 GbE controller has the ability to route Ethernet traffic to the host operating system as well as the ability to send Ethernet traffic over the sideband interface to an external MC. See Figure 38-128.

Figure 38-128.Sideband Interface



The sideband interface provides a mechanism by which the 10 GbE controller can be shared between the host and the MC. By providing this sideband interface, the MC can communicate with the LAN without requiring a dedicated Ethernet controller. The 10 GbE controller supports three sideband interfaces:

- SMBus (legacy or as part of MCTP)
- NC-SI
- PCIe (together with MCTP) - when the system is up.

Note: The usable bandwidth for either direction is up to 1 Mb/s when using SMBus and 100 Mb/s for the NC-SI interface. When working over PCIe, the bandwidth is limited only by the PCIe bandwidth and the the 10 GbE controller processing capabilities and can sustain any network bandwidth. The 10 GbE controller should support MCTP over PCIe pass-through traffic at a rate of up to 1 Gb/s. The maximum packet size supported for traffic received from the LAN to the MC is 1518 bytes and an additional STag or VLAN tags. For traffic from the MC to the LAN the maximum supported packet size is 1536 bytes including all tags.

Note: In MCTP mode, the PCIe and SMBus interface can receive MCTP commands in parallel. For example, the MCTP enumeration process can be done both over SMBus and over PCIe. However, only one of the interfaces can receive NC-SI commands or pass-through traffic.

38.37.1.1 Supported Topologies

The 10 GbE controller can support up to two channels to management controllers in some topologies. The following connections are available:

- Connection via legacy SMBus.
- Connection via NC-SI over RBT (RMII) (see Section 38.37.6).
- Connection via NC-SI over MCTP. This connection can be over SMBus, PCIe or both. This connection can be used either for pass through or for control only (see Section 38.37.7).
- Two connections — A connection via NC-SI over RBT for pass-through traffic and a connection via MCTP used only for control traffic (see Section 38.37.7).

The channel used is for pass through is defined in the *Redirection Sideband Interface* field in the Common Manageability Parameters NVM word and is common to all the ports in the device.

38.37.1.2 PT Packet Routing

When an Ethernet packet reaches the 10 GbE controller, it is examined and compared to a number of configurable filters. These filters are configurable by the MC and include, but not limited to, filtering on:

- MAC address
- IP address
- UDP/IP ports
- VLAN tags
- Ether-type

If the incoming packet matches any of the configured filters, it is passed to the MC. Otherwise, it is not passed.

The packet filtering process is described in Section 38.37.3.

38.37.2 Components of the Sideband Interface

There are two components to a sideband interface:

- Physical layer
- Logical layer

38.37.2.1 Physical Layer

This is the electrical connection between the 10 GbE controller and the MC.

38.37.2.1.1 SMBus

The SMBus physical layer is defined by the SMBus specification. The interface is made up of two connections: data and clock. There is also an optional third connection: the alert line. This line is used by the 10 GbE controller to notify the MC that there is data available for reading in legacy SMBus mode. Refer to the SMBus specification for details.

The SMBus can run at three speeds: 100 kHz (standard SMBus), or 400 kHz (I^2C fast mode) or 1 MHz (I^2C fast mode plus).The speed used while the 10 GbE controller is the master of the bus is selected by the *SMBus Connection Speed* field in the SMBus Notification Timeout and Flags NVM word. When acting as a slave, the 10 GbE controller can receive transactions with a clock running at up to 1 MHz.

38.37.2.1.2 PEC Support

SMBus transactions can be protected by using Packet Error Code (PEC). Packet error checking, when applicable, is implemented by appending a PEC byte at the end of each message transfer. The PEC byte is a CRC8 calculation on all the message bytes.

PEC is added in transmit and expected in receive for the following SMBus packets:

- ARP packets
- MCTP over SMBus transactions.

For ARA cycles and legacy SMBus transactions, a PEC is not expected.

The following table lists the behavior of the 10 GbE controller in each PEC configured mode for transactions directly handled by hardware after receiving packets with or without PEC.

Table 38-520.SMBus PEC Modes[1]

SMBus Transaction/PEC Mode		Target PEC Mode	
SMBus Transaction (Relative to the 10 GbE controller)	**Product Name PEC Mode**	**PEC Enabled**	**PEC Disabled**
Master Write[2]	Enabled	(A) Target ACKs the PEC byte.	(A) Target NACKs the PEC byte.
Master Write	Disabled	(A) Target receives stop before expected PEC byte.	(A) PEC byte is not expected.
Slave Write[3]	Enabled	(A) Target ACKs last data byte; PEC byte is NACKed.	(A) Target NACKs last data byte; No PEC byte is written by the slave.
Slave Write-	Disabled	(A) Target ACKs last data byte; PEC byte is 0xFF.	(A) Target NACKs last data byte and generates stop afterwards.
Slave Read[4]	Enabled	(A) Target sends the PEC byte; PEC byte is ACKed by the slave.	(A) Target does not send PEC byte and generates stop afterwards.
Slave Read	Disabled	(R) Target sends the PEC byte; PEC byte is NACKed by the slave.	(A) Target does not send PEC byte and generates stop afterwards.

Notes:

1. (A) - Accept transaction; (R) - Reject transaction.
2. Used in Legacy SMBus writes commands (direct receive) and in MCTP over SMBus (transmitted transactions.
3. Used in Legacy SMBus Read commands.
4. Used in Legacy SMBus mode (alert/async-notify) and in MCTP over SMBus (received transactions).

Note: In both SMBus ARP and MCTP, the specification indicates that PEC must be used. However, if PEC is not used by the master, the transaction is still accepted and processed by the 10 GbE controller.

The PEC behavior is controlled by the SMBus transaction PEC bit in the SMBus Notification Timeout and Flags NVM word. If this bit is set, PEC is added for master SMBus write transactions. A PEC is added to slave read transactions and can be received in slave write transaction. If this bit is cleared, PEC is not added to master write or slave read transactions, a slave write transaction with PEC is dropped. This bit should be set for MCTP mode and should be cleared in legacy SMBus mode.

38.37.2.1.3 NC-SI

The 10 GbE controller uses the DMTF standard sideband interface. This interface consists of seven lines for transmission and reception of Ethernet packets and two optional lines for arbitration among more than one physical network controller.

The physical layer of NC-SI is very similar to the RMII interface, although not an exact duplicate. Refer to the NC-SI specification for details of the differences.

Electrical characteristics

The 10 GbE controller complies with the electrical characteristics defined in the NC-SI 1.0.1 specification.

The 10 GbE controller's NC-SI behavior is configured at power-up in the following manner:

- The multi-drop NC-SI NVM bit defines the NC-SI topology (point-to-point or multi-drop; the default is point-to-point).

The 10 GbE controller dynamically drives its NC-SI output signals (NC-SI_DV and NC-SI_RX) as required by the sideband protocol:

- At power-up, the 10 GbE controller floats the NC-SI outputs.
- If the 10 GbE controller operates in point-to-point mode, it starts driving the NC-SI outputs some time following power-up.
- If the 10 GbE controller operates in a multi-drop mode, it drives the NC-SI outputs as configured by the BMC.

38.37.2.1.4 PCIe Vendor Defined Messages (VDMs)

The 10 GbE controller uses VDMs over PCIe defined in the DMTF MCTP specification to convey pass-through traffic or NC-SI control traffic.

38.37.2.2 Logical Layer

38.37.2.2.1 Legacy SMBus

The protocol layer for SMBus consists of commands the MC issues to configure filtering for the 10 GbE controller management traffic and the reading and writing of Ethernet frames over the SMBus interface. There is no industry standard protocol for sideband traffic over SMBus. The protocol layer for SMBus on the 10 GbE controller is Intel proprietary.

38.37.2.2.2 NC-SI

The DMTF defines the protocol layer for the NC-SI interface. NC-SI compliant devices are required to implement a minimum set of commands. The specification also provides a mechanism for vendors to add additional capabilities through the use of OEM commands. Intel OEM NC-SI commands for the 10 GbE controller are discussed in Section 38.37.6.4. For information on base NC-SI commands, see the NC-SI specification.

NC-SI traffic can run on top of three different Physical layers:

1. NC-SI physical layer as described in Section 38.37.2.1.3.
2. MCTP over PCIe VDM.This protocol enables control and pass-through traffic over PCIe of a NIC or a LOM device. The NC-SI over MCTP protocol is slightly different than the standard NC-SI as it includes additional NC-SI commands. This mode is usually paired with an MCTP over SMBus, where this mode is used in S0 states and the SMBus interface is used in Sx state.The MCTP protocol and the differences from standard NC-SI is described in Section 38.37.7.
3. MCTP over SMBus. As previously described, this layer is paired with the MCTP over PCIe to support Sx modes.

The 10 GbE controller exposes one NC-SI package with four channels, one per port. The 10 GbE controller implements a type C NC-SI interface (single package, common bus buffers and shared RX queue) as described in Section 5.2 of the *NC-SI Specification*.

Package ID Setting

The package ID can be set from the NVM *Package ID* field in the NC-SI Configuration 1 NVM word.

Channel ID Mapping

The mapping of the channels to physical ports is according to the NC-SI Channel to Port Mapping NVM word if the NC-SI Channel to Port Mapping Table *Valid* bit is set. If this bit is not set, the following algorithm should be used:

```
Channel_ID = 0

NC-SI_channel[3 :0] = -1 // ports not associated to channels yet.

For func = 0 to 15 { // loop on all functions

        Port_ID = PFGEN_PORTNUM[func] // Port associated with function.

        If (PRTGEN_STATUS.PORT_VALID[Port_ID]  && NC-SI_channel[Port_ID] == -1 ) {

        // Port is valid and port is not already associated to a channel

        NC-SI_channel[Port_ID] = Channel_ID; // assign channel

        Channel_ID++; // go to next channel

        }

    }
```

This algorithm maps channel numbers that match the order of the PCI function numbers. If more than one function is defined on a port, the function with the lowest value associated with this port is used.

38.37.3 Packet Filtering

Since both the host operating system and an MC use the 10 GbE controller to send and receive Ethernet traffic, there needs to be a mechanism by which incoming Ethernet packets can be identified as those that should be sent to the MC rather than the host operating system.

There are two different types of filtering available. The first is filtering based upon the MAC address. With this filtering, the BMC has at least one dedicated MAC address and incoming Ethernet traffic with the matching MAC address(es) are passed to the MC. This is the simplest filtering mechanism to use and it enables the MC to receive all types traffic (including, but not limited to, IPMI, NFS, HTTP etc).

The other type available uses a highly configurable mechanism by which packets can be filtered using a wide range of parameters. Using this method, the MC can share a MAC address (and IP address, if desired) with the host operating system and receive only specific Ethernet traffic. This method is useful if the MC is only interested in specific traffic, such as IPMI packets.

38.37.3.1 Manageability Receive Filtering

This section describes the manageability receive packet filtering flow. Packet reception by the 10 GbE controller can generate one of the following results:

- Discarded
- Sent to host memory
- Sent to the MC
- Sent to both the MC and host memory

The decisions regarding forwarding of packets to the host and to the MC are separate and are configured through two sets of registers. However, the MC might define some types of traffic as exclusive. This traffic is forwarded only to the MC, even if it passes the filtering process of the host. These types of traffic are defined using the PRT_MNG_MNGONLY register.

An example of packets that might be necessary to send exclusively to the MC might be specific TCP/UDP ports of a shared MAC address or a MAC address dedicated to the MC. If the MC configures the manageability filters to send these ports to the MC, it should configure the settings to not send them to the host; otherwise, these ports are received and handled by the host operating system.

The MC controls the types of packets that it receives by programming receive manageability filters. The following filters are accessible to the MC:

Table 38-521.Filters Accessible to MC

Filters	Functionality	When Reset?
Filters Enable	General configuration of manageability filters.	RSMRST#
Manageability Only	Enables routing of packets exclusively to manageability.	RSMRST#
Manageability Decision Filters [7:0]	Configuration of manageability decision filters.	RSMRST#
MAC Address [3:0]	Four unicast MAC manageability addresses.	RSMRST#
VLAN Filters [7:0]	Eight VLAN tag values.	RSMRST#
UDP/TCP Port Filters [15:0]	16 destination port values.	RSMRST#
Flexible 128 bytes TCO Filter	Length and values for one flex TCO filter.	RSMRST#
IPv4 and IPv6 Address Filters [3:0]	IP address for manageability filtering.	RSMRST#
Special Filters Modifier	Used to define some special filtering options like 24-bit filtering of IPv6 addresses and TCP/UDP selection of ASF ports.	RSMRST#

All filtering capabilities are available on both the NC-SI and legacy SMBus interfaces. In NC-SI modes, part of the filters are programmed via standard NC-SI commands and part of the filter are programmed via the Intel OEM commands described in Section 38.37.6.4. In legacy SMBus, the filtering is programmed either from NVM or via the commands previously described.

Note: Internal power on reset flows include a PWRBTN# override event. Refer to the Power Management flows previously described for more detail. Since all filters are reset, the BMC must reconfigure the necessary filters for correct functionality.

The high-level structure of manageability filtering is done using two or three steps.

1. The packet is routed by the switch. If the switch determines the packet should be routed to the manageability VSIs, the next steps are taken.
2. The packet is parsed and fields in the header are compared to programmed filters.
3. A set of decision filters are applied to the result of the first step.

The following sections describe steps 2 and 3 previously listed.

Some general rules apply:

- Fragmented packets are passed to manageability but not parsed beyond the IP header.
- Packets with L2 errors (CRC, alignment, etc.) are not forwarded to the MC.
- Packets longer than 2 KB are filtered out.

The following sections describe the manageability filtering, followed by the final filtering rules.

The filtering rules are created by programming the decision filters as described in Section 38.37.3.4.

All filters are reset only on internal power on reset. Register filters that enable filters or functionality are also reset by a firmware reset in NC-SI mode. These registers can be loaded from the NVM following a reset in SMBus mode. Refer to the NVM map for more details.

Note: Internal power on reset flows include the PWRBTN# override event. Refer to the Power Management flows previously described for more detail. Since all filters are reset, the BMC must reconfigure the necessary filters for correct functionality. Internal power on reset flows include a PWRBTN# override event. Refer to the Power Management flows previously described for more detail. Since all filters are reset, the BMC must reconfigure the necessary filters for correct functionality.

This reconfiguration is required because the management controller inside Lewisburg is also included in the global reset flow and the NC-SI configuration data is reset. Registers such as the BMC MAC address will require reconfiguration. Since BMC bring up network in first boot, the BMC firmware will need to repeat the network bring-up flow after a global reset event. There should be no network link drop after a host partition reset. Implementation options vary depending on BMC implementations. Below are available options:

1. If GBL_RST_WARN pin is already routed to the BMC, the BMC will get notice when the pin is asserted and be aware of a global reset occurring, and re-configure the network interface accordingly.

2. If GBL_RST_WARN pin is not routed to BMC, and there are no plan for a board spin, then there is a need to find a way for the BMC to be aware of a global reset, or link drop event, so that the BMC can do the re-configuration. One likely and reliable way is to let the BIOS notify the BMC through an existing communication channel, such as a GPIO pin.

3. The BMC can monitor eSPI_RESET# as it is triggered on a global reset.

4. (SLP_S3# or SLP_S4# or SLP_S5#) and PLT_RST# will be triggered on different resets. In order to verify if the Management filters in X722 were cleared on the global reset, the BMC can send any NC-SI command besides "Clear Initial State" and if the command succeeds then there is no additional action. If the command responds that initialization is required (Response code 0x01 Reason code 0x01 "Interface Initialization Required") then the BMC will need to re configure the NC-SI interface as well as the pass-through filters.

Global resets are a rare occurrence; however, the network controller will need to be reconfigured after this type of reset.

38.37.3.2 L2 Filters

38.37.3.2.1 MAC and VLAN Filters

The manageability MAC filters allow a comparison of the destination MAC address to one of 4 filters defined in the PRT_MNG_MMAH and PRT_MNG_MMAL registers.

The VLAN filters allow a comparison of the 12 bit inner VLAN tag to one of 8 filters defined in the PRT_MNG_MAVTV registers.

38.37.3.2.2 Ether-type Filters

Manageability L2 Ether-type filters enable filtering of received packets based on the Layer 2 Ether-type field. The L2 type field of incoming packets is compared against the Ether-type filters programmed in the manageability Ether-type filter (PRT_MNG_METF; up to 4 filters); the result is incorporated into decision filters.

Each manageability Ether-type filter can be configured as pass (positive) or reject (negative) using a polarity bit. In order for the reverse polarity mode to be effective and block certain type of packets, the Ether-type filter should be part of all the enabled decision filters.

An example for using L2 Ether-type filters is to determine the destination of 802.1X control packets. The 802.1X protocol is executed at different times in either the management controller or by the host. L2 Ether-type filters are used to route these packets to the proper agent.

In addition to the flexible Ether-type filters, the 10 GbE controller supports two fixed Ether-type filters used to block NC-SI control traffic (0x88F8) and flow control traffic (0x8808) from reaching the manageability interface. The NC-SI Ether-type is used for communication between the MC on the NC-SI link and the 10 GbE controller. Packets coming from the network are not expected to carry this Ether-type and such packets are blocked to prevent attacks on the MC. Flow control packets should be consumed by the MAC and as such are not expected to be forwarded to the management interface.

Note: Ether-type filters shouldn't configured with IPv4 or IPv6 Ether-type values.

38.37.3.3 L3/L4 Filtering

The manageability filtering stage combines checks done at previous stages with additional L3/L4 checks to make a decision about whether to route a packet to the MC. The following sections describe the manageability filtering done at layers L3/L4 and final filtering rules.

38.37.3.3.1 ARP Filtering

ARP filtering — The 10 GbE controller supports filtering of ARP request packets (initiated externally) and ARP responses (to requests initiated by the MC).

In legacy SMBus mode, the ARP filters can be used as part of the ARP offload described in Section 38.37.5.4. ARP offload is not specifically available when using NC-SI. However, the general filtering mechanism is used to filter incoming ARP traffic as requested using the Enable Broadcast Filtering NC-SI command.

In order to limit the reception of ARP packets to the ARP packets dedicated to this station (ARP target IP = MC IP), the ARP request/response filter can be bound to a specific IP address by setting both the ARP Request/Response and the IP AND bits in an MDEF filter. Note that the IP bit is also set if there is a match on the target IP (the TPA field in the ARP packet) of an ARP request or an ARP response.

Note: If the OR section of the MDEF is cleared and one of the IPv4 address are set, then ARP packets matching the IP address pass the filter. If these packets should be dropped, then an OR Ether-type filter with a a value of 0x0800 (IPv4) should be added.

Refer to the section describing the format of ARP packets.

38.37.3.3.2 Neighbor Discovery Filtering and MLD

The 10 GbE controller supports filtering of the following ICMPv6 packets.

Neighbor discovery packets:

1. 0x86 (134d) - Router Advertisement.
2. 0x87 (135d) - Neighbor Solicitation.
3. 0x88 (136d) - Neighbor Advertisement.
4. 0x89 (137d) - Redirect.

MLD packets:

1. 0x82 (130d) - MLD Query
2. 0x83 (131d) - MLDv1 Report
3. 0x84 (132d) - MLD Done
4. 0x8F (143d) - MLDv2 Report

The neighbor discovery packets has dedicated enables for each type in the decision filters. For MLD, a single enable controls the forwarding of all the MLD packets. This means that either all the MLD packets types are selected for reception or none of them.

Refer to the section describing the format of ICMPv6 packets.

38.37.3.3.3 RMCP Filtering

The 10 GbE controller supports filtering by fixed destination port numbers, port 0x26F and port 0x298. These ports are IANA reserved for RMCP.

UDP or TCP protocols can be included in the comparison using the *PRT_MNG_MSFM.PORT_26F/298_UDP/TCP* fields.

In SMBus mode, there are filters that can be enabled for these ports. When using NC-SI, they are not specifically available. However, the general filtering mechanism can be utilized to filter incoming RMCP traffic.

38.37.3.3.4 ICMP Filtering

The 10 GbE controller supports filtering by ICMPv4. This filter matches if the IP *Protocol* field equals to 1b.

Refer to the section describing the format of ICMP packets.

38.37.3.3.5 Flexible Port Filtering

The 10 GbE controller implements 16 flex destination port filters. The 10 GbE controller directs packets whose L4 destination port matches to the MC. The MC must ensure that only valid entries are enabled in the decision filters.

For each flex port filter, filtering can be enabled for UDP, TCP or both. It can be enabled either on source or destination port.

38.37.3.3.6 IP Address Filtering

The 10 GbE controller supports filtering by destination IP address using IPv4 and IPv6 address filters. These are dedicated to manageability. The 10 GbE controller provides four IPv6 address filters and four IPv4 address filters.

For each IPv6 filter, the matching *PRT_MNG_MSFM*.IPV6_n_MASK bit defines if all the IP address should be compared to the PRT_MNG_MIPAF6 register or only the 24 LSBits should be compared to the 24 LSBits of the PRT_MNG_MIPAF6 register.

The IPv4 match also rises for ARP packets for which the target IP matches the IP address in the PRT_MNG_MIPAF4 register.

38.37.3.3.7 Checksum Filtering

The 10 GbE controller might be instructed to direct packets to the MC only if they pass L3/L4 checksum (if they exist) in addition to matching other filters previously described.

Enabling the XSUM filter when using the SMBus interface is accomplished by setting the *Enable XSUM Filtering to Manageability* bit. This is done using the Update Management Receive Filter Parameters command.

To enable the XSUM filtering when using NC-SI, use the Enable Checksum Offloading command. See Section 38.37.6.4.13.

38.37.3.4 Flexible 128-Byte Filter

The 10 GbE controller provides one flex TCO filter. This filter looks for a pattern match within the first 128 bytes of the packet.

From the first 128 bytes, some of the fields are skipped for this comparison. These are field that are not exposed to the MC. The tag skipped is STag.

The flex filter programming should ignore the presence of these fields.

Note: The flex filter comparison should be disabled in the MDEF registers while the flex filter is being updated.

Note: The flexible filter is not applied to transmit packets and a transmit packet is considered as if it did not pass the filter.

38.37.3.4.1 Flexible Filter Structure

The filter is composed of the following fields:

1. Flexible filter length — This field indicates the number of bytes in the packet header that should be inspected. The field also indicates the minimal length of packets inspected by the filter. Packet below that length is not inspected. Valid values for this field are: 8*n, where n=1…16.
2. Data — This is a set of up to 128 bytes comprised of values that header bytes of packets are tested against.
3. Mask — This is a set of 128 bits corresponding to the 128 data bytes that indicate for each corresponding byte if is tested against its corresponding byte. The general filter is 128 bytes that the MC configures; all of these bytes might not be needed or used for the filtering, so the mask is used to indicate which of the 128 bytes are used for the filter.

Each filter tests the first 128 bytes (or less) of a packet, where not all bytes must necessarily be tested.

38.37.3.4.2 TCO Filter Programming

Programming each filter is done using the following commands (NC-SI or SMBus) in a sequential manner:

1. Filter mask and length — This command configures the following fields:
   a. Mask — A set of 16 bytes containing the 128 bits of the mask. Bit 0 of the first byte corresponds to the first byte on the wire.
   b. Length — A 1-byte field indicating the length.

2. Filter data — The filter data is divided into groups of bytes as follows:

Group	Test Bytes
0x0	0-29
0x1	30-59
0x2	60-89
0x3	90-119
0x4	120-127

Each group of bytes need to be configured using a separate command, where the group number is given as a parameter. The command has the following parameters:

a. Group number — A 1-byte field indicating the current group addressed.

b. Data bytes — Up to 30 bytes of test-bytes for the current group.

Flexible TCO Filter Configuration in NVM (Global MNG Offset 0x05)

This section describes the NVM module used to store the flex filter initial data in SMBus mode.

This module is pointed to by global offset 0x08 of the manageability module header section.

Section Header — Offset 0x0

Bits	Name	Default	Description
15:0	Block Length	0xC	Section length in words (including CRC word and length word).

Flexible Filter Length and Control — Offset 0x01

Bits	Name	Default	Description
15:8	Flexible Filter Length (bytes)		
7:5	Reserved		Reserved.
4	Last Filter		
3	Apply Filter to LAN 3		
2	Apply Filter to LAN 2		
1	Apply Filter to LAN 1		
0	Apply Filter to LAN 0		

Flexible Filter Enable Mask — Offset 0x02 – 0x09

Bits	Name	Default	Description
15:0	Flexible Filter Enable Mask		

Flexible Filter Data — Offset 0x0A – 0x49

Bits	Name	Default	Description
15:0	Flexible Filter Data		

Note: This section loads all of the flexible filters. The control + mask + filter data are repeatable as the number of filters. Section length in offset 0 is for all filters.

Section Footer — Offset Block Length

Bits	Name	Default	Description
15:8	CRC 8		CRC8 of the previous section.
7:0	Reserved		Reserved.

38.37.3.5 Configuring Manageability Filters

There are a number of pre-defined filters that are available for the MC to enable, such as ARPs and IPMI ports 0x298 and 0x26F. These are generally enabled by setting the appropriate bit within the PRT_MNG_MANC register using specific commands.

For more advanced filtering needs, the MC has the ability to configure a number of configurable filters. It is a two-step process to use these filters. They must first be configured and then enabled.

38.37.3.5.1 Manageability Decision Filters

Manageability Decision Filters (MDEF) are a set of eight filters, each with the same structure. The filtering rule for each decision filter is programmed by the MC and defines which of the L2, VLAN, Ether-type and L2/L3 filters participate in decision making. Any packet that passes at least one rule is directed to manageability and possibly to the host.

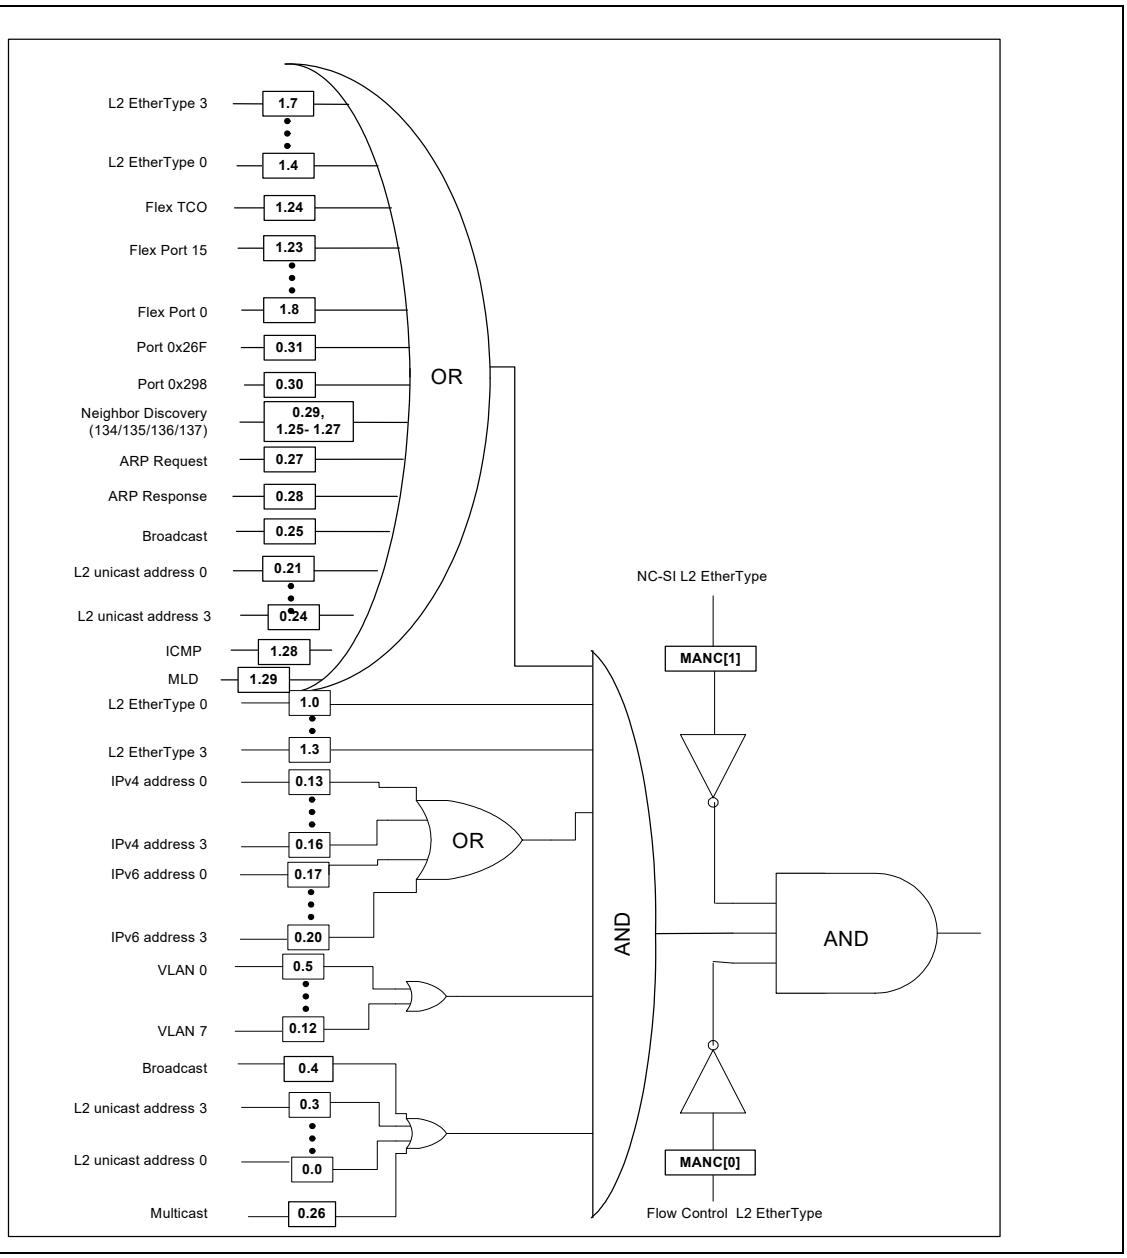
The inputs to each decision filter are:

- Packet passed a valid management L2 exact address filter.
- Packet is a broadcast packet.
- Packet has a VLAN header and it passed a valid manageability VLAN filter.
- Packet matched one of the valid IPv4 or IPv6 manageability address filters.
- Packet is a multicast packet.
- Packet passed ARP filtering (request or response).
- Packet passed neighbor solicitation filtering.
- Packet passed MLD filtering.
- Packet passed 0x298/0x26F port filter.
- Packet passed a valid flex port filter.
- Packet passed a valid flex TCO filter.
- Packet is an ICMPv4 packet.
- Packet passed or failed an L2 Ether-type filter.
- Packet passed or failed Flow Control or NC-SI L2 Ether-type Discard filter.

The structure of each decision filter is shown in Figure 38-129. A boxed number indicates that the input is conditioned by a mask bit defined in the MDEF register and MDEF_EXT register for this rule. Decision filter rules are as follows:

- At least one bit must be set in one of the two registers. If all bits are cleared (MDEF/MDEF_EXT = 0x0000), then the decision filter is disabled and ignored.
- All enabled AND filters must match for the decision filter to match. An AND filter not enabled in the MDEF/MDEF_EXT registers is ignored. If an AND filter is preceded by a OR filter, then at least one of the enabled OR inputs must match for the filter to pass.
- If no OR filter is enabled in the register, the OR filters are ignored in the decision (the filter might still match).
- If one or more OR filters are enabled in the register, then at least one of the enabled OR filters must match for the decision filter to match.

Figure 38-129.Manageability Decision Filters



A decision filter (for any of the eight filters) defines which of the previously described inputs are enabled as part of a filtering rule. The MC programs two 32-bit registers per rule (MDEF[7:0] and MDEF_EXT[7:0]). A set bit enables its corresponding filter to participate in the filtering decision.

In addition to the controls previously described, the *PRT_MNG_MDEF_EXT.apply_to_host_traffic* and *PRT_MNG_MDEF_EXT.apply_to_network_traffic* bits define which traffic is compared to this filter. At least one of these bits must be set for the filter to be valid.

If the *PRT_MNG_MDEF_EXT.apply_to_host_traffic* bit is set, the traffic from the host is a candidate for this filter. If the *PRT_MNG_MDEF_EXT.apply_to_network_traffic* bit is set, the traffic from the network is a candidate for this filter. If both bits are set, this filter is applied to all traffic.

38.37.3.5.2 Exclusive Traffic

The decisions regarding forwarding of packets to the host for LAN traffic or to the LAN for host traffic are independent from the management decision filters. However, the MC might define some types of traffic as exclusive. The behavior for such traffic is defined by the using the bits corresponding to the decision filter in the PRT_MNG_MNGONLY register (one bit per each of the eight decision rules) and the *PRT_MNG_MDEF_EXT.apply_to_host_traffic* and *PRT_MNG_MDEF_EXT.apply_to_network_traffic* bits. Table 38-522 lists the behavior in each case. If one or more filters match the traffic and at least one of the filters is set as exclusive, the traffic is treated as exclusive.

Table 38-522.Exclusive Traffic Behavior

	Filter Match		Filter Does Not Match
Traffic Source	**PRT_MNG_MNGONLY = 0**	**PRT_MNG_MNGONLY = 1**	**N/A**
From network	Traffic is forwarded to manageability. Traffic is forwarded to the host according to host filtering.	Traffic is forwarded only to manageability.	Traffic is forwarded to the host according to host filtering.
From host	Traffic is forwarded to manageability and to the LAN.	Traffic is forwarded only to manageability.	Traffic is forwarded to the LAN.

Any traffic matching any of the configurable filters (see Section 38.37.3.5.1) can be used as filters to pass traffic to the host.

Table 38-523.PRT_MNG_MNGONLY Register Description and Usage

Bits	Description	Default
0	Decision Filter 0	Determines if packets that have passed decision filter 0 are sent exclusively to the manageability path.
1	Decision Filter 1	Determines if packets that have passed decision filter 1 are sent exclusively to the manageability path.
2	Decision Filter 2	Determines if packets that have passed decision filter 2 are sent exclusively to the manageability path.
3	Decision Filter 3	Determines if packets that have passed decision filter 3 are sent exclusively to the manageability path.
4	Decision Filter 4	Determines if packets that have passed decision filter 4 are sent exclusively to the manageability path.
5	Unicast and Mixed	NC-SI mode: Determines if unicast and mixed packets are sent exclusively to the manageability path. SMBus mode: Determines if packets that have passed decision filter 5 are sent exclusively to the manageability path.
6	Global Multicast	NC-SI mode: Determines if multicast packets are sent exclusively to the manageability path. SMBus mode: Determines if packets that have passed decision filter 6 are sent exclusively to the manageability path.
7	Broadcast	NC-SI mode: Determines if broadcast packets are sent exclusively to the manageability path. SMBus mode: Determines if ARP packets are sent exclusively to the manageability path.
31:8	Reserved	Reserved.

When using the SMBus interface, the MC enables these filters by issuing the Update Management Receive Filter Parameters command (with the parameter of 0x0F).

PRT_MNG_MNGONLY is also configurable when using NC-SI using the Set Intel Filters — Manageability Only command.

All manageability filters are controlled by the MC only and not by the LAN software device driver.

Note: PRT_MNG_MNGONLY should not be set for traffic type that the MC might also send to the network (such as multicast traffic). If set, the MC might receive the packets it sent and the packets might not be sent to the network or the host.

38.37.3.5.3 Global Controls

On top of the PRT_MNG_MDEF filters, the PRT_MNG_MANC registers contain some global controls applied to all the packets in order to be a candidate for manageability filtering:

- Receive enable bits:
  - The *RCV_TCO_EN* field controls the reception of manageability traffic. It should be set only if one of the following bits is also set.
  - The *EN_BMC2OS* bit controls the reception of manageability traffic from the host.
  - The *EN_BMC2NET* bit controls the reception of manageability traffic from the network.
- VLAN filtering— In order to support the NC-SI VLAN modes the following controls are provided:
  - The *FIXED_NET_TYPE* field controls if only VLAN tagged or VLAN untagged traffic is received. If this bit is cleared both types are received. If it is set, only the type described by the *NET_TYPE* field is accepted.
  - If set, the NET_TYPE field indicates that only VLAN tagged traffic is received, if cleared only packets without VLAN is accepted. This field is validated by the *FIXED_NET_TYPE* field.

  Both fields relates to the inner VLAN.

Table 38-524 lists the relationship between the previously mentioned bits and the forwarding decisions:

Table 38-524.PRT_MNG_MANC Bits Impact

CASE\ PRT_MNG_MANC Bits	RCV_TCO_EN=0b	FIXED_NET_TYPE= 1b and NET_TYPE!= What's in the Packet	EN_BMC2OS=0b (Assume EN_BMC2NET = 1b)	EN_BMC2NET=0b (Assume EN_BMC2HOST = 1b)
Packet sent from host and hits MDEF filters (host-to-MC traffic).	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is sent to the MC.
Packet sent from host and matches one of the EMP VSI (host-to-EMP traffic).	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.
Packet received from LAN and hits MDEF filters (LAN-to-MC traffic).	Packet is not sent to the MC.	Packet is not sent to the MC.	Packet is sent to the MC.	Packet is not sent to the MC.
Packet received from LAN and matches on of the EMP VSI (LAN-to-EMP traffic).	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.	Packet is sent to the EMP.
Packet sent from EMP and matches one of the host VSIs (EMP-to-host traffic)	Packet is sent to a host (and optionally to LAN).	Packet is sent to the host (and optionally to LAN).	Packet is sent to the host (and optionally to LAN).	Packet is sent to the host (and optionally to LAN).

Table 38-524.PRT_MNG_MANC Bits Impact

CASE\ PRT_MNG_MANC Bits	RCV_TCO_EN=0b	FIXED_NET_TYPE= 1b and NET_TYPE!= What's in the Packet	EN_BMC2OS=0b (Assume EN_BMC2NET = 1b)	EN_BMC2NET=0b (Assume EN_BMC2HOST = 1b)
Packet sent from the EMP and does not match one of the host VSIs (EMP-to-LAN traffic).	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.
Packet sent from the MC and matches one of the host VSIs (MC-to-host traffic).	Packet is sent to the host (and optionally to LAN).	Packet is sent to the host (and optionally to LAN).	Packet is sent to the LAN.	Packet is sent to the host (and optionally to LAN).
Packet sent from the MC and does not match one of the host VSIs (MC-to-LAN traffic).	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is sent to the LAN.	Packet is not sent to the LAN (optionally sent to host).

38.37.3.6 Filtering Programming Interfaces

The 10 GbE controller provides multiple options to program the forwarding filters, depending on the interface used and the level of flexibility needed. Table 38-525 lists the different options and points to the description of the relevant commands.

Table 38-525.Filtering Programming Interfaces

Interface	Flexible/Abstract	Description
NC-SI (over RMII or over MCTP)	Abstract (dedicated MAC address)	The regular NC-SI commands can be used to enable forwarding based on a dedicated MAC address. The list of supported commands can be found in Section 38.37.6.2.1. When using these commands, one of the two other modes can be used to add finer grain filtering.
	Abstract (Shared MAC and IP)	The Intel OEM commands described in Section 38.37.3.6.1 and in Section 38.37.6.4.14 can be used to define which part of the shared MAC or shared IP traffic should be forwarded. When using these commands, the flexible filtering interface should not be used. This mode is activated using the Set Shared mode command.
	Flexible	This interface described in most of the sub-sections of Section 38.37.6.4. It uses the packet reduction commands to reduce the forwarding scope of the filters set by the regular NC-SI commands and the packet addition commands to add new packet types to the forwarding rules.
SMBus	Abstract	The Set Common filter command can be used to set the most common filters. When using this commands the flexible filtering interface should not be used. When sending this command, all previous filtering requests are cleared.
	Flexible	The Update MNG RCV Filter Parameters can be used to define the exact filtering rules to be applied.

38.37.3.6.1 Shared MAC and Shared IP Support

The 10 GbE controller operates in systems where the same MAC and IP are shared between a platform's host operating system and its MC. In order to support such systems, the 10 GbE controller supports additional shared MAC filtering options on top of what was supported in previous products. This section describes these options and the NC-SI commands used to program them.

Note: All filtering capabilities are exposed via the regular NC-SI packet reduction and packet addition commands and via the SMBus Set Filtering command. The interface described in this section is a more abstract NC-SI interface.

Sharing an IP and MAC Address

NC-SI over MCTP is used in desktop and mobile platforms. These platforms are typically used in enterprise environments outside of a data center. IP subnets in these environments are commonly designed such that more than 50% of their available addresses are assigned.

Hence, assigning a second IP address to an MC would generally necessitate a subnet redesign. Instead, a single IP address is typically shared between the host operating system and an MC in these platforms.

Because it's possible to bind multiple IP addresses to a single MAC address, the 10 GbE controller needs to know the IP address shared by an MC in order to deliver packets to it. An MC uses the *Set IP Address* command to communicate its IP address to the 10 GbE controller.

In order to notify the 10 GbE controller that the MC intends to use a shared MAC, the *Set Shared Mode* command should be given before programming any filter using the regular NC-SI commands (Set MAC address or Set VLAN) or the Intel OEM commands (Section 38.37.6.4.14).

TCP/UDP Ports Owned by an MC

A small subset of the TCP and UDP ports might be dedicated to an MC. The remaining ports are assigned to the host operating system. Hence, port-based filtering and the commands to configure it is required. For example, port-based filtering would be used to route WS-management packets to an MC.

The 10 GbE controller needs to know the ports owned by an MC in order to deliver packets to it. An MC uses the *Set Port* command to communicate its ports to the 10 GbE controller. The 10 GbE controller supports 10 port filters.

The Set Binding command is used to define the combination of MAC, VLAN, IP and ports that should be met to forward packets to the MC.

Sharing Network Infrastructure Packets

In addition to management traffic, an MC needs to monitor network infrastructure traffic along with the host. For each flow, it is possible to define if it should include host traffic only, both host and network or only network.

ARP Filters Enhancement

ARP request message filtering is controlled by the Enable Broadcast Filter command. However, as currently defined, this command causes either all or no ARP requests to go to an MC. For MCTP over SMBus, attempting to forward all ARP requests within a subnet to an MC can easily overwhelm the available bandwidth. Therefore, an option to have the 10 GbE controller forward only ARP requests that contain a Target IP Address value that matches the IP address used by an MC. An amendment to the Enable Broadcast Filter command is defined in the sections that follow to address this requirement.

38.37.3.7 Possible Configurations

This section describes ways of using management filters. Actual usage might vary.

38.37.3.7.1 Dedicated MAC Packet Filtering

- Select one of the eight rules for dedicated MAC filtering.
- Load the host MAC address to one of the management MAC address filters and set the appropriate bit in field 3:0 of the MDEF register.
- Set other bits to qualify which packets are allowed to pass through. For example:
  - Set bit 5 in the MDEF register to qualify with the first manageability VLAN.
  - Set relevant bits 13 to 20 in the MDEF register to qualify with a match to one of the IP addresses.
  - Set any L3/L4 bits (bits 27 to 31 in the MDEF register and bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

38.37.3.7.2 Broadcast Packet Filtering

- Select one of the eight rules for broadcast filtering.
- Set bit 25 in the MDEF register of the decision rule to enforce broadcast filtering.
- Set other bits to qualify which broadcast packets are allowed to pass through. For example:
  - Set bit 5 in the MDEF register to qualify with the first manageability VLAN.
  - Set relevant bits 13 to 20 in the MDEF register to qualify with a match to one of the IP addresses.
  - Set any L3/L4 bits (bits 27 to 31 in the MDEF register and bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

38.37.3.7.3 VLAN Packet Filtering

- Select one of the eight rules for VLAN filtering.
- Set bit 5 to 12 in the MDEF register to qualify with the relevant manageability VLANs.
- Set other bits to qualify which VLAN packets are allowed to pass through. For example:
  - Set any L3/L4 bits (bits 27 to 31 in the MDEF register and bits 16 to 23 in MDEF_EXT) to qualify with any of a set of L3/L4 filters.

38.37.3.7.4 IPv6 Filtering

IPv6 filtering is done using the following IPv6-specific filters:

- IP unicast filtering — requires filtering for link local address and a global address. Filtering setup might depend on whether or not the MAC address is shared with the host or dedicated to manageability:
  - Dedicated MAC address (for example, dynamic address allocation with DHCP does not support multiple IP addresses for one MAC address). In this case, filtering can be done at L2 using two dedicated unicast MAC filters.
  - Shared MAC address (for example, static address allocation sharing addresses with host). In this case, filtering needs to be done at L3, requiring two IPv6 address filters, one per address.
- A neighbor discovery filter — The 10 GbE controller supports IPv6 neighbor discovery protocol. Since the protocol relies on multicast packets, the 10 GbE controller supports filtering of these packets. IPv6 multicast addresses are translated into corresponding Ethernet multicast addresses in the form of 33-33-xx-xx-xx-xx, where the last 32 bits of the address are taken from the last 32 bits of

the IPv6 multicast address. As a result, two direct MAC filters can be used to filter IPv6 solicited-node multicast packets as well as IPv6 all node multicast packets.

38.37.3.7.5 Receive Filtering with Shared IP

When using the legacy SMBus interface or the MCTP interface, it is possible to share the host MAC and IP address with an MC. This functionality is also available when using base NC-SI using Intel OEM commands.

When an MC shares the MAC and IP address with the host, receive filtering is based on identifying specific flows through port allocation. The following setting might be used when using the legacy SMBus interface:

- Select one of the eight rules.
- Set a manageability dedicated MAC filter to the host MAC address and set the matching bit (0-3) in the MDEF register.
- If VLAN is used for management, load one or more management VLAN filters and set the matching bit (5- 12) in the MDEF register.

ARP filter/neighbor discovery filter is enabled when an MC is responsible for handling the ARP protocol. Set bit 27 or bit 28 in the MDEF register for this functionality.

In NC-SI over MCTP, dedicated commands are used to enable shared IP filtering.

38.37.3.8 Determining Manageability MAC Address

If an MC needs to use a dedicated MAC address or configure the automatic ARP response mechanism (only available in SMBus mode), it might be beneficial for an MC to be able to determine the MAC address used by the host.

Both the NC-SI and SMBus interfaces provide an Intel OEM command to read the system MAC address.

A possible use for this is that the MAC address programmed at manufacturing time does not increment by one each time, but rather by two. In this way, an MC can read the system MAC address and add one to it and be guaranteed of a unique MAC address.

Note: Determining the IP address being used by the host is beyond the scope of this document.

38.37.4 OS-to-BMC Traffic

38.37.4.1 Overview

Traditionally, the communication between a host and a local MC is not handled through the network interface and requires a dedicated interface such as an IPMI KCS interface. The 10 GbE controller enables the host and the local MC communication via the regular pass-through interface, and thus enable management of a local console using the same interface used to manage any MC in the network.

When this flow is used, the host sends packets to an MC through the network interface. The 10 GbE controller examines these packets and it then decides if they should be forwarded to an MC. On the inverse path, when an MC sends a packet on the pass-through interface, the 10 GbE controller checks if it should be forwarded to the network, the host, or both. Figure 38-130 shows the flow for OS-to-BMC traffic for the NC-SI over RBT case. OS2BMC is also available when operating over MCTP. It is not available in legacy SMBus mode.

The OS-to-BMC flow can be enabled using the *OS2BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the NVM.

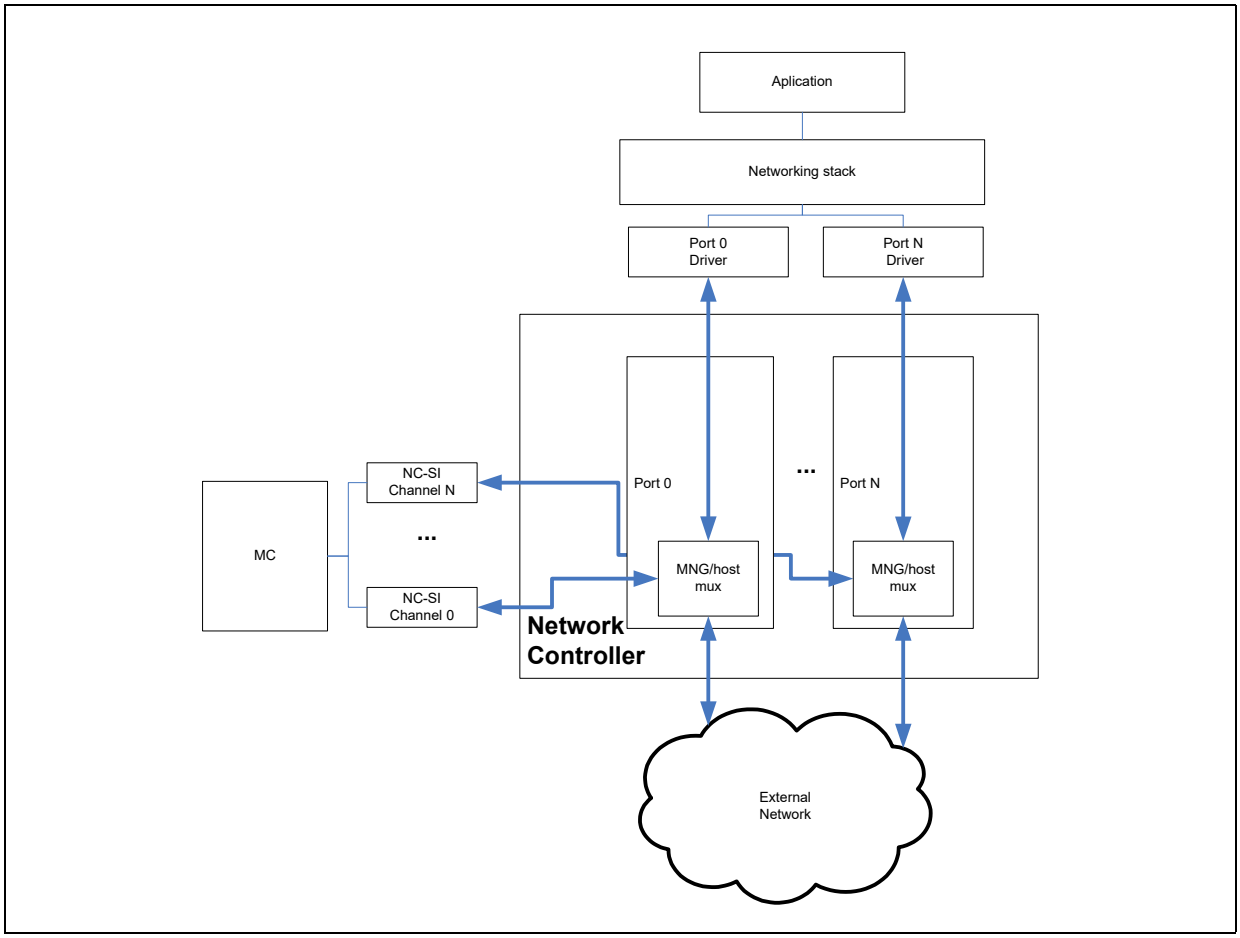


Figure 38-130.OS-to-BMC Flow

The OS-to-BMC flow is enabled only for ports enabled by the NC-SI Enable Channel command or via the *OS2BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the NVM.

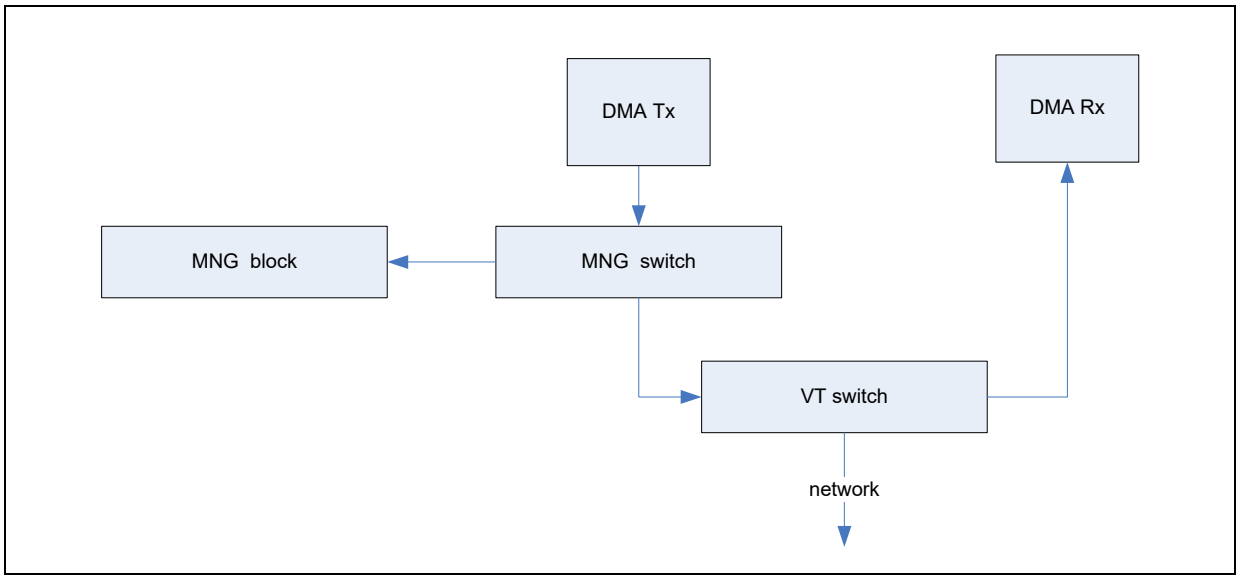
OS-to-BMC traffic must comply with NC-SI specifications and is therefore limited to maximum sized frames of 1536 bytes (in both directions).

38.37.4.2 Filtering

38.37.4.2.1 OS-to-BMC Filtering

Refer to the flow used to filter packets from the MC to the host previously described.

Figure 38-131.OS-to-BMC and VM-to-VM Filtering



Note: Traffic coming from the EMP should not be a candidate for OS2BMC traffic filtering.

Note: In the 10 GbE controller, traffic from the EMP is considered for OS2BMC traffic.

38.37.4.2.2 BMC-to-OS Filtering

Refer to the flow used to filter packets from the host to the BMC previously described.

Note: Traffic sent from the MC does not cause a PME event, even if it matches one of the wake-up filters set by the port.

38.37.4.3 Blocking network-to-BMC Flow

In some systems the MC might have its own private connection to the network and might use a Shortened Product Name port only for the OS-to-BMC traffic. In this case, the BMC-to-network flow should be blocked while enabling the OS-to-BMC and OS-to-network flows.

This can be done by clearing the *PRT_MNG_MANC.EN_BMC2NET* bit for the relevant port. The MC can control this functionality using the Enable Network-to-BMC flow and Disable Network-to-BMC flow NC-SI OEM commands. This can also be controlled using the *Network to BMC disable* field in the NVM OS2BMC Configuration Structure.

Note: The NC-SI channel should not be enabled for receive or transmit before at least one of the *PRT_MNG_MANC.EN_BMC2NET* or *PRT_MNG_MANC.EN_BMC2OS* fields is set, unless only used for AEN transmissions. In this case, the channel might be enabled for receive, but all receive filters should be cleared.

38.37.4.4 OS-to-BMC and Flow Control

The traffic between the host and manageability uses the same buffers as any loopback traffic. Thus, it flows through the transmit buffer and then through the receive buffer. If the transmit buffer is flow controlled, then the host-to-MC traffic is also stopped. If the receive buffer is full, the traffic is dropped or the transmit is stopped according to the flow control policy of this traffic class.

Packets received by manageability (either from the host or from the network) might be dropped if the manageability internal buffers are full.

38.37.4.5 Statistics

Packets sent from the operating system to the MC should be counted by all statistical counters as packets sent by the operating system. If they are sent to both the network and to the MC, then they are counted once.

Packets sent from the MC to the host are counted as packets received by the host. If they are sent to the host and to the network, then they are counted both as received packets and as packet transmitted to the network.

38.37.4.6 OS-to-BMC Enablement

The 10 GbE controller supports the unified network software model for OS-to-BMC traffic, where the OS- to-BMC traffic is shared with the regular traffic. In this model, there is no need for a special configuration of the operating networking stack or the BMC stack, but if the link is down, then the OS-to-BMC communication is stopped.

In order to enable OS-to-BMC either:

- Enable OS2BMC in the port traffic type field in the Traffic Type Parameters NVM word for the relevant port.
- Send an Enable Network-to-BMC command

Note: When OS2BMC is enabled, the operating system must avoid sending packets longer than 1.5 KB to the MC. Such packets are dropped.

38.37.5 SMBus PT Interface

SMBus is the system management bus defined by Intel. It is used in personal computers and servers for low-speed system management communications. This section describes how the SMBus interface operates in legacy PT mode.

38.37.5.1 General

The SMBus sideband interface includes standard SMBus commands used for assigning a slave address and gathering device information as well as Intel proprietary commands used specifically for the pass-through interface.

38.37.5.2 PT Capabilities

This section details manageability capabilities the 10 GbE controller provides while in SMBus mode. PT traffic is carried by the sideband interface as described in Section 38.37.1.

These services are not available in NC-SI mode.

- When operating in SMBus mode, in addition to exposing a communication channel to the LAN for the MC, the 10 GbE controller provides the following manageability services to the MC:
- ARP handling — The 10 GbE controller can be programmed to auto-ARP replying for ARP request packets to reduce the traffic over the MC interconnect.
- Default configuration of filters by NVM — When working in SMBus mode, the default values of the manageability receive filters can be set according to the PT LAN and flex TCO NVM structures.
- Padding of short packets. Packets smaller than 60 bytes but larger than 14 bytes are padded to a legal Ethernet packet.
- CRC calculation — The 10 GbE controller adds an Ethernet CRC on all sent packets.

38.37.5.3 Port-to-SMBus Mapping

The 10 GbE controller is identified on the SMBus manageability link as four different devices (for example, via four different SMBus addresses on which each device is connected to a different LAN port). There is no logical connection between the four devices.

The fail-over between the LAN ports is done by the MC (by sending/receiving packets through different devices). The status report to the MC, ARP handling, DHCP, and other pass-through functionality are unique for each port and configured by the MC.

38.37.5.4 Automatic Ethernet ARP Operation

The 10 GbE controller can offload the Ethernet Address Resolution Protocol (ARP) for the MC in order to reduce the bandwidth required on the SMBus link.

Automatic Ethernet ARP parameters are loaded from the NVM when the 10 GbE controller is powered up or configured through the sideband management interface. The following parameters should be configured in order to enable ARP operation:

- ARP auto-reply enabled
- ARP IP address (to filter ARP packets)
- ARP MAC addresses (for ARP responses)

These are all configurable over the sideband interface using the advanced version of the Receive Enable command.

When an ARP request packet is received and ARP auto-reply is enabled, the 10 GbE controller checks the targeted IP address (after the packet has passed L2 checks and ARP checks). If the targeted IP matches the IP configuration for the 10 GbE controller, it replies with an ARP response.

The 10 GbE controller responds to ARP request targeted to the ARP IP address with the configured ARP MAC address. In case that there is no match, the 10 GbE controller silently discards the packets. If the 10 GbE controller is not configured to do an auto-ARP response, it can be configured to forward the ARP packets to the MC, which can respond to ARP requests.

When the external MC uses the same IP and MAC address of the operating system, the ARP operation should be coordinated with the host operating system.

Note: If sharing the MAC and IP with the host operating system is possible, the 10 GbE controller provides the ability to read the system MAC address, enabling the MC to share the MAC address. However, there is no mechanism provided by the 10 GbE controller to read the IP address. The host operating system (or an agent within) and the MC must coordinate the sharing of IP addresses.

38.37.5.5 SMBus Transactions

This section gives a brief overview of the SMBus protocol. Following is an example for a format of a typical SMBus transaction.

Table 38-526.Typical SMBus Transaction

1	7	1	1	8	1	8	1	1
S	Slave Address	Wr	A	Command	A	PEC	A	P
	1100 001	0	0	0000 0010	0	[Data Dependent]	0	

The top row of the table identifies the bit length of the field in a decimal bit count. The middle row (bordered) identifies the name of the fields used in the transaction. The last row appears only with some transactions, and lists the value expected for the corresponding field. This value can be either hexadecimal or binary.

The SMBus controller is a master for some transactions and a slave for others. The differences are identified in this document.

Shorthand field names are listed in Table 38-527 and are fully defined in the SMBus specification.

Table 38-527.Shorthand Field Names

Field Name	Definition
S	SMBus START Symbol.
P	SMBus STOP Symbol.
PEC	Packet Error Code.
A	ACK (Acknowledge).
N	NACK (Not Acknowledge).
Rd	Read Operation (Read Value = 1b).
Wr	Write Operation (Write Value = 0b).

38.37.5.5.1 SMBus Addressing

The SMBus is presented as up to four SMBus devices on the SMBus (four addresses). All PT functionality is duplicated on the SMBus address, where each SMBus address is connected to a different LAN port. Note that it is not permitted to configure multiple ports to the same SMBus address. When a LAN function is disabled, the corresponding SMBus address is not presented to the MC.

SMBus addresses (enabled from the NVM) can be re-assigned using the SMBus ARP protocol.

In addition to the SMBus address values, all parameters of the SMBus (SMBus channel selection, address mode, and address enable) can be set only through NVM configuration. Note that the NVM is read at the 10 GbE controller's power up and resets.

38.37.5.5.2 SMBus ARP Functionality

The 10 GbE controller supports the SMBus ARP protocol as defined in the SMBus 2.0 specification. The 10 GbE controller is a persistent slave address device so its SMBus address is valid after power-up and loaded from the NVM. The 10 GbE controller supports all SMBus ARP commands defined in the SMBus specification both general and directed.

SMBus ARP capability can be disabled through the NVM.

38.37.5.5.3 SMBus ARP Flow

SMBus ARP flow is based on the status of two flags:

- Address Valid (AV): This flag is set when the 10 GbE controller has a valid SMBus address.
- Address Resolved (AR): This flag is set when the 10 GbE controller SMBus address is resolved (SMBus address was assigned by the SMBus ARP process).

These flags are internal Product Name flags and are not exposed to external SMBus devices.

Since the 10 GbE controller is a Persistent SMBus Address (PSA) device, the AV flag is always set, while the AR flag is cleared after power up until the SMBus ARP process completes. Since AV is always set, the 10 GbE controller always has a valid SMBus address.

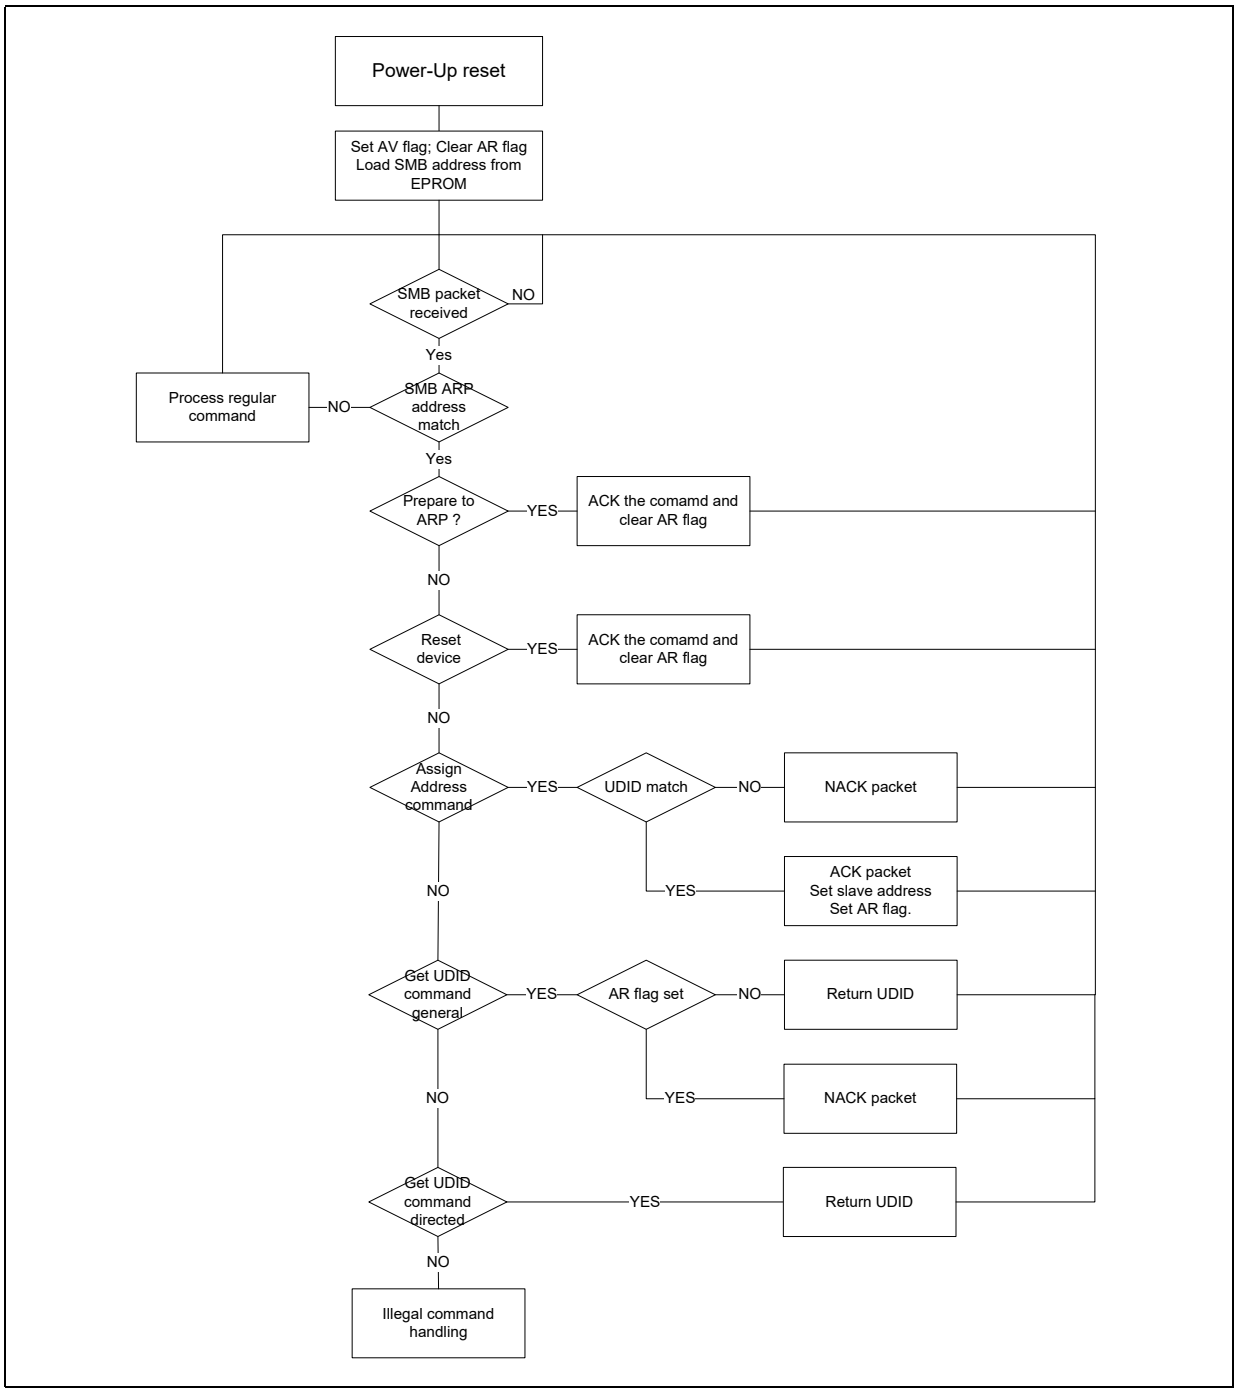
When the SMBus master needs to start an SMBus ARP process, it resets (in terms of ARP functionality) all devices on SMBus by issuing either Prepare to ARP or Reset Device commands. When the 10 GbE controller accepts one of these commands, it clears its AR flag (if set from previous SMBus ARP process), but not its AV flag (the current SMBus address remains valid until the end of the SMBus ARP process).

Clearing the AR flag means that the 10 GbE controller responds to SMBus ARP transactions that are issued by the master. The SMBus master issues a Get UDID command (general or directed) to identify the devices on the SMBus. The 10 GbE controller always responds to the Directed command and to the General command only if its AR flag is not set.

After the Get UDID, The master assigns the 10 GbE controller SMBus address by issuing an Assign Address command. The 10 GbE controller checks whether the UDID matches its own UDID and if it matches, it switches its SMBus address to the address assigned by the command (byte 17). After accepting the Assign Address command, the AR flag is set and from this point (as long as the AR flag is set), the 10 GbE controller does not respond to the Get UDID General command. Note that all other commands are processed even if the AR flag is set. The 10 GbE controller stores the SMBus address that was assigned in the SMBus ARP process in the NVM, so at the next power up, it returns to its assigned SMBus address.

Figure 38-132 shows the 10 GbE controller SMBus ARP flow.

Figure 38-132.SMBus ARP Flow



38.37.5.5.4 SMBus ARP UDID Content

The UDID provides a mechanism to isolate each device for the purpose of address assignment. Each device has a unique identifier. The 128-bit number is comprised of the following fields:

Table 38-528.UDID

1 Byte	1 Byte	2 Bytes	2 Bytes	2 Bytes	2 Bytes	2 Bytes	4 Bytes
Device Capabilities	Version/ Revision	Vendor ID	Device ID	Interface	Subsystem Vendor ID	Subsystem Device ID	Vendor Specific ID
See notes that follow	See notes that follow	0x8086	0x3A84	0x0004/ 0x0024	0x0000	0x0000	See notes that follow
MSB							LSB

Where:

Vendor ID:	The device manufacturer's ID as assigned by the SBS Implementers' Forum or the PCI SIG. Constant value: 0x8086.
Device ID:	The device ID as assigned by the device manufacturer (identified by the Vendor ID field). Constant value: 0x3A84.
Interface:	Identifies the protocol layer interfaces supported over the SMBus connection by the device. Bits 3:0 = 0x4 indicates SMBus Version 2.0. Bit 5 (ASF bit) = 1 in MCTP mode.
Subsystem Fields:	These fields are not supported and return zeros.

Device Capabilities: Dynamic and Persistent Address, *PEC Support* bit:

7	6	5	4	3	2	1	0
Address Type		Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)	PEC Supported
0b	1b	0b	0b	0b	0b	0b	0/1b[1]
MSB							LSB

Notes:

1. The value is set according to the SMBus transaction PEC bit in the NVM.

Version/Revision: UDID Version 1, Silicon Revision:

7	6	5	4	3	2	1	0
Reserved (0)	Reserved (0)	UDID Version			Silicon Revision ID		
0b	0b	001b			See the following table		
MSB							LSB

Silicon Revision ID:

Silicon Version	Revision ID
A0	000b
B0	001b
B1	010b

Vendor Specific ID: Four LSB bytes of the device Ethernet MAC address of the relevant port. The port Ethernet address is taken from the *PRTGL_SAL* registers of the relevant ports. Note that in the 10 GbE controller there are four MAC addresses (one for each port).

1 Byte	1 Byte	1 Byte	1 Byte
MAC Address, Byte 3	MAC Address, Byte 2	MAC Address, Byte 1	MAC Address, Byte 0
MSB			LSB

38.37.5.5.5 SMBus ARP and Multi-Port

The 10 GbE controller responds as four SMBus devices having four sets of AR/AV flags (one for each port). The 10 GbE controller responds four time to the SMBus ARP master, once each for each port. All SMBus addresses are taken from the SMBus ARP address word of the NVM.

Note that the Unique Device Identifier (UDID) is different for the four ports in the version ID field, which represents the MAC address and is different for the four ports. The 10 GbE controller first respond as port 0, and only when an address is assigned, then start responding as port 1, 2 and 3 to the Get UDID command.

38.37.5.5.6 Concurrent SMBus Transactions

The SMBus interface is single threaded. Thus, concurrent SMBus transactions are not permitted. Once a transaction starts, it must complete before an additional transaction is initiated.

A transaction is defined as:

- All the SMBus commands used to receive a packet.
- All the SMBus commands used to send a packet.
- Refer to the read and write SMBus commands used as part of read parameters previously described.
- Refer to the single write SMBus commands previously described.

38.37.5.6 SMBus Notification Methods

The 10 GbE controller supports three methods of notifying the MC that it has information that needs to be read by the MC:

- SMBus alert — Refer to Section 38.37.5.6.1.
- Asynchronous notify.
- Direct receive — refer to Section 38.37.5.6.3.

The notification method used by the 10 GbE controller can be configured from the SMBus using the Receive Enable command. The default method is set by the NVM in the *Notification Method* field in LAN Receive Enable 1.

Note: The SMBus notification method used must be the same for all ports.

The following events cause the 10 GbE controller to send a notification event to the MC:

- Receiving a LAN packet that is designated to the MC.
- Firmware was reset and requires re-initialization.
- Receiving a Request Status command from the MC initiates a status response.

- The 10 GbE controller is configured to notify the MC upon status changes (by setting the EN_STA bit in the Receive Enable command) and one of the following events happen:
  - TCO Command aborted.
  - Link status changed.
  - Power state change.

There can be cases where the MC is hung and not responding to the SMBus notification. The 10 GbE controller has a time-out value (defined in the NVM) to avoid hanging while waiting for the notification response. If the MC does not respond until the time out expires, the notification is de-asserted and all pending data is silently discarded.

Note that the SMBus notification time-out value can only be set in the NVM. The MC cannot modify this value.

38.37.5.6.1 SMBus Alert and Alert Response Method

The SMBus Alert# (SMBALERT_N) signal is an additional SMBus signal that acts as an asynchronous interrupt signal to an external SMBus master. The 10 GbE controller asserts this signal each time it has a message that it needs the MC to read and if the chosen notification method is the SMBus alert method. Note that the SMBus alert method is an open-drain signal which means that other devices besides the 10 GbE controller can be connected on the same alert pin. As a result, the MC needs a mechanism to distinguish between the alert sources.

The MC can respond to the alert by issuing an ARA Cycle command to detect the alert source device. The 10 GbE controller responds to the ARA cycle with its own SMBus slave address (if it was the SMBus alert source) and de-asserts the alert when the ARA cycle is completes. Following the ARA cycle, the MC issues a read command to retrieve the 10 GbE controller message.

Some MCs do not implement the ARA cycle transaction. These MCs respond to an alert by issuing a Read command to the 10 GbE controller (0xC0/0xD0 or 0xDE). The 10 GbE controller always responds to a Read command, even if it is not the source of the notification. The default response is a status transaction. If the 10 GbE controller is the source of the SMBus Alert, it replies the read transaction and then de-asserts the alert after the command byte of the read transaction.

Note: In SMBus Alert mode, the SMBALERT_N pin is used for notification. Each port generate alerts on events that are independent of each other.

Note: If two ports have events to notify, the second alert is asserted only after the first event is handled.

The ARA cycle is an SMBus receive byte transaction to SMBus Address 0001b - 100b. Note that the ARA transaction does not support PEC. The ARA transaction format is as follows:

1	7	1	1	8	1	1	1
S	Alert Response Address	Rd	A	Slave Device Address		A	P
	0001 100	1	0	Manageability Slave SMBus Address	0	1	

Note: If the MC does not react to the alert in the delay defined by the *SMBus Notification Timeout* NVM field, the ALERT pin is de-asserted and the Rx packet indication in the status word is cleared (and packet is dropped).

38.37.5.6.2 Asynchronous notify method

When configured using the asynchronous notify method, the 10 GbE controller acts as a SMBus master and notifies the BMC of one of the events listed in Section 38.37.5.6 by issuing a modified form of the write word transaction. The asynchronous notify transaction SMBus address and data payload is configured using the Section "Receive Enable Command" or using the NVM defaults. Note that the asynchronous notify is not protected by a PEC byte.

1	7	1	1	7	1	1	8	1	8	1	1
S	Target Address	Wr	A	Sending Device Address		A	Data Byte Low	A	Data Byte High	A	P
	MC Slave Address	0	0	MNG Slave SMBus Address	0	0	Interface	0	Alert Value	0	

The target address and data byte low/high are taken from the Section "Receive Enable Command" or NVM configuration.

If the MC does not read the status in the delay defined by the *SMBus Notification Timeout* NVM field, the Rx packet indication in the status word is cleared (and packet is dropped).

38.37.5.6.3 Direct Receive Method

If configured, the 10 GbE controller has the capability to send a message it needs to transfer to the external MC as a master over the SMBus instead of alerting the MC and waiting for it to read the message.

The message format follows. Note that the command that is used is the same command that is used by the external MC in the Block Read command. The opcode that the 10 GbE controller puts in the data is also the same as it put in the Block Read command of the same functionality. The rules for the *F* and *L* flags (bits) are also the same as in the Block Read command.

1	7	1	1	1	1	6	1	
S	Target Address	Wr	A	F	L	Command	A	...
	BMC Slave Address	0	0	First Flag	Last Flag	Receive TCO Command 01 0000b	0	

8	1	8	1		1	8	1	1
Byte Count	A	Data Byte 1	A	...	A	Data Byte N	A	P
N	0		0		0		0	

38.37.5.7 Receive PT flow

The 10 GbE controller is used as a channel for receiving packets from the network link and passing them to the external MC. The MC configures the 10 GbE controller to pass these specific packets to the MC. Once a full packet is received from the link and identified as a manageability packet that should be transferred to the MC, the 10 GbE controller starts the receive TCO flow to the MC.

The 10 GbE controller uses the SMBus notification method to notify the MC that it has data to deliver. Since the packet size might be larger than the maximum SMBus fragment size, the packet is divided into fragments, where the 10 GbE controller uses the maximum fragment size allowed in each fragment (configured via the NVM). The last fragment of the packet transfer is always the status of the packet. As a result, the packet is transferred in at least two fragments. The data of the packet is transferred as part of the receive TCO LAN packet transaction.

When SMBus alert is selected as the MC notification method, the 10 GbE controller notifies the MC on each fragment of a multi-fragment packet. When asynchronous notify is selected as the MC notification method, the 10 GbE controller notifies the MC only on the first fragment of a received packet. It is the MC's responsibility to read the full packet including all the fragments.

Any timeout on the SMBus notification results in discarding the entire packet. Any NACK by the MC causes the fragment to be re-transmitted to the MC on the next Receive Packet command.

The maximum size of the received packet is limited by the 10 GbE controller to 1536 bytes. Packets larger than 1536 bytes are silently discarded. Any packet smaller than 1536 bytes is processed.

38.37.5.8 Transmit PT Flow

The 10 GbE controller is used as the channel for transmitting packets from the external MC to the network link. The network packet is transferred from the MC over the SMBus and then, when fully received by the 10 GbE controller, is transmitted over the network link.

Each SMBus address is connected to a different LAN port. When a packet is received during a SMBus transaction using SMBus address #0, it is transmitted to the network using LAN port #0; it is transmitted through LAN port #1 if received on SMBus address #1, etc.

The 10 GbE controller supports packets up to an Ethernet packet length of 1536 bytes. Since SMBus transactions can only be up to 240 bytes in length, packets might need to be transferred over the SMBus in more than one fragment. This is achieved using the *F* and *L* bits in the command number of the transmit TCO packet Block Write command. When the *F* bit is set, it is the first fragment of the packet. When the *L* bit is set, it is the last fragment of the packet. When both bits are set, the entire packet is in one fragment. The packet is sent over the network link only after all its fragments are received correctly over the SMBus. The maximum SMBus fragment size is defined within the NVM and cannot be changed by the BMC.

The minimum packet length defined by the 802.3 specification is 64 bytes. The 10 GbE controller pads packets that are less than 64 bytes to meet the specification requirements (there is no need for the external MC to pad packets less than 64 bytes). If the packet sent by the MC is larger than 1536 bytes, the 10 GbE controller silently discards the packet. The minimal packet size that the 10 GbE controller can handle is 14 bytes.

The 10 GbE controller calculates the L2 CRC on the transmitted packet and adds its four bytes at the end of the packet. Any other packet field (such as XSUM or VLAN) must be calculated and inserted by the MC (the 10 GbE controller does not change any field in the transmitted packet, other than adding padding and CRC bytes).

If the network link is down when the 10 GbE controller has received the last fragment of the packet from the MC, it silently discards the packet. Note that any link down event during the transfer of any packet over the SMBus does not stop the operation since the 10 GbE controller waits for the last fragment to end to see whether the network link is up again.

38.37.5.8.1 Transmit Errors in Sequence Handling

Once a packet is transferred over the SMBus from the MC to the 10 GbE controller, the *F* and *L* flags should follow specific rules. The *F* flag defines the first fragment of the packet; the *L* flag that the transaction contains the last fragment of the packet. Table 38-529 lists the different flag options in transmit packet transactions.

Table 38-529.Flag Options During Transmit Packet Transactions

Previous	Current	Action/Notes
Last	First	Accept both.
Last	Not First	Error for the current transaction. Current transaction is discarded and an abort status is asserted.
Not Last	First	Error in previous transaction. Previous transaction (until previous First) is discarded. Current packet is processed. No abort status is asserted.
Not Last	Not First	Process the current transaction.

Note: Since every other Block Write command in TCO protocol has both *F* and *L* flags set, they cause flushing any pending transmit fragments that were previously received. When running the TCO transmit flow, no other Block Write transactions are allowed in between the fragments.

38.37.5.8.2 TCO Command Aborted Flow

The 10 GbE controller indicates to the MC an error or an abort condition by setting the *TCO Abort* bit in the general status. The 10 GbE controller might also be configured to send a notification to the MC.

Following is a list of possible error and abort conditions:

- Any error in the SMBus protocol (NACK, SMBus timeouts, etc.).
- If the MC does not respond until the notification timeout (programmed in the NVM) expires.
- Any error in compatibility between required protocols to specific functionality (for example, Rx Enable command with a byte count not equal to 1/14, as defined in the command specification).
- If the 10 GbE controller does not have space to store the transmitted packet from the MC (in its internal buffer space) before sending it to the link, the packet is discarded and the external MC is notified via the *Abort* bit.
- Error in the *F*/*L* bit sequence during multi-fragment transactions.
- An internal reset to the 10 GbE controller's firmware.

38.37.5.9 SMBus Link State Control

While in SMBus mode, the default setting of the link is defined by the *EMP_LINK_ON* bit in Common Firmware Parameters 2 NVM word.

When a channel is enabled through NVM setting or through the RCV_EN option of the Receive Enable command, the link is established (if not already required for other purposes).

If the channel is disabled by clearing of the RCV_EN option, then the link might move back to the default defined by the EMP_LINK_ON if not needed for other purposes.

Note: Before a transition to D3 it is the responsibility of the software device driver to request the PHY to be active for wake-up activities.

38.37.5.10 SMBus ARP Transactions

All SMBus ARP transactions include the PEC byte.

38.37.5.11 Prepare to ARP

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address and is used to inform all devices that the ARP master is starting the ARP process:

1	7	1	1	8	1	8	1	1
S	Slave Address	Wr	A	Command	A	PEC	A	P
	1100 001	0	0	0000 0001	0	[Data Dependent Value]	0	

38.37.5.11.1 Reset device (general)

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address.

1	7	1	1	8	1	8	1	1
S	Slave Address	Wr	A	Command	A	PEC	A	P
	1100 001	0	0	0000 0010	0	[Data Dependent Value]	0	

38.37.5.11.2 Reset Device (Directed)

The Command field is NACKed if bits 7:1 do not match the current SMBus address. This command clears the *Address Resolved* flag (set to false) and does not affect the status or validity of the dynamic SMBus address.

1	7	1	1	8	1	8	1	1
S	Slave Address	Wr	A	Command	A	PEC	A	P
	1100 001	0	0	Targeted Slave Address | 0	0	[Data Dependent Value]	0	

38.37.5.11.3 Assign Address

This command assigns SMBus address. The address and command bytes are always acknowledged.

The transaction is aborted (NACKed) immediately if any of the UDID bytes is different from Product Name UDID bytes. If successful, the manageability system internally updates the SMBus address. This command also sets the *Address Resolved* flag (set to true).

1	7	1	1	8	1	8	1	
S	Slave Address	Wr	A	Command	A	Byte Count	A	· · ·
	1100 001	0	0	0000 0100	0	0001 0001	0	

8	1	8	1	8	1	8	1	
Data 1	A	Data 2	A	Data 3	A	Data 4	A	· · ·
UDID Byte 15 (MSB)	0	UDID Byte 14	0	UDID Byte 13	0	UDID Byte 12	0	

8	1	8	1	8	1	8	1	
Data 5	A	Data 6	A	Data 7	A	Data 8	A	· · ·
UDID Byte 11	0	UDID Byte 10	0	UDID Byte 9	0	UDID Byte 8	0	

8	1	8	1	8	1	
Data 9	A	Data 10	A	Data 11	A	· · ·
UDID Byte 7	0	UDID Byte 6	0	UDID Byte 5	0	

8	1	8	1	8	1	8	1	
Data 12	A	Data 13	A	Data 14	A	Data 15	A	· · ·
UDID Byte 4	0	UDID Byte 3	0	UDID Byte 2	0	UDID Byte 1	0	

8	1	8	1	8	1	1
Data 16	A	Data 17	A	PEC	A	P
UDID Byte 0 (LSB)	0	Assigned Address	0	[Data Dependent Value]	0	

38.37.5.11.4 Get UDID (General and Directed)

The general get UDID SMBus transaction supports a constant command value of 0x03 and, if directed, supports a Dynamic command value equal to the dynamic SMBus address.

If the SMBus address has been resolved (*Address Resolved* flag set to true), the manageability system does not acknowledge (NACK) this transaction. If it's a General command, the manageability system always acknowledges (ACKs) as a directed transaction.

This command does not affect the status or validity of the dynamic SMBus address or the *Address Resolved* flag.

S	Slave Address	Wr	A	Command	A	S	· · ·
	1100 001	0	0	See Below	0		

7	1	1	8	1	
Slave Address	Rd	A	Byte Count	A	· · ·

7	1	1	8	1	
1100 001	1	0	0001 0001	0	

8	1	8	1	8	1	8	1	
Data 1	A	Data 2	A	Data 3	A	Data 4	A	· · ·
UDID Byte 15 (MSB)	0	UDID Byte 14	0	UDID Byte 13	0	UDID Byte 12	0	

8	1	8	1	8	1	8	1	
Data 5	A	Data 6	A	Data 7	A	Data 8	A	· · ·
UDID Byte 11	0	UDID Byte 10	0	UDID Byte 9	0	UDID Byte 8	0	

8	1	8	1	8	1	
Data 9	A	Data 10	A	Data 11	A	· · ·
UDID Byte 7	0	UDID Byte 6	0	UDID Byte 5	0	

8	1	8	1	8	1	8	1	
Data 12	A	Data 13	A	Data 14	A	Data 15	A	· · ·
UDID Byte 4	0	UDID Byte 3	0	UDID Byte 2	0	UDID Byte 1	0	

8	1	8	1	8	1	1
Data 16	A	Data 17	A	PEC	~Ã	P
UDID Byte 0 (LSB)	0	Device Slave Address	0	[Data Dependent Value]	1	

The Get UDID command depends on whether or not this is a Directed or General command.

The General Get UDID SMBus transaction supports a constant command value of 0x03.

The Directed Get UDID SMBus transaction supports a Dynamic command value equal to the dynamic SMBus address with the LSB bit set.

Note: Bit 0 (LSB) of Data byte 17 is always 1b.

38.37.5.12 SMBus PT Transactions

This section details commands (both read and write) that the 10 GbE controller SMBus interface supports for PT.

38.37.5.12.1 Write SMBus Transactions

This section details the commands that the MC can send to the 10 GbE controller over the SMBus interface. The SMBus write transactions table lists the different SMBus write transactions supported by the 10 GbE controller.

TCO Command	Transaction	Command	Fragmentation
Transmit Packet	Block Write	First: 0x84 Middle: 0x04 Last: 0x44	Multiple
Transmit Packet	Block Write	Single: 0xC4	Single
Request Status	Block Write	Single: 0xDD	Single
Receive Enable	Block Write	Single: 0xCA	Single
Force TCO	Block Write	Single: 0xCF	Single
Management Control	Block Write	Single: 0xC1	Single
Update MNG RCV Filter Parameters	Block Write	Single: 0xCC	Single
Set Common Filters	Block Write	Single: 0xC2	Single
Clear All Filters	Block Write	Single: 0xC3	Single

Transmit Packet Command

The Transmit Packet command behavior is detailed in Section 38.37.5.8. The transmit packet fragments have the following format.

The payload length is limited to the maximum payload length set in the NVM. If the overall packet length is bigger than 1536 bytes, the packet is silently discarded.

Function	Command	Byte Count	Data 1	...	Data N
Transmit first fragment	0x84	N	Packet data MSB	...	Packet data LSB
Transmit middle fragment	0x04				
Transmit last fragment	0x44				
Transmit single fragment	0xC4				

Request Status Command

An external MC can initiate a request to read Product Name manageability status by sending a Request Status command. When received, the 10 GbE controller initiates a notification to an external MC when status is ready. After this, the external controller is able to read the status, by issuing a Read Status command (see Section 38.37.5.12.3).

The format is as follows:

Function	Command	Byte Count	Data 1
Request Status	0xDD	1	0

Receive Enable Command

The Receive Enable command is a single fragment command used to configure the 10 GbE controller. This command has two formats: short, 1-byte legacy format (providing backward compatibility with previous components) and long, 14-byte advanced format (allowing greater configuration capabilities). The Receive Enable command format is as follows:

Function	CMD	Byte Count	Data 1	Data 2	...	Data 7	Data 8	...	Data 11	Data 12	Data 13	Data 14
Legacy Receive Enable	0xCA	1	Receive Control Byte	-	...	-	-	...	-	-	-	-
Advanced Receive Enable		14 (0x0E)		MAC Addr MSB		MAC Addr LSB	IP Addr MSB		IP Addr LSB	BMC SMBus Addr	I/F Data Byte	Alert Value Byte

Field	Bit(s)	Description
RCV_EN	0	Receive TCO Enable. 0b = Disable receive TCO packets. 1b = Enable Receive TCO packets. Setting this bit enables all manageability receive filtering operations. Enabling specific filters is done via the NVM or through special configuration commands. ***Note:*** When the *RCV_EN* bit is cleared, all receive TCO functionality is disabled, not just the packets that are directed to the MC (also auto ARP packets).
RCV_ALL	1	Receive All Enable. 0b = Disable receiving all packets. 1b = Enable receiving all packets. Forwards all packets received over the wire that passed L2 filtering to the external MC. This flag has no effect if bit 0 (Enable TCO packets) is disabled.
EN_STA	2	Enable Status Reporting. 0b = Disable status reporting. 1b = Enable status reporting.
EN_ARP_RES	3	Enable ARP Response. 0b = Disable the 10 GbE controller ARP response. The 10 GbE controller treats ARP packets as any other packet, for example, packet is forwarded to the MC if it passed other (non-ARP) filtering. 1b = Enable the 10 GbE controller ARP response. The 10 GbE controller automatically responds to all received ARP requests that match the IP address programmed by the MC. The MC IP address is provided as part of the Receive Enable message (bytes 8:11). If a short version of the command is used, the 10 GbE controller uses IP address configured in the most recent long version of the command in which the EN_ARP_RES bit was set. If no such previous long command exists, then the 10 GbE controller uses the IP address configured in the NVM as ARP Response IPv4 address in the PT LAN configuration structure. If the *CBDM* bit is set, the 10 GbE controller uses the BMC dedicated MAC address in ARP response packets. If the *CBDM* bit is not set, the MC uses the host MAC address. When the enable ARP response feature is activated, the 10 GbE controller uses the following registers to filter in ARP requests. MC should not modify these registers: Manageability Decision Filter – MDEF7 (and corresponding bit 7 in Management Only traffic register – MNGONLY). Fourth IPv4 Filter.

Field	Bit(s)	Description
NM	5:4	Notification Method. Define the notification method the 10 GbE controller uses. 00b = SMBUS alert. 01b = Asynchronous notify. 10b = Direct receive. 11b = Not supported. Changing the notification method in any port updates the notification method of all ports.
Reserved	6	Reserved. Must be set to 1b.
CBDM	7	Configure the MC Dedicated MAC Address. ***Note:*** This bit should be 0b when the *RCV_EN* bit (bit 0) is not set. 0b = The 10 GbE controller shares the MAC address for MNG traffic with the host MAC address, which is specified in NVM words 0x0-0x2. The MAC filtering is not enforced. See the note at the bottom of this table. 1b = The 10 GbE controller uses the MC dedicated MAC address as a filter for incoming receive packets. The MC MAC address is set in bytes 2-7 in this command. If a short version of the command is used, the 10 GbE controller uses the MAC address configured in the most recent long version of the command in which the *CBDM* bit was set. When the dedicated MAC address feature is activated, the 10 GbE controller uses the following registers to filter in all the traffic addressed to the BMC MAC. BMC can not modify these registers: Manageability Decision Filter – MDEF7 (and corresponding bit 7 in Management Only traffic register – PRT_MNG_MNGONLY). Manageability Decision Filter – MDEF6 (and corresponding bit 6 in Management Only traffic register – MNGONLY). Manageability MAC Address Low – PRT_MNG_MMAL[3]. Manageability MAC Address High – PRT_MNG_MMAH[3]. When the dedicated MAC address feature is cleared, these registers are not programmed and the BMC may use other filters to enforce MAC filtering using the Update Management Receive Filter Parameters command.

Management MAC Address (Data Bytes 7:2)

Ignored if the *CBDM* bit is not set. This MAC address is used to configure the dedicated MAC address. In addition, it is used in the ARP response packet when the *EN_ARP_RES* bit is set. This MAC address is also used when *CBDM* bit is set in subsequent short versions of this command.

Management IP Address (Data Bytes 11:8)

This IP address is used to filter ARP request packets.

Asynchronous Notification SMBus Address (Data Byte 12)

This address is used for the asynchronous notification SMBus transaction and for direct receive. The SMBus address is stored in bit 7:1 of this byte. Bit 0 is always 0b.

Interface Data (Data Byte 13)

Interface data byte used in asynchronous notification.

Alert Value Data (Data Byte 14)

Alert value data byte used in asynchronous notification.

Force TCO Command

This command causes the 10 GbE controller to perform a TCO reset, TCO isolate, or firmware reset

TCO reset — If force TCO reset is enabled in the NVM, the force TCO reset clears the data path (Rx/Tx) of the 10 GbE controller to enable the MC to transmit/receive packets through the 10 GbE controller by asserting a global reset. This command should only be used when the MC is unable to transmit receive and suspects that the 10 GbE controller is inoperable. The command also causes the LAN software device driver to unload. It is recommended to perform a system restart to resume normal operation.

TCO isolate — if TCO isolate is enabled in the NVM, the TCO Isolate command disables PCIe write operations to the LAN port. If TCO isolate is disabled in NVM, the 10 GbE controller does not execute the command but sends a response to the MC with successful completion. Following a TCO isolate, management sets *EMP_TCO_ISOLATE.EMP_TCO_ISOLATE* to 1b for all the PFs associated with the port on which this command is received.

Firmware reset — This command causes re-initialization of all the embedded controller functions and re-load of related NVM words (like a firmware patch code). Applying this command resets the entire device as well as having an effect on TCO reset. A firmware reset is achieved by setting the *GSCR.SET_FWRST* aux bit.

Note: A firmware reset causes a global reset of the entire device (GLOBR).

The 10 GbE controller considers the Force TCO Reset command as an indication that the operating system is unavailable. The Force TCO command format is as follows:

Function	Command	Byte Count	Data 1
Force TCO Reset	0xCF	1	TCO Mode

Where TCO mode is:

Field	Bit(s)	Description
DO_TCO_RST	0	Perform TCO Reset. 0b = Do nothing. 1b = Perform TCO reset.
DO_TCO_ISOLATE[1]	1	Do TCO Isolate. 0b = Enable PCIe write access to LAN port. 1b = Isolate host PCIe write operation to the port. Should be used for debug only.
RESET_MGMT	2	Reset Manageability; re-load manageability NVM words. 0b = Do nothing. 1b = Issue firmware reset to manageability. Setting this bit generates a one-time firmware reset. Following the reset, management related data from NVM is loaded.
Reserved	7:3	Reserved (set to 0x00).

Notes:

1. TCO isolate host write operation enabled in NVM.

Note: Only one of the fields should be set in a given command. Setting more than one field might yield unexpected results.

Management Control

This command is used to set generic manageability parameters. The parameters are listed in Table 38-530. The command is 0xC1 stating that it is a Management Control command. The first data byte is the parameter number and the data afterwards (length and content) are parameter specific as listed in Table 38-530.

Note: If the parameter that the MC sets is not supported by the 10 GbE controller. The 10 GbE controller does not NACK the transaction. After the transaction ends, the 10 GbE controller discards the data and asserts a transaction abort status.

The Management Control command format is as follows:

Function	Command	Byte Count	Data 1	Data 2	...	Data N
Management Control	0xC1	N	Parameter Number	Parameter Dependent		

Table 38-530.Management control command parameters/content

Parameter	#	Parameter Data
Keep PHY Link Up	0x00	A single byte parameter: Data 2: Bit 0 = Set to indicate that the PHY link for this port should be kept up throughout system resets. This is useful when the server is reset and the MC needs to keep connectivity for a manageability session. Bit [7:1] = Reserved. 0b = Disabled. 1b = Enabled.

Update Management Receive Filter Parameters

This command is used to set the manageability receive filters parameters. The command is 0xCC. The first data byte is the parameter number and the data that follows (length and content) are parameter specific as listed in management RCV filter parameters.

If the parameter that the MC sets is not supported by the 10 GbE controller, then the 10 GbE controller does not NACK the transaction. After the transaction ends, the 10 GbE controller discards the data and asserts a transaction abort status.

The update management RCV receive filter parameters command format is as follows:

Function	Command	Byte Count	Data 1	Data 2	...	Data N
Update Manageability Filter Parameters	0xCC	N	Parameter Number	Parameter Dependent		

Table 38-531 lists the different parameters and their content.

Table 38-531.Management Receive Filter Parameters

Parameter	Number	Parameter Data
Filters Enables	0x1	Defines the generic filters configuration. The structure of this parameter is four bytes as the Manageability Control (PRT_MNG_MANC) register. The general filter enable is in the Receive Enable command that enables receive filtering.
MNGONLY Configuration	0xF	This parameter defines which of the packets types identified as manageability packets in the receive path will never be directed to the host memory. Data 2:5 = PRT_MNG_MNGONLY register bytes - Data 2 is the MSB.
Flex Filter 0 Enable Mask and Length	0x10	Flex Filter 0 Mask. Data 17:2 = Mask. Bit 0 in data 2 is the first bit of the mask. Data 19:18 = Reserved. Should be set to 00b. Date 20 = Flexible filter length.

Table 38-531.Management Receive Filter Parameters

Parameter	Number	Parameter Data
Flex Filter 0 Data	0x11	Data 2 — Group of flex filter's bytes: 0x0 = bytes 0-29. 0x1 = bytes 30-59. 0x2 = bytes 60-89. 0x3 = bytes 90-119. 0x4 = bytes 120-127. Data 3:32 = Flex filter data bytes. Data 3 is LSB. Group's length is not a mandatory 30 bytes; it might vary according to filter's length and must NOT be padded by zeros.
Decision Filters	0x61	This command is obsolete and should not be used. Use 0x68 instead.
VLAN Filters	0x62	Three bytes are required to load the VLAN tag filters. Data 2: VLAN filter number. Data 3: MSB of VLAN filter. Data 4: LSB of VLAN filter.
Flex Port Filters	0x63	Three to four bytes are required to load the manageability flex port filters. Data 2 = Flex port filter number. Data 3 = MSB of flex port filter. Data 4 = LSB of flex port filter. Data 5: Bit 0 = Match UDP ports. Bit 1 = Match TCP ports. Bit 2 = Match destination port (0) or source port (1). If Data 5 is not present, the match is done on TCP and UDP destination ports (legacy behavior).
IPv4 Filters	0x64	Five bytes are required to load the IPv4 address filter. Data 2 = IPv4 address filter number (3:0). Data 3 = LSB of IPv4 address filter. … Data 6 = MSB of IPv4 address filter.
IPv6 Filters	0x65	17 bytes are required to load the IPv6 address filter. Data 2 = IPv6 address filter number (3:0). Data 3 = LSB of IPv6 address filter. … Data 18 = MSB of IPv6 address filter.
MAC Filters	0x66	Seven bytes are required to load the MAC address filters. Data 2 = MAC address filters pair number (3:0). Data 3 = MSB of MAC address. … Data 8 = LSB of MAC address.
EtherType Filters	0x67	Five bytes to load EtherType filters (METF). Data 2 = METF filter index (valid values are 0, 1, 2, 3). Data 3 = MSB of METF. ... Data 6 = LSB of METF.
Extended Decision Filter	0x68	Nine bytes to load the extended decision filters (MDEF_EXT and MDEF). Data 2 = MDEF filter index (valid values are 0...6). Data 3 — MSB of MDEF_EXT (DecisionFilter1). .... Data 6 = LSB of MDEF_EXT (DecisionFilter1). Data 7 = MSB of MDEF (DecisionFilter0). .... Data 10 = LSB of MDEF (DecisionFilter0). The command overwrites any previously stored value.

Table 38-531.Management Receive Filter Parameters

Parameter	Number	Parameter Data
Management Special Filter Modifiers	0x69	Four bytes to load the management special filter modifiers. Data 2 = MSB of MSFM register. ... Data 5 = LSB of MSFM register.

Table 38-532.Filter enable parameters

Bit	Name	Description
16:0	Reserved	Reserved.
17	RCV_TCO_EN	Receive TCO Packets Enabled. When this bit is set it enables the receive flow to the manageability block. This bit should be set only if at least one of EN_BMC2OS or EN_BMC2NET bits are set. This bit is usually set using the receive enable command (see Section , "Receive Enable Command").
18	KEEP_PHY_LINK_UP	Block PHY reset and power state changes. When this bit is set the PHY reset and power state changes does not get to the PHY.
22:19	Reserved	Reserved.
23	Enable Xsum Filtering to MNG	When this bit is set, only packets that pass the L3 and L4 checksum are send to the manageability block.
24	Reserved	Reserved.
25	FIXED_NET_TYPE	Fixed Net Type. If set, only packets matching the net type defined by the *NET_TYPE* field passes to manageability. Otherwise, both tagged and un-tagged packets can be forwarded to the manageability engine.
26	NET_TYPE	Net Type. 0b = Pass only un-tagged packets. 1b = Pass only VLAN tagged packets. Valid only if *FIXED_NET_TYPE* is set.
31:27	Reserved	Reserved.

Set Common Filters Command

The Set Common Filters command is a single fragment command capable of configuring the most common filters.

Note: If this command is used, all the other commands that programs forwarding filters should not be used (apart from the Clear All Fitters command). When this command is received, an implied Clear All Filters command is done before the application of this command.

The Set Common Filters command has two possible formats:

IPv4 format:

Function	Command	Byte Count	Data 1	Data 2:4	5:10	Data 11	Data 12	Data 13	Data 14:17
Set Common Filters	0xC2	17	Opcode = 0	Receive Control - see Table 38-533	MAC Address	BMC Alert Address	Interface Data Byte	Alert Value Byte	IPv4 Address

IPv6 format:

Function	Command	Byte Count	Data 1	Data 2:4	5:10	Data 11	Data 12	Data 13	Data 14:29
Set Common Filters	0xC2	29	Opcode = 0	Receive Control - see Table 38-533	MAC Address	BMC Alert Address	Interface Data Byte	Alert Value Byte	IPv6 Address

Table 38-533.Set Common Filters Receive Control Bytes

Byte	Bit	Field	Description
1	0	RCV_EN	Receive TCO Packets Enabled. When this bit is set it enables the receive flow to the manageability block. This bit should be set only if at least one of EN_BMC2O or EN_BMC2NET bits are set.
	1	EN_STA	Enable Status Reporting. 0b = Disable status reporting. 1b = Enable status reporting.
	2	Auto ARP	Automatically respond to ARP packets. Ignored in IPv6 mode. If this bit is set, broadcast ARP packets are handled by the 10 GbE controller and ARP requests to the IP address set in the command are responded to. Mutually exclusive to Configure ARP/ Neighborhood Filter bit. If this bit is set, the IP address must be valid. This bit is ignored if RCV_EN is cleared.
	3	Enable Xsum Filtering to MNG	When this bit is set, only packets that pass the L3 and L4 checksum are send to the manageability block. This bit is ignored if RCV_EN is cleared.
	5:4	Reserved	Reserved.
	7:6	Notification Method	Notification Method. Define the notification method the 10 GbE controller uses. 00b = SMBus alert. 01b = Asynchronous notify. 10b = Direct receive. 11b = Not supported.

Table 38-533.Set Common Filters Receive Control Bytes

Byte	Bit	Field	Description
2	8	CBDM	Configure the BMC Dedicated MAC Address. 0b = The 10 GbE controller shares the MAC address for manageability traffic with the host MAC address, which is specified in NVM words 0x0-0x2. 1b = The 10 GbE controller uses the MC dedicated MAC address as a filter for incoming receive packets. The MC MAC address is set in bytes 5:1 in this command. This bit is ignored if RCV_EN is cleared.
	9	Configure IP Address Filter	Automatically configure an IP address filter. If this bit is set, only packets matching this IP address is forwarded. If the *CBDM* bit is set, only packets matching the MAC and IP address is forwarded. This bit is ignored if RCV_EN is cleared.
	10	Configure RMCP 0x26F Filter	Automatically configure standard IPMI port 0x26F filters. If this bit is set, only packets matching this port is forwarded. If the *CBDM/ Configure IP Address Filter* bits are set, only packets matching the MAC and IP address and this port is forwarded. The other port enable bit (11) might add additional forwarding conditions. This bit is ignored if RCV_EN is cleared.
	11	Configure RMCP 0x298 Filter	Automatically configure standard IPMI port 0x298 filter. If this bit is set, only packets matching this port is forwarded. If the *CBDM/ Configure IP Address Filter* bits are set, only packets matching the MAC and IP address and this port is forwarded. The other port enable bit (10) might add additional forwarding conditions. This bit is ignored if RCV_EN is cleared.
	12	Configure ARP/ Neighborhood Filter	Automatically configure filters to enable this traffic to the MC (mutually exclusive to *Auto ARP* bit). If this bit is set, broadcast ARP packets are forwarded to the MC. In IPv4 mode, setting this bit enables forwarding of broadcast ARP requests and responses and unicast ARP responses. If the IP address is set, only a response to this address is forwarded. In IPv6 mode, setting this bit enables forwarding of all types of neighbor discovery and MLD ICMPv6 packet types: 0x86 (134d) = Router advertisement. 0x87 (135d) = Neighbor solicitation. 0x88 (136d) = Neighbor advertisement. 0x89 (137d) = Redirect. 0x82 (130d) = MLD query. 0x83 (131d) = MLDv1 report. 0x84 (132d) = MLD done. 0x8F (143d) = MLDv2 report.
	13	Configure DHCP port 0x44 Filter	Automatically configure DHCP port 44 filter to the MC. If this bit is set, multicast packets matching this port is forwarded. Otherwise, multicast packets are not forwarded to the MC. This bit is ignored if RCV_EN is cleared or in IPv6 mode.
	15:14	Reserved	Reserved.
3	16	Disable Host ARP	Configure ARP requests and network neighborhood packets not to go to the host. This bit should be cleared during normal operation. Ignored if both bit 12 and bit 2 are cleared or if RCV_EN is cleared.
	17	Disable Host DHCP	Configure DHCP packets (port 0x44) not to go to host. This bit should be cleared in normal operation. Ignored if bit 13 is cleared, RCV_EN is cleared, or in IPv6 mode.
	24:18	Reserved	Reserved.

Clear All Filters Command

The Clear all Filters command is a single fragment command capable of clearing all the receive filters currently programmed for manageability traffic.

Function	Command	Byte Count	Data
Clear all Filters	0xC3	1	0x00

38.37.5.12.2 Read SMBus Transactions

This section details the PT read transactions that the MC can send to the 10 GbE controller over the SMBus.

SMBus read transactions lists the different SMBus read transactions supported by the 10 GbE controller. All the read transactions are compatible with SMBus read block protocol format.

Table 38-534.SMBus Read Transactions

TCO Command	Transaction	Command	Opcode	Fragments
Receive TCO Packet	Block Read	0xD0 or 0xC0	First: 0x90 Middle: 0x10 Last[1]: 0x50	Multiple
Read Status	Block Read	0xD0 or 0xC0 or 0xDE	Single: 0xDD	Single
Get System MAC Address	Block Read	0xD4	Single: 0xD4	Single
Read Management Parameters	Block Read	0xD1	Single: 0xD1	Single
Read Management RCV Filter Parameters	Block Read	0xCD	Single: 0xCD	Single
Read Receive Enable Configuration	Block Read	0xDA	Single: 0xDA	Single
Get Controller Information	Block Read	0xD5	Single: 0xD5	Single
Get Common Filters	Block Read	0xD3	Single: 0xD3	Single

Notes:

1. The last fragment of the receive TCO packet is the packet status.

0xC0 or 0xD0 commands are used for more than one payload. If the MC issues these read commands, and the 10 GbE controller has no pending data to transfer, it always returns as default opcode 0xDD with the 10 GbE controller status and does not NACK the transaction.

If an SMBus Quick Read command is received, it is handled as a Product Name Request Status command.

Receive TCO LAN Packet Transaction

The MC uses this command to read packets received on the LAN and its status. When the 10 GbE controller has a packet to deliver to the MC, it asserts the SMBus notification for the MC to read the data (or direct receive). Upon receiving notification of the arrival of a LAN receive packet, the MC begins issuing a Receive TCO packet command using the block read protocol.

A packet can be transmitted to the MC in at least two fragments (at least one for the packet data and one for the packet status). As a result, the MC should follow the *F* and *L* bit of the opcode.

The opcode can have these values:

- 0x90 — First fragment
- 0x10 — Middle fragment
- When the opcode is 0x50, this indicates the last fragment of the packet, which contains packet status.

If a notification timeout is defined (in the NVM) and the MC does not finish reading the entire packet within the timeout period, since the packet has arrived, the packet is silently discarded. The time spent in ARA cycle or in reading the packet is not counted by the timeout counter.

Following is the receive TCO packet format and the data format returned from the 10 GbE controller.

Function	Command
Receive TCO Packet	0xC0 or 0xD0

Function	Byte Count	Data 1 (Opcode)	Data 2	...	Data N
Receive TCO First Fragment	N	0x90	Packet Data Byte	...	Packet Data Byte
Receive TCO Middle Fragment		0x10			
Receive TCO Last Fragment	9 (0x9)	0x50	See the section that follows.		

Receive TCO LAN Status Payload Transaction

This transaction is the last transaction that the 10 GbE controller issues when a packet received from the LAN is transferred to the MC. The transaction contains the status of the received packet.

The format of the status transaction is as follows:

Function	Byte Count	Data 1 (Opcode)	Data 2 – Data 17 (Status Data)
Receive TCO Long Status	9 (0x9)	0x50	See as follows.

The status is 8 bytes where byte 0 (bits 7:0) is set in Data 2 of the status and byte 7 in Data 9 of the status. Table 38-535 lists the content of the status data.

Table 38-535.CO LAN Packet Status Data

Name	Bits	Description
Packet Length	13:0	Packet length including CRC, only 14 LSB bits.
Reserved	15:14	Reserved.
Packet status	31:16	See Table 38-536.
VLAN	47:32	The two bytes of the VLAN header tag.
MNG status	63:48	See Table 38-537. This field should be ignored if Receive TCO is not enabled.

Table 38-536.Packet Status Information

Field	Bit(s)	Description
Reserved	15:4	Reserved.
LAN#	3:2	Indicates the source port of the packet.
VP	1	VLAN Stripped (indicates if the VLAN is part of the packet, or was removed).
CRC stripped	0	Insertion of CRC is needed.

Table 38-537.MNG Status

Name	Bits	Description
Reserved	15:9	Reserved.
Decision Filter match	8	Set when there is a match to one of the decision filters.
Decision Filter index	7:4	Indicates which of the decision filters match the packet. (allows for up to 16 filters - although only 8 are currently supported).
MNG VLAN Address Match	3	Set when the manageability packet matches one of the manageability VLAN filters.
Pass MNG VLAN Filter Index	2:0	Indicates which of the VLAN filters match the packet.

38.37.5.12.3 Read Status Command

The MC should use this command after receiving a notification from the 10 GbE controller (such as SMBus alert). The 10 GbE controller also sends a notification to the MC in either of the following two cases:

- The MC asserts a request for reading the status.
- The 10 GbE controller detects a change in one of the Status Data 1 bits or NVM error bit in Data 2 (and was set to send status to the MC on status change) in the Receive Enable command.

Note: Commands 0xC0/0xD0 are for backward compatibility and can be used for other payloads. The 10 GbE controller defines these commands in the opcode as well as which payload this transaction is. When the 0XDE command is set, the 10 GbE controller always returns opcode 0XDD with the 10 GbE controller status. The MC reads the event causing the notification, using the Read Status command as follows.

The 10 GbE controller's response to one of the commands (0xC0 or 0xD0) in a given time as defined in the SMBus Notification Timeout and Flags word in the NVM.

Function	Command
Read Status	0XC0 or 0XD0 or 0XDE

Function	Byte Count	Data 1 (Opcode)	Data 2 (Status Data 1)	Data 3 (Status Data 2)
Receive TCO Partial Status	3	0XDD	See as follows.	

This command can also be executed using the I^2C quick read format as follows.

1	7	1	1	8	1	8	1	8	1	1
Start	Slave Address	Rd	Ack	Byte Count	Ack	Status Data 1	Ack	Status Data 2	Ack	Stop
		1	0	0000 0002	0		0		1	

Table 38-538 lists the status data byte 1 parameters.

Table 38-538.Status Data Byte 1

Bit	Name	Description
7	LAN Port LSB	LAN port LSB together with LAN Port MSB define port that sent status. See further information in the description of LAN Port MSB (bit 2).
6	TCO Command Aborted	1b = A TCO command abort event occurred since the last read status cycle. 0b = A TCO command abort event did not occur since the last read status cycle.
5	Link Status Indication	0b = LAN link down. 1b = LAN link up.
4	PHY Link Forced Up	Contains the value of the *PHY_Link_Up* bit. When set, indicates that the PHY link is configured to keep the link up.
3	Initialization Indication	0b = An NVM reload event has not occurred since the last read status cycle. 1b = An NVM reload event has occurred since the last read status cycle[1].
2	LAN Port MSB	Defines together with LAN Port LSB the port that sent the status: Lan Port MSB / Lan Port LSB 0 / 0 — Status came from LAN port 0. 0 / 1 — Status came from LAN port 1. 1 / 0 — Status came from LAN port 2. 1 / 1 — Status came from LAN port 3.
1:0	Power State	00b = Dr state. 01b = D0u state. 10b = D0 state. 11b = D3 state. When more than one function is mapped to the same port, the highest power state of the mapped functions is reported according to the following order: Dr < D3 < D0u < D0.

Notes:

1. This indication is asserted when the 10 GbE controller the manageability block reloads the NVM and its internal database is updated to the NVM default values. This is an indication that the external MC should reconfigure the 10 GbE controller, if other values other than the NVM default should be configured.

Status data byte 2 is used by the MC to indicate whether the LAN device driver is up and running.

The LAN device driver valid indication is a bit set by the LAN device driver during initialization; the bit is cleared when the LAN device driver enters a Dx state or is cleared by the hardware on a PCI reset.

Table 38-539 lists status data byte 2.

Table 38-539.Status Data Byte 2

Bit	Name	Description
7:6	Reserved	Reserved.
5	NVM Error	If set, indicates that a CRC/checksum error was detected in one of the manageability related NVM sections.
4	Reserved	Reserved.
3	Driver Valid Indication	0b = LAN driver is not up. 1b = LAN driver is up.

Get System MAC Address

The get system MAC address returns the system MAC address over to the SMBus. This command is a single-fragment read block transaction that returns the system MAC address.

When a single function is defined on the port, it returns the LAN MAC address of this function as read from the PF allocations NVM section or from the alternate RAM or as set by the Manage MAC Address Write AQ command. When more than one function is defined on the port, it returns the address of the lowest defined function on this port.

Get system MAC address format:

Function	Command
Get system MAC address	0xD4

Data returned from the 10 GbE controller:

Function	Byte Count	Data 1 (Opcode)	Data 2	...	Data 7
Get system MAC address	7	0xD4	MAC address MSB	...	MAC address LSB

Read Management Parameters

In order to read the management parameters, the MC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the MC wants to read. The second transaction is block read that reads the parameter.

Block write transaction:

Function	Command	Byte Count	Data 1
Management control request	0xC1	1	Parameter number

Following the block write, the MC should issue a block read that reads the parameter that was set in the Block Write command:

Function	Command
Read management parameter	0xD1

Data returned:

Function	Byte Count	Data 1 (Opcode)	Data 2	Data 3	...	Data N
Read management parameter	N	0xD1	Parameter number	Parameter dependent		

The returned data is in the same format of the MC command.

The returned data is as follow.

Parameter	#	Parameter Data
Keep PHY Link Up	0x00	A single byte parameter: Data 2 — Bit 0 = Set to indicate that the PHY link for this port should be kept up. Sets the keep_PHY_link_up bit. When cleared, clears the keep_PHY_link_up bit. Bit [7:1] = Reserved.
Wrong parameter request	0xFE	Returned by the 10 GbE controller only. This parameter is returned on a read transaction, if in the previous Read command the MC sets a parameter that is not supported by the 10 GbE controller.
Product Name is not ready	0xFF	Returned by the 10 GbE controller only, on a Read Parameters command when the data that should have been read is not ready. This parameter has no data. The MC should retry the read transaction. This value is also returned if the byte count is illegal or if the read command is not preceded by a Write command.

The parameter that is returned might not be the parameter requested by the MC. The MC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the 10 GbE controller is not ready yet. The MC should retry the read transaction.

It is responsibility of the MC to follow the procedure previously defined. When the MC sends a Block Read command (as previously described) that is not preceded by a Block Write command with bytecount=1, the 10 GbE controller sets the parameter number in the read block transaction to be 0xFF.

Read Management Receive Filter Parameters

In order to read the management receive filter parameters, the MC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the MC wants to read. The second transaction is block read that read the parameter.

Block write transaction:

Function	Command	Byte Count	Data 1	Data 2
Update MNG RCV filter parameters	0xCC	1 or 2	Parameter number	Parameter data

The different parameters supported for this command are the same as the parameters supported for the update management receive filter parameters.

Following the block write the MC should issue a block read that reads the parameter that was set in the Block Write command:

Function	Command
Request MNG RCV filter parameters	0xCD

Data returned from the 10 GbE controller:

Function	Byte Count	Data 1 (Opcode)	Data 2	Data 3	...	Data N
Read MNG RCV filter parameters	N	0xCD	Parameter number	Parameter dependent		

The parameter that is returned might not be the parameter requested by the MC. The MC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the 10 GbE controller should supply is not ready yet. The MC should retry the read transaction.

It is MC's responsibility to follow the procedure previously defined. When the MC sends a Block Read command (as previously described) that is not preceded by a Block Write command with bytecount=1, the 10 GbE controller sets the parameter number in the read block transaction to be 0xFF.

Parameter	#	Parameter Data
Filters Enable	0x01	None.
MNGONLY Configuration	0x0F	None.
Flex Filter Enable Mask and Length	0x10	None.

Parameter	#	Parameter Data
Flex Filter Data	0x11	Data 2 — Group of Flex Filter's Bytes: 0x0 = Bytes 0-29. 0x1 = Bytes 30-59. 0x2 = Bytes 60-89. 0x3 = Bytes 90-119. 0x4 = Bytes 120-127.
Filters Valid	0x60	None.
Decision Filters	0x61	This command is obsolete. Use 0x68 instead.
VLAN Filters	0x62	One byte to define the accessed VLAN tag filter (PRT_MNG_MAVTV). Data 2 — VLAN Filter number.
Flex Ports Filters	0x63	One byte to define the accessed manageability flex port filter (PRT_MNG_MFUTP). Data 2 — Flex port filter number.
IPv4 Filter	0x64	One byte to define the accessed IPv4 address filter (PRT_MNG_MIPAF4). Data 2 — IPv4 address filter number.
IPv6 Filters	0x65	One byte to define the accessed IPv6 address filter (PRT_MNG_MIPAF6). Data 2 — Pv6 address filter number.
MAC Filters	0x66	One byte to define the accessed MAC address filters pair (PRT_MNG_MMAL, PRT_MNG_MMAH). Data 2 — MAC address filters pair number (0-3).
EtherType Filters	0x67	1 byte to define EtherType filters (PRT_MNG_METF). Data 2 — METF filter index (valid values are 0 - 3).
Extended Decision Filter	0x68	1 byte to define the extended decisions filters (PRT_MNG_MDEF_EXT and PRT_MNG_MDEF). Data 2 — MDEF filter index (valid values are 0 - 6).
Management Special Filter Modifiers	0x69	
Wrong parameter request	0xFE	Returned by the 10 GbE controller only. This parameter is returned on a read transaction, if in the previous Read command the MC sets a parameter that is not supported by the 10 GbE controller.
Intel® C620 Series Chipset is not ready	0xFF	Returned by the 10 GbE controller only on a Read Parameters command when the data that should have been read is not ready. This parameter has no data. This value is also returned if the byte count is illegal or if the Read command is not preceded by a Write command.

Get Controller Information Command

The MC uses this command to get the controller identification. Each parameter is returned using a different parameter in the block write transaction.

In order to read the controller information, the MC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the MC wants to read. The second transaction is block read that read the parameter.

Block write transaction:

Function	Command	Byte Count	Data 1
Get Controller Information	0xD5	1	Parameter number

Following the block write, the MC should issue a block read that reads the parameter that was set in the Block Write command:

Function	Command
Get Controller Information	0xD5

Data returned from the 10 GbE controller:

Function	Byte Count	Command	Data 2 (Op-Code)	Data 3 -n
Get Controller Information	See Table 38-540.	0xD5	See Table 38-540.	See Table 38-540 for the data for each opcode.

Table 38-540.Get Controller Information Data

Parameter	Byte Count	Description	Notes
0x00	5	Data 4:3: Device ID. Data 5: Silicon Revision (RevID).	This is the hardware default value, not any value programmed via the NVM.
0x0B	4	Data 4:3 NVM Image version.	
0x0C	6	Data 6:3: Firmware ROM Internal version.	
0x0D	6	Data 6:3: Firmware Flash Internal version.	
0x0E	4	Data 4:3: PXE firmware version.	MajorVersion.MinorVersion.Build.SubBuild. If a version is not found, a value of 0xFFFF is returned.
0x0F	4	Data 4:3: iSCSI firmware version.	
0x10	4	Data 4:3: uEFI firmware version.	
0x16	4	Reserved.	
0xFE	2	Wrong parameter request.	Returned by the 10 GbE controller only. This parameter is returned on a read transaction, if in the previous Read command the MC sets a parameter that is not supported by the 10 GbE controller.
0xFF	2	Product Name is not ready.	Returned by the 10 GbE controller only, on a Read Parameters command when the data that should have been read is not ready. This parameter has no data. The MC should retry the read transaction. This value is also returned if the byte count is illegal or if the Read command is not preceded by a Write command.

Get Common Filters Command

The MC uses this command to get the common filters setting. This data can be configured when using Set Common Filters command. The first transaction is a block write that alerts that the MC wants to read the filters configuration. The second transaction is block read that read the configuration.

Block write transaction:

Function	Command	Byte count	Data
Get Common Filters	0xD3	1	0x00

Following the block write the MC should issue a block read that reads the filter settings:

Function	Command
Get Common filters	0xD3

Data returned from the 10 GbE controller:

Function	Byte Count	Command	Data 1	Data 2:4	5:10	Data 11	Data 12	Data 13	Data 14:17
Get Common Filters	18	0xD3	0	Receive Control - see Table 38-533	MAC Address	BMC Alert Address	Interface Data Byte	Alert Value Byte	IPv4 Address

Function	Byte Count	Command	Data 1	Data 2:4	5:10	Data 11	Data 12	Data 13	Data 14:29
Get Common Filters	30	0xD3	0	Receive Control - see Table 38-533	MAC Address	BMC Alert Address	Interface Data Byte	Alert Value Byte	IPv6 Address

If an error occurs, the following answers might be returned:

Function	Command	Byte Count	Data 1
Get Common Filters	0xD3	1	0xFF

This response is by the 10 GbE controller on a Read Common Filter command when the data that should have been read is not ready. This parameter has no data. The MC should retry the read transaction.

Read Receive Enable Configuration

The MC uses this command to read the receive configuration data. This data can be configured when using the Receive Enable command or through the NVM.

The Read Receive Enable Configuration command format (SMBus read block) is as follows:

Function	Command
Read Receive Enable	0xDA

Data returned from the 10 GbE controller:

Function	Byte Count	Data 1 (Opcode)	Data 2	Data 3	...	Data 8	Data 9	...	Data 12	Data 13	Data 14	Data 15
Read Receive Enable	15 (0x0F)	0xDA	Receive Control Byte	MAC Addr MSB	...	MAC Addr LSB	IP Addr MSB	...	IP Addr LSB	BMC SMBus Addr	I/F Data Byte	Alert Value Byte

The details of each field is specified in sub-section Section “Receive Enable Command”.

38.37.5.13 Example Configuration Steps

This section provides sample configuration settings for common filtering configurations. Four examples are presented. The examples are in pseudo code format, with the name of the SMBus command followed by the parameters for that command and an explanation.

Example 1 - Shared MAC, RMCP Only Ports

This example is the most basic configuration. The MAC address filtering is shared with the host operating system and only traffic directed the RMCP ports (0x26F and 0x298) is filtered. For this example, the MC must issue gratuitous ARPs because no filter is enabled to pass ARP requests to the MC.

Step 1: Disable existing filtering

`Receive Enable[00]`

Using the basic form of the Receive Enable command, this prevents any packets from reaching the MC by disabling filtering:

Receive Enable Control 0x00:

- Bit 0 [0] – Disable Receiving of packets

Step 2: Configure MDEF[0]

`Update Manageability Filter Parameters [68, 0, C0000000, 00000000]`

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x68). This updates MDEF[0], as indicated by the second parameter (0).

MDEF[0] value of 0xC0000000:

- Bit 30 [1] – port 0x298
- Bit 31 [1] – port 0x26F

MDEF_EXT[0] value of 0x0000000:

Step 3: Configure *MNGONLY*

`Update Manageability Filter Parameters [F, 0, 00000001]`

Use the Update Manageability Filter Parameters command to update Manageability Only (*MNGONLY*) (parameter 0xF) so that port 0x298 and 0x26F would not be sent to the host.

- Bit [0] - *MDEF[0]* is exclusive to the MC.

Step 4: - Enable Filtering

`Receive Enable [05]`

Using the basic form of the Receive Enable command:

Receive Enable Control 0x05:

- Bit 0 [1] = Enable receiving of packets
- Bit 2 [1] = Enable status reporting (such as link lost)
- Bit 5:4 [00] = Notification method = SMB alert
- Bit 7 [0] = Use shared MAC

The resulting MDEF filters are as follows:

Table 38-541.Example 1 MDEF Results

Manageability Decision Filter (MDEF)									
Filter		0	1	2	3	4	5	6	7
L2 Unicast Address[3:0]	AND								
Broadcast	AND								
Manageability VLAN[7:0]	AND								
IPv6 Address[3:0]	AND								
IPv4 Address[3:0]	AND								
L2 Unicast Address[3:0]	OR								
Broadcast	OR								
Multicast	AND								
ARP Request	OR								
ARP Response	OR								
Neighbor Discovery	OR								
Port 0x298	OR	X							
Port 0x26F	OR	X							
Flex Port 7:0	OR								
Flex TCO	OR								

Example 2 - Dedicated MAC, auto ARP Response and RMCP Port Filtering

This example shows a common configuration; the MC has a dedicated MAC and IP address. Automatic ARP responses are enabled as well as RMCP port filtering. By enabling automatic ARP responses, the MC is not required to send the gratuitous ARPs as it did in Example 1.

For demonstration purposes, the dedicated MAC address is calculated by reading the system MAC address and adding a one to it; assume the system MAC is AABBCCDC. The IP address for this example is 1.2.3.4. Additionally, the XSUM filtering is enabled.

Note that not all Intel Ethernet controllers support automatic ARP responses, refer to product specific documentation.

Example 2 - Pseudo Code

Step 1: Disable existing filtering

```
Receive Enable[00]
```

Using the basic form of the Receive Enable command, this prevents any packets from reaching the MC by disabling filtering:

Receive Enable Control 0x00:

- Bit 0 [0] – Disable Receiving of packets

Step 2: Read System MAC Address

```
Get System MAC Address []
```

Reads the system MAC address. Assume a returned AABBCCDC for this example.

Step 3: Configure XSUM Filter

```
Update Manageability Filter Parameters [01, 00800000]
```

Use the Update Manageability Filter Parameters command to update Filters Enable settings (parameter 1). This sets the Manageability Control (*PRT_MNG_MANC*) register.

PRT_MNG_MANC Register 0x00800000:

- Bit 23 [1] - XSUM Filter Enable

  Note that some of the following configuration steps manipulate the *PRT_MNG_MANC* register indirectly, this command sets all bits except XSUM to 0b. It is important to either do this step before the others, or to read the value of the *PRT_MNG_MANC* and then write it back with only bit 32 changed. Also note that the XSUM enable bit might differ between Ethernet controllers, refer to product specific documentation.

Step 4: Configure MDEF[0]

```
Update Manageability Filter Parameters [68, 0, C0000000, 00000000]
```

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x68). This updates MDEF[0], as indicated by the second parameter (0).

MDEF value of 0x00000C00:

- Bit 30 [1] – port 0x298
- Bit 31 [1] – port 0x26F

MDEF_EXT[0] value of 0x0000000:

Step 5: Configure MDEF[1]

```
Update Manageability Filter Parameters [68, 1, 10000000, 00000000]
```

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x61). This updates MDEF[1], as indicated by the second parameter (1).

MDEF value of 0x10000000:

- Bit 28 [1] – ARP Requests

MDEF_EXT[1] value of 0x0000000:

When enabling automatic ARP responses, the ARP requests still go into the manageability filtering system and as such need to be designated as also needing to be sent to the host. For this reason a separate MDEF is created with only ARP request filtering enabled.

Refer to the next step for more details.

Step 6: Configure Manageability only

```
Update Manageability Filter Parameters [F, 0, 00000001]
```

Use the Update Manageability Filter Parameters command to update Manageability Only (MNGONLY) (parameter 0xF) so that port 0x298 and 0x26F would not be sent to the host.

- Bit [0] - MDEF[0] is exclusive to the MC.

  This enables ARP requests to be passed to both manageability and to the host. Specified separate MDEF filter for ARP requests. If ARP requests had been added to *MDEF[0]* and then *MDEF[0]* specified in management only configuration then not only would RMCP traffic (ports 0x26F and 0x298) be sent only to the MC, ARP requests would have also been sent to the MC only.

Step 7: Enable Filtering

```
Receive Enable [8D, AABBCCDD, 01020304, 00, 00, 00]
```

Using the advanced version Receive Enable command, the first parameter:
Receive Enable Control 0x8D:

- Bit 0 [1] – Enable receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 3 [1] – Enable automatic ARP responses
- Bit 5:4 [00] – Notification method = SMB alert
- Bit 7 [1] - Use dedicated MAC
  Second parameter is the MAC address (AABBCCDD).
  Third parameter is the IP address(01020304).

The last three parameters are zero when the notification method is SMB alert.

The resulting MDEF filters are as follows:

Table 38-542.Example 2 MDEF Results

Manageability Decision Filter (MDEF)									
Filter		0	1	2	3	4	5	6	7
L2 Unicast Address[3:0]	AND								
Broadcast	AND								
Manageability VLAN[7:0]	AND								
IPv6 Address[3:0]	AND								
IPv4 Address[3:0]	AND								
L2 Unicast Address[3:0]	OR								
Broadcast	OR								
Multicast	AND								
ARP Request	OR		X						
ARP Response	OR								
Neighbor Discovery	OR								
Port 0x298	OR	X							
Port 0x26F	OR	X							
Flex Port [7:0]	OR								
Flex TCO	OR								

38.37.5.13.1 Example 3 - Dedicated MAC and IP Address

This example provided, the MC with a dedicated MAC and IP address enables it to receive ARP requests. The MC is then responsible for responding to ARP requests.

For demonstration purposes, the dedicated MAC address is calculated by reading the system MAC address and adding a one to it; assume the system MAC is AABBCCDC. The IP address for this example is 1.2.3.4. For this example, the Receive Enable command is used to configure the MAC address filter.

In order for the MC to be able to receive ARP requests, it needs to specify a filter for this, and that filter needs to be included in the manageability-to-host filtering so that the host operating system can also receive ARP requests.

Example 3 - Pseudo Code

Step 1: Disable existing filtering

`Receive Enable[00]`

Using the basic form of the Receive Enable command, this prevents any packets from reaching the MC by disabling filtering:

Receive Enable Control 0x00:

- Bit 0 [0] – Disable receiving of packets

Step 2: Read System MAC Address

`Get System MAC Address []`

Reads the system MAC address. Assume a returned AABBCCDC for this example.

Step 3: Configure IP Address Filter

`Update Manageability Filter Parameters [64, 00, 01020304]`

Use the update manageability filter parameters to configure an IPv4 filter.

The first parameter (0x64) specifies that we are configuring an IPv4 filter.

The second parameter (0x00) indicates which IPv4 filter is being configured; in this case filter 0.

The third parameter is the IP address – 1.2.3.4.

Step 4: Configure MAC Address Filter

`Update Manageability Filter Parameters [66, 00, AABBCCDD]`

Use the update manageability filter parameters to configure a MAC address filter.

The first parameter (0x66) specifies that we are configuring a MAC address filter.

The second parameter (0x00) indicates which MAC address filter is being configured; in this case filter 0.

The third parameter is the MAC address - AABBCCDD

Step 5: Configure MDEF[0] for IP and MAC Filtering

`Update Manageability Filter Parameters [68, 0, 00002001, 00000000]`

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x68). This updates MDEF[0], as indicated by the second parameter (0).

MDEF value of 00002001:

- Bit 0 [1] – MAC[0] address filtering
- Bit 13 [1] – IP[0] address filtering

MDEF_EXT[0] value of 0x0000000:

Step 6: Configure MDEF[1]

`Update Manageability Filter Parameters [68, 1, 10000000]`

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x68). This updates MDEF[1], as indicated by the second parameter (1).

MDEF value of 10000000:

- Bit 28 [1] – ARP requests

MDEF_EXT[1] value of 0x0000000:

Step 7: Configure the Management to Host Filter

`Update Manageability Filter Parameters [F, 0, 00000001]`

Use the Update Manageability Filter Parameters command to update Manageability Only (*MNGONLY*) (parameter 0xF) so that the dedicated MAC/IP traffic would not be sent to the host. Note that given the host does not program this address in it's L2 filtering, this step is not a must, unless the host chooses to work in promiscuous mode.

- Bit [0] - MDEF[0] is exclusive to the MC.

Step 8: Enable Filtering

`Receive Enable [05]`

Using the basic form of the Receive Enable command,:

Receive Enable Control 0x05:

- Bit 0 [1] – Enable receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB alert

The resulting MDEF filters are as follows:

Table 38-543.Example 3 MDEF Results

Manageability Decision Filter (MDEF)									
Filter		**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
L2 Unicast Address[3:0]	AND	0001							
Broadcast	AND								
Manageability VLAN[7:0]	AND								
IPv6 Address[3:0]	AND								
IPv4 Address[3:0]	AND	0001							
L2 Unicast Address[3:0]	OR								
Broadcast	OR								
Multicast	AND								
ARP Request	OR		X						
ARP Response	OR								
Neighbor Discovery	OR								
Port 0x298	OR								
Port 0x26F	OR								
Flex Port [7:0]	OR								
Flex TCO	OR								

38.37.5.13.2 Example 4 - Dedicated MAC and VLAN Tag

This example shows an alternate configuration; the MC has a dedicated MAC and IP address, along with a VLAN tag of 0x32 are required for traffic to be sent to the MC. This means that all traffic with a VLAN and matching tag is sent to the MC.

For demonstration purposes, the dedicated MAC address is calculated by reading the system MAC address and adding a one to it; assume the system MAC is AABBCCDC. The IP address for this example is 1.2.3.4 and the VLAN tag is 0x0032.

Additionally, the XSUM filtering is enabled.

Example 4 - Pseudo Code

Step 1: Disable existing filtering

`Receive Enable[00]`

Using the basic form of the Receive Enable command, this prevents any packets from reaching the MC by disabling filtering:

Receive Enable Control 0x00:

- Bit 0 [0] – Disable receiving of packets

Step 2: - Read System MAC Address

`Get System MAC Address []`

Reads the system MAC address. Assume a returned AABBCCDC for this example.

Step 3: Configure XSUM Filter

`Update Manageability Filter Parameters [01, 00800000]`

Use the Update Manageability Filter Parameters command to update filters enable settings (parameter 1). This sets the Manageability Control (*PRT_MNG_MANC*) register.

PRT_MNG_MANC Register 0x00800000:

- Bit 23 [1] – XSUM filter enable

Note that some of the following configuration steps manipulate the *PRT_MNG_MANC* register indirectly. This command sets all bits except XSUM to 0b. It is important to either do this step before the others, or to read the value of the *PRT_MNG_MANC* and then write it back with only bit 32 changed. Also note that the XSUM enable bit might differ between Ethernet controllers, refer to product specific documentation.

Step 4: Configure VLAN 0 Filter

`Update Manageability Filter Parameters [62, 0, 0032]`

Use the Update Manageability Filter Parameters command to configure VLAN filters. Parameter 0x62 indicates an update to the VLAN filter. The second parameter indicates which VLAN filter (0 in this case). The last parameter is the VLAN ID (0x0032).

Step 5: Configure MDEF[0]

`Update Manageability Filter Parameters [68, 0, 00000020, 00000000]`

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 0x68). This updates MDEF[0], as indicated by the second parameter (0).

MDEF value of 0x00000020:

- Bit 5 [1] – VLAN[0] AND

MDEF_EXT[0] value of 0x0000000:

Step 6: Enable Filtering

`Receive Enable [85, AABBCCDD, 01020304, 00, 00, 00]`

Using the advanced version Receive Enable command, the first parameter:

Receive Enable Control 0x85:

- Bit 0 [1] – Enable receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)

- Bit 5:4 [00] – Notification method = SMB alert
- Bit 7 [1] – Use dedicated MAC
  Second parameter is the MAC address: AABBCCDD.
  The third parameter is the IP address: 01020304.
  The last three parameters are zero when the notification method is SMBus alert.

The resulting MDEF filters are as follows:

Table 38-544.Example 4 MDEF Results

Manageability Decision Filter (MDEF)									
Filter		0	1	2	3	4	5	6	7
L2 Unicast Address[3:0]	AND								0001
Broadcast	AND								
Manageability VLAN[7:0]	AND	X							
IPv6 Address[3:0]	AND								
IPv4 Address[3:0]	AND								
L2 Unicast Address[3:0]	OR								
Broadcast	OR								
Multicast	AND								
ARP Request	OR								
ARP Response	OR								
Neighbor Discovery	OR								
Port 0x298	OR								
Port 0x26F	OR								
Flex Port [7:0]	OR								
Flex TCO	OR								

38.37.5.14 SMBus Troubleshooting

This section outlines the most common issues found while working with PT using the SMBus sideband interface.

38.37.5.14.1 TCO Alert Line Stays Asserted After a Power Cycle

After the 10 GbE controller resets, all its ports indicates a status change. If the MC only reads status from one port (slave address), the other one continues to assert the TCO alert line.

Ideally, the MC should use the ARA transaction (see Section 38.37.5.10) to determine which slave asserted the TCO alert. Many customers only want to use one port for manageability, thus using ARA might not be optimal.

An alternative to using ARA is to configure part of the ports to not report status and to set its SMBus timeout period. In this case, the SMBus timeout period determines how long a port asserts the TCO alert line awaiting a status read from a MC; by default this value is zero (indicates an infinite timeout).

The SMBus configuration section of the NVM has a *SMBus Notification Timeout* (ms) field that can be set to a recommended value of 0xFF (for this issue). Note that this timeout value is for all slave addresses. Along with setting the *SMBus Notification*

Timeout to 0xFF, it is recommended that the other ports be configured in the NVM to disable status alerting. This is accomplished by having the *Enable Status Reporting* bit set to 0b for the desired ports in the LAN configuration section of the NVM.

The third solution for this issue is to have the MC hard-code the slave addresses to always read from all ports. As with the previous solution, it is recommend that the other ports have status reporting disabled.

38.37.5.14.2 When SMBus Commands are Always NACK'd

There are several reasons why all commands sent to the 10 GbE controller from a MC could be NACK'd. The following are most common:

- Invalid NVM Image — The image itself might be invalid or it could be a valid image and is not a PT image, as such SMBus connectivity is disabled.
- The MC is not using the correct SMBus address — Many MC vendors hard-code the SMBus address(es) into their firmware. If the incorrect values are hard-coded, the 10 GbE controller does not respond.
- The SMBus address(es) can be dynamically set using the SMBus ARP mechanism.
- The MC is using the incorrect SMBus interface — The NVM might be configured to use one physical SMBus port; however, the MC is physically connected to a different one.
- Bus Interference — The bus connecting the MC and the 10 GbE controller might be unstable.

38.37.5.14.3 SMBus Clock Speed is 16.6666 kHz

This can happen when the SMBus connecting the MC and the 10 GbE controller is also tied into another device (such as an ICH) that has a maximum clock speed of 16.6666 kHz. The solution is to not connect the SMBus between the 10 GbE controller and the MC to this device.

38.37.5.14.4 A network Based Host Application is Not Receiving Any Network Packets

Reports have been received about an application not receiving any network packets. The application in question was NFS under Linux. The problem was that the application was using the RMPC/RMCP+ IANA reserved port 0x26F (623) and the system was also configured for a shared MAC and IP address with the operating system and the MC.

The management control to host configuration, in this situation, was setup not to send RMCP traffic to the operating system (this is typically the correct configuration). This means that no traffic send to port 623 was being routed.

The solution in this case is to configure the problematic application NOT to use the reserved port 0x26F.

38.37.5.14.5 Unable to Transmit Packets From the MC

If the MC has been transmitting and receiving data without issue for a period of time and then begins to receive NACKs from the 10 GbE controller when it attempts to write a packet, the problem is most likely due to the fact that the buffers internal to the 10 GbE controller are full of data that has been received from the network but has yet to be read by the MC.

Being an embedded device, the 10 GbE controller has limited buffers that are shared for receiving and transmitting data. If a MC does not keep the incoming data read, the 10 GbE controller can be filled up. This prevents the MC form transmitting more data, resulting in NACKs.

If this situation occurs, the recommended solution is to have the MC issue a Receive Enable command to disable more incoming data, read all the data from the 10 GbE controller, and then use the Receive Enable command to enable incoming data.

38.37.5.14.6 SMBus Fragment Size

The SMBus specification indicates a maximum SMBus transaction size of 32 bytes. Most of the data passed between the 10 GbE controller and the MC over the SMBus is RMCP/RMCP+ traffic, which by its very nature (UDP traffic) is significantly larger than 32 bytes in length. Multiple SMBus transactions might therefore be required to move data from the 10 GbE controller to the MC or to send a data from the MC to the 10 GbE controller.

Recognizing this bottleneck, the 10 GbE controller handles up to 240 bytes of data in a single transaction. This is a configurable setting in the NVM. The default value in the NVM images is 32, per the SMBus specification. If performance is an issue, increase this size.

During initialization, firmware within the 10 GbE controller allocates buffers based upon the SMBus fragment size setting within the NVM. Product Name firmware has a finite amount of RAM for its use: the larger the SMBus fragment size, the fewer buffers it can allocate. Because this is true, MC implementations must take care to send data over the SMBus efficiently.

For example, the 10 GbE controller firmware has 3 KB of RAM it can use for buffering SMBus fragments. If the SMBus fragment size is 32 bytes then the firmware could allocate 96 buffers of size 32 bytes each. As a result, the MC could then send a large packet of data (such as KVM) that is 800 bytes in size in 25 fragments of size 32 bytes apiece.

However, this might not be the most efficient way because the MC must break the 800 bytes of data into 25 fragments and send each one at a time.

If the SMBus fragment size is changed to 240 bytes, the 10 GbE controller firmware can create 12 buffers of 240 bytes each to receive SMBus fragments. The MC can now send that same 800 bytes of KVM data in only four fragments, which is much more efficient.

The problem of changing the SMBus fragment size in the NVM is if the MC does not also reflect this change. If a programmer changes the SMBus fragment size in the 10 GbE controller to 240 bytes and then wants to send 800 bytes of KVM data, the MC can still only send the data in 32 byte fragments. As a result, firmware runs out of memory.

This is because firmware created the 12 buffers of 240 bytes each for fragments; however, the MC is only sending fragments of size 32 bytes. This results in a memory waste of 208 bytes per fragment. Then when the MC attempts to send more than 12 fragments in a single transaction, the 10 GbE controller NACKs the SMBus transaction due to not enough memory to store the KVM data.

In summary, if a programmer increases the size of the SMBus fragment size in the NVM (recommended for efficiency purposes) take care to ensure that the MC implementation reflects this change and uses that fragment size to its fullest when sending SMBus fragments.

38.37.5.14.7 Losing Link

Normal behavior for the Ethernet controller when the system powers down or performs a reset is for the link to temporarily go down and then back up again to re-negotiate the link speed. This behavior can have adverse affects on manageability.

For example, if there is an active FTP or Serial Over LAN (SoL) session to the MC, this connection can be lost. In order to avoid this possible situation, the MC can use the Management Control command to ensure the link stays active at all times.

This command is available when using the NC-SI sideband interface as well.

Care should be taken with this command, if the software device driver negotiates the maximum link speed, the link speed remains the same when the system powers down or resets. This can have undesirable power consumption consequences. Currently, when using NC-SI, the MC can re-negotiate the link speed. That functionality is not available when using the SMBus interface.

38.37.5.14.8 Enable Checksum Filtering

If checksum filtering is enabled, the MC does not need to perform the task of checking this checksum for incoming packets. Only packets that have a valid checksum is passed to the MC. All others are silently discarded.

This is a way to offload some work from the MC.

38.37.5.14.9 Still Having Problems?

If problems still exist, contact your field representative. Be prepared to provide the following:

- A SMBus trace if possible.
- A dump of the NVM image. This should be taken from the actual Product Name, rather than the NVM image provided by Intel. Parts of the NVM image are changed after writing (such as the physical NVM size).

38.37.6 Network Controller Sideband Interface (NC-SI) PT Interface

The NC-SI is a DMTF industry standard protocol for the sideband interface. NC-SI uses a modified version of the industry standard RMII interface for the physical layer as well as defining a new logical layer.

The NC-SI specification can be found at:

http://www.dmtf.org/

38.37.6.1 Overview

38.37.6.1.1 Terminology

The terminology in this section is taken from the NC-SI specification.

Table 38-545.NC-SI Terminology

Term	Definition
Frame Versus Packet	Frame is used in reference to Ethernet, whereas packet is used everywhere else.
External Network Interface	The interface of the network controller that provides connectivity to the external network infrastructure (port).
Internal Host Interface	The interface of the network controller that provides connectivity to the host operating system running on the platform.
Management Controller (BMC)	An intelligent entity comprising of hardware/firmware/software, that resides within a platform and is responsible for some or all management functions associated with the platform (BMC, service processor, etc.).
Network Controller (NC)	The component within a system that is responsible for providing connectivity to the external Ethernet network world.

Table 38-545.NC-SI Terminology

Term	Definition
Remote Media	The capability to allow remote media devices to appear as if they were attached locally to the host.
Network Controller Sideband Interface	The interface of the network controller that provides connectivity to a management controller. It can be shorten to sideband interface as appropriate in the context.
Interface	This refers to the entire physical interface, such as both the transmit and receive interface between the management controller and the network controller.
Integrated Controller	The term integrated controller refers to a network controller device that supports two or more channels for NC-SI that share a common NC-SI physical interface. For example, a network controller that has two or more physical network ports and a single NC-SI bus connection.
Multi-Drop	Multi-drop commonly refers to the case where multiple physical communication devices share an electrically common bus and a single device acts as the master of the bus and communicates with multiple slave or target devices. In NC-SI, a management controller serves the role as the master, and the network controllers are the target devices.
Point-to-Point	Point-to-point commonly refers to the case where only two physical communication devices are interconnected via a physical communication medium. The devices might be in a master/slave relationship, or could be peers. In NC-SI, point-to-point operation refers to the situation where only a single management controller and single network controller package are used on the bus in a master/slave relationship where the management controller is the master.
Channel	The control logic and data paths supporting NC-SI pass-through operation on a single network interface (port). A network controller that has multiple network interface ports can support an equivalent number of NC-SI channels.
Package	One or more NC-SI channels in a network controller that share a common set of electrical buffers and common buffer control for the NC-SI bus. Typically, there will be a single, logical NC-SI package for a single physical network controller package (chip or module). However, the specification allows a single physical chip or module to hold multiple NC-SI logical packages.
Control Traffic/Messages/Packets	Command, response and notification packets transmitted between BMC and the 10 GbE controller for the purpose of managing NC-SI.
Pass-Through Traffic/Messages/ Packets	Non-control packets passed between the external network and the BMC through the 10 GbE controller.
Channel Arbitration	Refer to operations where more than one of the network controller channels can be enabled to transmit pass-through packets to the BMC at the same time, where arbitration of access to the RXD, CRS_DV, and RX_ER signal lines is accomplished either by software of hardware means.
Logically Enabled/Disabled NC	Refers to the state of the network controller wherein pass-through traffic is able/unable to flow through the sideband interface to and from the management controller, as a result of issuing Enable/Disable Channel command.
NC RX	Defined as the direction of ingress traffic on the external network controller interface
NC TX	Defined as the direction of egress traffic on the external network controller interface
NC-SI RX	Defined as the direction of ingress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.
NC-SI TX	Defined as the direction of egress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.

38.37.6.1.2 System Topology

In NC-SI each physical endpoint (NC package) can have several logical slaves (NC channels).

NC-SI defines that one MC and up to four network controller packages can be connected to the same NC-SI link.

Figure 38-133 shows an example topology for a single MC (also know as BMC) and a single NC package. In this example, the NC package has two NC channels.

Figure 38-133.Single NC Package, Two NC Channels

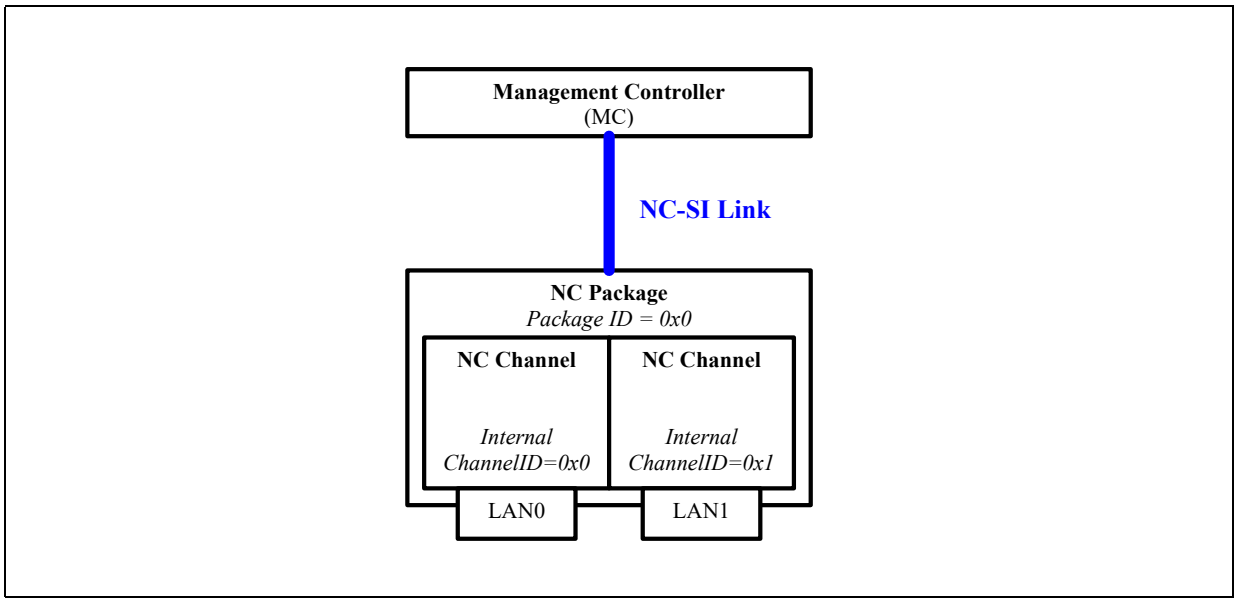


Figure 38-134 shows an example topology for a single MC and two NC packages. In this example, one NC package has two NC channels and the other has only one NC channel. Scenarios in which the NC-SI lines are shared by multiple NCs (Figure 38-134) mandate an arbitration mechanism.

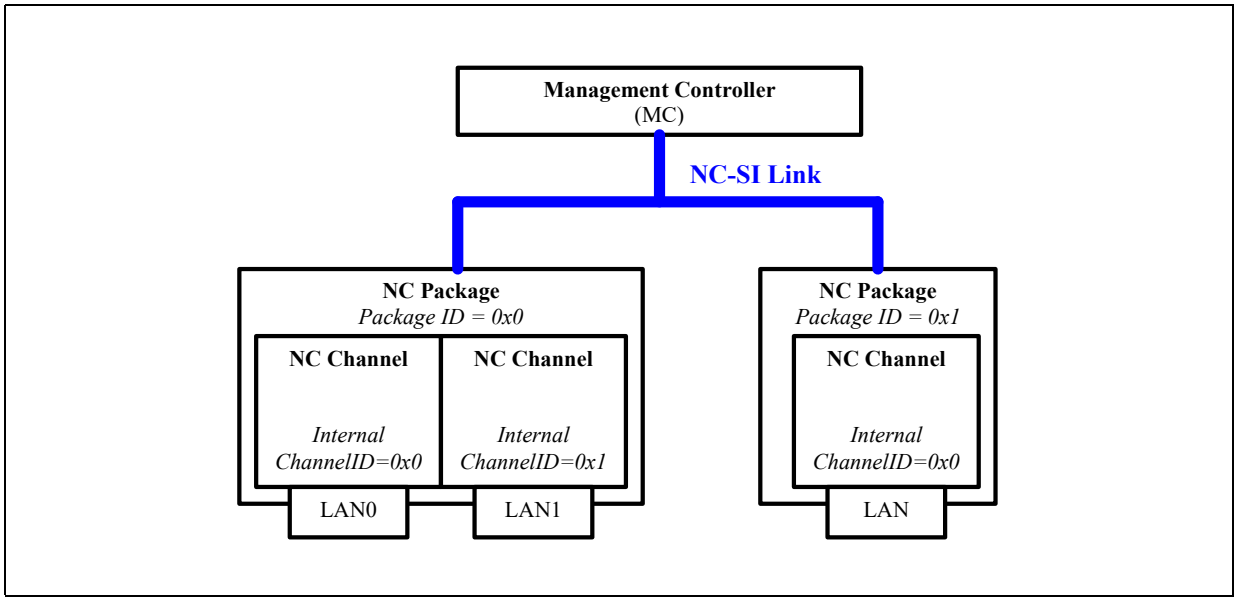
The arbitration mechanism is described in Section 38.37.6.9.1.

Figure 38-134.Two NC Packages (Left, With Two NC Channels and Right, With One NC Channel)



38.37.6.1.3 Data Transport

Since NC-SI is based upon the RMII transport layer, data is transferred in the form of Ethernet frames.

NC-SI defines two types of transmitted frames:

1. Control frames:
   a. Configures and control the interface.
   b. Identified by a unique EtherType in their L2 header.
2. PT frames:
   a. Actual LAN pass-through frames transferred from/to the MC.
   b. Identified as not being a control frame.
   c. Attributed to a specific NC channel by their source MAC address (as configured in the NC by the MC).

38.37.6.1.4 Control Frames

NC-SI control frames are identified by a unique NC-SI EtherType (0x88F8).

Control frames are used in a single-threaded operation, meaning commands are generated only by the MC and can only be sent one at a time. Each command from the MC is followed by a single response from the NC (command-response flow), after which the MC is allowed to send a new command.

The only exception to the command-response flow is the Asynchronous Event Notification (AEN). These control frames are sent unsolicited from the NC to the MC.

AEN functionality by the NC must be disabled by default, until activated by the MC using the Enable AEN commands.

In order to be considered a valid command, a control frame must:

1. Comply with the NC-SI header format.
2. Be targeted to a valid channel in the package via the *Package ID* and *Channel ID* fields. For example, to target a NC channel with package ID of 0x2 and internal channel ID of 0x5, the MC must set the channel ID inside the control frame to 0x45. The channel ID is composed of three bits of package ID and five bits of internal channel ID.
3. Contain a correct payload checksum (if used).
4. Meet any other condition defined by NC-SI.

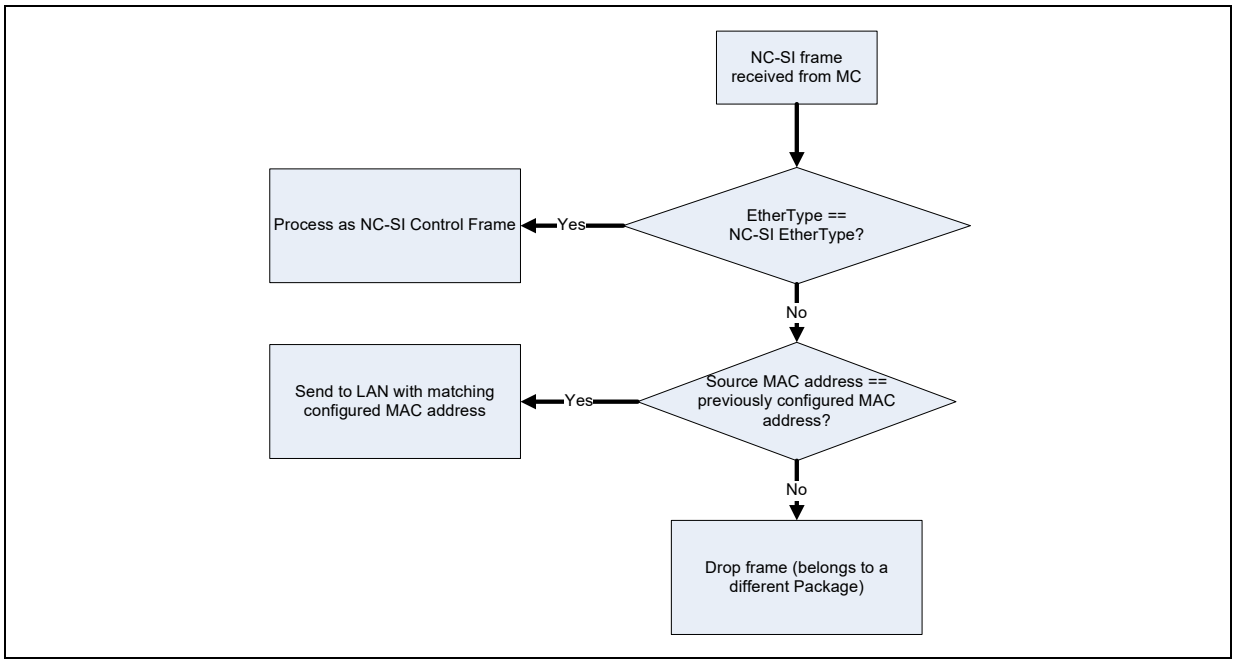
There are also commands (such as select package) targeted to the package as a whole. These commands must use an internal channel ID of 0x1F.

For details, refer to the NC-SI specification.

NC-SI Frames Receive Flow

Figure 38-135 shows the flow for frames received on the NC from the MC.

Figure 38-135.NC-SI Frames Receive Flow for the NC



38.37.6.2 NC-SI Standard Support

38.37.6.2.1 Supported Features

The 10 GbE controller supports all the mandatory features of the NC-SI specification (rev 1.0.1). Table 38-546 lists the supported commands.

Table 38-547 lists optional features supported and the level of support for partially supported commands.

Table 38-546.Supported NC-SI Commands

Command	Supported Over RMII	Supported Over MCTP With Pass Through	Supported Over MCTP Without Pass Through
Clear Initial State	Yes	Yes	Yes
Get Version ID	Yes	Yes	Yes
Get Parameters	Yes	Yes	Yes
Get Controller Packet Statistics	Yes, partially	Yes, partially	Yes, partially
Get Link Status[6]	Yes	Yes	Yes
Enable Channel	Yes	Yes	Yes
Disable Channel	Yes	Yes	Yes
Reset Channel	Yes	Yes	Yes
Enable VLAN	Yes[1,2]	Yes	No[3]
Disable VLAN	Yes	Yes	No-
Enable Broadcast Filter	Yes	Yes	No
Disable Broadcast Filter	Yes	Yes	No

Table 38-546.Supported NC-SI Commands

Command	Supported Over RMII	Supported Over MCTP With Pass Through	Supported Over MCTP Without Pass Through
Set MAC Address	Yes	Yes	No
Get NC-SI Statistics	Yes	Yes	Yes
Set NC-SI Flow Control	Yes	No	No
Set Link Command	Yes	Yes	Yes
Enable Global Multicast Filter	Yes	Yes	No
Disable Global Multicast Filter	Yes	Yes	No
Get Capabilities	Yes	Yes	Yes[4]
Set VLAN Filters	Yes	Yes	No
AEN Enable	Yes	Yes	Yes
Get NC-SI Pass-through Statistics	Yes, partially	Yes, partially	No
Select Package	Yes	Yes	Yes
Deselect Package	Yes	Yes	Yes
Enable Channel Network Tx	Yes	Yes	No
Disable Channel Network Tx	Yes	Yes	No
OEM Command[5]	Yes	Yes	Yes

Notes:

1. In cases that one of the LAN devices is assigned for the sole use of the manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation, results in the lowest possible speed chosen. To enable link of higher a speed, the MC should not advertise speeds that are below the desired link speed. When doing it, changing the power state of the LAN device has no effect and the link speed is not re-negotiated.
2. The 10 GbE controller does not support filtering of *User Priority/CFI* bits of VLAN.
3. In MCTP without PT mode, only control commands are supported and not PT traffic. Thus many of the regular NC-SI commands are not supported or are supported in a limited manner, only to enable control and status reporting for the device.
4. When PT is disabled, the Get Capabilities command does not expose all the filtering capabilities of the device.
5. See Section 38.37.6.3.2 for details.

6.Parallel Detection flag in this command response is not supported.

Table 38-547.Optional NC-SI features support

Feature	Implement	Details
AENs	Yes	The software device driver state AEN might be emitted up to one minute after actual driver change if the driver was taken down unexpectedly. When more than one function is associated with a channel, the driver status is enabled if at least one driver is up.
Get Controller Packet Statistics Command	Yes, partially	Supports the following counters[1]: 0-8,11-16, 21-36[2]. The statistics are not cleared between reads. ***Note:*** The packets counted by counter #35 (1523 - 9022 byte frames transmitted) are up to 9522 bytes and not 9022 as requested in the specification.
Get NC-SI Statistics	Yes	Support all the counters[3].
Get NC-SI Pass-through Statistics	Yes, partially	Support the following counters: 1, 6, 7.
VLAN Modes	Yes, partially	Support only modes 1, 3.
Buffering Capabilities	Yes	8 Kb.
MAC Address Filters	Yes	Supports 2 MAC addresses per port.
Channel Count	Yes	Supports 4 channels.

Table 38-547.Optional NC-SI features support

Feature	Implement	Details
VLAN Filters	Yes	Support 8 VLAN filters per port. Filtering is ignoring the *CFI* bit and the 802.1P priority bits.
Broadcast Filters	Yes	Support the following filters: ARP. DHCP. Net BIOS.
Multicast Filters	Yes	Supports the following filters: IPv6 neighbor advertisement. IPv6 router advertisement. DHCPv6 relay and server multicast.
Hardware Arbitration	Yes	Supports NC-SI hardware arbitration.

Notes:

1. *TCTL.EN* should be set to 1b to activate Tx-related counters and *RCTL.RXEN*, *PRT_MNG_MANC.RCV_EN* or *WUC.APME* should be set to enable Rx-related counters.
2. As described in the Get Controller Packet Statistics Counter Numbers table in NC-SI specification.
3. The 10 GbE controller does not increment the NC-SI control packets dropped counter when packets with checksum errors are dropped. In this case, only the NC-SI command checksum errors counter is updated.

38.37.6.2.2 AEN Handling

Asynchronous events might occur when the device is not allowed to send them. The following rules defines the behavior of the 10 GbE controller in these cases:

1. While the device is disabled, for each type of AEN only the last event is kept.
2. Outstanding AENs that occurred while a package was deselected is transmitted when a package is selected.
3. On a transition from channel disabled to channel enabled, all outstanding events are erased to prevent stale event notifications.
4. If the AEN becomes outdated before being sent (for example a link down, link up sequence occurring before the AEN is sent), then no AEN is sent.

Table 38-548.Get NC-SI PT Statistics Generation

Counter Number	Statistic Name	Source
1	Total PT Tx Packets Received	Sum of GLV_UPTCL, GLV_MPTCL and GLV_BPTCL for relevant VSI.
6	Total PT Rx Packets	Sum of GLV_UPRCL, GLV_MPRCL and GLV_BPRCT
7	Total PT Rx Packets Dropped	GLV_RDPC.

38.37.6.3 External Link Control via NC-SI

38.37.6.3.1 NC-SI Link State Control

In NC-SI mode, the device might dynamically change the PHY power mode according to the NC-SI channel state assuming no other functionality requires the PHY to be active (host or wake up).

The following algorithm is used to define if PHY activity is required:

- At initialization time, the PHY is required to be active only if the *EMP_LINK_ON* bit in *Common Firmware Parameters 2* NVM word is set.
- Once a channel is enabled via a Enable Channel NC-SI command, The PHY is powered up.

- If the channel is disabled via a Disable Channel command with the *ALD* bit set, the PHY is disabled.
- If the channel is disabled via a Reset Channel command, the PHY power state is set back to the initial value as define by the *EMP_LINK_ON* bit.

Note: Before a transition to D3 it is the responsibility of the software device driver to request the PHY to be active for wake-up activities.

38.37.6.3.2 Set Link Error Codes

The following rules are used to define the error code returned for a Set Link command in case an invalid configuration is requested:

1. Host driver check — If a host device driver is present, return a Command Specific Response (0x9) with a Set Link Host OS/Driver Conflict Reason (0x1).
2. Speed present check — If no speed is selected, return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
3. Parameter Validity:
   a. Auto-negotiation Parameter Validation — If auto-negotiation is requested and none of the selected parameters are valid for the device, return a General Reason Code for a failed command (0x1) with a Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).

Note: This means, for example, a command requesting 10 GbE on a 1 GbE device succeeds provided that the command requests at least one other supported speed.

For the 10 GbE controller, setting the auto-negotiation enabled field is ignored. For speed and connection types that only accept force mode, force mode is used. For modes that only support auto-negotiation, auto-negotiation is used to enforce a speed by only negotiating this speed. There are no modes supported by the 10 GbE controller that supports both auto-negotiation and force modes.

The same goes for an unsupported duplex setting (a device with no HD support accepts a command with both FD and HD set), and also for HD being requested with speeds of 1 GbE and higher as long as a speed below 1 GbE is also requested (and is supported in HD). The device simply ignores the unsupported parameters.

   a. Force mode parameter validation:
      - If more than one link speed is being forced, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with a Set Link Speed Conflict Error (0x0905).
      - If more than one duplex setting is being forced, then return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
      - If 1 GbE and above is requested with HD, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Parameter Conflict Reason (0x0903).

4. Media type compatibility check — If current media type is not compatible for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Media Conflict Error (0x0902).
5. Power state compatibility check — If current power state does not allow for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Power Mode Conflict Reason (0x0904).

6. If for some reason the hardware cannot perform the flow required for the command, return a General Reason Code for a failed command (0x1) and a Command Specific Response (0x9) with Link Command Failed-Hardware Access Error (0x6).

38.37.6.4 NC-SI Mode — Intel Specific Commands

In addition to regular NC-SI commands, the following Intel vendor specific commands are supported. The purpose of these commands is to provide a means for the MC to access some of the Intel-specific features present in the 10 GbE controller.

38.37.6.4.1 Overview

The following features are available via the NC-SI OEM specific commands:

- Receive filters.
- Packet addition decision filters 0x0…0x4.
- Packet reduction decision filters 0x5…0x7.
- *PRT_MNG_MNGONLY* register (controls the forwarding of manageability packets to the host).
- Flex 128 filters.
- Flex TCP/UDP port filters 0x0...0x2.
- IPv4/IPv6 filters.
- Get system MAC address — This command enables the MC to retrieve the system MAC address used by the MC. This MAC address can be used for a shared MAC address mode.
- Keep PHY link up (*Veto* bit) enable/disable — This feature enables the MC to block PHY reset, which might cause session loss.
- TCO reset — Enables the MC to reset the 10 GbE controller.
- Checksum offloading — Offloads IP/UDP/TCP checksum checking from the MC.
- OS2BMC control commands.
- Firmware version commands.
- Shared MAC and shared IP commands.

These commands are designed to be compliant with their corresponding SMBus commands (if existing). All of the commands are based on a single DMTF defined NC-SI command, known as OEM Command. This command is as follows.

OEM Command (0x50)

The OEM command can be used by the MC to request the sideband interface to provide vendor-specific information. The Vendor Enterprise Number (VEN) is the unique MIB/SNMP private enterprise number assigned by IANA per organization. Vendors are free to define their own internal data structures in the vendor data fields.

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...	Intel Command Number	Optional Data		

	Bits	
...	...	
...	Optional Data	Padding To 32 Bits (0x00)
...	Checksum	

OEM Response (0xD0)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	Intel Command Number	Optional Return Data		
...	...			
...	Optional Return Data		Padding To 32 Bits (0x00)	
...	Checksum			

Note: Responses have no command-specific reason code, unless otherwise specified within the command.

Note: The commands/responses described as follows includes only the part up to the data. The padding and checksum are implied.

38.37.6.4.2 OEM Commands Summary

Table 38-549.OEM Specific Command Response Reason Codes

Response Code		Reason Code	
Value	**Description**	**Value**	**Description**
0x1	Command Failed	0x5081	Invalid Intel command number.
		0x5082	Invalid Intel command parameter number.
		0x5085	Internal network controller error.
		0x5086	Invalid vendor enterprise code.
		0x508D	Returned when one of the shared IP commands is received with an out of range resource (IP, port, binding) index.
		0x508E	Returned when a request to disable a port or an IP address used in a active binding is received.
		0x5090	Returned when a binding of a non enabled resource (MAC, VLAN, IP address, port) is required.
		0x5091	Returned when the *Set Port* command is received with an unsupported protocol.
		0x5092	Not is shared mode. Returned when shared mode commands are used while not in shared MAC/IP mode.
		0x008E	Returned when a request to disable a VLAN or a MAC address used in a active binding is received.

Table 38-550.OEM Commands Summary

Intel Command	Parameter	Command Name	Supported in MCTP Without PT
0x00	0x00	Set IP Filters Control	No
0x01	0x00	Get IP Filters Control	No
0x02	0x0F	Set Manageability Only	No
	0x10	Set Flexible 128 Filter Mask and Length	
	0x11	Set Flexible 128 Filter Data	
	0x63	Set Flex TCP/UDP Port Filters	
	0x64	Set Flex IPv4 Address Filters	
	0x65	Set Flex IPv6 Address Filters	
	0x67	Set EtherType Filter	
	0x68	Set Packet Addition Extended Filter	
	0x69	Set Special Filter Modifiers	
0x03	0x0F	Get Manageability Only	No
	0x10	Get Flexible 128 Filter Mask and Length	
	0x11	Get Flexible 128 Filter Data	
	0x63	Get Flex TCP/UDP Port Filters	
	0x64	Get Flex IPv4 Address Filters	
	0x65	Get Flex IPv6 Address Filters	
	0x67	Get EtherType Filter	
	0x68	Get Packet Addition Extended Filter	
	0x69	Get Special Filter Modifiers	
0x04	0x10	Set Extended Unicast Packet Reduction	No
	0x11	Set Extended Multicast Packet Reduction	
	0x12	Set Extended Broadcast Packet Reduction	
0x5	0x10	Get Extended Unicast Packet Reduction	No
	0x11	Get Extended Multicast Packet Reduction	
	0x12	Get Extended Broadcast Packet Reduction	
0x06	N/A	Get System MAC Address	Yes
0x20	N/A	Set Intel Management Control	No
0x21	N/A	Get Intel Management Control	No
0x22	N/A	TCO Reset	Yes
0x23	N/A	Enable IP/UDP/TCP Checksum Offloading	No
0x24	N/A	Disable IP/UDP/TCP Checksum Offloading	No

Table 38-550.OEM Commands Summary

Intel Command	Parameter	Command Name	Supported in MCTP Without PT
0x25	0x0	Set IP Address	No
	0x1	Get IP Address	
	0x2	Set Port	
	0x3	Get Port	
	0x4	Enable Unicast Infrastructure Filter	
	0x5	Get Shared IP Capabilities Command	
	0x6	Shared IP Enable Broadcast Filtering	
	0x7	Shared IP Enable Global Multicast Filtering	
	0x8	Get Shared IP Parameters	
	0x9	Set Binding	
	0xA	Get Binding	
	0xB	Set Shared Mode	
0x40	0x01	Enable OS2BMC Flow	No
	0x02	Enable Network to BMC Flow	
	0x03	Enable Both Network-to-BMC and Host-to-BMC Flow	
0x40	0x04	Set BMC IP Address	No
0x41	N/A	Get OS2BMC Parameters	No
0x48	0x1	Get Controller Information	Yes

Note: All the commands are supported both over RMII NC-SI and over MCTP.

38.37.6.4.3 Set Intel Filters Control — IP Filters Control Command (Intel Command 0x00, Filter Control Index 0x00)

This command controls different aspects of the Intel filters.

Set Intel Filters Control — IP Filters Control Command

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x00	0x00	IP Filters Control (3-2)	
24...27	IP Filters Control (1-0)			

Where IP filters control has the following format.

Bit #	Name	Description	Default Value
0	IPv4/IPv6 Mode	IPv6 (0b) = There are zero IPv4 filters and four IPv6 filters. IPv4 (1b) = There are four IPv4 filters and four IPv6 filters.	1b
1...31	Reserved		

Note: This command is kept for compatibility with other projects and has no effect in Product Name.

Set Intel Filters Control — IP Filters Control Response

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x00	0x00		

38.37.6.4.4 Get Intel Filters Control Commands (Intel Command 0x01)

Get Intel Filters Control — IP Filters Control Command (Intel Command 0x01, Filter Control Index 0x00)

This command controls different aspects of the Intel filters.

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x01	0x00		

Get Intel Filters Control — IP Filters Control Response (Intel Command 0x01, Filter Control Index 0x00)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...27	0x01	0x00	IP Filters Control (3-2)	
28...29	IP Filters Control (1-0)			

Note: This command is kept for compatibility with other projects and returns always 0x1 in the 10 GbE controller.

38.37.6.4.5 Set Intel Filters Formats

Set Intel Filters Command (Intel Command 0x02)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...21	0x02	Parameter Number	Filters Data (optional)	

Set Intel Filters Response (Intel Command 0x02)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...	0x02	Filter Control Index	Return Data (Optional)	

Set Intel Filters — Manageability Only Command (Intel Command 0x02, Filter Parameter 0x0F)

This command sets the PRT_MNG_MNGONLY register. The PRT_MNG_MNGONLY register controls whether PT packets destined to the MC are not forwarded to the Host operating system. The PRT_MNG_MNGONLY register is listed in Table 38-523.

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x0F	Manageability Only (3-2)	
24...25	Manageability Only (1-0)			

Set Intel Filters — Manageability Only Response (Intel Command 0x02, Filter Parameter 0x0F)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x0F		

Set Intel Filters — Flex Filter Enable Mask and Length Command (Intel Command 0x02, Filter Parameter 0x10)

The following command sets the Intel flex filters mask and length.

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x10	Mask Byte 1	Mask Byte 2
24...27	...	...	...	...
28...31	...	...	...	...
32...35	...	...	...	...
36...37	Mask Byte 15	Mask Byte 16	Reserved	Reserved
38	Length			

Set Intel Filters — Flex Filter Enable Mask and Length Response (Intel Command 0x02, Filter Parameter 0x10)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x10		

Set Intel Filters — Flex Filter Data Command (Intel Command 0x02, Filter Parameter 0x11)

Table 38-551.Filter data group

Code	Bytes Programmed	Filter Data Length
0x0	Bytes 0-29	1 - 30
0x1	Bytes 30-59	1 - 30
0x2	Bytes 60-89	1 - 30
0x3	Bytes 90-119	1 - 30
0x4	Bytes 120-127	1 - 8

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...	0x02	0x11	Filter Data Group	Filter Data 1
	...	Filter Data N		

Note: Using this command to configure the filters data must be done after the flex filter mask command is issued and the mask is set.

Set Intel Filters — Flex Filter Data Response (Intel Command 0x02, Filter Parameter 0x11)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x11		

Set Intel Filters — Packet Addition Decision Filter Command (Intel Command 0x02, Filter Parameter 0x61)

This command is no longer supported. Use the Section "Set Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x02, Filter Parameter 0x68)" instead.

Set Intel Filters — Flex TCP/UDP Port Filter Command

(Intel Command 0x02, Filter Parameter 0x63)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x63	Port Filter Index	TCP/UDP Port MSB
24..27	TCP/UDP Port LSB	Port Flags		

Filter index range: 0x0...0xA.

Port flags are as follows:

- Bit 0: Match UDP ports
- Bit 1: Match TCP ports
- Bit 2: Match destination port (0) or source port (1).
- Bit 7:3: Reserved

If flags are not present (payload length = 9), the match is done on TCP and UDP destination ports (legacy behavior).

If the filter index is larger than 10, a command failed response code is returned with Invalid Intel Parameter Number reason (0x5082).

Set Intel Filters — Flex TCP/UDP Port Filter Response

(Intel Command 0x02, Filter Parameter 0x63)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			

	Bits			
24...25	0x02	0x63		

Set Intel Filters — Ipv4 Filter Command (Intel Command 0x02, Filter Parameter 0x64)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x64	IP Filter Index	IPv4 Address (3)
24...26	IPv4 Address (2-0)			

Filter index range: 0x0...0x3.

Set Intel Filters — Ipv4 Filter Response (Intel Command 0x02, Filter Parameter 0x64)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x64		

If the IP filter index is larger than three, a command failed response code is returned Invalid Intel Parameter Number reason (0x5082).

Set Intel Filters — Ipv6 Filter Command (Intel Command 0x02, Filter Parameter 0x65)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x65	IP Filter Index	...IPv6 Address (MSB, Byte 15)
24...27	...	...	...	...
28...31	...	...	...	...
32...35	...	...	...	...
36...37	...		IPv6 Address (LSB, Byte 0)	

Note: The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x1...0x3.

IPv6 Mode: Filter index range: 0x0...0x3.

Set Intel Filters — Ipv6 Filter Response (Intel Command 0x02, Filter Parameter 0x65)

	Bits			
Bytes	**31:24**	**23:16**	**15:08**	**07:00**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x65		

If the IP filter index is larger than three, a command failed Response Code is returned, Invalid Intel Parameter Number reason (0x5082).

Set Intel Filters - EtherType Filter Command (Intel Command 0x02, Filter Parameter 0x67)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x67	EtherType Filter Index	EtherType Filter MSB
24...27	...	...	EtherType Filter LSB	

Where the EtherType filter has the format previously described.

38.37.6.4.6 Set Intel Filters - EtherType Filter Response (Intel Command 0x02, Filter Parameter 0x67)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x67		

If the EtherType filter index is different than two or three, a command failed Response Code is returned Invalid Intel Parameter Number reason (0x5082).

Set Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x02, Filter Parameter 0x68)

See Figure 38-129 for description of the decision filters structure.

The command must overwrite any previously stored value. The value set is not checked.

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x68	Extended Decision Filter Index	Extended Decision Filter 1 MSB
24...27	...	...	Extended Decision Filter 1 LSB	Extended Decision Filter 0 MSB
28...30	...	...	Extended Decision Filter 0 LSB	

Extended decision filter index range: 0...4

Filter 0: See Table 38-552.

Filter 1: See Table 38-553.

Table 38-552.Filter Values

Bit #	Name	Description
3:0	Unicast (AND)	If set, packets must match unicast filter 0 to 3, respectively.
4	Broadcast (AND)	If set, packets must match the broadcast filter.
12:5	VLAN (AND)	If set, packets must match VLAN filter 0 to 7, respectively.
16:13	IPv4 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively
20:17	IPv6 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively
24:21	Unicast (OR)	If set, packets can pass if match unicast filter 0 to 3, respectively or a different OR filter.
25	Broadcast (OR)	If set, packets can pass if match the broadcast filter or a different OR filter.
26	Multicast (AND)	If set, packets must match the multicast filter.
27	ARP Request (OR)	If set, packets can pass if match the ARP request filter or a different OR filter.
28	ARP Response (OR)	If set, packets can pass if match the ARP response filter or a different OR filter.
29	Neighbor Discovery - 134 (OR)	If set, packets can pass if match the neighbor discovery filter (type134 - router advertisement) or a different OR filter.
30	Port 0x298 (OR)	If set, packets can pass if match a fixed TCP/UDP port 0x298 filter or a different OR filter.
31	Port 0x26F (OR)	If set, packets can pass if match a fixed TCP/UDP port 0x26F filter or a different OR filter.

Table 38-553. Extended Filter 1 Values (Sheet 1 of 2)

Bit #	Name	Description
3:0	EtherType 0 -3 (AND)	If set, packets must match the EtherType filter 0 to 3, respectively.
7:4	EtherType 0 -3 (OR)	If set, packets must match the EtherType filter 0 to 3, respectively or a different OR filter.
18:8	Flex Port 10:0 (OR)	If set, packets can pass if match the TCP/UDP port filter 10:0.
19	DHCPv6 (OR)	If set, packets can pass if match the DHCPv6 port (0x0223).
20	DHCP Client (OR)	If set, packets can pass if match the DHCP server port (0x0043).
21	DHCP Server (OR)	If set, packets can pass if match the DHCP client port (0x0044).
22	NetBIOS Name Service (OR)	If set, packets can pass if match the NetBIOS name service port (0x0089).
23	NetBIOS Datagram Service (OR)	If set, packets can pass if match the NetBIOS datagram service port (0x008A).

Table 38-553. Extended Filter 1 Values (Sheet 2 of 2)

Bit #	Name	Description
24	Flex TCO (OR)	If set, packets can pass if match the flex 128 TCO filter.
25	Neighbor Discovery - 135 (OR)	If set, packets must also match the neighbor discovery filter (type135 - neighbor solicitation). or a different OR filter.
26	Neighbor Discovery - 136 (OR)	If set, packets must also match the neighbor discovery filter (type136 - neighbor advertisement) or a different OR filter.
27	Neighbor Discovery - 137 (OR)	If set, packets must also match the neighbor discovery filter (type137 - Redirect) or a different OR filter.
28	ICMPv4 (OR)	Controls the inclusion of ICMPv4 filtering in the manageability filter decision (OR section).
29	MLD	If set, packets must also match one of the MLD ICMPv6 types or a different OR filter.
31:30	Reserved	Reserved

Set Intel Filters – Packet Addition Extended Decision Filter Response (Intel Command 0x02, Filter Parameter 0x68)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Response Code		Reason Code	
20...23	Manufacturer ID (Intel 0x157)			
24...25	0x02	0x68		

If the extended decision filter index is larger than five, a command failed Response Code is returned Invalid Intel Parameter Number reason (0x5082).

Set Intel Filters - Special Modifier Command (Intel Command 0x02, Filter Parameter 0x69)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x02	0x69	Special Modifier Register MSB	
24...27	Special Modifier Register LSB		Padding	

Where the special modifier filter has the format previously described.

Set Intel Filters - Special Modifier Response (Intel Command 0x02, Filter Parameter 0x69)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**

28...29	Special Modifier Register LSB		Padding	

38.37.6.4.7 Set Intel Packet Reduction Filters Formats

The non-extended commands are obsolete. The extended commands should be used instead.

Set Intel Packet Reduction Filters Command (Intel Command 0x04)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20...23	0x04	Packet Reduction Index	Packet Reduction Data...	

Note: It is advised that the MC only use the extended packet reduction commands.

The *Packet Reduction* data field has the following structure:

Table 38-555.Packet Reduction Field Description

Bit #	Name	Description
12:0	Reserved	Reserved
16:13	IPv4 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
20:17	IPv6 Address (AND)	If set, packets must match IPv4 filter 0 to 3, respectively.
27:21	Reserved	Reserved.
28	ARP Response (OR)	If set, packets can pass if match the ARP response filter or a different OR filter.
29	Reserved	Reserved.
30	Port 0x298	If set, packets can pass if match a fixed TCP/UDP port 0x298 filter.
31	Port 0x26F	If set, packets can pass if match a fixed TCP/UDP port 0x26F filter.

Table 38-556.Extended Packet Reduction Field Description (Sheet 1 of 2)

Bit #	Name	Description
3:0	EtherType 0 -3 (AND)	If set, packets must match the EtherType filter 0 to 3, respectively.
7:4	EtherType 0-3 (OR)	If set, packets can pass if match the EtherType filter 0 to 3, respectively.
15:12	Reserved	Reserved.
8:18	Flex port 10:0 (OR)	If set, packets can pass if match the TCP/UDP Port filter 10:0.
23:19	Reserved	Reserved.
24	Flex TCO (OR)	If set, packets can pass if match the Flex 128 TCO filter.
27:25	Reserved	Reserved.

Table 38-556.Extended Packet Reduction Field Description (Sheet 2 of 2)

Bit #	Name	Description
28	ICMPv4	Is set, ICMPv4 packets can pass.
31:29	Reserved	Reserved.

The filtering is divided into two decisions:

- Bit 20:13 in Table 38-555 and bits 3:2 in Table 38-556 works in an AND manner; it must be true in order for a packet to pass (if was set).

Bits 28 in Table 38-555 and bits 24:10 in Table 38-556 work in an OR manner; at least one of them must be true for a packet to pass (if any were set).

Set Intel Packet Reduction Filters Response (Intel Command 0x04)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header

30...31	Broadcast Packet Reduction (1-0)			

38.37.6.4.9 System MAC Address

Get System MAC Address Command (Intel Command 0x06)

In order to support a system configuration that requires the NC to hold the MAC address for the MC (such as shared MAC address mode), the following command is provided to enable the MC to query the NC for a valid MAC address.

The NC must return the system MAC addresses. The MC should use the returned MAC addressing as a shared MAC address by setting it using the Set MAC Address command as defined in NC-SI 1.0.

When a single function is defined on the port, it returns the LAN MAC address of this function as read from the PF allocations NVM section or from the alternate RAM or as set by the Manage MAC address Write AQ command. When more than one function is defined on the port, it returns the address of the lowest defined function on this port.

It is also recommended that the MC use packet reduction and the Manageability-to-Host command to set the proper filtering method.

38.37.6.4.12 TCO Reset

Depending on the bit set in the TCO mode field this command causes the 10 GbE controller to perform either:

1. TCO reset — If force TCO reset is enabled in the NVM. The force TCO reset clears the data path (Rx/Tx) of the 10 GbE controller to enable the MC to transmit/receive packets through the 10 GbE controller.
   - If the MC has detected that the operating system is hung and has blocked the Rx/Tx path, the force TCO reset clears the data-path (Rx/Tx) of the NC to enable the MC to transmit/receive packets through the NC.
   - When this command is issued to a channel in a package, it applies only to the specific channel.
   - After successfully performing the command, the NC considers the Force TCO command as an indication that the operating system is hung and clears the internal driver up indication. If TCO reset is disabled in the NVM, the 10 GbE controller does not reset the data path and notifies the MC on successful completion.
2. TCO isolate — If TCO isolate is enabled in the NVM. The TCO Isolate command disables PCIe write operations to the LAN port.
   - If TCO isolate is disabled in NVM, the 10 GbE controller does not execute the command but sends a response to the MC with successful completion.
   - Following a TCO isolate, management sets *EMP_TCO_ISOLATE.EMP_TCO_ISOLATE* to 1b for all PFs associated with the port on which this command is received.
3. Firmware reset — This command causes re-initialization of all the manageability functions and re-loads of manageability related NVM words (such as firmware patch code).
   - When the MC loads a new management related NVM image (like a firmware patch) the Firmware Reset command loads the management related NVM information without the need to power down the system.
   - This command is issued to the package and affects all channels. After the firmware reset, the FW Semaphore register (FWSM) is re-initialized.

Note: Applying this command resets the entire device and also has an effect on TCO reset. TCO isolate affects only the channel (port) that the command was issued to. Force TCO resets the entire device (all channels in the package).

Following firmware reset, the MC needs to re-initialize all ports. A firmware reset causes a global reset of the entire device (GLOBR).

Note: Only one of the fields should be set in a given command. Setting more than one field might yield unexpected results.

Perform Intel TCO Reset Command (Intel Command 0x22)

	Bits			
Bytes	**[31:24]**	**[23:16]**	**[15:08]**	**[07:00]**
00...15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20	0x22	TCO Mode		

Where TCO mode is:

Field	Bit(s)	Description
DO_TCO_RST	0	Do TCO Reset. 0b = Do nothing. 1b = Perform TCO reset.
DO_TCO_ISOLATE[1]	1	Do TCO Isolate. 0b = Enable PCIe write access to LAN port. 1b = Isolate Host PCIe write operation to the port ***Note:*** Should be used for debug only. ***Note:*** The TCO Isolate do not impact MCTP traffic ***Note:*** When isolate is set, the OS2BMC flow is also disabled.
RESET_MGMT	2	Reset Manageability; Re-load Manageability NVM Words. 0b = Do nothing. 1b = Issue firmware reset to manageability. Setting this bit generates a one-time firmware reset. Following the reset, management related data from the NVM is loaded. ***Note:*** A reset of the internal firmware causes a reset of the entire device.
Reserved	7:3	Reserved (set to 0x00).

Note: For compatibility, the TCO Reset command without the TCO mode parameter is accepted (TCO reset is done).

Notes:

1. TCO isolate host write operation enabled in the NVM.

38.37.6.4.14 Shared MAC and Shared IP Support Commands (Intel Command 0x25)

To meet the requirements introduced by sharing IP addresses, modifications and additions to the NC-SI command set are required. These changes include the new commands in this section and the modifications described in Section 38.37.3.6.

Note: All indexes in this command set starts at one to match the NC-SI methodology.

Set IP Address Command (Intel Command 0x25, Index = 0x0)

The *Set IP Address* command is used by the MC to communicate its IP address to a NC. The format of a *Set IP Address* command packet is listed in Table 38-557.

If at least one IP address filter is enabled, only unicast packets that match one of the enabled filters are forwarded through the NC-SI interface. Otherwise, the IP address is ignored in the unicast filtering process.

This command does not impact the forwarding results. It is used as a preliminary stage to the *Set Binding* command.

Table 38-557.Set IP Address Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16...19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x0	Reserved	
24..27	Management Controller IP Address			
28..31				
32..35				
36..39				
40..43	Reserved		IP Address Number	Set IP Flags
44..47	Checksum			

- MC IP Address — An IP address that is used by the MC. If the *IP Version* bit of the *Flags* field is 0b (IPv4), this is a 4-byte unicast IPv4 address in network byte order. In this case, the address occupies bytes 24-27 of the packet, and bytes 28-39 are ignored. If the *IP Version* bit of the *Flags* field is 1b (IPv6), this is a 16-byte unicast IPv6 address in network byte order. In this case, the address occupies the full field (bytes 24-39 of the packet).
- IP Address Number — Indicates which IP address filter is configured by the command. The value can relate to one of three pools of filters according to Table 38-558.

Table 38-558.IP filters Pools

Set IP Flag.IP Version	Set IP Flag.Mixed Index	Pool to Use	Allowed Values
0	0	IPv4	One to the number of IPv4 only addresses.
1	0	IPv6	One to the number of IPv6 only addresses.
X (0/1)	1	Mixed	One to the number of mixed IP addresses.

Note: The values shown in the allowed values column refers to the Get Shared IP Capabilities Response.

- Table 38-559 lists the bits fields in the *Set IP Flags* field.

Table 38-559.Set IP Flag Field

Bit Position	Field Description	Value Description
0	Enable	0b = Disable the filter. 1b = Enable the filter.
1	IP Version	0b = IPv4. 1b = IPv6.
2	Mixed Index	0b = Index relates to the IPv4 or IPv6 only IP filter sets according to the IP version field. 1b = Index relates to the mixed IP filter set.
3	MAC Based IP	This flags define if the Ipv6 address is derived from a MAC address and thus only the 24 LSB should be used for the comparison. This flag is relevant only if the IP version = IPv6. 0b = Filter according to the full 128 bits of IPv6 address. 1b = Filter according to the 24 LS bits of the IPv6 address.
7:4	Reserved	Reserved.

Set IP Address Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set IP Address command and send a response using the format listed in Table 38-560.

Table 38-560.Set IP Address Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x0	Reserved	
28..31	Checksum			

Get IP Address Command (Intel Command 0x25, Index = 0x1)

An MC uses the *Get* IP Address command to determine the IP address programmed in one of the IP address filters in a NC. The format of a Get IP Address command packet is listed in Table 38-561.

Table 38-561.Get IP Address Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x1	Reserved	
24..27	Reserved		IP Address Number	IP Filter Pool
28..31	Checksum			

- IP address number. Defines the index of the IP address in the pool defined by the IP filter pool. The allowed values are listed in Table 38-558.
- IP filter pool:
  - 0x0: Mixed IP filters
  - 0x1: IPv4 filters
  - 0x2: IPv6 filters
  - 0x3 - 0xFF: Reserved

Get IP Address Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the *Get IP Address* command and send a response using the format listed in Table 38-562.

Table 38-562.Get IP Address Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header

32..35				
36..39				
40..43				
44..47	Checksum			

- MC IP Address — An IP address that is used by the MC. If the *IP Version* bit of the *Flags* field is 0b (IPv4), this is a 4-byte unicast IPv4 address in network byte order. In this case, the address occupies bytes 28-31 of the packet, and bytes 32-43 are ignored. If the *IP Version* bit of the *Flags* field is 1b (IPv6), this is a 16-byte unicast IPv6 address in network byte order. In this case, the address occupies the full field (bytes 28-43 of the packet).
- IP Address Number — Indicates which IP address filter is described in the response. Should be equal to the IP address number in the command.
- Table 38-563 lists the bits fields in the *Get IP Flags* field.

Table 38-563.Get IP Flag Field

Bit Position	Field Description	Value Description
0	Enable	0b = Filter is disabled. 1b = Filter is enabled.
1	IP Version	0b = IPv4. 1b = IPv6.
2	Mixed Index	0b = Index relates to the IPv4 or IPv6 only IP filter sets according to the IP version field. 1b = Index relates to the mixed IP filter set.

Table 38-563.Get IP Flag Field

Bit Position	Field Description	Value Description
3	MAC Based IP	This flag defines if the IPpv6 address is derived from a MAC address and thus only the 24 LSB should be used for the comparison. This flag is relevant only if the IP version = IPv6. 0b = Filter according to the full 128 bits of IPv6 address. 1b = Filter according to the 24 LS bits of the IPv6 address.
7:4	Reserved	Reserved.

Set Port Command (Intel Command 0x25, Index = 0x2)

An MC uses the Set Port command to communicate one of its TCP or UDP ports to a NC. The format of a Set Port command packet is listed in Table 38-564.

This command does not impact the forwarding results. It is used as a preliminary stage to the Set Binding command.

If the *Ignore Protocol* flag is cleared, the protocol should also match the *Protocol* field; otherwise, the *Protocol* field is ignored.

Table 38-564.Set Port Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x2	Set Port Flags	Reserved
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
24..27	Port Index	Protocol	Port	
28..31	Checksum			

- Protocol — The value to match in the IPv4 header *Protocol* field or IPv6 header *Next Header* field. These values are defined by IANA. Allowed values are 0x6 (TCP) and 0x11 (UDP).
- Port — The value to match in the *Destination Port* or *Source Port* field of the TCP or UDP header. The legal port range for both TCP and UDP is 0-65,535. The compared field is defined by the port type flag.
- Port Index — Indicates which port filter is configured by the command. Allowed values are 1 to n, where n is the number of port filters supported by the network controller.

Table 38-565 lists the fields in the *Set Port Flags* field.

Table 38-565.Set Port Flags Field Descriptions

Bit Position	Field Description	Value Description
0	Enable	0b = Disable the filter. 1b = Enable the filter.
1	Ignore Protocol	0b = Filter by port and protocol. 1b = Filter by port only.
2	Port Type	0b = Compare destination port. 1b = Compare source port.
7:3	Reserved	Reserved.

Set Port Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set Port command and send a response using the format listed in Table 38-566.

Table 38-566.Set Port Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
12..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x2	Reserved

16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x3	Reserved	
24..27	Reserved		Port Index	Reserved
28..31	Checksum			

Table 38-568 lists the fields in the Get Port command.

Table 38-568.Get Port Command Field Descriptions

Field	Field Description	Value Description
Port Index	Indicates which port filter is requested by the command.	1 to *n*, where *n* is the number of port filters supported by the NC.

Get Port Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Port command and send a response using the format listed in Table 38-569.

Table 38-569.Get Port Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x3	Get Port Flags	Reserved
28..31	Port Index	Protocol	Port	
32..35	Checksum			

- Protocol — The value compared in the IPv4 header *Protocol* field or IPv6 header *Next Header* field. Possible values are 0x6 (TCP) and 0x11 (UDP).
- Port — The value compared in the *Destination Port or Source Port* field of the TCP or UDP header.
- Port Index — Indicates which port filter is reported by the response. Should match the Port Index in the command.

Table 38-570 lists the fields in the *Get Port Flags* field.

Table 38-570.Get Port Flags Field Descriptions

Bit Position	Field Description	Value Description
0	Enable	0b = Filter is disabled. 1b = Filter is enabled.
1	Ignore Protocol	0b = Filter by port and protocol. 1b = Filter by port only.
2	Port Type	0b = Compare destination port. 1b = Compare source port.
7:3	Reserved	Reserved.

Enable Unicast Infrastructure Filter Command (Intel Command 0x25, Index = 0x4)

A MC uses the Enable Unicast Infrastructure Filter command to configure a NC to forward copies of network infrastructure packets to it. Network infrastructure packets contain messages that are necessary for operating the network infrastructure layers (such as DHCP, ARP, and DNS messages). This is required when the MC shares an IP address with the host. In this case, both the host and the MC need to process the messages. As a result, the NC must forward the packets to both the MC and the host.

This command should be applied only after a MAC address is added using the Set MAC Address NC-SI command.

All the IP addresses added through the Set IP command before this command is given are considered as IP addresses of the MC for the purpose of this command.

If a Set IP command is received after this command was received, the list of IP address is not updated and this command should be given again.

The format of an Enable Unicast Infrastructure Filter command packet is listed in Table 38-571.

Table 38-571.Enable Unicast Infrastructure Filter Command

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header

32..35	Checksum			
36..29	Padding			

Table 38-572 lists the sub fields of the *Unicast Infrastructure Filter Settings* field.

Table 38-572.Unicast Infrastructure Packet Filter Settings Field

Bit Position	Field Description	Value Description
0	ARP Response Packets Received From Wire	0x1 = Forward this packet type to both the host and the MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, an ARP response packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x0806 (ARP). The ARP *Opcode* field is set to 0x0002 (response). The ARP *Target Protocol Address* field contains the IP address assigned to the MC.
1	ICMPv4 Request Packets Received From Wire	0x1 = Forward this packet type to both the host and the MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, an ICMP request packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x0800 (IPv4). The IP *Destination Address* field contains the IPv4 address assigned to the MC. The IP *Protocol* field contains 1 (ICMP).
2	ICMPv6 Request Packets Received From Wire	0x1 = Forward this packet type to both the host and the MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, an ICMPv6 request packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6). The IP *Destination Address* field contains the IPv6 address assigned to the MC. The IP *Next Header* field contains 58 (ICMPv6). This filter is not supported by the 10 GbE controller.

Table 38-572.Unicast Infrastructure Packet Filter Settings Field

Bit Position	Field Description	Value Description
3	DHCP Server Unicast Packets Received From Wire	0x1 = Forward this packet type to both the host and the MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, a DHCP server unicast packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x0800 (IPv4). The IP *Destination Address* field contains either 255.255.255.255 (the local broadcast address) or the IPv4 address assigned to the MC. The IP *Protocol* field contains 17 (UDP). The UDP *Destination Port* field contains 68 (bootstrap protocol client).
4	DNS Server Packets Received From Wire	0x1 = Forward this packet type to both the host and the MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, a DNS server unicast packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x0800 (IPv4). The IP *Destination Address* field contains the IPv4 address assigned to the MC. The IP *Protocol* field contains 17 (UDP). The UDP *Source Port* field contains 53 (domain name server).
5	DHCP Client Packets Transmitted By Host	0x1 = Forward this packet type to both the wire and the MC. 0x0 = Forward this packet type to the wire only. For the purposes of this filter, a DHCP client unicast packet is defined to be any packet that meets all of the following requirements: The Ethernet *Source Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x0800 (IPv4). The IP *Protocol* field contains 17 (UDP). The UDP *Destination Port* field contains 67 (bootstrap protocol server).
6	DHCPv6 Server Unicast Packets Received From Wire	0x1 = Forward this packet type to both the host and MC. 0x0 = Forward this packet type to the host only. For the purposes of this filter, a DHCPv6 server unicast packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6). The IPv6 *Destination Address* field contains the IPv6 address assigned to the MC. The IP *Protocol* field contains 17 (UDP). The UDP *Destination Port* field contains 546 (DHCPv6 protocol client).
7	RMCP Primary Port - UDP	0x1 = Forward this packet type to the MC only. 0x0 = Forward this packet type to the host. For the purposes of this filter, a RMCP primary UDP packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). The IP *Destination Address* field contains the one of the IP address assigned to the MC. The IP *Protocol* field contains 17 (UDP). The UDP *Destination Port* field contains 623 [aux bus shunt (primary RMCP port)].

Table 38-572.Unicast Infrastructure Packet Filter Settings Field

Bit Position	Field Description	Value Description
8	RMCP Primary Port - TCP	0x1 = Forward this packet type to the MC only. 0x0 = Forward this packet type to the host. For the purposes of this filter, a RMCP primary TCP packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). The IP *Destination Address* field contains the one of the IP address assigned to the MC. The IP *Protocol* field contains 6 (TCP). The UDP *Destination Port* field contains 623 [aux bus shunt (primary RMCP port)].
9	RMCP Secondary Port - UDP	0x1 = Forward this packet type to the MC only. 0x0 = Forward this packet type to the host For the purposes of this filter, a RMCP secondary UDP packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6) or 0x0800 (IPv4). The IP *Destination Address* field contains the one of the IP address assigned to the MC. The IP *Protocol* field contains 17 (UDP). The UDP *Destination Port* field contains 664 [secure aux bus (secondary RMCP port)].
10	RMCP Secondary Port - TCP	0x1 = Forward this packet type to the MC only. 0x0 = Forward this packet type to the host. For the purposes of this filter, a RMCP secondary TCP packet is defined to be any packet that meets all of the following requirements: The Ethernet *Destination Address* field contains the MAC address assigned to the MC. The Ethernet *Type* field contains 0x86DD (IPv6) 0r 0x0800 (IPv4). The IP *Destination Address* field contains the one of the IP address assigned to the MC. The IP *Protocol* field contains 6 (TCP). The TCP *Destination Port* field contains 664 [secure aux bus (secondary RMCP port)].
31:11	Reserved	None.

Enable Unicast Infrastructure Filter Response

The NC, in the absence of a checksum error or identifier mismatch, always accept the Enable Unicast Infrastructure Filter command and send a response using the format listed in Table 38-573. Currently no command-specific reason codes are identified for this response.

Table 38-573.Enable Unicast Infrastructure Filter Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x4	Reserved	
28..29	Checksum			

38.37.6.4.15 Get Shared IP Capabilities Command (Intel Command 0x25, Index = 0x5)

An MC uses the Get Shared IP Capabilities command to determine the level of support of shared IP of the device. The format of a Get Shared IP Capabilities command packet is listed in Table 38-574.

Table 38-574. Get Shared IP Capabilities Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x5	Reserved	
24..27	Checksum			

Get Shared IP Capabilities Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Shared IP Capabilities command and send a response, using the format listed in Table 38-575. Currently no command-specific reason codes are identified for this response.

Table 38-575. Get Shared IP Capabilities Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x5	Number of Mixed IP Address	Number of IPv4 Only Addresses
28..31	Number of IPv6 only addresses	Number of Ports	Number Of Bindings	Filtering Capabilities
32..35	Unicast Infrastructure Filter Capabilities			
36..30	Checksum			

- Number of mixed IP addresses — The number of supported IP filters that can be used for IPv4 or IPv6. The 10 GbE controller does not support mixed IP address filters.
- Number of IPv4 only addresses — The number of supported IP filters that can be used for IPv4 only. The 10 GbE controller supports three IPv4 address filters.
- Number of IPv6 only addresses — The number of supported IP filters that can be used for IPv6 only. The 10 GbE controller supports four IPv6 address filters.
- Number of ports — The number of supported port filters.
- Number of bindings — Defines the number of IP addresses that can be bound with different ports.
- Unicast infrastructure filter capabilities — Defines the optional unicast infrastructure filter capabilities that the channel supports. The bit definitions for this field correspond directly with the bit definitions for the *Unicast Infrastructure Filter Settings* field defined for the Unicast Infrastructure Filter command listed in Table 38-572. A bit set to 1b indicates that the channel supports the filter associated with that bit position; otherwise, the channel does not support that

filter. The 10 GbE controller supports all filters but ICMPv6 filtering, so the returned value is 0x7FB.

- Table 38-576 lists the bits fields in the *Filtering Capabilities* field.

Table 38-576.Filtering Capabilities Field

Bit Position	Field Description	Value Description
0	IPv4 support	0b = IPv4 filtering is not supported. 1b = IPv4 filtering is supported.
1	IPv6 support	0b = IPv6 filtering is not supported. 1b = IPv6 filtering is supported.
2	Protocol filtering support	0b = Filtering by protocol is not supported. 1b = Filtering by protocol is supported.
3	Source port filtering support	0b = Port filtering is supported only for destination port. 1b = Port filtering is supported for destination port or source port.
7:4	Reserved	Reserved.

Shared IP Enable Broadcast Filtering Command (Intel Command 0x25, Index = 0x6)

A new *shared IP enable broadcast filtering* is defined to enable the MC to limit the flow of ARP requests to those that contain a target IP address value that matches the MC IP address.

This command should be used instead of the regular NC-SI Enable Broadcast Filtering command.

Note: Receiving a standard NC-SI Enable Broadcast Filtering command enables the matching bits in this command. Receiving a standard NC-SI Disable Broadcast Filter Command clears the settings in this command.

The format of an Shared IP Enable Broadcast Filtering command packet is listed in Table 38-571.

Table 38-577.Shared IP Enable Broadcast Filtering Command

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x6	Reserved	
28..31	Shared IP Broadcast Packet Filter Settings			
32..35	Checksum			
36..29	Padding			

The content of the *Shared IP Broadcast Packet Filter Settings* field is listed in Table 38-578. Bit 4 has been added to the standard enable broadcast filtering command limit ARP broadcast packets to the MC IP add*ress*.

Table 38-578.Shared IP Broadcast Packet Filter Settings Field

Bit Position	Field Description	Value Description
3:0	As defined in DSP0222	As defined in DSP0222 in 8.4.33 Enable Broadcast Filter command (0x10) - table 68.
4	Limit ARP Broadcast Packets to Management Controller IP Address	When bit 0 is set, it limits the flow of ARP packets to the MC as follows: 0x1 = Forward only ARP broadcast packets that are targeted at IP addresses bound to the MC. 0x0 = Forward all ARP broadcast packets to the MC. All the IPs set by the *Set IP* command before this command is given will be included in forwarding. This field is optional. If unsupported, the behavior for ARP packets is set according to bit 1 in this structure. The value must be set to 0b if unsupported.
31:5	Reserved	None.

Shared IP Enable Broadcast Filtering Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Shared IP Enable Broadcast Filtering command and send a response using the format listed in Table 38-573. Currently no command-specific reason codes are identified for this response.

Table 38-579.Shared IP Enable Broadcast Filtering Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**

24..27	0x25	0x6	Reserved	
28..29	Checksum			

Shared IP Enable Global Multicast Filtering Command (Intel Command 0x25, Index = 0x7)

A new shared IP enable global multicast filtering is defined to enable the MC to enable the forwarding of IEEE 802.1X Extensible Authentication Protocol over LAN (EAPOL) frames to the MC IP address. IEEE 802.1X defines methods for port-based network access control.

This command should be used instead of the regular NC-SI Enable Global Multicast Filtering command.

Note: Receiving a standard NC-SI Enable Global Multicast Filtering command enables the matching bits in this command. Receiving a standard NC-SI Disable Global Multicast Filter command clears the settings in this command.

The format of an Shared IP Enable Global Multicast Filtering command packet is listed in Table 38-580.

Table 38-580.Shared IP Enable Global Multicast Filtering Command

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code

28..31	Shared IP Multicast Packet Filter Settings			
32..35	Checksum			
36..29	Padding			

The content of the *Shared IP Multicast Packet Filter Settings* field is listed in Table 38-581. Bit 4 has been added to the standard enable broadcast filtering command limit ARP broadcast packets to MC IP address.

Table 38-581.Shared IP Multicast Packet Filter Settings Field

Bit Position	Field Description	Value Description
2:0	As defined in DSP0222	As defined in DSP0222 in 8.4.37 Enable Global Multicast Filter Command (0x12) - table 74.
3	IEEE 802.1X EAPOL	0x1 = Forward this packet type to the MC. 0x0 = Filter out this packet type. For the purposes of this filter, a IEEE 802.1X multicast packet is defined to be any packet that meets all of the following requirements: The destination MAC address field is set to the layer 2 multicast address 01:80:c2:00:00:03. The EtherType field is set to 0x888E (802.1X PAE). This field is optional. If unsupported, multicast 802.1X packets are blocked when multicast filtering is enabled, unless they are matched by an address filter configured using the Set MAC Address command. The value must be set to 0b if unsupported.
31:4	Reserved	None.

Shared IP Enable Global Multicast Filtering Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Shared IP Enable Global Multicast Filtering command and send a response using the format listed in Table 38-582. Currently no command-specific reason codes are identified for this response.

Table 38-582.Shared IP Enable Global Multicast Filtering Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header

24..27	0x25	0x7	Reserved	
28..29	Checksum			

Get Shared IP Parameters Command (Intel Command 0x25, Index = 0x8).

The Get Shared IP parameters command can be used by the MC to request that the channel send the MC a copy of part of the currently stored parameter settings that have been put into effect by the MC related to shared IP filtering. The format of a Get Shared IP Capabilities command packet is listed in Table 38-583.

Table 38-583.Get Shared IP Parameters Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x8	Reserved	
24..27	Checksum			

Get Shared IP Parameters Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Shared IP parameters command and send a response using the format listed in Table 38-584. Currently no command-specific reason codes are identified for this response.

Table 38-584.Get Shared IP Parameters Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x5	Reserved	
28..31	Number of IP Addresses	IP addresses Flags		
32..35	Number of ports	Ports Flags		
36..39	Unicast Infrastructure Filter Settings			
40..43	Broadcast Filtering Settings			
44..47	Multicast Filtering Settings			
48..51	Checksum			

- Number of IP addresses — The number of supported IP filters including all the types of IP addresses (IPv4 only, IPv6 only and mixed).
- IP address flags — The enable/disable state for each supported IP address. See Table 38-585.

Table 38-585.IP Address Flags Field

Bit Position	Field Description	Value Description
0	IP Address 1 Status	0b = Default or unsupported or disabled. 1b = Enabled.
1	IP Address 2 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
2	IP Address 3 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.

Table 38-585.IP Address Flags Field

Bit Position	Field Description	Value Description
...		
23	IP Address 24 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.

Note: IP address flags are organized in the following order: IPv4 addresses first, followed by IPv6 addresses, followed by mixed addresses, with the number of each corresponding to those reported through the Get Shared IP Capabilities command.

For example, if the interface reports four IPv4 filters, two IPv6 filters, and two mixed filters, then IP addresses 1 through 4 are those currently configured through the interface's IPv4 filters, IP addresses 5 and 6 are those configured through the IPv6 filters, and 7 and 8 are those configured through the mixed filters.

The actual settings of each enabled IP address can be found using the Get IP address command.

- Number of ports — The number of supported port filters.
- Port flags — The enable/disable state for each supported ports. See Table 38-585.

Table 38-586.Port Flags Field

Bit Position	Field Description	Value Description
0	Port 1 Status	0b = Default or unsupported or disabled. 1b = Enabled.
1	Port 2 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
2	Port 3 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.
...		
23	Port 24 Status or Reserved	0b = Default or unsupported or disabled. 1b = Enabled.

Note: The actual settings of each enabled port can be found using the Get Port command

- Unicast Infrastructure Filter Settings — Defines the optional unicast infrastructure filter capabilities settings. The bit definitions for this field correspond directly with the bit definitions for the *Unicast Infrastructure Filter Settings* field defined for the Unicast Infrastructure Filter command in Table 38-572. A bit set to 1b indicates that the filter associated with that bit position is enabled; otherwise, the filter is not enabled.
- Broadcast Filter Settings — Defines the optional broadcast filter settings. The bit definitions for this field correspond directly with the bit definitions for the *Broadcast Filter Settings* field defined for the Shared IP Broadcast Filtering command in Table 38-578. A bit set to 1b indicates that the filter associated with that bit position is enabled; otherwise, the filter is not enabled.
- Global Multicast Filter Settings — Defines the optional multicast filter capabilities settings. The bit definitions for this field correspond directly with the bit definitions for the *Multicast Filter Settings* field defined for the Shared IP Global Multicast Filtering command in Table 38-578. A bit set to 1b indicates that the filter associated with that bit position is enabled; otherwise, the filter is not enabled.

Set Binding Command (Intel Command 0x25, Index = 0x9)

The Set Binding command is used by the MC to define which combination of MAC addresses, VLAN tags, IP addresses and TCP/UDP ports should be forwarded to the MC. The format of a Set Binding command packet is listed in Table 38-587.

Once a Set Binding command is activated, all the previous forwarding rules based on the Set MAC Address or Set VLAN filter commands are disabled and should be re-enabled using the Set Binding command. Subsequent Set MAC Address or Set VLAN filter commands are used to enable MAC or VLAN addresses for the Set Binding command but does not impact the forwarding rules.

Table 38-587.Set Binding Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
16...19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0x9	Binding Index	Set Binding Flags
24..27	Enabled MAC Addresses			
28..31	Enabled VLAN			
32..35	Enabled IP addresses			
36..39	Enabled Ports (MSB)			
40..43	Enabled Ports (LSB)			
44..47	Checksum			

Table 38-588 lists the fields in the *Set Binding Flags* field.

Table 38-588.Set Binding Flags Field Descriptions

Bit Position	Field Description	Value Description
0	Enable	0b = Disable the binding. 1b = Enable the binding.
1	Exclusive to MC	0b = Traffic matching this filter is sent to the MC and to the host. 1b= Traffic matching this filter is sent to the MC only.
2	Apply to Network[1]	0b = Do not compare traffic received from the network when checking this binding. 1b = Compare traffic received from the network when checking this binding.
3	Apply to Host	0b = Do not compare traffic received from the host when checking this binding. 1b = Compare traffic received from the host when checking this binding.
7:4	Reserved	Reserved.

Notes:

1. At least one of the apply to network/host flags should be set for enabled bindings. Clearing both of them is equivalent to disabling the filter.

- Binding Index — Indicates which binding is configured by the command.The value should be smaller than the number of supported bindings as reported in the get shared IP capabilities response in the *Number of Bindings* field.
- Enabled MAC Addresses — The MAC addresses participating in this binding. The numbering of the MAC addresses is similar to the one used in the MAC address flags in the get parameters response. Namely, MAC addresses are returned in the following order: unicast filtered addresses first, followed by multicast filtered

addresses, followed by mixed filtered addresses, with the number of each corresponding to those reported through the Get Capabilities command. A MAC address can be added to a binding only if previously enabled through a Set MAC Address NC-SI command.

- Enabled VLAN — The VLAN IDs participating in this binding. The numbering of the VLAN IDs. A VLAN tag can be added to a binding only if previously enabled through a Set VLAN Filter NC-SI command.
- Enabled IP Addresses — The IP addresses participating in this binding. The numbering of the IP addresses is similar to the one used in Section "Get Shared IP Parameters Command (Intel Command 0x25, Index = 0x8)." An IP address can be added to a binding only if previously enabled through a Set IP Address Intel OEM command.
- Enabled Ports — The ports participating in this binding. A port can be added to a binding only if previously enabled through a Set Port Intel OEM command.

Set Binding Address Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set Binding command and send a response using the format listed in Table 38-589.

Table 38-589.Set binding response packet format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0x9	Reserved	
28..31	Checksum			

Get Binding Command (Intel Command 0x25, Index = 0xA)

A MC uses the Get Binding command to determine the current programming of one of the bindings in a NC. The format of a Get Binding command packet is listed in Table 38-590.

Table 38-590.Get Binding Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0xA	Binding Number	Reserved
24..27	Checksum			

- Binding Index — Indicates which binding is requested by the command. The value should be smaller than the number of supported bindings as reported in the Get Shared IP Capabilities Response in the *Number of Bindings* field.

Get Binding Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Get Binding command and send a response using the format listed in Table 38-591.

Table 38-591.Get Binding Response Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (Intel 0x157)			
24..27	0x25	0xA	Binding Number	Get Binding Flags
28..31	Enabled MAC Addresses			
32..35	Enabled VLAN			
36..39	Enabled IP Addresses			
40..43	Enabled Ports (MSB)			
44..47	Enabled Ports (LSB)			
48..51	Checksum			

The fields in the Get Binding response are equivalent to their counterparts in the Set Binding command.

Set Shared Mode Command (Intel Command 0x25, Index = 0xB)

An MC uses the Set Shared Mode command to indicate to the NIC it intends to operate in shared MAC/IP mode or in dedicated MAC mode.

If used, this command should be sent before any of the regular or OEM NC-SI commands used to set forwarding filters. When this command is received, all the filters are cleared.

This command is only needed when the Intel OEM commands with command ID 0x25 are used to configure the shared behavior. If other commands are used, users should take care of the right configuration of the filters.

When shared mode is activated, the Set MAC and Set VLAN NC-SI commands do not impact the receive filtering until a Set Binding or Enable Unicast Infrastructure Filter command is received.

Any other command from this section (38.37.6.4.14) received before shared mode is set fails with a Not is Shared Mode (0x5092) reason.

The format of a Set Shared Mode command packet is listed in Table 38-592.

Table 38-592.Set Shared Mode Command Packet Format

	Bits			
Bytes	**31..24**	**23..16**	**15..08**	**07..00**
00..15	NC-SI Header			
16..19	Manufacturer ID (Intel 0x157)			
20..23	0x25	0xB	Shared Mode	Reserved
24..27	Checksum			

- Shared mode:
  — 0x0: Dedicated MAC mode.
  — 0x1: Shared MAC/IP mode.

Set Shared Mode Response

The NC must, in the absence of a checksum error or identifier mismatch, always accept the Set Shared Mode command and send a response using the format listed in Table 38-593.

Table 38-593.Set Shared Mode Response Packet Format

	Bits

20...23	Manufacturer ID (Intel 0x157)			
24...25	0x40	0x03		

Set MC IP Address Command (Intel Command 0x40, Index 0x4)

This command is used to expose the MC IP address to the host. This command is supported by the 10 GbE controller, but no action is taken upon reception. The IP address is not stored and when a Get OS2BMC Parameters command is received, the IP valid flag is cleared.

The IP type entry indicate whether the IP address is an IPv4 or an IPv6 address:

0 = IPv4.

1 = IPv6.

2 = No IP address, then the command should not include an IP address.

...	Controller Info Item n ID	Controller Info Item n Length	Controller Info Item n Data	
...	....			

The possible inventory items are described as follows. Note that not all the inventory items would be present in all the implementations of this command.

Table 38-595.Controller Information Items

ID	Length (In Bytes)	Data	Notes
0x00	3	Device ID (2 bytes) + RevID	This is the hardware default value (no value programmed via the NVM).
0x0B	2	NVM Image Version	
0x0C	4	EMP ROM Internal Version	
0x0D	4	EMP Flash Internal Version	Same version as in Get Version Admin command.
0x0E	2	PXE Firmware Version	MajorVersion.MinorVersion.Build.
0x0F	2	iSCSI Firmware Version	
0x10	2	uEFI Firmware Version	

38.37.6.4.18 NVM Error AEN (Intel AEN 0x82)

The following is the AEN that might be sent by the NC following a detection of a wrong CRC/checksum on a firmware related section in the NVM. NC is required to store this AEN internally until a connection to the MC is established so the report could be issued in all cases.

This AEN must be enabled using the NC-SI AEN Enable command, using bit 18 (0x40000) of the AEN enable mask.

	Bits

00...15	NC-SI AEN Header			
20...23	Reserved			0x82
24...27	Index of module on which the error was found. The encoding is as defined in *GL_MNG_FWSM.EXT_ERR_IND* field.			

38.37.6.5 Basic NC-SI Workflows

38.37.6.5.1 Package States

A NC package can be in one of the following two states:

1. Selected — The package is allowed to use the NC-SI lines, meaning the NC package might send data to the MC.
2. De-selected — The package is not allowed to use the NC-SI lines, meaning, the NC package cannot send data to the MC.

The MC must select no more than one NC package at any given time. Package selection can be accomplished in one of two methods:

1. Select Package command — This command explicitly selects the NC package.
2. Any other command targeted to a channel in the package also implicitly selects that NC package.

Package de-select can be accomplished only by issuing the De-Select Package command. The MC should always issue the Select Package command as the first command to the package before issuing channel-specific commands. For further details on package selection, refer to the NC-SI specification.

38.37.6.5.2 Channel states

A NC channel can be in one of the following states:

1. Initial State — The channel only accepts the Clear Initial State command (the package also accepts the Select Package and De-Select Package commands).
2. Active State — This is the normal operational mode. All commands are accepted.

For normal operation mode, the MC should always send the Clear Initial State command as the first command to the channel.

38.37.6.5.3 Discovery

After interface power-up, the MC should perform a discovery process to discover the NCs that are connected to it. This process should include an algorithm similar to the following:

1. For package_id=0x0 to MAX_PACKAGE_ID:
   a. Issue a Select Package command to package ID package_id.
   b. If a response was received:
   c. For internal_channel_id = 0x0 to MAX_INTERNAL_CHANNEL_ID.
   d. Issue a Clear Initial State command for package_id | internal_channel_id (the combination of package_id and internal_channel_id to create the channel ID).
   e. If a response was received:
   f. Consider internal_channel_id as a valid channel for the package_id package.
   g. The MC can now optionally discover channel capabilities and version ID for the channel.
   h. Else, if a response was not received, then issue a Clear Initial State command three times.
   i. Issue a De-Select Package command to the package (and continue to the next package).
   j. Else, if a response was not received, issue a Select Packet command three times.

38.37.6.5.4 Configurations

This section details different configurations that should be performed by the MC.

It is good practice that the MC not consider any configuration valid unless the MC has explicitly configured it after every reset (entry into the initial state). As a result, it is recommended that the MC re-configure everything at power-up and channel/package resets.

NC Capabilities Advertisement

NC-SI defines the Get Capabilities command. It is recommended that the MC use this command and verify that the capabilities match its requirements before performing any configurations. For example, the MC should verify that the NC supports a specific AEN before enabling it.

Receive Filtering

In order to receive traffic, the BMC must configure the NC with receive filtering rules. These rules are checked on every packet received on the LAN interface (such as from the network). Only if the rules matched, will the packet be forwarded to the BMC.

MAC Address Filtering

NC-SI defines three types of MAC address filters: unicast, multicast and broadcast. To be received (not dropped) a packet must match at least one of these filters. The MC should set one MAC address using the Set MAC Address command and enable broadcast and global multicast filtering.

Unicast/Exact Match (Set MAC Address command)

This filter filters on specific 48-bit MAC addresses. The MC must configure this filter with a dedicated MAC address.

The NC might expose three types of unicast/exact match filters (such as MAC filters that match on the entire 48 bits of the MAC address): unicast, multicast and mixed. The 10 GbE controller exposes two mixed filters, which might be used both for unicast and multicast filtering. The MC should use one mixed filter for its MAC address.

Refer to NC-SI specification — Set MAC Address for further details.

Broadcast (Enable/Disable Broadcast Filter command)

NC-SI defines a broadcast filtering mechanism that has the following states:

1. Enabled — All broadcast traffic is blocked (not forwarded) to the BMC, except for specific filters (such as ARP request, DHCP, and NetBIOS).
2. Disabled — All broadcast traffic is forwarded to the BMC, with no exceptions.

Refer to NC-SI specification Enable/Disable Broadcast Filter command.

Global Multicast (Enable/Disable Global Multicast Filter)

NC-SI defines a multicast filtering mechanism which has the following states:

1. Enabled — All multicast traffic is blocked (not forwarded) to the BMC.
2. Disabled — All multicast traffic is forwarded to the BMC, with no exceptions.

The recommended operational mode is Enabled, with specific filters set. Not all multicast filtering modes are necessarily supported. Refer to NC-SI specification Enable/Disable Global Multicast Filter command for further details.

VLAN

NC-SI defines the following VLAN work modes:

Mode	Command and Name	Descriptions
Disabled	Disable VLAN command.	In this mode, no VLAN frames are received.
Enabled #1	Enable VLAN command with VLAN only.	In this mode, only packets that matched a VLAN filter are forwarded to the MC.
Enabled #2	Enable VLAN command with VLAN only + non-VLAN.	In this mode, packets from mode 1 + non-VLAN packets are forwarded.
Enabled #3	Enable VLAN command with Any-VLAN + non-VLAN.	In this mode, packets are forwarded regardless of their VLAN state.

Refer to NC-SI specification — Enable VLAN command for further details.

The 10 GbE controller only supports modes #1 and #3. Recommendation:

1. Modes:
   a. If VLAN is not required — Use the disabled mode.
   b. If VLAN is required — Use the enabled #1 mode.
2. If enabling VLAN, The MC should also set the active VLAN ID filters using the NC-SI Set VLAN Filter command prior to setting the VLAN mode.

38.37.6.5.5 PT Traffic States

The MC has independent, separate controls for enablement states of the receive (from LAN) and of the transmit (to LAN) PT paths.

38.37.6.5.6 Channel Enable

This mode controls the state of the receive path:

1. Disabled — The channel does not pass any traffic from the network to the MC.
2. Enabled — The channel passes any traffic from the network (that matched the configured filters) to the MC.

This state also affects AENs: AENs is only sent in the enabled state.

The default state is disabled.

It is recommended that the MC complete all filtering configuration before enabling the channel.

38.37.6.5.7 Network Transmit Enable

This mode controls the state of the transmit path:

1. Disabled — the channel does not pass any traffic from the MC to the network.
2. Enabled — the channel passes any traffic from the MC (that matched the source MAC address filters) to the network.

The default state is disabled.

The NC filters PT packets according to their source MAC address. The NC tries to match that source MAC address to one of the MAC addresses configured by the Set MAC Address command. As a result, the MC should enable network transmit only after configuring the MAC address.

It is recommended that the MC complete all filtering configuration (especially MAC addresses) before enabling the network transmit.

This feature can be used for fail-over scenarios. See Section 38.37.6.9.3.

38.37.6.6 Asynchronous Event Notifications (AENs)

AENs are unsolicited messages sent from the NC to the MC to report status changes (such as link change, operating system state change, etc.).

Recommendations:

- The MC firmware designer should use AENs. To do so, the designer must take into account the possibility that a NC-SI response frame (such as a frame with the NC-SI EtherType), arrives out-of-context (not immediately after a command, but rather after an out-of-context AEN).
- To enable AENs, the MC should first query which AENs are supported, using the Get Capabilities command, then enable desired AEN(s) using the Enable AEN command, and only then enable the channel using the Enable Channel command.

38.37.6.7 Querying Active Parameters

The MC can use the Get Parameters command to query the current status of the operational parameters.

38.37.6.8 Resets

In NC-SI there are two types of resets defined:

1. Synchronous entry into the initial state.
2. Asynchronous entry into the initial state.

Recommendations:

- It is very important that the MC firmware designer keep in mind that following any type of reset, all configurations are considered as lost and thus the MC must re-configure both the synchronous and asynchronous entries.
- As an asynchronous entry into the initial state might not be reported and/or explicitly noticed, the MC should periodically poll the NC with NC-SI commands (such as Get Version ID, Get Parameters, etc.) to verify that the channel is not in the initial state. Should the NC channel respond to the command with a Clear Initial State Command Expected reason code, the MC should consider the channel (and most probably the entire NC package) as if it underwent a (possibly unexpected) reset event. Thus, the MC should re-configure the NC. See the NC-SI specification section on Detecting Pass-through Traffic Interruption.
- The Intel recommended polling interval is 2-3 seconds.

For exact details on the resets, refer to NC-SI specification.

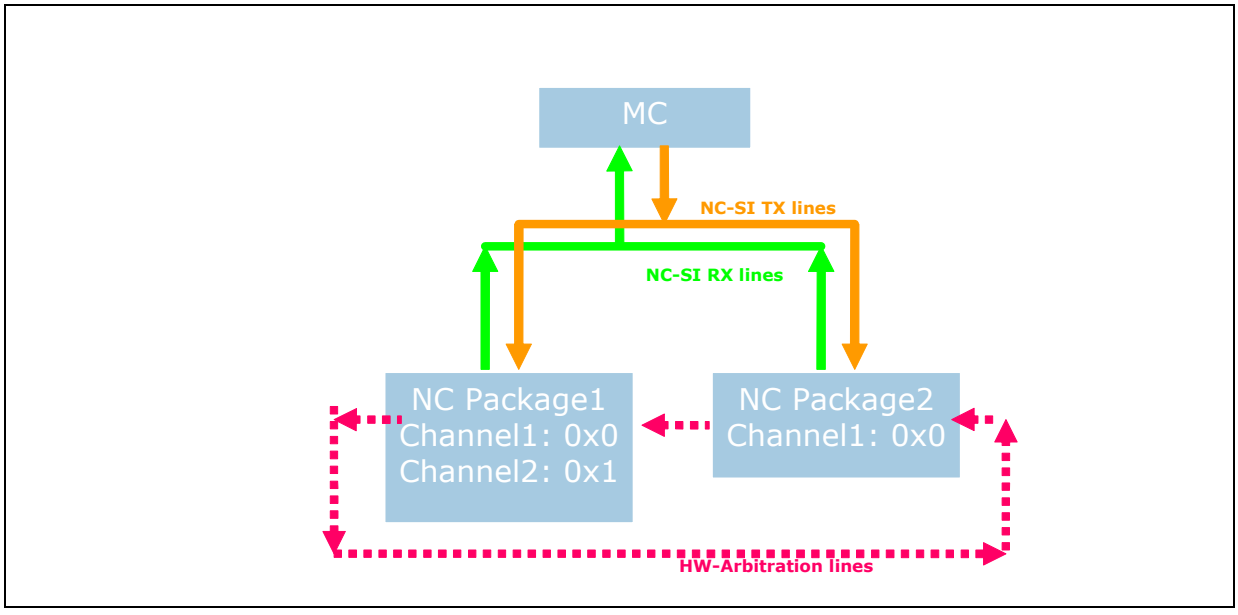
38.37.6.9 Advanced Workflows

38.37.6.9.1 Multi-NC Arbitration

As described in Section 38.37.6.1.2, in a multi-NC environment, there is a need to arbitrate the NC-SI lines.

Figure 38-136 shows the system topology of such an environment.

Figure 38-136.Multi-NC Environment



See Figure 38-136. The NC-SI Rx lines are shared between the NCs. To enable sharing of the NC-SI Rx lines, NC-SI has defined an arbitration scheme.

The arbitration scheme mandates that only one NC package can use the NC-SI Rx lines at any given time. The NC package that is allowed to use these lines is defined as selected. All the other NC packages are de-selected.

NC-SI has defined two mechanisms for the arbitration scheme:

1. Package selection by the MC. In this mechanism, the MC is responsible for arbitrating between the packages by issuing NC-SI commands (Select/De-Select Package). The MC is responsible for having only one package selected at any given time.
2. Hardware arbitration. In this mechanism, two additional pins on each NC package are used to synchronize the NC package. Each NC package has an ARB_IN and ARB_OUT line and these lines are used to transfer tokens. A NC package that has a token is considered selected.

Note: Hardware arbitration is enabled by the NC-SI *HW Arbitration Enable* configuration bit in the NC-SI Configuration 1 NVM word.

For details, refer to the NC-SI specification.

38.37.6.9.2 Package Selection Sequence Example

Following is an example work flow for a MC and occurs after the discovery, initialization, and configuration.

Assuming the MC needs to share the NC-SI bus between packages, the MC should:

1. Define a time-slot for each device.
2. Discover, initialize, and configure all the NC packages and channels.
3. Issue a De-Select Package command to all the channels.
4. Set active_package to 0x0 (or the lowest existing package ID).
5. At the beginning of each time slot the MC should:
   a. Issue a De-Select Package command to the active_package. The MC must then wait for a response and then an additional timeout for the package to become de-selected (200 us). See the NC-SI specification table 10 — parameter NC Deselect to Hi-Z Interval.
   b. Find the next available package (typically active_package = active_package + 1).
   c. Issue a Select Package command to active_package.

38.37.6.9.3 Multiple Channels (Fail-Over)

In order to support a fail-over scenario, it is required from the MC to operate two or more channels. These channels might or might not be in the same package.

The key element of a fault-tolerance fail-over scenario is having two (or more) channels identifying to the switch with the same MAC address, but only one of them being active at any given time (such as switching the MAC address between channels). To accomplish this, NC-SI provides the following commands:

1. Enable Network Tx command — This command enables shutting off the network transmit path of a specific channel. This enables the MC to configure all the participating channels with the same MAC address but only enable one of them.
2. Link Status Change AEN or Get Link Status command.

38.37.6.9.4 Fail-Over Algorithm Example

The following is a sample work flow for a fail-over scenario for the 10 GbE controller (one package and four channels):

1. The MC initializes and configures all channels after power-up. However, the MC uses the same MAC address for all of the channels.

2. The MC queries the link status of all the participating channels. The MC should continuously monitor the link status of these channels. This can be accomplished by listening to AENs (if used) and/or periodically polling using the Get Link Status command.
3. The MC then only enables channel 0 for network transmission.
4. The MC then issues a gratuitous ARP (or any other packet with its source MAC address) to the network. This packet informs the switch that this specific MAC address is registered to channel 0's specific LAN port.
5. The MC begins normal work flow.
6. Should the MC receive an indication (AEN or polling) that the link status for the active channel (channel 0) has changed, the MC should:
   a. Disable channel 0 for network transmission.
   b. Check if a different channel is available (link is up).
   c. If found:
      - Enable network Tx for that specific channel.
      - Issue a gratuitous ARP (or any other packet with its source MAC address) to the network. This packet informs the switch that this specific MAC address is registered to channel 0's specific LAN port.
      - Resume normal work flow.
      - If not found, report the error and continue polling until a valid channel is found.

The previous algorithm can be generalized such that the start-up and normal work flow are the same. In addition, the MC might need to use a specific channel (such as channel 0). In this case, the MC should switch the network transmit to that specific channel as soon as that channel becomes valid (link is up).

Recommendations:

- Wait for a link-down-tolerance timeout before a channel is considered invalid. For example, a link re-negotiation might take a few seconds (normally 2 to 3 or might be up to 9). Thus, the link must be re-established after a short time.
- Typically, this timeout is recommended to be three seconds.
- Even when enabling and using AENs, periodically poll the link status, as dropped AENs might not be detected.

38.37.6.9.5 Statistics

The MC might use the statistics commands as defined in NC-SI. These counters are intended for debug purposes and are not all supported.

The statistics are divided into three commands:

1. Controller statistics — These are statistics on the network interface (to the host operating system and the PT traffic). See the NC-SI specification for details.
2. NC-SI statistics — These are statistics on the NC-SI control frames (such as commands, responses, AENs, etc.). See the NC-SI specification for details.
3. NC-SI PT statistics — These are statistics on the NC-SI PT frames. See the NC-SI specification for details.

38.37.6.10 External Link Control

The MC can use the NC-SI Set Link command to control the external interface link settings. This command enables the MC to set the auto-negotiation, link speed, duplex, and other parameters.

This command is only available when the host operating system is not present. Indicating the host operating system status can be obtained via the Get Link Status command and/or Host OS Status Change AEN command.

Recommendation:

- Unless explicitly needed, it is not recommended to use this feature. The NC-SI Set Link command does not expose all the possible link settings and/or features. This might cause issues under different scenarios. Even if you decided to use this feature, use it only if the link is down (trust the 10 GbE controller until proven otherwise).
- It is recommended that the MC first query the link status using the Get Link Status command. The MC should then use this data as a basis and change only the needed parameters when issuing the Set Link command.

For details, refer to the NC-SI specification.

38.37.6.10.1 Set Link While LAN PCIe Functionality is Disabled

In cases where the 10 GbE controller is used solely for manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation results in the lowest possible speed chosen.

To enable a higher link speed, the MC should not advertise speeds that are below the desired link speed, as the lowest advertised link speed is chosen.

When the 10 GbE controller is only used for manageability and the link speed advertisement is configured by the MC, changes in the power state of the LAN device is not effected and the link speed is not re-negotiated by the LAN device.

38.37.7 Management Component Transport Protocol (MCTP)

38.37.7.1 MCTP Overview

MCTP defines a communication model intended to facilitate communication between:

- MCs and other MCs
- MCs and management devices

The communication model includes a message format, transport description, message exchange patterns, and configuration and initialization messages.

The basic MCTP specification is described in DMTF's DSP0236 document.

MCTP is designed so that it can potentially be used on many bus types. The protocol is intended to be used for intercommunication between elements of platform management subsystems used in computer systems, and is suitable for use in mobile, desktop, workstation, and server platforms.

Currently, specifications exists for MCTP over PCIe (DMTF's DSP0238) and over SMBus (DMTF's DSP0237). A specification for MCTP over USB is also planned.

MCs such as a Baseboard Management Controller (BMC) can use this protocol for communication between one another, as well as for accessing management devices within the platform.

38.37.7.1.1 NC-SI Over MCTP

MCTP is a transport layer protocol that does not include the functionality required to control the PT traffic required for an MC connection to the network. This functionality is provided by encapsulating NC-SI traffic as defined in DMTF's DSP0222 document.

The details of NC-SI over MCTP protocol are defined in the DMTF's DSP0261 - NC-SI Over MCTP Specification.

An NC-SI over MCTP implementation guide can be found in the DMTF's DSP0219 white paper.

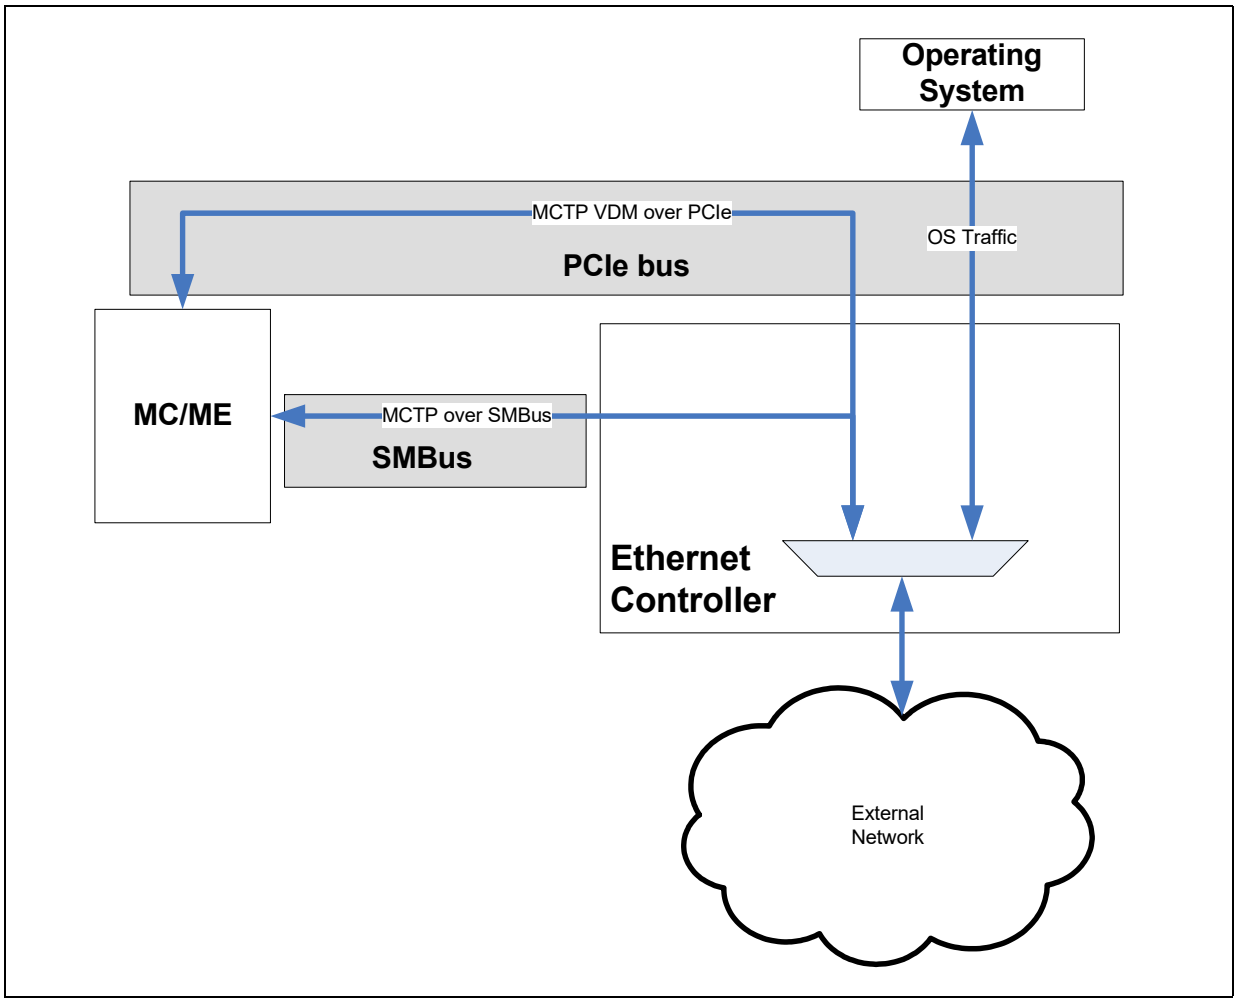
The NC-SI over MCTP specification defines two types of MCTP message types: NC-SI (0x2) and Ethernet (0x3). The 10 GbE controller supports both messages. When used only for control, then only the NC-SI (0x2) message type is supported.

Refer to the section about NC-SI over MCTP.

38.37.7.1.2 MCTP Usage Model

The 10 GbE controller supports NC-SI over MCTP protocol over the PCIe and SMBus busses. The 10 GbE controller can connect through MCTP to a MC or the Intel ME engine in the chipset as described in Figure 38-137.

Figure 38-137.10 BGBE Controller MCTP Connections



38.37.7.2 NC-SI to MCTP Mapping

The four network ports of the 10 GbE controller (mapped to two NC-SI channels) are mapped to a single MCTP endpoint on SMBus and to another endpoint over PCIe.

The PCIe endpoint is mapped to a PCIe requester ID according to the following flow:

1. If the *Bus Master Enable* bit of at least one of the functions is set, the endpoint is mapped to function the first available function.
2. If the *Bus Master Enable* bits of all functions are cleared, the MCTP endpoint on PCIe is not exposed and the MCTP traffic is routed through the SMBus endpoint.

The slave address used for the SMBus endpoint is the slave address of the first port.

Section 38.37.7.2.1 describes the transition between the two busses.

Both endpoints (SMBus and PCIe) might be active concurrently. However, PT traffic might be transferred only through one of them. If the PCIe endpoint is active, it is used for PT traffic; otherwise, the SMBus endpoint is used. The Set EID command can be used to force the transition for the PCIe endpoint to the SMBus endpoint if the bus owner determines the PCIe channel is not functional.

For each channel (SMBus or PCIe), the 10 GbE controller should expect MCTP commands from two sources: the bus owner and the MC. In addition, it should expect PT traffic through one interface only. Thus, it should be able to process up to five interleaved commands/data:

- An MCTP control/OEM command from the PCIe bus owner (single packet message).
- An MCTP control/OEM command from the SMBus bus owner (single packet message).
- An MCTP control/OEM command from the MC over SMBus (single packet message).
- An MCTP control/OEM command from the MC over PCIe (single packet message).
- An NC-SI command or Ethernet packet from the MC over the active channel.

A single source should not interleave packets it sends.

The topology used for MCTP connection is shown in Figure 38-138.

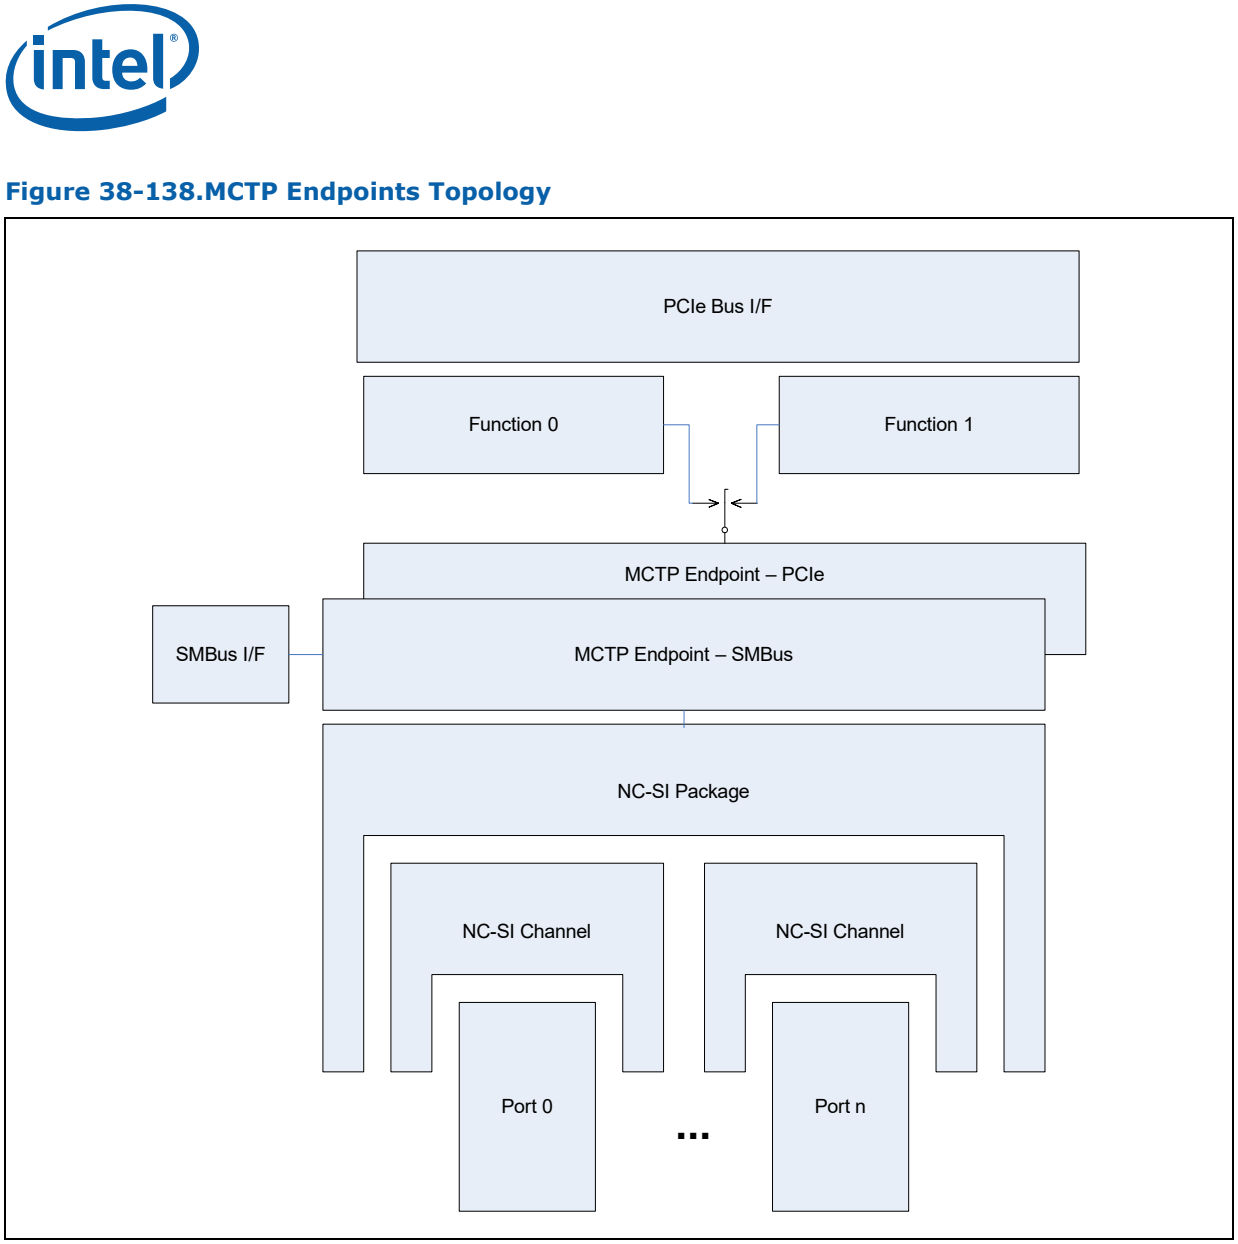


Figure 38-138.MCTP Endpoints Topology

38.37.7.2.1 Detecting an MC EID and Physical Address

In order to enable transactions between the MC and the NIC, the bus physical address (SMBus or PCIe) and the EID of the partner needs to be discovered. NICs do not try to discover the MC and assume the MC initiates the connection. If the NIC is in an NC-SI initial state, then the EID and the physical address of the MC are extracted from the Clear Initial State command parameters or any other NC-SI command received later with a channel ID of the 10 GbE controller. Subsequent PT traffic is received from or sent to this address only.

If the EID or the physical address of the NIC changes, it indicates the changes to bus owner so that the routing tables can be updated. There is no attempt to directly send an indication to the MC about the change.

See more details in next section.

38.37.7.2.2 Bus Transition

The following section defines the transition flow between PCIe and SMBus as the bus on which MCTP flows. Figure 38-139 describes the flow to transition between PCIe and SMBus. The following parameters are used to define the flow:

- NIC EID on PCIe
- NIC EID on SMBus
- NIC PCIe Target ID
- Bus Owner EID on PCIe
- Bus Owner EID on SMBus
- Bus Owner PCIe Target ID
- Bus Owner SMBus Address
- MC EID on PCIe
- MC EID on SMBus
- MC PCIe Target ID
- MC SMBus Address
- NIC SMBus Address

All these variables are initialized to zero at power on apart from the SMBus address of the endpoint (NIC), which might be initialized from a NVM value.

Initial Assignment Flow

- At power on, the NIC or MC MCTP channel is connected to the SMBus, is not assigned an EID and is in an undiscovered state.
- The bus owner might preform an SMBus ARP cycle to assign an SMBus address to the NIC or to the MC. Otherwise, a fixed address might be used. It is assumed that the SMBus address does not change after initialization time.
- The bus owner performs an EID assignment using a Set Endpoint ID MCTP command. The NIC or the MC captures the SMBus address of the bus owner from the SMBus Source Slave address field, the bus owner EID from the Source Endpoint ID field and the NIC/MC EID from the Destination Endpoint ID field in the MCTP header as described in Section 10.3 of *DSP0236*. The NIC/MC is now in a discovered state.
- The MC might detect the NIC EID using one of the two following modes:
  - Static configuration of the NIC SMBus address in the MC database and Get Routing Table Entries command to find the EID matching the SMBus address.
  - Get all endpoints through a Get Routing Table Entries command and find endpoints supporting NC-SI using the Get Message Type Support command for each endpoint.
- Once the NIC is found, the MC might send a Clear Initial State command to the NIC to start the NC-SI configuration. The NIC captures the MC SMBus address and MC EID from any NC-SI command received.
- After the NC-SI channels are enabled, traffic might be sent using the MC and NIC addresses previously discovered.
- The MC might also send a Get UUID command to get a unique identifier of the NIC that might be used later for re-connection upon topology changes.

SMBus to PCIe Transition

- If the NIC or the MC detects that the PCIe bus is available by detecting a function that moved to D0 state, it might request a transition using a Discovery Notify MCTP command on the PCIe bus. This command should be sent with a route to root-complex addressing as described in the *MCTP PCIe VDM Transport Binding Specification (DSP0238)* Section 6.8. The source EID should be the EID previously assigned on the SMBus.
- After receiving the Discovery Notify MCTP command on the PCIe bus, the bus owner sends a Set Endpoint ID MCTP command on the PCIe bus and updates the routing table. The bus owner might choose to wait for the Discovery Notify MCTP command of both the MC and the NIC to do the transition. The bus owner should try to keep the EID previously assigned on the SMBus as the EID on PCIe bus.
- After receiving the Set Endpoint ID MCTP command, the NIC waits for an NC-SI command from the MC indicating it is ready to transition the connection to PCIe. After receiving such a command, the NIC transitions its PT traffic to the PCIe bus using the newly received addresses.
- The MC on its side, needs to discover the PCIe address of the NIC. This can be done using the Resolve Endpoint ID command if only the physical address changed or using the Resolve Endpoint UUID command also if both EID and physical address changed. It can then send an NC-SI command to the NIC to initiate the transition. The MC should not send any PT packets from the moment it sent the first NC-SI command on the PCIe and the moment a response is received for this command.
- The transition of NC-SI traffic (PT or commands/responses) from SMBus to PCIe should be done on a packet boundary and should not interrupt a packet fragmentation or reassembly.

PCIe Target ID Change

The target ID of one of the endpoints might change due to a new enumeration of the PCIe bus. In this case the following flow should be used:

The target ID of one of the endpoints might change, either due to a new enumeration of the PCIe bus or due to the disabling of one of the functions in the device (move to a non D0 state). In this case, the following flow should be used:

- The endpoint should send a Discovery Notify MCTP command on the PCIe bus using the new Requester ID.
- After receiving the Discovery Notify MCTP command with the new requester ID, the bus owner sends a Set Endpoint ID MCTP command on the PCIe bus and updates the routing table. The bus owner should try to keep the EID previously assigned on the SMBus as the EID on the previous requester ID.
- The bus owner sends an Routing Information Update command to all supporting endpoints that might then update the parameters of their counterpart they use.

PCIe to SMBus Transition

- If the NIC or the MC detects that the PCIe bus is not available by detecting a transition of all functions to a non D0 state, it stops using the PCIe for PT traffic or NC-SI traffic.
- Upon detection of the unavailability of the PCIe bus, the MC transitions the NC-SI channel to the MCTP over SMBus as previously described.
- The transition of NC-SI traffic (PT or commands/responses) from PCIe to SMBus might done at any stage and might interrupt a packet fragmentation or reassembly,

as it is assumed that such a transition occurs only when the PCIe bus is not available anymore.

38.37.7.3 MCTP Over PCIe

38.37.7.3.1 Message Format

The message format used for NC-SI over MCTP over PCIe is as follows:

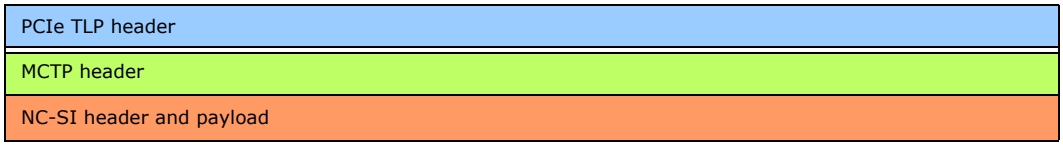

Table 38-596.NC-SI/Ethernet Over MCTP Over PCIe Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
FMT 011			Type 10r2r1r0[1]					R	TC 000			R	Attr	R	TH	TD	EP	Attr [1:0]		AT 00		Length 00_000x_xxxx											
PCI Requester ID																PCI Tag Field								Message Code Vendor Defined = 0111_1111b							
																R		Pad Len		MCTP VDM code - 0000b											
PCI Target ID (For Route by ID messages, otherwise = Reserved)																Vendor ID = 0x1AB4 (DMTF)															
MCTP Reserved				Header version = 1				Destination endpoint ID								Source endpoint ID								SOM	EOM	SEQ#			TO	Tag			
IC[2]	Message Type = 0x02/ 0x03							NC-SI Command/Pass Through data																							
.....																															
NC-SI Command/Pass Through data																															

Notes:

1. r2r1r0 =.
000b: Route to Root Complex.
010b: Route by ID.
011b: Broadcast from Root Complex.
2. TD = 0, EP = 0, IC = 0,TH = 0, Attr[2:0] = 0 for sent packets and is ignored for received packets.

38.37.7.3.2 PCIe Discovery Process

The 10 GbE controller follows the discovery process described in Section 5.9 of the *MCTP PCIe VDM Transport Binding Specification (DSP0238)*.

After receiving an endpoint discovery message (while in undiscovered stage), the 10 GbE controller exposes the endpoint on the selected function as previously described.

If the selected function moves after the endpoint was discovered, or if the bus number of the 10 GbE controller changes due to a re-enumeration of the bus, the 10 GbE controller sends a discovery notify message to indicate to the MC that it should do a re-enumeration of the device to discover the new endpoint.

38.37.7.3.3 MCTP Over PCIe Special Features

The 10 GbE controller supports the following optional features of MCTP when running over PCIe: rate limiting.

MCTP Uplink Rate Limiting

As the PCIe link can carry a traffic bandwidth much higher than what the MC can sustain, in order to avoid drop of packets, the 10 GbE controller allows rate limiting of the MCTP PT traffic. The 10 GbE controller supports rate limiting between 1 Mb/s and 1 Gb/s. The following parameters define the behavior of the rate limiter:

- Max rate limit (fixed from NVM via the MCTP rate in the MCTP Rate Limiter Config 1 word).
- The max burst size (fixed from NVM via the MCTP *Max Credits* field in the in the MCTP Rate Limiter Config 2 word). To limit the max burst to one VDM, set this parameter to five.
- Decision point (fixed from NVM via the *Decision Point* field in the in the MCTP Rate Limiter Config 2 word).

38.37.7.4 MCTP Over SMBus

The message format used for NC-SI over MCTP over SMBus is as follows:

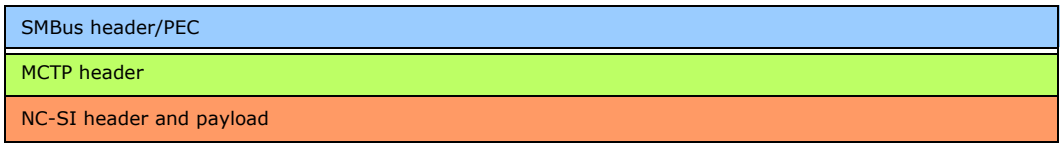

Table 38-597.NC-SI/Ethernet Over MCTP Over SMBus Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
Destination Slave Address							0	Command Code = MCTP = 0Fh								Byte count								Source Slave Address							1
MCTP Reserved				Header version = 1				Destination endpoint ID								Source endpoint ID								SOM	EOM	SEQ#			TO	Tag	
IC[1]	Message Type = 0x02/ 0x03							NC-SI Command/Pass Through data																							
.....																															
NC-SI Command/Pass Through data																															
PEC																															

Notes:

1. IC = 0.

38.37.7.4.1 SMBus Discovery Process

The 10 GbE controller follows the discovery process described in Section 6.5 of the *MCTP SMBus/I²C Transport Binding Specification (DSP0237)*. It indicates support for ASF in the SMBus getUID command (see Section 38.37.5.5.4). It responds to any SMBus command using the MCTP command code. This ensures that the bus owner knows the 10 GbE controller supports MCTP.

Note: MCTP commands over SMBus are received from any master address and are answered to the sender. There is no capturing of the bus owner address from any specific command.

38.37.7.4.2 MCTP Over SMBus Special Features

The 10 GbE controller supports the following optional feature of MCTP when running over SMBus:

1. Simplified MCTP mode.
2. Fairness arbitration.

Simplified MCTP Mode

For some point-to-point implementations of MCTP, the assembly process is simplified. In this mode, the destination EID, source EID, packet sequence number, Tag Owner (TO) bit and message tag are ignored and the assembly is based only on the *SOM* and *EOM* bits. This bit is set according to the *Simplified MCTP* bit in the MCTP configuration word in the NVM.

Note: This mode is not compliant with the MCTP specification.

In this mode, a Set EID command is not needed to start operation.

This mode is relevant only for MCTP over SMBus traffic and when the redirection sideband interface is set to 10b (MCTP over SMBus only - no pass through).

Fairness Arbitration

When sending MCTP messages over SMBus and when fairness arbitration is enabled, the 10 GbE controller should adhere to the fairness arbitration as defined in Section 5.13 of *DSP0237* when sending MCTP messages.

38.37.7.5 NC-SI Over MCTP

The 10 GbE controller support for NC-SI over MCTP is similar to the support for NC-SI over RBT with the following exceptions:

1. A set of new NC-SI OEM commands used to expose the NC-SI over MCTP capabilities.
2. The format of the packets is modified to account for the new transport layer as described in the sections that follow.

38.37.7.5.1 NC-SI Packets Format

NC-SI over MCTP defines two different message type for pass through and for control packets.

Packets with a message type equal to the *Control packets message type* field (default = 0x02) in the NVM are NC-SI control packets (commands, responses and AENs) and packets with a message type equal to the *Pass through packets message type* field (default = 0x03) in the NVM are NC-SI pass-through packets.

Control Packets

The format used for control packets (commands, responses and AENs) is as follows:

Table 38-598.NC-SI Over MCTP Over PCIe/SMBus Message Format

+0								+1								+2								+3							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

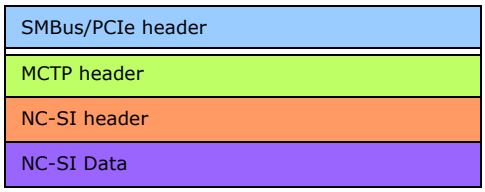
IID								Command								Channel ID[1]								Reserved							
Payload Length[7:0]								Reserved																Payload Length[11:8]							
Reserved																															
Reserved								Command Data																							
....																															
Command Data																Checksum															
Checksum																															

Notes:

1. The channel ID is defined as described in Section 38.37.2.2.2.



Note that the MAC header and MAC FCS present when working over NC-SI are not part of the packet in MCTP mode.

PT Packets

The format used for PT packets are as follows. This format is the same for either packets received from the network or packets received from the host.

The CRC is never included in the packet. In receive, the CRC is checked and removed by the 10 GbE controller in transmit, the CRC is added by the 10 GbE controller.

Table 38-599.Ethernet Over MCTP Over PCIe/SMBus Message Format

+0								+1								+2								+3

38.37.7.6 MCTP Programming

The MCTP programming model is based on:

1. A set of MCTP commands used for the discovery process and for the link management. The list of supported commands is described in Section 38.37.7.6.1.
2. A subset of the NC-SI commands used in the regular NC-SI interface, including all the OEM commands as described in Section 38.37.6.2 (NC-SI programming I/F). The specific commands supported are listed in Table 38-546 and Table 38-550.

Note: For all MCTP commands (both native MCTP commands and NCSI over MCTP), the response uses the Msg tag received in the request with *TO* bit cleared.

38.37.7.6.1 MCTP Commands Support

Table 38-600 lists the MCTP commands supported by the 10 GbE controller.

Table 38-600.MCTP Commands Support (Sheet 1 of 2)

Command Code	Command Name	General Description	10 GbE Controller Support As Initiator	10 GbE Controller Support As Responder
0x00	Reserved	Reserved	–	–
0x01	Set Endpoint ID	Assigns an EID to the endpoint at the given physical address.	N/A	Yes
0x02	Get Endpoint ID	Returns the EID presently assigned to an endpoint. Also returns information about what type the endpoint is and its level of use of static EIDs.	No	Yes
0x03	Get Endpoint UUID	Retrieves a per-device unique UUID associated with the endpoint.	No	Yes
0x04	Get MCTP Version Support	Lists which versions of the MCTP control protocol are supported on an endpoint.	No	Yes
0x05	Get Message Type Support	Lists the message types that an endpoint supports.	No	Yes
0x06	Get Vendor Defined Message Support	Used to discover an MCTP endpoint's vendor specific MCTP extensions and capabilities.	No	Yes

Table 38-600.MCTP Commands Support (Sheet 2 of 2)

Command Code	Command Name	General Description	10 GbE Controller Support As Initiator	10 GbE Controller Support As Responder
0x07	Resolve Endpoint ID	Used to get the physical address associated with a given EID.	No	N/A
0x08	Allocate Endpoint IDs	Used by the bus owner to allocate a pool of EIDs to an MCTP bridge.	N/A	N/A
0x09	Routing Information Update	Used by the bus owner to extend or update the routing information that is maintained by an MCTP bridge.	N/A	N/A
0x0A	Get Routing Table Entries	Used to request an MCTP bridge to return data corresponding to its present routing table entries.	No	N/A
0x0B	Prepare for Endpoint Discovery	Used to direct endpoints to clear their discovered flags to enable them to respond to the Endpoint Discovery command.	N/A	Yes[1]
0x0C	Endpoint Discovery	Used to discover MCTP-capable devices on a bus, provided that another discovery mechanism is not defined for the particular physical medium.	No	Yes
0x0D	Discovery Notify	Used to notify the bus owner that an MCTP device has become available on the bus.	Yes	N/A
0x0E	Get Network ID	Used to get the MCTP network ID.	No	No
0x0F	Query Hop	Used to discover what bridges, if any, are in the path to a given target endpoint and what transmission unit sizes the bridges will pass for a given message type when routing to the target endpoint.	No	No

Notes:

1. These commands are supported only for MCTP over PCIe.

Get Endpoint ID

The get endpoint ID response of the 10 GbE controller is listed in the following table.

Byte	Description	Value
1	Completion Code	
2	Endpoint ID	0x00 = EID not yet assigned. Otherwise = Returns EID assigned using Set Endpoint ID command.
3	Endpoint Type	0x00 (Dynamic EID, simple endpoint).
4	Medium Specific	SMBus = 0x01 - Fairness arbitration protocol supported. PCIe = 0x00.

Get Endpoint UUID

The UUID returned is calculated according to the following function:

- Time Low = Read from NVM words at offset 0x9 and 0xA of the sideband configuration structure.
- Time mid = Read from NVM word at offset 0xB of the sideband configuration structure.
- Time High and version = Read from NVM word at offset 0xC of the sideband configuration structure.
- Clock Sec and Reserved = Read from NVM word at offset 0xD of the sideband configuration structure.
- Node = MAC address as taken from the GLPCI_SERL and GLPCI_SERH registers.

Get MCTP Version Support

The following table lists the returned value according to the requested message type.

Byte	Description	Message Type					
		0xFF(Base)	0x00 (Control Protocol Message)	0x02 (NC-SI Over MCTP)	0x03 (Ethernet)	0x7E (PCIe Based VDM Messages)	All Other Or Unsupported Messages
1	Completion Code	0x0					0x80
2	Version Number Entry Count	3	3	1	1	2	0
6:3	Version Number Entry	0xF1F0FF00 (1.0)	0xF1F0FF00 (1.0)	0xF1F0FF00 (1.0)	0xF1F0FF00 (1.0)	0xF1F0FF00 (1.0)	0
9:7	Version Number Entry 2	0xF1F1F000 (1.1.0)	0xF1F1F000 (1.1.0)			0xF1F1F000 (1.1.0)	
13:10	Version Number Entry 3	0xF1F2F000 (1.2.0)	0xF1F2F000 (1.2.0)				

Get Message Type Support Command

The get message type support response of the 10 GbE controller is listed in the following table.

Byte	Description	Value
1	Completion Code	0x00.
2	MCTP Message Type Count	0x01/0x02/0x03 - The 10 GbE controller supports up to three additional message types, depending on the mode of operation and the bus used.
3:5	List of Message Type Numbers	0x02 (NC-SI over MCTP).
		0x03 (Ethernet).
		0x7E (PCIe based VDM messages) - over PCIe only.

Get Vendor Defined Message Support Command

The get vendor defined message type support response of Product Name is listed in the following table if vendor ID set selector equals 0x00:

Byte	Description	Value
1	Completion Code	0x00.
2	Vendor ID Set Selector	0xFF = No more capability sets.
2:4	Vendor ID	0x008086 (PCI ID indicator + Intel vendor ID).
5:6	Version	0x0100 (version 1.0).

Set Endpoint ID Command

The 10 GbE controller supports the set EID and force EID operations defined in the Set Endpoint ID command. When operating over PCIe, the set discovered flag operation is also supported. As endpoints in the 10 GbE controller can be set only through their own interface, set EID and force EID are equivalent. The Reset EID operation is not supported by the 10 GbE controller.

The Set Endpoint ID response of the 10 GbE controller is described in the following table.

Byte	Description	Value
1	Completion Code	0x00.
2	Completion Status	[7:6] = 00b - Reserved.
		[5:4] = 00b - EID assignment accepted.
		[3:2] = 00b - Reserved.
		[1:0] = 00b - Device does not use an EID pool.
3	EID Setting	If the EID setting was accepted, this value matches the EID passed in the request. Otherwise, this value returns the present EID setting.
4	EID Pool Size	Always return a zero.

38.37.7.7 Host Isolate Support

If a MC decides that malicious software prevents its usage of the LAN, it might decide to isolate the NIC from its driver. This is done using the TCO reset command (Section 38.37.6.4.12).

If TCO isolate is enabled in the NVM, The TCO Isolate command disables PCIe write operations to the LAN port. As the software device driver needs to access the CSR space in order to provide descriptors to the NIC, this operation also stops the network traffic including OS2BMC and MC-to-OS traffic as soon as the existing transmit and receive descriptor queues are exhausted.

MCTP over PCIe VDM are still available in this mode.

38.38 Programming Interface

This section details the programmer visible state inside the 10 GbE controller. In some cases, it describes hardware structures invisible to software in order to clarify a concept.

The 10 GbE controller address space is mapped into four regions with PCI Base Address registers. These regions are listed in the following table.

Table 38-601.Address Space Regions

Addressable Content	How Mapped	Size of Region
Memory BAR (Internal registers, memories and Flash)	Direct memory-mapped	4 MB - 16 MB
I/O BAR (optional Internal registers)	I/O Window mapped	32 bytes[1]
MSI-X BAR (optional)	Direct memory-mapped	32 KB
Expansion ROM BAR (optional)	Direct memory-mapped	64 KB - 8 MB

Notes:

1. The internal registers can be accessed though I/O space indirectly as explained in the sections that follow.

Rules for unsupported accesses:

- Accesses to non-implemented or disabled regions within a BAR are dropped for write accesses or responded with arbitrary data for read accesses. A PCIe error event is not generated and completions return with successful status.
- Refer to the section about supported PCIe access sizes to each of the BARs and its components.

38.38.1 Access Mechanisms

38.38.1.1 Memory-Mapped Access to Internal Registers and Memories

The internal registers and memories might be accessed as direct memory-mapped offsets from the Base Address register (BAR0 or BAR 0/1). Refer to the section about the appropriate offset for each specific internal register.

In IOV mode, this area is partially duplicated per VF. All replications contain only the subset of the register set that is available for VF programming. Refer to the section about the appropriate offset for each specific internal register for VFs.

38.38.1.2 Memory-Mapped Access to Flash

The external Flash can be accessed using direct memory-mapped offsets from the memory base address register (BAR0 in 32-bit addressing or BAR0/BAR1 in 64-bit addressing). See Table 38-604 for the location of Flash memory within the memory BAR. Access to Flash memory is restricted to the first 64 KB when GLPCI_LBARCTRL.FLASH_EXPOSE is set to 0b.

38.38.1.3 Memory-Mapped Access to MSI-X Tables

The MSI-X tables can be accessed as direct memory-mapped offsets from the base address register (BAR3 or BAR3/4). Refer to the section about the appropriate offset for each specific internal MSI-X register.

In IOV mode, this area is duplicated per VF. It requires a memory space of the maximum between 16 KB and the page size.

38.38.1.4 Memory-Mapped Access to Expansion ROM

The external Flash can also be accessed as a memory-mapped expansion ROM. Accesses to offsets starting from the expansion ROM base address reference the Flash provided that access is enabled from NVM, and if the expansion ROM base address register contains a valid (non-zero) base memory address.

38.38.1.5 I/O-Mapped Access to internal registers

To support pre-boot operation, all internal registers can be accessed using I/O operations. I/O accesses are supported only if an I/O base address is allocated and mapped (BAR2), and I/O address decoding is enabled in the PCIe configuration.

When an I/O BAR is mapped, the I/O address range allocated opens a 32-byte window in the system I/O address map. Within this window, two I/O addressable registers are implemented: IOADDR and IODATA. The IOADDR register is used to specify a reference to an internal Register and then the IODATA register is used as a window to the register address specified by IOADDR as listed in Table 38-602.

Table 38-602.IOADDR and IODATA in I/O Address Space

Offset	Abbreviation	Name	RW	Size
0x00	IOADDR	Internal Register Address. Covers the (4 MB - 64 KB) CSR space 0x00000-0x3EFFFF – Internal Registers. 0x3F0000-0xFFFFFFFF – Undefined.	RW	4 bytes
0x04	IODATA	Data field for reads or writes to the Internal Register location as identified by the current value in IOADDR. All 32 bits of this register can be read from and written to.	RW	4 bytes
0x08 – 0x1F	Reserved	Reserved.	RO	4 bytes

38.38.1.5.1 IOADDR (I/O Offset 0x00)

The IOADDR register must always be written as a Dword access. Refer to the section that describes how other access sizes are handled.

For IA programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Because writes must be to a 32-bit quantity, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command). For reads, the IN instruction can have any size target register, but it is recommended that the 32-bit EAX register be used.

At hardware reset (RSMRST#) or PCI reset, this register value resets to 0x00000000. Once written, the value is retained until the next write or reset.

38.38.1.5.2 IODATA (I/O Offset 0x04)

The IODATA register must always be written as a Dword access (assuming the IOADDR register contains a value for the internal register space). Reads to IODATA returns a Dword of data. Refer to the section that describes how other access sizes are handled.

For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Where 32-bit quantities are required on writes, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command).

Note: There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses are immediate, except when data is not readily available or acceptable. In this case, the 10 GbE controller delays the results through normal bus methods (for example, split transaction or transaction retry).

Note: Because a register read or write takes two I/O cycles to complete, software must provide a guarantee that the two I/O cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

38.38.1.5.3 Undefined I/O Offsets

I/O offsets 0x08 through 0x1F are considered to be reserved offsets with the I/O window.

38.38.1.6 Configuration Access to Internal Registers

To support legacy pre-boot 16-bit operating environments without requiring I/O address space, the 10 GbE controller enables accessing CSRs via configuration address space by mapping the *IOADDR* and *IODATA* registers into configuration address space. If the GLPCI_CAPSUP.CSR_CONF_EN bit is set to 1b, access to CSRs via configuration address space is enabled. The register mappings in this case are listed in Table 38-603.

Table 38-603.IOADDR and IODATA in Configuration Address Space

Configuration Address	Abbreviation	Name	RW	Size
0x98	IOADDR	Internal Register Address. Covers the (4 MB - 64 KB) CSR space. 0x00000-0x3EFFFF – Internal registers. 0x3F0000-0x7FFFFF – Undefined.	RW	4 bytes
0x9C	IODATA	Data field for reads or writes to the internal register location as identified by the current value in IOADDR. All 32 bits of this register can be read from and written to.	RW	4 bytes

Software writes data to an internal CSR via configuration space in the following manner:

1. CSR address is written to IOADDR where:
   a. Bit 31 (*IOADDR.Configuration IO Access Enable*) of IOADDR should be set to 1b.
   b. Bits 30:0 of IOADDR should hold the actual address of the internal register being written to.
2. Data to be written is written into IODATA.
   — IODATA is used as a window to the register address specified by IOADDR. As a result, the data written to IODATA is written into the CSR pointed to by bits 30:0 of IOADDR.
3. IOADDR is cleared (all bits [31:0]), to avoid un-intentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

Software reads data from an internal CSR via configuration space in the following manner:

1. The CSR address is written to IOADDR where:
   a. Bit 31 (*IOADDR.Configuration IO Access Enable*) of IOADDR should be set to 1b.
   b. Bits 30:0 of IOADDR should hold the actual address of the internal register being read.
2. The CSR value is read from IODATA.
   a. IODATA is used as a window to the register address specified by IOADDR. As a result, the data read from IODATA is the data of the CSR pointed to by bits 30:0 of IOADDR.
3. IOADDR is cleared (all bits [31:0]), to avoid un-intentional CSR read operations (that might cause clear by read) by other applications scanning the configuration space.

Note: In the event that the GLPCI_CAPSUP.CSR_CONF_EN bit is cleared, accesses to IOADDR and IODATA via the configuration address space are ignored and have no effect on the register and the CSRs referenced by IOADDR.

Note: When a function is in D3 state, software should not attempt to access CSRs via IOADDR and IODATA.

Note: To enable CSR access via configuration space, software should set bit 31 (*IOADDR.Configuration IO Access Enable*) of IOADDR to 1b. Software should clear bit 31 of IOADDR after completing CSR access to avoid an unintentional clear by read operation, by another application scanning the configuration address space. Software should also clear bits 30:0 of IOADDR to remove any trace of previous accesses to the configuration space (see previous flows.

Note: Bit 31 of IOADDR (*IOADDR.Configuration IO Access Enable*) has no effect when initiating access via IO address space.

38.38.2 Memory BAR

38.38.2.1 PF BAR Structure

The memory BAR provides access to internal CSRs, to the protocol engine doorbells, and to the external Flash (NVM). This section describes where each of these is located within the BAR space.

The following configuration parameters define the structure of the PF memory BAR 0:

- *Flash_Expose* bit from the NVM (or the GLPCI_LBARCTRL.FLASH_EXPOSE CSR bit)
  - 0b = Flash memory is not mapped in the memory BAR
  - 1b = Flash memory is mapped in the memory BAR. Hardware default; Flash memory is exposed when during initialization the Flash is found to be blank or in error.
- Flash *Size* field from the NVM (or the GLPCI_LBARCTRL.FL_SIZE CSR field) - size is calculated as 64 KB * (2 ** Flash Size). Default value is 8 MB
- PE_DB_Size field from the NVM (or the GLPCI_LBARCTRL,PE_DB_SIZE CSR field) - determines the size of the memory space allocated to protocol engine doorbells
  - 00b = Memory space is not allocated for PE doorbells
  - 01b = A 64 KB area is allocated
  - 10b = A (4MB + 64KB)area is allocated
  - 11b = Reserved

Table 38-604 lists all supported partitions of the memory BAR as a function of the previously described parameters. Other combinations of the parameters (not covered in the table) are not supported and considered reserved for future expansion. The following rules apply:

- CSR space is located from the beginning of the BAR until address (4 MB-64 KB-1) (such as the first 4 MB - 64 KB)
- PE space (if exists) is located from address (4MB-64KB) and extends up to address 4MB or up to address 8MB (not including)
- The Flash space (if exposed) is always aligned to multiples of its size.

The default configuration of the memory BAR (like when the Flash is empty) is defined by hardware default values of the read-only GLPCI_LBARCTRL CSR. GLPCI_LBARCTRL is loaded from the NVM during normal operation (such as when Flash contents are valid).

Table 38-605.Structure of the PF Memory BAR

Flash Expose	Flash Size	PE_DB Size	PE Space		Flash Space		BAR Size
			Min Addr	Max Addr	Min Addr	Max Addr	
0	x	00	x	x	x	x	4 MB
"	"	01	4 MB-64 KB	4 MB	x	x	4 MB
"	"	10	4 MB-64 KB	8 MB	x	x	8MB

38.38.2.2 VF BAR Structure

The VF memory BAR provides access to on-die CSRs and (optionally) to PE doorbells for VFs.

The GLPCI_LBARCTRL.VF_PE_DB_SIZE CSR field determines whether the PE doorbells are provided with a separate region within the BAR:

- 0b = Memory space is not allocated for PE doorbells
- 1b = A 64 KB area is allocated

Note: Although only 32 VFs supports RDMA, all the VFs requires the same memory space.

Table 38-606 lists all supported partitions of the memory BAR as function of the previously described parameters.

Table 38-606.Structure of the VF Memory BAR

VF_PE_DB Size	BAR Size
0	Max (64 KB, Page Size)
1	Max (128 KB, Page Size)

Table 38-607.Structure of the VF memory BAR

VF_PE_DB Size	Doorbells Space		BAR Size
	Min Addr	Max Addr	
0	x	x	Max (64 KB, Page Size)
1	64 KB	128 KB	Max (128 KB, Page Size)

38.38.3 MSI-X BAR

Refer to the section about the structure of the MSI-X BAR for a PF and VF.

38.38.4 CSR Organization and Mapping

This section describes how CSRs are mapped into the PF and VF memory BAR. This section does not apply to the following address space:

- The MSI-X BAR (defined per the PCI specifications)
- The memory space allocated to protocol engine doorbells

38.38.4.1 Mapping by Scope

Registers are associated with a scope. A scope is a set of attributes for a register that define which functions can access the register and how many instances exist for the register. The following table lists the different scopes.

Table 38-608.Scope Mapping

Scope	PF/VF	Quantity	Exposure	Comments
GL	PF	1	To all PFs.	
GLVF	PF, VF	1	To all PFs and VFs.	Registers are RO.
PRT	PF	4	Each PF has access to the registers of the port it is associated with.	Registers are shared by all PFs on a port.
PRTVF	PF, VF	4	Each PF or VF has access to the registers of the port it is associated with (for a VF, the port is the port the PF is associated with).	Registers are RO. Registers are shared by all PFs and VFs on a port.
PF	PF	16	Each PF has access to its copy only.	
VF[1]	PF, VF	128	Each PF has access to the registers of its VFs only. Each VF has access to its copy only.	
VP	PF	128	Each PF has access to the registers of its VFs only.	These registers control VF functionality.
Q	PF, VF	1536	Each PF has access to the registers allocated to it (including. its VFs). Each VF has access to the registers allocated to it.	
VSI	PF	384	All PFs.	Registers are shared by all PFs.
INTPF	PF	512	Each PF has access to the registers allocated to it[2].	
INTVF	PF, VF	512	Each VF has access to the registers allocated to it. Each PF has access to the registers of its VFs only.	
INTVP	PF	512	Each PF has access to the registers of its VFs only.	These registers handle VF interrupts.

Notes:

1. PE VF registers are a special case of VF registers. PE resources are provided only to a subset of the VFs (total of 32 VFs). However, all VFs have PE registers mapped in their address space. When a VF accesses a PE register, it is mapped into the internal address space as described here, followed by another translation into one of the 32 physical PE instances. This later translation is not described in this section.
2. The register descriptions in section Device Registers - PF and section Device Registers - VF list 512 instances per register.

38.38.5 Register Conventions

All registers in the 10 GbE controller are defined to be 32 bits, should be accessed as 32-bit Dwords, There are some exceptions to this rule:

- Register pairs where two 32-bit registers make up a larger 64-bit logical unit
- Accesses to Flash memory (via expansion ROM space, secondary BAR space, or the I/O space) might be byte, word or double word accesses. I/O accesses are limited to Dword accesses (see Section 38.38.1.5).
- Accesses to BAR0 of a VF might be byte, word or Dword accesses. 64-bit (Qword) accesses to this BAR are completed with an Completer Abort (CA) error.

- Access to the MSI-X BAR of the PFs and the VFs might be Dword or Qword accesses.

Reserved bit positions — Some registers contain certain bits that are marked as reserved. Writes to a reserved field must set the field to its initial value unless specified differently in the field description. Reads from registers containing reserved bits might return indeterminate values in the reserved bit-positions unless read values are explicitly stated. When read, these reserved bits should be ignored by software.

Reserved and/or undefined addresses — Any register address not explicitly declared in this AN should be considered to be reserved, and should not be written to. Writing to reserved or undefined register addresses might cause indeterminate behavior. Reads from reserved or undefined configuration register addresses might return indeterminate values unless read values are explicitly stated for specific addresses.

Initial values: most registers define the initial hardware values prior to being programmed. In some cases, hardware initial values are undefined and is listed as such via the text undefined, unknown, or X. Such configuration values might need to be set via NVM configuration or via software in order for proper operation to occur; this need is dependent on the function of the bit. Other registers might cite a hardware default which is overridden by a higher-precedence operation. Operations that might supersede hardware defaults might include a valid NVM load, completion of a hardware operation (such as hardware auto-negotiation), or writing of a different register whose value is then reflected in another bit.

For registers that should be accessed as 32-bit Dwords, partial writes (less than a 32-bit Dword) does not take effect (the write is ignored). Partial reads returns all 32 bits of data regardless of the byte enables.

Note: Partial reads to clear-on-read registers (ICR) can have unexpected results since all 32 bits are actually read regardless of the byte enables. Partial reads should not be done.

Note: All statistics registers are implemented as 32-bit registers. Though some logical statistics registers represent counters in excess of 32 bits in width, registers must be accessed using 32-bit operations (for example, independent access to each 32-bit field). When reading 64-bit statistics registers the least significant 32-bit register should be read first.

See special notes for VLAN filter table, multicast table arrays and packet buffer memory that appear in the specific register definitions.

38.38.6 Register Terminologies

The following table lists the access type of registers' bit fields. The access rights of the PFs and the VFs to the entire registers are defined per PF and VF registers. In some cases, the PFs and VFs might have Read Only (RO) access rights to registers that can be programmed by the internal logic (either auto-load from the NVM or programmed by the firmware). Registers defined as RO access, override any access type defined for its fields.

Abbreviation	Description
RO	**Read Only** - A register bit field with this attribute can be read. Writes have no effect on the bit field value.
RSV	**Reserved** - A register bit field with this attribute can be read and returns an indeterministic value. Writes must set the bit field to its initial value unless specified differently in the field description.
RW	**Read/Write** - A register with this attribute can be read and written. Read return the default value, the last value written, or updated status from a previous operation. The field description specifies the field's actual behavior.

Abbreviation	Description
RCW	**Read Clear / Write** - A register bit field with this attribute can be written or read. The value returned on the read might be different than the value written (typically a counter) and the value is cleared after the read.
RW1C	**Read/Write 1 to Clear** - A register bit field with this attribute can be read and written. Writing an individual bit within the field to a 1b clears (sets to 0b) the corresponding bit and a write of a 0b has no effect. The value read might return the last value written or the status of a previous operation. The field description specifies the field's actual read behavior.
RW1S	**Read/Write 1 to Set** - A register bit field with this attribute can be read and written. Writing an individual bit within the field to a 1b sets (sets to 1b) the corresponding bit and a write of a 0b has no effect. The value read might return the last value written or the status of a previous operation. The field description specifies the field's actual read behavior.

38.39.2 Detailed Register Description - BAR0

38.39.2.1 PF - General Registers

This category contains registers for general device control and status.

38.39.2.1.1 VF Reset Status - VFGEN_RSTAT[VF] (0x00074400 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
VFR_STATE	1:0	00b	RW	**VFR State** Defines the VFR reset progress as follows: 00b = VFR in progress 01b = VFR completed 10b = Reserved 11b = Reserved This field is used to communicate the reset progress to the VF with no impact on hardware functionality.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.1.2 Firmware Status Register - GL_FWSTS (0x00083048; RO)

This register reports the status of the EMP.

Field	Bit(s)	Init.	Type	Description
FWS0B	7:0	0x0	RO	**Firmware Status 0 Byte** This bit is RO through the host interface.
FWROWD	8	0b	RW1C	**Firmware Reset on WD indication** Set when a firmware reset is asserted due to watch dog expiration. Cleared when the host writes a 1b to it. Writing a 0b to this bit does not change its value. This bit is also set after LAN_PWR_GOOD, and is RO through the AUX interface.
FWRI	9	1b	RW1C	**Firmware Reset Indication** Set when a firmware reset is asserted. Cleared when the host writes a 1b to it. Writing a 0b to this bit does not change its value. This bit is also set after LAN_PWR_GOOD, and is RO through the AUX interface.
RESERVED	15:10	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
FWS1B	23:16	0x0	RO	**Firmware Status 1 Byte** This bit is RO through the host interface. 0x30 = STATUS_RECOVERY_MODE_CORER. 0x31 = STATUS_RECOVERY_MODE_GLOBR. 0x32 = STATUS_RECOVERY_MODE_TRANSITION. 0x33 = STATUS_RECOVERY_MODE_NVM. Others = Reserved.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.1.3 PF State - PFGEN_STATE (0x00088000; RO)

This register defines the main characteristics of the PF to software. It does not have any direct impact on device functionality.

Field	Bit(s)	Init.	Type	Description
RESERVED	0	0b	RSV	Reserved.
RESERVED	1	0b	RW	**Reserved.**
PFLINKEN	2	0b	RW	**PF Link Enable** 0b = The PF driver is disabled. The software device driver must at minimum report it does not have link. 1b = The PF driver is enabled.
PFSCEN	3	0b	RW	**PF iSCSI Enable** 0b = iSCSI should not be used for this function. 1b = iSCSI can be used for this function.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.1.4 Global GPIO Control - GLGEN_GPIO_CTL[n] (0x00088100 + 0x4*n, n=0...29; RW)

General GPIO control registers. These registers control the mode of operation of general purpose I/O (GPIOn) pins. There are 30 GPIO pins that can be configured to different modes and assigned to different ports. There is one register per GPIOn pin. Register GLGEN_GPIO_CTL [n] controls GPIOn pin. This register is initialized only at LAN Power Good, preserving the GPIO states across software and PCIe resets.

Field	Bit(s)	Init.	Type	Description
PRT_NUM	1:0	00b	RW	**Port Number** Controls the port number associated with this GPIOn pin. This field is valid when the un-assigned port number bit (*PRT_NUM_NA*) is set to 0b. If a port number is not assigned, this GPIOn pin is a global resource not associated with any specific port.
RESERVED	2	0b	RSV	Reserved.
PRT_NUM_NA	3	0b	RW	**Port Number Not Assigned** Set to 1b if this GPIOn pin is not assigned to any port. The *PRT_NUM* field is ignored when this bit is set 1b (used by software/firmware only).
PIN_DIR	4	0b	RW	**Pin Direction** Controls whether this GPIOn pin is configured as an input or output: 0b = Input. 1b = Output. This bit is not affected by software or system reset, only by initial power-on or direct software writes. ***Note:*** When GPIO functionality is set to LED, the pin direction is set implicitly to output regardless of this field's value.

Field	Bit(s)	Init.	Type	Description
TRI_CTL	5	0b	RW	**Tristate Control** When this GPIOn pin is configured as an output, this field controls whether the pin is driven to tristate or driven high when *SDP_DATA* is set to 1b: 0b = Tristate. 1b = Driven high. The pin is driven to active low when the *SDP_DATA* is set to 0b. This bit is not affected by software or system reset, only by initial power-on or direct software writes. The *SDP_DATA* is set through the GLGEN_GPIO_SET register (Section 38.39.2.1.8). ***Note:*** This field is not used when GPIO is set to LED functionality.
OUT_CTL	6	0b	RW	**Output Control** Controls the output state during reset or D3 power state when no WoL or no manageability. 0b = The output transitions to tri-state during reset or D3 power state. 1b = The output is driven high during reset or D3 power state. This bit is ignored when this GPIO pin is configured as an input. This bit is not affected by software or system reset, only by initial power-on or direct software writes. ***Note:*** This field is not used when GPIO functionality is set to LED.
PIN_FUNC	9:7	000b	RW	**Pin Functionality** Controls the operation mode (or functionality) for this GPIOn pin. 000b = SDP (software definable input or output) 001b = LED (drives external LEDs) 010b = RoL (Reset on LAN) 011b = Timesync 0 100b = Timesync 1 All other values are reserved. When this pin is configure in SDP mode, the output value is set through GLGEN_GPIO_SET register (Section 38.39.2.1.8), and the value of the GPIO pin is read through GLGEN_GPIO_STAT register (Section 38.39.2.1.6).
LED_INVRT	10	0b	RW	**LED Invert** Specifies the polarity/inversion of the LED source prior to output or blink control. By default, the output drives the cathode of the LED so when the LED output is 0b the LED is on. 0b = LED output is active low. 1b = LED output is active high. The *LED_INVRT* setting is meaningful only if the *PIN_FUNC* is set to LED (001b).
LED_BLINK	11	0b	RW	**LED Blink** Specifies whether to apply blink logic to the (inverted) LED control source prior to the LED output. 0b = Do not blink LED output. 1b = Blink LED output. The *LED_BLINK* setting is meaningful only if the *PIN_FUNC* is set to LED (001b).
LED_MODE	15:12	0x0	RW	**LED Mode** Specifies the control source for the LED output. LED modes are described in detail in the LED section. The *LED_MODE* setting is meaningful only if the *PIN_FUNC* is set to LED (001b).
RESERVED	16	0b	RSV	Reserved.
INT_MODE	18:17	00b	RW	**Interrupt Mode** Selects the interrupt mode for this GPIOn pin. 00b = No interrupt. 01b = Interrupt on rising edge. 10b = Interrupt on falling edge. 11b = Interrupt on any transition. Set this field to generate interrupts only when *PIN_FUNC* is set to SDP (000b).

Field	Bit(s)	Init.	Type	Description
OUT_DEFAULT	19	0b	RW	**Output Default** Default value driven on this GPIOn pin when configured as a SDP output. 0b = Output driven low. 1b = Output driven high. The value is ignored when GPIO pin is configured as a SDP input or when *PIN_FUNC* is not SDP (000b).
PHY_PIN_NAME	25:20	0x0	RW	**PHY Pin Name** Used to indicate to firmware the name and functionality for which this GPIO pin is being used when connecting to an external PHY/module control/status pin. 0x3F = SDP is not used for PHY/module connectivity. 0x0 to 0x7 = Control/status pin names when connecting to an SFP+ module. 0x0 = Rx_LOS. 0x1 = Mod_ABS. 0x2 = RS0/RS1. 0x3 = TxDisable. 0x4 = TxFault. All other values are reserved. 0x8 to 0xF = Control status pin names when connecting to a QSFP+ module. 0x8 = IntL. 0x9 = ResetL. 0xA = ModPresL. 0xB = LPMode. 0xC = ModSelL. All other values are reserved. 0x10 to 0x17 = Control status pin names when connecting to 10GBASE-T PHYs. 0x10 = PhyInt. 0x11 = PhyRst. 0x12 = TxDisable. All other values are reserved.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.1.5 Global LED Control - GLGEN_LED_CTL (0x00088178; RW)

Field	Bit(s)	Init.	Type	Description
GLOBAL_BLINK__MODE	0	0b	RW	**Global Blink Mode** Specifies the blink mode of all LEDs. 0b = Blink at 200 ms on and 200 ms off. 1b = Blink at 83 ms on and 83 ms off.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.6 Global GPIO Status - GLGEN_GPIO_STAT (0x0008817C; RO)

Field	Bit(s)	Init.	Type	Description
GPIO_VALUE	29:0	0x0	RO	**GPIO Value** Each bit 'n' in this field reflects the value of GPIOn pin (either input or output). For example, Bit[0] reflects the value on GPIO0 pin (1b is high and 0b is low), Bit[1] indicates the value of GPIO1 pin, and so on.
RESERVED	31:30	00b	RSV	Reserved.

38.39.2.1.7 Global GPIO Transition Status - GLGEN_GPIO_TRANSIT (0x00088180; RW1C)

Field	Bit(s)	Init.	Type	Description
GPIO_TRANSITION	29:0	0x0	RW1C	**GPIO Transition** These register bits are used to latch any transition (low-to-high or high-to-low) on the GPIOn pins (either input or output) since the last time the register bits were cleared. Bit[0] reflects the transition status of GPIO0 pin, Bit[1] indicates the transition status of GPIO1 pin, and so on. The PF is expected to clear those flags that it cares about by writing 1b to the corresponding bit position. The PF is expected to clear the flags only for the GPIOn pins that it owns.
RESERVED	31:30	00b	RSV	Reserved.

38.39.2.1.8 Global GPIO Set - GLGEN_GPIO_SET (0x00088184; RW)

This register is used to set the value of the GPIOn output pins (0b = low, 1b = high). Attempting to write a value to GPIO input pins has no effect.

Field	Bit(s)	Init.	Type	Description
GPIO_INDX	4:0	0x0	RW	**GPIO Index** Defines the GPIO pin number that is driven to *SDP_DATA* value. The *GPIO_INDX* can be set to any value between 0 and 29 decimal (00000b to 11001b). Software is permitted to drive only GPIO pins that are defined as output SDPs by the GLGEN_GPIO_CTL registers (Section 38.39.2.1.4). Any PFs or EMP can access all GPIOs. It is the PF software responsibility to control only those GPIOs that the PF owns.
SDP_DATA	5	0b	RW	**SPD Data** The value in this field is driven to a GPIOn pin pointed to by the index *GPIO_INDX*. 0b = Driven low. 1b = Driven high.
DRIVE_SDP	6	0b	RW	**Drive SPD** Set this flag to 1b to drive the *SDP_DATA* to the GPIOn pin pointed by the index GPIO_INDX.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.1.9 MDI Single Command and Address - GLGEN_MSCA[n] (0x0008818C + 0x4*n, n=0...3; RW)

This register is used for writing the command and address to initiate read/write access over the MDIO interface. It is used when the MDIOn_SDAn/MDCn_SCLn pins are configured for MDIO operation through the GLGEN_MDIO_I2C_SEL[n] register (Section 38.39.2.1.13).

Field	Bit(s)	Init.	Type	Description
MDIADD	15:0	0x0	RW	**MDI Address** Address used for new protocol MDI accesses (default = 0x0000).
DEVADD	20:16	0x0	RW	**Device Type/Reg Address** Five bits representing either device type if *STCODE* = 00b, or register address if *STCODE* = 01b.
PHYADD	25:21	0x0	RW	**PHY Address** The address of the external device.

Field	Bit(s)	Init.	Type	Description
OPCODE	27:26	00b	RW	**Op Code** Two bits identifying operation to be performed (default = 00b). 00b = Address cycle (new protocol only) 01b = Write operation 10b = Read, increment address (new protocol only) 11b = Read operation
STCODE	29:28	01b	RW	**ST Code** Two bits identifying start of frame and old or new protocol (default = 01b). 00b = New protocol 01b = Old protocol 1xb = Illegal
MDICMD	30	0b	RW1C	**MDI Command** Perform the MDI operation in this register. Cleared when done. 0b = MDI ready; operation complete (default). 1b = Perform operation; operation in progress.
MDIINPROGEN	31	0b	RW	**MDI in Progress Enable** Generate MDI in progress when operation completes. 0b = MDI ready disable (default). 1b = MDI in progress enable.

38.39.2.1.10 MDI Single Read and Write Data - GLGEN_MSRWD[n] (0x0008819C + 0x4*n, n=0...3; RW)

This register is used for reading and writing data to and from the MDIO interface. It is used when the MDIOn_SDAn/MDCn_SCLn pins are configured for MDIO operation through the GLGEN_MDIO_I2C_SEL[n] register (Section 38.39.2.1.13).

Field	Bit(s)	Init.	Type	Description
MDIWRDATA	15:0	0x0	RW	**MDI Write Data** For MDI writes to the external device.
MDIRDDATA	31:16	0x0	RO	**MDI Read Data** Read data from the external device.

38.39.2.1.11 I^2C Parameters - GLGEN_I2CPARAMS[n] (0x000881AC + 0x4*n, n=0...3; RW)

This register is used to set the parameters for I^2C access to the 2-wire management interface, and to enable bit banging access to the I^2C interface. It is used when the MDIOn_SDAn/MDCn_SCLn pins are configured for I^2C interface operation through the GLGEN_MDIO_I2C_SEL[n] register (Section 38.39.2.1.13).

Field	Bit(s)	Init.	Type	Description
WRITE_TIME	4:0	0x6	RW	**Write Time** Defines the delay between a write access and the next access. The value is in milliseconds. A value of zero is not valid.
READ_TIME	7:5	010b	RW	**Read Time** Defines the delay between a read access and the next access. The value is in milliseconds. A value of zero is not valid.
I2CBB_EN	8	0b	RW	**I^2C Bit Bang Enable** If set, the I2C_CLK and I2C_DATA lines are controlled via the *CLK*, *DATA* and *DATA_OE_N* fields of this register. Otherwise, they are controlled by the hardware machine activated via the GLGEN_I2CCMD[n] register (Section 38.39.2.1.15).

Field	Bit(s)	Init.	Type	Description
CLK	9	1b	RW	**I²C Clock out value** Used to drive the value of I2C_CLK (SCL output to PAD). While in bit bang mode, controls the value driven on the I²C clock pad MDCn_SCLn.
DATA_OUT	10	1b	RW	**I²C Data Out value** Used to drive the value of I²C data (SDA output to PAD). While in bit bang mode, and when the *DATA_OE_N* field is zero, controls the value driven on the I²C data pad MDIOn_SDAn.
DATA_OE_N	11	0b	RW	**I²C Data Output Enable** While in bit bang mode, controls the direction of the I2C_DATA pad MDIOn_SDAn. Pad is output. Pad is input.
DATA_IN	12	0b	RO	**I²C Data In value** Provides the value of I2C_DATA (SDA input from external PAD). This bit is RO. Reflects the value of the I2C_DATA pad MDIOn_SDAn. While in bit bang mode when the *DATA_OE_N* field is zero, this field reflects the value set in the *DATA_OUT* field.
CLK_OE_N	13	0b	RW	**I²C Clock Output Enable** While in bit bang mode, controls the direction of the I2C_CLK pad MDCn_SCLn. Pad is output. Pad is input.
CLK_IN	14	0b	RO	**I²C Clock In value** (SCL input from external PAD) This bit is RO. Reflects the value of the I²C CLK pad MDCn_SCLn. While in bit bang mode when the *CLK_OE_N* field is zero, this field reflects the value set in the *CLK_OUT* field.
CLK_STRETCH_DIS	15	0b	RW	**I²C Clock Stretch Disable** 0b = Enable slave clock stretching support in I²C access. 1b = Disable clock stretching support in I²C access.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.1.12 Global Device Timer - GLVFGEN_TIMER (0x000881BC; RW)

Field	Bit(s)	Init.	Type	Description
GTIME	31:0	0x0	RW	GTIME is a free running timer fed by a 1 us clock.

38.39.2.1.13 Global MDIO or I²C Select - GLGEN_MDIO_I2C_SEL[n] (0x000881C0 + 0x4*n, n=0...3; RW)

This register is used to select between the MDIO interface or I²C interface on the MDIOn_SDAn/MDCn_SCLn pins. Each pair of these pins can be independently configured for MDIO or I²C interface protocol by using GLGEN_MDIO_I2C_SEL[n] registers.

Field	Bit(s)	Init.	Type	Description
MDIO_I2C_SEL	0	0b	RW	**MDIO/I^{2}C Select** Used to select between the MDIO interface or I^{2}C interface over the MDIOn_SDAn/MDCn_SCLn pins, where n=0..3. 0b = MDIO interface is selected. 1b = I^{2}C interface is selected.
PHY_PORT_NUM	4:1	0x0	RW	**PHY Port Number** Each bit in this field indicates the port number of the external PHY/module accessed through this interface. For MDC/MDIO, one or more PHYs can be managed by the same pair of pins. Therefore, more than one bit can be set in this field. In I^{2}C mode, only a single bit can be set since only a single module might be connected. Bit[0] = Port 0 PHY/module. Bit[1] = Port 1 PHY/module. Bit[2] = Port 2 PHY/module. Bit[3] = Port 3 PHY/module.
PHY0_ADDRESS	9:5	0x0	RW	**PHY0 Address** If this interface is used for connecting to PHY0, this is the address of the PHY device to use. This field is used by firmware.
PHY1_ADDRESS	14:10	0x0	RW	**PHY1 Address** If this interface is used for connecting to PHY1, this is the address of the PHY device to use. This field is used by firmware.
PHY2_ADDRESS	19:15	0x0	RW	**PHY2 Address** If this interface is used for connecting to PHY2, this is the address of the PHY device to use. This field is used by firmware.
PHY3_ADDRESS	24:20	0x0	RW	**PHY3 Address** If this interface is used for connecting to PHY3, this is the address of the PHY device to use. This field is used by firmware.
MDIO_IF_MODE	28:25	0x0	RW	**MDIO IF Mode** When interface mode is set to MDC/MDIO, this field indicates to firmware the frame structure to use. This field contains a bit per port for scenarios where more than one PHY device is connected through a single interface. Each bit indicates the following options: 0b = Use IEEE Clause 45 Frame Structure. 1b = Use IEEE Clause 22 Frame Structure. where: Bit[0] = Port0 MDIO_IF_MODE. Bit[1] = Port1 MDIO_IF_MODE. Bit[2] = Port2 MDIO_IF_MODE. Bit[3] = Port3 MDIO_IF_MODE.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.1.14 MDIO Control - GLGEN_MDIO_CTRL[n] (0x000881D0 + 0x4*n, n=0...3; RW)

This register is used to control the MDC clock speed and mode when the MDIOn_SDAn/MDCn_SCLn pins are configured for use as MDIO interface. Each pair of these pins are independently configured as MDIO or I^{2}C interface through the GLGEN_MDIO_I2C_SEL[n] registers, where n=0..3 (Section 38.39.2.1.13).

Field	Bit(s)	Init.	Type	Description
LEGACY_RSVD2	16:0	0x2FFB	RW	Reserved. Do not modify this value.
CONTMDC	17	0b	RW	**Continuous MDC** Turn off MDC between MDIO packets. 0b = MDC off between packets (default). 1b = Continuous MDC.
LEGACY_RSVD1	31:18	0x400	RW	Reserved. Do not modify this value.

38.39.2.1.15 I²C command - GLGEN_I2CCMD[n] (0x000881E0 + 0x4*n, n=0...3; RW)

This register is used to read or write to the configuration registers over the I²C interface when the MDIOn_SDAn/MDCn_SCLn pins are configured for I²C operation. Each pair of these pins are independently configured as a MDIO or I²C interface through the GLGEN_MDIO_I2C_SEL[n] registers, where n=0..3 (Section 38.39.2.1.13).

Field	Bit(s)	Init.	Type	Description
DATA	15:0	0x0	RW	**I²C Data** For a write command, firmware/software places the data bits in this field and hardware shifts them out to the I²C bus. For a read command, hardware reads the bits serially from the I²C bus and places the data in this field so firmware/software can fetch the data from this location. This field is read in byte order and not in word order. Ordering can be changed by using GLGEN_I2CPARAMS.*I2C_DATA_ORDER* bit (Section 38.39.2.1.11).
REGADD	23:16	0x0	RW	**I²C Register Address** For example, register 0, 1, 2... 255.
PHYADD	26:24	000b	RW	**PHY Address** Device Address Bits[2:0]. The actual address used is 1010b (PHYADD[2:0]).
OP	27	0b	RW	**Op Code** 0b = I²C write. 1b = I²C read.
RESET	28	0b	RW1C	**Reset Sequence** If set, sends a reset sequence before the actual read or write. This bit is self clearing. A reset sequence is defined as nine consecutive stop conditions.
R	29	0b	RW	**Ready Bit** Indicates a read or write operation on the I²C interface has completed. Set to 1b by hardware at the end of the I²C transaction. Reset by a firmware/software write of a new command to this register.
RESERVED	30	0b	RSV	Reserved.
E	31	0b	RW	**Error** This bit set is to 1b by hardware when it fails to complete an I²C read. Reset by a firmware/software write of a new command. This bit is valid only when Ready bit *R* is set to 1b by hardware.

38.39.2.1.16 VM Reset Trigger - VSIGEN_RTRIG[VSI] (0x00090000 + 0x4*VSI, VSI=0...383; RW)

Field	Bit(s)	Init.	Type	Description
VMSWR	0	0b	RW	**VM Software Reset** VM software reset is initiated by setting the *VMSWR* bit. At completion of the reset flow, the PF software clears this bit.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.17 VM Reset Status - VSIGEN_RSTAT[VSI] (0x00090800 + 0x4*VSI, VSI=0...383; RO)

Field	Bit(s)	Init.	Type	Description
VMRD	0	1b	RO	**VM Software Reset Done Indication** This flag is cleared when the VM reset is initiated (by setting the *VMSWR* flag in the matched VSIGEN_RTRIG register (Section 38.39.2.1.16), or any stronger reset that affects the VM). It is set back to 1b when hardware completes its VM reset sequence.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.18 VF Reset Trigger - VPGEN_VFRTRIG[VF] (0x00091800 + 0x4*VF, VF=0...127; RW)

This register affects the VF, but is exposed only to the parent PF.

Field	Bit(s)	Init.	Type	Description
VFSWR	0	0b	RW	**VF Software Reset** VF software reset is done by the PF setting the *VFSWR* bit. At reset completion, the PF clears this bit.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.19 VF Reset Status - VPGEN_VFRSTAT[VF] (0x00091C00 + 0x4*VF, VF=0...127; RO)

This register affects the VF, but is exposed only to the parent PF.

Field	Bit(s)	Init.	Type	Description
VFRD	0	1b	RO	**VF Software Reset Done Indication** This flag is cleared when the VF reset is initiated by setting the *VFSWR* flag in the matched VPGEN_VFRTRIG register (Section 38.39.2.1.18) or any stronger reset that affects the VF. It is set back to 1b when hardware completes its VF reset sequence.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.20 PF Control - PFGEN_CTRL (0x00092400; RW)

Field	Bit(s)	Init.	Type	Description
PFSWR	0	0b	RW	**PF Software Reset** PF software reset is done by setting the *PFSWR* bit. At reset completion, hardware clears this bit.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.21 PF Driver Unload - PFGEN_DRUN (0x00092500; RW)

Field	Bit(s)	Init.	Type	Description
DRVUNLD	0	0b	RW	**Driver Unload** The PF sets this bit to indicate its driver is unloading.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.22 Global VF Level Reset Status - GLGEN_VFLRSTAT[n] (0x00092600 + 0x4*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
VFLRE	31:0	0x0	RW1C	**VFLR Status Indication** Bit 'm' in register 'n' reflects a VFLR event on VF index '32 x n + m', where 'n' is the register index and 'm' is the bit index.

38.39.2.1.23 Global Status - GLGEN_STAT (0x000B612C; RO)

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
DCBEN	2	0b	RW	**Global DCB Enable** Defines if DCB is enabled. Loaded from NVM. Can be overridden by firmware. 0b = DCB disabled. 1b = DCB enabled.
VTEN	3	0b	RW	**Global VT Enable** Defines if the virtualization offloads are enabled. Loaded from NVM. Can be overridden by Firmware. 0b = VT disabled. 1b = VT enabled.
RESERVED	4	0b	RW	Reserved.
EVBEN	5	0b	RW	**Global EVB Enable** Defines if the PE structures (s-comp/M-comp) offloads are enabled. 0b = EVB disabled. 1b = EVB enabled.
RESERVED	31:6	0x0	RSV	Reserved.

38.39.2.1.24 General Port Status - PRTGEN_STATUS (0x000B8100; RO)

This register contains general port status information.

Field	Bit(s)	Init.	Type	Description
PORT_VALID	0	0b	RO	**Port Valid** Denotes if the respective Ethernet port is enabled. 0b = Port is disabled. 1b = Port is enabled.
PORT_ACTIVE	1	0b	RO	**Port Active** Denotes if the respective Ethernet port is active. 0b = Port is inactive and its respective PHY is in power down. 1b = Port is active and its respective PHY is powered up. *PORT_ACTIVE* is 1b when: *PORT_VALID* = 1b AND If (device is in D0 state) then port should be active: If the software device driver activated the link (*ACTIVATE_PORT_LINK* = 1b) or link is used for manageability. Else, when device is in Dr state, the port should be active+ If link is used for manageability or WoL.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.1.25 General Port Configuration - PRTGEN_CNF (0x000B8120; RO)

This register contains configuration per Ethernet port loaded from the NVM.

Field	Bit(s)	Init.	Type	Description
PORT_DIS	0	1b	RW	**Port Disable** Defines if the Ethernet port is enabled from the NVM. Exception: Port 0 is always enabled and cannot be disabled from the NVM. 0b = Enabled. 1b = Disabled. Default: 0b = Port 0. 1b = Other ports.
ALLOW_PORT_DIS	1	0b	RW	**Allow Port Disable** 0b = Asserting LAN_DIS_N has no effect on this port. 1b = Asserting LAN_DIS_N disables this port.
EMP_PORT_DIS	2	0b	RW	**EMP Port Disable** Set by the EMP to disable the Ethernet port. The NVM value for this bit should always be 0b (enabled). NVM should use the *PORT_DIS* bit to disable a port.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.1.26 General Port Configuration2 - PRTGEN_CNF2 (0x000B8160; RO)

This register contains configuration per Ethernet port loaded from the NVM.

Field	Bit(s)	Init.	Type	Description
ACTIVATE_PORT_LINK	0	1b	RW	**Activate Port Link** When this field is set to 0b, the port's link is powered down. This field can be used by an application to disable the link until the software device driver is loaded and enables the link. ***Notes:*** 1. The PCIe functions associated with the port are not affected by the link loss. 2. Deactivating the link using this configuration is ignored when the interface is used for manageability. To implement this, hardware masks this configuration when the relevant port's PRTPM_GC.*EMP_LINK_ON* is set to 1b (Section 38.39.2.4.1). 3. If APM or ACPI power management are used, this bit should be set.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.1.27 Global Reset Delay - GLGEN_RSTCTL (0x000B8180; RO)

Field	Bit(s)	Init.	Type	Description
GRSTDEL	5:0	0x8	RW	**Global Reset Delay** Global/Core and EMP resets delay defined in 100 ms units. Setting *GRSTDEL* to zero bypasses the delay counter.
RESERVED	7:6	00b	RSV	Reserved.
ECC_RST_ENA	8	0b	RW	**ECC Reset Enable** Graceful GLOBR reset on ECC in any memory other than the EMP memories. 0b = A detected ECC error on these memories generates only an interrupt to the PFs. 1b = A detected ECC error generated a graceful GLOBR.
RESERVED	31:9	0x0	RSV	Reserved.

38.39.2.1.28 Global Clock Status - GLGEN_CLKSTAT (0x000B8184; RO)

Field	Bit(s)	Init.	Type	Description
CLKMODE	0	0b	RW	**Clock Mode** Controls the operating mode of internal clocks: 0b = Performance mode — Device operates at its highest internal frequencies, independent of the Ethernet link speed. 1b = Power mode — Device adjusts its internal frequencies to match the speed of the Ethernet link.
RESERVED	3:1	000b	RSV	Reserved.
U_CLK_SPEED	5:4	00b	RO	**Upper Clock Speed** Debug Feature. Represents the current speed of the upper clock (core_clk) as follows: 00b = 390.625 MHz. 01b = 195.3125 MHz. 10b = 97.65625 MHz. 11b = Reserved.
RESERVED	7:6	00b	RSV	Reserved.
P0_CLK_SPEED	10:8	000b	RO	**P0 Clock Speed** Debug Feature. Represents the current speed of the Rx clock for MAC 0. 3 bits per port (synchronized to the equivalent MAC clock). Speeds are represented as follows: 000b = Reserved. 001b = 1 GbE. 010b = 10 GbE. 011b = Reserved. All other values are reserved.
RESERVED	11	0b	RSV	Reserved.
P1_CLK_SPEED	14:12	000b	RO	**P1 Clock Speed** Debug Feature. Represents the current speed of the Rx clock for MAC 1. 3 bits per port (synchronized to the equivalent MAC clock). Speeds are represented as follows: 000b = Reserved. 001b = 1 GbE. 010b = 10 GbE. 011b = Reserved. All other values are reserved.
RESERVED	15	0b	RSV	Reserved.
P2_CLK_SPEED	18:16	000b	RO	**P2 Clock Speed** Debug Feature. Represents the current speed of the Rx clock for MAC 2. 3 bits per port (synchronized to the equivalent MAC clock). Speeds are represented as follows: 000b = Reserved. 001b = 1 GbE. 010b = 10 GbE. 011b = Reserved. All other values are reserved.
RESERVED	19	0b	RSV	Reserved.
P3_CLK_SPEED	22:20	000b	RO	**P3 Clock Speed** Debug Feature. Represents the current speed of the Rx clock for MAC 3. 3 bits per port (synchronized to the equivalent MAC clock). Speeds are represented as follows: 000b = Reserved. 001b = 1 GbE. 010b = 10 GbE. 011b = Reserved. All other values are reserved.
RESERVED	31:23	0x0	RSV	Reserved.

38.39.2.1.29 Global Reset Status - GLGEN_RSTAT (0x000B8188; RO)

Field	Bit(s)	Init.	Type	Description
DEVSTATE	1:0	00b	RO	**Device State** Device can be at one of the following states: 00b = Device active. 01b = Reset requested. 10b = Reset in progress. 11b = Reserved.
RESET_TYPE	3:2	00b	RO	**Reset Type** Reflects one of the following resets that are/were in progress: 00b = POR. 01b = CORER. 10b = GLOBR. 11b = EMPR.
CORERCNT	5:4	00b	RO	**Core Reset Count** Counts the number of initiated core resets since POR. The counter wraps around from 11b to 00b.
GLOBRCNT	7:6	00b	RO	**Global Reset Count** Counts the number of initiated global resets since POR. The counter wraps around from 11b to 00b.
EMPRCNT	9:8	00b	RO	**EMP Reset Count** Counts the number of initiated EMP resets since POR. The counter wraps around from 11b to 00b.
TIME_TO_RST	15:10	0x0	RO	**Time to Reset** The reset time is a down counter, loaded by GLRSTDEL following a GLOBR or CORER or EMPR. When GLOBRTIME reaches a zero value, the actual reset is initiated.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.1.30 Global Reset Trigger - GLGEN_RTRIG (0x000B8190; RW)

Field	Bit(s)	Init.	Type	Description
CORER	0	0b	RW	**Core Reset** Setting the CORER triggers a graceful core reset flow.
GLOBR	1	0b	RW	**Global Reset** Setting the GLOBR triggers a graceful global reset flow.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.1.31 LAN Port Number - PFGEN_PORTNUM (0x001C0480; RO)

Field	Bit(s)	Init.	Type	Description
PORT_NUM	1:0	00b	RW	**Port Number** Indicates the LAN port connected to this function. 00b = Port 0. 01b = Port 1. 10b = Port 2. 11b = Port 3.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.1.32 PCI Function Count - GLGEN_PCIFCNCNT (0x001C0AB4; RO)

Field	Bit(s)	Init.	Type	Description
PCIPFCNT	4:0	0x1	RW	**PCI PF Count** Reports the function number of the highest PCI physical function plus 1 as it is loaded from the NVM. For example, if the NVM enables two functions 0 and 7, the value is 8 (7+1). Used to partition the interrupt vectors among supported PFs.
RESERVED	15:5	0x0	RSV	Reserved.
PCIVFCNT	23:16	0x0	RW	**PCI VF Count** Reports the function number of highest PCI virtual function plus 1 for all PFs combined, as it is loaded from the NVM. Used to partition the interrupt vectors among supported VFs.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.2 PF - PCIe Registers

This category contains registers for PCIe configuration and control.

38.39.2.2.1 Function Requester ID Information Register - PF_FUNC_RID (0x0009C000; RO)

Field	Bit(s)	Init.	Type	Description
FUNCTION_NUMBER	2:0	000b	RO	**Function Number** Function number assigned to the function based on BIOS/OS enumeration.
DEVICE_NUMBER	7:3	0x0	RO	**Device Number** No-ARI mode: Device number assigned to the function based on BIOS/OS enumeration. ARI mode: Upper 5 bits of the 8-bit function number.
BUS_NUMBER	15:8	0x0	RO	**Bus Number** Bus number assigned to the function based on BIOS/OS enumeration.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.2.2 PCIe Configuration Indirect Access Address - PF_PCI_CIAA (0x0009C080; RW)

Field	Bit(s)	Init.	Type	Description
ADDRESS	11:0	0x0	RW	**Address** The configuration space address to access.
VF_NUM	18:12	0x0	RW	**VF Number** Defines the VF number to access. The VF number is the absolute VF number in the device.
RESERVED	31:19	0x0	RSV	Reserved. Ignore on read. Write 0b.

38.39.2.2.3 PCIe Configuration Indirect Access Data - PF_PCI_CIAD (0x0009C100; RW)

Field	Bit(s)	Init.	Type	Description
DATA	31:0	0x0	RW	**Data** Used to access the configuration registers of the VF. Operates together with the PF_PCI_CIAA register (Section 38.39.2.2.2) as follows: Reading this register returns the content of the register at offset = ADDRESS in the configuration space of VF index = VF_NUM (the ADDRESS and VF_NUM parameters are defined by the PF_PCI_CIAA register).

38.39.2.2.4 Function Active and Power State - PFPCI_FACTPS (0x0009C180; RO)

This register is provided for internal firmware use, notifying firmware about function state.

Field	Bit(s)	Init.	Type	Description
FUNC_POWER_STATE	1:0	00b	RO	**Function Power State** Power state indication of the function. 00b = Dr. 01b = D3. 10b = D0a. 11b = D0u.
RESERVED	2	0b	RSV	Reserved.
FUNC_AUX_EN	3	0b	RO	**Function Aux Enable** Reflects the *Auxiliary Power PM Enable* bit from the PCI configuration space.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.2.5 PCIe VM Pending Index - PFPCI_VMINDEX (0x0009C300; RW)

Field	Bit(s)	Init.	Type	Description
VMINDEX	8:0	0x0	RW	**VM Index** Software sets the VMINDEX that its transaction pending flag should be reflected in the PFPCI_VMPEND register (Section 38.39.2.2.6). The VM index is an absolute index in the range of 0 through 383. It can only be set by software to VMs that the PF owns and only to VMs that are not assigned to a VF.
RESERVED	31:9	0x0	RSV	Reserved.

38.39.2.2.6 PCIe VM Pending Status - PFPCI_VMPEND (0x0009C380; RO)

Field	Bit(s)	Init.	Type	Description
PENDING	0	0b	RO	**PCIe Transaction Pending Status** The reported VM is controlled by the *VMINDEX* field in the PFPCI_VMINDEX register (Section 38.39.2.2.5). This flag is set to 1b as long as there is at least one PCIe transaction pending for its completion.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.7 PCIe Default Revision ID - GLPCI_DREVID (0x0009C480; RO)

Field	Bit(s)	Init.	Type	Description
DEFAULT_REVID	7:0	0x0	RO	**Default Revision ID** Mirroring of default Rev ID prior to an NVM load.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.2.8 PCIe Statistic Control Register #1 - GLPCI_GSCL_1 (0x0009C48C; RW)

This register controls the operation of the PCIe performance counters.

Field	Bit(s)	Init.	Type	Description
GIO_COUNT_EN_0	0	0b	RW	**GIO Counter Enable 0** Enables PCIe statistic counter number 0.
GIO_COUNT_EN_1	1	0b	RW	**GIO Counter Enable 1** Enables PCIe statistic counter number 1.
GIO_COUNT_EN_2	2	0b	RW	**GIO Counter Enable 2** Enables PCIe statistic counter number 2.
GIO_COUNT_EN_3	3	0b	RW	**GIO Counter Enable 3** Enables PCIe statistic counter number 3.
LBC_ENABLE_0	4	0b	RW	**Leaky Bucket Counter Enable 0** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 0 operates in leaky bucket mode.
LBC_ENABLE_1	5	0b	RW	**Leaky Bucket Counter Enable 1** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 1 operates in leaky bucket mode.
LBC_ENABLE_2	6	0b	RW	**Leaky Bucket Counter Enable 2** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 2 operates in leaky bucket mode.
LBC_ENABLE_3	7	0b	RW	**Leaky Bucket Counter Enable 3** 0b = Leaky bucket mode is disabled and the counter is incremented by one for each event. 1b = Statistics counter 3 operates in leaky bucket mode.
RESERVED	27:8	0x0	RSV	Reserved.
GIO_64_BIT_EN	28	0b	RW	**GIO 64-Bit Enable** Enables two 64-bit counters instead of four 32-bit counters.
GIO_COUNT_RESET	29	0b	RW1S	**GIO Counter Reset** Reset indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_STOP	30	0b	RW1S	**GIO Counter Stop** Stop indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_START	31	0b	RW1S	**GIO Counter Start** Start indication of PCIe statistic counters. Reading this bit returns a 0b.

38.39.2.2.9 PCIe Statistic Control Register #2 - GLPCI_GSCL_2 (0x0009C490; RW)

This register defines the events counted by the performance counters.

Field	Bit(s)	Init.	Type	Description
GIO_EVENT_NUM_0	7:0	0x0	RW	**GIO Event Number 0** Event number that counter 0 counts (GSCN_0).
GIO_EVENT_NUM_1	15:8	0x0	RW	**GIO Event Number 1** Event number that counter 1 counts (GSCN_1).
GIO_EVENT_NUM_2	23:16	0x0	RW	**GIO Event Number 2** Event number that counter 2 counts (GSCN_2).
GIO_EVENT_NUM_3	31:24	0x0	RW	**GIO Event Number 3** Event number that counter 3 counts (GSCN_3).

38.39.2.2.10 PCIe Statistic Control Registers #5...#8 - GLPCI_GSCL_5_8[n] (0x0009C494 + 0x4*n, n=0...3; RW)

These registers control the operation of the leaky bucket counter n.

GSCL_5 corresponds to n=0
GSCL_6 corresponds to n=1
GSCL_7 corresponds to n=2
GSCL_8 corresponds to n=3

Field	Bit(s)	Init.	Type	Description
LBC_THRESHOLD_N	15:0	0x0	RW	**Leaky Bucket Counter Threshold N** Threshold for the leaky bucket counter n.
LBC_TIMER_N	31:16	0x0	RW	**Leaky Bucket Counter Timer N** Time period between decrementing the value in leaky bucket counter n. The time period is defined in µs units.

38.39.2.2.11 PCIe Statistic Counter Registers #0...#3 - GLPCI_GSCN_0_3[n] (0x0009C4A4 + 0x4*n, n=0...3; RO)

These registers contain the performance counters 0-3.

GSCL_0 corresponds to n=0
GSCL_1 corresponds to n=1
GSCL_2 corresponds to n=2
GSCL_3 corresponds to n=3

Field	Bit(s)	Init.	Type	Description
EVENT_COUNTER	31:0	0x0	RO	**Event Counter** A 32-bit event counter. These registers are stuck at their maximum value of 0xFF...F. Refer to the section on Performance and Statistics Counters.

38.39.2.2.12 PCIe PQs Max Used Space - GLPCI_PQ_MAX_USED_SPC (0x0009C4EC; RO)

Field	Bit(s)	Init.	Type	Description
GLPCI_PQ_MAX_USED_SPC_12	7:0	0x0	RO	**PCIe PQ Max Used Space 12**
GLPCI_PQ_MAX_USED_SPC_13	15:8	0x0	RO	**PCIe PQ Max Used Space 13**
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.2.13 PCIe Mux Selector for PFB - GLPCI_PM_MUX_PFB (0x0009C4F0; RW)

Field	Bit(s)	Init.	Type	Description
PFB_PORT_SEL	4:0	0x0	RW	**PFB Port Select**
RSVD_0	15:5	0x0	RSV	Reserved.
INNER_PORT_SEL	18:16	000b	RW	**Inner Port Select**
RSVD_1	31:19	0x0	RSV	Reserved.

38.39.2.2.14 PCIe Mux Selector for NPQs - GLPCI_PM_MUX_NPQ (0x0009C4F4; RW)

Field	Bit(s)	Init.	Type	Description
NPQ_NUM_PORT_SEL	2:0	000b	RW	**NPQ Number Port Select**
RSVD_0	15:3	0x0	RSV	Reserved.
INNER_NPQ_SEL	20:16	0x0	RW	**Inner NPQ Select**
RSVD_1	31:21	0x0	RSV	Reserved.

38.39.2.2.15 PCIe Regs Spare Bits 0 - GLPCI_SPARE_BITS_0 (0x0009C4F8; RW)

Field	Bit(s)	Init.	Type	Description
SPARE_BITS	31:0	0x0	RW	**Spare Bits**

38.39.2.2.16 PCIe Regs Spare Bits 1 - GLPCI_SPARE_BITS_1 (0x0009C4FC; RW)

Field	Bit(s)	Init.	Type	Description
SPARE_BITS	31:0	0x0	RW	**Spare Bits**

38.39.2.2.17 PCIe NPQ Current Status of Allowed Resources for RLAN - GLPCI_CUR_RLAN_ALWD (0x0009C500; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1BE	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x40	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.18 PCIe NPQ Current Status of Allowed Resources for TLAN - GLPCI_CUR_TLAN_ALWD (0x0009C504; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1BE	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x11	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.19 PCIe NPQ Current Status of Allowed Resources for RXPE - GLPCI_CUR_RXPE_ALWD (0x0009C508; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0xE9	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x18	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.20 PCIe NPQ Statistic Control Register #0 - GLPCI_GSCL_0 (0x0009CA8C; RO)

This register controls the operation of the PCIe performance counters.

Field	Bit(s)	Init.	Type	Description
RESERVED	28:0	0x0	RSV	Reserved.
GIO_COUNT_RESET	29	0b	RW1S	Reset indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_STOP	30	0b	RW1S	Stop indication of PCIe statistic counters. Reading this bit returns a 0b.
GIO_COUNT_START	31	0b	RW1S	Start indication of PCIe statistic counters. Reading this bit returns a 0b.

38.39.2.2.21 PCIe NPQ Current Status of Allowed Resources for TXPE - GLPCI_CUR_TXPE_ALWD (0x0009C50C; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0xE9	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x18	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.22 PCIe NPQ Current Status of Allowed Resources for PMAT - GLPCI_CUR_PMAT_ALWD (0x0009C510; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x4C0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0xBC	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.23 PCIe NPQ Current Status of Allowed Resources for MNG - GLPCI_CUR_MNG_ALWD (0x0009C514; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1B3	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x9	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.24 PCIe NPQ Current Status of Allowed Resources for TDPU - GLPCI_CUR_TDPU_ALWD (0x0009C518; RO)

This register reports the current value of resources that a client might use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x21F	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x50	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.25 PCIe NPQ Current Status of Reserved Resources for RLAN - GLPCI_CUR_RLAN_RSVD (0x0009C580; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.26 PCIe NPQ Current Status of Reserved Resources for TLAN - GLPCI_CUR_TLAN_RSVD (0x0009C584; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.27 PCIe NPQ Current Status of Reserved Resources for RXPE - GLPCI_CUR_RXPE_RSVD (0x0009C588; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.28 PCIe NPQ Current Status of Reserved Resources for TXPE - GLPCI_CUR_TXPE_RSVD (0x0009C58C; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.29 PCIe NPQ Current Status of Reserved Resources for PMAT - GLPCI_CUR_PMAT_RSVD (0x0009C590; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.30 PCIe NPQ Current Status of Reserved Resources for MNG - GLPCI_CUR_MNG_RSVD (0x0009C594; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.31 PCIe NPQ Current Status of Reserved Resources for TDPU - GLPCI_CUR_TDPU_RSVD (0x0009C598; RO)

This register reports the current value of resources that are reserved for clients.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.32 PCIe VF Flush Done - PFPCI_VF_FLUSH_DONE[VF] (0x0009C600 + 0x4*VF, VF=0...127; RO)

Field	Bit(s)	Init.	Type	Description
FLUSH_DONE	0	0b	RO	**Flush Done**
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.33 PCIe PF Flush Done - PFPCI_PF_FLUSH_DONE (0x0009C800; RO)

Field	Bit(s)	Init.	Type	Description
FLUSH_DONE	0	0b	RO	**Flush Done**
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.34 PCIe VM Flush Done - PFPCI_VM_FLUSH_DONE (0x0009C880; RO)

Field	Bit(s)	Init.	Type	Description
FLUSH_DONE	0	0b	RO	**Flush Done**
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.35 PCIe NPQ Config - GLPCI_NPQ_CFG (0x0009CA00; RW)

This register controls some parameters of NPQ.

Field	Bit(s)	Init.	Type	Description
EXTEND_TO	0	0b	RW	**Extend Timeout** Extends timeout in the permitted range.
SMALL_TO	1	0b	RW	**Small Timeout** Reduce timeout value for simulation
WEIGHT_AVG	5:2	0x2	RW	**Weight Average** Controls the weight of the average filter for average round trip calculation.
NPQ_SPARE	15:6	0x0	RW	**NPQ Spare Bits**
NPQ_ERR_STAT	19:16	0x0	RO	**NPQ Error Stats**
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.2.36 PCIe NPQ Current Status of Common Bucket - GLPCI_CUR_CLNT_COMMON (0x0009CA18; RO)

This register reports the current value of common resources in NPQ.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x53B	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0xD0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.37 PCIe NPQ Current Status of Pipe Monitor - GLPCI_CUR_CLNT_PIPEMON (0x0009CA20; RO)

This register reports the current value of pipe monitor in NPQ.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x53B	RO	**Data Lines** Amount of data lines available.
RESERVED	31:16	0x0	RO	Reserved.

38.39.2.2.38 PCIe NPQ Watermark of Common Bucket - GLPCI_CUR_WATMK_CLNT_COMMON (0x0009CA28; RO)

This register reports a watermark of the common resources in NPQ.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x53B	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x0	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.39 PCIe NPQ Watermark of Pipe Monitor - GLPCI_WATMK_CLNT_PIPEMON (0x0009CA30; RO)

This register reports the current value of the pipe monitor in NPQ.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x53B	RO	**Data Lines** Amount of data lines available.
RESERVED	31:16	0x0	RO	Reserved.

38.39.2.2.40 PCIe NPQ Watermark of Allowed Resources for RLAN - GLPCI_WATMK_RLAN_ALWD (0x0009CB00; RO)

This register reports the watermark of resources that client are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1BE	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x40	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.41 PCIe NPQ Watermark of Allowed Resources for TLAN - GLPCI_WATMK_TLAN_ALWD (0x0009CB04; RO)

This register reports the watermark of resources that clients are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1BE	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x11	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.42 PCIe NPQ Watermark of Allowed Resources for RXPE - GLPCI_WATMK_RXPE_ALWD (0x0009CB08; RO)

This register reports the watermark of resources that client are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0xE9	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x18	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.43 PCIe NPQ Watermark of Allowed Resources for TXPE - GLPCI_WATMK_TXPE_ALWD (0x0009CB0C; RO)

This register reports the watermark of resources that client are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0xE9	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x18	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.44 PCIe NPQ Watermark of Allowed Resources for PMAT - GLPCI_WATMK_PMAT_ALWD (0x0009CB10; RO)

This register reports the watermark of resources that clients are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x4C0	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0xBC	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.45 PCIe NPQ Watermark of Allowed Resources for MNG - GLPCI_WATMK_MNG_ALWD (0x0009CB14; RO)

This register reports the watermark of resources that clients are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x1B3	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x9	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.46 PCIe NPQ Watermark of Allowed Resources for TDPU - GLPCI_WATMK_TPDU_ALWD (0x0009CB18; RO)

This register reports the watermark of resources that clients are allowed to use.

Field	Bit(s)	Init.	Type	Description
DATA_LINES	15:0	0x21F	RO	**Data Lines** Amount of data lines available.
OSR	31:16	0x50	RO	**Outstanding Requests** Amount of outstanding requests available.

38.39.2.2.47 PCIe PF Configuration - PFPCI_CNF (0x000BE000; RO)

Contains per-PF configuration loaded from the NVM.

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
MSI_EN	2	1b	RW	**MSI Enable** Enables the MSI capability structure for this PCI function. 0b = MSI is disabled. 1b = MSI is enabled.
EXROM_DIS	3	0b	RW	**Expansion ROM Disable** 0b = The Expansion ROM BAR in the PCI configuration space is enabled. 1b = The Expansion ROM BAR in the PCI configuration space is disabled.
IO_BAR	4	0b	RW	**I/O BAR Support** 0b = I/O BAR is not supported. 1b = I/O BAR is supported.
INT_PIN	6:5	00b	RW	**Interrupt Pin** Controls the value advertised in the Interrupt Pin field of the PCI configuration header for this function. 00b = INTA# 01b = INTB# 10b = INTC# 11b = INTD# The value advertised in the PCI configuration header is the value loaded from the NVM plus one.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.2.48 PCIe PF Device ID - PFPCI_DEVID (0x000BE080; RO)

Contains the per-PF device ID.

Field	Bit(s)	Init.	Type	Description
PF_DEV_ID	15:0	0x374C	RW	**PF Device ID** Contains the device ID for this PF.
VF_DEV_ID	31:16	0x374D	RW	**VF Device ID** Contains the device ID for the VFs of this PF.

38.39.2.2.49 PCIe Functions Configuration 2 - PFPCI_FUNC2 (0x000BE180; RO)

Field	Bit(s)	Init.	Type	Description
RESERVED	31:0	0x0	RSV	Reserved.

38.39.2.2.50 PCIe Functions Configuration - PFPCI_FUNC (0x000BE200; RO)

Field	Bit(s)	Init.	Type	Description
FUNC_DIS	0	1b	RW	**Function Disable** Defines if the PCI function is enabled from the NVM. Exception: This bit is RO for PF0. It is always enabled and cannot be disabled from the NVM. 0b = Enabled 1b = Disabled Default: 0b = PF0. 1b = Other functions.
ALLOW_FUNC_DIS	1	0b	RW	**Allow Function Disable** 0b = Asserting PCI_DIS_N has no effect on this PCI function. 1b = Asserting PCI_DIS_N disables this PCI function.
DIS_FUNC_ON_PORT_DIS	2	0b	RW	**Disable Function On Port Disable** Defines whether this PF is disabled when the LAN_DIS_N pin is asserted. 0b = Asserting LAN_DIS_N has no effect on this PCI function. 1b = Asserting LAN_DIS_N disables this PCI function.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.2.51 PCIe Function Status 1 - PFPCI_STATUS1 (0x000BE280; RO)

Field	Bit(s)	Init.	Type	Description
FUNC_VALID	0	0b	RO	**Function Valid** 0b = Function is disabled. 1b = Function is enabled. This bit is valid to firmware even when the function is disabled.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.52 PCIe PM - PFPCI_PM (0x000BE300; RW)

Field	Bit(s)	Init.	Type	Description
PME_EN	0	0b	RW	**PME Enable** Used by the software device driver to generate a PME event without writing to the PMCSR in the PCIe configuration space. The internal PME Enablement is a logic OR function of the following: *PME_EN* flag in the PMCSR, *PME_EN* flag in the PFPCI_PM CSR, and *APME* flag in the PFPM_APM CSR. The bit is reset on Sticky Reset (STRST). Bit is reset only on power-on reset (LAN_PWR_GOOD). When *AUX_PWR* = 0b, this bit is also reset when de-asserting PE_RST_N.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.53 PCIe Storage Class - PFPCI_CLASS (0x000BE400; RO)

Contains per-PF configuration loaded from the NVM.

Field	Bit(s)	Init.	Type	Description
STORAGE_CLASS	0	0b	RW	**Storage Class** 0b = The class code of this function is set to 0x020000 (LAN). 1b = The class code of this function is set to 0x010000 (SCSI).
RESERVED	1	0b	RSV	Reserved.
PF_IS_LAN	2	0b	RW	**PF Is LAN** 0b = Reserved. 1b = LAN function.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.2.54 PCI BAR Control - GLPCI_LBARCTRL (0x000BE484; RO)

Field	Bit(s)	Init.	Type	Description
PREFBAR	0	1b	RW	**Prefetchable BAR** Prefetchable bit indication in the memory BAR and MSI-X BAR (should be set when 64-bit BARs are used). 0b = BARs are marked as non prefetchable. 1b = BARs are marked as prefetchable.
BAR32	1	0b	RW	**BAR 32-bit Enable** 0b = 64-bit BAR addressing mode is selected. 1b = 32-bit BARs are enabled.
RESERVED	2	0b	RSV	Reserved.
FLASH_EXPOSE	3	1b	RW	**Flash Exposed** When set, the Flash memory is accessible through the memory BAR.
PE_DB_SIZE	5:4	00b	RW	**PE DB Size** Determines the size of the memory space allocated to the protocol engine door bells in the PF BARs 00b = Memory space is not allocated for PE door bells. 01b = A 64 KB area is allocated. 10b = A (4 MB + 64 KB) area is allocated. 11b = Reserved.
FL_SIZE	8:6	111b	RW	**Flash Size** Indicates the size of the external Flash as = 64 KB x (2 ** FL_SIZE). 101b = 2 MB. 110b = 4 MB. 111b = 8 MB. All other values are reserved.
RESERVED	10:9	00b	RSV	Reserved.
EXROM_SIZE	13:11	011b	RW	**Expansion ROM Size** Indicates the size of the expansion ROM BAR as = 64 KB x (2 ** EXROM_SIZE). 000b = 64 KB. 001b = 128 KB. 010b = 256 KB. 011b = 512 KB. 100b = 1 MB. 101b = 2 MB. 110b = 4 MB. 111b = 8 MB. Default value is 512 KB.
RESERVED	31:14	0x0	RSV	Reserved.

38.39.2.2.55 PCIe Subsystem ID - GLPCI_SUBVENID (0x000BE48C; RO)

Field	Bit(s)	Init.	Type	Description
SUB_VEN_ID	15:0	0x8086	RW	**Subsystem Vendor ID** Loaded to the PCI configuration Subsystem Vendor ID register.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.2.56 PCIe Power Data Register - GLPCI_PWRDATA (0x000BE490; RO)

Field	Bit(s)	Init.	Type	Description
D0_POWER	7:0	0x0	RW	**D0 Power** The value in this field is reflected in the PCI Power Management Data register of the LAN functions for D0 power consumption and dissipation (Data_Select = 0 or 4).
COMM_POWER	15:8	0x0	RW	**Common Power** The value in this field is reflected in the PCI Power Management Data register of function 0 when the Data_Select field is set to eight (common function).
D3_POWER	23:16	0x0	RW	**D3 Power** The value in this field is reflected in the PCI Power Management Data register of the LAN functions for D3 power consumption and dissipation (Data_Select = 3 or 7).
DATA_SCALE	25:24	00b	RW	**Data Scale** The value in this field reflects the Data_Scale field in the PCI PMCSR register.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.2.57 PCIe Global Config 2 - GLPCI_CNF2 (0x000BE494; RO)

This register contains global status fields of PCIe configuration.

Field	Bit(s)	Init.	Type	Description
RO_DIS	0	0b	RW	**Relaxed Ordering Disable** 0b = Relaxed ordering is specified per request type. 1b = The device does not request any relaxed ordering transactions.
CACHELINE_SIZE	1	0b	RW	**Cache Line Size** Determines the system cache line size. 0b = 64 bytes. 1b = 128 bytes. This field is loaded from the NVM.
MSI_X_PF_N	12:2	0x80	RW	**MSI_X PF Table Size** System software reads this field to determine the MSI-X table size N, which is encoded as N-1. This field is loaded from the NVM *MSI_X_N_PF* field and reflects the same field in the PCIe MSI-X configuration (Message Control register).
MSI_X_VF_N	23:13	0x04	RW	**MSI_X VF Table Size** System software reads this field to determine the MSI-X table size N for VFs, which is encoded as N-1. This field is loaded from the NVM *MSI_X_N_VF* field and reflects the same field in the PCIe MSI-X configuration (VF MSI-X Control register).
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.2.58 PCIe Serial Number MAC Address Low - GLPCI_SERL (0x000BE498; RO)

Field	Bit(s)	Init.	Type	Description
SER_NUM_L	31:0	0x0	RW	**Serial Number Low** The low DWord of the Ethernet MAC address used to generate the PCIe serial number. The register contents is loaded from NVM. The location in NVM is pointed by the 4th item in the Auto-Generated Pointers Module. It is a per device manufacturing value which represents the whole device. It can be set identical to the concatenated [PFPM_SAL1|PFPM_SAL0] words of the EMP Settings Module.

38.39.2.2.59 PCIe Serial Number MAC Address High - GLPCI_SERH (0x000BE49C; RO)

Field	Bit(s)	Init.	Type	Description
SER_NUM_H	15:0	0x0	RW	**Serial Number High** The high word of the Ethernet MAC address used to generate the PCIe serial number. The register contents is loaded from the NVM. The location in NVM is pointed by the 5th item in the auto-generated pointers module. It is a per device manufacturing value which represents the entire device. It can be set identical to the concatenated [PFPM_SAH1|PFPM_SAH0] words of the EMP settings module.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.2.60 PCIe Capabilities Control - GLPCI_CAPCTRL (0x000BE4A4; RW)

Determines PCIe capabilities supported by the device, and that software is allowed to enable or disable.

Field	Bit(s)	Init.	Type	Description
VPD_EN	0	0b	RW	**VPD Enable** 0b = The PCIe VPD capability is not present and is not exposed. 1b = The PCIe VPD capability is present and exposed.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.2.61 PCIe Capabilities Support - GLPCI_CAPSUP (0x000BE4A8; RO)

Determines PCIe capabilities supported by the device.

Field	Bit(s)	Init.	Type	Description
PCIE_VER	0	1b	RW	**PCIE Capability Version** Determines the PCIe capability version. 0b = Capability version: 0x1. 1b = Capability version: 0x2.
RESERVED	2:1	0b	RSV	Reserved.
TPH_EN	3	1b	RW	**TPH Enable** A value of 1b indicates support for the PCIe TPH requester capability.
ARI_EN	4	1b	RW	**ARI Enable** A value of 1b indicates support for PCIe ARI capability.
IOV_EN	5	1b	RW	**IOV Enable** A value of 1b indicates support for PCIe SR-IOV capability.
ACS_EN	6	1b	RW	**ACS Enable** A value of 1b indicates support for PCIe ACS capability.
SEC_EN	7	1b	RW	**Secondary Enable** A value of 1b indicates support for the secondary PCIe extended capability.

Field	Bit(s)	Init.	Type	Description
RESERVED	15:8	0x0	RSV	Reserved.
ECRC_GEN_EN	16	1b	RW	**ECRC Generation Enable** Loaded into the ECRC. Generation capable bit of the PCIe configuration registers.
ECRC_CHK_EN	17	1b	RW	**ECRC Check Enable** Loaded into the ECRC. Check capable bit of the PCIe configuration registers.
IDO_EN	18	1b	RW	**IDO Enable** Enables ID-based ordering (IDO).
MSI_MASK	19	1b	RW	**MSI Per-vector Masking Setting** Loaded to the masking bit (bit 8) in the message control of the MSI configuration capability structure.
CSR_CONF_EN	20	1b	RW	**CSR Configuration Enable** Enables access to CSRs via the PCI configuration space. Refer to the section on Configuration Access to Internal Registers.
WAKUP_EN	21	0b	RW	**Wake-up Enable** If set, wake-up in D3 is exposed in *PME_Support* field in the PMCR.
RESERVED	29:22	0x0	RSV	Reserved.
LOAD_SUBSYS_ID	30	0b	RW	**Load Subsystem IDs** When set to 1b, indicates that the device loads its PCIe sub-system ID and sub-system vendor ID from the NVM.
LOAD_DEV_ID	31	0b	RW	**Load Device ID** When set to 1b, indicates that the device loads its PCI device IDs from the NVM.

38.39.2.2.62 PCIe Link Capabilities - GLPCI_LINKCAP (0x000BE4AC; RO)

Determines PCIe Link capabilities supported by the device.

Field	Bit(s)	Init.	Type	Description
LINK_SPEEDS_VECTOR	5:0	0x0	RW	**Supported Link Speeds Vector** Loaded to the Link Capabilities 2 register in the PCIe capability values: Bit[0] = 5.0 GT/s. Bit[1] = 8.0 GT/s. Bits[5:2] = Reserved. 2.5 GT/s is always supported.
MAX_PAYLOAD	8:6	100b	RW	**Max Payload Size Supported** Loaded to the PCIe Device Capabilities register. Support values are: 000b = 128 bytes. 001b = 256 bytes. 010b = 512 bytes. 001b = 1 KB. 100b = 2 KB. Otherwise, keep the hardware default.
MAX_LINK_WIDTH	12:9	0x07	RW	**Max Link Width** Loaded to the PCIe Link Capabilities register. 0001b = Limit max link width to x1. 0011b = Limit max link width to x4. 0100b = Limit max link width to x8. 0111b = Do not limit max link width. Negotiate to the max width supported by the link. All other values are reserved.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.2.63 PCIe PM Support - GLPCI_PMSUP (0x000BE4B0; RO)

This register contains parameters that define PCIe power management support.

Field	Bit(s)	Init.	Type	Description
RESERVED	7:0	0x0	RSV	Reserved.
L0S_ACC_LAT	10:8	011b	RW	**L0s Acceptable Latency** Loaded to the Endpoint L0s Acceptable Latency field in the PCIe Device Capabilities register.
L1_ACC_LAT	13:11	110b	RW	**L1 Acceptable Latency** Loaded to the Endpoint L1 Acceptable Latency field in the PCIe Device Capabilities register.
RESERVED	14	0b	RSV	Reserved.
OBFF_SUP	16:15	00b	RW	**OBFF Supported** Loaded to the OBFF Supported field in the PCIe Device Capabilities 2 register. Must be set to 0b in the NVM (OBFF is not supported).
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.2.64 PCIe Revision ID - GLPCI_REVID (0x000BE4B4; RO)

This register is shared by all physical functions.

Field	Bit(s)	Init.	Type	Description
NVM_REVID	7:0	0x0	RW	**NVM Revision ID** Value of the Rev ID loaded from the NVM.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.2.65 PCIe VF Capabilities Support - GLPCI_VFSUP (0x000BE4B8; RO

Field	Bit(s)	Init.	Type	Description
VF_PREFETCH	0	1b	RW	**VF Prefetchable** 0b = IOV memory BAR and MSI-X BAR are declared as non-prefetchable. 1b = IOV memory BAR and MSI-X BAR are declared as prefetchable.
VR_BAR_TYPE	1	1b	RW	**VF BAR Type** 0b = VF BARs advertise 32-bit size. 1b = VF BARs advertise 64-bit size.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.2.66 PCIe Global Config - GLPCI_CNF (0x000BE4C0; RO)

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
WAKE_PIN_EN	2	0b	RW	**Wake Pin Enable** When set to 1b, enables the use of the WAKE pin for a PME event in all power states.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.2.67 PCIe Upper Address - GLPCI_UPADD (0x000BE4F8; RW)

This register is used to block PCIe master accesses above some address.

Field	Bit(s)	Init.	Type	Description
RESERVED	0	0b	RSV	Reserved.
ADDRESS	31:1	0x0	RW	**Address** Bits[31:1] correspond to Bits[63:33] in the PCIe address space, respectively.

38.39.2.2.68 PCIe Vendor ID - GLPCI_VENDORID (0x000BE518; RO)

Field	Bit(s)	Init.	Type	Description
VENDORID	15:0	0x8086	RW	**Vendor ID** Contains the vendor ID exposed in offset 0x0 in the config space of all functions. A value of 0xFFFF is ignored.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.3 PF - MAC Registers

38.39.2.3.1 Port MAC Address Low - PRTGL_SAL (0x001E2120; RO)

This register contains the NVM-loaded lower bits of the 48-bit per-PF Ethernet MAC address. All 32 bits are valid.

Field	Bit(s)	Init.	Type	Description
FC_SAL	31:0	0x0	RW	**Station Address Low** Used for flow control packet processing. The lower 32 bits of the 48-bit Ethernet MAC address. This field is defined in big endian (LS byte of SAL is first on the wire).

38.39.2.3.2 Port MAC Address High - PRTGL_SAH (0x001E2140; RO)

This register contains the NVM-loaded upper bits of the 48-bit per-PF Ethernet MAC address. All 32 bits are valid. The complete address is (PFPM_SAH, PFPM_SAL). PFPM_SAH.*AV* determines whether this address is valid.

Field	Bit(s)	Init.	Type	Description
FC_SAH	15:0	0x0	RW	**Station Address High** Used for flow control packet processing. The upper 16 bits of the 48-bit Ethernet MAC address. This field is defined in big endian (MS byte of SAH is last on the wire).
MFS	31:16	0x2600	RW	**Maximum Frame Size** Defines the maximum receive frame size in bytes from MAC addresses up to and including the CRC. Frames received that are larger than this value might be dropped based on the SBP configuration. This configuration has no effect on maximum transmit frame size.

38.39.2.3.3 Link Down Counter - PRTMAC_LINK_DOWN_COUNTER (0x001E2440; RW1C)

Field	Bit(s)	Init.	Type	Description
LINK_DOWN_COUNTER	15:0	0x0	RW1C	**Link Down Counter** Increments on link down event. Does not do wrap around.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.4 PF - Power Management Registers

38.39.2.4.1 General Control - PRTPM_GC (0x000B8140; RO)

Field	Bit(s)	Init.	Type	Description
EMP_LINK_ON	0	0b	RW	**EMP Link On** 0b = This Ethernet port is not required for EMP functionality. 1b = This Ethernet port is required to be up for EMP functionality.
MNG_VETO	1	0b	RW	**Manageability Veto** Manageability Veto for link LPLU and reset. Access is read/write by manageability, read only to the host. Impact on LPLU: 0b = No specific constraints on link from manageability. 1b = Hold off any low-power link mode changes. This is done to avoid link loss and interrupting manageability activity. Impact on reset: Reset impact is global for the device and is received as a logical OR between the per port bits. When at least one of the per port bits is set, PCI reset triggers internal CORER which does not impact the MAC and PHY interfaces. When all bits are cleared, PCI reset triggers internal GLOBR which initialize also the MAC and PHY interfaces.
RATD	2	0b	RW	**Restart Auto-negotiation on Transition to Dx** Enables the functionality to restart KX/KR backplane auto-negotiation on transitions to Dx(Dr/D3). 0b = Does not restart auto-negotiation when all port's functions moves to the Dx state. 1b = Restarts auto-negotiation to reach a low-power link mode (1 GbE link) when all port's functions transitions to the Dx state.
LCDMP	3	0b	RW	**Lowest Common Denominator (LCD) on Dx(Dr/D3) without Main Power** 0b = No specific action. 1b = Move to lowest common denominator link speed when main power is removed. When *RATD* bit is also set to 1b, it causes the link mode to auto-negotiate to the lowest common denominator (if enabled) when the main power (MAIN_PWR_OK) is removed.
RESERVED	30:4	0x0	RSV	Reserved.
LPLU_ASSERTED	31	0b	RW	**LPLU Asserted** Reflects the LPLU status of the port

38.39.2.5 PF - Wake Up and Proxying Registers

38.39.2.5.1 Wake Up Control Register - PFPM_WUC (0x0006B200; RW)

The *PME_En* and *PME_Status* bits of this register are reset when LAN_PWR_GOOD is 0b. When AUX_PWR = 0b, these register bits also reset by de-asserting PE_RST_N and during a D3 to D0 transition.

Note: For each PF only the WUC register placed in the first WoL and Proxying register set is valid. The values programmed to the WUC registers in higher numbered WoL and Proxying register sets is ignored.

Field	Bit(s)	Init.	Type	Description
RESERVED	4:0	0x0	RSV	Reserved.
EN_APM_D0	5	0b	RW	**Enable APM Wake Also On D0** 0b = Enable wake only when function is in D3/Dr. 1b = Enable wake also in D0.
RESERVED	31:6	0x0	RSV	Reserved.

38.39.2.5.2 Wake Up Filter Control Register - PFPM_WUFC (0x0006B400; RW)

This register is used to enable each of the pre-defined and flexible filters for wake-up support. A value of 1b means the filter is turned on, a value of 0b means the filter is turned off.

Field	Bit(s)	Init.	Type	Description
LNKC	0	0b	RW	**Link Status Change Wake-up Enable**
MAG	1	0b	RW	**Magic Packet Wake-up Enable**
RESERVED	2	0b	RSV	Reserved.
MNG	3	0b	RW	**Manageability** Manageability wake up enable.
RESERVED	30:4	0x0	RSV	Reserved.
FW_RST_WK	31	0b	RW	**Enable Wake On Firmware Reset Assertion** When set, a firmware reset causes system wake so that the software device driver can re-send proxying information to firmware.

38.39.2.5.3 Wake Up Status Register - PFPM_WUS (0x0006B600; RW1C)

This register is used to record statistics about all wake-up packets received. If a packet matches multiple criteria, multiple bits could be set. Writing a 1b to any bit clears that bit. This register is not cleared when RST# is asserted. It is only cleared when LAN_PWR_GOOD is de-asserted, or when cleared by the software device driver.

Note: If additional packets are received that match one of the wake-up filters, after the original wake-up packet is received, the WUS register is not updated with the new match detection until the register is cleared.

Field	Bit(s)	Init.	Type	Description
LNKC	0	0b	RW1C	**Link status Changed**
MAG	1	0b	RW1C	**Magic Packet Received**
PME_STATUS	2	0b	RW1C	**PME Status** This bit is set when device receives a wake-up event. It is the same as the *PME_Status* bit in the PMCSR. Writing a 1b to this bit also clears the *PME_STATUS* bit in the PMCSR. This bit is reset only on power-on reset (LAN_PWR_GOOD). When AUX_PWR = 0b, this bit is also reset on de-assertion of PE_RST_N.
MNG	3	0b	RW1C	**Manageability** Manageability wake-up status.
RESERVED	30:4	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
FW_RST_WK	31	0b	RW1C	**Wake Due To Firmware Reset Assertion Event** When set to 1b, indicates that firmware reset assertion caused system wake so that the software device driver can re-send proxying information to firmware.

38.39.2.5.4 WU on MNG Control - GLPM_WUMC (0x0006C800; RO)

Field	Bit(s)	Init.	Type	Description
RESERVED	15:0	0x0	RW	Reserved.
MNG_WU_PF	31:16	0x0	RW	**Manageability Wake Up Per PF** *MNG_WU_PF* EMP can set a bit in this field to indicate a management-initiated wake-up event (bit per PF).

38.39.2.5.5 APM Control Register - PFPM_APM (0x000B8080; RW)

Field	Bit(s)	Init.	Type	Description
APME	0	0b	RW	**Advance Power Management Enable** If set to 1b, APM wake up is enabled. Bit is reset on Power-on reset (LAN_PWR_GOOD) only.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.5.6 Station Address Low - PRTPM_SAL[n] (0x001E4440 + 0x20*n, n=0...3; RO)

This register contains the lower bits of the NVM pre-loaded 48-bit Ethernet MAC address. All 32 bits are valid.

Field	Bit(s)	Init.	Type	Description
PFPM_SAL	31:0	0x0	RW	**Station Address Low** The lower 32 bits of the 48-bit NVM pre-assigned Ethernet MAC address. Field is defined in big endian (LS byte of SAL is first on the wire).

38.39.2.5.7 Station Address High - PRTPM_SAH[n] (0x001E44C0 + 0x20*n, n=0...3; RO)

This register contains the upper bits of the NVM pre-loaded 48-bit Ethernet MAC address. The complete address is (PFPM_SAH, PFPM_SAL). PFPM_SAH.*AV* determines whether this address is valid and compared against the incoming packet. After reset, if the NVM is present, the station address is loaded from the NVM, and its *Address Valid* field is 1b.

Field	Bit(s)	Init.	Type	Description
PFPM_SAH	15:0	0x0	RW	**Station Address High** The upper 16 bits of the 48-bit Ethernet MAC address. Field is defined in big Indian (MS byte of PRTPM_SAH is Last on the wire).
RESERVED	25:16	0x0	RSV	Reserved.
PF_NUM	29:26	0x0	RW	**PF Number** PF number to be used for reporting the waking PF. Value is written by firmware.
MC_MAG_EN	30	0b	RW	**Multicast Magic Packet Enable** Enable promiscuous multicast for magic packets. If this bit is set to 1b, every multicast magic packet generates a WoL event if enabled in PFPM_WUFC.*MAG* (Section 38.39.2.5.2).

Field	Bit(s)	Init.	Type	Description
AV	31	0b	RW	**Address Valid** If the NVM is present, the station address is assigned by firmware after loading from the NVM, and its *Address Valid* field is set to 1b.

38.39.2.6 PF - NVM Registers

38.39.2.6.1 Unit Load Status - GLNVM_ULD (0x000B6008; RO)

This register provides indications on the completion of loading the Shadow RAM and Alternate Module into the device units.

Field	Bit(s)	Init.	Type	Description
PCIER_DONE	0	0b	RW	**PCIe Reset Done** The PCIe reset process is done (all related registers are loaded).
PCIER_DONE_1	1	0b	RW	**PCIe Reset Done 1** The PCIe reset process is done (all related registers are loaded). Mirror of Bit[0].
RESERVED	2	1b	RSV	Reserved.
CORER_DONE	3	0b	RW	**Core Reset Done** The core reset process is done (all related registers are loaded).
GLOBR_DONE	4	0b	RW	**Global Reset Done** The global reset process is done (all related registers are loaded).
POR_DONE	5	0b	RW	**Power On Reset Done** The power-on reset process is done (all related registers are loaded).
RESERVED	7:6	11b	RSV	Reserved.
POR_DONE_1	8	0b	RW	**Power On Reset Done 1** The power-on reset process is done (all related registers are loaded). Mirror of Bit[5].
PCIER_DONE_2	9	0b	RW	**PCIe Reset Done 2** The PCIe reset process is done (all related registers are loaded). Mirror of Bit[0].
PE_DONE	10	0b	RW	**PE Reset Done** The PE core reset process is done (all related registers are loaded).
RESERVED2	31:11	0x0	RSV	Reserved.

38.39.2.6.2 Protected CSR list - GLNVM_PROTCSR[n] (0x000B6010 + 0x4*n, n=0...59; RO)

Field	Bit(s)	Init.	Type	Description
ADDR_BLOCK	23:0	0xFFFFFF	RW	**CSR Blocked Address** Contains the address of a blocked register included in the CSR protected list NVM module. Blocked registers cannot be loaded from a CSR format module (type 1/2/3). The register is loaded from shadow RAM at POR events only, and only from the CSR protected list module in the NVM. It can be written by EMP. It can also be written by a host only when in blank Flash programming mode.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.6.3 Global NVM General Status Register - GLNVM_GENS (0x000B6100; RO)

This register cannot be loaded from the NVM via one of the CSR format modules.

Field	Bit(s)	Init.	Type	Description
NVM_PRES	0	0b	RO	**NVM Present** Setting this bit to 1b indicates that a Flash part is present and that a correct validity field was found in one of the two basic banks (such as a validity field value read is 01b).
RESERVED	4:1	0x0	RSV	Reserved.
SR_SIZE	7:5	110b	RO	**Shadow RAM Size** Defines the size of the internal shadow RAM. This is equal to the size of the internal shadow RAM in power of 2 KB units. Initial value is 110b = 64 KB.
BANK1VAL	8	0b	RW	**Basic Bank 1 Valid** Indicates that the content of basic bank 0 is valid. Indicates that the content of the basic bank 1 of the Flash device is valid. Meaningful only when *NVM_PRES* bit is read as 1b. It is written by hardware once at power-up, and then toggled only by EMP.
RESERVED	31:9	0x0	RSV	Reserved.

38.39.2.6.4 Flash ID Register - GLNVM_FLASHID (0x000B6104; RO)

Field	Bit(s)	Init.	Type	Description
FLASHID	23:0	0x0	RO	**Flash ID** It is formed by the 3-bytes JEDEC-ID of the device. • Byte 0 (Bits[7:0]) is the first byte read from the Flash after the read JEDEC-ID Op Code (0x9F) is issued to it. It contains the manufacturer's ID. • Byte 1 (Bits[15:8]) is the second byte read from the flash after the read JEDEC-ID opcode (0x9F) is issued to it. It contains the memory type. • Byte 2 (Bits[23:16]) is the third byte read from the flash after the read JEDEC-ID opcode (0x9F) is issued to it. It contains the memory capacity.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.6.5 Flash Access Register - GLNVM_FLA (0x000B6108; RO)

This register is writable by the host only when the device is in the blank flash programming mode. It cannot be loaded from the NVM via one of the CSR format modules.

Field	Bit(s)	Init.	Type	Description
RESERVED	5:0	0x0	RSV	Reserved.
LOCKED	6	1b	RW	**Locked** Normal NVM programming mode. 0b = The device is in blank Flash programming mode. 1b = The device is in normal NVM programming mode. The bit can be cleared by EMP or by hardware.
RSV1	31:7	0x0	RSV	Reserved.

38.39.2.6.6 Auto-load Timers - GLNVM_ALTIMERS (0x000B6140; RO)

Field	Bit(s)	Init.	Type	Description
PCI_ALTIMER	11:0	0x010	RW	**PCIe Auto-Load Timer** Default is 16 to 15 ms. resolution is in ms.
GEN_ALTIMER	31:12	0x0012C	RW	**General Auto-Load Timer** Default is ~ 300 ms. resolution is in ms.

38.39.2.6.7 Unit Load Timeout - GLNVM_ULT (0x000B6154; RO)

This register cannot be loaded from the NVM via one of the CSR format modules.

Field	Bit(s)	Init.	Type	Description
CONF_PCIR_AE	0	0b	RW	When set, indicates that the PCIe auto-load timer has ended before the respective NVM module has been initialized.
CONF_PCIRTL_AE	1	0b	RW	When set, indicates that the PCIe auto-load timer has ended before the respective NVM module has been initialized.
RESERVED	2	0b	RSV	Reserved.
CONF_CORE_AE	3	0b	RW	When set, indicates that the general auto-load timer has ended before the respective NVM module has been initialized.
CONF_GLOBAL_AE	4	0b	RW	When set, indicates that the general auto-load timer has ended before the respective NVM module has been initialized.
CONF_POR_AE	5	0b	RW	When set, indicates that the general auto-load timer has ended before the respective NVM module has been initialized.
RESERVED	7:6	0b	RW	Reserved.
CONF_EMP_AE	8	0b	RW	When set, indicates that the general auto-load timer has ended before the respective NVM module has been initialized.
CONF_PCIALT_AE	9	0b	RW	When set, indicates that the PCIe auto-load timer has ended before the respective NVM module has been initialized.
RESERVED_4	31:10	0x0	RW	Reserved.

38.39.2.6.8 MEM_INIT_DONE_STAT - MEM_INIT_DONE_STAT (0x000B615C; RO)

Each bit in this register is connected to the corresponding signal indication from the block, indicating memory initialization after reset is done.

Field	Bit(s)	Init.	Type	Description
CMLAN_MEM_INIT_DONE	0	0b	RO	**CMLAN Memory Initialization Done** CMLAN memory initialization done indication (from MNG.V pin).
PMAT_MEM_INIT_DONE	1	0b	RO	**PMAT Memory Initialization Done** PMAT memory initialization done indication (from MNG.V pin).
RCU_MEM_INIT_DONE	2	0b	RO	**RCU Memory Initialization Done** RCU memory initialization done indication (from MNG.V pin).
TDPU_MEM_INIT_DONE	3	0b	RO	**TDPU Memory Initialization Done** TDPU memory initialization done indication (from MNG.V pin).
TLAN_MEM_INIT_DONE	4	0b	RO	**TLAN Memory Initialization Done** TLAN memory initialization done indication (from MNG.V pin).
RLAN_MEM_INIT_DONE	5	0b	RO	**RLAN Memory Initialization Done** RLAN memory initialization done indication (from MNG.V pin).
RDPU_MEM_INIT_DONE	6	0b	RO	**RDPU Memory Initialization Done** RDPU memory initialization done indication (from MNG.V pin).

Field	Bit(s)	Init.	Type	Description
PPRS_MEM_INIT_DONE	7	0b	RO	**PPRS Memory Initialization Done** PPRS memory initialization done indication (from MNG.V pin).
RPB_MEM_INIT_DONE	8	0b	RO	**RPB Memory Initialization Done** RPB memory initialization done indication (from MNG.V pin).
TPB_MEM_INIT_DONE	9	0b	RO	**TUPM Memory Initialization Done** TUPM memory initialization done indication (from MNG.V pin).
FOC_MEM_INIT_DONE	10	0b	RO	**FOC Memory Initialization Done** FOC memory initialization done indication (from MNG.V pin).
TSCD_MEM_INIT_DONE	11	0b	RO	**TSCD Memory Initialization Done** TSCD memory initialization done indication (from MNG.V pin).
TCB_MEM_INIT_DONE	12	0b	RO	**TCB Memory Initialization Done** TCB memory initialization done indication (from MNG.V pin).
RCB_MEM_INIT_DONE	13	0b	RO	**RCB Memory Initialization Done** RCB memory initialization done indication (from MNG.V pin).
WUC_MEM_INIT_DONE	14	0b	RO	**WUC Memory Initialization Done** WUC memory initialization done indication (from MNG.V pin).
STAT_MEM_INIT_DONE	15	0b	RO	**STAT Memory Initialization Done** STAT memory initialization done indication (from MNG.V pin).
ITR_MEM_INIT_DONE	16	0b	RO	**ITR Memory Initialization Done** ITR memory initialization done indication (from MNG.V pin).
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.6.9 GLNVM_AL_REQ - GLNVM_AL_REQ (0x000B6164; RO)

Auto-load requests.

Field	Bit(s)	Init.	Type	Description
POR	0	0b	RW	Reset indication.
PCIE_IMIB	1	0b	RW	Reset indication.
GLOBR	2	0b	RW	Reset indication.
CORER	3	0b	RW	Reset indication.
PE	4	0b	RW	Reset indication.
PCIE_IMIB_ASSERT	5	0b	RW	Reset indication.
RESERVED	31:6	0x0	RSV	Reserved.

38.39.2.7 PF - Analyzer Registers

38.39.2.7.1 L2 Tag - Enable - PRT_L2TAGSEN[PRT] (0x001C0B20 + 0x4*PRT, PRT=0...3; RW)

Field	Bit(s)	Init.	Type	Description
ENABLE	7:0	0x0	RW	**Enable** Defines the L2 tags expected on this port.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.8 PF - Switch Registers

38.39.2.8.1 Switching Table Default Action Enable Bitmap - GL_SWR_DEF_ACT_EN[n] (0x0026CFB8 + 0x4*n, n=0...1; RO)

Switching table default action enable bitmap corresponding to GL_SWR_DEF_ACT (Section 38.39.2.8.2).

Field	Bit(s)	Init.	Type	Description
DEF_ACT_EN_BITMAP	31:0	0x0	RW	**Default Action Enable Bitmap** Switching table default action enabling bitmap.

38.39.2.8.2 Switching Table Default Action - GL_SWR_DEF_ACT[n] (0x00270200 + 0x4*n, n=0...35; RO)

For each switching table that does not hit for a packet, the default action takes place in case its corresponding enable bit is set in GL_SWR_DEF_ACT_EN register (Section 38.39.2.8.1).

Field	Bit(s)	Init.	Type	Description
DEF_ACTION	31:0	0x0	RW	**Default Action** 32-bit switching action per table.

38.39.2.9 PF - Interrupt Registers

38.39.2.9.1 VF Interrupt Throttling for Interrupt N - VFINT_ITRN[n,INTVF] (0x00020000 + 0x800*n + 0x4*INTVF, n=0...2, INTVF=0...511; RW)

Register index ‘n’ relates to interrupt ‘n+1’, while interrupt zero is controlled by the VFINT_ITR0 register (Section 38.39.2.9.6).

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR ‘n’ interval, where ‘n’ is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.9.2 VF Interrupt N Dynamic Control - VFINT_DYN_CTLN[INTVF] (0x00024800 + 0x4*INTVF, INTVF=0…511; RW)

Register index ‘n’ relates to interrupt ‘n+1’, while interrupt zero is controlled by the VFINT_DYN_CTL0 register (Section 38.39.2.9.8).

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or No ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.39.2.9.3 Protected VF Interrupt N Linked List - VPINT_LNKLSTN[INTVF] (0x00025000 + 0x4*INTVF, INTVF=0...511; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the VPINT_LNKLST0 register (Section 38.39.2.9.9).

Field	Bit(s)	Init.	Type	Description
FIRSTQ_INDX	10:0	0x7FF	RW	**First Queue Index** First queue index in the MSI-X cause list Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF points to an empty linked list (might be useful for other cause interrupt).
FIRSTQ_TYPE	12:11	00b	RW	**First Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.9.4 Protected VF Interrupt N Rate Limit - VPINT_RATEN[INTVF] (0x00025800 + 0x4*INTVF, INTVF=0...511; RW)

These registers affect the VF, but are exposed only to the parent PF. Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the VPINT_RATE0 register (Section 38.39.2.9.10).

Field	Bit(s)	Init.	Type	Description
INTERVAL	5:0	0x0	RW	**Interval** Time interval defined in 4 us units between consecutive credit incremental. When the interrupt rate limit is enabled by the *INTRL_ENA* flag in this register, the *INTERVAL* must be greater than zero. For accurate rate limit, the *INTERVAL* must be smaller than 0x3C (up to 236 μs).
INTRL_ENA	6	0b	RW	**Interrupt Rate Limit Enable** Enable interrupt rate limit on this interrupt vector.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.9.5 VF PE Completion Event Queue Interrupt Cause Control - VPINT_CEQCTL[INTVF] (0x00026800 + 0x4*INTVF, INTVF=0...511; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.

Field	Bit(s)	Init.	Type	Description
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.
NEXTQ_INDX	26:16	0x0	RW	**Next Queue Index** Next queue index in the MSI-X cause list. Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF is a NULL pointer indicating the end of the linked list.
NEXTQ_TYPE	28:27	00b	RW	**Next Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	29	0b	RSV	Reserved.
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
INTEVENT	31	0b	RO	**Interrupt Event indication** Triggered by the specific event on the queue, and cleared when the interrupt is acknowledged by the interrupt signal logic.

38.39.2.9.6 VF Interrupt Throttling for Interrupt Zero - VFINT_ITR0[n,VF] (0x00028000 + 0x400*n + 0x4*VF, n=0...2, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR 'n' interval, where 'n' is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.9.7 VF Interrupt Zero Static Control - VFINT_STAT_CTL0[VF] (0x0002A000 + 0x4*VF, VF=0...127; RW)

In case of MSI or Legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
OTHER_ITR_INDX	3:2	00b	RW	**Other ITR Index** ITR index of the other interrupt causes: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.9.8 VF Interrupt Zero Dynamic Control - VFINT_DYN_CTL0[VF] (0x0002A400 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or No ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.39.2.9.9 Protected VF Interrupt Zero Linked List - VPINT_LNKLST0[VF] (0x0002A800 + 0x4*VF, VF=0...127; RW)

In case of MSI or legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
FIRSTQ_INDX	10:0	0x7FF	RW	**First Queue Index** First queue index in the MSI-X cause list. Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF points to an empty linked list (might be useful for other cause interrupt).
FIRSTQ_TYPE	12:11	00b	RW	**First Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.9.10 Protected VF Interrupt Zero Rate Limit - VPINT_RATE0[VF] (0x0002AC00 + 0x4*VF, VF=0...127; RW)

This register affects the VF, but is exposed only to the parent PF.

Field	Bit(s)	Init.	Type	Description
INTERVAL	5:0	0x0	RW	**Interval** Time interval defined in 4 us units between consecutive credit incremental. When the interrupt rate limit is enabled by the *INTRL_ENA* flag in this register, the *INTERVAL* must be greater than zero. For accurate rate limit, the *INTERVAL* must be smaller than 0x3C (up to 236 μs).
INTRL_ENA	6	0b	RW	**Interrupt Rate Limit Enable** Enable interrupt rate limit on this interrupt vector.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.9.11 VF PE Asynchronous Event Queue Interrupt Cause Control - VPINT_AEQCTL[VF] (0x0002B800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.

Field	Bit(s)	Init.	Type	Description
RESERVED	29:16	0x0	RSV	Reserved.
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
RESERVED	31	0b	RSV	Reserved.

38.39.2.9.12 VF Interrupt Zero Cause - VFINT_ICR0[VF] (0x0002BC00 + 0x4*VF, VF=0...127; RCW)

Field	Bit(s)	Init.	Type	Description
INTEVENT	0	0b	RCW	**Interrupt Event indication** This bit is set on assertion of any causes for this interrupt, and cleared when the interrupt is asserted to the rate limit logic.
QUEUE_0	1	0b	RCW	**Queue 0** Queue 0 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_1	2	0b	RCW	**Queue 1** Queue 1 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_2	3	0b	RCW	**Queue 2** Queue 2 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_3	4	0b	RCW	**Queue 3** Queue 3 interrupt for LAN transmit and receive queues and PE CEQs.
RESERVED	29:5	0x0	RSV	Reserved.
ADMINQ	30	0b	RCW	**Admin Queue** Send/receive admin queue interrupt indication.
SWINT	31	0b	RCW	**Software Interrupt indication**

38.39.2.9.13 VF Interrupt Zero Cause Enablement - VFINT_ICR0_ENA[VF] (0x0002C000 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	29:0	0x0	RSV	Reserved.
ADMINQ	30	0b	RW	**Admin Queue** Enable this interrupt at 1b.
RESERVED	31	0b	RW	Reserved.

38.39.2.9.14 PF Interrupt Throttling for Interrupt N - PFINT_ITRN[n,INTPF] (0x00030000 + 0x800*n + 0x4*INTPF, n=0...2, INTPF=0...511; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the PFINT_ITR0 register (Section 38.39.2.9.19). In case of MSI or legacy INTA, only interrupt zero is valid, so none of these registers impact the device functionality.

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR 'n' interval, where 'n' is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.9.15 PF Interrupt N Dynamic Control - PFINT_DYN_CTLN[INTPF] (0x00034800 + 0x4*INTPF, INTPF=0...511; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the PFINT_DYN_CTL0 register (Section 38.39.2.9.21). In case of MSI or legacy INTA, only interrupt zero is valid, so none of these registers impact the device functionality.

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or No ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.39.2.9.16 PF Interrupt N Linked List - PFINT_LNKLSTN[INTPF] (0x00035000 + 0x4*INTPF, INTPF=0...511; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the PFINT_LNKLST0 register (Section 38.39.2.9.22). In case of MSI or legacy INTA, only interrupt zero is valid, so none of these registers impact the device functionality.

Field	Bit(s)	Init.	Type	Description
FIRSTQ_INDX	10:0	0x7FF	RW	**First Queue Index** First queue index in the MSI-X cause list Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF points to an empty linked list (might be useful for "other cause" interrupt).
FIRSTQ_TYPE	12:11	00b	RW	**First Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.9.17 PF Interrupt N Rate Limit - PFINT_RATEN[INTPF] (0x00035800 + 0x4*INTPF, INTPF=0...511; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the PFINT_RATE0 register (Section 38.39.2.9.23). In case of MSI or legacy INTA, only interrupt zero is valid, so none of these registers impact the device functionality.

Field	Bit(s)	Init.	Type	Description
INTERVAL	5:0	0x0	RW	**Interval** Time interval defined in 4 us units between consecutive credit incremental. When the interrupt rate limit is enabled by the *INTRL_ENA* flag in this register, the *INTERVAL* must be greater than zero. For accurate rate limit, the *INTERVAL* must be smaller than 0x3C (up to 236 μs).
INTRL_ENA	6	0b	RW	**Interrupt Rate Limit Enable** Enable interrupt rate limit on this interrupt vector.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.9.18 PF PE Completion Event Queue Interrupt Cause Control - PFINT_CEQCTL[INTPF] (0x00036800 + 0x4*INTPF, INTPF=0...511; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.

Field	Bit(s)	Init.	Type	Description
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.
NEXTQ_INDX	26:16	0x0	RW	**Next Queue Index** Next queue index in the MSI-X cause list. Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF is a NULL pointer indicating the end of the linked list.
NEXTQ_TYPE	28:27	00b	RW	**Next Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	29	0b	RSV	Reserved.
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
INTEVENT	31	0b	RO	**Interrupt Event indication** Triggered by the specific event on the queue, and cleared when the interrupt is acknowledged by the interrupt signal logic.

38.39.2.9.19 PF Interrupt Throttling for Interrupt Zero - PFINT_ITR0[n] (0x00038000 + 0x80*n, n=0...2; RW)

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR 'n' interval, where 'n' is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.9.20 PF Interrupt Zero Static Control - PFINT_STAT_CTL0 (0x00038400; RW)

In case of MSI or legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
OTHER_ITR_INDX	3:2	00b	RW	**Other ITR Index** ITR index of the other interrupt causes: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.9.21 PF Interrupt Zero Dynamic Control - PFINT_DYN_CTL0 (0x00038480; RW)

In case of MSI or legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or No ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.39.2.9.22 PF Interrupt Zero Linked List - PFINT_LNKLST0 (0x00038500; RW)

In case of MSI or legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
FIRSTQ_INDX	10:0	0x7FF	RW	**First Queue Index** First queue index in the MSI-X cause list Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF points to an empty linked list (might be useful for other cause interrupt).
FIRSTQ_TYPE	12:11	00b	RW	**First Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.9.23 PF Interrupt Zero Rate Limit - PFINT_RATE0 (0x00038580; RW)

Field	Bit(s)	Init.	Type	Description
INTERVAL	5:0	0x0	RW	**Interval** Time interval defined in 4 us units between consecutive credit incremental. When the interrupt rate limit is enabled by the *INTRL_ENA* flag in this register, the *INTERVAL* must be greater than zero. For accurate rate limit, the *INTERVAL* must be smaller than 0x3C (up to 236 µs).
INTRL_ENA	6	0b	RW	**Interrupt Rate Limit Enable** Enable interrupt rate limit on this interrupt vector.
RESERVED	31:7	0x0	RSV	Reserved.

38.39.2.9.24 PF PE Asynchronous Event Queue Interrupt Cause Control - PFINT_AEQCTL (0x00038700; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.
RESERVED	29:16	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
RESERVED	31	0b	RSV	Reserved.

38.39.2.9.25 PF Interrupt Zero Cause - PFINT_ICR0 (0x00038780; RCW)

Field	Bit(s)	Init.	Type	Description
INTEVENT	0	0b	RCW	**Interrupt Event indication** This bit is set on assertion of any causes for this interrupt, and cleared when the interrupt is asserted to the rate limit logic.
QUEUE_0	1	0b	RCW	**Queue 0** Queue 0 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_1	2	0b	RCW	**Queue 1** Queue 1 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_2	3	0b	RCW	**Queue 2** Queue 2 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_3	4	0b	RCW	**Queue 3** Queue 3 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_4	5	0b	RCW	**Queue 4** Queue 4 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_5	6	0b	RCW	**Queue 5** Queue 5 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_6	7	0b	RCW	**Queue 6** Queue 6 i.nterrupt for LAN transmit and receive queues and PE CEQs
QUEUE_7	8	0b	RCW	**Queue 7** Queue 7 interrupt for LAN transmit and receive queues and PE CEQs.
RESERVED	15:9	0x0	RSV	Reserved.
ECC_ERR	16	0b	RCW	**Unrecoverable ECC Error** This bit is set when an unrecoverable error is detected in one of the device memories.
RESERVED	18:17	00b	RSV	Reserved.
MAL_DETECT	19	0b	RCW	**Malicious Programming Detected**
GRST	20	0b	RCW	**Global Resets Requested** (CORER, GLOBR or EMPR)
RESERVED	21	0b	RSV	Reserved.
GPIO	22	0b	RCW	**GPIO Event** Indicates an event on any of the GPIO pins enabled for interrupt by the PFINT_GPIOCTL register. The GPIO state can be fetched on the GLGEN_GPIO_STAT register (Section 38.39.2.1.6). The level transition that generates an interrupt is set for GPIO 'n' by the *INT_MODE* field in the matched GLGEN_GPIO_CTL[n] register (Section 38.39.2.1.4).
TIMESYNC	23	0b	RCW	**TimeSynch** Any of the TimeSync interrupt causes as described in the interrupts section of the TimeSync (IEEE1588 and 802.1AS) section.
RESERVED	25:24	00b	RSV	Reserved.
HMC_ERR	26	0b	RCW	**HMC Error** HMC error as indicated in the PFHMC_ERRORINFO and PFHMC_ERRORDATA registers (Section 38.39.2.13.8 and Section 38.39.2.13.9, respectively).
RESERVED	28:27	00b	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
VFLR	29	0b	RCW	**VFLR** VFLR was initiated by one of the VFs of the PF. The PF should read the GLGEN_VFLRSTAT register (Section 38.39.2.1.22) for an indication for the VF that generated the VFLR.
ADMINQ	30	0b	RCW	**Admin Queue** Send/receive admin queue interrupt indication.
SWINT	31	0b	RCW	**Software Interrupt Indication**

38.39.2.9.26 PF Interrupt Zero Cause Enablement - PFINT_ICR0_ENA (0x00038800; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	15:0	0x0	RSV	Reserved.
ECC_ERR	16	0b	RW	**ECC Error** Enable this interrupt at 1b.
RESERVED	18:17	00b	RSV	Reserved.

GRST	20	0b	RW	**Global Resets Requested** Enable this interrupt at 1b.
PCI_EXCEPTION	21	0b	RW	**PCI Exception** Enable this interrupt at 1b.
GPIO	22	0b	RW	**GPIO Event** Enable this interrupt at 1b.
TIMESYNC	23	0b	RW	**TimeSynch** Enable this interrupt at 1b.
RESERVED	25:24	00b	RSV	Reserved.
HMC_ERR	26	0b	RW	**HMC Error** Enable this interrupt at 1b.
RESERVED	28:27	00b	RSV	Reserved.
VFLR	29	0b	RW	**VFLR** Enable this interrupt at 1b.
ADMINQ	30	0b	RW	**Admin Queue** Enable this interrupt at 1b.
RESERVED	31	0b	RSV	Reserved.

38.39.2.9.27 Receive Queue Interrupt Cause Control - QINT_RQCTL[Q] (0x0003A000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.
NEXTQ_INDX	26:16	0x0	RW	**Next Queue Index** Next queue index in the MSI-X cause list. Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF is a NULL pointer indicating the end of the linked list.
NEXTQ_TYPE	28:27	00b	RW	**Next Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	29	0b	RSV	Reserved.
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
INTEVENT	31	0b	RO	**Interrupt Event indication** Triggered by the specific event on the queue, and cleared when the interrupt is acknowledged by the interrupt signal logic.

38.39.2.9.28 Transmit Queue Interrupt Cause Control - QINT_TQCTL[Q] (0x0003C000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
MSIX_INDX	7:0	0x0	RW	**MSI-X Index** MSI-X vector index within the function space. Software should set the *MSIX_INDX* field to values in the range of allocated interrupt vectors to the function.
RESERVED	10:8	000b	RSV	Reserved.
ITR_INDX	12:11	00b	RW	**ITR Index** ITR index of the interrupt cause: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.

Field	Bit(s)	Init.	Type	Description
MSIX0_INDX	15:13	000b	RW	**MSI-X 0 Index** The index of the QUEUE_x bits in the ICR0 register ('x' = 0,...7), which is set as a result of an event on the queue. This field is relevant only if *MSIX_INDX* equals zero.
NEXTQ_INDX	26:16	0x0	RW	**Next Queue Index** Next queue index in the MSI-X cause list. Transmit and receive queue indexes are within the PF space. CEQ indexes are within the function's space. Setting the index to 0x7FF is a NULL pointer indicating the end of the linked list.
NEXTQ_TYPE	28:27	00b	RW	**Next Queue Type** It can be one of the following: 00b = Receive queues. 01b = Transmit queues. 10b = PE completion event queues. 11b = Reserved.
RESERVED	29	0b	RSV	Reserved.
CAUSE_ENA	30	0b	RW	**Cause Enable** Enable interrupt by this queue. When this bit is cleared, interrupts are not generated by the queue. The queue remains in the interrupt linked list and is processed at ITR expiration.
INTEVENT	31	0b	RO	**Interrupt Event indication** Triggered by the specific event on the queue, and cleared when the interrupt is acknowledged by the interrupt signal logic.

38.39.2.9.29 LAN Port MDIO Number - PFGEN_PORTMDIO_NUM (0x0003F100; RO)

Field	Bit(s)	Init.	Type	Description
PORT_NUM	1:0	00b	RW	**Port Number** Indicates the LAN port connected to this function. 00b = Port 0. 01b = Port 1. 10b = Port 2. 11b = Port 3. This field must be identical to the PFGEN_PORTNUM register (Section 38.39.2.1.31).
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.9.30 PF General Purpose I/O Interrupt Enablement - PFINT_GPIO_ENA (0x00088080; RW)

Field	Bit(s)	Init.	Type	Description
GPIO0_ENA	0	0b	RW	Enable interrupt on GPIO 0.
GPIO1_ENA	1	0b	RW	Enable interrupt on GPIO 1.
GPIO2_ENA	2	0b	RW	Enable interrupt on GPIO 2.

38.39.2.10 PF - Virtualization PF Registers

38.39.2.10.1 Malicious Driver TX Data Checks Enable - GL_MDCK_TDAT (0x000442F4)

This register selects which TX data checks are enabled, for a list of the defined bits see the Virtualization section.

Field	Bit(s)	Init.	Type	Description
Reserved	1:0	1b	RW	Reserved.
MAL_ LENGTH _DIS	2	0b	RW	Disable malicious detection of bad header length in the transmit descriptor.
MAL_CMD_ DIS	3	0b	RW	Disable malicious detection of bad combination of commands in the transmit descriptor.
Reserved	31:4	0x0	RSV	Reserved.

38.39.2.10.2 Malicious Driver Detected on TX - VP_MDET_TX[VF] (0x000E6000 + 0x4*VF, VF=0...127; RW1C)

This register records a malicious event detected on the Tx queues. Once read, driver must write 0xFFFF to clear.

Field	Bit(s)	Init.	Type	Description
VALID	0	0b	RW1C	**Valid** A malicious event has been detected on this function.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.10.3 Malicious Driver Detected on Tx - PF_MDET_TX (0x000E6400; RW1C)

This register records a malicious event detected on the Tx queues. Once read, driver must write 0xFFFF to clear.

Field	Bit(s)	Init.	Type	Description
VALID	0	0b	RW1C	**Valid** A malicious event has been detected on this function.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.10.4 Malicions Driver RX checks enabled - GL_MDCK_RX (0x0012A50C)

This register selects which RX command checks are enabled, for a list of the defined bits see the Virtualization section.

Field	Bit(s)	Init.	Type	Description
DESC_ADDR	0	1b	RW	Enable malicious event: descriptor fetch failed. For proper operation this flag must be active.
Reserved	31:1	0x0	RSV	Reserved.

38.39.2.10.5 Malicious Driver TX Command Checks Enable - GL_MDCK_TCMD (0x000E648C)

This register selects which TX command checks are enabled, for a list of the defined bits see the Virtualization section.

Field	Bit(s)	Init.	Access Type	CFG Policy	Description
DESC_ADDR	0	1b	RW		Enable malicious event: descriptor fetch failed
RESERVED	1	0b	RSV		
MAX_BUFF	2	1b	RW		Enable malicious event: Single send packet or large send segment is spread on more than 8 data descriptors.
MAX_HEAD	3	1b	RW		Enable malicious event: LSO with header spanning more than 3 buffers.
NO_HEAD	4	1b	RW		Enable malicious event: Zero header length when Large send Offload enabled.
WRONG_SIZE	5	1b	RW		Enable malicious event: A single send packet or large send segment that is not between min / max sizes defined in the GLTLAN_MIN_MAX_PKT register.
RESERVED	6	1b	RW		Reserved

Field	Bit(s)	Init.	Access Type	CFG Policy	Description
ENDLESS_TX	7	1b	RW		Enable malicious event: endless transmit ring. When this flag is cleared, endless transmit ring option is enabled. When this flag is set, endless transmit ring (a tail update larger than the ring size) is considered a malicious event.
BAD_LSO_LEN	8	1b	RW		Enable malicious event: LSO PKT_LEN not equal sum of buffers
BAD_LSO_MSS	9	1b	RW		Enable malicious event: LSO with MSS of 0. Functionality of this flag is a subset of bit 13.
RESERVED	10	0b	RSV		
BAD_FD_DES	11	1b	RW		Enable malicious event: When this bit is set, and a certain queue with FD = 0 in queue context tries to send FD init packets, then the queue will be considered as malicious. SW/NVM should not clear it.
M_CONTEXTS	12	1b	RW		Enable malicious event: 7 or more consecutive non-data descriptors are fetched in a transmit queue. Functionality of this flag is a subset of bit 13.
BAD_DESC_SEQUENCE	13	1b	RW		Enable malicious event: Bad descriptors sequence. Include: MSS min/max; Max number of non-data descriptors; DIF/DIX descriptors (enabled by bit 16); Flex descriptors (enabled by bit 17).
BAD_FC_DESC	14	1b	RW		Enable malicious event: When this bit is set then the queue will be considered as malicious. SW/NVM should not clear it.
NO_PACKET	15	1b	RW		Enable malicious event: Tail update that does not contain at least one full packet.
DIS_DIF_DIX	16	1b	RW		Enable malicious event: DIF/DIX descriptors are considered malicious descriptors.
DIS_FLEX	17	1b	RW		Enable malicious event: Flexible descriptors are considered malicious descriptors.
ZERO_BSIZE	18	1b	RW		Enable Malicious event: a descriptor with a zero value in BSIZE
RESERVED	31:19	0x0	RSV		

38.39.2.10.6 Malicious Driver Tx Event Details - GL_MDET_TX (0x000E6480; RW1C)

This register records the details of the first Tx event detected.

Field	Bit(s)	Init.	Type	Description
QNUM	11:0	0x0	RW1C	**Queue Number** Absolute queue ID on which the event was detected.
VF_NUM	20:12	0x0	RW1C	**VF Number** Absolute VF number on which the event was detected.
PF_NUM	24:21	0x0	RW1C	**PF Number** PF/parent PF number on which the event was detected.
MAL_TYPE	29:25	0x0	RW1C	**Malicious Drive Type** ID of the event that has been recorded. For more information, see the Malicious Driver - Tx descriptor checks table.
RESERVED	30	0b	RSV	Reserved.
VALID	31	0b	RW1C	**Valid** Indicates that an event has been captured.

38.39.2.10.7 Malicious Driver Detected on Rx - VP_MDET_RX[VF] (0x0012A000 + 0x4*VF, VF=0...127; RW1C)

This register records a malicious event detected on the Rx queues. Once read, the software device driver must write 0xFFFF to clear.

Field	Bit(s)	Init.	Type	Description
VALID	0	0b	RW1C	**Valid** A malicious event has been detected on this function.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.10.8 Malicious Driver Detected on Rx - PF_MDET_RX (0x0012A400; RW1C)

This register records a malicious event detected on the Rx queues. Once read, the software device driver must write 0xFFFF to clear.

Field	Bit(s)	Init.	Type	Description
VALID	0	0b	RW1C	**Valid** A malicious event has been detected on this function.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.10.9 Malicious Driver Rx Event Details - GL_MDET_RX (0x0012A510; RW1C)

This register records the details of the first Rx event detected.

Field	Bit(s)	Init.	Type	Description
FUNCTION	7:0	0x0	RW1C	**Function** The function that triggered the event.
EVENT	16:8	0x0	RW1C	**Event** ID of the event that has been recorded.
QUEUE	30:17	0x0	RW1C	**Queue** Queue ID on which the event was detected.
VALID	31	0b	RW1C	**Valid** Indicates that an event has been captured.

38.39.2.10.10 PF Resources Allocation - PF_VT_PFALLOC (0x001C0500; RO)

Field	Bit(s)	Init.	Type	Description
FIRSTVF	7:0	0x0	RW	**First VF** The first VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-127.
LASTVF	15:8	0x0	RW	**Last VF** The last VF allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-127.
RESERVED	30:16	0x0	RSV	Reserved.
VALID	31	0b	RW	**Valid** The *FIRSTVF* and *LASTVF* fields in this register are valid. If cleared no VFs are allocated to this PF. If cleared, the SR-IOV capability should not be exposed for this PF.

38.39.2.11 PF - DCB Registers

38.39.2.11.1 Port DCB General Control - PRTDCB_GENC (0x00083000; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
NUMTC	5:2	0x1	RW	**Number of TCs** Number of TCs for the port. This field must be set consistently with the settings made in the Tx-scheduler.
RESERVED	8:6	011b	RW	Reserved.
RESERVED	9	1b	RW	1b = Reserved.
RESERVED	15:10	0x0	RSV	Reserved.
PFCLDA	31:16	0x079D	RW	**PFC Link Delay Allowance** Expressed in 16-byte units. Default value assumes 9.5 KB jumbo frames over a 10 GbE link with a 10GBASE-T PHY and 100-meter CAT6 cable (no optimization done for lower link speeds). For a 40 GbE link, the number is 0x1E70.

38.39.2.11.2 Port DCB General Status - PRTDCB_GENS (0x00083020; RO)

Field	Bit(s)	Init.	Type	Description
DCBX_STATUS	2:0	000b	RW	**DCBX Status** 000b = Not_Started. 001b = In_Progress. 010b = Done. 011b = Multiple_Peers. 100b = Reserved. 101b = Reserved. 110b = Reserved. 111b = Disabled.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.11.3 Global DCB General Control - GLDCB_GENC (0x00083044; RW)

Field	Bit(s)	Init.	Type	Description
PCIRTT	15:0	0x009C	RW	**PCIe Round Trip Time** Expressed in 16-byte units. Default is 2 us PCIe round trip time assuming 10 GbE links (no optimization done for lower link speeds).
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.4 DCB Transmit ETS Control for TPB - PRTDCB_TETSC_TPB (0x00098060; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	7:0	0x0	RSV	Reserved.
LLTC	15:8	0x0	RW	**Low Latency TC** 8-bit wide bitmap with a 1-bit entry per each TC. Each entry controls whether the TC is considered to have low latency needs for the transmit path. 0b = TC is defined to be a Bulk TC for transmit. 1b = TC is defined to be a Low Latency TC for transmit.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.5 DCB Transmit Frame Monitoring Status Per TC - PRTDCB_TFMSTC[n] (0x000A0040 + 0x20*n, n=0...7; RO)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
MSTC	19:0	0x0	RW	**Monitoring Status of the TC** Number of bytes in transit from the host to the TPB (TPB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.11.6 DCB Transmit Data Pipe Monitor Control - PRTDCB_TDPMC (0x000A0180; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	31:0	0x0	RSV	Reserved.

38.39.2.11.7 DCB Transmit Command Waiting Status Per TC - PRTDCB_TCMSTC[n] (0x000A2040 + 0x20*n, n=0...7; RO)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
MSTC	19:0	0x0	RW	**Monitoring Status of the TC** Number of commands in transit from the host to the TCB (TCB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.11.8 DCB Transmit Command Pipe Monitor Control - PRTDCB_TCPMC (0x000A21A0; RW)

Field	Bit(s)	Init.	Type	Description
CPM	12:0	0x098	RW	**Command Pipe Monitor** Depth of the per-Port Monitor applied over the Tx Command Pipe. Expressed in commands units.
LLTC	20:13	0x0	RW	**Low Latency TC** 0b = TC is bulk. 1b = TC is low latency.
RESERVED2	31:21	0x0	RSV	Reserved.

38.39.2.11.9 DCB Transmit ETS Control for TCB - PRTDCB_TETSC_TCB (0x000AE060; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	7:0	0x0	RSV	Reserved.
LLTC	15:8	0x0	RW	**Low Latency TC** 8-bit wide bitmap with a 1-bit entry per each TC. Each entry controls whether the TC is considered to have low latency needs for the transmit path. 0b = TC is defined to be a Bulk TC for transmit. 1b = TC is defined to be a Low Latency TC for transmit.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.10 DCB Receive ETS Per TC Control - PRTDCB_RETSTCC[n] (0x00122180 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
RESERVED	29:0	0x0	RSV	Reserved.
UPINTC_MODE	30	0b	RW	Rx-ETS operating mode when several UPs are attached to TC n, where n is the register index in the array. 0b = Strict Priority (SP) mode. 1b = Round Robin (RR) mode.
ETSTC	31	0b	RW	**ETS TC** Controls the use of ETS as the Transmit Selection Algorithm (TSA) in Rx for TC n, where n is the register index in the array. 0b = TC n uses a strict priority or other TSA in Rx. 1b = TC n uses ETS scheme in Rx.

38.39.2.11.11DCB Receive Per Port Pipe Monitor Control - PRTDCB_RPPMC (0x001223A0; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	15:0	0x0	RSV	Reserved.
RX_FIFO_SIZE	23:16	0x08	RW	**Rx Command FIFO Size** The number of Rx commands per TC that can be accumulated in RCB before sending back pressure to RCU.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.11.12DCB Receive ETS Control - PRTDCB_RETSC (0x001223E0; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	0	0b	RSV	Reserved.
NON_ETS_MODE	1	0b	RW	**Rx Non-ETS Operating Mode** 0b = Strict Priority (SP) mode. 1b = Round Robin (RR) mode.
RESERVED	7:2	0x0	RSV	Reserved.
LLTC	15:8	0x0	RW	**Low Latency TC** 8-bit wide bitmap with a 1-bit entry per each TC. Each entry controls whether the TC is considered to have low latency needs for the receive path. 0b = TC is defined to be a Bulk TC for receive. 1b = TC is defined to be a Low Latency TC for receive.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.13DCB Receive Per UP PFC Timer Indication - GLDCB_RUPTI (0x00122618; RO)

Field	Bit(s)	Init.	Type	Description
PFCTIMEOUT_UP	31:0	0x0	RW1C	**PFC Time-Out UPs** Bitmap where a bit set to 1b means that the PFC timer corresponding to the port/UP has timed out. Bits[0:7] = Port 0, UP 0 to 7. Bits[8:15] = Port 1, UP 0 to 7. Bits[23:16] = Port 2, UP 0 to 7. Bits[24:31] = Port 3, UP 0 to 7. Writing a bit with 1b restarts the corresponding PFC timer.

38.39.2.11.14DCB TC to PFC Mapping - PRTDCB_TC2PFC (0x001C0980; RW)

Field	Bit(s)	Init.	Type	Description
TC2PFC	7:0	0x0	RW	**TC to PFC** Bitmap that controls the use of Priority Flow Control (PFC) per each TC. Bit n set to: 0b = The device does not issue PFC pause frames with bits set to 1b in the priority_enable_vector for the UPs attached to that TC. It does not react to bits set to 1b for the UPs attached to that TC in the priority_enable_vector of a received PFC pause frame. The TC is referred as a drop UP. 1b = TC n uses PFC in Rx and Tx. The TC is referred as a no-drop TC.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.11.15DCB Receive UP to TC Mapping for RCB - PRTDCB_RUP2TC (0x001C09A0; RW)

24-bit wide bitmap with 3-bit entries per each UP. Each entry controls the mapping of a UP to a 3-bit TC index in receive. Higher TC index means higher priority of the TC. The same mapping is used for packets received from the wires and for those looped back internally. It defines on the account of which TC a packet is stored in the Rx packet buffer, and which UPs bits are set in the PFC XOFF/XON frames issued to the link partner when the filling state of a TC requires it. Default mapping maps all UPs to TC0.

Field	Bit(s)	Init.	Type	Description
UP0TC	2:0	000b	RW	TC index to which UP 0 is mapped.
UP1TC	5:3	000b	RW	TC index to which UP 1 is mapped.
UP2TC	8:6	000b	RW	TC index to which UP 2 is mapped.
UP3TC	11:9	000b	RW	TC index to which UP 3 is mapped.
UP4TC	14:12	000b	RW	TC index to which UP 4 is mapped.
UP5TC	17:15	000b	RW	TC index to which UP 5 is mapped.
UP6TC	20:18	000b	RW	TC index to which UP 6 is mapped.
UP7TC	23:21	000b	RW	TC index to which UP 7 is mapped.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.11.16DCB Receive UP in PPRS - PRTDCB_RUP (0x001C0B00; RW)

Field	Bit(s)	Init.	Type	Description
NOVLANUP	2:0	000b	RW	Assigns a default UP value to untagged incoming packets. The default UP is not inserted in the packet itself, but it controls in which a linked list of RPB untagged packets are stored. UP 0 is the default.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.11.17MAC Flow Control Register - PRTDCB_MFLCN (0x001E2400; RW)

Field	Bit(s)	Init.	Type	Description
PMCF	0	0b	RW	**Pass MAC Control Frames** Filter out unrecognized pause (flow control opcode doesn't match) and other control frames 0b = Filter unrecognized pause frames. 1b = Pass/forward unrecognized pause frames.
DPF	1	0b	RW	**Discard Pause Frame** 0b = Pause frames are sent to the host. 1b = Pause frames are discarded when *RFCE* or *RPFCM* is set to 1b. Setting this bit to 1b has no effect otherwise (if both *RFCE* and *RPFCM* are set to 0b).
RPFCM	2	0b	RW	**Receive PFC Mode** Indicates that the device responds to the reception of PFC packets. If auto-negotiation is enabled, this bit should be set by software to the negotiated flow control value. This bit is set as a logical OR over the *RPFCE*[7:0] bitmap. It is useful to control forwarding of PFC frames to host, if required. ***Notes:*** 1. Receive PFC and receive link flow control are mutually exclusive, and designers should not configure both of them to be enabled at the same time. 2. This bit should not be set if Bit[3] is set.

Field	Bit(s)	Init.	Type	Description
RFCE	3	0b	RW	**Receive Link Flow Control Enable** Indicates that the device responds to the reception of link flow control packets. If auto-negotiation is enabled, this bit should be set by software to the negotiated flow control value. ***Note:*** This bit should not be set if Bit[2] is set.
RPFCE	11:4	0x0	RW	**Receive PFC Enable bitmap** When bit n is: 0b = PFC indications received for UPn are ignored. 1b = Upon reception of PFC packets for UPn, the device stops transmit over the TC to which UPn is mapped in Tx.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.11.18Transmit Flow Control Status - PRTDCB_TFCS (0x001E4560; RO)

Field	Bit(s)	Init.	Type	Description
TXOFF	0	0b	RO	**Transmission Paused** Pause state indication of the transmit function when symmetrical link flow control is enabled.
RESERVED	7:1	0x0	RSV	Reserved.
TXOFF0	8	0b	RO	**TC 0 Transmission Paused** Pause state indication of TC 0 when PFC is enabled.
TXOFF1	9	0b	RO	**TC 1 Transmission Paused** Pause state indication of TC 1 when PFC is enabled.
TXOFF2	10	0b	RO	**TC 2 Transmission Paused** Pause state indication of TC 2 when PFC is enabled.
TXOFF3	11	0b	RO	**TC 3 Transmission Paused** Pause state indication of TC 3 when PFC is enabled.
TXOFF4	12	0b	RO	**TC 4 Transmission Paused** Pause state indication of TC 4 when PFC is enabled.
TXOFF5	13	0b	RO	**TC 5 Transmission Paused** Pause state indication of TC 5 when PFC is enabled.
TXOFF6	14	0b	RO	**TC 6 Transmission Paused** Pause state indication of TC 6 when PFC is enabled.
TXOFF7	15	0b	RO	**TC 7 Transmission Paused** Pause state indication of TC 7 when PFC is enabled.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.19Flow Control Transmit Timer Value n - PRTDCB_FCTTVN[n] (0x001E4580 + 0x20*n, n=0...3; RW)

Field	Bit(s)	Init.	Type	Description
TTV_2N	15:0	0xFFFF	RW	**Transmit Timer Value 2n** Timer value included in XOFF frames as timer (2n). The same value is set to UPs attached to the same TC, as defined in the PRTDCB_RUP2TC register (Section 38.39.2.11.15). For legacy 802.3x flow control packets, TTV0 is the only timer that is used.
TTV_2N_P1	31:16	0xFFFF	RW	**Transmit Timer Value 2n+1** Timer value included in XOFF frames as timer (2n+1). The same value is set to UPs attached to the same TC, as defined in PRTDCB_RUP2TC register (Section 38.39.2.11.15).

38.39.2.11.20 Flow Control Refresh Threshold Value - PRTDCB_FCRTV (0x001E4600; RW)

Field	Bit(s)	Init.	Type	Description
FC_REFRESH_TH	15:0	0x7FFF	RW	**Flow Control Refresh Threshold** Used to calculate the actual refresh period for sending the next pause frame if conditions for a pause state are still valid (buffer fullness above low threshold value). The formula for the refresh period for user priority N is: FCTTV[N/2].*TTV*[Nmod2] - FCRTV.*FC_REFRESH_TH*
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.11.21 Flow Control Configuration - PRTDCB_FCCFG (0x001E4640; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	2:0	000b	RSV	Reserved.
TFCE	4:3	00b	RW	**Transmit Flow Control Enable** Indicate that the 10 GbE controller transmits flow control packets (XON/XOFF frames) based on receive fullness. If auto-negotiation is enabled this bit should be set by software to the negotiated flow control value. 00b = Transmit flow control disabled. 01b = Link flow control enabled. 10b = PFC enabled. 11b = Reserved.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.11.22 DCB Transmit PFC Timer Status - PRTDCB_TPFCTS[n] (0x001E4660 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
PFCTIMER	13:0	0x0	RW	**PFC Timer** Current value of the PFC timer of TC n in Tx, where n is the register index in the array. The amount is expressed in milliseconds. The timer saturates to 0x3FFF. Writing to this field has the effect of loading a new current timer value, which can be useful for diagnostic purposes.
RESERVED	31:14	0x0	RSV	Reserved.

38.39.2.12 PF - Receive Packet Buffer Registers

38.39.2.12.1 RPB Dedicated Pool High Watermark - PRTRPB_DHW[n] (0x000AC100 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
DHW_TCN	19:0	0x0	RW	**Dedicated Pool High Watermark For TC n** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.2 RPB Dedicated Pool Low Watermark - PRTRPB_DLW[n] (0x000AC220 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
DLW_TCN	19:0	0x0	RW	**Dedicated Pool Low Watermark For TC n** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.3 RPB Dedicated Pool Size - PRTRPB_DPS[n] (0x000AC320 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
DPS_TCN	19:0	0x0	RW	**Dedicated Pool Size For TC n** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.4 RPB Shared Pool High Threshold - PRTRPB_SHT[n] (0x000AC480 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
SHT_TCN	19:0	0x3C800	RW	**Shared Pool High Threshold For TC n** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.5 RPB Shared Pool High Watermark - PRTRPB_SHW (0x000AC580; RW)

Field	Bit(s)	Init.	Type	Description
SHW	19:0	0x3C800	RW	**Shared Pool High Watermark** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.6 RPB Shared Pool Low Threshold - PRTRPB_SLT[n] (0x000AC5A0 + 0x20*n, n=0...7; RW)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
SLT_TCN	19:0	0x0	RW	**Shared Pool Low Threshold For TC n** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.7 RPB Shared Pool Low Watermark - PRTRPB_SLW (0x000AC6A0; RW)

Field	Bit(s)	Init.	Type	Description
SLW	19:0	0x0	RW	**Shared Pool Low Watermark** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.8 RPB Shared Pool Size - PRTRPB_SPS (0x000AC7C0; RW)

Field	Bit(s)	Init.	Type	Description
SPS	19:0	0x3C800	RW	**Shared Pool Size** Number of bytes allocated to the shared pool of the port.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.9 RPB Dedicated Pool Size for Single Shared Buffer State - GLRPB_DPSS (0x000AC828; RW)

Field	Bit(s)	Init.	Type	Description
DPS_TCN	19:0	0x0	RW	**Dedicated Pool Size For TC n** Dedicated pool size for the single shared buffer state, for all TCs of all ports. Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.10 RPB Global High Watermark - GLRPB_GHW (0x000AC830; RW)

Field	Bit(s)	Init.	Type	Description
GHW	19:0	0xF2000	RW	**Global High Watermark** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.11 RPB Global Low Watermark - GLRPB_GLW (0x000AC834; RW)

Field	Bit(s)	Init.	Type	Description
GLW	19:0	0x0	RW	**Global Low Watermark** Expressed in bytes.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.12 RPB Packet High Watermark - GLRPB_PHW (0x000AC844; RW)

Field	Bit(s)	Init.	Type	Description
PHW	19:0	0x1246	RW	**Packet High Watermark** Relative to the total number of packets stored in the RPB.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.12.13 RPB Packet Low Watermark - GLRPB_PLW (0x000AC848; RW)

Field	Bit(s)	Init.	Type	Description
PLW	19:0	0x0846	RW	**Packet Low Watermark** Relative to the total number of packets stored in the RPB.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.13 PF - Host Memory Cache Registers

38.39.2.13.1 PEOC Cache Attributes - GLPEOC_CACHESIZE (0x000A60E8; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	7:0	0x40	RO	**Word Size** The cache line size in bytes.
SETS	19:8	0x400	RO	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.2 PBLOC Cache Attributes - GLPBLOC_CACHESIZE (0x000A80BC; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	7:0	0x40	RO	**Word Size** The cache line size in bytes.
SETS	19:8	0x400	RO	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.3 FOC Cache Attributes - GLFOC_CACHESIZE (0x000AA0DC; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	7:0	0x40	RO	**Word Size** The cache line size in bytes.
SETS	19:8	0x80	RO	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.4 Private Memory Space Segment Descriptor Command - PFHMC_SDCMD (0x000C0000; RW)

This register is used to access the HMC's segment table. The HMC's segment table is partitioned per PCI function. However, each PCIe PF is able access any segment table entry.

For read operations, PFHMC_SDCMD must be written with *PMSDWR* set to 0b, and *PMSDIDX* must be set to the segment table index to be read. After the write operation completes, PFHMC_SDDATALOW and PFHMC_SDDATAHIGH registers might be read to retrieve the segment descriptor contents (Section 38.39.2.13.5 and Section 38.39.2.13.6, respectively).

For write operations, the PFHMC_SDDATALOW and PFHMC_SDDATAHIGH registers must be written before writing PFHMC_SDCMD, with *PMSDWR* set to 1b and *PMSDIDX* set to the segment table index to be written.

Field	Bit(s)	Init.	Type	Description
PMSDIDX	11:0	0x0	RW	**Private Memory Space Descriptor Index** Relative index of the HMC segment descriptor to be read or written. The actual absolute index to be used to access the segment table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function (Section 38.39.2.13.10 and Section 38.39.2.13.11, respectively). On write operations, if (*PMSDIDX* ≥ *PMSDSIZE*), the write is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function.
RESERVED	14:12	000b	RSV	Reserved.
PMSDPARTSEL	15	0b	RW	**Private Memory Space Descriptor Partition Select** 0b = The GLHMC_SDPART register is used for calculating the absolute SD Index to access within the segment table, and for checking whether *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD Index to access within the segment table, and for checking whether *PMSDIDX* is within this function's allocated range.
RESERVED	30:16	0x0	RSV	Reserved.
PMSDWR	31	0b	RW	**Private Memory Space Descriptor Write or Read** 0b = Read operations. 1b = Write operations.

38.39.2.13.5 Private Memory Space Segment Descriptor Data Low - PFHMC_SDDATALOW (0x000C0100; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATAHIGH to access the HMC's segment table (Section 38.39.2.13.4 and Section 38.39.2.13.6, respectively).

Field	Bit(s)	Init.	Type	Description
PMSDVALID	0	0b	RW	**Private Memory Space Descriptor Valid** Valid bit of an HMC segment descriptor table entry.
PMSDTYPE	1	0b	RW	**Private Memory Space Descriptor Type** 0b = The segment descriptor is paged (the SD points to a the physical address of a host memory page that contains an array of page descriptors). 1b = The segment descriptor directly points the physical address of a physically contiguous 2 MB memory region.
PMSDBPCOUNT	11:2	0x0	RW	**Private Memory Space Descriptor Backing Page Count** Backing page count of an HMC segment descriptor table entry. Every SD entry in a given FPM space must be set to 512 except the last SD. The last SD can have a value from 1 to 512. This field is used to calculate the end of the FPM space associated with a Segment Descriptor without having to read the valid bit for each individual PD entry.
PMSDDATALOW	31:12	0x0	RW	**Private Memory Space Descriptor Data Low** Bits[31:12] of an HMC segment descriptor table entry.

38.39.2.13.6 Private Memory Space Segment Descriptor Data High - PFHMC_SDDATAHIGH (0x000C0200; RW)

This register is used in conjunction with PFHMC_SDCMD and PFHMC_SDDATALOW to access the HMC's segment table (Section 38.39.2.13.4 and Section 38.39.2.13.5, respectively).

Field	Bit(s)	Init.	Type	Description
PMSDDATAHIGH	31:0	0x0	RW	**Private Memory Space Descriptor Data High** Most significant 32 bits of a segment descriptor.

38.39.2.13.7 Private Memory Space Page Descriptor Invalidate - PFHMC_PDINV (0x000C0300; RW)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software.

Field	Bit(s)	Init.	Type	Description
PMSDIDX	11:0	0x0	RW	**Private Memory Space Descriptor Index** Relative index of the HMC segment descriptor associated with the HMC page descriptor that is to be invalidated. For PFs, the actual index to be used to access the segment table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function (Section 38.39.2.13.10 and Section 38.39.2.13.11, respectively). If (*PMSDIDX* ≥ *PMSDSIZE*), the invalidate request is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function. For PE enabled VFs, the actual index to be used to invalidate a segment table entry is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the GLHMC_VFSDPART register associated with this function (Section 38.39.2.13.73). For VFs, if (*PMSDIDX* ≥ GLHMC_VFSDPART.*PMSDSIZE*), the invalidate request is dropped. The *PMSDPARTSEL* bit is ignored in the GLHMC_VFPDINV registers.
RESERVED	14:12	000b	RSV	Reserved.
PMSDPARTSEL	15	0b	RW	**Private Memory Space Descriptor Partition Select** 0b = The GLHMC_SDPART register is used for calculating the absolute SD Index to invalidate within the segment table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD index to invalidate within the segment table, and for checking whether or not *PMSDIDX* is within this function's allocated range. This field is ignored in the GLHMC_VFPDINV versions of this register.
PMPDIDX	24:16	0x0	RW	**Private Memory Page Descriptor Index** Index of the page descriptor within the page descriptor page indicated by *PMSDIDX*.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.13.8 Host Memory Cache Error Information Register - PFHMC_ERRORINFO (0x000C0400; RW)

This register reports the errors detected by the HMC. Errors reported through this register might also trigger interrupts.

Field	Bit(s)	Init.	Type	Description
PMF_INDEX	4:0	0x0	RW	**Private Memory Function Index** Reports the HMC private memory function associated with the error. Writes to this field are ignored.
RESERVED	6:5	00b	RSV	Reserved.
PMF_ISVF	7	0b	RW	**Private Memory Function Is VF** 0b = The private memory function reported in *PMF_INDEX* is associated with a PF. 1b = The private memory function reported in *PMF_INDEX* is associated with a PE enabled VF. Writes to this field are ignored.
HMC_ERROR_TYPE	11:8	0x0	RW	**HMC Error Type** Reports the error type detected by the HMC. The values are: 0 = Private memory function is not valid. 1 = Invalid private memory function index for a PE enabled VF. 2 = Invalid PF for a PE enabled VF. 3 = Invalid LAN queue index. 4 = Object index from transaction was larger than the value specified in the object's GLHMC_*CNT register. 5 = Private memory address extends beyond the limits of the segment descriptors assigned to the PCIe function. 6 = Segment descriptor Invalid. 7 = Segment descriptor too small (only applies to direct mapped SDs). 8 = Page Descriptor Invalid. 9 = Received Unsupported Request (UR) completion from PCIe read of object. 10 = LAN queue is not valid. 11 = Invalid object type was detected. 12 = Reserved. The PFHMC_ERRORDATA register (Section 38.39.2.13.9) can be read to determine the following: • The LAN Queue index. • The HMC object index associated with error types 4 and 12. • The HMC function relative *SD_Index* and *PD_Index* associated with error types 5 through 9.
RESERVED	15:12	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
HMC_OBJECT_TYPE	20:16	0x0	RW	**HMC Object Type** Specifies the object type associated with the error. The encodings for the object type are as follows: 00000b = QP_CNTXT. 00001b = ARP_TBL_ENTRY. 00010b = TXFIFO. 00011b = IRRQ. 00100b = MRTE. 00101b = PBLE. 00110b = CQ_CNTXT. 00111b = SRQ_CNTXT. 01000b = APBVT_INUSE. 01001b = FSI_ADR_VCTR. 01010b = FSI_MCAST_GRP. 01011b = XF_FL. 01100b = Q1_FL. 01101b = TIMER. 10000b = LAN_TXQ_CNTXT. 10001b = LAN_RXQ_CNTXT. 10010b = Reserved. 10011b = Reserved. 10110b = QUAD_HTE. 11001b = PD. All other values are reserved.
RESERVED	30:21	0x0	RSV	Reserved.
ERROR_DETECTED	31	0b	RW	**Error Detected** This field is set to 1b when a new error is detected by the HMC. No subsequent errors are recorded until this field is written with a value of 0b. A write of a 0b to this register clears the error and allows a subsequent error to be reported. Writes of 1b to this field are ignored.

38.39.2.13.9 Host Memory Cache Error Data Register - PFHMC_ERRORDATA (0x000C0500; RO)

This register reports the private memory address or HMC object index related to an error detected by the HMC.

Field	Bit(s)	Init.	Type	Description
HMC_ERROR_DATA	29:0	0x0	RO	**HMC Error Data** Reports either the HMC function relative *SD_Index*, *PD_Index*, LAN queue index or HMC object index associated with the error reported in the PFHMC_ERRORINFO register (Section 38.39.2.13.8). • When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 3, HMC_ERROR_DATA[27:0] reports the LAN queue index and HMC_ERROR_DATA[29:28] should be zero. • When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 4 or 12, HMC_ERROR_DATA[27:0] reports the object index associated with the error, and HMC_ERROR_DATA[29:28] should be zero. • When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 5 through 9, HMC_ERROR_DATA[29:9] reports the HMC function relative *SD_Index* and *PD_Index* associated with the error detected by the HMC. HMC_ERROR_DATA[29:18] is set to HMC function relative *SD_Index* for the affected HMC function, HMC_ERROR_DATA[17:9] is set to the *PD_Index*. HMC_ERROR_DATA[8:0] are reserved for error types 5 through 9. • When PFHMC_ERRORINFO.*HMC_ERROR_TYPE* is 0 through 2, or 10 through 11, HMC_ERROR_DATA[29:0] is not valid, and should be zero.
RESERVED	31:30	00b	RSV	Reserved.

38.39.2.13.10 Private Memory Segment Table Partitioning Registers - GLHMC_SDPART[n] (0x000C0800 + 0x4*n, n=0...15; RO)

This register is used to partition the shared Host Memory Cache segment table.

Field	Bit(s)	Init.	Type	Description
PMSDBASE	11:0	0x0	RW	**Private Memory SD Base** Base segment table index for the function n.
RESERVED	15:12	0x0	RSV	Reserved.
PMSDSIZE	28:16	0x0	RW	**Private Memory SD Size** Number of valid segment table entries for the function n.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.11 Private Memory Segment Table Partitioning Registers - GLHMC_PFPESDPART[n] (0x000C0880 + 0x4*n, n=0...15; RO)

This register is used to partition the shared HMC segment table for the PE resources associated with PFs.

Note: This register must be read only in the PF CSR space.

Field	Bit(s)	Init.	Type	Description
PMSDBASE	11:0	0x0	RW	**Private Memory SD Base** Base segment table index for the function n.
RESERVED	15:12	0x0	RSV	Reserved.
PMSDSIZE	28:16	0x0	RW	**Private Memory SD Size** Number of valid segment table entries for the function n.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.12 Private Memory LAN Tx Object Size - GLHMC_LANTXOBJSZ (0x000C2004; RO)

Field	Bit(s)	Init.	Type	Description
PMLANTXOBJSZ	3:0	0x7	RO	**Private Memory LAN Transmit Object Size** Used to calculate the amount of memory to allocate for HMC LAN Tx queue objects. The value in this register is decoded such that the value = log2(ObjSize). 0x7 = 128 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.13 Private Memory LAN Queue Maximum - GLHMC_LANQMAX (0x000C2008; RO)

Field	Bit(s)	Init.	Type	Description
PMLANQMAX	10:0	0x600	RO	**Private Memory LAN Queue Maximum** Reports the maximum number of LAN transmit or receive queue resources supported by the HMC. A given PCI function might be restricted to a smaller value by the NVRAM settings and the total number of enabled PCI functions.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.13.14 Private Memory LAN Rx Object Size - GLHMC_LANRXOBJSZ (0x000C200C; RO)

Field	Bit(s)	Init.	Type	Description
PMLANRXOBJSZ	3:0	0x5	RO	**Private Memory LAN Receive Object Size** Used to calculate the amount of memory to allocate for HMC LAN Rx queue objects. The value in this register is decoded such that the value = log2(ObjSize). 0x5 = 32 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.15 Private Memory PE QP Object Size - GLHMC_PEQPOBJSZ (0x000C201C; RO)

Field	Bit(s)	Init.	Type	Description
PMPEQPOBJSZ	3:0	0x9	RO	**Private Memory PE Queue Pair Object Size** Used to calculate the amount of memory to allocate for HMC PE queue pair objects. 0x9 = 512 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.16 Private Memory PE CQ Object Size - GLHMC_PECQOBJSZ (0x000C2020; RO)

Field	Bit(s)	Init.	Type	Description
PMPECQOBJSZ	3:0	0x6	RO	**Private Memory PE Completion Queue Object Size** Used to calculate the amount of memory to allocate for HMC PE completion queue objects. 0x6 = 64 bytes
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.17 Private Memory PE S-RQ Object Size - GLHMC_PESRQOBJSZ (0x000C2024; RO)

Field	Bit(s)	Init.	Type	Description
PMPESRQOBJSZ	3:0	0x6	RO	**Private Memory PE Shared Receive Queue Object Size** Used to calculate the amount of memory to allocate for HMC Shared Receive Queue (S-RQ) objects. 0x6 = 64 bytes.
RESERVED	31:4	0x0	RO	Reserved.

38.39.2.13.18 Private Memory Protocol Engine SRQ Max - GLHMC_PESRQMAX (0x000C2028; RO)

Field	Bit(s)	Init.	Type	Description
PMPESRQMAX	15:0	0x8000	RO	**Private Memory PE Shared Receive Queue Maximum** Reports the maximum number of S-RQs supported by the HMC.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.13.19 Private Memory PE Hash Table Entry Object Size - GLHMC_PEHTEOBJSZ (0x000C202C; RO)

Field	Bit(s)	Init.	Type	Description
PMPEHTEOBJSZ	3:0	0x6	RO	**Private Memory PE Hash Table Entry Object Size** Used to calculate the amount of memory to allocate for HMC PE hash table entry objects. PE hash tables can be configured to be IPv4 or IPv6 per function. 0x6 = 64 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.20 Private Memory Protocol Engine Hash Entry Max - GLHMC_PEHTMAX (0x000C2030; RO)

Field	Bit(s)	Init.	Type	Description
PMPEHTMAX	20:0	0x140000	RO	**Private Memory PE Hash Table Maximum** Reports the maximum number of Hash Table Entries supported by the HMC.
RESERVED	31:21	0x0	RSV	Reserved.

38.39.2.13.21 Private Memory PE ARP Table Entry Object Size - GLHMC_PEARPOBJSZ (0x000C2034; RO)

Field	Bit(s)	Init.	Type	Description
PMPEARPOBJSZ	2:0	100b	RO	**Private Memory PE ARP Object Size** Used to calculate the amount of memory to allocate for HMC ARP table entry objects. 100b = 16 bytes.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.13.22 Private Memory Protocol Engine ARP Table Entry Max - GLHMC_PEARPMAX (0x000C2038; RO)

Field	Bit(s)	Init.	Type	Description
PMPEARPMAX	16:0	0x10000	RO	**Private Memory PE ARP Maximum** Reports the maximum number of ARP table entries supported by the HMC.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.13.23 Private Memory PE Memory Region Table Entry Object Size - GLHMC_PEMROBJSZ (0x000C203C; RO)

Field	Bit(s)	Init.	Type	Description
PMPEMROBJSZ	3:0	0x5	RO	**Private Memory PE Memory Region Object Size** Used to calculate the amount of memory to allocate for HMC memory region table entry objects. 0x5 = 32 bytes
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.24 Private Memory Protocol Engine Memory Registration Max - GLHMC_PEMRMAX (0x000C2040; RO)

Field	Bit(s)	Init.	Type	Description
PMPEMRMAX	22:0	0x400000	RO	**Private Memory PE Memory Registration Maximum** Reports the maximum number of memory registration table entries supported by the HMC.
RESERVED	31:23	0x0	RSV	Reserved.

38.39.2.13.25 Private Memory PE Transmit FIFO Object Size - GLHMC_PEXFOBJSZ (0x000C2044; RO)

Field	Bit(s)	Init.	Type	Description
PMPEXFOBJSZ	3:0	0x5	RO	**Private Memory PE Transmit FIFO Object Size** Used to calculate the amount of memory to allocate for HMC transmit FIFO objects. 0x5 = 32 bytes.
RESERVED	31:4	0x0	RO	Reserved.

38.39.2.13.26 Private Memory Protocol Engine Transmit FIFO Entry mMax - GLHMC_PEXFMAX (0x000C2048; RO)

Field	Bit(s)	Init.	Type	Description
PMPEXFMAX	25:0	0x2000000	RO	**Private Memory PE Transmit FIFO Maximum** Reports the maximum number of transmit FIFO entries supported by the HMC.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.13.27 Private Memory Protocol Engine Transmit FIFO Free List xax - GLHMC_PEXFFLMAX (0x000C204C; RO)

Field	Bit(s)	Init.	Type	Description
PMPEXFFLMAX	24:0	0x1000000	RO	**Private Memory PE Transmit FIFO Free List Maximum** Reports the maximum number of transmit FIFO free list entries supported by the HMC.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.13.28 Private Memory PE IRRQ Object Size - GLHMC_PEQ1OBJSZ (0x000C2050; RO)

Field	Bit(s)	Init.	Type	Description
PMPEQ1OBJSZ	3:0	0x6	RO	**Private Memory PE Q1 Object Size** Used to calculate the amount of memory to allocate for HMC inbound RDMA read (Q1) objects. 0x6 = 64 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.29 Private Memory Protocol Engine Q1 Max - GLHMC_PEQ1MAX (0x000C2054; RO)

Field	Bit(s)	Init.	Type	Description
PMPEQ1MAX	25:0	0x2000000	RO	**Private Memory PE Q1 Maximum** Reports the maximum number of inbound RDMA read queue (Q1) entries supported by the HMC.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.13.30 Private Memory Protocol Engine Q1 Free List Max - GLHMC_PEQ1FLMAX (0x000C2058; RO)

Field	Bit(s)	Init.	Type	Description
PMPEQ1FLMAX	25:0	0x2000000	RO	**Private Memory PE Q1 Free List Maximum** Reports the maximum number of inbound RDMA read queue (Q1) free list entries supported by the HMC.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.13.31 Private Memory FSI Multicast Group Object Size - GLHMC_FSIMCOBJSZ (0x000C205C; RO)

Field	Bit(s)	Init.	Type	Description
PMFSIMCOBJSZ	3:0	0x6	RO	**Private Memory FSI Multicast Object Size** Used to calculate the amount of memory to allocate for HMC FSI multicast group objects. 0x6 = 64 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.32 Private Memory FSI Multicast Group Max - GLHMC_FSIMCMAX (0x000C2060; RO)

Field	Bit(s)	Init.	Type	Description
PMFSIMCMAX	13:0	0x2000	RO	**Private Memory FSI Multicast Maximum** Reports the maximum number of FSI multicast group entries supported by the HMC.
RESERVED	31:14	0x0	RSV	Reserved.

38.39.2.13.33 Private Memory FSI Address Vector Object Size - GLHMC_FSIAVOBJSZ (0x000C2064; RO)

Field	Bit(s)	Init.	Type	Description
PMFSIAVOBJSZ	3:0	0x5	RO	**Private Memory FSI Address Vector Object Size** Used to calculate the amount of memory to allocate for HMC FSI address vector objects. 0x5 = 32 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.34 Private Memory FSI Address Vector Max - GLHMC_FSIAVMAX (0x000C2068; RO)

Field	Bit(s)	Init.	Type	Description
PMFSIAVMAX	16:0	0x10000	RO	**Private Memory FSI Address Vector Maximum** Reports the maximum number of FSI address vectors supported by the HMC.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.13.35 Private Memory Protocol Engine Physical Buffer List Max - GLHMC_PEPBLMAX (0x000C206C; RO)

Field	Bit(s)	Init.	Type	Description
PMPEPBLMAX	28:0	0x10000000	RO	**Private Memory PE Physical Buffer List Maximum** Reports the maximum number of physical buffer list entries supported by the HMC.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.36 Private Memory PE Timer Object Size - GLHMC_PETIMEROBJSZ (0x000C2080; RO)

Field	Bit(s)	Init.	Type	Description
PMPETIMEROBJSZ	3:0	0x6	RO	**Private Memory PE Timer Object Size** Used to calculate the amount of memory to allocate for HMC PE timer objects. The value in this register is decoded such that the value = log2(ObjSize). 0x6 = 64 bytes.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.13.37 Private Memory PE Timer Object Max - GLHMC_PETIMERMAX (0x000C2084; RO)

Field	Bit(s)	Init.	Type	Description
PMPETIMERMAX	28:0	0x10000000	RO	**Private Memory PE Timer Maximum** Reports the maximum number of PE timer objects supported by the HMC.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.38 Protocol Engine PF First SD - GLHMC_PEPFFIRSTSD (0x000C20E4; RO)

This register is set to the number of HMC segment descriptors consumed by LAN for all PFs. This value is programmed from the NVM.

Field	Bit(s)	Init.	Type	Description
GLHMC_PEPFFIRSTSD	11:0	0x0	RW	**PE PF First SD** First SD that is available to the PE to use.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.13.39 Private Memory Protocol Engine Queue Pair Max - GLHMC_DBQPMAX (0x000C20EC; RO)

Field	Bit(s)	Init.	Type	Description
GLHMC_DBQPMAX	18:0	0x40000	RO	**Doorbell Queue Pair Maximum** Reports the maximum number of PE queue pairs supported by the HMC and doorbell array.
RESERVED	31:19	0x0	RSV	Reserved.

38.39.2.13.40 Private Memory Protocol Engine Completion Queue Max - GLHMC_DBCQMAX (0x000C20F0; RO)

Field	Bit(s)	Init.	Type	Description
GLHMC_DBCQMAX	17:0	0x020000	RO	**Doorbell Completion Queue Maximum** Reports the maximum number of PE completion queues supported by the HMC and doorbell array.
RESERVED	31:18	0x0	RSV	Reserved.

38.39.2.13.41 FPM PE QP Base - GLHMC_PEQPBASE[n] (0x000C4000 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEQPBASE	23:0	0x0	RW	**Function Private Memory PE Queue Pair Base** Reports the FPM space base address for the PE queue pair objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.42 FPM PE QP Object Count - GLHMC_PEQPCNT[n] (0x000C4100 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.41) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEQPCNT	28:0	0x0	RW	**Function Private Memory PE Queue Pair Count** Used to set the FPM space size for the PE queue pair objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.43FPM PE CQ Base - GLHMC_PECQBASE[n] (0x000C4200 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPECQBASE	23:0	0x0	RW	**Function Private Memory PE Completion Queue Base** Reports the FPM space base address for the PE completion queue objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.44FPM PE CQ Object Count - GLHMC_PECQCNT[n] (0x000C4300 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.43) is updated after the commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPECQCNT	28:0	0x0	RW	**Function Private Memory PE Completion Queue Count** Used to set the FPM space size for the PE completion queue objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.45FPM PE Shared RQ Base - GLHMC_PESRQBASE[n] (0x000C4400 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPESRQBASE	23:0	0x0	RW	**Function Private Memory PE Shared Receive Queue Base** Reports the FPM space base address for the PE shared receive queue objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.46FPM PE Shared RQ Size - GLHMC_PESRQCNT[n] (0x000C4500 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.45) is updated after the commit FPM values CQP operation is performed to inform hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPESRQCNT	28:0	0x0	RW	**Function Private Memory PE Shared Receive Queue Count** Used to set the FPM space size for the PE shared receive queue objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.47FPM PE Hash Table Entry Base - GLHMC_PEHTEBASE[n] (0x000C4600 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEHTEBASE	23:0	0x0	RW	**Function Private Memory PE Hash Table Entry Base** Reports the FPM space base address for the PE hash table entry objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.48FPM PE Hash Table Object Count - GLHMC_PEHTCNT[n] (0x000C4700 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.47) is updated after the commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEHTCNT	28:0	0x0	RW	**Function Private Memory PE Hash Table Count** Used to set the FPM space size for the PE hash table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.49FPM PE ARP Table Base - GLHMC_PEARPBASE[n] (0x000C4800 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEARPBASE	23:0	0x0	RW	**Function Private Memory PE ARP Base** Reports the FPM space base address for the PE ARP table objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.50FPM PE ARP Table Object Count - GLHMC_PEARPCNT[n] (0x000C4900 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.49) is updated after the commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEARPCNT	28:0	0x0	RW	**Function Private Memory PE ARP Count** Used to set the FPM space size for the PE ARP table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.51 FPM PE APBVT In-Use Base - GLHMC_APBVTINUSEBASE[n] (0x000C4A00 + 0x4*n, n=0...15; RO)

There is a single APBVT in-use object for each PCI function and it is a fixed 8 KB in size. Since there is only a single object and it is a fixed size, there is not a corresponding object size or region size register. This register is updated by hardware when commit FPM values CQP operation is performed.

Field	Bit(s)	Init.	Type	Description
FPMAPBINUSEBASE	23:0	0x0	RW	**Function Private Memory Accelerated Port Bit In-Use Base** Reports the base FPM space address of the accelerated port bit in-use object in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.52 FPM PE MRT Base - GLHMC_PEMRBASE[n] (0x000C4C00 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEMRBASE	23:0	0x0	RW	**Function Private Memory PE Memory Region Base** Reports the FPM space base address for the PE memory region table objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.53 FPM PE Memory Region Table Object Count - GLHMC_PEMRCNT[n] (0x000C4D00 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.52) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEMRSZ	28:0	0x0	RW	**Function Private Memory PE Memory Region Size** Used to set the FPM space size for the PE memory region table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.54 FPM PE Transmit FIFO Base - GLHMC_PEXFBASE[n] (0x000C4E00 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEXFBASE	23:0	0x0	RW	**Function Private Memory PE Transmit FIFO Base** Reports the FPM space base address for the PE transmit FIFO objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.55FPM PE Transmit FIFO Object Count - GLHMC_PEXFCNT[n] (0x000C4F00 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.54) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEXFCNT	28:0	0x0	RW	**Function Private Memory PE Transmit FIFO Count** Used to set the FPM space size for the PE transmit FIFO objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.56FPM PE Transmit FIFO Free List Base - GLHMC_PEXFFLBASE[n] (0x000C5000 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEXFFLBASE	23:0	0x0	RW	**Function Private Memory PE Transmit FIFO Free List Base** Reports the FPM space base address for the PE transmit FIFO free list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.57FPM PE IRRQ Base - GLHMC_PEQ1BASE[n] (0x000C5200 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1BASE	23:0	0x0	RW	**Function Private Memory PE Q1 Base** Reports the FPM space base address for the PE inbound RDMA read queue (Q1) objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.58FPM PE IRRQ Object Count - GLHMC_PEQ1CNT[n] (0x000C5300 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.57) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1CNT	28:0	0x0	RW	**Function Private Memory PE Q1 Count** Used to set the FPM space size for the PE inbound RDMA read queue (Q1) objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.59 FPM PE IRRQ Free List Base - GLHMC_PEQ1FLBASE[n] (0x000C5400 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1FLBASE	23:0	0x0	RW	**Function Private Memory PE Q1 Free List Base** Reports the FPM space base address for the PE inbound RDMA read queue (Q1) free list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.60 FPM FSI Address Vector Base - GLHMC_FSIAVBASE[n] (0x000C5600 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMFSIAVBASE	23:0	0x0	RW	**Function Private Memory FSI Address Vector Base** Reports the FPM space base address for the FSI address vector objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.61 FPM FSI Address Vector Object Count - GLHMC_FSIAVCNT[n] (0x000C5700 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.60) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMFSIAVCNT	28:0	0x0	RW	**Function Private Memory FSI Address Vector Count** Used to set the FPM space size for the FSI address vector objects.
RESERVED	31:29	000b	RW	Reserved.

38.39.2.13.62 FPM PE Physical Buffer List Base - GLHMC_PEPBLBASE[n] (0x000C5800 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMPEPBLBASE	23:0	0x0	RW	**Function Private Memory PE Physical Buffer List Base** Reports the FPM space base address for the PE physical buffer list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.63 FPM PE PBL Object Count - GLHMC_PEPBLCNT[n] (0x000C5900 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.62) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMPEPBLCNT	28:0	0x0	RW	**Function Private Memory PE Physical Buffer List Count** Used to set the FPM space size for the PE physical buffer list objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.64 FPM PE Timer Base - GLHMC_PETIMERBASE[n] (0x000C5A00 + 0x4*n, n=0...15; RO)

The value of this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

Field	Bit(s)	Init.	Type	Description
FPMPETIMERBASE	23:0	0x0	RW	**Function Private Memory PE Timer Base** Reports the FPM space base address for the PE timer objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.65 FPM PE Timer Object Count - GLHMC_PETIMERCNT[n] (0x000C5B00 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.64) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

Field	Bit(s)	Init.	Type	Description
FPMPETIMERCNT	28:0	0x0	RW	**Function Private Memory PE Timer Count** Used to set the FPM space size for the PE timer objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.66 FPM FSI Multicast Group Base - GLHMC_FSIMCBASE[n] (0x000C6000 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Field	Bit(s)	Init.	Type	Description
FPMFSIMCBASE	23:0	0x0	RW	**Function Private Memory FSI Multicast Base** Reports the FPM space base address for the FSI multicast group objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.67 FPM FSI Multicast Group Object Count - GLHMC_FSIMCCNT[n] (0x000C6100 + 0x4*n, n=0...15; RO)

The associated base register (Section 38.39.2.13.66) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Field	Bit(s)	Init.	Type	Description
FPMFSIMCSZ	28:0	0x0	RW	**Function Private Memory FSI Multicast Size** Used to set the FPM space size for the FSI multicast group objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.68 FPM LAN Tx Queue Base - GLHMC_LANTXBASE[n] (0x000C6200 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space.

Field	Bit(s)	Init.	Type	Description
FPMLANTXBASE	23:0	0x0	RW	**Function Private Memory LAN Transmit Base** Reports the FPM space base address for the LAN transmit queue objects in 512-byte increments.
RESERVED	31:24	0x0	RW	Reserved.

38.39.2.13.69 FPM LAN Tx Queue Object Count - GLHMC_LANTXCNT[n] (0x000C6300 + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	Description
FPMLANTXCNT	10:0	0x0	RW	**Function Private Memory LAN Transmit Count** Used to set the FPM space size for the LAN Tx queue objects.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.13.70 FPM LAN Rx Queue Base - GLHMC_LANRXBASE[n] (0x000C6400 + 0x4*n, n=0...15; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space.

Field	Bit(s)	Init.	Type	Description
FPMLANRXBASE	23:0	0x0	RW	**Function Private Memory LAN Receive Base** Reports the FPM space base address for the LAN receive queue objects in 512 - byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.71 FPM LAN Rx Queue Object Count - GLHMC_LANRXCNT[n] (0x000C6500 + 0x4*n, n=0...15; RO)

Field	Bit(s)	Init.	Type	Description
FPMLANRXCNT	10:0	0x0	RW	**Function Private Memory LAN Receive Count** Used to set the FPM space size for the LAN Rx queue objects.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.13.72 Private Memory Space Page Descriptor Invalidate - GLHMC_VFPDINV[n] (0x000C8300 + 0x4*n, n=0...31; RO)

This register is used to invalidate cached HMC page descriptors that have been set to the invalid state by software. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
PMSDIDX	11:0	0x0	RW	**Private Memory Space Descriptor Index** Relative index of the HMC segment descriptor associated with the HMC page descriptor that is to be invalidated. For PFs, the actual index to be used to access the segment table is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the *PMSDBASE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function (Section 38.39.2.13.10 and Section 38.39.2.13.11, respectively). If (*PMSDIDX* ≥ *PMSDSIZE*), the invalidate request is dropped, where *PMSDSIZE* is from the *PMSDSIZE* field of the GLHMC_SDPART or GLHMC_PFPESDPART register associated with this function. The *PMSDPARTSEL* bit of this register determines which SD partition register is selected for the absolute SD index calculation and for the check that *PMSDIDX* is within the range allowed by this function. For PE enabled VFs, the actual index to be used to invalidate a Segment Table entry is (*PMSDBASE* + *PMSDIDX*), where *PMSDBASE* is from the GLHMC_VFSDPART register associated with this function (Section 38.39.2.13.73). For VFs, if (*PMSDIDX* ≥ GLHMC_VFSDPART.*PMSDSIZE*), the invalidate request is dropped. The *PMSDPARTSEL* bit is ignored in the GLHMC_VFPDINV registers.
RESERVED	14:12	000b	RSV	Reserved.
PMSDPARTSEL	15	0b	RW	**Private Memory Space Descriptor Partition Select** 0b = The GLHMC_SDPART register is used for calculating the absolute SD index to invalidate within the segment table, and for checking whether or not *PMSDIDX* is within this function's allocated range. 1b = The GLHMC_PFPESDPART register is used for calculating the absolute SD index to invalidate within the segment table, and for checking whether or not *PMSDIDX* is within this function's allocated range. This field is ignored in the GLHMC_VFPDINV versions of this register.
PMPDIDX	24:16	0x0	RW	**Private Memory Page Descriptor Index** Index of the page descriptor within the page descriptor page indicated by *PMSDIDX*.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.13.73 Private Memory Segment Table Partitioning Registers - GLHMC_VFSDPART[n] (0x000C8800 + 0x4*n, n=0...31; RO)

This register is used to partition the shared HMC segment table associated with PE enabled VFs. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
PMSDBASE	11:0	0x0	RW	**Private Memory SD Base** Base segment table index for the function n.
RESERVED	15:12	0x0	RSV	Reserved.
PMSDSIZE	28:16	0x0	RW	**Private Memory SD Size** Number of valid segment table entries for the function n.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.74 FPM PE QP Base - GLHMC_VFPEQPBASE[n] (0x000CC000 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEQPBASE	23:0	0x0	RW	**Function Private Memory PE Queue Pair Base** Reports the FPM space base address for the PE queue pair objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.75 FPM PE QP Object Count - GLHMC_VFPEQPCNT[n] (0x000CC100 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.74) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEQPCNT	28:0	0x0	RW	**Function Private Memory PE Queue Pair Count** Used to set the FPM space size for the PE queue pair objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.76 FPM PE CQ Base - GLHMC_VFPECQBASE[n] (0x000CC200 + 0x4*n, n=0…31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPECQBASE	23:0	0x0	RW	**Function Private Memory PE Completion Queue Base** Reports the FPM space base address for the PE completion queue objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.77 FPM PE CQ Object Count - GLHMC_VFPECQCNT[n] (0x000CC300 + 0x4*n, n=0…31; RO)

The associated base register (Section 38.39.2.13.76) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPECQCNT	28:0	0x0	RW	**Function Private Memory PE Completion Queue Count** Used to set the FPM space size for the PE completion queue objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.78 FPM PE Shared RQ Base - GLHMC_VFPESRQBASE[n] (0x000CC400 + 0x4*n, n=0…31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPESRQBASE	23:0	0x0	RW	**Function Private Memory PE Shared Receive Queue Base** Reports the FPM space base address for the PE shared receive queue objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.79 FPM PE Shared RQ Size - GLHMC_VFPESRQCNT[n] (0x000CC500 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.78) is updated after commit FPM values CQP operation is performed to inform hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPESRQCNT	28:0	0x0	RW	**Function Private Memory PE Shared Receive Queue Count** Used to set the FPM space size for the PE shared receive queue objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.80 FPM PE Hash Table Entry Base - GLHMC_VFPEHTEBASE[n] (0x000CC600 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEHTEBASE	23:0	0x0	RW	**Function Private Memory PE Hash Table Entry Base** Reports the FPM space base address for the PE hash table entry objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.81 FPM PE Hash Table Object Count - GLHMC_VFPEHTCNT[n] (0x000CC700 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.80) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEHTCNT	28:0	0x0	RW	**Function Private Memory PE Hash Table Count** Used to set the FPM space size for the PE hash table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.82 FPM PE ARP Table Base - GLHMC_VFPEARPBASE[n] (0x000CC800 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEARPBASE	23:0	0x0	RW	**Function Private Memory PE ARP Base** Reports the FPM space base address for the PE ARP table objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.83 FPM PE ARP Table Object Count - GLHMC_VFPEARPCNT[n] (0x000CC900 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.82) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEARPCNT	28:0	0x0	RW	**Function Private Memory PE ARP Count** Used to set the FPM space size for the PE ARP table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.84 FPM PE APBVT In-Use Base - GLHMC_VFAPBVTINUSEBASE[n] (0x000CCA00 + 0x4*n, n=0...31; RO)

There is a single APBVT in-use object for each PCI function and it is a fixed 8 KB in size. Since there is only a single object and it is a fixed size, there is not a corresponding object size or region size register. This register is updated by hardware when commit FPM values CQP operation is performed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMAPBINUSEBASE	23:0	0x0	RW	**Function Private Memory Accelerated Port Bit In-Use Base** Reports the base FPM space address of the accelerated port bit in-use object in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.85 FPM PE MRT Base - GLHMC_VFPEMRBASE[n] (0x000CCC00 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEMRBASE	23:0	0x0	RW	**Function Private Memory PE Memory Region Base** Reports the FPM space base address for the PE memory region table objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.86 FPM PE Memory Region Table Object Count - GLHMC_VFPEMRCNT[n] (0x000CCD00 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.85) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEMRSZ	28:0	0x0	RW	**Function Private Memory PE Memory Region Size** Used to set the FPM space size for the PE memory region table objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.87 FPM PE Transmit FIFO Base - GLHMC_VFPEXFBASE[n] (0x000CCE00 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEXFBASE	23:0	0x0	RW	**Function Private Memory PE Transmit FIFO Base** Reports the FPM space base address for the PE transmit FIFO objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.88 FPM PE Transmit FIFO Object Count - GLHMC_VFPEXFCNT[n] (0x000CCF00 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.87) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEXFCNT	28:0	0x0	RW	**Function Private Memory PE Transmit FIFO Count** Used to set the FPM space size for the PE transmit FIFO objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.89 FPM PE Transmit FIFO Free List Base - GLHMC_VFPEXFFLBASE[n] (0x000CD000 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEXFFLBASE	23:0	0x0	RW	**Function Private Memory PE Transmit FIFO Free List Base** Reports the FPM space base address for the PE transmit FIFO free list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.90 FPM PE IRRQ Base - GLHMC_VFPEQ1BASE[n] (0x000CD200 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1BASE	23:0	0x0	RW	**Function Private Memory PE Q1 Base** Reports the FPM space base address for the PE inbound RDMA read queue (Q1) objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.91 FPM PE IRRQ Object Count - GLHMC_VFPEQ1CNT[n] (0x000CD300 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.90) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1CNT	28:0	0x0	RW	**Function Private Memory PE Q1 Count** Used to set the FPM space size for the PE inbound RDMA read queue (Q1) objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.92 FPM PE IRRQ Free List Base - GLHMC_VFPEQ1FLBASE[n] (0x000CD400 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEQ1FLBASE	23:0	0x0	RW	**Function Private Memory PE Q1 Free List Base** Reports the FPM space base address for the PE inbound RDMA read queue (Q1) free list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.93 FPM FSI Address Vector Base - GLHMC_VFFSIAVBASE[n] (0x000CD600 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMFSIAVBASE	23:0	0x0	RW	**Function Private Memory FSI Address Vector Base** Reports the FPM space base address for the FSI address vector objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.94 FPM FSI Address Vector Object Count - GLHMC_VFFSIAVCNT[n] (0x000CD700 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.93) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMFSIAVCNT	28:0	0x0	RW	**Function Private Memory FSI Address Vector Count** Used to set the FPM space size for the FSI address vector objects.
RESERVED	31:29	000b	RW	Reserved.

38.39.2.13.95 FPM PE Physical Buffer List Base - GLHMC_VFPEPBLBASE[n] (0x000CD800 + 0x4*n, n=0...31; RO)

The value in this register must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only and is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEPBLBASE	23:0	0x0	RW	**Function Private Memory PE Physical Buffer List Base** Reports the FPM space base address for the PE physical buffer list objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.96 FPM PE PBL Object Count - GLHMC_VFPEPBLCNT[n] (0x000CD900 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.95) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
FPMPEPBLCNT	28:0	0x0	RW	**Function Private Memory PE Physical Buffer List Count** Used to set the FPM space size for the PE physical buffer list objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.97FPM VF PE Timer Base - GLHMC_VFPETIMERBASE[n] (0x000CDA00 + 0x4*n, n=0...31; RO)

The value of this registers must be multiplied by 512 to get the actual address out of the 8 GB FPM address space. This register is updated by hardware when commit FPM values CQP operation is performed. Other than for debug purposes, this register should be treated as read only.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

Field	Bit(s)	Init.	Type	Description
FPMPETIMERBASE	23:0	0x0	RW	**Function Private Memory PE Timer Base** Reports the FPM space base address for the PE timer objects in 512-byte increments.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.98FPM VF PE Timer Object Count - GLHMC_VFPETIMERCNT[n] (0x000CDB00 + 0x4*n, n=0...31; RO)

The associated base register (Section 38.39.2.13.97) is updated after commit FPM values CQP operation is performed to indicate to hardware that all of the FPM size registers have been set properly and the FPM map should be recomputed.

Note: 16 instances of this register are implemented for this product. The remaining instances are reserved for future expansion.

Field	Bit(s)	Init.	Type	Description
FPMPETIMERCNT	28:0	0x0	RW	**Function Private Memory PE Timer Count** Used to set the FPM space size for the PE timer objects.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.13.99PDOC Cache Attributes - GLPDOC_CACHESIZE (0x000D0088; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	7:0	0x40	RO	**Word Size** The cache line size in bytes.
SETS	19:8	0x40	RO	**Sets** The number of cache sets.
WAYS	23:20	0x8	RO	**Ways** The number of cache ways.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.13.100 Private Memory CQ Doorbell Partition Registers - GLHMC_DBCQPART[n] (0x00131240 + 0x4*n, n=0...15; RO)

These registers are used to partition the shared doorbell array for PE completion queues PCIe PFs.

Field	Bit(s)	Init.	Type	Description
PMDBCQBASE	13:0	0x0	RW	**Private Memory Doorbell Completion Queue Base** Base CQ doorbell array index for the HMC PCI function n in multiples of eight CQs.
RESERVED	15:14	00b	RSV	Reserved.
PMDBCQSIZE	30:16	0x0	RW	**Private Memory Doorbell Completion Queue Size** Number of valid doorbell array elements for the HMC PCI function n in increments of eight CQs.
RESERVED	31	0b	RSV	Reserved.

38.39.2.13.101 Private Memory CEQ Partitioning Registers - GLHMC_CEQPART[n] (0x001312C0 + 0x4*n, n=0...15; RO)

This register is used to partition the shared pool of PE completion event queues for PCIe PFs.

Field	Bit(s)	Init.	Type	Description
PMCEQBASE	7:0	0x0	RW	**Private Memory Completion Event Queue Base** Base CEQ index for the function n.
RESERVED	15:8	0x0	RSV	Reserved.
PMCEQSIZE	24:16	0x0	RW	**Private Memory Completion Event Queue Size** Number of valid CEQs index for the function n.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.13.102 Private Memory CQ Doorbell Partition Registers - GLHMC_VFDBCQPART[n] (0x00132140 + 0x4*n, n=0...31; RO)

These registers are used to partition the shared doorbell array for PE completion queues associated with PE enabled VFs. Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
PMDBCQBASE	13:0	0x0	RW	**Private Memory Doorbell Completion Queue Base** Base CQ doorbell array index for the HMC PCI function n in multiples of eight CQs.
RESERVED	15:14	00b	RSV	Reserved.
PMDBCQSIZE	30:16	0x0	RW	**Private Memory Doorbell Completion Queue Size** Number of valid doorbell array elements for the HMC PCI function n in increments of eight CQs.
RESERVED	31	0b	RSV	Reserved.

38.39.2.13.103Private Memory CEQ Partitioning Registers - GLHMC_VFCEQPART[n] (0x00132240 + 0x4*n, n=0...31; RO)

This register is used to partition the shared pool of PE completion event queues associated with PE enabled VFs. Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
PMCEQBASE	7:0	0x0	RW	**Private Memory Completion Event Queue Base** Base CEQ index for the function n.
RESERVED	15:8	0x0	RSV	Reserved.
PMCEQSIZE	24:16	0x0	RW	**Private Memory Completion Event Queue Size** Number of valid CEQs index for the function n.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.13.104Private Memory QP Doorbell Partition Registers - GLHMC_DBQPPART[n] (0x00138D80 + 0x4*n, n=0...15; RO)

These registers are used to partition the shared doorbell array for PE queue pairs associated with PCIe PFs.

Field	Bit(s)	Init.	Type	Description
PMDBQPBASE	13:0	0x0	RW	**Private Memory Doorbell Queue Pair Base** Base QP doorbell array index for the HMC PCI function n in multiples of 16 QPs.
RESERVED	15:14	00b	RSV	Reserved.
PMDBQPSIZE	30:16	0x0	RW	**Private Memory Doorbell Queue Pair Size** Number of valid doorbell array elements for the HMC PCI function n in increments of 16 QPs.
RESERVED	31	0b	RSV	Reserved.

38.39.2.13.105Private Memory VF QP Doorbell Partition Registers - GLHMC_VFDBQPPART[n] (0x00138E00 + 0x4*n, n=0...31; RO)

These registers are used to partition the shared doorbell array for PE queue pairs associated with PE enabled VFs. Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
PMDBQPBASE	13:0	0x0	RW	**Private Memory Doorbell Queue Pair Base** Base QP doorbell array index for the HMC PCI function n in multiples of 16 QPs.
RESERVED	15:14	00b	RSV	Reserved.
PMDBQPSIZE	30:16	0x0	RW	**Private Memory Doorbell Queue Pair Size** Number of valid doorbell array elements for the HMC PCI function n in increments of 16 QPs.
RESERVED	31	0b	RSV	Reserved.

38.39.2.14 PF - Context Manager Registers

38.39.2.14.1 CMLAN Context Data Registers - PFCM_LANCTXDATA[n] (0x0010C100 + 0x80*n, n=0...3; RW)

This register is indexed by PF index (n) and by context word index. Word index 0 is the least significant word, and line 3 is the most significant word.

Field	Bit(s)	Init.	Type	Description
DATA	31:0	0x0	RW	**Data** 32-bit portion of the 128-bit context sub-line data.

38.39.2.14.2 CMLAN Context Control Register - PFCM_LANCTXCTL (0x0010C300; RW)

This register provides an interface into the context cache for pre-boot context initialization.

Field	Bit(s)	Init.	Type	Description
QUEUE_NUM	11:0	0x0	RW	**Queue Number** Specifies the LAN queue index to be loaded or invalidated. This number is an absolute queue number.
SUB_LINE	14:12	000b	RW	**Sub-line** Specifies the 16-byte sub-line to be accessed for write operations.
QUEUE_TYPE	16:15	00b	RW	**Queue Type** Specifies the queue type: 00b = LAN Rx context. 01b = LAN Tx context. 10b = Reserved. 11b = Reserved.
OP_CODE	18:17	00b	RW	**Op Code** Specifies the operation type: 00b = Read. 01b = Write. 10b = Invalidate. 11b = Reserved.
RESERVED	31:19	0x0	RSV	Reserved.

38.39.2.14.3 CMLAN Context Status Register - PFCM_LANCTXSTAT (0x0010C380; RO)

This register provides completion status for operations initiated via the CMLAN context control register.

Field	Bit(s)	Init.	Type	Description
CTX_DONE	0	0b	RO	**Context Operation Done** 0b = A previous LAN context operation that was initiated by a write to the PFCM_LANCTXCTL register is in progress, or no LAN context operation has been issued. 1b = A previous LAN context operation that was initiated by a write to the PFCM_LANCTXCTL register has completed.
CTX_MISS	1	0b	RO	**Context Queue Number Not Present** Reports if the queue was in the context cache before the operation specified in the PFCM_LANCTXCTL.*OP_CODE*. 0b = The requested queue number was resident in the context cache. 1b = The requested queue number was not resident in the context cache.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.14.4 CMLAN Cache Attributes - GLCM_LAN_CACHESIZE (0x0010C4D8; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	11:0	0x80	RO	**Word Size** The cache line size in bytes.
SETS	15:12	0x1	RO	**Sets** The number of cache sets.
WAYS	25:16	0x200	RO	**Ways** The number of cache ways.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.14.5 CMPE Cache Attributes - GLCM_PE_CACHESIZE (0x00138FE4; RO)

Field	Bit(s)	Init.	Type	Description
WORD_SIZE	11:0	0x200	RO	**Word Size** The cache line size in bytes.
SETS	15:12	0x1	RO	**Sets** The number of cache sets.
WAYS	24:16	0x100	RO	**Ways** The number of cache ways.
RESERVED	31:25	0x0	RSV	Reserved.

38.39.2.15 PF - Admin Queue

38.39.2.15.1 PF Admin Transmit Queue Base Address Low - PF_ATQBAL (0x00080000; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAL	31:0	0x0	RW	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.2 Global Admin Transmit Queue Base Address Low - GL_ATQBAL (0x00080040; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAL	31:0	0x0	RW	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.3 PF Admin Receive Queue Base Address Low - PF_ARQBAL (0x00080080; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAL	31:0	0x0	RW	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.4 Global Admin Receive Queue Base Address Low - GL_ARQBAL (0x000800C0; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAL	31:0	0x0	RW	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.5 PF Admin Transmit Queue Base Address High - PF_ATQBAH (0x00080100; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAH	31:0	0x0	RW	**Admin Transmit Queue Base Address High** Transmit descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.6 Global Admin Transmit Queue Base Address High - GL_ATQBAH (0x00080140; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAH	31:0	0x0	RW	**Admin Transmit Queue Base Address High** Transmit descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.7 PF Admin Receive Queue Base Address High - PF_ARQBAH (0x00080180; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAH	31:0	0x0	RW	**Admin Receive Queue Base Address High** Receive descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.8 Global Admin Receive Queue Base Address High - GL_ARQBAH (0x000801C0; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAH	31:0	0x0	RW	**Admin Receive Queue Base Address High** Receive descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.9 PF Admin Transmit Queue Length - PF_ATQLEN (0x00080200; RW)

Field	Bit(s)	Init.	Type	Description
ATQLEN	9:0	0x0	RW	**Admin Transmit Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ATQVFE	28	0b	RW	**Admin Transmit Queue VF Error** Set by firmware on a PF queue when one of its VFs has an admin queue error.
ATQOVFL	29	0b	RW	**Admin Transmit Queue Overflow Error** Set by firmware when a message is lost because there is no room in the queue.
ATQCRIT	30	0b	RW	**Admin Transmit Queue Critical Error** Set by firmware when a critical error is detected on this queue.

Field	Bit(s)	Init.	Type	Description
ATQENABLE	31	0b	RW	**Admin Transmit Queue Enable** Set by driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by PFR.

38.39.2.15.10Global Admin Transmit Queue Length - GL_ATQLEN (0x00080240; RW)

Field	Bit(s)	Init.	Type	Description
ATQLEN	9:0	0x0	RW	**Admin Transmit Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ATQVFE	28	0b	RW	**Admin Transmit Queue VF Error** Set by firmware on a PF queue when one of its VFs has an admin queue error.
ATQOVFL	29	0b	RW	**Admin Transmit Queue Overflow Error** Set by firmware when a message is lost because there is no room in the queue.
ATQCRIT	30	0b	RW	**Admin Transmit Queue Critical Error** Set by firmware when a critical error is detected on this queue.
ATQENABLE	31	0b	RW	**Admin Transmit Queue Enable** Set by the software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by CORER.

38.39.2.15.11PF Admin Receive Queue Length - PF_ARQLEN (0x00080280; RW)

Field	Bit(s)	Init.	Type	Description
ARQLEN	9:0	0x0	RW	**Admin Receive Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ARQVFE	28	0b	RW	**Admin Receive Queue VF Error** Set by firmware on a PF queue when one of its VFs has an admin queue error.
ARQOVFL	29	0b	RW	**Admin Receive Queue Overflow Error** Set by firmware when a message is lost because there is no room in the queue.
ARQCRIT	30	0b	RW	**Admin Receive Queue Critical Error** Set by firmware when a critical error is detected on this queue.
ARQENABLE	31	0b	RW	**Admin Receive Queue Enable** Set by the software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by PFR.

38.39.2.15.12PF Admin Transmit Head - PF_ATQH (0x00080300; RW)

Field	Bit(s)	Init.	Type	Description
ATQH	9:0	0x0	RW	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.13Global Admin Transmit Head - GL_ATQH (0x00080340; RW)

Field	Bit(s)	Init.	Type	Description
ATQH	9:0	0x0	RW	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.14PF Admin Receive Queue Head - PF_ARQH (0x00080380; RW)

Field	Bit(s)	Init.	Type	Description
ARQH	9:0	0x0	RW	**Admin Receive Queue Head** Receive queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.15Global Admin Receive Queue Head - GL_ARQH (0x000803C0; RW)

Field	Bit(s)	Init.	Type	Description
ARQH	9:0	0x0	RW	**Admin Receive Queue Head** Receive queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.16PF Admin Transmit Tail - PF_ATQT (0x00080400; RW)

Field	Bit(s)	Init.	Type	Description
ATQT	9:0	0x0	RW	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.17Global Admin Transmit Tail - GL_ATQT (0x00080440; RW)

Field	Bit(s)	Init.	Type	Description
ATQT	9:0	0x0	RW	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.18PF Admin Receive Queue Tail - PF_ARQT (0x00080480; RW)

Field	Bit(s)	Init.	Type	Description
ARQT	9:0	0x0	RW	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.19Global Admin Receive Queue Tail - GL_ARQT (0x000804C0; RW)

Field	Bit(s)	Init.	Type	Description
ARQT	9:0	0x0	RW	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.20VF Admin Transmit Queue Base Address Low - VF_ATQBAL[VF] (0x00080800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAL	31:0	0x0	RW	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.21VF Admin Receive Queue Base Address Low - VF_ARQBAL[VF] (0x00080C00 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAL	31:0	0x0	RW	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned. Contains the lower bits of the 64-bit descriptor base address.

38.39.2.15.22VF Admin Transmit Queue Base Address High - VF_ATQBAH[VF] (0x00081000 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAH	31:0	0x0	RW	**Admin Transmit Queue Base Address High** Transmit descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.23VF admin receive queue base address high - VF_ARQBAH[VF] (0x00081400 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAH	31:0	0x0	RW	**Admin Receive Queue Base Address High** Receive descriptor base address high. Contains the upper bits of the 64-bit descriptor base address.

38.39.2.15.24VF Admin Transmit Queue Length - VF_ATQLEN[VF] (0x00081800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ATQLEN	9:0	0x0	RW	**Admin Transmit Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ATQVFE	28	0b	RW	**Admin Transmit Queue VF Error** Set by firmware on a PF queue when one of its VFs has an admin queue error.
ATQOVFL	29	0b	RW	**Admin Transmit Queue Overflow Error** Set by firmware when a message is lost because there is no room in the queue.

Field	Bit(s)	Init.	Type	Description
ATQCRIT	30	0b	RW	**Admin Transmit Queue Critical Error** Set by firmware when a critical error is detected on this queue.
ATQENABLE	31	0b	RW	**Admin Transmit Queue Enable** Set by the software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by VFR.

38.39.2.15.25VF Admin Receive Queue Length - VF_ARQLEN[VF] (0x00081C00 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ARQLEN	9:0	0x0	RW	**Admin Receive Queue Length** Descriptor ring length. Max size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ARQVFE	28	0b	RW	**Admin Receive Queue VF Error** Set by firmware on a PF queue when one of its VFs has an admin queue error.
ARQOVFL	29	0b	RW	**Admin Receive Queue Overflow Error** Set by firmware when a message is lost because there is no room in the queue.
ARQCRIT	30	0b	RW	**Admin Receive Queue Critical Error** Set by firmware when a critical error is detected on this queue.
ARQENABLE	31	0b	RW	**Admin Receive Queue Enable** Set by the software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by PFR.

38.39.2.15.26VF Admin Transmit Head - VF_ATQH[VF] (0x00082000 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ATQH	9:0	0x0	RW	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.27VF Admin Receive Queue Head - VF_ARQH[VF] (0x00082400 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ARQH	9:0	0x0	RW	**Admin Receive Queue Head** Transmit queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.28 VF Admin Transmit Tail - VF_ATQT[VF] (0x00082800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ATQT	9:0	0x0	RW	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.15.29 VF Admin Receive Queue Tail - VF_ARQT[VF] (0x00082C00 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
ARQT	9:0	0x0	RW	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.16 PF - Statistics Registers

Statistics counters. Refer to the Statistics section for more details.

38.39.2.16.1 Port Good Octets Received Count Low - GLPRT_GORCL[n] (0x00300000 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
GORCL	31:0	0x0	RW1C	**Good Octets Received Count Low** Counts number of bytes received by this port. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.2 Port good octets received count high - GLPRT_GORCH[n] (0x00300004 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
GORCH	15:0	0x0	RW1C	**Good Octets Received Count High** Counts number of bytes received by this port. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.3 Port MAC local fault count - GLPRT_MLFC[n] (0x00300020 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
MLFC	31:0	0x0	RW1C	**MAC Local Fault Count** Number of faults in the local MAC.

38.39.2.16.4 Port MAC Remote Fault Count - GLPRT_MRFC[n] (0x00300040 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
MRFC	31:0	0x0	RW1C	**MAC Remote Fault Count** Number of faults in the remote MAC.

38.39.2.16.5 Port CRC Error Count - GLPRT_CRCERRS[n] (0x00300080 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
CRCERRS	31:0	0x0	RW1C	**CRC Error Count** Counts the number of receive packets with CRC errors. This includes packets that are also counted by other error registers.

38.39.2.16.6 Receive Length Error Count - GLPRT_RLEC[n] (0x003000A0 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RLEC	31:0	0x0	RW1C	**Receive Length Error Count** Number of packets with receive length errors. A length error occurs if an incoming packet length field in the MAC header does not match the packet length.

38.39.2.16.7 Port Illegal Byte Error Count - GLPRT_ILLERRC[n] (0x003000E0 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
ILLERRC	31:0	0x0	RW1C	**Illegal Byte Error Packet Count** Counts the number of receive packets with illegal bytes errors. For example, there is an illegal symbol in the packet.

38.39.2.16.8 Receive Undersize Count - GLPRT_RUC[n] (0x00300100 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RUC	31:0	0x0	RW1C	**Receive Undersize Count** Counts the number of received frames that are shorter than minimum size (64 bytes from <Destination Address> through <CRC>, inclusively), and had a valid CRC.

38.39.2.16.9 Receive Oversize Count - GLPRT_ROC[n] (0x00300120 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
ROC	31:0	0x0	RW1C	**Receive Oversize Count** Counts the number of received frames that are longer than maximum size as defined by the Set MAC config command (from <Destination Address> through <CRC>, inclusively), and have valid CRC.

38.39.2.16.10 Port Link XON Received Count - GLPRT_LXONRXC[n] (0x00300140 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
LXONRXCNT	31:0	0x0	RW1C	**Link XON Received Count** Number of XON packets received.

38.39.2.16.11 Port Link XOFF Received Count - GLPRT_LXOFFRXC[n] (0x00300160 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
LXOFFRXCNT	31:0	0x0	RW1C	**Link XOFF Received Count** Number of XOFF packets received.

38.39.2.16.12 Priority XON Received Count - GLPRT_PXONRXC[n,m] (0x00300180 + 0x8*n + 0x20*m, n=0...3, m=0...7; RW1C)

Port priority FC XON received count (array of eight per port).

Field	Bit(s)	Init.	Type	Description
PRPXONRXCNT	31:0	0x0	RW1C	**Priority XON Received Count** Number of XON packets received.

38.39.2.16.13 Priority XOFF Received Count - GLPRT_PXOFFRXC[n,m] (0x00300280 + 0x8*n + 0x20*m, n=0...3, m=0...7; RW1C)

Port priority FC XOFF received count (array of eight per port).

Field	Bit(s)	Init.	Type	Description
PRPXOFFRXCNT	31:0	0x0	RW1C	**Priority XOFF Received Count** Number of XOFF packets received.

38.39.2.16.14 Priority XON to XOFF Count - GLPRT_RXON2OFFCNT[n,m] (0x00300380 + 0x8*n + 0x20*m, n=0...3, m=0...7; RW1C)

Counts the number of times the priority egress was paused (array of eight per port).

Field	Bit(s)	Init.	Type	Description
PRRXON2OFFCNT	31:0	0x0	RW1C	**Priority XON to XOFF Count** Number of times transmitter transitioned from XON to XOFF.

38.39.2.16.15 Packets Received [64 Bytes] Count Low - GLPRT_PRC64L[n] (0x00300480 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC64H (Section 38.39.2.16.16) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC64L	31:0	0x0	RW1C	**Packets Received Count [64 Bytes] Low** Number of good packets received that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.16 Packets Received [64 Bytes] Count High - GLPRT_PRC64H[n] (0x00300484 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC64L (Section 38.39.2.16.15) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC64H	15:0	0x0	RW1C	**Packets Received Count [64 Bytes] High** Number of good packets received that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.17 Packets Received [65-127 Bytes] Count Low - GLPRT_PRC127L[n] (0x003004A0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC127H (Section 38.39.2.16.18) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC127L	31:0	0x0	RW1C	**Packets Received Count [65-127 Bytes] Low** Number of packets received that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.18 Packets Received [65-127 Bytes] Count High - GLPRT_PRC127H[n] (0x003004A4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC127L (Section 38.39.2.16.17) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC127H	15:0	0x0	RW1C	**Packets Received Count [65-127 Bytes] High** Number of packets received that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.19 Packets Received [128-255 Bytes] Count Low - GLPRT_PRC255L[n] (0x003004C0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC255H (Section 38.39.2.16.20) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC255L	31:0	0x0	RW1C	**Packets Received Count [128-255 Bytes] Low** Number of packets received that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.20 Packets Received [128-255 Bytes] Count High - GLPRT_PRC255H[n] (0x003004C4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC255L (Section 38.39.2.16.19) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRTPRC255H	15:0	0x0	RW1C	**Packets Received Count [128-255 Bytes] High** Number of packets received that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.21 Packets Received [256-511 Bytes] Count Low - GLPRT_PRC511L[n] (0x003004E0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC511H (Section 38.39.2.16.22) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC511L	31:0	0x0	RW1C	**Packets Received Count [256-511 Bytes] Low** Number of packets received that are 256-511 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.22 Packets Received [256-511 Bytes] Count High - GLPRT_PRC511H[n] (0x003004E4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC511L (Section 38.39.2.16.21) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC511H	15:0	0x0	RW1C	**Packets Received Count [256-511 Bytes] High** Number of packets received that are 256-511 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.23 Packets Received [512-1023 Bytes] Count Low - GLPRT_PRC1023L[n] (0x00300500 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC1023H (Section 38.39.2.16.24) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1023L	31:0	0x0	RW1C	**Packets Received Count [512-1023 Bytes] Low** Number of packets received that are 512-1023 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.24 Packets Received [512-1023 Bytes] Count High - GLPRT_PRC1023H[n] (0x00300504 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC1023L (Section 38.39.2.16.23) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1023H	15:0	0x0	RW1C	**Packets Received Count [512-1023 Bytes] High** Number of packets received that are 512-1023 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.25 Packets Received [1024-1522 bytes] Count Low - GLPRT_PRC1522L[n] (0x00300520 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC1522H (Section 38.39.2.16.26) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1522L	31:0	0x0	RW1C	**Packets Received Count [1024-1522 Bytes] Low** Number of packets received that are 1024-max bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.26 Packets Received [1024-1522 bytes] Count High - GLPRT_PRC1522H[n] (0x00300524 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC1522L (Section 38.39.2.16.25) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1522H	15:0	0x0	RW1C	**Packets Received Count [1024-1522 Bytes] High** Number of packets received that are 1024-max bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.27 Packets Received [1523-9522 Bytes] Count Low - GLPRT_PRC9522L[n] (0x00300540 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC9522H (Section 38.39.2.16.28) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1522L	31:0	0x0	RW1C	**Packets Received Count [1523-9522 Bytes] Low** Number of packets received that are 1024-max bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.28 Packets Received [1523-9522 Bytes] Count High - GLPRT_PRC9522H[n] (0x00300544 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PRC9522L (Section 38.39.2.16.27) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PRC1522H	15:0	0x0	RW1C	**Packets Received Count [1523-9522 Bytes] High** Number of packets received that are 1024-max bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.29 Receive Fragment Count - GLPRT_RFC[n] (0x00300560 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RFC	31:0	0x0	RW1C	**Receive Fragments Count** Counts the number of received frames that are shorter than minimum size (64 bytes from <Destination Address> through <CRC>, inclusively), and had an invalid CRC.

38.39.2.16.30 Receive Jabber Count - GLPRT_RJC[n] (0x00300580 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RJC	31:0	0x0	RW1C	**Receive Jabber Count** Counts the number of received packets that passed address filtering, and are greater than maximum size and have bad CRC (this is slightly different from the Receive Oversize Count register). The packet length is counted from <Destination Address> through <CRC>, inclusively.

38.39.2.16.31 Port Unicast Packets Received Count Low - GLPRT_UPRCL[n] (0x003005A0 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
UPRCL	31:0	0x0	RW1C	**Unicast Packets Received Count Low** Counts number of unicast packets received by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.32 Port Unicast Packets Received Count High - GLPRT_UPRCH[n] (0x003005A4 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
UPRCH	15:0	0x0	RW1C	**Unicast Packets Received Count High** Counts number of unicast packets received by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.33 Port Multicast Packets Received Count Low - GLPRT_MPRCL[n] (0x003005C0 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
MPRCL	31:0	0x0	RW1C	**Multicast Packets Received Count Low** Counts number of multicast packets received by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.34 Port Multicast Packets Received Count High - GLPRT_MPRCH[n] (0x003005C4 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
MPRCH	15:0	0x0	RW1C	**Multicast Packets Received Count High** Counts number of multicast packets received by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.35 Port Broadcast Packets Received Count Low - GLPRT_BPRCL[n] (0x003005E0 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
BPRCL	31:0	0x0	RW1C	**Broadcast Packets Received Count Low** Counts number of broadcast packets received by this port. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.36 Port Broadcast Packets Received Count High - GLPRT_BPRCH[n] (0x003005E4 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
BPRCH	15:0	0x0	RW1C	**Broadcast Packets Received Count High** Counts number of broadcast packets received by this port. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.37 Port Receive Packets Discarded Count - GLPRT_RDPC[n] (0x00300600 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RDPC	31:0	0x0	RW1C	**Receive Discarded Packets Count**

38.39.2.16.38 VM-VM Loopback Packets Discarded Count - GLPRT_LDPC[n] (0x00300620 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
LDPC	31:0	0x0	RW1C	**Loopback Discarded Packets Count**

38.39.2.16.39 Port Received with No Destination - GLPRT_RUPP[n] (0x00300660 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
RUPP	31:0	0x0	RW1C	**Received Unknown Packet Protocol count** Receive packets dropped for this port because they did not match any STag. (No forwarding rule).

38.39.2.16.40 Port Good Octets Transmit Count Low - GLPRT_GOTCL[n] (0x00300680 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCL	31:0	0x0	RW1C	**Good Octets Transmit Count Low** Counts number of bytes transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.41 Port Good Octets Transmit Count High - GLPRT_GOTCH[n] (0x00300684 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCH	15:0	0x0	RW1C	**Good Octets Transmit Count High** Counts number of bytes transmitted by this port. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.42 Packets Transmitted [64 Bytes] Count Low - GLPRT_PTC64L[n] (0x003006A0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC64H (Section 38.39.2.16.43) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC64L	31:0	0x0	RW1C	**Packets Transmitted Count [64 Bytes] Low** Number of packets transmitted that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.43 Packets Transmitted [64 Bytes] Count High - GLPRT_PTC64H[n] (0x003006A4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC64L (Section 38.39.2.16.42) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC64H	15:0	0x0	RW1C	**Packets Transmitted Count [64 Bytes] High** Number of packets transmitted that are 64 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.44 Packets Transmitted [65-127 Bytes] Count Low - GLPRT_PTC127L[n] (0x003006C0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC127H (Section 38.39.2.16.45) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC127L	31:0	0x0	RW1C	**Packets Transmitted Count [65-127 Bytes] Low** Number of packets transmitted that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.45 Packets Transmitted [65-127 Bytes] Count High - GLPRT_PTC127H[n] (0x003006C4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC127L (Section 38.39.2.16.44) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC127H	15:0	0x0	RW1C	**Packets Transmitted Count [65-127 Bytes] High** Number of packets transmitted that are 65-127 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.46 Packets Transmitted [128-255 Bytes] Count Low - GLPRT_PTC255L[n] (0x003006E0 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC255H (Section 38.39.2.16.47) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC255L	31:0	0x0	RW1C	**Packets Transmitted Count [128-255 Bytes] Low** Number of packets transmitted that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.47 Packets Transmitted [128-255 Bytes] Count High - GLPRT_PTC255H[n] (0x003006E4 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC255L (Section 38.39.2.16.46) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC255H	15:0	0x0	RW1C	**Packets Transmitted Count [128-255 Bytes] High** Number of packets transmitted that are 128-255 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.48 Packets Transmitted [256-511 Bytes] Count Low - GLPRT_PTC511L[n] (0x00300700 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC511H (Section 38.39.2.16.49) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC511L	31:0	0x0	RW1C	**Packets Transmitted Count [256-511 Bytes] Low** Number of packets transmitted that are 256-511 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.49 Packets Transmitted [256-511 Bytes] Count High - GLPRT_PTC511H[n] (0x00300704 + 0x8*n, n=0...3; RW1C)

Combined with GLPRT_PTC511L (Section 38.39.2.16.48) to form a 64-bit register.

Field	Bit(s)	Init.	Type	Description
PTC511H	15:0	0x0	RW1C	**Packets Transmitted Count [256-511 Bytes] High** Number of packets transmitted that are 256-511 bytes in length (from <Destination Address> through <CRC>, inclusively). The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
MPTCL	31:0	0x0	RW1C	**Multicast Packets Transmit Count Low** Counts number of multicast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.63 Port Multicast Packets Transmit Count High - GLPRT_MPTCH[n] (0x003009E4 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
MPTCH	15:0	0x0	RW1C	**Multicast Packets Transmit Count High** Counts number of multicast packets transmitted by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.64 Port Broadcast Packets Transmit Count Low - GLPRT_BPTCL[n] (0x00300A00 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
BPTCL	31:0	0x0	RW1C	**Broadcast Packets Transmit Count Low** Counts number of broadcast packets transmitted by this port. Lower 32-bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.65 Port Broadcast Packets Transmit Count High - GLPRT_BPTCH[n] (0x00300A04 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
BPTCH	15:0	0x0	RW1C	**Broadcast Packets Transmit Count High** Counts number of broadcast packets transmitted by this port. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.66 Transmit Discard on Link Down - GLPRT_TDOLD[n] (0x00300A20 + 0x8*n, n=0...3; RW1C)

Field	Bit(s)	Init.	Type	Description
GLPRT_TDOLD	31:0	0x0	RW1C	**Transmit Discard On Link Down** Packets discarded at the port because the link was down.

38.39.2.16.67VSI Received Discard Packet Count - GLV_RDPC[n] (0x00310000 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
RDPC	31:0	0x0	RW1C	**Received Discard Packet Count** Counts (per VSI) packets that were dropped due to no descriptors in host queue. For EMP VSIs it counts dropped packets due to no EMP buffer space.

38.39.2.16.68Receive Error Counter 1 Low - GL_RXERR1_L[n] (0x00318000 + 0x8*n, n=0...143; RW1C)

Field	Bit(s)	Init.	Type	Description
RESERVED	31:0	0x0	RW1C	**Reserved.**

38.39.2.16.69VSI Good Octets Transmit Count Low - GLV_GOTCL[n] (0x00328000 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCL	31:0	0x0	RW1C	**Good Octets Transmit Count Low** Counts number of bytes transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.70VSI Good Octets Transmit Count High - GLV_GOTCH[n] (0x00328004 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCH	15:0	0x0	RW1C	**Good Octets Transmit Count High** Counts number of bytes transmitted by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.71Switch Good Octets Transmit Count Low - GLSW_GOTCL[n] (0x0032C000 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCL	31:0	0x0	RW1C	**Good Octets Transmit Count Low** Counts number of bytes transmitted. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.72Switch Good Octets Transmit Count High - GLSW_GOTCH[n] (0x0032C004 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
GOTCH	15:0	0x0	RW1C	**Good Octets Transmit Count High** Counts number of bytes transmitted. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.73VEB VLAN Transmit Byte Count Low - GLVEBVL_GOTCL[n] (0x00330000 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLBCL	31:0	0x0	RW1C	**VEB per VLAN Byte Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.74VEB VLAN Transmit Byte Count High - GLVEBVL_GOTCH[n] (0x00330004 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLBCH	15:0	0x0	RW1C	**VEB per VLAN Byte Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.75VEB TC Transmit Byte Count Low - GLVEBTC_TBCL[n,m] (0x00334000 + 0x8*n + 0x40*m, n=0...7, m=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
TCBCL	31:0	0x0	RW1C	**VEB per TC Byte Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.76VEB TC Transmit Byte Count High - GLVEBTC_TBCH[n,m] (0x00334004 + 0x8*n + 0x40*m, n=0...7, m=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
TCBCH	15:0	0x0	RW1C	**VEB per TC Byte Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.77VEB TC Transmit Packet Count Low - GLVEBTC_TPCL[n,m] (0x00338000 + 0x8*n + 0x40*m, n=0...7, m=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPCL	31:0	0x0	RW1C	**VEB per TC Packet Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.78VEB TC Transmit Packet Count High - GLVEBTC_TPCH[n,m] (0x00338004 + 0x8*n + 0x40*m, n=0...7, m=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPCH	15:0	0x0	RW1C	**VEB per TC Packet Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.79VSI Unicast Packets Transmit Count Low - GLV_UPTCL[n] (0x0033C000 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
UPTCL	31:0	0x0	RW1C	**Unicast Packets Transmit Count Low** Counts number of unicast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.80VSI Unicast Packets Transmit Count High - GLV_UPTCH[n] (0x0033C004 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
UPTCH	15:0	0x0	RW1C	**Unicast Packets Transmit Count High** Counts number of unicast packets transmitted by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.81VSI Multicast Packets Transmit Count Low - GLV_MPTCL[n] (0x0033CC00 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
MPTCL	31:0	0x0	RW1C	**Multicast Packets Transmit Count Low** Counts number of multicast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.82VSI Multicast Packets Transmit Count High - GLV_MPTCH[n] (0x0033CC04 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
MPTCH	15:0	0x0	RW1C	**Multicast Packets Transmit Count High** Counts number of multicast packets transmitted by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.83VSI Broadcast Packets Transmit Count Low - GLV_BPTCL[n] (0x0033D800 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
BPTCL	31:0	0x0	RW1C	**Broadcast Packets Transmit Count Low** Counts number of broadcast packets transmitted by this VSI. Lower 32 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.84VSI Broadcast Packets Transmit Count High - GLV_BPTCH[n] (0x0033D804 + 0x8*n, n=0...383; RW1C)

Field	Bit(s)	Init.	Type	Description
BPTCH	15:0	0x0	RW1C	**Broadcast Packets Transmit Count High** Counts number of broadcast packets transmitted by this VSI. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

BPRCH	15:0	0x0	RW1C	**Broadcast Packets Received Count High** Counts number of broadcast packets received. Upper 16 bits. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.116Switch Received Unknown Packet Protocol Count - GLSW_RUPP[n] (0x00370180 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
RUPP	31:0	0x0	RW1C	**Received Unknown Packet Protocol count** Receive Packets dropped because of an a unknown protocol or no forward destination.

38.39.2.16.117VEB VLAN Unicast Packet Count Low - GLVEBVL_UPCL[n] (0x00374000 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLUPCL	31:0	0x0	RW1C	**VEB per VLAN Unicast Packet Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.118VEB VLAN Unicast Packet Count High - GLVEBVL_UPCH[n] (0x00374004 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLUPCH	15:0	0x0	RW1C	**VEB per VLAN Unicast Packet Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.119VEB VLAN Multicast Packet Count Low - GLVEBVL_MPCL[n] (0x00374400 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLMPCL	31:0	0x0	RW1C	**VEB per VLAN Multicast Packet Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.120VEB VLAN Multicast Packet Count High - GLVEBVL_MPCH[n] (0x00374404 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLMPCH	15:0	0x0	RW1C	**VEB per VLAN Multicast Packet Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.16.121VEB VLAN Broadcast Packet Count Low - GLVEBVL_BPCL[n] (0x00374800 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLBPCL	31:0	0x0	RW1C	**VEB per VLAN Broadcast Packet Count Low** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.

38.39.2.16.122VEB VLAN Broadcast Packet Count High - GLVEBVL_BPCH[n] (0x00374804 + 0x8*n, n=0...127; RW1C)

Field	Bit(s)	Init.	Type	Description
VLBPCH	15:0	0x0	RW1C	**VEB per VLAN Broadcast Packet Count High** The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17 PF - Protocol Engine Statistics Registers

38.39.2.17.1 Protocol engine Statistics Received VLAN_ID Errors - GLPES_PFRXVLANERR[n] (0x00010000 + 0x4*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
RXVLANERR	23:0	0x0	RW1C	**Received VLAN Errors** Counts the number of packets received by the PE with incorrect VLAN_ID.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.2 Protocol engine Statistics IPv4 Received Octets Low - GLPES_PFIP4RXOCTSLO[n] (0x00010200 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXOCTSLO	31:0	0x0	RW1C	**IPv4 Received Octets Low** Counts the number of IPv4 octets received by the PE. This is the lower 32 bits of the 48-bit counter. This counter is not incremented for received IPv4 multicast packets. Software must add the value of this counter to the IPv4 multicast octet counter to calculate a total number of octets received. The low and high registers are part of a 64 bit register, and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.3 Protocol Engine Statistics IPv4 Received Octets High - GLPES_PFIP4RXOCTSHI[n] (0x00010204 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXOCTSHI	15:0	0x0	RW1C	**IPv4 Received Octets High** Counts the number of IPv4 octets received by the PE. This is the upper 16 bits of the 48-bit counter. This counter is not incremented for received IPv4 multicast packets. Software must add the value of this counter to the IPv4 multicast octet counter to calculate a total number of octets received. The low and high registers are part of a 64 bit register, and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.4 Protocol Engine Statistics IPv4 Received Packets Low - GLPES_PFIP4RXPKTSLO[n] (0x00010400 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXPKTSLO	31:0	0x0	RW1C	**IPv4 Received Packets Low** Counts the number of IPv4 packets received by the PE. This is the lower 32 bits of the 48-bit counter. This counter is not incremented for received IPv4 multicast packets. Software must add the value of this counter to the IPv4 multicast octet packet to calculate a total number of octets received. The low and high registers are part of a 64 bit register, and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.5 Protocol Engine Statistics IPv4 Received Packets High - GLPES_PFIP4RXPKTSHI[n] (0x00010404 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXPKTSHI	15:0	0x0	RW1C	**IPv4 Received Packets High** Counts the number of IPv4 packets received by the PE. This is the upper 16 bits of the 48-bit counter. This counter is not incremented for received IPv4 multicast packets. Software must add the value of this counter to the IPv4 multicast octet packet to calculate a total number of octets received. The low and high registers are part of a 64 bit register, and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.6 Protocol Engine Statistics IPv4 Discards - GLPES_PFIP4RXDISCARD[n] (0x00010600 + 0x4*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXDISCARD	31:0	0x0	RW1C	**IPv4 Received Discards** Counts the number of IPv4 packets received by the PE without errors and are discarded.

38.39.2.17.7 Protocol Engine Statistics IPv4 Truncated Packets - GLPES_PFIP4RXTRUNC[n] (0x00010700 + 0x4*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXTRUNC	31:0	0x0	RW1C	**IPv4 Received Truncated** Counts the number of IPv4 packets received by the PE and truncated due to insufficient payload or header buffering space in RQ descriptors.

38.39.2.17.8 Protocol Engine Statistics IPv4 Received Fragments Low - GLPES_PFIP4RXFRAGSLO[n] (0x00010800 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXFRAGSLO	31:0	0x0	RW1C	**IPv4 Received Fragments Low** Counts the number of IPv4 fragments received by the PE. This is the lower 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.9 Protocol Engine Statistics IPv4 Received Fragments High - GLPES_PFIP4RXFRAGSHI[n] (0x00010804 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4RXFRAGSHI	15:0	0x0	RW1C	**IPv4 Received Fragments High** Counts the number of IPv4 fragments received by the PE. This is the upper 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Field	Bit(s)	Init.	Type	Description
IP4TXFRAGSLO	31:0	0x0	RW1C	**IPv4 Transmitted Fragments Low** Counts the number of IPv4 fragments supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.31 Protocol Engine Statistics IPv4 Transmitted Fragments High - GLPES_PFIP4TXFRAGSHI[n] (0x00011E04 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4TXFRAGSHI	15:0	0x0	RW1C	**IPv4 Transmitted Fragments High** Counts the number of IPv4 fragments supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.32 Protocol Engine Statistics IPv4 Transmitted Multicast Octets Low - GLPES_PFIP4TXMCOCTSLO[n] (0x00012000 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4TXMCOCTSLO	31:0	0x0	RW1C	**IPv4 Transmitted Multicast Octets Low** Counts the number of IPv4 multicast octets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.33 Protocol Engine Statistics IPv4 Transmitted Multicast Octets High - GLPES_PFIP4TXMCOCTSHI[n] (0x00012004 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
IP4TXMCOCTSHI	15:0	0x0	RW1C	**IPv4 Transmitted Multicast Octets High** Counts the number of IPv4 multicast octets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Field	Bit(s)	Init.	Type	Description
RDMATXWRSLO	31:0	0x0	RW1C	**RDMA Transmitted Writes Low** Counts the number of RDMA write messages transmitted by the PE. This is the lower 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.66 Protocol Engine Statistics RDMA Transmitted Write Messages High - GLPES_PFRDMATXWRSHI[n] (0x00014204 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMATXWRSHI	15:0	0x0	RW1C	**RDMA Transmitted Writes High** Counts the number of RDMA write messages transmitted by the PE. This is the upper 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.67 Protocol Engine Statistics RDMA Transmitted Read Request Messages Low - GLPES_PFRDMATXRDSLO[n] (0x00014400 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMATXRDSLO	31:0	0x0	RW1C	**RDMA Transmitted Reads Low** Counts the number of RDMA read request messages transmitted by the PE. This is the lower 32 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.68 Protocol Engine Statistics RDMA Transmitted Read Request Messages High - GLPES_PFRDMATXRDSHI[n] (0x00014404 + 0x8*n, n=0...15; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMATXRDSHI	15:0	0x0	RW1C	**RDMA Transmitted Reads High** Counts the number of RDMA read request messages transmitted by the PE. This is the upper 16 bits of the 48-bit counter. The low and high registers are part of a 64-bit register and are read using 64-bit read accesses only. It is implemented internally, breaking the read request into two 32-bit reads. Reading the low 32 bits latches the high 32 bits into a shadow register. Reading the high 32 bits returns the value in the shadow register.

38.39.2.17.78 Protocol Engine Statistics IPv4 Received Packets Low - GLPES_VFIP4RXPKTSLO[n] (0x00018400 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXPKTSLO	31:0	0x0	RW1C	**IPv4 Received Packets Low** Counts the number of IPv4 packets received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.79 Protocol Engine Statistics IPv4 Received Packets High - GLPES_VFIP4RXPKTSHI[n] (0x00018404 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXPKTSHI	15:0	0x0	RW1C	**IPv4 Received Packets High** Counts the number of IPv4 packets received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.80 Protocol Engine Statistics IPv4 Discards - GLPES_VFIP4RXDISCARD[n] (0x00018600 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXDISCARD	31:0	0x0	RW1C	**IPv4 Received Discards** Counts the number of IPv4 packets received by the PE without errors and discarded.

38.39.2.17.81 Protocol Engine Statistics IPv4 Truncated Packets - GLPES_VFIP4RXTRUNC[n] (0x00018700 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXTRUNC	31:0	0x0	RW1C	**IPv4 Received Truncated** Counts the number of IPv4 packets received by the PE and truncated due to insufficient payload or header buffering space in RQ descriptors.

38.39.2.17.82 Protocol Engine Statistics IPv4 Received Fragments Low - GLPES_VFIP4RXFRAGSLO[n] (0x00018800 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXFRAGSLO	31:0	0x0	RW1C	**IPv4 Received Fragments Low** Counts the number of IPv4 fragments received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.83 Protocol Engine Statistics IPv4 Received Fragments High - GLPES_VFIP4RXFRAGSHI[n] (0x00018804 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXFRAGSHI	15:0	0x0	RW1C	**IPv4 Received Fragments High** Counts the number of IPv4 fragments received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.84 Protocol Engine Statistics IPv4 Received Multicast Octets Low - GLPES_VFIP4RXMCOCTSLO[n] (0x00018A00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXMCOCTSLO	31:0	0x0	RW1C	**IPv4 Received Multicast Octets Low** Counts the number of IPv4 multicast octets received by the PE. This is the lower 32 bits of the 48-bit counter. This register does not count number of octets of the multicast packets replicated inside the PE.

38.39.2.17.85 Protocol Engine Statistics IPv4 Received Multicast Octets High - GLPES_VFIP4RXMCOCTSHI[n] (0x00018A04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4RXMCOCTSHI	15:0	0x0	RW1C	**IPv4 Received Multicast Octets High** Counts the number of IPv4 multicast octets received by the PE. This is the upper 16 bits of the 48-bit counter. This register does not count number of octets of the multicast packets replicated inside the PE.

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4TXMCOCTSLO	31:0	0x0	RW1C	**IPv4 Transmitted Multicast Octets Low** Counts the number of IPv4 multicast octets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.107 Protocol Engine Statistics IPv4 Transmitted Multicast Octets High - GLPES_VFIP4TXMCOCTSHI[n] (0x0001A004 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4TXMCOCTSHI	15:0	0x0	RW1C	**IPv4 Transmitted Multicast Octets High** Counts the number of IPv4 multicast octets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.108 Protocol Engine Statistics IPv4 Transmitted Multicast Packets Low - GLPES_VFIP4TXMCPKTSLO[n] (0x0001A200 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4TXMCPKTSLO	31:0	0x0	RW1C	**IPv4 Transmitted Multicast Packets Low** Counts the number of IPv4 multicast packets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.109 Protocol Engine Statistics IPv4 Transmitted Multicast Packets High - GLPES_VFIP4TXMCPKTSHI[n] (0x0001A204 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4TXMCPKTSHI	15:0	0x0	RW1C	**IPv4 Transmitted Multicast Packets High** Counts the number of IPv4 multicast packets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.110 Protocol Engine Statistics IPv6 Transmitted Octets Low - GLPES_VFIP6TXOCTSLO[n] (0x0001A400 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXOCTSLO	31:0	0x0	RW1C	**IPv6 Transmitted Octets Low** Counts the number of IPv6 octets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.111 Protocol Engine Statistics IPv6 Transmitted Octets High - GLPES_VFIP6TXOCTSHI[n] (0x0001A404 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXOCTSHI	15:0	0x0	RW1C	**IPv6 Transmitted Octets High** Counts the number of IPv6 octets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.112 Protocol Engine Statistics IPv6 Transmitted Packets Low - GLPES_VFIP6TXPKTSLO[n] (0x0001A600 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXPKTSLO	31:0	0x0	RW1C	**IPv6 Transmitted Packets Low** Counts the number of IPv6 packets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.113 Protocol Engine Statistics IPv6 Transmitted Packets High - GLPES_VFIP6TXPKTSHI[n] (0x0001A604 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXPKTSHI	15:0	0x0	RW1C	**IPv6 Transmitted Packets High** Counts the number of IPv6 packets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.114 Protocol Engine Statistics IPv6 Transmitted Fragments Low - GLPES_VFIP6TXFRAGSLO[n] (0x0001A800 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXFRAGSLO	31:0	0x0	RW1C	**IPv6 Transmitted Fragments Low** Counts the number of IPv6 fragments supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.115 Protocol Engine Statistics IPv6 Transmitted Fragments High - GLPES_VFIP6TXFRAGSHI[n] (0x0001A804 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXFRAGSHI	15:0	0x0	RW1C	**IPv6 Transmitted Fragments High** Counts the number of IPv6 fragments supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.116 Protocol Engine Statistics IPv6 Transmitted Multicast Octets Low - GLPES_VFIP6TXMCOCTSLO[n] (0x0001AA00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXMCOCTSLO	31:0	0x0	RW1C	**IPv6 Transmitted Multicast Octets Low** Counts the number of IPv6 multicast octets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.117 Protocol Engine Statistics IPv6 Transmitted Multicast Octets High - GLPES_VFIP6TXMCOCTSHI[n] (0x0001AA04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXMCOCTSHI	15:0	0x0	RW1C	**IPv6 Transmitted Multicast Octets High** Counts the number of IPv6 multicast octets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.118 Protocol Engine Statistics IPv6 Transmitted Multicast Packets Low - GLPES_VFIP6TXMCPKTSLO[n] (0x0001AC00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXMCPKTSLO	31:0	0x0	RW1C	**IPv6 Transmitted Multicast Packets Low** Counts the number of IPv6 multicast packets supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.119 Protocol Engine Statistics IPv6 Transmitted Multicast Packets High - GLPES_VFIP6TXMCPKTSHI[n] (0x0001AC04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXMCPKTSHI	15:0	0x0	RW1C	**IPv6 Transmitted Multicast Packets High** Counts the number of IPv6 multicast packets supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.120 Protocol Engine Statistics IPv4 Discarded No Route Packets - GLPES_VFIP4TXNOROUTE[n] (0x0001AE00 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP4TXNOROUTE	23:0	0x0	RW1C	**IPv4 Transmitted No Route** Counts the number of IPv4 packets discarded due to routing problem (no hit in ARP table).
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.121 Protocol Engine Statistics IPv6 Discarded No Route Packets - GLPES_VFIP6TXNOROUTE[n] (0x0001AF00 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IP6TXNOROUTE	23:0	0x0	RW1C	**IPv6 Transmitted No Route** Counts the number of IPv6 packets discarded due to routing problem (no hit in ARP table).
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.122 Protocol Engine Statistics TCP Received Segments Low - GLPES_VFTCPRXSEGSLO[n] (0x0001B000 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPRXSEGSLO	31:0	0x0	RW1C	**TCP Received Segments Low** Counts the number of TCP segments received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.123 Protocol Engine Statistics TCP Received Segments High - GLPES_VFTCPRXSEGSHI[n] (0x0001B004 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPRXSEGSHI	15:0	0x0	RW1C	**TCP Received Segments High** Counts the number of TCP segments received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.124 Protocol Engine Statistics TCP Received Segments with Unsupported Options - GLPES_VFTCPRXOPTERR[n] (0x0001B200 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPRXOPTERR	23:0	0x0	RW1C	**TCP Received Options Error** Counts the number of TCP segments received by the PE with unsupported TCP options and TCP option length errors.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.125 Protocol Engine Statistics TCP Dropped Segments Due to Protocol Errors - GLPES_VFTCPRXPROTOERR[n] (0x0001B300 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPRXPROTOERR	23:0	0x0	RW1C	**TCP Received Protocol Error** Counts the number of TCP segments received and dropped by the PE due to TCP protocol errors.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.126 Protocol Engine Statistics TCP Transmitted Segments Low - GLPES_VFTCPTXSEGLO[n] (0x0001B400 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPTXSEGLO	31:0	0x0	RW1C	**TCP Transmitted Segments Low** Counts the number of TCP segments supplied by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.127 Protocol Engine Statistics TCP Transmitted Segments High - GLPES_VFTCPTXSEGHI[n] (0x0001B404 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPTXSEGHI	15:0	0x0	RW1C	**TCP Transmitted Segments High** Counts the number of TCP segments supplied by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.128 Protocol Engine Statistics TCP Retransmitted Segments - GLPES_VFTCPRTXSEG[n] (0x0001B600 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
TCPRTXSEG	31:0	0x0	RW1C	**TCP Retransmitted Segments** Counts the number of TCP segments retransmitted by the PE.

38.39.2.17.129 Protocol Engine Statistics UDP Received Packets Low - GLPES_VFUDPRXPKTSLO[n] (0x0001B800 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
UDPRXPKTSLO	31:0	0x0	RW1C	**UDP Received Packets Low** Counts the number of UDP packets received by the PE without errors. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.130 Protocol Engine Statistics UDP Received Packets High - GLPES_VFUDPRXPKTSHI[n] (0x0001B804 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
UDPRXPKTSHI	15:0	0x0	RW1C	**UDP Received Packets High** Counts the number of UDP packets received by the PE without errors. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.131 Protocol Engine Statistics UDP Transmitted Packets Low - GLPES_VFUDPTXPKTSLO[n] (0x0001BA00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
UDPTXPKTSLO	31:0	0x0	RW1C	**UDP Transmitted Packets Low** Counts the number of UDP packets submitted by the PE to the lower layers for transmission. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.132 Protocol Engine Statistics UDP Transmitted Packets High - GLPES_VFUDPTXPKTSHI[n] (0x0001BA04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
UDPTXPKTSHI	15:0	0x0	RW1C	**UDP Transmitted Packets High** Counts the number of UDP packets submitted by the PE to the lower layers for transmission. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.133 Protocol Engine Statistics RDMA Received Write Messages Low - GLPES_VFRDMARXWRSLO[n] (0x0001BC00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXWRSLO	31:0	0x0	RW1C	**RDMA Received Writes Low** Counts the number of RDMA write messages received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.134 Protocol Engine Statistics RDMA Received Write Messages High - GLPES_VFRDMARXWRSHI[n] (0x0001BC04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXWRSHI	15:0	0x0	RW1C	**RDMA Received Writes High** Counts the number of RDMA write messages received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.135 Protocol Engine Statistics RDMA Received Read Request Messages Low - GLPES_VFRDMARXRDSLO[n] (0x0001BE00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXRDSLO	31:0	0x0	RW1C	**RDMA Received Reads Low** Counts the number of RDMA read request messages received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.136 Protocol Engine Statistics RDMA Received Read Request Messages High - GLPES_VFRDMARXRDSHI[n] (0x0001BE04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXRDSHI	15:0	0x0	RW1C	**RDMA Received Reads High** Counts the number of RDMA read request messages received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.137 Protocol Engine Statistics RDMA Received Send Messages Low - GLPES_VFRDMARXSNDSLO[n] (0x0001C000 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXSNDSLO	31:0	0x0	RW1C	**RDMA Received Sends Low** Counts the number of RDMA send messages received by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.138 Protocol Engine Statistics RDMA Received Send Messages High - GLPES_VFRDMARXSNDSHI[n] (0x0001C004 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMARXSNDSHI	15:0	0x0	RW1C	**RDMA Received Sends High** Counts the number of RDMA send messages received by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.139 Protocol Engine Statistics RDMA Transmitted Write Messages Low - GLPES_VFRDMATXWRSLO[n] (0x0001C200 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXWRSLO	31:0	0x0	RW1C	**RDMA Transmitted Writes Low** Counts the number of RDMA write messages transmitted by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.140 Protocol Engine Statistics RDMA Transmitted Write Messages High - GLPES_VFRDMATXWRSHI[n] (0x0001C204 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXWRSHI	15:0	0x0	RW1C	**RDMA Transmitted Writes High** Counts the number of RDMA write messages transmitted by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.141 Protocol Engine Statistics RDMA Transmitted Read Request Messages Low - GLPES_VFRDMATXRDSLO[n] (0x0001C400 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXRDSLO	31:0	0x0	RW1C	**RDMA Transmitted Reads Low** Counts the number of RDMA read request messages transmitted by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.142 Protocol Engine Statistics RDMA Transmitted Read Request Messages High - GLPES_VFRDMATXRDSHI[n] (0x0001C404 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXRDSHI	15:0	0x0	RW1C	**RDMA Transmitted Reads High** Counts the number of RDMA read request messages transmitted by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.143 Protocol Engine Statistics RDMA Transmitted Send Messages Low - GLPES_VFRDMATXSNDSLO[n] (0x0001C600 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXSNDSLO	31:0	0x0	RW1C	**RDMA Transmitted Sends Low** Counts the number of RDMA send messages transmitted by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.144 Protocol Engine Statistics RDMA Transmitted Send Messages High - GLPES_VFRDMATXSNDSHI[n] (0x0001C604 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMATXSNDSHI	15:0	0x0	RW1C	**RDMA Transmitted Sends High** Counts the number of RDMA send messages transmitted by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.145 Protocol Engine Statistics RDMA Verbs Bind Operations Low - GLPES_VFRDMAVBNDLO[n] (0x0001C800 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMAVBNDLO	31:0	0x0	RW1C	**RDMA Verbs Bind Low** Counts the total number of RDMA verb bind operations carried out by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.146 Protocol Engine Statistics RDMA Verbs Bind Operations High - GLPES_VFRDMAVBNDHI[n] (0x0001C804 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMAVBNDHI	15:0	0x0	RW1C	**RDMA Verbs Bind High** Counts the total number of RDMA verb bind operations carried out by the PE. This is the upper 16 bits of the 48-bit counter.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.17.147 Protocol Engine Statistics RDMA Verbs Invalidate Operations Low - GLPES_VFRDMAVINVLO[n] (0x0001CA00 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMAVINVLO	31:0	0x0	RW1C	**RDMA Verbs Invalidate Low** Counts the total number of RDMA verb invalidate operations carried out by the PE. This is the lower 32 bits of the 48-bit counter.

38.39.2.17.148 Protocol Engine Statistics RDMA Verbs Invalidate Operations High - GLPES_VFRDMAVINVHI[n] (0x0001CA04 + 0x8*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
RDMAVINVHI	31:0	0x0	RW1C	**RDMA Verbs Invalidate High** Counts the total number of RDMA verb invalidate operations carried out by the PE. This is the upper 16 bits of the 48-bit counter.

38.39.2.17.149 Protocol Engine Statistics RDMA Received Unaligned FPDUs - GLPES_RDMARXUNALIGN (0x0001E000; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMRXUNALIGN	31:0	0x0	RW1C	**RDMA Received Unaligned** Counts the number of TCP segments received by the PE that probably carried unaligned FPDUs.

38.39.2.17.150 Protocol Engine Statistics RDMA Received Out of Order No Markers FPDUs - GLPES_RDMARXOOONOMARK (0x0001E004; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMAOOONOMARK	31:0	0x0	RW1C	**RDMA Out of Order No Markers** This register counts RDMA FPDUs received by the PE out of order and not carrying markers.

38.39.2.17.151 Protocol Engine Statistics RDMA Received Multiple FPDUs Low - GLPES_RDMARXMULTFPDUSLO (0x0001E010; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMARXMULTFPDUSLO	31:0	0x0	RW1C	**RDMA Received Multiple FPDUs Low** Counts the number of TCP segments received by the PE that probably have multiple FPDUs. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.152 Protocol Engine Statistics RDMA Received Multiple FPDUs High - GLPES_RDMARXMULTFPDUSHI (0x0001E014; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMARXMULTFPDUSHI	23:0	0x0	RW1C	**RDMA Received Multiple FPDUs High** Counts the number of TCP segments received by the PE that probably have multiple FPDUs. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.153 Protocol Engine Statistics RDMA Out of Order Placed DDP Segments Low - GLPES_RDMARXOOODDPLO (0x0001E018; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMARXOOODDPLO	31:0	0x0	RW1C	**RDMA Received Out of Order DDP Low** Counts the number of the DDP segments received by the PE and out order placed. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.154 Protocol Engine Statistics RDMA Out of Order Placed DDP Segments High - GLPES_RDMARXOOODDPHI (0x0001E01C; RW1C)

Field	Bit(s)	Init.	Type	Description
RDMARXOOODDPHI	23:0	0x0	RW1C	**RDMA Received Out of Order DDP High** Counts the number of the DDP segments received by the PE and out order placed. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.155 Protocol Engine Statistics TCP Received Pure Acks Low - GLPES_TCPRXPUREACKSLO (0x0001E020; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXPUREACKLO	31:0	0x0	RW1C	**TCP Received Pure ACKs Low** Counts the number of TCP ACKs received by the PE carrying no data. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.156 Protocol Engine Statistics TCP Received Pure Acks High - GLPES_TCPRXPUREACKHI (0x0001E024; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXPUREACKSHI	23:0	0x0	RW1C	**TCP Received Pure ACKs High** Counts the number of TCP ACKs received by the PE carrying no data. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.157 Protocol Engine Statistics TCP Receive First Hole Low - GLPES_TCPRXONEHOLELO (0x0001E028; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXONEHOLELO	31:0	0x0	RW1C	**TCP Receive One (First) Hole Low** Counts the number of TCP segments received by the PE and opened a first TCP hole in TCP sequence space. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.158 Protocol Engine Statistics TCP Received First Hole High - GLPES_TCPRXONEHOLEHI (0x0001E02C; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXONEHOLEHI	23:0	0x0	RW1C	**TCP Receive One (First) Hole High** Counts the number of TCP segments received by the PE and opened a first TCP hole in TCP sequence space. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.159 Protocol Engine Statistics TCP Receive Second Hole Low - GLPES_TCPRXTWOHOLELO (0x0001E030; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXTWOHOLELO	31:0	0x0	RW1C	**TCP Receive Two (Second) Hole Low** Counts the number of TCP segments received by the PE and opened a second TCP hole in TCP sequence space. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.160 Protocol Engine Statistics TCP Received Second Hole High - GLPES_TCPRXTWOHOLEHI (0x0001E034; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXTWOHOLEHI	23:0	0x0	RW1C	**TCP Receive Two (Second) Hole High** Counts the number of TCP segments received by the PE and opened a second TCP hole in TCP sequence space. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.161 Protocol Engine Statistics TCP Receive Third Hole Low - GLPES_TCPRXTHREEHOLELO (0x0001E038; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXTHREEHOLELO	31:0	0x0	RW1C	**TCP Receive Three (Third) Hole Low** Counts the number of TCP segments received by the PE and opened a third TCP hole in TCP sequence space. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.162 Protocol Engine Statistics TCP Received Third Hole High - GLPES_TCPRXTHREEHOLEHI (0x0001E03C; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXTHREEHOLEHI	23:0	0x0	RW1C	**TCP Receive Three (third) Hole High** Counts the number of TCP segments received by the PE and opened a third TCP hole in TCP sequence space. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.163 Protocol Engine Statistics TCP Receive Fourth Hole Low - GLPES_TCPRXFOURHOLELO (0x0001E040; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXFOURHOLELO	31:0	0x0	RW1C	**TCP Receive Four (Fourth) Hole Low** Counts the number of TCP segments received by the PE and opened a fourth TCP hole in TCP sequence space. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.164 Protocol Engine Statistics TCP Receive Fourth Hole High - GLPES_TCPRXFOURHOLEHI (0x0001E044; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPRXFOURHOLEHI	23:0	0x0	RW1C	**TCP Receive Four (Fourth) Hole High** Counts the number of TCP segments received by the PE and opened a fourth TCP hole in TCP sequence space. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.165 Protocol Engine Statistics TCP Fast Re-transmissions Low - GLPES_TCPTXRETRANSFASTLO (0x0001E048; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXRETRANSFASTLO	31:0	0x0	RW1C	**TCP Re-transmissions Fast Low** Counts the number of TCP fast re-transmissions by the PE. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.166 Protocol Engine Statistics TCP Fast Re-transmissions High - GLPES_TCPTXRETRANSFASTHI (0x0001E04C; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXRETRANSFASTHI	23:0	0x0	RW1C	**TCP Re-transmissions Fast High** Counts the number of TCP fast re-transmissions by the PE. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.167 Protocol Engine Statistics TCP Fast Re-transmissions Timeouts Low - GLPES_TCPTXTOUTSFASTLO (0x0001E050; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXTOUTSFASTLO	31:0	0x0	RW1C	**TCP Re-transmission Timeouts Fast Low** Counts the number of TCP re-transmission timeouts by the PE on the connections attempting fast re-transmit. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.168 Protocol Engine Statistics TCP Fast Re-Transmissions Timeouts High - GLPES_TCPTXTOUTSFASTHI (0x0001E054; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXTOUTSFASTHI	23:0	0x0	RW1C	**TCP Re-transmission Timeouts Fast High** Counts the number of TCP re-transmission timeouts by the PE on the connections attempting fast re-transmit. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.17.169 Protocol Engine Statistics TCP Re-Transmissions Timeouts Low - GLPES_TCPTXTOUTSLO (0x0001E058; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXTOUTSLO	31:0	0x0	RW1C	**TCP Re-transmission Timeouts Low** Counts the number of TCP re-transmission timeouts by the PE on the connections that are not currently attempting fast re-transmit. This is the lower 32 bits of the 56-bit counter.

38.39.2.17.170 Protocol Engine Statistics TCP Re-Transmissions Timeouts High - GLPES_TCPTXTOUTSHI (0x0001E05C; RW1C)

Field	Bit(s)	Init.	Type	Description
TCPTXTOUTSHI	23:0	0x0	RW1C	**TCP Re-transmission Timeouts High** Counts the number of TCP re-transmission timeouts by the PE on the connections that are not currently attempting fast re-transmit. This is the upper 24 bits of the 56-bit counter.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.18 PF - LAN Transmit Receive Registers

38.39.2.18.1 Global TSO TCP Mask First - GLLAN_TSOMSK_F (0x000442D8; RW)

Field	Bit(s)	Init.	Type	Description
TCPMSKF	11:0	0x0	RW	**TCP Mask First** TCP flags mask for the first segment in the TSO. Any bit set to one in the *TCPMSK* field clears the respective TCP flag in the TSO. Bit 0 relates to *FIN* flag, bit 1 relates to the *SYN* flag and so on.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.18.2 Global TSO TCP Mask Middle - GLLAN_TSOMSK_M (0x000442DC; RW)

Field	Bit(s)	Init.	Type	Description
TCPMSKM	11:0	0x0	RW	**TCP Mask Middle** TCP flags mask for the middle segments in the TSO. See *TCPMSKF* in Section 38.39.2.18.1 for the impact of each bit in the field.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.18.3 Global TSO TCP Mask Last - GLLAN_TSOMSK_L (0x000442E0; RW)

Field	Bit(s)	Init.	Type	Description
TCPMSKL	11:0	0x0	RW	**TCP Mask Last** TCP flags mask for the middle segments in the TSO. See *TCPMSKF* in Section 38.39.2.18.1 for the impact of each bit in the field.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.18.4 Receive Processing Block Control - GL_RDPU_CNTRL (0x00051060; RW)

Field	Bit(s)	Init.	Type	Description
RX_PAD_EN	0	1b	RW	**Receive Pad Enable** Pad Rx packets with zeros that do not include CRC or the CRC is stripped to be at least 60 bytes long. ***Note:*** Padding and CRC stripping for EMP packets is always done regardless of the setting of this flag.
ECO	31:1	0xFFFF	RW	**ECO** Reserved for future ECO.

38.39.2.18.5 VF PF Queue Mapping Table - VPLAN_QTABLE[n,VF] (0x00070000 + 0x400*n + 0x4*VF, n=0...15, VF=0...127; RW)

This register affects the VF, but is exposed only to the parent PF.

Field	Bit(s)	Init.	Type	Description
QINDEX	10:0	0x7FF	RW	**Queue Index** Defines the index of VF queue 'n' in the PF queues space, where 'n' is the register index. Setting the *QINDEX* to 0x7FF means that the queue is not valid for the VF. Relevant only if VPLAN_QBASE.*VFQTABLE_ENA* is set to 1b (see Section 38.39.2.18.7).
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.18.6 VF LAN Enablement - VPLAN_MAPENA[VF] (0x00074000 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
TXRX_ENA	0	0b	RW	**Transmit/Receive Enable** The VFLAN_QTABLE for the VF is enabled only when the *TXRX_ENA* flag is set.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.18.7 VF PF Queue Range - VPLAN_QBASE[VF] (0x00074800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
VFFIRSTQ	10:0	0x0	RW	**VF First Queue** Defines the base index of VF 'n' within the range of the PF queues, where 'n' is the VF register index. The *VFFIRSTQ* is meaningful for this VSI only if the *VFQTABLE_ENA* is cleared.
VFNUMQ	18:11	0x0	RW	**VF Number of Queues** Defines the number of queues allocated to VF 'n' within the range of the PF queues, where 'n' is the VF register index. The value should be set to the number of queues -1 (a value of 0 means 1 queue and a value of 255 means 256 queues). The *VFNUMQ* is meaningful for this VSI only if the *VFQTABLE_ENA* is cleared.
RESERVED	30:19	0x0	RSV	Reserved.
VFQTABLE_ENA	31	1b	RW	**VF Queue Table Enable** Selects between contiguous range of queues for this VSI versus a scattered range. 0b = The VF is assigned a contiguous range starting at VFBASE 1b = The VF is assigned a scattered range defined by the VFLAN_QTABLE

38.39.2.18.8 Global Transmit Queue Head - QTX_HEAD[Q] (0x000E4000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	31:0	0x0	RSV	Reserved.

38.39.2.18.9 Global Transmit Pre Queue Disable - GLLAN_TXPRE_QDIS[n] (0x000E6500 + 0x4*n, n=0...11; RW)

Field	Bit(s)	Init.	Type	Description
QINDX	10:0	0x0	RW	**Queue Index** Absolute index in the device space. Each register 'n' covers 128*n-128*n-1 queues. Software is expected to use the matched register when accessing a specific queue.
RESERVED	29:11	0x0	RSV	Reserved.
SET_QDIS	30	0b	RW	**Set Queue Disable** Setting this flag to 1b sets an internal *QDIS* flag of the transmit queue (that is indicated by *QINDX* field in this register). As a result, any accumulated quanta of the queue are invalidated, which is a needed step before the queue is disabled. Setting the *SET_QDIS* flag is mutually exclusive with the *CLEAR_QDIS* flag.
CLEAR_QDIS	31	0b	RW	**Clear Queue Disable** Setting this flag to 1b clears an internal QDIS flag of the transmit queue (that is indicated by *QINDX* field in this register). This step should be made before the queue is enabled. Setting the *CLEAR_QDIS* flag is mutually exclusive with the *SET_QDIS* flag.

38.39.2.18.10 Global Transmit Queue Enable - QTX_ENA[Q] (0x00100000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
QENA_REQ	0	0b	RW	**Transmit Queue Enable Request** If this bit is set, the software should poll the *QENA_STAT* flag (in this register) before using the queue. After clearing this flag, the software should poll the *QENA_STAT* flag before releasing the memory structures. Once software changes the state of the *QENA_REQ* flag, it must poll the *QENA_STAT* before it is permitted to revert the state of the *QENA_REQ* once again.
FAST_QDIS	1	0b	RW	**Fast Queue Disable** See the Fast Transmit Queue Disable Flow section for the usage of this flag.
QENA_STAT	2	0b	RO	**Transmit Queue Enable Status Indication** 0b = Indicates that the queue is inactive. 1b = Indicates that the queue is active.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.18.11 Global Transmit Queue Control - QTX_CTL[Q] (0x00104000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
PFVF_Q	1:0	00b	RW	**PF/VF Queue** Queue association to PF or VF as follows: 00b = VF queue. 01b = VM queue. 10b = PF queue. 11b = Reserved.
PF_INDX	5:2	0x0	RW	**PF Index** Index between 0 and 15.
RESERVED	6	0b	RSV	Reserved.
VFVM_INDX	15:7	0x0	RW	**VF/VM Index** Should be programmed per PFVF_Q setting as follows: **PFVF_Q Setting** — **Matched VF/VM Index Programming** 00b = VF queue — The absolute VF index (between 0-127). 01b = VM queue — The absolute VSI index (between 0-383). Else = PF or EMP queue — Must be set to zero.
RESERVED	31:16	0x0	RSV	Reserved

38.39.2.18.12 Global Transmit Queue Tail - QTX_TAIL[Q] (0x00108000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	**Transmit Tail** Defines the first descriptor that the software prepares for the hardware (it is the last valid descriptor plus one). The tail is a relative descriptor index to the beginning of the transmit descriptor ring.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.18.13Global Receive Queue Enable - QRX_ENA[Q] (0x00120000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
QENA_REQ	0	0b	RW	**Receive Queue Enable Request** If this bit is set, the software should poll the *QENA_STAT* flag (in this register) before using the queue. After clearing this flag, the software should poll the *QENA_STAT* flag before releasing the memory structures. Once software changes the state of the *QENA_REQ* flag it must poll the *QENA_STAT* before it is permitted to revert the state of the *QENA_REQ* once again.
FAST_QDIS	1	0b	RW1C	**Fast Queue Disable** See the Fast Receive Queue Disable Flow section for the usage of this flag. This flag is auto-cleared by hardware.
QENA_STAT	2	0b	RO	**Receive Queue Enable Status Indication** 0b = Indicates that the queue is inactive. 1b = Indicates that the queue is active.
RESERVED	31:3	0x0	RSV	Reserved.

38.39.2.18.14Global Receive Queue Tail - QRX_TAIL[Q] (0x00128000 + 0x4*Q, Q=0...1535; RW)

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	**Receive Tail** Defines the first descriptor that software hands to hardware (it is the last valid descriptor plus one). The tail is a relative descriptor index to the beginning of the receive descriptor ring.
RESERVED	31:13	0x0	RSV	Reserved.

38.39.2.18.15Global RLAN Control 0 - GLLAN_RCTL_0 (0x0012A500; RW1C)

Field	Bit(s)	Init.	Type	Description
PXE_MODE	0	1b	RW1C	**PXE Mode** When this flag is set, the device fetches and writes back a single descriptor at a time. During normal performance operation, (non-PXE mode) this flag must be cleared.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.18.16PF Queue Allocation - PFLAN_QALLOC (0x001C0400; RO)

These registers define the LAN queue pairs allocation to the PFs.

Field	Bit(s)	Init.	Type	Description
FIRSTQ	10:0	0x0	RW	**First Queue** The first LAN queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-1535.
RESERVED	15:11	0x0	RSV	Reserved.
LASTQ	26:16	0x0	RW	**Last Queue** The last LAN queue pair allocated to this PF. Valid only if the *VALID* flag is set. Valid values are 0-1535.
RESERVED	30:27	0x0	RSV	Reserved.
VALID	31	0b	RW	**Valid** Indicates that queues are allocated to this PF. For any active PF this flag must be set.

38.39.2.18.17 VSI Receive Queue Mapping Table - VSILAN_QTABLE[n,VSI] (0x00200000 + 0x800*n + 0x4*VSI, n=0...7, VSI=0...383; RO)

Field	Bit(s)	Init.	Type	Description
QINDEX_0	10:0	0x0	RW	**Queue Index 0** Defines the index of the VSI queue '2*n' in the PF queues space, where 'n' is the register index. The absolute queue index in the device space equals *QINDEX* plus PFLAN_QALLOC.*FIRSTQ* of the parent PF. Setting the *QINDEX* to 0x7FF means the queue is not valid.
RESERVED	15:11	0x0	RSV	Reserved.
QINDEX_1	26:16	0x0	RW	**Queue Index 1** Defines the index of the VSI queue '2*n+1' in the PF queues space, where 'n' is the register index. The absolute queue index in the device space equals to *QINDEX* plus PFLAN_QALLOC.*FIRSTQ* of the parent PF. Setting the *QINDEX* to 0x7FF means the queue is not valid.
RESERVED	31:27	0x0	RSV	Reserved.

38.39.2.18.18 VSI Queue Control - VSILAN_QBASE[VSI] (0x0020C800 + 0x4*VSI, VSI=0...383; RO)

Field	Bit(s)	Init.	Type	Description
VSIBASE	10:0	0x0	RW	**VSI Base** Defines the base index of VSI 'n' within the range of the PF queues, where 'n' is the VSI register index. The *VSIBASE* is meaningful for this VSI only if the *VSIQTABLE_ENA* is cleared.
VSIQTABLE_ENA	11	0b	RW	**VSI Queue Table Enable** Selects between contiguous range of queues for this VSI vs. scattered range: 0b = The VSI is assigned a contiguous range starting at *VSIBASE*. 1b = The VSI is assigned a scattered range defined by the *VSILAN_QTABLE*.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.19 PF - Rx Filters Registers

38.39.2.19.1 VF Queue Filter Control - VPQF_CTL[VF] (0x001C0000 + 0x4*VF, VF=0...127; RO)

This register affects the VF, but is exposed only to the parent PF.

Field	Bit(s)	Init.	Type	Description
PEHSIZE	4:0	0x0	RW	**PE Hash Size** Defines the number of buckets of the PE quad hash filter table for the VF. It is defined in power of 2 equal to 1K x 2 ** *PEHSIZE*. *PEHSIZE* can have any value between 0 and 10. *PEHSIZE* = 0, 1,... 10 is equivalent to 1 K, 2 K, 4 K... 1 M buckets.
PEDSIZE	9:5	0x0	RW	**PEDSIZE** Defines the number of PE quad hash contexts for the VF. It is defined in power of 2 equal to 0.5K x 2 ** *PEDSIZE*. *PEDSIZE* can have any value between 0 and 9. *PEHSIZE* = 0, 1,... 9 is equivalent to 0.5 K, 1 K, 2 K, 4 K... 256 K contexts.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.19.2 PF Queue Filter Control 0 - PFQF_CTL_0 (0x001C0AC0; RW)

Settings in this register allow the hardware to auto-clear internal table pointers, as well as the internal PE Quad Hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	Description
RESERVED	9:0	0x0	RSV	Reserved.
PFFCHSIZE	15:10	0x0	RW	Reserved.
HASHLUTSIZE	16	0b	RW	**Hash LUT Size** Defines the size of the Hash LUT as follows: 128 512
FD_ENA	17	0b	RW	**Flow Director Enable** Enable flow director filters for the PF and its VFs.
ETYPE_ENA	18	0b	RW	**EtherType Enable** Enable EtherType queue filters for the PF and its VFs.
MACVLAN_ENA	19	0b	RW	**MAC/LAN Enable** Enable MAC/VLAN queue filters for the PF and its VFs.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.19.3 VSI Receive Traffic Class Queues - VSIQF_TCREGION[n,VSI] (0x00206000 + 0x800*n + 0x4*VSI, n=0...3, VSI=0...383; RO)

Field	Bit(s)	Init.	Type	Description
TC_OFFSET	8:0	0x0	RW	**Traffic Class Offset** Indicates the relative queue index to the beginning of the VSI that the TC '2*n' uses, where 'n' is the register index. Hardware does not check if the queue index exceeds the VSI range. It is the responsibility of PF software to ensure that *TC_SIZE* + *TC_OFFSET* does not exceed the VSI range.
TC_SIZE	11:9	000b	RW	**Traffic Class Size** Indicates the number of receive queues allocated to TC '2*n' for the VSI, where 'n' is the register index. The *TC_SIZE* field can have a value of 0 to 7, which means any of the following respective number of allocated queues: 000b = 1. 001b = 2. 010b = 4. 011b = 8. 100b = 16. 101b = 32. 110b = 64. 111b = 128.
RESERVED	15:12	0x0	RSV	Reserved.
TC_OFFSET2	24:16	0x0	RW	**Traffic Class Offset 2** Indicates the relative queue index to the beginning of the VSI that the TC '2*n+1' uses, where 'n' is the register index. Hardware does not check if the queue index exceeds the VSI range. It is the responsibility of PF software to ensure that *TC_SIZE2* + *TC_OFFSET2* does not exceeds the VSI range.

Field	Bit(s)	Init.	Type	Description
TC_SIZE2	27:25	000b	RW	**Traffic Class Size 2** Indicates the number of receive queues allocated to TC '2*n+1' for the VSI, where 'n' is the register index. The TC_SIZE2 field can have any value of 0 to 7, which means any of the following respective number of allocated queues: 000b = 1. 001b = 2. 010b = 4. 011b = 8. 100b = 16. 101b = 32. 110b = 64. 111b = 128.
RESERVED	31:28	0x0	RSV	Reserved.

38.39.2.19.4 VSI Queue Filter Control - VSIQF_CTL[VSI] (0x0020D800 + 0x4*VSI, VSI=0...383; RO)

38.39.2.19.9 PF Queue Filter Hash Region of Queues - PFQF_HREGION[n] (0x00245400 + 0x80*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	Description
OVERRIDE_ENA_0	0	0b	RW	**Override Enable 0** Override TC region for packet type '8* n', where 'n' is the register index.
REGION_0	3:1	000b	RW	**Region 0** Receive queue region for packet type '8*n', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_1	4	0b	RW	**Override Enable 1** Override TC region for packet type '8*n+1', where 'n' is the register index.
REGION_1	7:5	000b	RW	**Region 1** Receive queue region for packet type '8*n+1', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_2	8	0b	RW	**Override Enable 2** Override TC region for packet type '8*n+2', where 'n' is the register index.
REGION_2	11:9	000b	RW	**Region 2** Receive queue region for packet type 8*n+2', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_3	12	0b	RW	**Override Enable 3** Override TC region for packet type '8*n+3', where 'n' is the register index.
REGION_3	15:13	000b	RW	**Region 3** Receive queue region for packet type '8*n+3', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_4	16	0b	RW	**Override Enable 4** Override TC region for packet type '8*n+4', where 'n' is the register index.
REGION_4	19:17	000b	RW	**Region 4** Receive queue region for packet type '8*n+4', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_5	20	0b	RW	**Override Enable 5** Override TC region for packet type '8*n+5', where 'n' is the register index.

Field	Bit(s)	Init.	Type	Description
REGION_5	23:21	000b	RW	**Region 5** Receive queue region for packet type '8*n+5', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_6	24	0b	RW	**Override Enable 6** Override TC region for packet type '8*n+6', where 'n' is the register index.
REGION_6	27:25	000b	RW	**Region 6** Receive queue region for packet type '8*n+6', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.
OVERRIDE_ENA_7	28	0b	RW	**Override Enable 7** Override TC region for packet type '8*n+7', where 'n' is the register index.
REGION_7	31:29	000b	RW	**Region 7** Receive queue region for packet type '8*n+7', where 'n' is the register index. This field is meaningful only if the OVERRIDE_ENA_1 flag is set.

38.39.2.19.10PF Queue Filter Hash Enabled Packet Type - PFQF_HENA[n] (0x00245900 + 0x80*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
PTYPE_ENA	31:0	0x0	RW	**Packet Type Enable** Packet type enablement of the hash filter for the function. Bit 'm' in register 'n' enables packet type '32*n+m' as defined in the Packet Types for the Classification Filters table.

38.39.2.19.11PF Queue Filter Control 1 - PFQF_CTL_1 (0x00245D80; RW)

Field	Bit(s)	Init.	Type	Description
CLEARFDTABLE	0	0b	RW1C	**Clear Flow Director Table** If software sets this flag, hardware invalidates all entries of the PF in the FD table. Once all entries of the PF are invalidated, this flag is cleared as well.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.19.12PF Queue Filter Flow Director Allocation - PFQF_FDALLOC (0x00246280; RW)

Field	Bit(s)	Init.	Type	Description
FDALLOC	7:0	0x0	RW	**Flow Director Allocation** Defines the number of guaranteed entries in the FD table. It is defined in granularity of 32 entries.
FDBEST	15:8	0x0	RW	**Flow Director Best Effort** Defines the maximum number of entries the PF can consume from the shared space. It is defined in granularity of 32 entries.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.19.13PF Queue Filter Flow Director Allocation Status - PFQF_FDSTAT (0x00246380; RO)

Field	Bit(s)	Init.	Type	Description
GUARANT_CNT	12:0	0x0	RO	**Guaranteed Count** Indicates the number of FD entries consumed by the PF out of its guaranteed space.
RESERVED	15:13	000b	RSV	Reserved.
BEST_CNT	28:16	0x0	RO	**Best Effort Count** Indicates the number of FD entries consumed by the PF out of its best effort space.
RESERVED	31:29	000b	RSV	Reserved.

38.39.2.19.14Port Queue Filter Flow Director Input Set - PRTQF_FD_FLXINSET[n] (0x00253800 + 0x20*n, n=0...63; RW)

Field	Bit(s)	Init.	Type	Description
INSET	7:0	0x0	RW	**Inset** Bit 'i' of *INSET* enables word 7 minus 'i' of the flexible payload in the field vector.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.19.15Port Queue Filter - Flexible Parser Information Table - PRTQF_FLX_PIT[n] (0x00255200 + 0x20*n, n=0...8; RW)

These registers define the byte stream extracted to the field vector (unique setting option per LAN port).

Field	Bit(s)	Init.	Type	Description
SOURCE_OFF	4:0	0x0	RW	**Source Offset** Source word offset in the mapped protocol layer header starting from its beginning. Setting Source Offset rules: • *SOURCE_OFF* + *FSIZE* should not exceed byte 480 of the packet. • Must be programmed in ascending order: Current Offset >= previous offset + previous *FSIZE*. • The previous rule applies for all entries, including non-used ones.
FSIZE	9:5	0x0	RW	**Field Size** Defined in word units. A zero value means that this register has no impact. For non used registers, this field should be set to 1.
DEST_OFF	15:10	0x0	RW	**Destination Offset** Destination word offset in the Field Vector. The destination offset can be set to 50...57 matching offset 0...7 in the flexible field vector, respectively, where *DEST_OFF* + *FSIZE* must not be greater than 58. For non-used registers the *DEST_OFF* must be set to 0x63 (outside of active entries).
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.19.16Port Queue Filter Control 0 - PRTQF_CTL_0 (0x00256E60; RW)

Field	Bit(s)	Init.	Type	Description
HSYM_ENA	0	0b	RW	**Symmetric Hash Enable** Enable symmetric hash for this physical port.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.19.17Global Queue Filter Accelerated Port Bit Vector - GLQF_APBVT[n] (0x00260000 + 0x4*n, n=0...2047; RO)

Field	Bit(s)	Init.	Type	Description
APBVT	31:0	0x0	RW	**Accelerated Port Bit Vector** Each bit 'i' in the APBVT or register 'n' enables port number 32 x 'n' + 'i'.

38.39.2.19.18Global Queue Filter Packet Counter - GLQF_PCNT[n] (0x00266800 + 0x4*n, n=0...511; RW1C)

Field	Bit(s)	Init.	Type	Description
PCNT	31:0	0x0	RW1C	**Packet Counter** Packet counter indicated by the FD filter(s). The counter wraps around after 0xFF...F.

38.39.2.19.19Global Queue Filter SWAP Fields - GLQF_SWAP[n,m] (0x00267E00 + 0x4*n + 0x8*m, n=0...1, m=0...63; RW)

Field	Bit(s)	Init.	Type	Description
OFF0_SRC0	5:0	0x0	RW	**Offset 0/Source 0** Offset of the first field of the first couple in the field vector to be swapped. The offset is defined in word units.
OFF0_SRC1	11:6	0x0	RW	**Offset 0/Source 1** Offset of the second field of the first couple in the field vector to be swapped. The offset is defined in word units.
FLEN0	15:12	0x0	RW	**Field Length 0** (in word units) When the *FLEN0* is set to zero, the fields defined by *OFF0* are not candidates for swapping.
OFF1_SRC0	21:16	0x0	RW	**Offset 1/Source 0** Offset of the first field of the second couple in the field vector to be swapped. The offset is defined in word units.
OFF1_SRC1	27:22	0x0	RW	**Offset 1/Source 1** Offset of the second field of the second couple in the field vector to be swapped. The offset is defined in word units.
FLEN1	31:28	0x0	RW	**Field Length 1** (in word units) When the *FLEN1* is set to zero, the fields defined by *OFF1* are not candidates for swapping.

38.39.2.19.20 Flow Director PCTYPE Translation Table - GLQF_FD_PCTYPES[n] (0x00268000 + 0x4*n, n=0...63; RW)

For each PCTYPE, this table defines the target PCTYPE to be used for flow director processing.

Field	Bit(s)	Init.	Type	Description
FD_PCTYPE	5:0	0x0	RW	**Flow Directory PCTYPE** Defines the PCTYPE to be used for FD processing if the incoming packet is mapped to PCTYPE #n. By default, an identity mapping is used (default value of filter #n is n).
RESERVED	31:6	0x0	RSV	Reserved.

38.39.2.19.21 Global Queue Filter Control - GLQF_CTL (0x00269BA4; RO)

Field	Bit(s)	Init.	Type	Description
RESERVED	0	0b	RSV	Reserved.
HTOEP	1	0b	RW	**Hash Toeplitz** Hash Toeplitz select for all packet types. 0b = The hash filters are based on a simple 32 bit XOR. 1b = The hash filters are based on the standard Toeplitz scheme, where the hash key is defined per function by the xxQFHKEY registers.
RESERVED	2	0b	RW	**Reserved.**
PCNT_ALLOC	5:3	000b	RW	**Packet Counters Allocation** Controls the GLQF_PCNT counters allocation to the PF as follows: 000b = All counters are exposed to all PFs. 100b = Each PF is allocated 1/2 of the GLQF_PCNT counters. 101b = Each PF is allocated 1/4 of the GLQF_PCNT counters. 110b = Each PF is allocated 1/8 of the GLQF_PCNT counters. 111b = Each PF is allocated 1/16 of the GLQF_PCNT counters. All other values are reserved.
FD_AUTO_PCTYPE	6	0b	RW	**Flow Director Auto PCTYPE** 0b = The *PCTYPE* of FD filter entries are defined by the *PCTYPE* field in the FD programming descriptor. 1b = The *PCTYPE* of FD filter entries are extracted from the programming packet, the same as it is done for received packets.
RESERVED	16:7	0b	RSV	Reserved.
FDBEST	24:17	0x0	RW	**Flow Director Best Effort** Defines the total number of entries in the FD table. It must not exceed the FD table size (equal to 8 KB) minus the sum of *FDALLOC* for all PFs. The global *FDBEST* is defined in granularity of 32 entries.
PROGPRIO	25	0b	RW	**Programming Priority** Priority ordering at filter programming between best effort space and guaranteed space. 0b = At filter programming, hardware tries the guaranteed space first. Only when it is exhausted, does the hardware use the best effort space. 1b = At filter programming, hardware tries the best effort space first. Only when it is exhausted or the PF exhausted its budget in the best effort space, does the hardware use the guaranteed space.

Field	Bit(s)	Init.	Type	Description
INVALPRIO	26	0b	RW	**Invalid Priority** Priority ordering at filter invalidation between best effort space and guaranteed space. 0b = At filter invalidation, hardware first tries to increment the best effort space. The guaranteed space is incremented only when the global best effort space is at it maximum value, or the best effort space of the PF is at its maximum value. 1b = At filter invalidation, hardware first tries to increment its guaranteed space. The best effort space is incremented only when it is already at its maximum value.
IGNORE_IP	27	0b	RW	**Ignore IP** PE quad hash filters ignore (bypass) the IP address table hit/miss indication.
RESERVED	31:28	0x0	RSV	Reserved.

38.39.2.19.22 Global Queue Filter Flow Director Status 0 - GLQF_FDCNT_0 (0x00269BAC; RO)

Field	Bit(s)	Init.	Type	Description
GUARANT_CNT	12:0	0x0	RO	**Guaranteed Count** Total number of FD entries in guaranteed spaces of all PFs.
BESTCNT	25:13	0x0	RO	**Best Effort Count** Total number of FD entries in the best effort space.
RESERVED	31:26	0x0	RSV	Reserved.

38.39.2.19.23 Global Queue Filter Symmetric Hash Enablement - GLQF_HSYM[n] (0x00269D00 + 0x4*n, n=0...63; RW)

Field	Bit(s)	Init.	Type	Description
SYMH_ENA	0	0b	RW	**Symmetric Hash Enable** Enables symmetric hash for PCTYPE ‘n’, where ‘n’ is the register index.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.19.24 Global Queue Filter Hash Key - GLQF_HKEY[n] (0x00270140 + 0x4*n, n=0...12; RW)

Field	Bit(s)	Init.	Type	Description
KEY_0	7:0	0x0	RW	**Key 0** Toeplitz key byte ‘4*n+0’, where ‘n’ is the register index.
KEY_1	15:8	0x0	RW	**Key 1** Toeplitz key byte ‘4*n+1’, where ‘n’ is the register index.
KEY_2	23:16	0x0	RW	**Key 2** Toeplitz key byte ‘4*n+2’, where ‘n’ is the register index.
KEY_3	31:24	0x0	RW	**Key 3** Toeplitz key byte ‘4*n+3’, where ‘n’ is the register index.

38.39.2.19.25PF Queue Filter Control 2 - PFQF_CTL_2 (0x00270300; RO)

Settings in this register enables hardware to auto-clear internal table pointers, as well as the internal PE quad hash context counter and table pointers of the function.

Field	Bit(s)	Init.	Type	Description
PEHSIZE	4:0	0x0	RW	**PE Hash Size** Defines the number of buckets of the PE quad hash filter table for the VF. It is defined in power of 2 equal to 1 K x 2 ** *PEHSIZE*. The *PEHSIZE* can have any value between 0 and 10. *PEHSIZE* = 0, 1,... 10 is equivalent to 1 K, 2 K, 4 K... 1 M buckets.
PEDSIZE	9:5	0x0	RW	**PEDSIZE** Defines the number of PE quad hash contexts for the VF. It is defined in power of 2 equal to 0.5K x 2 ** *PEDSIZE*. The *PEDSIZE* can have any value between 0 and 9. *PEHSIZE* = 0, 1,... 9 is equivalent to 0.5 K, 1 K, 2 K, 4 K... 256 K contexts.
RESERVED	31:10	0x0	RSV	Reserved.

38.39.2.19.26Global Flow Director PCTYPE Evict Enable - GLQF_FDEVICTENA[n] (0x00270384 + 0x4*n, n=0...1; RW)

Defines the PCTYPES which are candidates for hardware eviction of flow director filters.

Field	Bit(s)	Init.	Type	Description
GLQF_FDEVICTENA	31:0	0x0	RW	**Flow Director Eviction Enable** Defines if a packet matching this PCTYPE is candidate to filter eviction. • For register 'n'=0, any bit 'k' relates to line item 'k' in the Protocol Layers Table. • For register 'n'=1, any bit 'k' relates to line item 32+ 'k' in the Protocol Layers Table.

38.39.2.19.27Global Flow Director Flag Evict Enable - GLQF_FDEVICTFLAG (0x00270280; RW)

Field	Bit(s)	Init.	Type	Description
TX_FLAGS	7:0	0x05	RW	**Transmit Flags** Defines the TCP flags that a Tx packet should match to cause an ATR filter removal: 0 = FIN. 1 = SYN. 2 = Reset. 3 = Push. 4 = ACK. 5 = Urgent flag. 7:6 = Reserved.
RX_FLAGS	15:8	0x05	RW	**Receive Flags** Defines the TCP flags that a Rx packet should match to cause an ATR filter removal: 0 = FIN. 1 = SYN. 2 = Reset. 3 = Push. 4 = ACK. 5 = Urgent flag. 7:6 = Reserved.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.19.28VSI Queue Filter Hash Key - VSIQF_HKEY[n,VSI] (0x002A0000 + 0x800*n + 0x4*VSI, n=0...12, VSI=0...383; RW)

Field	Bit(s)	Init.	Type	Description
KEY_0	7:0	0x0	RW	**Key 0** Toeplitz key byte '4*n+0', where 'n' is the register index.
KEY_1	15:8	0x0	RW	**Key 1** Toeplitz key byte '4*n+1', where 'n' is the register index.
KEY_2	23:16	0x0	RW	**Key 2** Toeplitz key byte '4*n+2', where 'n' is the register index.
KEY_3	31:24	0x0	RW	**Key 3** Toeplitz key byte '4*n+3', where 'n' is the register index.

38.39.2.20 PF - Timesync (IEEE 1588) Registers

38.39.2.20.1 Port Time Sync Control 1 - PRTTSYN_CTL1 (0x00085020; RW)

Field	Bit(s)	Init.	Type	Description
V1MESSTYPE0	7:0	0x01	RW	**V1 Message Type 0** PTP V1 message type 0 for sampled time stamp of received 1588 packets. Default setting is 0x01 for sync and Delay_Req packets. Setting this field to 0xFF is like a wild card option, enabling all PTP V1 packets.
V1MESSTYPE1	15:8	0x01	RW	**V1 Message Type 1** PTP V1 message type 1 for sampled time stamp of received 1588 packets. Default setting is 0x01 for Sync and Delay_Req packets. Setting this field to 0xFF is like a wild card option, enabling all PTP V1 packets.
V2MESSTYPE0	19:16	0x0	RW	**V2 Message Type 0** PTP V2 message type 0 for sampled timestamp of received 1588 packets. Default setting is 0x0 for sync packets. Other values are: 0x1 = Delay Req. 0x2 = Pdelay Req. 0x3 = Pdelay Resp. Setting this field to 0xF is like a wild card option, enabling all PTP V2 packets.
V2MESSTYPE1	23:20	0x1	RW	**V2 Message Type 1** PTP V2 message type 1 for sampled time stamp of received 1588 packets. Default setting is 0x1 for delay request.
TSYNTYPE	25:24	00b	RW	**Time Sync Type** Receive packets types sampled by the 1588 timer. 00b = L2 version 2 packets (message type is defined by the PRTTSYN_CTL1 register). 01b = UDP version 1 packets (UDP ports are enabled by *UDP_ENA* field in this register and *Message Type* field is defined by the PRTTSYN_CTL1 register). 10b = L2 and UDP version 2 packets (UDP ports are enabled by *UDP_ENA* field in this register and message type is defined by the PRTTSYN_CTL1 register). 11b = L2 and UDP version 2 event packets (UDP ports are enabled by *UDP_ENA* field in this register and message type < 8).
UDP_ENA	27:26	00b	RW	**UDP Enable** Enable the UDP ports recognized as 1588 packets. 00b = No UDP packet recognition. 01b = UDP port number equals to 0x013F. 10b = UDP port number equals to 0x0140. 11b = UDP port numbers equals to either 0x013F or 0x140.
RESERVED	30:28	000b	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
TSYNENA	31	0b	RW	**Time Sync Enable** Enable the 1588 logic. When the *TSYNENA* flag is cleared, the 1588 logic is not functional. This flag must be set the same as the *TSYNENA* flag in the PRTTSYN_CTL0 register (Section 38.39.2.20.15).

38.39.2.20.2 Port Time Sync Receive PTP Packet Time High - PRTTSYN_RXTIME_H[n] (0x00085040 + 0x20*n, n=0...3; RO)

Field	Bit(s)	Init.	Type	Description
RXTIME_H	31:0	0x0	RO	**Receive Time High** 32 MS bits of the receive PTP packet time matches the units of the TSYN_TIME_H register (Section 38.39.2.20.10).

38.39.2.20.3 Port Time Sync Receive PTP Packet Time Low - PRTTSYN_RXTIME_L[n] (0x000850C0 + 0x20*n, n=0...3; RO)

Field	Bit(s)	Init.	Type	Description
RXTIME_L	31:0	0x0	RO	**Receive Time Low** 32 LS bits of the receive PTP packet time matches the units of the TSYN_TIME_L register (Section 38.39.2.20.9).

38.39.2.20.4 Port Time Sync Status 1 - PRTTSYN_STAT_1 (0x00085140; RO)

Field	Bit(s)	Init.	Type	Description
RXT0	0	0b	RO	**Receive Timestamp 0** PRTTSYN_RXTIME[0] register contains valid timestamp. This bit is set by hardware when received packet reception time is captured in the PRTTSYN_RXTIME[0] register, and it is auto-cleared when software reads the PRTTSYN_RXTIME[0] register.
RXT1	1	0b	RO	**Receive Timestamp 1** PRTTSYN_RXTIME[1] register contains valid timestamp. This bit is set by hardware when received packet reception time is captured in the PRTTSYN_RXTIME[1] register, and it is auto-cleared when software reads the PRTTSYN_RXTIME[1] register.
RXT2	2	0b	RO	**Receive Timestamp 2** PRTTSYN_RXTIME[2] register contains valid timestamp. This bit is set by hardware when received packet reception time is captured in the PRTTSYN_RXTIME[2] register, and it is auto-cleared when software reads the PRTTSYN_RXTIME[2] register.
RXT3	3	0b	RO	**Receive Timestamp 3** PRTTSYN_RXTIME[3] register contains valid timestamp. This bit is set by hardware when received packet reception time is captured in the PRTTSYN_RXTIME[3] register. and it is auto-cleared when software reads the PRTTSYN_RXTIME[3] register.
RESERVED	31:4	0x0	RSV	Reserved.

38.39.2.20.5 Port Time Sync Increment Value Low - PRTTSYN_INC_L (0x001E4040; RW)

Field	Bit(s)	Init.	Type	Description
TSYNINC_L	31:0	0x0	RW	**Time Sync Increment Low** 32 LS bits of the increment value added to the 96-bit TSYNTIME registers for each MAC clock.

38.39.2.20.6 Port Time Sync Increment Value High - PRTTSYN_INC_H (0x001E4060; RW)

Field	Bit(s)	Init.	Type	Description
TSYNINC_H	5:0	0x0	RW	**Time Sync Increment High** 6 MS bits of the increment value added to the 96-bit TSYNTIME registers for each MAC clock.
RESERVED	31:6	0x0	RSV	Reserved.

38.39.2.20.7 Port Time Sync Event Time Low - PRTTSYN_EVNT_L[n] (0x001E4080 + 0x20*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	Description
TSYNEVNT_L	31:0	0x0	RO	**Time Synch Event Time Low** 32 LS bit of the sampled event time. The sampled event is defined by *EVNTLVL* field in the PRTTSYN_AUX_0 register (Section 38.39.2.20.19).

38.39.2.20.8 Port Time Sync Event Time High - PRTTSYN_EVNT_H[n] (0x001E40C0 + 0x20*n, n=0...1; RO)

Field	Bit(s)	Init.	Type	Description
TSYNEVNT_H	31:0	0x0	RO	**Time Synch Event Time High** 32 MS bit of the sampled event time of a 1588 event defined by the PRTTSYN_AUX_0 register (Section 38.39.2.20.19).

38.39.2.20.9 Port Time Sync Time Low - PRTTSYN_TIME_L (0x001E4100; RW)

Field	Bit(s)	Init.	Type	Description
TSYNTIME_L	31:0	0x0	RW	**Time Synch Time Low** Bits 32...63 of the 96-bit timer. If the lowest 32 bits define the fraction of ns, this register defines the lower 32 bits of the ns units.

38.39.2.20.10 Port Time Sync Time High - PRTTSYN_TIME_H (0x001E4120; RW)

Field	Bit(s)	Init.	Type	Description
TSYNTIME_H	31:0	0x0	RW	**Time Synch Time High** Upper 32 bit of the 96-bit timer.

38.39.2.20.11 Port Time Sync Target Time Low - PRTTSYN_TGT_L[n] (0x001E4140 + 0x20*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
TSYNTGTT_L	31:0	0x0	RW	**Time Sync Target Time Low** 32 LS bits of the target time of an event out in one of the AUX IO signals.

38.39.2.20.12 Port Time Sync Target Time High - PRTTSYN_TGT_H[n] (0x001E4180 + 0x20*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
TSYNTGTT_H	31:0	0x0	RW	**Time Sync Target Time High** 32 MS bits of the target time of an event out in one of the AUX IO signals.

38.39.2.20.13 Port Time Sync Transmit Packet Time Low - PRTTSYN_TXTIME_L (0x001E41C0; RO)

Field	Bit(s)	Init.	Type	Description
TXTIME_L	31:0	0x0	RO	**Transmit Time Low** 32 LS bits of the sampled 1588 Time of a Tx packet matches the units of the TSYN_TIME_L register (Section 38.39.2.20.9).

38.39.2.20.14 Port Time Sync Transmit Packet Time High - PRTTSYN_TXTIME_H (0x001E41E0; RO)

Field	Bit(s)	Init.	Type	Description
TXTIME_H	31:0	0x0	RO	**Transmit Time High** 32 MS bits of the sampled 1588 Time of a Tx packet matches the units of the TSYN_TIME_H register (Section 38.39.2.20.10).

38.39.2.20.15 Port Time Sync Control 0 - PRTTSYN_CTL0 (0x001E4200; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	0	0b	RSV	Reserved.
TXTIME_INT_ENA	1	0b	RW	**Transmit Time Interrupt Enable** Interrupt enable when the TSYNTXTIME registers samples the transmission time in this port. The event is reported in the *TXTIME* bit in the PRTTSYN_STAT_0 register (Section 38.39.2.20.16).
EVENT_INT_ENA	2	0b	RW	**Event Interrupt Enable** Interrupt enable when an event is sampled in any of the PRTTSYN_EVNT registers.
TGT_INT_ENA	3	0b	RW	**Target Time Interrupt Enable** Interrupt enable when the target time is sampled in any of the PRTTSYN_TGT registers.
RESERVED	7:4	0x0	RSV	Reserved.
PF_ID	11:8	0x0	RW	**PF ID** Software indication for the PF Function ID that controls the 1588 logic of the port (no hardware impact). This field is expected to be loaded from NVM or set by management agent. During normal operation the PF software driver is not expected to change its setting.
TSYNACT	13:12	00b	RW	**Time Sync Active** Software indication for 1588 mode of operation (no hardware impact). 00b = Inactive agent. 01b = Synchronized to local time. 10b = Synchronized to the standard TAI. 11b = Reserved.
RESERVED	30:14	0x0	RSV	Reserved.
TSYNENA	31	0b	RW	**Time Sync Enable** Enables the 1588 logic. When the *TSYNENA* flag is cleared, the 1588 logic is not functional. This flag must be set the same as the *TSYNENA* flag in the PRTTSYN_CTL1 register (Section 38.39.2.20.1).

38.39.2.20.16Port Time Sync Status 0 - PRTTSYN_STAT_0 (0x001E4220; RCW)

Field	Bit(s)	Init.	Type	Description
EVENT0	0	0b	RCW	**Event Time 0** Set to one when the PRTTSYN_EVNT[0] captures an input event times tamp.
EVENT1	1	0b	RCW	**Event Time 1** Set to one when the PRTTSYN_EVNT[1] captures an input event time stamp.
TGT0	2	0b	RCW	**Target Time 0** Set to one when the PRTTSYN_TGT[0] timer is expired.
TGT1	3	0b	RCW	**Target Time 1** Set to one when the PRTTSYN_TGT[1] timer is expired.
TXTIME	4	0b	RCW	**Transmit Time** Set to one when the PRTTSYN_TXTIME register samples a Tx packet.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.20.17Port Time Sync Clock Out Duration - PRTTSYN_CLKO[n] (0x001E4240 + 0x20*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
TSYNCLKO	31:0	0x0	RW	**Time Sync Clock Out** Clock output duration as described in the Auxiliary 1588 IO Signals section.

38.39.2.20.18Port Time Sync Adjustment - PRTTSYN_ADJ (0x001E4280; RW)

Field	Bit(s)	Init.	Type	Description
TSYNADJ	30:0	0x0	RW	**Time Sync Adjustment** Absolute value of the time adjust matched to the units of the TSYN_TIME_L register (Section 38.39.2.20.9).
SIGN	31	0b	RW	**Sign** The sign of the time adjustment. 0b = Positive adjustment 1b = Negative adjustment

38.39.2.20.19Port Time Sync AUX Control 0 - PRTTSYN_AUX_0[n] (0x001E42A0 + 0x20*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
OUT_ENA	0	0b	RW	**Output Enable** Synchronized output enablement. When set to 1b, the synchronized output signal is enabled according to the other parameters in this register.
OUTMOD	2:1	00b	RW	**Output Mode** Output signal mode of operation 00b = Output Level Mode. 01b = Flipped Output Mode. 10b = Output Pulse Mode. 11b = Output Clock Mode. The GPIO signals should be set as 1588 output by the GLGEN_GPIO_CTL[n] registers.
OUTLVL	3	0b	RW	**Output Level** Output level driven on the IO signal at the target time.
RESERVED	7:4	0x0	RSV	Reserved.
PULSEW	11:8	0x0	RW	**Pulse Width** Output pulse width for output pulse mode equals 16 x (*PULSEW* + 1) clocks. The clock frequency is defined per link speed in the 1588 Clock Registers section.

Field	Bit(s)	Init.	Type	Description
RESERVED	15:12	0x0	RSV	Reserved.
EVNTLVL	17:16	00b	RW	**Event Level** Event level on the I/O signal configured as 1588 input. It can be set to one of the following options: 00b = Disable. 01b = Rising edge. 10b = Falling edge. 11b = Any transition. The GPIO signals should be set as 1588 input by the GLGEN_GPIO_CTL[n] registers.
RESERVED	31:18	0x0	RSV	Reserved.

38.39.2.20.20 Port Time Sync AUX Control 1 - PRTTSYN_AUX_1[n] (0x001E42E0 + 0x20*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
INSTNT	0	0b	RW	**Instant** If this flag is set, the OUTSIG signal is forced to OUTLVL value. This flag is auto-cleared by hardware.
SAMPLE_TIME	1	0b	RW	**Sampling Time** Setting this flag triggers instant sampling of the PRTTSYN_TIME to the matched PRTTSYN_EVNT register. This flag is auto-cleared by hardware.
RESERVED	31:2	0x0	RSV	Reserved.

38.39.2.21 PF - Protocol Engine Registers

38.39.2.21.1 Protocol Engine VF CQP Doorbell - VFPE_CQPDB[VF] (0x00000000 + 0x4*VF, VF=0...127; RW)

This register is used to post work of the PE control QP. Software can determine if CQP has pending work by comparing *WQHEAD* to *WQTAIL* after reading this register. Software must first populate one or more WQEs in the CQP WQ and then put the index of the WQE following the last populated WQE into *WQHEAD* in order to submit work to CQP.

Field	Bit(s)	Init.	Type	Description
WQHEAD	10:0	0x0	RW	**Work Queue Head** Indicates the WQE index of the next WQE that software posts to the CQP.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.21.2 Protocol Engine VF CQP Tail - VFPE_CQPTAIL[VF] (0x00000400 + 0x4*VF, VF=0...127; RO)

This register is used to determine how much work the PE control QP has pending. Software can determine if CQP has pending work by comparing the last value written to *WQHEAD* in the CQPDB register to *WQTAIL* after reading this register.

Field	Bit(s)	Init.	Type	Description
WQTAIL	10:0	0x0	RW	**Work Queue Tail** Indicates the WQE index of the next WQE that the CQP processes.
RESERVED	30:11	0x0	RSV	Reserved.
CQP_OP_ERR	31	0b	RW	**CQP Operation Error** Indicates that CQP encountered an error processing an operation. If software has multiple requests outstanding to CQP at the time of the error, *WQTAIL* might not indicate the WQE that caused the error.

38.39.2.21.3 Protocol Engine VF Create CQP Status - VFPE_CCQPSTATUS[VF] (0x00000800 + 0x4*VF, VF=0...127; RW)

This register is used to indicate the progress of creating the control QP for a given PCI function. During host software initialization, these bits are initially zero. Each bit is set when the associated step of the initialization process completes.

Field	Bit(s)	Init.	Type	Description
CCQP_DONE	0	0b	RW	**Create CQP Done** 0b = Indicates that CQP has not been created. 1b = Indicates that the create CQP operation triggered by writing to PECCQPHIGH and PECCQPLOW completes.
RESERVED	3:1	000b	RSV	Reserved.
HMC_PROFILE	6:4	000b	RW	**Host Memory Cache (HMC) Profile** Specifies the HMC resource profile that is active. 000b = Reserved. 001b = Default. 010b = SR-IOV VF primary. 011b = SR-IOV even distribution. All other values are reserved.
RESERVED	15:7	0x0	RSV	Reserved.
RDMA_EN_VFS	21:16	0x0	RW	**RDMA Enabled VFs** Specifies the number of RDMA enabled VFs allocated in the HMC resource profile.
RESERVED	30:22	0x0	RSV	Reserved.
CCQP_ERR	31	0b	RW	**Create CQP Error** Indicates that the CQP encountered an error processing the last create CQP request. This bit is reset when CQP is not created.

38.39.2.21.4 Protocol Engine VF Create CQP Low - VFPE_CCQPLOW[VF] (0x00000C00 + 0x4*VF, VF=0...127; RW)

This register stores the lower 32 bits of the 64-bit physical address of the control QP context for its associated PCI function. Under host software control, each PCI function uses its Create Control QP High/Low registers to create its corresponding Control QP (QP0). The 64-bit address must always be updated by writing the *PECCQPLOW* field last.

Field	Bit(s)	Init.	Type	Description
PECCQPLOW	31:0	0x0	RW	**PE Create CQP Low** Least significant bits of the control QP context physical address in host memory.

38.39.2.21.5 Protocol Engine VF Create CQP High - VFPE_CCQPHIGH[VF] (0x00001000 + 0x4*VF, VF=0...127; RW)

This register stores the upper 32 bits of the 64-bit physical address of the control QP context for its associated PCI function.

Field	Bit(s)	Init.	Type	Description
PECCQPHIGH	31:0	0x0	RW	**PE Create CQP High** Most significant bits of the control QP context physical address in host memory.

38.39.2.21.6 Protocol Engine VF IP Config 0 - VFPE_IPCONFIG0[VF] (0x00001400 + 0x4*VF, VF=0...127; RW)

This register is used to set or view the *IPID* field that the PE writes into the IP header. The PE increments this value for each outgoing IP datagram.

Field	Bit(s)	Init.	Type	Description
PEIPID	15:0	0x0	RW	**PE IP Identification** Specifies the *IP Identification* field used for IPv4 IP header generation. This register is initialized by firmware or software device driver, and incremented by hardware with each IPv4 datagram transmitted by PE both UDA and iWARP on the given PCI function.
USEENTIREIDRANGE	16	0b	RW	**Use Entire ID Range** Specifies that the PE should use the entire 16-bit range for the IPID value.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.7 Protocol Engine CQP Error Codes - VFPE_CQPERRCODES[VF] (0x00001800 + 0x4*VF, VF=0...127; RO)

This register reports errors encountered by CQP when CQ0 is not available. The contents of this register are only valid when the associated CCQPSTATUS.*CCQP_ERR* bit or CQPTAIL.*CQP_ERR* bit is set.

Field	Bit(s)	Init.	Type	Description
CQP_MINOR_CODE	15:0	0x0	RW	**CQP Minor Code** Minor code that would have been reported in a CQP completion.
CQP_MAJOR_CODE	31:16	0x0	RW	**CQP Major Code** Major code that would have been reported in a CQP completion.

38.39.2.21.8 Protocol Engine VF TCP Now Timer - VFPE_TCPNOWTIMER[VF] (0x00002C00 + 0x4*VF, VF=0...127; RO)

Field	Bit(s)	Init.	Type	Description
TCP_NOW	31:0	0x0	RO	**TCP Now** Contains the current value of tcp_now. *TCP_NOW* is a 32-bit counter and provides the TCP time measurement for the all of the timers. It is also used to calculate the TS value sent in the TCP time stamp option, tcp_now is added to tsval_tick_delta to form the TS value.

38.39.2.21.9 Protocol Engine VF MRTE Index Mask - VFPE_MRTEIDXMASK[VF] (0x00003000 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
MRTEIDXMASKBITS	4:0	0x0	RW	**MRTE Index Mask Bits** Specifies the number of bits to be used for the MRTE index from the software device driver portion of STag. The remaining bits (24 - *MRTEIDEMASKBITS*) are randomized by the software device driver. The minimum value for this field is 14 and the maximum is 22. Values outside of this range are normalized to 14 or 22 by the hardware.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.21.10 Protocol Engine VF Unexpected Error - VFPE_RCVUNEXPECTEDERROR[VF] (0x00003400 + 0x4*VF, VF=0...127; RO)

Field	Bit(s)	Init.	Type	Description
TCP_RX_UNEXP_ERR	23:0	0x0	RW	**TCP Received Unexpected Error** For PE accelerated connections only, counts the total number of Ethernet frames received by the product that failed TCP sanity checks indicating unexpected filtering error in preceding module.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.21.11 Protocol Engine CQP Doorbell - PFPE_CQPDB (0x00008000; RW)

This register is used to post the work of the PE control QP. Software can determine if CQP has pending work by comparing WQHEAD to WQTAIL after reading this register. Software must first populate one or more WQEs in the CQP WQ and then put the index of the WQE following the last populated WQE into *WQHEAD* in order to submit work to CQP.

Field	Bit(s)	Init.	Type	Description
WQHEAD	10:0	0x0	RW	**Work Queue Head** Indicates the WQE index of the next WQE that software posts to the CQP.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.21.12Protocol Engine CQP Tail - PFPE_CQPTAIL (0x00008080; RO)

This register is used to determine how much work the PE control QP has pending. Software can determine if the CQP has pending work by comparing the last value written to *WQHEAD* in the CQPDB register to *WQTAIL* after reading this register. This register is updated after the CQP operation completes.

Field	Bit(s)	Init.	Type	Description
WQTAIL	10:0	0x0	RW	**Work Queue Tail** Indicates the WQE index of the next WQE that the CQP processes.
RESERVED	30:11	0x0	RSV	Reserved.
CQP_OP_ERR	31	0b	RW	**CQP Operation Error** Indicates that the CQP encountered an error processing an operation. If software has multiple requests outstanding to the CQP at the time of the error, *WQTAIL* might not indicate the WQE that caused the error.

38.39.2.21.13Protocol Engine Create CQP Status - PFPE_CCQPSTATUS (0x00008100; RW)

This register is used to indicate the progress of creating the control QP for a given PCI function. During host software initialization, these bits are initially 0. Each bit is set when the associated step of the initialization process completes.

Field	Bit(s)	Init.	Type	Description
CCQP_DONE	0	0b	RW	**Create CQP Done** 0b = Indicates that the CQP has not been created. 1b = Indicates that the create CQP operation triggered by writing to PECCQPHIGH and PECCQPLOW completed.
RESERVED	3:1	000b	RSV	Reserved.
HMC_PROFILE	6:4	000b	RW	**HMC Profile** Specifies the HMC resource profile that is active. 000b = Reserved. 001b = Default. 010b = SR-IOV VF primary. 011b = SR-IOV even distribution. All other values are reserved.
RESERVED	15:7	0x0	RSV	Reserved.
RDMA_EN_VFS	21:16	0x0	RW	**RDMA Enabled VFs** Specifies the number of RDMA enabled VFs allocated in the HMC resource profile.
RESERVED	30:22	0x0	RSV	Reserved.
CCQP_ERR	31	0b	RW	**Create CQP Error** Indicates that the CQP encountered an error processing the last create CQP request. This bit is reset when CQP is not created.

38.39.2.21.14Protocol Engine Create CQP Low - PFPE_CCQPLOW (0x00008180; RW)

This register stores the lower 32 bits of the 64-bit physical address of the control QP context for its associated PCI function. Under host software control, each PCI function uses its Create Control QP High/Low registers to create its corresponding Control QP.

Field	Bit(s)	Init.	Type	Description
PECCQPLOW	31:0	0x0	RW	**PE Create CQP Low** Least significant bits of the control QP context physical address in host memory.

38.39.2.21.15Protocol Engine Create CQP High - PFPE_CCQPHIGH (0x00008200; RW)

This register stores the upper 32 bits of the 64-bit physical address of the control QP context for its associated PCI function.

Field	Bit(s)	Init.	Type	Description
PECCQPHIGH	31:0	0x0	RW	**PE Create CQP High** Most significant bits of the control QP context physical address in host memory.

38.39.2.21.16Protocol Engine IP Config 0 - PFPE_IPCONFIG0 (0x00008280; RW)

This register is used to set or view the *IPID* field that the PE writes into the IP header. The PE increments this value for each outgoing IP datagram.

Field	Bit(s)	Init.	Type	Description
PEIPID	15:0	0x0	RW	**PE IP Identification** Specifies the *IP Identification* field used for IPv4 IP header generation. This register is initialized by firmware or the software device driver, and incremented by hardware with each IPv4 datagram transmitted by PE both UDA and iWARP on the given PCI function.
USEENTIREIDRANGE	16	0b	RW	**Use Entire ID Range** Specifies that the PE should use the entire 16-bit range for the IPID value.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.17Protocol Engine TCP Now Timer - PFPE_TCPNOWTIMER (0x00008580; RO

Field	Bit(s)	Init.	Type	Description
TCP_NOW	31:0	0x0	RO	**TCP Now** Contains the current value of tcp_now. *TCP_NOW* is a 32-bit counter and provides the TCP time measurement for the all of the timers. It is also used to calculate the TS value sent in the TCP time stamp option, tcp_now is added to tsval_tick_delta to form the TS value.

38.39.2.21.18Protocol Engine MRTE Index Mask - PFPE_MRTEIDXMASK (0x00008600; RW)

Field	Bit(s)	Init.	Type	Description
MRTEIDXMASKBITS	4:0	0x0	RW	**MRTE Index Mask Bits** Specifies the number of bits to be used for the MRTE index from the software device driver portion of STag. The remaining bits (24 - *MRTEIDEMASKBITS*) are randomized by the software device driver. The minimum value for this field is 14 and the maximum is 22. Values outside of this range are normalized to 14 or 22 by hardware.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.21.19 Protocol Engine Unexpected Error - PFPE_RCVUNEXPECTEDERROR (0x00008680; RO)

Field	Bit(s)	Init.	Type	Description
TCP_RX_UNEXP_ERR	23:0	0x0	RW	**TCP Received Unexpected Error** For PE accelerated connections only, counts the total number of Ethernet frames received by the product that failed TCP sanity checks indicating unexpected filtering error in preceding module.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.21.20 Protocol Engine UDA Control Register - PFPE_UDACTRL (0x00008700; RW)

This register is used to set up the user-space direct access acceleration configuration.

Field	Bit(s)	Init.	Type	Description
IPV4MCFRAGRESBP	0	0b	RW	**IPv4 Multicast Fragment Resolution Bypass** Indicates whether IPv4/UDP multicast fragments are allowed to bypass fragment resolution phase, and be replicated based on the destination IP address and multicast group context configuration. 0b = All UDA accelerated UDP multicast fragments must have their destination UDP port resolved, and replicated based on pair of destination IP address and destination UDP port. 1b = All UDA accelerated UDP multicast fragments should bypass fragment resolution logic and be replicated based on Multicast Group Context configuration.
IPV4UCFRAGRESBP	1	0b	RW	**IPv4 Unicast Fragment Resolution Bypass** Indicates whether IPv4/UDP unicast fragments are allowed to bypass fragment resolution logic. 0b = UDP unicast fragments must be processed by fragment resolution logic. 1b = UDP unicast fragments can bypass fragment resolution logic, and be processed based on configuration of PF/VFPE_UDAUCFBQPN register.
IPV6MCFRAGRESBP	2	0b	RW	**IPv6 Multicast Fragment Resolution Bypass** Indicates whether IPv6/UDP multicast fragments are allowed to bypass fragment resolution phase, and be replicated based on the destination IP address. and multicast group context configuration. 0b = All UDA accelerated UDP multicast fragments must have their destination UDP port resolved, and replicated based on pair of destination IP address and destination UDP port. 1b = All UDA accelerated UDP multicast fragments should bypass fragment resolution logic and be replicated based on Multicast Group Context configuration.
IPV6UCFRAGRESBP	3	0b	RW	**IPv6 Unicast Fragment Resolution Bypass** Indicates whether IPv6/UDP unicast fragments are allowed to bypass fragment resolution logic. 0b = UDP unicast fragments must be processed by fragment resolution logic. 1b = UDP unicast fragments can bypass fragment resolution logic, and be processed based on configuration of PF/VFPE_UDAUCFBQPN register
UDPMCFRAGRESFAIL	4	0b	RW	**UDP Multicast Fragment Resolution Failed** Defines handling of the multicast fragment that failed fragment resolution. 0b = Fragment should be silently dropped. 1b = Fragment should be replicated based on Multicast Group Context Configuration.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.21.21 Protocol Engine UDA Unicast Fallback QP Number - PFPE_UDAUCFBQPN (0x00008780; RW)

This register specifies an UDA QP Number that should be used as a target QP for all UDP unicast fragments that failed fragment resolution. If QPN is not valid, fragment should be silently dropped.

Field	Bit(s)	Init.	Type	Description
QPN	17:0	0x0	RW	**QPN** UDA QPN.
RESERVED	30:18	0x0	RSV	Reserved.
VALID	31	0b	RW	**Valid** 0b = QPN is not valid. 1b = QPN is valid.

38.39.2.21.22 Protocol Engine CQP Error Codes - PFPE_CQPERRCODES (0x00008880; RO)

This register reports errors encountered by CQP when CQ0 is not available. The contents of this register are only valid when the associated CCQPSTATUS.*CCQP_ERR* bit or CQPTAIL.*CQP_ERR* bit is set.

Field	Bit(s)	Init.	Type	Description
CQP_MINOR_CODE	15:0	0x0	RW	**CQP Minor Code** Minor code that would have been reported in a CQP completion.
CQP_MAJOR_CODE	31:16	0x0	RW	**CQP Major Code** Major code that would have been reported in a CQP completion.

38.39.2.21.23 Protocol Engine FLM transmit Allocate Error - PFPE_FLMXMITALLOCERR (0x00008900; RO)

This register holds a count of the transmit free list allocation errors.

Field	Bit(s)	Init.	Type	Description
ERROR_COUNT	15:0	0x0	RO	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.24 Protocol Engine FLM Q1 Allocate Error - PFPE_FLMQ1ALLOCERR (0x00008980; RO)

This register holds a count of the Q1 free list allocation errors.

Field	Bit(s)	Init.	Type	Description
ERROR_COUNT	15:0	0x0	RO	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.25 Protocol Engine UDA Control Register - GLPE_VFUDACTRL[n] (0x0000C000 + 0x4*n, n=0...31; RW)

This register is used to setup user-space direct access acceleration configuration. Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
IPV4MCFRAGRESBP	0	0b	RW	**IPv4 Multicast Fragment Resolution Bypass** Indicates whether IPv4/UDP multicast fragments are allowed to bypass fragment resolution phase, and be replicated based on the destination IP address and multicast group context configuration. 0b = All UDA accelerated UDP multicast fragments must have their destination UDP port resolved, and replicated based on pair of destination IP address and destination UDP port. 1b = All UDA accelerated UDP multicast fragments should bypass fragment resolution logic and be replicated based on multicast group context configuration.
IPV4UCFRAGRESBP	1	0b	RW	**IPv4 Unicast Fragment Resolution Bypass** Indicates whether IPv4/UDP unicast fragments are allowed to bypass fragment resolution logic. 0b = UDP unicast fragments must be processed by fragment resolution logic. 1b = UDP unicast fragments can bypass fragment resolution logic, and be processed based on configuration of PF/VFPE_UDAUCFBQPN register.
IPV6MCFRAGRESBP	2	0b	RW	**IPv6 Multicast Fragment Resolution Bypass** Indicates whether IPv6/UDP multicast fragments are allowed to bypass fragment resolution phase, and be replicated based on the destination IP address. and multicast group context configuration. 0b = All UDA accelerated UDP multicast fragments must have their destination UDP port resolved, and replicated based on pair of destination IP address and destination UDP port. 1b = All UDA accelerated UDP multicast fragments should bypass fragment resolution logic and be replicated based on multicast group context configuration.
IPV6UCFRAGRESBP	3	0b	RW	**IPv6 Unicast Fragment Resolution Bypass** Indicates whether IPv6/UDP unicast fragments are allowed to bypass fragment resolution logic. 0b = UDP unicast fragments must be processed by fragment resolution logic. 1b = UDP unicast fragments can bypass fragment resolution logic, and be processed based on configuration of PF/VFPE_UDAUCFBQPN register
UDPMCFRAGRESFAIL	4	0b	RW	**UDP Multicast Fragment Resolution Failed** Defines handling of the multicast fragment that failed fragment resolution. 0b = Fragment should be silently dropped. 1b = Fragment should be replicated based on multicast group context Configuration.
RESERVED	31:5	0x0	RSV	Reserved.

38.39.2.21.26 Protocol Engine UDA Unicast Fallback QP Number - GLPE_VFUDAUCFBQPN[n] (0x0000C100 + 0x4*n, n=0...31; RW)

This register specifies an UDA QP number that should be used as a target QP for all UDP unicast fragments that failed fragment resolution. Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index. If QPN is not valid, fragment should be silently dropped.

Field	Bit(s)	Init.	Type	Description
QPN	17:0	0x0	RW	**QPN** UDA QPN.
RESERVED	30:18	0x0	RSV	Reserved.
VALID	31	0b	RW	**Valid** 0b = QPN is not valid. 1b = QPN is valid.

38.39.2.21.27 Protocol Engine VF FLM transmit Allocate Error - GLPE_VFFLMXMITALLOCERR[n] (0x0000C600 + 0x4*n, n=0...31; RO)

This register holds a count of the transmit free list allocation errors.

Field	Bit(s)	Init.	Type	Description
ERROR_COUNT	15:0	0x0	RO	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.28 Protocol Engine VF FLM Q1 Allocate Error - GLPE_VFFLMQ1ALLOCERR[n] (0x0000C700 + 0x4*n, n=0...31; RO)

This register holds a count of the Q1 free list allocation errors.

Field	Bit(s)	Init.	Type	Description
ERROR_COUNT	15:0	0x0	RO	**Error Count** The number of failed free list allocations for this function. Counter does not roll over. Software read resets
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.29 Protocol Engine CPU Status 0 - GLPE_CPUSTATUS0 (0x0000D040; RW)

Field	Bit(s)	Init.	Type	Description
PECPUSTATUS0	31:0	0x0	RW	**PE CPU Status 0** Provides the host with the current status of one of the PE internal CPUs. Typically, the exclusive writer of this register is CQP, and the exclusive reader is host software, but other usage models are supported. Details on the meaning of each status code are not defined in this datasheet and might change with a firmware revision.

38.39.2.21.30 Protocol Engine CPU Status 1 - GLPE_CPUSTATUS1 (0x0000D044; RW)

Field	Bit(s)	Init.	Type	Description
PECPUSTATUS1	31:0	0x0	RW	**PE CPU Status 1** Provides the host with the current status of one of the PE internal CPUs. Typically, the exclusive writer of this register is TEP, and the exclusive reader is host software, but other usage models are supported. Details on the meaning of each status code are not defined in this datasheet and might change with a firmware revision.

38.39.2.21.31 Protocol Engine CPU Status 2 - GLPE_CPUSTATUS2 (0x0000D048; RW)

Field	Bit(s)	Init.	Type	Description
PECPUSTATUS2	31:0	0x0	RW	**PE CPU Status 2** Provides the host with the current status of one of the PE internal CPUs. Typically, the exclusive writer of this register is OOP, and the exclusive reader is host software, but other usage models are supported. Details on the meaning of each status code are not defined in this datasheet and might change with a firmware revision.

38.39.2.21.32 Protocol Engine CPU Trigger 0 - GLPE_CPUTRIG0 (0x0000D060; RW)

This register provides the host and other CPUs with the ability to signal another CPU that CPU-specific registers have been changed, but other usage models are supported.

Field	Bit(s)	Init.	Type	Description
PECPUTRIG0	15:0	0x0	RW	**PE CPU Trigger 0** Host software writes 0x1 to request CQP to re-read register configuration. A write of 0x0 has no effect. Hardware auto-clears these bits when this register is read by the PE CPU.
RESERVED	16	0b	RSV	Reserved.
TEPREQUEST0	17	0b	RW	**TEP Request 0** TEP writes 1b to request CQP to re-read register configuration. A write of 0b has no effect. Hardware auto-clears this bit when this register is read by the PE CPU.
OOPREQUEST0	18	0b	RW	**OOP Request 0** OOP writes 1b to request CQP to re-read register configuration. A write of 0b has no effect. Hardware auto-clears this bit when this register is read by the PE CPU.
RESERVED	31:19	0x0	RSV	Reserved.

38.39.2.21.33 Protocol Engine VF FLM Object Control - GLPE_VFFLMOBJCTRL[n] (0x0000D400 + 0x4*n, n=0...31; RW)

This register is used for FLM VF object control.

Field	Bit(s)	Init.	Type	Description
XMIT_BLOCKSIZE	2:0	001b	RW	**Transmit Block Size** The number of transmit entries per block using a power of two encoding. Entries per block = 2^XMIT_BLOCKSIZE The supported range is 2^1, 2^2, 2^3, or 2, 4, 8.
RESERVED	7:3	0x0	RSV	Reserved.
Q1_BLOCKSIZE	10:8	000b	RW	**Q1 Block Size** The number of Q1 entries per block using a power of two encoding. entries per block = 2^Q1_BLOCKSIZE The supported range is 2^0, 2^1, 2^2, 2^3, or 1, 2, 4, 8.
RESERVED	31:11	0x0	RSV	Reserved.

38.39.2.21.34 Protocol Engine RUPM General Control Register - GLPE_RUPM_GCTL (0x0000DA00; RW)

General control register for PE upper pipe monitor.

Field	Bit(s)	Init.	Type	Description
ALLOFFTH	7:0	0x0	RW	**All PFC-enabled TCs OFF Threshold** High threshold on the total number of spads allocated to PFC TCs. Only valid when spads are shared across all ports (*SWLB_MODE* set to 1b).
RESERVED	25:8	0x0	RSV	Reserved.
RUPM_P0_DIS	26	0b	RW	**RDMA Upper Pipe Monitor Port 0 Disable** When set, disables the regular pipe monitor of port 0.
RUPM_P1_DIS	27	0b	RW	**RDMA Upper Pipe Monitor Port 1 Disable** When set, disables the regular pipe monitor of port 1.
RUPM_P2_DIS	28	0b	RW	**RDMA Upper Pipe Monitor Port 2 Disable** When set, disables the regular pipe monitor of port 2.
RUPM_P3_DIS	29	0b	RW	**RDMA Upper Pipe Monitor Port 3 Disable** When set, disables the regular pipe monitor of port 3.
RUPM_DIS	30	0b	RW	**RDMA Upper Pipe Monitor Disable** 0b = Enabled. 1b = Disabled (all full and flow control signals are driven to 0).
SWLB_MODE	31	0b	RW	**RDMA Upper Pipe Monitor spad buffer mode** Per port spad allocation. 0b = spad allocation shared across ports. 1b = This bit should be set to 0b.

38.39.2.21.35 Protocol Engine RUPM DUAL40 Config Register - GLPE_DUAL40_RUPM (0x0000DA04; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	31:0	0x0	RSV	Reserved.

38.39.2.21.36 Protocol Engine RUPM Enable Register - GLPE_RUPM_TXHOST_EN (0x0000DA08; RW)

Field	Bit(s)	Init.	Type	Description
TXHOST_EN	0	1b	RW	**Host Transmit Enable** When cleared, no new transmit spads are provided to the host. It affects PE traffic. Those spads already allocated are processed for completion.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.21.37 Protocol Engine RUPM Spad Thresholds - PRTPE_RUPM_THRES (0x0000DA20; RW)

This register sets minimum and maximum thresholds for spads across ports and TCs. It is independent of PFC or LL/bulk thresholds.

Field	Bit(s)	Init.	Type	Description
MINSPADSPERTC	7:0	0x2	RW	**Minimum Spads per TC** Minimum number of spads per TC on the port.
MAXSPADS	15:8	0x1B	RW	**Maximum Spads** Maximum number of spads on the port.

Field	Bit(s)	Init.	Type	Description
MAXSPADSPERTC	23:16	0x1B	RW	**Maximum Spads per TC** Maximum number of spads per TC on the port.
RESERVED	31:24	0x0	RSV	Reserved.

38.39.2.21.38 Protocol Engine RUPM Control Register - PRTPE_RUPM_CTL (0x0000DA40; RW)

This register holds RUPM control bits.

Field	Bit(s)	Init.	Type	Description
RESERVED	12:0	0x0	RSV	Reserved.
LLTC	20:13	0x0	RW	**Low Latency TC** Per bit TC configuration. 0b = TC is bulk. 1b = TC is LL.
RESERVED	29:21	0x0	RSV	Reserved.
RUPM_MODE	30	0b	RW	**Per TC RUPM Mode** 0b = Conditioned XOFF forwarding mode (default). XOFF notifications received from RLPM are internally forwarded upward to the Tx-scheduler only once the TUPM for this TC is full. This mode provides better XON recovering time. 1b = Immediate XOFF forwarding mode. XOFF notification received form the TC data pipe monitor are immediately forwarded internally upward to the Tx-scheduler. This mode is useful to support PFC-enabled TCs of the port like true independent TCs when more than two such TCs are configured over the port. This bit should be set to 0b.
RESERVED	31	0b	RSV	Reserved.

38.39.2.21.39 Protocol Engine RUPM PFC Control Register - PRTPE_RUPM_PFCCTL (0x0000DA60; RW)

Field	Bit(s)	Init.	Type	Description
TC2PFC	7:0	0x0	RW	**Per bit TC configuration** 0b = TC ignores PFC thresholds. 1b = TC is configured as PFC.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.40 Protocol Engine RUPM PFC Port Control Register - PRTPE_RUPM_PFCPC (0x0000DA80; RW)

This register configures the port threshold for PFC traffic.

Field	Bit(s)	Init.	Type	Description
PORTOFFTH	7:0	0x0	RW	**Port OFF Threshold** High threshold on the total amount of spads in WQM for all PFC-enabled TCs.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.41 Protocol Engine RUPM PFC TC Control Register - PRTPE_RUPM_PFCTCC (0x0000DAA0; RW)

This register configures the TCs for PFC traffic.

Field	Bit(s)	Init.	Type	Description
TCOFFTH	7:0	0x0	RW	**TC OFF Threshold** The total amount of spads that can accumulate in WQM for a single PFC-enabled TC.
RESERVED	15:8	0x0	RSV	Reserved.
LL_PRI_TH	23:16	0x0	RW	**Low Latency PRI Threshold** Port Low Latency spad threshold.
RESERVED	30:24	0x0	RSV	Reserved.
LL_PRI_EN	31	0b	RW	**Low Latency PRI Enable** 0b = LL_PRI_THRESH is ignored. 1b = Block bulk (non-Low latency) traffic when total port spads exceeds LL_PRI_THRESH.

38.39.2.21.42 Protocol Engine RUPM Push Pool - GLPE_RUPM_PUSHPOOL (0x0000DAC0; RW)

Field	Bit(s)	Init.	Type	Description
PUSHSPADS	7:0	0x0	RW	**Push Spads** Number of spads reserved for push WQEs.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.43 Protocol Engine RUPM FLR Pool - GLPE_RUPM_FLRPOOL (0x0000DAC4; RW)

Field	Bit(s)	Init.	Type	Description
FLRSPADS	7:0	0x8	RW	**FLR Spads** Number of spads reserved for FLR markers.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.44 Protocol Engine RUPM PTX Pool - GLPE_RUPM_PTXPOOL (0x0000DAC8; RW)

Field	Bit(s)	Init.	Type	Description
PTXSPADS	7:0	0x12	RW	**PTX Spads** Number of spads reserved for PTX spads.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.45 Protocol Engine RUPM CQP Pool - GLPE_RUPM_CQPPOOL (0x0000DACC; RW)

Field	Bit(s)	Init.	Type	Description
CQPSPADS	7:0	0x8	RW	**CQP Spads** Number of spads reserved for CQP flush markers.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.46 Protocol Engine RUPM TC Counters 0-3 - PRTE_RUPM_TCCNTR03 (0x0000DAE0; RO)

Field	Bit(s)	Init.	Type	Description
TC0COUNT	7:0	0x0	RO	**TC0 Count** Number of spads on TC0 not yet sent to PTX.
TC1COUNT	15:8	0x0	RO	**TC1 Count** Number of spads on TC1 not yet sent to PTX.
TC2COUNT	23:16	0x0	RO	**TC2 Count** Number of spads on TC2 not yet sent to PTX.
TC3COUNT	31:24	0x0	RO	**TC3 Count** Number of spads on TC3 not yet sent to PTX.

38.39.2.21.47 Protocol Engine RUPM TC Counters 4-7 - PRTPE_RUPM_TCCNTR47 (0x0000DB00; RO)

Field	Bit(s)	Init.	Type	Description
TC4COUNT	7:0	0x0	RO	**TC4 Count** Number of spads on TC4 not yet sent to PTX.
TC5COUNT	15:8	0x0	RO	**TC5 Count** Number of spads on TC5 not yet sent to PTX.
TC6COUNT	23:16	0x0	RO	**TC6 Count** Number of spads on TC6 not yet sent to PTX.
TC7COUNT	31:24	0x0	RO	**TC7 Count** Number of spads on TC7 not yet sent to PTX.

38.39.2.21.48 Protocol Engine RUPM Counters - PRTPE_RUPM_CNTR (0x0000DB20; RO)

Field	Bit(s)	Init.	Type	Description
COUNT	7:0	0x0	RO	**Count** Number of spads not yet sent to PTX.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.49 Protocol Engine RUPM PTX TC Counters 0-3 - PRTPE_RUPM_PTXTCCNTR03 (0x0000DB40; RO)

Field	Bit(s)	Init.	Type	Description
TC0COUNT	7:0	0x0	RO	**TC0 Count** Number of spads on TC0 sent to PTX.
TC1COUNT	15:8	0x0	RO	**TC1 Count** Number of spads on TC1 sent to PTX.
TC2COUNT	23:16	0x0	RO	**TC2 Count** Number of spads on TC2 sent to PTX.
TC3COUNT	31:24	0x0	RO	**TC3 Count** Number of spads on TC3 sent to PTX.

38.39.2.21.50Protocol Engine RUPM PTX TC Counters 4-7 - PRTPE_RUPM_PTCTCCNTR47 (0x0000DB60; RO)

Field	Bit(s)	Init.	Type	Description
TC4COUNT	7:0	0x0	RO	**TC4 Count** Number of spads on TC4 sent to PTX.
TC5COUNT	15:8	0x0	RO	**TC5 Count** Number of spads on TC5 sent to PTX.
TC6COUNT	23:16	0x0	RO	**TC6 Count** Number of spads on TC6 sent to PTX.
TC7COUNT	31:24	0x0	RO	**TC7 Count** Number of spads on TC7 sent to PTX.

38.39.2.21.51DCB Transmit Command Monitoring Status per TC - PRTDCB_TCMSTC_RLPM[n] (0x0001F040 + 0x20*n, n=0...7; RO)

One register per TC. Register index corresponds to TCID.

Field	Bit(s)	Init.	Type	Description
MSTC	19:0	0x0	RW	**Monitoring Status of the TC** Number of commands that are in transit from the host to the TCB (TCB waiting list included) for TC n, where n is the index of the register in the array.
RESERVED	31:20	0x0	RSV	Reserved.

38.39.2.21.52DCB TC to PFC Mapping - PRTDCB_RLPMC (0x0001F140; RW)

Field	Bit(s)	Init.	Type	Description
TC2PFC	7:0	0x0	RW	**TC to PFC** Bitmap that controls the use of PFC per each TC. Bit n set to: 0b = The device does not issue PFC pause frames with bits set to 1b in the priority_enable_vector for the UPs attached to that TC. It does not react to bits set to 1b for the UPs attached to that TC in the priority_enable_vector of a received PFC pause frame. The TC is referred as a drop UP. 1b = TC n uses PFC in Rx and Tx. The TC is referred as a no-drop TC.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.21.53DCB Transmit Command Pipe Monitor Control - PRTDCB_TCPMC_RLPM (0x0001F1A0; RW)

Field	Bit(s)	Init.	Type	Description
CPM	12:0	0x098	RW	**Command Pipe Monitor** Depth of the per Port Monitor applied over the Tx Command Pipe. It is expressed in commands units.
LLTC	20:13	0x0	RW	**Low Latency TC** 0b = TC is bulk. 1b = TC is LL.
RESERVED2	29:21	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
TCPM_MODE	30	0b	RW	**Per TC Tx Command Pipe Monitor Mode.** 0b = Conditioned XOFF forwarding mode (default). XOFF notifications received from the TC data pipe monitor are internally forwarded upward to the Tx-scheduler only once the command pipe monitor for this TC is full. This mode provides better XON recovering time. 1b = Immediate XOFF forwarding mode. XOFF notifications received from the TC data pipe monitor are immediately forwarded internally upward to the Tx-scheduler. This mode is useful to support PFC-enabled TCs of the port like true independent TCs when more than two such TCs are configured over the port.
RESERVED1	31	0b	RSV	Reserved.

38.39.2.21.54 Protocol Engine VF CQ Arm - VFPE_CQARM[VF] (0x00130400 + 0x4*VF, VF=0...127; RW)

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to arm a PE completion queue for generating events in conjunction with the completion queue doorbell shadow area located in host memory. Arming is also frequently referred to as requesting notification for a completion queue. Events can be generated when the next completion is generated or when the next completion related to a solicited operation is generated. On read, this register returns the value of 0x0.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.55 Protocol Engine VF CQ ACK - VFPE_CQACK[VF] (0x00130800 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to enable new events for a PE completion queue. The interrupt processing logic that handles completion events must write this register in order to enable new events for a completion queue.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.56 Protocol Engine VF AEQ Allocate - VFPE_AEQALLOC[VF] (0x00130C00 + 0x4*VF, VF=0...127; RW)

Field	Bit(s)	Init.	Type	Description
AECOUNT	31:0	0x0	RW	**Asynchronous Event Count** Specifies the number of asynchronous event queue entries that have been processed by software and can now be reused by hardware.

38.39.2.21.57 Protocol Engine CQ Arm - PFPE_CQARM (0x00131080; RW)

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to arm a PE completion queue for events in conjunction with the completion queue doorbell shadow area located in host memory. Arming is also frequently referred to as requesting notification for a completion queue. Events can be generated when the next completion is generated or when the next completion related to a solicited operation is generated. On read, this register returns the value of 0x0.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.58 Protocol Engine CQ ACK - PFPE_CQACK (0x00131100; RW)

This register is used to acknowledge a completion event for a PE completion queue. The interrupt processing logic that handles completion events must write this register in order to enable new events for a completion queue.

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to enable new events for a PE completion queue.
RESERVED	31:17	0x0	RSV	Reserved.

38.39.2.21.59 Protocol Engine AEQ Allocate - PFPE_AEQALLOC (0x00131180; RW)

Field	Bit(s)	Init.	Type	Description
AECOUNT	31:0	0x0	RW	**Asynchronous Event Count** Specifies the number of asynchronous event queue entries that have been processed by software and can now be reused by hardware.

38.39.2.21.60 Protocol Engine CQE Drop Count - GLPE_PFCQEDROPCNT[n] (0x00131340 + 0x4*n, n=0...15; RW1C)

Note: There are 16 of these registers, one per PF.

Field	Bit(s)	Init.	Type	Description
CQEDROPCNT	15:0	0x0	RW1C	**CQE Drop Count** Counts the number of CQEs that are dropped due to the *Valid* bit being cleared in the CQ context for this PF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.61 Protocol Engine CEQE Drop Count - GLPE_PFCEQEDROPCNT[n] (0x001313C0 + 0x4*n, n=0...15; RW1C)

Note: There are 16 of these registers, one per PF.

Field	Bit(s)	Init.	Type	Description
CEQEDROPCNT	15:0	0x0	RW1C	**CEQE Drop Count** Counts the number of CEQEs that are dropped due to the *Valid* bit being cleared in the CEQ Context for this PF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.62 Protocol Engine AEQE Drop Count - GLPE_PFAEQEDROPCNT[n] (0x00131440 + 0x4*n, n=0...15; RW1C)

Note: There are 16 of these registers, one per PF.

Field	Bit(s)	Init.	Type	Description
AEQEDROPCNT	15:0	0x0	RW1C	**AEQE Drop Count** Counts the number of AEQEs that are dropped due to the *Valid* bit being cleared in the AEQ context for this PF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.63 Protocol Engine CQE Drop Count - GLPE_VFCQEDROPCNT[n] (0x00132340 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
CQEDROPCNT	15:0	0x0	RW1C	**CQE Drop Count** Counts the number of CQEs that are dropped due to the *Valid* bit being cleared in the CQ context for this VF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.64 Protocol Engine CEQE Drop Count - GLPE_VFCEQEDROPCNT[n] (0x00132440 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
CEQEDROPCNT	15:0	0x0	RW1C	**CEQE Drop Count** Counts the number of CEQEs that are dropped due to the *Valid* bit being cleared in the CEQ Context for this VF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.65 Protocol Engine AEQE Drop Count - GLPE_VFAEQEDROPCNT[n] (0x00132540 + 0x4*n, n=0...31; RW1C)

Up to 32 PCI VFs can be enabled for PE support. This register is indexed by the HMC VF index.

Field	Bit(s)	Init.	Type	Description
AEQEDROPCNT	15:0	0x0	RW1C	**AEQE Drop Count** Counts the number of AEQEs that are dropped due to the *Valid* bit being cleared in the AEQ Context for this VF.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.21.66 Protocol Engine VF WQE Allocate Register - VFPE_WQEALLOC[VF] (0x00138000 + 0x4*VF, VF=0...127; RW)

This register is used to post the work of the PE queue pairs.

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PEQPID	17:0	0x0	RW	**PE Queue Pair ID** This field should be used to notify hardware the new work is available to be processed.
RESERVED	19:18	00b	RSV	Reserved.
WQE_DESC_INDEX	31:20	0x0	RW	**WQE Index** Indicates a high 12 bits of the WQE index in the send queue. This field is used to identify a push mode message in the head of the SQ. Push mode message is processed by hardware only if it is in the head of the send queue; otherwise, it is dropped and processed when WQE is re-fetched during regular transmit operation. This field is used for the push mode doorbells only. For regular doorbells, this field should be treated as reserved, and ignored by hardware.

38.39.2.21.67 Protocol Engine WQE Allocate Register - PFPE_WQEALLOC (0x00138C00; RW)

This register is used to post work the PE queue pairs.

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PEQPID	17:0	0x0	RW	**PE Queue Pair ID** This field should be used to notify hardware the new work is available to be processed.
RESERVED	19:18	00b	RSV	Reserved.
WQE_DESC_INDEX	31:20	0x0	RW	**WQE Index** Indicates a high 12 bits of the WQE Index in the send queue. This field is used to identify a push mode message in the head of the SQ. Push mode message is processed by hardware only if it is in the head of the send queue; otherwise, it is dropped and processed when WQE is re-fetched during regular transmit operation. This field is used for the push mode doorbells only. For regular doorbells, this field should be treated as reserved, and ignored by hardware.

38.39.2.22 PF - Manageability Registers

38.39.2.22.1 Firmware Reset Count - GL_FWRESETCNT (0x00083100; RO)

Field	Bit(s)	Init.	Type	Description
FWRESETCNT	31:0	0x0	RO	**Firmware Reset Count** Updated by Hardware. saturates at 0xFFFF,FFFF.

38.39.2.22.2 Flexible TCO Filter Table Registers - Mask - PRT_MNG_FTFT_MASK[n] (0x00085160 + 0x20*n, n=0...7; RO)

Note: The mask field must be 8-byte aligned even if the length field is not 8-byte aligned. Because hardware implementation compares eight bytes at a time, it should get extra masks until the end of the next Qword. Any mask bit that is located after the length should be set to 0x0, indicating no comparison should be done.

Note: In case the actual length defined by the length field register and the mask bits is not 8-byte aligned, there might be a case that a packet that is shorter than the actual required length passes the flexible filter. This can occur due to comparison of up to 7 bytes that come after the packet, but are not a real part of the packet.

Field	Bit(s)	Init.	Type	Description
MASK	15:0	0x0	RW	**Mask** Masks for the filter bytes: PRT_MNG_FTFT_MASK[0] : Mask for bytes 0:15. PRT_MNG_FTFT_MASK[1] : Mask for bytes 16:31. .... PRT_MNG_FTFT_MASK[6] : Mask for bytes 96:111. PRT_MNG_FTFT_MASK[7] : Mask for bytes 112:127. Values are: Ignore. Compare.
RESERVED	31:16	0x0	RSV	Reserved.

38.39.2.22.3 Flexible TCO Filter Table Registers - Length - PRT_MNG_FTFT_LENGTH (0x00085260; RO)

Field	Bit(s)	Init.	Type	Description
LENGTH	7:0	0x0	RW	**Length** Contains the length of the filter defining the number of bytes from the beginning of the packet compared by this filter. If actual packet length is less than length specified by this field, the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.22.4 Flexible TCO Filter Table Registers - Data - PRT_MNG_FTFT_DATA[n] (0x000852A0 + 0x20*n, n=0...31; RO)

The Flexible TCO Filter Table registers (FTFT) contains a 128-byte pattern and a corresponding 128-bit mask array. If enabled, the first 128 bytes of the received packet are compared against the masked bytes in the PRT_MNG_FTFT_DATA registers.

The 128-byte filter is composed of 32 DW entries, accompanied by a 128-bit mask (PRT_MNG_FTFT_MASK, one bit per filter byte). The bytes in each of the Dwords are written in network order (such as, Byte0 written to Bits[7:0], Byte1 to Bits[15:8], and so on). The mask field is set so that Bit[0] in the mask masks Byte0, Bit[1] masks

Byte1, and so on. A value of 1b in the mask field means that the appropriate byte in the filter should be compared to the appropriate byte in the incoming packet.

The PRT_MNG_FTFT_LENGTH register contains a length field defining the number of bytes from the beginning of the packet compared by this filter. If actual packet length is less than length specified by this field, the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.

Field	Bit(s)	Init.	Type	Description
DWORD	31:0	0x000000	RW	**Dword** Filter data.

38.39.2.22.5 Hardware Arbitration Control - GL_MNG_HWARB_CTRL (0x000B6130; RO)

Field	Bit(s)	Init.	Type	Description
NCSI_ARB_EN	0	0b	RW	**Hardware Arbitration Enable** If this bit is set, it is assumed the NCSI_ARB_IN and NCSI_ARB_OUT are connected to a hardware arbitration ring. Otherwise, the NCSI_ARB_IN pin is pulled up internally.
RESERVED	31:1	0x0	RSV	Reserved.

38.39.2.22.6 Firmware Semaphore - GL_MNG_FWSM (0x000B6134; RO)

Field	Bit(s)	Init.	Type	Description
FW_MODES	2:0	00b	RW	**Firmware Mode** Indicates in which mode the firmware operates. 000 = Normal mode. 001 = Debug mode. 010 = GLOBR/CORER recovery mode. 011 = Debug and GLOBR/CORER recovery mode. 100 = NVM recovery mode. 101 = Debug and NVM recovery mode.
RESERVED	9:23	0x0	RSV	Reserved.
EEP_RELOAD_IND	10	0b	RW	**NVM Reloaded Indication** Set to 1b after firmware reloads the NVM configuration after a Core reset. Cleared by firmware once the first AQ command is received from one of the drivers.
CRC_ERROR_MODULE	14:11	0x0	RW	**CRC Error Module** Index of (first) module for which a CRC error was found by EMP check. 0x0 = No CRC error found by EMP. ***Note:*** The PE might have found a CRC error in one of the modules it handles. 0x1 = CRC error on EMP Image module. 0x2 = Reserved 0x3 = CRC error on PHY Analog module. 0x4 = CRC error on EMP Global module. 0x5 = CRC error on Manageability module. 0x6 = CRC error on EMP Settings module. All other values are reserved.

Field	Bit(s)	Init.	Type	Description
FW_STATUS_VALID	15	0b	RW	**Firmware Status Valid** (firmware Valid bit) Hardware clears Bits[15:0] in EMP reset de-assertion so software can know firmware status is invalid. Firmware should set this bit to 1b when it is ready (end of init sequence). Whenever setting this bit to 1b, a PFINT_ICR0.*ADMINQ* interrupt must be issued to host (see Section 38.39.2.9.25).
RESERVED	18:16	000b	RW	Reserved.
EXT_ERR_IND	24:19	0x0	RW	**External Error Indication** Firmware writes here the reason that the firmware operation has stopped. For example, NVM CRC error, etc. Possible values: 0x0 = No error. 0x1 = CRC error on a module handled by EMP. Refer to *CRC_ERROR_MODULE* field for details. 0x2 = Switch module failed. 0x3 = Scheduler module failed. 0x4 = DCB module failed. 0x5 = Link module failed. 0x6 = LLDP module failed. 0x7 = Manage module failed. All other values are reserved. ***Note:*** Following error detection and GL_MNG_FWSM.*EXT_IND_ERR* update, the PFINT_ICR0.*ADMINQ* bit is set, and an interrupt is sent to the Host. However, when a value of 0x0 is placed in this field, the PFINT_ICR0.*ADMINQ* bit is not set, and an interrupt is not generated.
RESERVED	25	0b	RSV	Reserved.
PHY_SERDES0_CONFIG_ERR	26	0b	RW	**PHY/SerDes Configuration Error Indication - Port 0** Set by firmware when it fails to configure LAN PHY/SerDes. Cleared by firmware upon successful configuration of LAN PHY/SerDes.
PHY_SERDES1_CONFIG_ERR	27	0b	RW	**PHY/SerDes Configuration Error Indication - Port 1** Set by firmware when it fails to configure LAN PHY/SerDes. Cleared by firmware upon successful configuration of LAN PHY/SerDes.
PHY_SERDES2_CONFIG_ERR	28	0b	RW	**PHY/SerDes Configuration Error Indication - Port 2** Set by firmware when it fails to configure LAN PHY/SerDes. Cleared by firmware upon successful configuration of LAN PHY/SerDes.
PHY_SERDES3_CONFIG_ERR	29	0b	RW	**PHY/SerDes Configuration Error Indication - Port 3** Set by firmware when it fails to configure LAN PHY/SerDes. Cleared by firmware upon successful configuration of LAN PHY/SerDes.
RESERVED	31:30	00b	RSV	Reserved.

38.39.2.22.7 Manageability IPv6 Address Filter - PRT_MNG_MIPAF6[n] (0x00254200 + 0x20*n, n=0...15; RO)

The Manageability IPv6 Address Filter register stores IPv6 addresses for manageability filtering.

Note: These registers should be written in network order.

Field	Bit(s)	Init.	Type	Description
MIPAF	31:0	0x000000	RW	**Manageability IP Address Filters** For each n, m, m=0...3, n=0...3, MIPAF[m,n] register holds Dword `n' of IPv6 filter `m' (4 x IPv6 filters).

38.39.2.22.8 Management Flex UDP/TCP Ports - PRT_MNG_MFUTP[n] (0x00254E00 + 0x20*n, n=0...15; RO)

Each 32-bit register (n=0...15) refers to one UDP/TCP port filter. The MFUTP registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets.

The MFUTP registers are cleared on LAN_PWR_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset

Note: The MFUTP_N fields should be written in network order.

Field	Bit(s)	Init.	Type	Description
MFUTP_N	15:0	0x0	RW	**Management Flex UDP/TCP Port N** n-th management flex UDP/TCP port.
UDP	16	0b	RW	**UDP** Match if port is UDP.
TCP	17	0b	RW	**TCP** Match if port is TCP.
SOURCE_DESTINATION	18	0b	RW	**Source/Destination** 0b = Compare destination port. 1b = Compare source port.
RESERVED	31:19	0x0	RSV	Reserved.

38.39.2.22.9 Management VLAN TAG Value - PRT_MNG_MAVTV[n] (0x00255900 + 0x20*n, n=0...7; RO)

The MAVTV registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets.

Field	Bit(s)	Init.	Type	Description
VID	11:0	0x0	RW	**VLAN ID** Contains the VLAN ID that should be compared with the incoming packet's inner VLAN ID, if the corresponding bit in MDEF is set.
RESERVED	31:12	0x0	RSV	Reserved.

38.39.2.22.10Manageability Decision Filters1 - PRT_MNG_MDEF[n] (0x00255D00 + 0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	Description
MAC_EXACT_AND	3:0	0x0	RW	**MAC Exact AND** Controls the inclusion of exact MAC address 0 to 3 in the manageability filter decision (AND section). Bit[0] corresponds to exact MAC address 0 (MMAL0 and MMAH0), etc.
BROADCAST_AND	4	0b	RW	**Broadcast AND** Controls the inclusion of broadcast address filtering in the manageability filter decision (AND section).
VLAN_AND	12:5	0x0	RW	**VLAN AND** Controls the inclusion of VLAN tag 0 to 7, respectively, in the manageability filter decision (AND section). Bit[5] corresponds to VLAN tag 0, etc.
IPV4_ADDRESS_AND	16:13	0x0	RW	**IPv4 Address AND** Controls the inclusion of IPV4 address 0 to 3, respectively, in the manageability filter decision (AND section). Bit[13] corresponds to IPV4 address 0, etc. ***Note:*** These bits are set also for an ARP request packet if the Target IP match the IP address configured in the MIPAF register
IPV6_ADDRESS_AND	20:17	0x0	RW	**IPv6 Address AND** Controls the inclusion of IPV6 address 0 to 3, respectively, in the manageability filter decision (AND section). Bit[17] corresponds to IPV6 address 0, etc
MAC_EXACT_OR	24:21	0x0	RW	**MAC Exact OR** Controls the inclusion of exact MAC address 0 to 3 in the manageability filter decision (OR section). Bit[21] corresponds to exact MAC address 0 (MMAL0 and MMAH0), etc.
BROADCAST_OR	25	0b	RW	**Broadcast OR** Controls the inclusion of broadcast address filtering in the manageability filter decision (OR section).
MULTICAST_AND	26	0b	RW	**Multicast AND** Controls the inclusion of multicast address filtering in the manageability filter decision (AND section). Broadcast packets are not included by this bit.
ARP_REQUEST_OR	27	0b	RW	**ARP Request OR** Controls the inclusion of ARP request filtering in the manageability filter decision (OR section).
ARP_RESPONSE_OR	28	0b	RW	**ARP Response OR** Controls the inclusion of ARP response filtering in the manageability filter decision (OR section).
NEIGHBOR_DISCOVERY_134_OR	29	0b	RW	**Neighbor Discovery 134 OR** Controls the inclusion of neighbor discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x86 (134).
PORT_0X298_OR	30	0b	RW	**Port 0x298 OR** Controls the inclusion of port 0x298 filtering in the manageability filter decision (OR section).
PORT_0X26F_OR	31	0b	RW	**Port 0x26F OR** Controls the inclusion of port 0x26F filtering in the manageability filter decision (OR section).

38.39.2.22.11Manageability Decision Filters - PRT_MNG_MDEF_EXT[n] (0x00255F00 + 0x20*n, n=0...7; RO)

Field	Bit(s)	Init.	Type	Description
L2_ETHERTYPE_AND	3:0	0x0	RW	**L2 EtherType AND** Controls the inclusion of L2 EtherType filtering in the manageability filter decision (AND section).
L2_ETHERTYPE_OR	7:4	0x0	RW	**L2 EtherType OR** Controls the inclusion of L2 EtherType filtering in the manageability filter decision (OR section).
FLEX_PORT_OR	23:8	0x0	RW	**Flex Port OR** Controls the inclusion of flex port filtering in the manageability filter decision (OR section). Bit[16] corresponds to flex port 0, etc.
FLEX_TCO	24	0b	RW	**Flex TCO** Controls the inclusion of flex TCO filtering in the manageability filter decision (OR section). Bit[24] corresponds to Flex TCO filter. ***Note:*** Supported only for Network traffic.
NEIGHBOR_DISCOVERY_135_OR	25	0b	RW	**Neighbor Discovery 135 OR** Controls the inclusion of neighbor discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x87 (135).
NEIGHBOR_DISCOVERY_136_OR	26	0b	RW	**Neighbor Discovery 136 OR** Controls the inclusion of neighbor discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x88 (136).
NEIGHBOR_DISCOVERY_137_OR	27	0b	RW	**Neighbor Discovery 137 OR** Controls the inclusion of neighbor discovery filtering in the manageability filter decision (OR section). The neighbor type accepted by this filter is type 0x89 (137).
ICMP_OR	28	0b	RW	**ICMP OR** Controls the inclusion of ICMP filtering in the manageability filter decision (OR section).
MLD	29	0b	RW	**MLD OR** Control the inclusion of MLD packets. These are ICMPv6 packets with the following types: 130, 131, 132, 143.
APPLY_TO_NETWORK_TRAFFIC	30	0b	RW	**Apply to Network Traffic** 0b =This decision filter does not apply to traffic received from the network. 1b =This decision filter applies to traffic received from the network.
APPLY_TO_HOST_TRAFFIC	31	0b	RW	**Apply to Host Traffic** 0b = This decision filter does not apply to traffic received from the host. 1b = This decision filter applies to traffic received from the host.

38.39.2.22.12 Manageability IPv4 Address Filter - PRT_MNG_MIPAF4[n] (0x00256280 + 0x20*n, n=0...3; RO)

The Manageability IPv4 Address Filter register stores IPv4 addresses for manageability filtering.

Note: These registers should be written in network order.

Field	Bit(s)	Init.	Type	Description
MIPAF	31:0	0x000000	RW	**Manageability IP Address Filters** For each n, m, m=0...3, n=0...3, MIPAF[m,n] register holds Dword `n' of IPv4 filter `m' (4 x IPv4 filters).

38.39.2.22.13 Manageability MAC Address High - PRT_MNG_MMAH[n] (0x00256380 + 0x20*n, n=0...3; RO)

These registers contain the upper 16 bits of the 48-bit Ethernet address. The complete address is (MMAH, MMAL). The MMAH registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets.

The initial values for this register can be loaded from the NVM after power-up reset or firmware reset.

Note: The *MMAH* field should be written in network order.

Field	Bit(s)	Init.	Type	Description
MMAH	15:0	0x000000	RW	**Manageability MAC Address High** The upper 16 bits of the 48-bit Ethernet address. Appears in big endian order (MS byte of MMAH is last on the wire).
RESERVED	31:16	0x0	RSV	Reserved. Reads as 0x0. Ignored on write.

38.39.2.22.14 Manageability MAC Address Low - PRT_MNG_MMAL[n] (0x00256480 + 0x20*n, n=0...3; RO)

These registers contain the lower 32 bits of the 48-bit Ethernet address. The MMAL registers are written by internal firmware and are not accessible to the host for writing. The registers are used to filter manageability packets.

The MMAL registers are cleared on LAN_PWR_GOOD only. The initial values for this register can be loaded from the NVM after power-up reset.

Note: The *MMAL* field should be written in network order.

Field	Bit(s)	Init.	Type	Description
MMAL	31:0	0x000000	RW	**Manageability MAC Address Low** The lower 32 bits of the 48-bit Ethernet address. Appears in big endian order (LS byte of MMAL is first on the wire).

38.39.2.22.15 Management Decision Filters Buffers - PRT_MNG_MDEFVSI[n] (0x00256580 + 0x20*n, n=0...3; RO)

This register is used to define the VSIs used to receive packets that matched a specific MDEF. In case of multiple match the VSI assigned to the MDEF with the highest index is used.

Field	Bit(s)	Init.	Type	Description
MDEFVSI_2N	15:0	0x0	RW	**Management Decision Filter VSI 2n** Defines the VSI used for packets matching MDEF 2*n.
MDEFVSI_2NP1	31:16	0x0	RW	**Management Decision Filter VSI 2n+1** Defines the VSI used for packets matching MDEF 2*n+1.

38.39.2.22.16 Management Ethernet Type Filters - PRT_MNG_METF[n] (0x00256780 + 0x20*n, n=0...3; RO)

The METF registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets.

The METF registers are cleared on LAN_PWR_GOOD only. The initial values for this register might be loaded from the EEPROM after power-up reset.

Field	Bit(s)	Init.	Type	Description
ETYPE	15:0	0x0	RW	**EtherType** Value to be compared against the *L2 EtherType* field in the Rx packet. Appears in little endian order (high byte first on the wire).
RESERVED	29:16	0x0	RSV	Reserved.
POLARITY	30	0b	RW	**Polarity** 0b = Positive filter. Filter enters the decision filters if a match occurred. 1b = Negative filter. Filter enters the decision filters if a match did not occur.
RESERVED	31	0b	RSV	Reserved.

38.39.2.22.17 Management Control Register - PRT_MNG_MANC (0x00256A20; RO)

The MANC register can be written by the BMC, and is not accessible to the host for writing.

Field	Bit(s)	Init.	Type	Description
FLOW_CONTROL_DISCARD	0	0b	RW	**Flow Control Discard** 0b = Apply filtering rules to packets with Flow control EtherType. 1b = Discard packets with Flow control EtherType. ***Note:*** Flow control EtherType is 0x8808.
NCSI_DISCARD	1	0b	RW	**NC-SI Discard** 0b = Apply filtering rules to packets with NC-SI EtherType. 1b = Discard packets with NC-SI EtherType. ***Note:*** NC-SI EtherType is 0x88F8.
RESERVED	16:2	0x0	RSV	Reserved.
RCV_TCO_EN	17	0b	RW	**Receive TCO Packets Enabled** When this bit is set, it enables the receive flow to the manageability block. This bit should be set only if at least one of MANC.*EN_BMC2OS* or MANC.*EN_BMC2NET* bits are set.
RESERVED	24:18	0x0	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
FIXED_NET_TYPE	25	0b	RW	**Fixed Next Type** If set, only packets matching the net type defined by the *NET_TYPE* field are passed to manageability. Otherwise, both tagged and un-tagged packets may be forwarded to manageability engine.
NET_TYPE	26	0b	RW	**Net Type** 0b = Pass only un-tagged packets. 1b = Pass only VLAN tagged packets. Valid only if *FIXED_NET_TYPE* is set.
RESERVED	27	0b	RSV	Reserved.
EN_BMC2OS	28	0b	RW	**Enable BMC to OS and OS to BMC Traffic** 0b = The BMC can not communicate with the operating system. 1b = The BMC can communicate with the operating system. When cleared the BMC traffic is not forwarded to the operating system, even if the host address filtering indicates that it should. When cleared, operating system traffic is not forwarded to the BMC even if the manageability decision filters indicates it should. This bit does not impact the BMC to network traffic. ***Note:*** Initial value loaded according to value of port n traffic types field in NVM.
EN_BMC2NET	29	0b	RW	**Enable BMC to network and network to BMC traffic** 0b = The BMC can not communicate with the network. 1b = The BMC can communicate with the network When cleared, the BMC traffic is not forwarded to the network and the network traffic is not forwarded to the BMC even if the decision filters indicates it should. This bit does not impact the host to BMC traffic. ***Note:*** Initial value loaded according to value of port n traffic types field in NVM.
RESERVED	31:30	00b	RSV	Reserved.

38.39.2.22.18Management Only Traffic Register - PRT_MNG_MNGONLY (0x00256A60; RO)

The MNGONLY register enables exclusive filtering of certain types of traffic to the BMC. Exclusive filtering enables the BMC to define certain packets that are forwarded to the BMC but not to the host. The packets are not forwarded to the host even if they pass the host L2 filtering process.

Each manageability decision filter (MDEF and MDEF_EXT) has a corresponding bit in the MNGONLY register. When a manageability decision filter (MDEF and MDEF_EXT) forwards a packet to manageability, it might also block the packet from being forwarded to the host if the corresponding *MNGONLY* bit is set.

Field	Bit(s)	Init.	Type	Description
EXCLUSIVE_TO_MANAGEABILITY	7:0	0x0	RW	**Exclusive to MNG** When set, indicates that packets forwarded by the manageability filters to manageability are not sent to the host. Bits[0...7] correspond to decision rules defined in registers MDEF[0...7] and MDEF_EXT[0...7].
RESERVED	31:8	0x0	RSV	Reserved.

38.39.2.22.19Manageability Special Filters Modifiers - PRT_MNG_MSFM (0x00256AA0; RO)

Field	Bit(s)	Init.	Type	Description
PORT_26F_UDP	0	1b	RW	**Port 0x26F UDP** Port 0x26F match if protocol is UDP.
PORT_26F_TCP	1	1b	RW	**Port 0x26F TCP** Port 0x26F match if protocol is TCP.
PORT_298_UDP	2	1b	RW	**Port 0x298 UDP** Port 0x298 match if protocol is UDP.
PORT_298_TCP	3	1b	RW	**Port 0x298 TCP** Port 0x298 match if protocol is TCP.
IPV6_0_MASK	4	0b	RW	**IPv6 Address 0 Mask** Compare only 24 LSB bits of IPv6 Address 0 (MIPAF[0]).
IPV6_1_MASK	5	0b	RW	**IPv6 Address 1 Mask** Compare only 24 LSB bits of IPv6 Address 1 (MIPAF[1]).
IPV6_2_MASK	6	0b	RW	**IPv6 Address 2 Mask** Compare only 24 LSB bits of IPv6 Address 2 (MIPAF[2]).
IPV6_3_MASK	7	0b	RW	**IPv6 Address 3 Mask** Compare only 24 LSB bits of IPv6 Address 3 (MIPAF[3]).
RESERVED	31:8	0x0	RSV	Reserved.

38.39.4 Detailed Register Description - PF BAR3

38.39.4.1 PF - MSI-X Table Registers

This category contains registers in the separate MSI-X BAR.

38.39.4.1.1 MSI-X Message Address Low - MSIX_TADD[n] (0x00000000 + 0x10*n, n=0...128; RW)

Message lower address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTADD10	1:0	0x0	RW	**Message Address 1:0** For proper Dword alignment, software must always write zeros to these two bits; otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.
MSIXTADD	31:2	0x0	RW	**Message Address** System-specified message lower address. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the Dword-aligned address (AD[31:02]) for the memory write transaction. This field is read/write.

38.39.4.1.2 MSI-X Message Address High - MSIX_TUADD[n] (0x00000004 + 0x10*n, n=0...128; RW)

Message upper address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTUADD	31:0	0x0	RW	**Message Upper Address** System-specified message upper address bits. If this field is zero, Single Address Cycle (SAC) messages are used. If this field is non-zero, Dual Address Cycle (DAC) messages are used. This field is read/write.

38.39.4.1.3 MSI-X Message Data - MSIX_TMSG[n] (0x00000008 + 0x10*n, n=0...128; RW)

Message data for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTMSG	31:0	0x0	RW	**Message Data** System-specified message data. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write.

38.39.4.1.4 MSI-X Vector Control - MSIX_TVCTRL[n] (0x0000000C + 0x10*n, n=0...128; RW)

Vector control for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MASK	0	1b	RW	**Mask Bit** When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1b (entry is masked).
RESERVED	31:1	0x0	RSV	Reserved. After reset, the state of these bits must be 0b. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other *Vector Control* bits. If software modifies the value of these reserved bits, the result is undefined.

38.39.4.1.5 MSI-X PBA Structure - MSIX_PBA[n] (0x00001000 + 0x4*n, n=0...5; RO)

Pending bits for MSI-X PBA entries.

Field	Bit(s)	Init.	Type	Description
PENBIT	31:0	0x0	RO	**MSI-X Pending Bits** Each bit is set to 1b when the appropriate interrupt request is set, and cleared to 0b when the appropriate interrupt request is cleared.

38.39.4.1.6 VF MSI-X PBA Structure - VFMSIX_PBA[n] (0x00002000 + 0x4*n, n=0...19; RO)

Pending bits for MSI-X PBA entries.

Field	Bit(s)	Init.	Type	Description
PENBIT	31:0	0x0	RO	**MSI-X Pending Bits** Each bit is set to 1b when the appropriate interrupt request is set, and cleared to 0b when the appropriate interrupt request is cleared.

38.39.4.1.7 VF MSI-X Message Address Low - VFMSIX_TADD[n] (0x00002100 + 0x10*n, n=0...639; RW)

Message lower address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTADD10	1:0	0x0	RW	**Message Address 1:0** For proper Dword alignment, software must always write zeros to these two bits; otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.
MSIXTADD	31:2	0x0	RW	**Message Address** System-specified message lower address. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the Dword-aligned address (AD[31:02]) for the memory write transaction. This field is read/write.

38.39.4.1.8 VF MSI-X Message Address High - VFMSIX_TUADD[n] (0x00002104 + 0x10*n, n=0...639; RW)

Message upper address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTUADD	31:0	0x0	RW	**Message Upper Address** System-specified message upper address bits. If this field is zero, SAC messages are used. If this field is non-zero, DAC messages are used. This field is read/write.

38.39.4.1.9 VF MSI-X Message Data - VFMSIX_TMSG[n] (0x00002108 + 0x10*n, n=0...639; RW)

Message data for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTMSG	31:0	0x0	RW	**Message Data** System-specified message data. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write.

38.39.4.1.10 VF MSI-X Vector Control - VFMSIX_TVCTRL[n] (0x0000210C + 0x10*n, n=0...639; RW)

Vector control for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MASK	0	1b	RW	**Mask Bit** When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1b (entry is masked).
RESERVED	31:1	0x0	RSV	Reserved. After reset, the state of these bits must be 0b. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other *Vector Control* bits. If software modifies the value of these reserved bits, the result is undefined.

38.40 Device Registers - VF

38.40.1 VF Registers Mapping in the PF Space

Table 38-611.VF Registers Summary

Abbreviation	Virtual Address	Physical Address

38.40.3 Detailed Register Description - VF BAR0

38.40.3.1 PF - PCIe Registers

38.40.3.1.1 PCIe VF Flush Done - PFPCI_VF_FLUSH_DONE (0x0000E400; RO)

Field	Bit(s)	Init.	Type	Description
FLUSH_DONE	0	0b	RO	**Flush Done**
RESERVED	31:1	0x0	RSV	Reserved.

38.40.3.2 VF - General Registers

This section describes the registers allocated to a VF for generic control and status. These registers are tied to the VF and are not dependent of any resource allocation.

38.40.3.2.1 VF Reset Status - VFGEN_RSTAT (0x00008800; RW)

Field	Bit(s)	Init.	Type	Description
VFR_STATE	1:0	00b	RW	**VFR State** Defines the VFR reset progress as follows: 00b = VFR in progress. 01b = VFR completed. 10b = Reserved. 11b = Reserved. This field is used to communicate the reset progress to the VF with no impact on hardware functionality.
RESERVED	31:2	0x0	RSV	Reserved.

38.40.3.3 VF - Interrupt Registers

38.40.3.3.1 VF Interrupt Throttling for Interrupt N - VFINT_ITRN[n,INTVF] (0x00002800 + 0x40*n + 0x4*INTVF, n=0…2, INTVF=0…15; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the VFINT_ITR0 register (Section 38.39.2.9.6).

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR 'n' interval, where 'n' is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.40.3.3.2 VF Interrupt N Dynamic Control - VFINT_DYN_CTLN[INTVF] (0x00003800 + 0x4*INTVF, INTVF=0…15; RW)

Register index 'n' relates to interrupt 'n+1', while interrupt zero is controlled by the VFINT_DYN_CTL0 register (Section 38.39.2.9.8).

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.

Field	Bit(s)	Init.	Type	Description
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or no ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.40.3.3.3 VF Interrupt Zero Cause - VFINT_ICR0 (0x00004800; RCW)

Field	Bit(s)	Init.	Type	Description
INTEVENT	0	0b	RCW	**Interrupt Event indication** This bit is set on assertion of any causes for this interrupt, and cleared when the interrupt is asserted to the rate limit logic.
QUEUE_0	1	0b	RCW	**Queue 0** Queue 0 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_1	2	0b	RCW	**Queue 1** Queue 1 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_2	3	0b	RCW	**Queue 2** Queue 2 interrupt for LAN transmit and receive queues and PE CEQs.
QUEUE_3	4	0b	RCW	**Queue 3** Queue 3 interrupt for LAN transmit and receive queues and PE CEQs.
RESERVED	29:5	0x0	RSV	Reserved.
ADMINQ	30	0b	RCW	**Admin Queue** Send/receive admin queue interrupt indication.
SWINT	31	0b	RCW	**Software Interrupt indication**

38.40.3.3.4 VF Interrupt Throttling for Interrupt Zero - VFINT_ITR0[n] (0x00004C00 + 0x4*n, n=0...2; RW)

Field	Bit(s)	Init.	Type	Description
INTERVAL	11:0	0x0	RW	**Interval** ITR 'n' interval, where 'n' is the register index = 0,1,2 for the three ITRs per interrupt. It is defined in 2 us units, enabling interval range from zero to 8160 us (0xFF0). Setting the INTERVAL to zero enables immediate interrupt. This register can also be programmed by setting the *INTERVAL* field in the matched xxINT_DYN_CTLx register.
RESERVED	31:12	0x0	RSV	Reserved.

38.40.3.3.5 VF Interrupt Zero Cause Enablement - VFINT_ICR0_ENA (0x00005000; RW)

Field	Bit(s)	Init.	Type	Description
RESERVED	29:0	0x0	RSV	Reserved.
ADMINQ	30	0b	RW	**Admin Queue** Enable this interrupt at 1b.
RESERVED	31	0b	RW	Reserved.

38.40.3.3.6 VF Interrupt Zero Static Control - VFINT_STAT_CTL0 (0x00005400; RW)

In case of MSI or legacy INTA mode of operation, interrupt zero is the only valid interrupt.

Field	Bit(s)	Init.	Type	Description
RESERVED	1:0	00b	RSV	Reserved.
OTHER_ITR_INDX	3:2	00b	RW	**Other ITR Index** ITR index of the other interrupt causes: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR.
RESERVED	31:4	0x0	RSV	Reserved.

38.40.3.3.7 VF Interrupt Zero Dynamic Control - VFINT_DYN_CTL0 (0x00005C00; RW)

Field	Bit(s)	Init.	Type	Description
INTENA	0	0b	RW	**Interrupt Enable** 0b = Interrupt disabled. 1b = Interrupt enabled. Refer to auto-clear policy in the Interrupt Enablement section. This bit is meaningful only if the *INTENA_MSK* flag in this register is not set.
CLEARPBA	1	0b	RW1C	**Clear PBA** Setting this bit clears the matched PBA bit. This bit is auto-cleared by hardware.
SWINT_TRIG	2	0b	RW1C	**Software Interrupt Trigger** When this bit is set, a software interrupt is triggered. This bit is auto-cleared by hardware.
ITR_INDX	4:3	00b	RW1C	**ITR Index** Defines the ITR index to be updated, as follows: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR update. This field is auto-cleared by hardware.
INTERVAL	16:5	0x0	RW1C	**Interval** The interval for the ITR defined by the *ITR_INDX* field in this register. This field is auto-cleared by hardware.
RESERVED	23:17	0x0	RSV	Reserved.
SW_ITR_INDX_ENA	24	0b	RW1C	**Software ITR Index Enable** Enables the programming of the *SW_ITR_INDX* field in this register. This flag is auto-cleared by hardware.

Field	Bit(s)	Init.	Type	Description
SW_ITR_INDX	26:25	00b	RW	**Software ITR Index** ITR index of the software interrupt: 00b = ITR0. 01b = ITR1. 10b = ITR2. 11b = No ITR. When programming this field, the *SW_ITR_INDX_ENA* flag in this register should be set as well.
RESERVED	29:27	000b	RSV	Reserved.
WB_ON_ITR	30	0b	RW	When this bit is set, completed descriptors are indicated to host memory on ITR completion (or No ITR) regardless of the interrupt enablement in this register.
INTENA_MSK	31	0b	RW1C	**Interrupt Enable Mask** When this bit is set, the *INTENA* setting does not impact the device setting. This bit is auto-cleared by hardware.

38.40.3.4 VF - Admin Queue

38.40.3.4.1 VF Admin Receive Queue Base Address High - VF_ARQBAH (0x00006000; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAH	31:0	0x0	RW	**Admin Receive Queue Base Address High** Receive descriptor base address high.

38.40.3.4.2 VF Admin Transmit Head - VF_ATQH (0x00006400; RW)

Field	Bit(s)	Init.	Type	Description
ATQH	9:0	0x0	RW	**Admin Transmit Queue Head** Transmit queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.40.3.4.3 VF Admin Transmit Queue Length - VF_ATQLEN (0x00006800; RW)

Field	Bit(s)	Init.	Type	Description
ATQLEN	9:0	0x0	RW	**Admin Transmit Queue Length** Descriptor ring length. Maximum size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ATQVFE	28	0b	RW	**Admin Transmit Queue** VF Error Set by firmware on a PF queue when one of its VFs has an admin queue error.
ATQOVFL	29	0b	RW	**Admin Transmit Queue** Overflow Error Set by firmware when a message is lost because there is no room in the queue.
ATQCRIT	30	0b	RW	**Admin Transmit Queue** Critical Error Set by firmware when a critical error is detected on this queue.
ATQENABLE	31	0b	RW	**Admin Transmit Queue** Enable Set by the software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by VFR.

38.40.3.4.4 VF admin receive queue base address low - VF_ARQBAL (0x00006C00; RW)

Field	Bit(s)	Init.	Type	Description
ARQBAL	31:0	0x0	RW	**Admin Receive Queue Base Address Low** Receive descriptor base address low. Must be 64-byte aligned.

38.40.3.4.5 VF Admin Receive Queue Tail - VF_ARQT (0x00007000; RW)

Field	Bit(s)	Init.	Type	Description
ARQT	9:0	0x0	RW	**Admin Receive Queue Tail** Receive queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once the queue is fully configured, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.40.3.4.6 VF Admin Receive Queue Head - VF_ARQH (0x00007400; RW)

Field	Bit(s)	Init.	Type	Description
ARQH	9:0	0x0	RW	**Admin Receive Queue Head** Receive queue head pointer. At queue initialization, software clears the head pointer. During normal operation, firmware increments the head following command execution.
RESERVED	31:10	0x0	RSV	Reserved.

38.40.3.4.7 VF Admin Transmit Queue Base Address High - VF_ATQBAH (0x00007800; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAH	31:0	0x0	RW	**Admin Transmit Queue Base Address High** Transmit descriptor base address high.

38.40.3.4.8 VF Admin Transmit Queue Base Address Low - VF_ATQBAL (0x00007C00; RW)

Field	Bit(s)	Init.	Type	Description
ATQBAL	31:0	0x0	RW	**Admin Transmit Queue Base Address Low** Transmit descriptor base address low. Must be 64-byte aligned.

38.40.3.4.9 VF Admin Receive Queue Length - VF_ARQLEN (0x00008000; RW)

Field	Bit(s)	Init.	Type	Description
ARQLEN	9:0	0x0	RW	**Admin Receive Queue Length** Descriptor ring length. Maximum size is 1024.
RESERVED	27:10	0x0	RSV	Reserved.
ARQVFE	28	0b	RW	**Admin Receive Queue** VF Error Set by firmware on a PF queue when one of its VFs has an admin queue error.
ARQOVFL	29	0b	RW	**Admin Receive Queue** Overflow Error Set by firmware when a message is lost because there is no room in the queue.
ARQCRIT	30	0b	RW	**Admin Receive Queue** Critical Error Set by firmware when a critical error is detected on this queue.
ARQENABLE	31	0b	RW	**Admin Receive Queue** Enable Set by software device driver to indicate that the queue is active. When setting the enable bit, software should initialize all other fields. This flag is cleared by PFR.

38.40.3.4.10 VF Admin Transmit Tail - VF_ATQT (0x00008400; RW)

Field	Bit(s)	Init.	Type	Description
ATQT	9:0	0x0	RW	**Admin Transmit Queue Tail** Transmit queue tail pointer. Incremented to indicate that there are new valid descriptors on the ring. Software can only write to this register once both transmit and receive queues are properly initialized, and clears to zero at queue initialization.
RESERVED	31:10	0x0	RSV	Reserved.

38.40.3.5 VF - LAN Transmit Receive Registers

38.40.3.5.1 Global Transmit Queue Tail - QTX_TAIL[Q] (0x00000000 + 0x4*Q, Q=0...15; RW)

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	**Transmit Tail** Defines the first descriptor that software prepares for hardware (it is the last valid descriptor plus one). The tail is a relative descriptor index to the beginning of the transmit descriptor ring.
RESERVED	31:13	0x0	RSV	Reserved.

38.40.3.5.2 Global Receive Queue Tail - QRX_TAIL[Q] (0x00002000 + 0x4*Q, Q=0...15; RW)

Field	Bit(s)	Init.	Type	Description
TAIL	12:0	0x0	RW	**Receive Tail** Defines the first descriptor that software hands to hardware (it is the last valid descriptor plus one). The tail is a relative descriptor index to the beginning of the receive descriptor ring.
RESERVED	31:13	0x0	RSV	Reserved.

38.40.3.6 VF - Rx Filters Registers

38.40.3.6.1 VF Queue Filter Hash Enabled Packet Type - VFQF_HENA[n] (0x0000C400 + 0x4*n, n=0...1; RW)

Field	Bit(s)	Init.	Type	Description
PTYPE_ENA	31:0	0x0	RW	**Packet Type Enable** Packet type enablement of the hash filter for the function. Bit 'm' in register 'n' enables packet type '32*n+m' as defined in the Packet Types for the Classification Filters table.

38.40.3.6.2 VF Queue Filter Hash Region of Queues - VFQF_HREGION[n] (0x0000D400 + 0x4*n, n=0...7; RW)

Field	Bit(s)	Init.	Type	Description
OVERRIDE_ENA_0	0	0b	RW	**Override Enable 0** Override TC region for packet type '8*n', where 'n' is the register index.
REGION_0	3:1	000b	RW	**Region 0** Receive queue region for packet type '8*n', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_1	4	0b	RW	**Override Enable 1** Override TC region for packet type '8*n+1', where 'n' is the register index.
REGION_1	7:5	000b	RW	**Region 1** Receive queue region for packet type '8*n+1', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_2	8	0b	RW	**Override Enable 2** Override TC region for packet type '8*n+2', where 'n' is the register index.
REGION_2	11:9	000b	RW	**Region 2** Receive queue region for packet type '8*n+2', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_3	12	0b	RW	**Override Enable 3** Override TC region for packet type '8*n+3', where 'n' is the register index.
REGION_3	15:13	000b	RW	**Region 3** Receive queue region for packet type '8*n+3', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_4	16	0b	RW	**Override Enable 4** Override TC region for packet type '8*n+4', where 'n' is the register index.
REGION_4	19:17	000b	RW	**Region 4** Receive queue region for packet type '8*n+4', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_5	20	0b	RW	**Override Enable 5** Override TC region for packet type '8*n+5', where 'n' is the register index.
REGION_5	23:21	000b	RW	**Region 5** Receive queue region for packet type 8*n+5', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_6	24	0b	RW	**Override Enable 6** Override TC region for packet type '8*n+6', where 'n' is the register index.
REGION_6	27:25	000b	RW	**Region 6** Receive queue region for packet type '8*n+6', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.
OVERRIDE_ENA_7	28	0b	RW	**Override Enable 7** Override TC region for packet type '8*n+7', where 'n' is the register index.

Field	Bit(s)	Init.	Type	Description
REGION_7	31:29	000b	RW	**Region 7** Receive queue region for packet type '8*n+7', where 'n' is the register index. This field is meaningful only if the *OVERRIDE_ENA_1* flag is set.

38.40.3.7 VF - Protocol Engine Registers

38.40.3.7.1 Protocol Engine VF IP Config 0 - VFPE_IPCONFIG0 (0x00008C00; RW)

This register is used to set or view the *IPID* field that the PE writes into the IP header. The PE increments this value for each outgoing IP datagram.

Field	Bit(s)	Init.	Type	Description
PEIPID	15:0	0x0	RW	**PE IP Identification** Specifies the *IP Identification* field used for IPv4 IP header generation. This register is initialized by firmware or the software device driver, and incremented by hardware with each IPv4 datagram transmitted by PE both UDA and iWARP on the given PCI function.
USEENTIREIDRANGE	16	0b	RW	**Use Entire ID Range** Specifies that the PE should use the entire 16-bit range for the IPID value.
RESERVED	31:17	0x0	RSV	Reserved.

38.40.3.7.2 Protocol Engine VF MRTE Index Mask - VFPE_MRTEIDXMASK (0x00009000; RW)

Field	Bit(s)	Init.	Type	Description
MRTEIDXMASKBITS	4:0	0x0	RW	**MRTE Index Mask Bits** Specifies the number of bits to be used for the MRTE index from the software device driver portion of STag. The remaining bits (24 - *MRTEIDEMASKBITS*) are randomized by the software device driver. The minimum value for this field is 14 and the maximum is 22. Values outside of this range are normalized to 14 or 22 by the hardware.
RESERVED	31:5	0x0	RSV	Reserved.

38.40.3.7.3 Protocol Engine VF Unexpected Error - VFPE_RCVUNEXPECTEDERROR (0x00009400; RO)

Field	Bit(s)	Init.	Type	Description
TCP_RX_UNEXP_ERR	23:0	0x0	RW	**TCP Received Unexpected Error** For PE accelerated connections only, counts the total number of Ethernet frames received by the product that failed TCP sanity checks indicating unexpected filtering error in preceding module.
RESERVED	31:24	0x0	RSV	Reserved.

38.40.3.7.4 Protocol Engine VF Create CQP High - VFPE_CCQPHIGH (0x00009800; RW)

This register stores the upper 32 bits of the 64-bit physical address of the control QP context for its associated PCI function.

Field	Bit(s)	Init.	Type	Description
PECCQPHIGH	31:0	0x0	RW	**PE Create CQP High** Most significant bits of the control QP context physical address in host memory.

38.40.3.7.5 Protocol Engine CQP Error Codes - VFPE_CQPERRCODES (0x00009C00; RO)

This register reports errors encountered by CQP when CQ0 is not available. The contents of this register are only valid when the associated CCQPSTATUS.*CCQP_ERR* bit or CQPTAIL.*CQP_ERR* bit is set.

Field	Bit(s)	Init.	Type	Description
CQP_MINOR_CODE	15:0	0x0	RW	**CQP Minor Code** Minor code that would have been reported in a CQP Completion.
CQP_MAJOR_CODE	31:16	0x0	RW	**CQP Major Code** Major code that would have been reported in a CQP Completion.

38.40.3.7.6 Protocol Engine CQP Tail - VFPE_CQPTAIL (0x0000A000; RO)

This register is used to determine how much work the PE control QP has pending. Software can determine if CQP has pending work by comparing the last value written to *WQHEAD* in the CQPDB register to *WQTAIL* after reading this register.

Field	Bit(s)	Init.	Type	Description
WQTAIL	10:0	0x0	RW	**Work Queue Tail** Indicates the WQE index of the next WQE that the CQP processes.
RESERVED	30:11	0x0	RSV	Reserved.
CQP_OP_ERR	31	0b	RW	**CQP Operation Error** Indicates that the CQP encountered an error processing an operation. If software has multiple requests outstanding to the CQP at the time of the error, *WQTAIL* might not indicate the WQE that caused the error.

38.40.3.7.7 Protocol Engine VF AEQ Allocate - VFPE_AEQALLOC (0x0000A400; RW)

Field	Bit(s)	Init.	Type	Description
AECOUNT	31:0	0x0	RW	**Asynchronous Event Count** Specifies the number of asynchronous event queue entries that have been processed by software and can now be reused by hardware.

38.40.3.7.8 Protocol Engine VF TCP Now Timer - VFPE_TCPNOWTIMER (0x0000A800; RO)

Field	Bit(s)	Init.	Type	Description
TCP_NOW	31:0	0x0	RO	**TCP Now** Contains the current value of tcp_now. *TCP_NOW* is a 32-bit counter and provides the TCP time measurement for the all of the timers. It is also used to calculate the TS value sent in the TCP time stamp option, tcp_now is added to tsval_tick_delta to form the TS value.

38.40.3.7.9 Protocol Engine VF Create CQP Low - VFPE_CCQPLOW (0x0000AC00; RW)

This register stores the lower 32 bits of the 64-bit physical address of the control QP context for its associated PCI function. Under host software control, each PCI function uses its Create Control QP High/Low registers to create its corresponding Control QP (QP0). The 64-bit address must always be updated by writing the *PECCQPLOW* field last.

Field	Bit(s)	Init.	Type	Description
PECCQPLOW	31:0	0x0	RW	**PE Create CQP Low** Least significant bits of the control QP context physical address in host memory.

38.40.3.7.10 Protocol Engine VF CQ ACK - VFPE_CQACK (0x0000B000; RW)

This register is used to acknowledge a completion event for a PE completion queue. The interrupt processing logic that handles completion events must write this register in order to enable new events for a completion queue.

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to enable new events for a PE completion queue.
RESERVED	31:17	0x0	RSV	Reserved.

38.40.3.7.11 Protocol Engine VF CQ Arm - VFPE_CQARM (0x0000B400; RW)

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PECQID	16:0	0x0	RW	**PE Completion Queue ID** Used to arm a PE completion queue for generating events in conjunction with the completion queue doorbell shadow area located in host memory. Arming is also frequently referred to as requesting notification for a completion queue. Events can be generated when the next completion is generated or when the next completion related to a solicited operation is generated. On read, this register returns the value of 0x0.
RESERVED	31:17	0x0	RSV	Reserved.

38.40.3.7.12 Protocol Engine VF Create CQP Status - VFPE_CCQPSTATUS (0x0000B800; RW)

This register is used to indicate the progress of creating the control QP for a given PCI function. During host software initialization, these bits are initially zero. Each bit is set when the associated step of the initialization process completes.

Field	Bit(s)	Init.	Type	Description
CCQP_DONE	0	0b	RW	**Create CQP Done** 0b = Indicates that the CQP has not been created. 1b = Indicates that the create CQP operation triggered by writing to PECCQPHIGH and PECCQPLOW completed.
RESERVED	3:1	000b	RSV	Reserved.

Field	Bit(s)	Init.	Type	Description
HMC_PROFILE	6:4	000b	RW	**HMC Profile** Specifies the HMC resource profile that is active. 000b = Reserved. 001b = Default. 010b = SR-IOV VF primary. 011b = SR-IOV even distribution. All other values are reserved.
RESERVED	15:7	0x0	RSV	Reserved.
RDMA_EN_VFS	21:16	0x0	RW	**RDMA Enabled VFs** Specifies the number of RDMA enabled VFs allocated in the HMC resource profile.
RESERVED	30:22	0x0	RSV	Reserved.
CCQP_ERR	31	0b	RW	**Create CQP Error** Indicates that the CQP encountered an error processing the last create CQP request. This bit is reset when CQP is not created.

38.40.3.7.13 Protocol Engine VF CQP Doorbell - VFPE_CQPDB (0x0000BC00; RW)

This register is used to post work the PE control QP. Software can determine if CQP has pending work by comparing *WQHEAD* to *WQTAIL* after reading this register. Software must first populate one or more WQEs in the CQP WQ and then put the index of the WQE following the last populated WQE into *WQHEAD* in order to submit work to CQP.

Field	Bit(s)	Init.	Type	Description
WQHEAD	10:0	0x0	RW	**Work Queue Head** Indicates the WQE index of the next WQE that software posts to the CQP.
RESERVED	31:11	0x0	RSV	Reserved.

38.40.3.7.14 Protocol Engine VF WQE Allocate Register - VFPE_WQEALLOC (0x0000C000; RW)

This register is used to post work the PE queue pairs.

Note: This register is also located in the PE doorbell page section of the BAR.

Field	Bit(s)	Init.	Type	Description
PEQPID	17:0	0x0	RW	**PE Queue Pair ID** This field should be used to notify hardware the new work is available to be processed.
RESERVED	19:18	00b	RSV	Reserved.
WQE_DESC_INDEX	31:20	0x0	RW	**WQE Index** Indicates a high 12 bits of the WQE index in the send queue. This field is used to identify a push mode message in the head of the SQ. Push mode message is processed by hardware only if it is in the head of the send queue, and otherwise it is dropped and processed when WQE is re-fetched during regular transmit operation. This field is used for the push mode doorbells only. For the regular doorbells, this field should be treated as reserved, and ignored by hardware.

38.40.4 BAR3 Registers Summary

Table 38-613.BAR3 Registers Summary

Offset / Alias Offset	Abbreviation	Name	Page
VF - MSI-X Table Registers			
0x00000000 + 0x10*n, n=0...16	VFMSIX_TADD[n]	VF MSI-X Message Address Low	3698
0x00000004 + 0x10*n, n=0...16	VFMSIX_TUADD[n]	VF MSI-X Message Address High	3698
0x00000008 + 0x10*n, n=0...16	VFMSIX_TMSG[n]	VF MSI-X Message Data	3699
0x0000000C + 0x10*n, n=0...16	VFMSIX_TVCTRL[n]	VF MSI-X Vector Control	3699
0x00002000	VFMSIX_PBA	VF MSI-X PBA Structure	3699

38.40.5 Detailed Register Description - VF BAR3

38.40.5.1 VF - MSI-X Table Registers

38.40.5.1.1 VF MSI-X Message Address Low - VFMSIX_TADD[n] (0x00000000 + 0x10*n, n=0...16; RW)

Message lower address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTADD10	1:0	0x0	RW	**Message Address 1:0** For proper Dword alignment, software must always write zeros to these two bits; otherwise, the result is undefined. The state of these bits after reset must be 0b. These bits are permitted to be read-only or read/write.
MSIXTADD	31:2	0x0	RW	**Message Address** System-specified message lower address. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the Dword-aligned address (AD[31:02]) for the memory write transaction. This field is read/write.

38.40.5.1.2 VF MSI-X Message Address High - VFMSIX_TUADD[n] (0x00000004 + 0x10*n, n=0...16; RW)

Message upper address for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTUADD	31:0	0x0	RW	**Message Upper Address** System-specified message upper address bits. If this field is zero, SAC messages are used. If this field is non-zero, DAC messages are used. This field is read/write.

38.40.5.1.3 VF MSI-X Message Data - VFMSIX_TMSG[n] (0x00000008 + 0x10*n, n=0…16; RW)

Message data for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MSIXTMSG	31:0	0x0	RW	**Message Data** System-specified message data. For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data driven on AD[31:0] during the memory write transaction's data phase. This field is read/write.

38.40.5.1.4 VF MSI-X Vector Control - VFMSIX_TVCTRL[n] (0x0000000C + 0x10*n, n=0…16; RW)

Vector control for MSI-X table entries.

Field	Bit(s)	Init.	Type	Description
MASK	0	1b	RW	**Mask Bit** When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1b (entry is masked).
RESERVED	31:1	0x0	RSV	Reserved. After reset, the state of these bits must be 0x0. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other *Vector Control* bits. If software modifies the value of these reserved bits, the result is undefined.

38.40.5.1.5 VF MSI-X PBA Structure - VFMSIX_PBA (0x00002000; RO)

Pending bits for MSI-X PBA entries.

Field	Bit(s)	Init.	Type	Description
PENBIT	31:0	0x0	RO	**MSI-X Pending Bits** Each bit is set to 1b when the appropriate interrupt request is set, and cleared to 0b when the appropriate interrupt request is cleared.

38.41 PCIe Programming Interface

The 10 GbE controller supports the following configuration register sets:

- PCI basic configuration registers.
- PCI and PCIe capabilities in the PCI configuration space (see Section 38.43).
  - Includes the PCIe capability structure.
- PCIe capabilities residing in the PCIe extended configuration Space (see Section 38.44).
- SR-IOV VF configuration space (see Section 38.45).

38.41.1 Functions Mapping

The 10 GbE controller is a multi-function device with the following characteristics:

- Up to 128 SR-IOV VFs
  - Each PF can be allocated a different number of VFs in the range {0,...,128} as long as the total number of VFs does not exceed 128.

The following rules apply regarding allocation of PCI functions to LAN ports:

- Each PCI function is associated with a single LAN port as indicated in the PFGEN_PORTNUM.PORT_NUM register field.

The number of enabled physical functions might be deducted from the PFPCI_STATUS1.FUNC_VALID bits (one per PF). Refer to the section about how enabled functions are determined.

The ARI capability enables interpretation of the device number part of the RID as part of the function number inside a device. Thus, a single device can span more than eight physical or virtual functions. Table 38-614 and Table 38-615 map the physical functions to PCI requester ID.

Table 38-614.RID Per PF - ARI Mode

PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
PF 15	B,1,7	B,00001,111	PF #15

Table 38-615.RID Per PF - non-ARI Mode

PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
PF 7	B,0,7	B,00000,111	PF #7

The requester ID of a PF (bus, device, and function numbers) is captured in the PF_FUNC_RID register.

38.41.2 Supported Features

Table 38-616 lists the PCI and PCIe capabilities supported per PCI function type. Some capabilities do not necessarily appear with each function or in all cases. See Section 38.43 and Section 38.44 for details on specific capabilities.

Table 38-616.PCI Capabilities Supported by Function

PCI Capability	PFs	VFs
PCI Configuration	Mandatory	Mandatory
Power Management	Yes	Yes
MSI	Yes	No
MSI-X	Yes	Yes
Vital Product Data (VPD)	Yes	No
PCIe	Yes	Yes
Advanced Error Reporting (AER)	Yes	Yes
Device Serial Number	Yes	No (N/A)
Alternative RID Interpretation (ARI)	Yes	Yes
Single Root I/O Virtualization (SR-IOV)	Yes	No (N/A)
TPH Requester	Yes	Yes
Access Control Services (ACS)	Yes	Yes
Secondary PCIe	Yes	No (N/A)

38.42 PCI Configuration Space

Configuration registers are assigned one of the attributes listed in the table that follows.

38.42.1 Register Attributes

The following table lists the register attributes used in this section.

RD/WR	Description
RO	Read-only register: Register bits are read-only and cannot be altered by software.
RW	Read-write register: Register bits are read-write and can be either set or reset.
RW1C	Read-only status, Write-1b-to-clear status register, Writing a 0b to RW1C bits has no effect.
ROS	Read-only register with sticky bits: Register bits are read-only and cannot be altered by software. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed below are also not reset on PERST# when aux power consumption is enabled.
RWS	Read-write register: Register bits are read-write and can be either set or cleared by software to the desired state. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed below are also not reset on PERST# when aux power consumption is enabled.
RW1CS	Read-only status, Write-1b-to-clear status register: Register bits indicate status when read, a set bit, indicating a status event, can be cleared by writing a 1b to it. Writing a 0b to RW1C bits has no effect. Bits are neither initialized nor modified by PCIe in-band reset or FLR. Specific bits listed in the sections that follow are also not reset on PERST# when aux power consumption is enabled.
HwInit	Hardware initialized: Register bits are initialized by firmware or hardware mechanisms such as pin strapping or serial NVM. Bits are read-only after initialization and can only be reset (for write-once by firmware) with the PWRGOOD signal.

RD/WR	Description
RsvdP	Reserved and preserved: Reserved for future read/write implementations; software must preserve value read for writes to these bits.
RsvdZ	Reserved and zero: Reserved for future RW1C implementations; software must use 0b for writes to these bits.

38.42.2 Reset Rules

Reset of the PCI configuration space (including any capability lists) is per the PCIe specification. Several cases require special attention.

38.42.2.1 Sticky REGISTERS

The following sticky register fields are also not reset on PERST# when aux power consumption is enabled (AUX_PWR pin is set).

- PME related fields:
  - Power Management Capabilities register — PME_En bit
  - Power Management Capabilities register — PME_Status bit
  - Device Control register — *Aux Power PM Enable* bit
  - The function Requester ID
- AER related fields:
  - Uncorrectable Error Status register
  - Uncorrectable Error Mask register
  - Uncorrectable Error Severity register
  - Correctable Error Status register
  - Correctable Error Mask register
  - Advanced Error Capabilities and Control register
  - Header log

38.42.2.2 Reset on FLR

The following registers are not affected by FLR:

- The *Max Payload Size* field in the Device Control register
- The *Active State Link PM Control* field in the Link Control register
- The *Common Clock Configuration* field in the Link Control register
- The *Extended Sync* field in the Link Control register
- The *Link Equalization Request* field in the Link Status 2 register

38.42.3 PCI Configuration Space Summary

Table 38-617 lists the PCI configuration registers while their detailed description is given in the sections that follow. Fields that have meaningful default values are indicated in parenthesis — (**value**).

The PCI configuration space from address 0x40 on is allocated for PCI capability structures as described in Section 38.43. However, the region of 0x98-0x9F (8 bytes) is dedicated to an address/data port, which provides access to the device I/O address space.

Table 38-617.PCI Configuration Space - PF

Section	Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
Mandatory PCI Register	0x0	Device ID		Vendor ID	
	0x4	Status Register		Command Register	
	0x8	Class Code (0x020000/0x010000)			Revision ID
	0xC	Reserved	Header Type (0x0/ 0x80)	Latency Timer	Cache Line Size (0x10)
	0x10	Base Address Register 0			
	0x14	Base Address Register 1			
	0x18	Base Address Register 2			
	0x1C	Base Address Register 3			
	0x20	Base Address Register 4			
	0x24	Base Address Register 5			
	0x28	CardBus CIS Pointer (0x0000)			
	0x2C	Subsystem ID		Subsystem Vendor ID	
	0x30	Expansion ROM Base Address			
	0x34	Reserved			Cap Ptr (0x40)
	0x38	Reserved			
	0x3C	Max Latency (0x00)	Min Grant (0x00)	Interrupt Pin (0x01...0x04)	Interrupt Line (0x00)

38.42.4 Sharing Among PCI Functions

The 10 GbE controller supports multiple PCI functions. As each function exposes a PCIe configuration space, each register and each field is either shared among the functions or is replicated per each PCI function. This section summarizes configuration sharing of the fixed PCI configuration space. See the description of each PCI capability structure for configuration sharing within it. Also, the description of each field describes special considerations regarding configuration sharing.

Table 38-618.Configuration Sharing of PCI Configuration Space

Field	Sub-field	Shared?	Replicated?	Comments
Vendor ID	Vendor ID	X		
Device ID	Device ID		X	
Command Register	I/O Access Enable		X	Issue UR per PF if disabled.
	Memory Access Enable		X	Issue UR per PF if disabled.
	Bus Master Enable		X	
	Parity Error Response		X	Enables certain error reporting per PF.
	SERR# Enable		X	Controls error reporting per PF.
	Interrupt Disable		X	Selection of interrupt method per PF.
Status Register	Interrupt Status		X	
	Capabilities List	X		Hardwired to 1b.
	Data Parity Reported / Master Data Parity Error		X	Reports poisoned packets per PF.
	Signaled Target Abort		X	Reports completer abort per PF.
	Received Target Abort		X	Reports receiving a completer abort per PF.

Table 38-618.Configuration Sharing of PCI Configuration Space

Field	Sub-field	Shared?	Replicated?	Comments
	Received Master Abort		X	Reports receiving an UR per PF.
	Signaled System Error		X	Reports Fatal / non-fatal message per PF.
	Detected Parity Error		X	Reports receiving a poisoned TLP per PF.
Revision Register		X		
Class Code Register			X	Per function type.
Cache Line Size Register			X	Does not affect device behavior.
Latency Timer		X		Hardwired to 0x00 in PCIe.
Header Type Register		X		
Reserved		X		
BARs	Memory BAR		X	
	I/O BAR		X	
	MSI-X BAR		X	See MSI-X capability.
I/O BAR mapping	IOADDR, IODATA		X	
Subsystem Vendor ID		X		
Subsystem ID			X	
Expansion ROM		X		Each PF has its own BAR.
Cap_Ptr Register		X		
Interrupt Line Register			X	Just store the register value.
Interrupt Pin Register			X	Separate interrupt number (A-D) per PF.
Min Grant		X		
Max Latency		X		

38.42.5 Mandatory PCI Configuration Registers — Except BARs

38.42.5.1 Vendor ID Register (0x0; RO)

This is a read-only register that has the same value for all PCI functions.

- Vendor ID is loaded from the NVM if the *GLPCI_CAPSUP.LOAD_DEV_ID* bit is set.
- The value for all PFs is loaded from the NVM *GLPCI_VENDORID.VENDOR_ID* field.

38.42.5.2 Device ID Register (0x2; RO)

This is a read-only register that identifies individual Product Name PCI functions. All functions have the same default value of 0x3A84, and can be auto-loaded from the NVM during initialization with different values for each function as well as the dummy function.

Device ID is loaded from the NVM according to the following rules:

- The Device ID is loaded from the NVM if the *GLPCI_CAPSUP.LOAD_DEV_ID* bit is set.
- The value of each PF is loaded to the respective *PFPCI_DEVID.PF_DEV_ID* field.

38.42.5.3 Command register (0x4; RW)

Shaded bits are not used by this implementation and are hardwired to 0b. Each function has its own Command register (see Table 38-618).

Bit(s)	Initial Value	RW	Description
0	0b	RW (see comment)	I/O Access Enable. This bit is RO if an I/O BAR is not supported by the device.
1	0b	RW	Memory Access Enable.
2	0b	RW	Enable mastering, also named Bus Master Enable (BME). • LAN functions RW field. • Dummy function RO as zero field.
3	0b	RO	Special Cycle Monitoring – Hardwired to 0b.
4	0b	RO	MWI Enable – Hardwired to 0b.
5	0b	RO	Palette Snoop Enable – Hardwired to 0b.
6	0b	RW	Parity Error Response.
7	0b	RO	Wait Cycle Enable – Hardwired to 0b.
8	0b	RW	SERR# Enable.
9	0b	RO	Fast Back-to-Back Enable – Hardwired to 0b.
10	0b	RW	Interrupt Disable. When set, devices are prevented from generating legacy interrupt messages. RO as 1b for a dummy function.
15:11	0b	RO	Reserved.

38.42.5.4 Status Register (0x6; RO)

Shaded bits are not used by this implementation and are hardwired to 0b. Each function has its own Status register.

Bits	Initial Value	RW	Description
2:0	0b		Reserved.
3	0b	RO	Interrupt Status.[1]
4	1b	RO	New Capabilities. Indicates that a device implements extended capabilities. The 10 GbE controller sets this bit and implements a capabilities list to indicate that it supports PCI and PCIe capabilities.
5	0b		66 MHz Capable – Hardwired to 0b.
6	0b		Reserved.
7	0b		Fast Back-to-Back Capable – Hardwired to 0b.
8	0b	RW1C	Data Parity Reported.
10:9	00b		DEVSEL Timing – Hardwired to 0b.
11	0b	RW1C	Signaled Target Abort.
12	0b	RW1C	Received Target Abort.
13	0b	RW1C	Received Master Abort.
14	0b	RW1C	Signaled System Error.
15	0b	RW1C	Detected Parity Error.

Notes:

1. The *Interrupt Status* field is a RO field that indicates that an interrupt message is pending internally to the device.

38.42.5.5 Revision Register (0x8; RO)

The default revision ID of this device is 0x00 for A0 step and 0x01 for B0 step. The default value is readable through the *GLPCI_DREVID* register. The value in the Revision register is a logic XOR between the default value and a value loaded from the NVM, reflected via the *GLPCI_REVID* register.

38.42.5.6 Class Code Register (0x9; RO)

The class code is a read-only value that identifies the device functionality:

- Class Code = 0x020000 (Ethernet adapter) if NVM->*Storage Class* = 0b.
- Class Code = 0x010000 (SCSI storage device) if NVM->*Storage Class* = 1b.

In the dummy function the class code equals to 0xFF0000.

Device default value is class code of an Ethernet adapter. The value is overwritten from the NVM. It is loaded to the RO PFPCI_CLASS register.

38.42.5.7 Cache Line Size Register (0xC; RW)

This field is implemented by PCIe devices as a read/write field for legacy compatibility purposes but has no impact on any PCIe device functionality. All functions are initialized to the same value of 0x00 (specification required).

38.42.5.8 Latency Timer (0xD; RO)

Not used. Hardwired to 0b.

38.42.5.9 Header Type Register (0xE; RO)

This indicates if a device is single- or multi-function:

- 0x00 — A single function is enabled
- 0x80 — At least two functions are enabled
- Dummy functions are considered as regular functions in this regard.
- Functions might be disabled during the power on reset flow (through strapping pins, SMASH/CLP commands, NC-SI commands) affecting this bit.

38.42.5.10 Subsystem Vendor ID Register (0x2C; RO)

This value is loaded from the NVM if the *GLPCI_CAPSUP.LOAD_SUBSYS_ID* bit is set. A value of 0x8086 is the default for this field. It can be read through the *GLPCI_SUBVENID* register.

38.42.5.11 Subsystem ID Register (0x2E; RO)

This value is loaded from the NVM if the *GLPCI_CAPSUP.LOAD_SUBSYS_ID* bit is set. Each PF is loaded to the respective PFPCI_SUBSYSID.PF_SUBSYS_ID field.

38.42.5.12 Capabilities Pointer Register (0x34; RO)

The *Capabilities Pointer* field (Cap_Ptr) is an 8-bit field that provides an offset in the 10 GbE controller's PCI configuration space for the location of the first item in the capabilities linked list. The 10 GbE controller supports this field and implements a capabilities list. Its value is 0x40, which is the address of the first entry: PCI power management.

38.42.5.13 Interrupt Line Register (0x3C; RW)

Read/write register programmed by software to indicate which of the system interrupt request lines the 10 GbE controller's interrupt pin is bound to. Refer to the PCI definition for more details.

38.42.5.14 Interrupt Pin Register (0x3D; RO)

Read-only register. — A value of 0x1...0x4 indicates that this function implements a legacy interrupt on INTA#...INTD# respectively. Loaded from the NVM. It can be read through the RO PFPCI_CNF register. Device default value is 0x0.

If only a single function is enabled, the I*nterrupt Pin* field of the enabled function reports INTA# usage.

Reports a value of 0x0 (function uses no legacy interrupt message) for a dummy function.

38.42.5.15 MIN_GNT and MAX_LAT (0x3E; RO)

Not used. Hardwired to 0b.

38.42.6 Mandatory PCI Configuration Registers — BARs

38.42.6.1 Memory and I/O BARs (0x10...0x27; RW)

BARs are used to map the 10 GbE controller register space of the device functions. The 10 GbE controller has a memory BAR, an I/O BAR (optional) an MSI-X BAR as listed in Table 38-619. The BARs location and sizes are listed in Table 38-619 and Table 38-620. The fields within each BAR are then listed in Table 38-621.

Table 38-619.Product Name BAR Description

Mapping Windows	Mapping Description
Memory BAR	The internal registers memories and external Flash devices are accessed as direct memory mapped offsets from the BAR. Software can access a Dword or 64 bits.
I/O BAR	All internal registers and memories can be accessed using I/O operations. There are two 4-byte registers in the I/O mapping window: Addr Reg and Data Reg accessible as Dword entities. The I/O BAR is supported depending on the NVM configuration. Device default value is that an I/O BAR is not supported. The state of the I/O BAR is exposed in the PFPCI_CNF register. This BAR is not present in dummy functions.
MSI-X BAR	The MSI-X vectors and PBA structures are accessed as direct memory mapped offsets from the MSI-X BAR. Software can access Dword entities. This BAR is not present in dummy functions.

Table 38-620.Product Name base Address Setting in 64-bit BARs Mode

BAR	Addr	31 5	4	3	2	1	0
0	0x10	Memory CSR + Flash BAR Low: 31:24 = RW; 23:18 = RW or 0b; 17:4 = 0b		0/1	1	0	0
1	0x14	Memory CSR + Flash BAR High (RW)					
2	0x18	IO BAR (RW — 31:5) (optional)	0	0	0	0	1
3	0x1C	MSI-X BAR Low (RW — 31:15; RO 0b — 14:4)		0/1	1	0	0
4	0x20	MSI-X BAR High (RW)					
5	0x24	Reserved (RO — 0)					

Table 38-621.Base Address Registers' Fields

Field	Bits	RW	Description
Memory and I/O Space Indication	0	RO	0b = Indicates memory space. 1b = Indicates I/O.
Memory Type	2:1	RO	This field is loaded from the NVM. Hardware default is 64-bit. The field is exposed in the GLPCI_LBARCTRL register. 00b = 32-bit BAR. 10b = 64-bit BAR.
Prefetch Memory	3	RO	This bit is loaded from NVM. This bit should be set only on systems that do not generate prefetchable cycles. Device default is 1b (prefetchable). It is exposed in the GLPCI_LBARCTRL register. 0b = Non-prefetchable space. 1b = Prefetchable space.
Address Space (low register for 64-bit memory BARs)	31:4	RW	The length of the RW bits and RO 0b bits depend on the mapping window sizes. Initial value of the RW fields is 0x0.

Mapping Window	RO bits
Memory space for CSRs and Flash memory access.	16:4 for 128 KB 17:4 for 256 KB and so on...
MSI-X space is 32 KB.	14:4
I/O space size is 32 bytes.	4:0

38.42.6.2 Expansion ROM Base Address Register (0x30; RW)

This register is used to define the address and size information for boot-time access to the optional Flash memory. This register returns a zero value for functions without an expansion ROM window and for dummy functions.

The expansion ROM BAR is disabled through the PFPCI_CNF.EXROM_DIS register field.

Field	Bit(s)	RW	Initial Value	Description
En	0	RW	0b	1b = Enables expansion ROM access. 0b = Disables expansion ROM access.
Reserved	10:1	R	0b	Always read as 0b. Writes are ignored.
Address	31:11	RW	0b	The number of bits that are not hardwired to 0b is determined by the value of the GLPCI_LBARCTRL.EXROM_SIZE register field, loaded from the NVM.

38.43 Capabilities in PCI Configuration Space

The first entry of the PCI capabilities link list is pointed to by the Cap_Ptr register. Table 38-622 lists the capabilities supported by the 10 GbE controller that reside in the PCI configuration space.

Table 38-622.PCI Capabilities List

Address range	Item	Cases Where Capability Does Not Exist	Next Pointer
0x40:4F	Power Management	None (always exists).	0x50 / 0xA0
0x50:6F	MSI	Dummy function.	0x70 / 0xA0
0x70:8F	MSI-X	1. PFPCI_CNF.MSI_EN is 0b. 2. Dummy function.	0xA0

Table 38-622.PCI Capabilities List

Address range	Item	Cases Where Capability Does Not Exist	Next Pointer
0xA0:DF	PCIe	None (always exists).	0xE0 / 0x00
0xE0:0xEF	VPD	1. VPD Enable bit (GLPCI_CAPCTRL.VPD_EN) is cleared. 2. Dummy function.	0x00

38.43.1 PCI power management capability

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x40	Power Management Capabilities		Next Pointer	Capability ID (0x01)
0x44	Data	Bridge Support Extensions	Power Management Control and Status	

Table 38-623 lists the sharing of the Power Management Capability registers among the different PCI functions.

Table 38-623.Sharing the Power Management Capability Registers

Field	Sub-field	Shared?	Replicated?	Comments
Capability ID		x		
Next Pointer			x	
Power Management Capabilities	PME_Support	x		
	D2_Support	x		
	D1_Support	x		
	AUX Current	x		
	DSI	x		
	PME Clock	x		Hardwired to 0b
	Version	x		
Power Management Control / Status	PME_Status		x	
	Data_Scale	x		
	Data_Select		x	
	PME_En		x	
	No_Soft_Reset	x		
	PowerState		x	
Data Register			x	

38.43.1.1 Capability ID Register (0x40; RO)

This field equals 0x01 indicating the linked list item as being the PCI Power Management registers.

38.43.1.2 Next Pointer Register (0x41; RO)

This field provides an offset to the next capability item in the capability list. See Table 38-622 for possible values of the next pointer register.

38.43.1.3 Power Management Capabilities — PMCR (0x42; RO)

This field describes the device functionality during the power management states as listed in the following table.

Bits	Default	RW	Description
15:11		RO	PME_Support. This 5-bit field indicates the power states in which the function can generate a PME event. condition functionality values are as follows: • No AUX Pwr PME at D0 and $D3_{HOT}$ = 01001b • AUX Pwr PME at D0, $D3_{HOT}$, and $D3_{COLD}$ = 11001b ***Note:*** For dummy function, this field is RO - zero.
10	0b	RO	D2_Support – The 10 GbE controller does not support the D2 state.
9	0b	RO	D1_Support – The 10 GbE controller does not support the D1 state.
8:6	000b	RO	AUX Current – Required current defined in the Data register.
5	1b	RO	DSI – The 10 GbE controller requires its device driver to be executed following a transition to the D0 uninitialized state.
4	0b	RsvdP	Reserved.
3	0b	RO	PME_Clock – Disabled. Hardwire to 0b.
2:0	011b	RO	Version – The 10 GbE controller complies with the PCI PM specification revision 1.2.

38.43.1.4 Power Management Control / Status Register — PMCSR (0x44; RW)

This register (listed in the following table) is used to control and monitor power management events in the device.

Bits	Default	RW	Description
15	0b (at power up)	RW1CS	PME_Status. This bit is set to 1b when the function detects a wake-up event independent of the state of the *PME_En* bit. Writing a 1b clears this bit.
14:13	00b	RO	Data_Scale. This field indicates the scaling factor that's used when interpreting the value of the Data register. This field is loaded from the NVM (through the GLPCI_PWRDATA.DATA_SCALE register) for legal values of Data_Select [0, 3, 4, 7, (and 8 for function 0)]. The normal value is 01b (indicating 0.1 watt/units). Reserved (00b) for any other values of Data_Select.
12:9	0000b	RW	Data_Select. This 4-bit field is used to select which data is to be reported through the Data register and *Data_Scale* field.
8	0b (at power up)	RWS	PME_En. Writing a 1b to this register enables wake up.
7:4	0000b	RO	Reserved.
3	1b	RO	No_Soft_Reset. This bit is always set to 1b to indicate that the 10 GbE controller does not perform an internal reset upon a transition from $D3_{HOT}$ to D0 via software control of the *PowerState* bits. Configuration context is maintained when performing the soft reset. Upon transition from the $D3_{HOT}$ to the D0 state, an initialization sequence is not needed in order to return the 10 GbE controller to the D0 Initialized state.
2	0b	RO	Reserved for PCIe.
1:0	00b	RW	PowerState. This field is used to set and report the power state of a function as follows: 00b = D0. 01b = D1 (cycle ignored if written with this value). 10b = D2 (cycle ignored if written with this value). 11b = D3

38.43.1.5 PMCSR_BSE Bridge Support Extensions Register (0x46; RO)

This register is not implemented in the 10 GbE controller; values set to 0x00.

38.43.1.6 Data Register (0x47; RO)

This optional register is used to report power consumption and heat dissipation. The reported register is controlled by the *Data_Select* field in the PMCSR; the power scale is reported in the *Data_Scale* field in the PMCSR. The data for this field is loaded from the NVM with a default value of 0x00. It is exposed through the GLPCI_PWRDATA register.

The values for the 10 GbE controller functions are as follows (the relevant column is selected based on the value of the Data_Select field):

Field	D0 (Consume/ Dissipate)	D3 (Consume/ Dissipate)	Common
Data_Select	(0x0/0x4)	(0x3/0x7)	(0x8)
Function 0	Loaded from NVM	Loaded from NVM	Multi-function value: Loaded from the NVM Single-function value: 0x00
Other functions	Loaded from NVM	Loaded from NVM	0x00

Note: For other Data_Select values the Data register output is reserved (0x00).

38.43.2 MSI Capability

This structure is enabled when the PFPCI_CNF.MSI_EN bit is set for the function

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x50	Message Control (0x0080)		Next Pointer	Capability ID (0x05)
0x54	Message Address			
0x58	Message Upper Address			
0x5C	Reserved		Message Data	
0x60	Mask Bits			
0x64	Pending Bits			

Table 38-624 lists configuration sharing of the MSI Capability registers among the different PCI functions.

Table 38-624.Configuration Sharing of the MSI Capability

Field	Sub-Field	Shared?	Replicated?	Comments
Capability ID		x		
Next Pointer			x	
Message Control	MSI Enable		x	
	Multiple Messages Capable	x		
	Multiple Message Enable		x	
	64-bit Capable	x		
	MSI Per-vector Masking	x

Pending Bits			x	

38.43.2.1 Capability ID Register (0x50; RO)

This field equals 0x05 indicating that the linked list item as being the MSI registers.

38.43.2.2 Next pointer Register (0x51; RO)

This field provides an offset to the next capability item in the capability list. See Table 38-622 for possible values of the next pointer register.

38.43.2.3 Message Control Register (0x52; RW)

Bits	Default	RW	Description
0	0b	RW	MSI Enable. 1b = Message Signaled Interrupts. The 10 GbE controller generates an MSI for interrupt assertion instead of INTx signaling.
3:1	000b	RO	Multiple Messages Capable. The 10 GbE controller indicates a single requested message per function.
6:4	000b	RW	Multiple Message Enable. Software writes to this field to indicate the number of allocated vectors Since The 10 GbE controller requests a single vector in the *Multiple Messages Capable* field, software is expected to write 000b to this field.
7	1b	RO	64-bit Capable. A value of 1b indicates that the 10 GbE controller is capable of generating 64-bit message addresses.
8	1b[1]	RO	MSI Per-vector Masking. A value of 0b indicates that the 10 GbE controller is not capable of per-vector masking. A value of 1b indicates that the 10 GbE controller is capable of per-vector masking. Exposed through the GLPCI_CAPSUP register.
15:9	0b	RO	Reserved. Reads as 0b

Notes:

1. Value loaded from the NVM.

38.43.2.4 Message Address Low Register (0x54; RW)

Written by the system to indicate the lower 32 bits of the address to use for the MSI memory write transaction. The lower two bits always return 0b regardless of the write operation.

38.43.2.5 Message Address High Register (0x58; RW)

Written by the system to indicate the upper 32 bits of the address to use for the MSI memory write transaction.

38.43.2.6 Message Data Register (0x5C; RW)

Written by the system to indicate the lower 16 bits of the data written in the MSI memory write Dword transaction. The upper 16 bits of the transaction are written as 0b.

38.43.2.7 Mask Bits Register (0x60; RW)

The Mask Bits and Pending Bits registers enable software to disable or defer message sending on a per-vector basis. Because the 10 GbE controller only supports one message, only bit 0 of these registers are implemented.

Bits	Default	RW	Description
0	0b	RW	MSI Vector 0 Mask. If set, the 10 GbE controller is prohibited from sending MSI messages.
31:1	0x0	RO	Reserved.

38.43.2.8 Pending Bits Register (0x64; RW)

Bits	Default	RW	Description
0	0b	RO	If set, the 10 GbE controller has a pending MSI message.
31:1	0x0	RO	Reserved.

38.43.3 MSI-X Capability

More than one MSI-X capability structure per function is prohibited while a function is permitted to have both an MSI and an MSI-X capability structure.

In contrast to the MSI capability structure, which directly contains all of the control/status information for the function's vectors, the MSI-X capability structure instead points to an MSI-X table structure and an MSI-X Pending Bit Array (PBA) structure, each residing in memory space.

A BAR is allocated for the MSI-X structures, described in Section 38.42.6. A BAR Indicator Register (BIR) indicates which BAR and a Qword-aligned offset indicates where the structure begins relative to the base address associated with the BAR. The BAR can be either 32-bit or is 64-bit.

The number of MSI-X vectors per PF (denoted as N) varies with the number of physical and virtual functions.

The MSI-X BAR is 32 KB long.

The location and size of the MSI-X vector table and the MSI-X pending bits table are determined as follows:

- MSI-X vector table:
  - The MSI-X table structure (Section 38.43.3.5) typically contains multiple entries, each consisting of several fields: *Message Address*, *Message Upper Address*, *Message Data*, and *Vector Control*. Each entry is capable of specifying a unique vector.
  - Starts at offset 0x0000 from start of BAR.
  - Contains the MSI-X vectors for the PF as well as the number of entries in table (N). The maximum value of N is 129 per PF (for the case of up to 4 PFs).
  - The vectors start with the Vector 0 (one per PF), followed by the other vectors allocated to the PF.
- MSI-X Pending Bits table:
  - The PBA structure [Section 38.43.3.5.2] contains the function's pending bits, one per table entry, organized as a packed array of bits within Qwords. The last Qword is not necessarily fully populated.

— Starts at offset 0x1000 (4 KB) from start of BAR.
— Contains the pending bits for the PF. The PF may be allocated a multiple of 64-bit registers. The total number of 32-bit registers is per the number of MSI-X vectors. The maximum number of registers is 6 (for the case of 129 vectors).
— The bits start with the Vector 0 bit (one per PF), followed by bits for the other vectors allocated to the PF.

To request service using a given MSI-X table entry, a function performs a Dword memory write transaction using:

- The contents of the *Message Data* field entry for data.
- The contents of the *Message Upper Address* field for the upper 32 bits of the address.
- The contents of the *Message Address* field entry for the lower 32 bits of the address.

A memory read transaction from the address targeted by the MSI-X message produces undefined results.

The MSI-X table and MSI-X PBA are permitted to co-reside within a naturally aligned 4 KB address range, though they must not overlap with each other.

38.43.3.1 Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	Message Control (0x00090)		Next Pointer	Capability ID (0x11)
0x74	Table Offset			
0x78	PBA Offset			

Table 38-625 lists configuration sharing of the MSI-X capability registers among the different PCI functions.

Table 38-625.Configuration Sharing of the MSI-X Capability

Capability ID		x		
Next Pointer			x	
Message Control	Table Size	x		
Function Mask			x	
MSI-X Enable			x	
MSI-X Table Offset	Table BIR		x	
	Table Offset		x	
MSI-X Pending Bit Array	PBA BIR		x	
	PBA Offset		x	
MSI-X Table			x	
MSI-X PBA Structure			x	

38.43.3.2 Capability ID Register (0x70; RO)

This field equals 0x11 indicating that the linked list item as being the MSI-X registers.

38.43.3.3 Next Pointer Register (0x71; RO)

This field provides an offset to the next capability item in the capability list. See Table 38-622 for possible values of the next pointer register.

38.43.3.4 Message Control Register (0x72; RW)

Bits	Default	RW	Description
10:0	0x80 (129 vectors)	RO	Table Size. System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. N varies with the number of physical functions. This field is loaded from the NVM. It is reflected in the GLPCI_CNF2.MSI_X_PF_N CSR field.
13:11	0x0	RO	Always returns 0b on a read. A write operation has no effect.
14	0b	RW	Function Mask. If 1b, all of the vectors associated with the function are masked, regardless of their per-vector *Mask* bit states. If 0b, each vector's *Mask* bit determines whether the vector is masked or not. Setting or clearing the MSI-X *Function Mask* bit has no effect on the state of the per-vector *Mask* bits.
15	0b	RW	MSI-X Enable. If 1b and the MSI *Enable* bit in the MSI Message Control register is 0b, the function is permitted to use MSI-X to request service and is prohibited from using its INTx# pin. System configuration software sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a function's service request. If 0b, the function is prohibited from using MSI-X to request service.

38.43.3.4.1 MSI-X Table Offset Register (0x74; RW)

Bits	Default	RW	Description
2:0	0x3	RO	Table BIR. Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X table into the memory space. While BIR values: 0...5 correspond to BARs 0x10:0x 24, respectively.
31:3	0x000	RO	Table Offset. Used as an offset from the address contained in one of the function's BARs to point to the base of the MSI-X table. The lower three *Table BIR* bits are masked off (set to 0b) by software to form a 32-bit Qword-aligned offset. Note that this field is read only.

38.43.3.4.2 MSI-X Pending Bit Array — PBA Offset (0x78; RW)

Bits	Default	RW	Description
2:0	0x3	RO	PBA BIR. Indicates which one of a function's BARs, beginning at 0x10 in the configuration space, is used to map the function's MSI-X PBA into the memory space. While BIR values: 0...5 correspond to BARs 0x10:0x 24, respectively.
31:3	0x200	RO	PBA Offset. Used as an offset from the address contained in one of the functions BARs to point to the base of the MSI-X PBA. The lower three PBA BIR bits are masked off (set to 0b) by software to form a 32-bit Qword-aligned offset. This field is read only.

38.43.3.5 PF MSI-X Table Structure

The MSI-X table is made of two structures:

- MSI-X Vector Table
- MSI-X Pending Bits Table

Both are described in the sections that follow.

38.43.3.5.1 MSI-X Vector Table

Dword3 — MSIXTVCTRL	Dword2 — MSIXTMSG	Dword1 — MSIXTUADD	Dword0 — MSIXTADD	Entry Number	BAR 3 — Offset
Vector Control	Msg Data	Msg Upper Addr	Msg Lower Addr	0	Base (0x0000)
Vector Control	Msg Data	Msg Upper Addr	Msg Lower Addr	1	Base + 1*16
Vector Control	Msg Data	Msg Upper Addr	Msg Lower Addr	2	Base + 2*16
…	…	…	…	…	
Vector Control	Msg Data	Msg Upper Addr	Msg Lower Addr	(N-1)	Base + (N-1)*16

38.43.3.5.2 MSI-X Pending Bits Table

Field	Bit(s)	Init Val.	Description
PENBIT	31:0	0x0	MSI-X Pending Bits. Each bit is set to 1b when the appropriate interrupt request is set and cleared to 0b when the appropriate interrupt request is cleared.

38.43.4 VPD Registers

The 10 GbE controller supports access to a VPD structure stored in the NVM using the following set of registers. A single VPD structure is provided, accessible through any of the physical functions.

Initial values of the configuration registers are marked in parenthesis.

Note: The VPD structure is available through all physical functions. As the interface is common to the functions, accessing the VPD structure of one function while an access to the NVM is in process on another function can yield to unexpected results.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0xE0	VPD Address		Next Pointer	Capability ID (0x03)
0xE4	VPD Data			

38.43.4.1 Capability ID Register (0xE0; RO)

This field equals 0x3 indicating the linked list item as being the VPD registers.

38.43.4.2 Next pointer Register (0xE1; RO)

Offset to the next capability item in the capability list. See Table 38-622 for possible values of the next pointer register.

38.43.4.3 VPD Address Register (0xE2; RW)

Word-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate.

Bits	Default	Rd/Wr	Description
14:0	X	RW	Address. Dword-aligned byte address of the VPD area in the NVM to be accessed. The register is read/write, and the initial value at power-up is indeterminate. The two LSBs are RO as zero.
15	0b	RW	F. A flag used to indicate when the transfer of data between the VPD Data register and the storage component completes. The Flag register is written when the VPD Address register is written. 0b = Read. Set by hardware when data is valid. 1b = Write. Cleared by hardware when data is written to the NVM. The VPD address and data should not be modified before the action is done.

38.43.4.4 VPD Data Register (0xE4; RW)

VPD read/write data.

Bits	Default	Rd/Wr	Description
31:0	X	RW	VPD Data. VPD data can be read or written through this register. The LSB of this register (at offset 4 in this capability structure) corresponds to the byte of VPD at the address specified by the VPD Address register. The data read from or written to this register uses the normal PCI byte transfer capabilities. Four bytes are always transferred between this register and the VPD storage component. Reading or writing data outside of the VPD space in the storage component is not allowed. In a write access, the data should be set before the address and the flag is set.

38.43.5 PCIe Capability Structure

The 10 GbE controller implements the PCIe capability structure linked to the legacy PCI capability list for endpoint devices as follows:

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0xA0	PCIe Capability Register (0x0002)		Next Pointer	Capability ID (0x10)
0xA4	Device Capability			
0xA8	Device Status		Device Control	
0xAC	Link Capability			
0xB0	Link Status		Link Control	
0xB4	Reserved			
0xB8	Reserved		Reserved	
0xBC	Reserved			
0xC0	Reserved		Reserved	
0xC4	Device Capability 2			
0xC8	Reserved		Device Control 2	
0xCC	Reserved			
0xD0	Link Status 2		Link Control 2	
0xD4	Reserved			
0xD8	Reserved		Reserved	

Table 38-626 lists configuration sharing of the PCIe Capability registers among the different PCI functions.

Table 38-626.Configuration Sharing of the PCIe Capability (Sheet 1 of 2)

Field	Sub-field	Shared?	Replicated?	Comments
Capability ID		X		
Next Pointer			X	
PCIe Capabilities		X		
Device Capabilities	Max Payload Size Supported	X		
	Phantom Functions Supported	X		Not supported.
	Extended Tag Field Supported	X

	Transactions Pending		X	
Link Capabilities	Supported Link Speeds	X		
	Max Link Width	X		
	Active State Link PM Support	X		
	L0s Exit Latency	X		
	L1 Exit Latency	X		
	Clock Power Management	X		

Table 38-626.Configuration Sharing of the PCIe Capability (Sheet 2 of 2)

Field	Sub-field	Shared?	Replicated?	Comments
	Port Number	X		
Link Control	Active State Link PM Control		X	Same policy for all PFs (logical AND of the PFs' bits). In ARI mode, use value in function 0.
	Read Completion Boundary (RCB)		X	
	Common Clock Configuration		X	Same policy for all PFs (logical AND of the PFs' bits). In ARI mode, use value in function 0.
	Extended Sync		X	Same policy for all PFs (logical OR of the PFs' bits).
Link Status	Current Link Speed	X		
	Negotiated Link Width	X		
	Slot Clock Configuration	X		
Device Capabilities 2	Completion Timeout Ranges Supported	X		
	Completion Timeout Disable Supported	X		
	TPH Completer Supported	X		
	Extended Fmt Field Supported	X		
	OBFF Supported	X		
Device Control 2	Completion Timeout Value		X	Completion timeout decision per PF or use the largest configured value among PFs.
	Completion Timeout Disable		X	Completion timeout mechanism enabled per PF.
	IDO Request Enable		X	
	IDO Completion Enable		X	
	OBFF Enable		X	PF0 only. RsvdP on other functions.
Link Capabilities 2		X		
Link Control 2		X		PF0 only. RsvdP on other functions.
Link Status 2		X		

38.43.5.1 Capability ID Register (0xA0; RO)

This field equals 0x10 indicating that the linked list item as being the PCIe Capabilities registers.

38.43.5.2 Next Pointer Register (0xA1; RO)

Offset to the next capability item in the capability list. See Table 38-622 for possible values of the next pointer register.

38.43.5.3 PCIe Capabilities Register (0xA2; RO)

The PCIe Capabilities register identifies PCIe device type and associated capabilities.

Bits	Default	RW	Description
3:0	0010b	RO	Capability Version. Indicates the PCIe capability structure version. The 10 GbE controller supports PCIe version 2 (loaded from the NVM). It is reflected in the GLPCI_CAPSUP register.
7:4	0000b/ 1001b	RO	Device/Port Type. Indicates the type of PCIe functions. All functions are native PCI functions with a value of 0000b if *strap_gbe_pci_endpoint_type* strap is set to native and are root complex integrated endpoint if set to RCIE.
8	0b	RO	Slot Implemented. The 10 GbE controller does not implement slot options. Therefore, this field is hardwired to 0b.
13:9	00000b	RO	Interrupt Message Number. This field is hardwired to 0x0 and is assumed to be irrelevant for endpoints.
15:14	00b	RO	Reserved.

38.43.5.4 Device Capabilities Register (0xA4; RO)

This register identifies the PCIe device specific capabilities.

Bits	Rd/Wr	Default	Description
2:0	RO	100b	Max Payload Size Supported. This field indicates the maximum payload that the 10 GbE controller can support for TLPs. Set according to the strap_gbe_imps strap. If strap_gbe_imps strap = 111b, then the default is 000b (128 bytes).
4:3	RO	00b	Phantom Function Supported. Not supported by the 10 GbE controller.
5	RO	1b	Extended Tag Field Supported. Maximum supported size of the *Tag* field. The 10 GbE controller supports an 8-bit *Tag* field for all functions.
8:6	RO	011b	Endpoint L0s Acceptable Latency. This field indicates the acceptable latency that the 10 GbE controller can withstand due to the transition from the L0s state to the L0 state. All functions share the same value loaded from the NVM. It is reflected in the *GLPCI_PMSUP* register. The default value of 011b denotes a maximum 512 ns.
11:9	RO	110b	Endpoint L1 Acceptable Latency. This field indicates the acceptable latency that the 10 GbE controller can withstand due to the transition from L1 state to the L0 state. The default value of 110b denotes a maximum of 64 µs. All functions share the same value loaded from the NVM. It is reflected in the *GLPCI_PMSUP* register.
12	RO	0b	Hardwired in the 10 GbE controller to 0b for all functions.
13	RO	0b	Hardwired in the 10 GbE controller to 0b for all functions.
14	RO	0b	Hardwired in the 10 GbE controller to 0b for all functions.
15	RO	1b	Role Based Error Reporting. Hardwired in the 10 GbE controller to 1b for all functions.
17:16	RO	000b	Reserved 0b.
25:18	RO	0x00	Slot Power Limit Value. Used in upstream ports only. Hardwired in the 10 GbE controller to 0x00 for all functions.
27:26	RO	00b	Slot Power Limit Scale. Used in upstream ports only. Hardwired in the 10 GbE controller to 0b for all functions.
28	RO	1b	Function Level Reset Capability – A value of 1b indicates the function supports the optional FLR mechanism.
31:29	RO	0000b	Reserved.

38.43.5.5 Device Control Register (0xA8; RW)

This register controls the PCIe specific parameters.

Bits	RW	Default	Description
0	RW	0b	Correctable Error Reporting Enable. Enable error report.
1	RW	0b	Non-Fatal Error Reporting Enable. Enable error report.
2	RW	0b	Fatal Error Reporting Enable. Enable error report.
3	RW	0b	Unsupported Request Reporting Enable. Enable error report.
4	RW	1b	Enable Relaxed Ordering. If this bit is set, the 10 GbE controller is permitted to set the *Relaxed Ordering* bit in the *Attribute* field of write transactions that do not need strong ordering.
7:5	RW	000b (128 bytes)	Max Payload Size. This field sets the maximum TLP payload size for the 10 GbE controller functions. As a receiver, the 10 GbE controller must handle TLPs as large as the set value. As a transmitter, the 10 GbE controller must not generate TLPs exceeding the set value. In ARI mode, *Max Payload Size* is determined solely by the field in function 0 (even when it is a dummy function) while it is meaningless in the other function(s).
8	RW	1b	Extended Tag Field Enable. The 10 GbE controller uses 8-bit tags when this bit is set and a 5-bit tag when disabled. If this bit is cleared in one of the functions, 5-bit tag is used by all functions.
9	RW	0b	Phantom Functions Enable. Not implemented in the 10 GbE controller.
10	RWS	0b	Aux Power PM Enable. When set, enables the 10 GbE controller to draw AUX power independent of PME AUX power. The 10 GbE controller is a multi-function device, therefore allowed to draw AUX power if at least one of the functions has this bit set.
11	RW	0b	Enable No Snoop. Hardwired to 0b as the 10 GbE controller never sets the no snoop attribute in a TLP.
14:12	RW	010b	Max Read Request Size. This field sets maximum read request size for the 10 GbE controller as a requester. 000b = 128 bytes. 001b = 256 bytes. 010b = 512 bytes. 011b = 1024 bytes. 100b = 2048 bytes. 101b = 4096 bytes 110b = Reserved. 111b = Reserved.
15	RW	0b	Initiate FLR. A write of 1b initiates FLR to the function. The value read by software from this bit is always 0b.

38.43.5.6 Device Status Register (0xAA; RW1C)

This register provides information about PCIe device specific parameters.

Bits	RW	Default	Description
0	RW1C	0b	Correctable Detected. Indicates status of correctable error detection.
1	RW1C	0b	Non-Fatal Error Detected. Indicates status of non-fatal error detection.
2	RW1C	0b	Fatal Error Detected. Indicates status of fatal error detection.
3	RW1C	0b	Unsupported Request Detected. Indicates that the 10 GbE controller received an unsupported request. This field is separate per PF. However, in case where an error cannot be associated with a PF, this bit is set in all PFs and VFs.
4	RO	0b	Aux Power Detected. If aux power is detected, this field is set to 1b. It is a strapping signal from the periphery and is identical for all functions. Resets on RSMRST# and PE_RST_N only.
5	RO	0b	Transactions Pending. Indicates whether the 10 GbE controller has ANY transactions pending. Transactions include completions for any outstanding non-posted request for all used traffic classes.
15:6	RsvdZ	0x00	Reserved.

38.43.5.7 Link Capabilities Register (0xAC; RO)

This register identifies PCIe link-specific capabilities.

A root complex integrated endpoint MUST not implement this register and return a value of zero when accessed.

If the gbe_pci_endpoint_type strap is set to RCIE, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
3:0	RO	N/A	Max Link Speed. This field indicates the maximum Link speed of the associated port. The encoding is the binary value of the bit location in the supported link speeds vector (in the Link Capabilities 2 register) that corresponds to the maximum link speed. For example, a value of 0011b in this field indicates that the maximum link speed is that corresponding to bit 2 in the supported link speeds vector, which is 8.0 GT/s. Multi-function devices associated with an upstream port must report the same value in this field for all functions. When the gbe_soc strap is set, this field must be set to 0x1 (Gen1) by setting the GLPCI_LINKCAPLINK_SPEEDS_VECTOR field in the NVM to 000001b.
9:4	RO	0x08 (0x1 if gbe_soc strap is set)	Max Link Width. Indicates the maximum link width. The 10 GbE controller supports a x1, x4 and x8-link width. This field is loaded from the NVM and is reflected in the GLPCI_LINKCAP register. Defined encoding: 000000b = Reserved. 000001b = x1. 000010b = Reserved. 000100b = x4. 001000b = x8. When the gbe_soc strap is set, this field must be set to 0x1 (x1).

Bits	RW	Default	Description
11:10	RO	11b	Active State Link PM Support. Indicates the level of the active state of power management supported in the 10 GbE controller. Defined encodings are: 00b = No ASPM support. 01b = L0s entry supported. 10b = L1 supported. 11b = L0s and L1 supported. All functions share the same value loaded from the NVM. It is reflected in the GLPCI_PMSUP register. When the gbe_soc strap is set, this field must be set to 11b (Gen1).
14:12	RO	101b (000b if gbe_soc strap is set)	L0s Exit Latency. Indicates the exit latency from L0s to L0 state. 000b = Less than 64 ns. 001b = 64 ns – 128 ns. 010b = 128ns – 256 ns. 011b = 256 ns – 512 ns. 100b = 512 ns – 1 µs. 101b = 1 µs – 2 µs. 110b = 2 µs – 4 µs. 111b = Reserved. All functions share the same value loaded from the NVM. It is reflected in the GLPCI_PMSUP register. When the gbe_soc strap is set, this field must be set to 000b (less than 64 ns).
17:15	RO	100b (000b if gbe_soc strap is set)	L1 Exit Latency. Indicates the exit latency from L1 to L0 state. 000b = Less than 1 µs. 001b = 1 µs – 2 µs. 010b = 2 µs – 4 µs. 011b = 4 µs – 8 µs. 100b = 8 µs – 16 µs. 101b = 16 µs – 32 µs. 110b = 32 µs – 64 µs. 111b = More than 64 µs. All functions share the same value loaded from the NVM. It is reflected in the GLPCI_PMSUP register. When the gbe_soc strap is set, this field must be set to 000b (less than 1 µs).
18	RO	0b	Clock Power Management (not supported).
19	RO	0b	Surprise Down Error Reporting Capable. Hardwired to 0b.
20	RO	0b	Data Link Layer Link Active Reporting Capable.
21	RO	0b	Link Bandwidth Notification Capability. Hardwired to 0b (not applicable to endpoints).
22	HwInit	1b	ASPM Optionality Compliance. Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests.
23	RO	0b	Reserved.
31:24	HwInit	0x0	Port Number. The PCIe port number for the given PCIe link. This field is set in the link training phase. The field is set through the gbe_DeviceNumberN strap.

38.43.5.8 Link Control Register (0xB0; RO)

This register controls PCIe link specific parameters.

If the gbe_pci_endpoint_type strap is set to RCIE, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
1:0	RW	00b	Active State Link PM Control. This field controls the active state PM enabled on the link. Link PM functionality is determined by the lowest common denominator of all functions. Defined encodings are: 00b = PM Disabled. 01b = L0s entry supported. 10b = L1 entry enabled 11b = L0s and L1 supported. In ARI mode, the ASPM is determined solely by the field in function 0 (even when it is a dummy function) while it is meaningless in the other function(s).
2	RsvdP	0b	Reserved.
3	RW	0b	Read Completion Boundary.
4	RO	0b	Link Disable. Reserved for endpoint devices. Hardwired to 0b.
5	RO	0b	Retrain Clock. Not applicable for endpoint devices. Hardwired to 0b.
6	RW	0b	Common Clock Configuration. When set, indicates that the 10 GbE controller and the component at the other end of the link are operating with a common reference clock. A value of 0b indicates that they are operating with an asynchronous clock. This parameter affects the L0s exit latencies. In ARI mode, the common clock configuration is determined solely by the field in function 0 (even when it is a dummy function) while it is meaningless in the other function(s).
7	RW	0b	Extended Sync. When set, this bit forces the transmission of additional ordered sets when exiting the L0s state and when in the recovery state. For multi-function devices, if any function has this bit set, then the component must transmit the additional ordered sets when exiting L0s or when in recovery
8	RO	0b	Enable Clock Power Management. Not supported - hardwired to 0b.
9	RO/RsvdP	0b	Hardware Autonomous Width Disable. When set to 1b, this bit disables hardware from changing the link width for reasons other than attempting to correct an unreliable link operation by reducing link width. Not supported - function 0 is hardwired to 0b (RO). Other functions are RsvdP.
10	RO	0b	Link Bandwidth Management Interrupt Enable. Not applicable to endpoints. Hardwired to 0b.
11	RO	0b	Link Autonomous Bandwidth Interrupt Enable. Not applicable to endpoints. Hardwired to 0b.
15:12	RsvdP	0x0	Reserved.

38.43.5.9 Link Status Register (0xB2; RO)

This register provides information about PCIe link specific parameters.

If the gbe_pci_endpoint_type strap is set to RCIE, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
3:0	RO	Undefined	Current Link Speed. This field indicates the negotiated link speed of the given PCIe link. The encoded value specifies a bit location in the supported link speeds vector (in the Link Capabilities 2 register) that corresponds to the current link speed. For example, a value of 0010b in this field indicates that the current Link speed is that corresponding to bit 1 in the supported link speeds vector, which is 5.0 GT/s. Returns 001b (Gen1) if gbe_soc strap is set.
9:4	RO	Undefined	Negotiated Link Width. Indicates the negotiated width of the link. Relevant encodings for the 10 GbE controller are: 000001b = x1. 000010b = X2. 000100b = x4. 001000b = x8. Returns 000001b (x1) if gbe_soc strap is set.
10	RO	0b	Undefined.
11	RO	0b	Link Training. Indicates that link training is in progress. This field is not applicable, is reserved for endpoint devices, and is hardwired to 0b.
12	HwInit	1b	Slot Clock Configuration. When set, indicates that the 10 GbE controller uses the physical reference clock that the platform provides at the connector. This bit must be cleared if the 10 GbE controller uses an independent clock. The *Slot Clock Configuration* bit is loaded from the NVM. It is reflected in the GLPCI_PMSUP register. Must be set if gbe_soc strap is set.
13	RO	0b	Data Link Layer Link Active. Not supported in the 10 GbE controller. Hardwired to 0b.
14	RO	0b	Link Bandwidth Management Status. Not supported in the 10 GbE controller. Hardwired to 0b.
15	RO	0b	Link Autonomous Bandwidth Status. This bit is not applicable and is reserved for endpoints.

The following registers are supported only if the capability version is two and above.

38.43.5.10 Device Capabilities 2 Register (0xC4; RO)

This register identifies the PCIe device-specific capabilities.

Bits	RW	Default	Description
3:0	RO	0011b	Completion Timeout Ranges Supported. This field indicates the 10 GbE controller's support for the optional completion timeout programmability mechanism. Four time value ranges are defined: • Range A: 50 µs – 10 ms. • Range B: 10 ms – 250 ms. • Range C: 250 ms – 4 s. • Range D: 4 s – 64 s. Bits are set according to the following values to show the timeout value ranges that the 10 GbE controller supports. • 0000b = Completion timeout programming not supported. The 10 GbE controller must implement a timeout value in the range of 50 µs – 50 ms. • 0001b = Range A. • 0010b = Range B. • 0011b = Ranges A and B. • 0110b = Ranges B and C. • 0111b = Ranges A, B and C. • 1110b = Ranges B, C and D. • 1111b = Ranges A, B, C and D. • All other values are reserved.
4	RO	1b	Completion Timeout Disable Supported. ***Note:*** For dummy functionality, a completion timeout is not relevant as a dummy function because it never sends non-posted requests.
5	RO	0b	ARI Forwarding Supported. Applicable only to Switch Downstream Ports and Root Ports; must be 0b for other function types.
10:6	RO	0x00	Not supported - hardwired to 0x00
11	RO	0b	Reserved.
13:12	RO	00b	TPH Completer Supported - Value indicates Completer support for TPH or Extended TPH This capability is not supported.
17:14	RsvdP	0x0	Reserved
19:18	HWinit	00b	OBFF Supported. 00b = OBFF not supported. 01b = Reserved. 10b = Reserved. 11b = Reserved. Loaded from the NVM with a value of 00b. The value loaded from the NVM is reflected in the GLPCI_PMSUP register.
21:20	RO	0b	Reserved.
31:22	RsvdP	0x0	Reserved

38.43.5.11 Device Control 2 Register (0xC8; RW)

This register controls the PCIe specific parameters.

Bits	RW	Default	Description
3:0	RW	0x0	Completion Timeout Value. For devices that support completion timeout programmability, this field enables system software to modify the completion timeout value. Defined encodings: • 0000b = Default range: 50 µs to 50 ms. ***Note:*** It is strongly recommended that the completion timeout mechanism not expire in less than 10 ms. Values available if range A (50 µs to 10 ms) programmability range is supported: • 0001b = 50 µs to 100 µs. • 0010b = 1 ms to 10 ms. Values available if range B (10 ms to 250 ms) programmability range is supported: • 0101b = 16 ms to 55 ms. • 0110b = 65 ms to 210 ms. Values available if range C (250 ms to 4 s) programmability range is supported: • 1001b = 260 ms to 900 ms. • 1010b = 1 s to 3.5 s. Values available if the range D (4 s to 64 s) programmability range is supported: • 1101b = 4 s to 13 s. • 1110b = 17 s to 64 s. Values not defined are reserved. Software is permitted to change the value of this field at any time. For requests already pending when the completion timeout value is changed, hardware is permitted to use either the new or the old value for the outstanding requests and is permitted to base the start time for each request either on when this value was changed or on when each request was issued. Specifically, FLR clears this field to its default, so that completions are expected to return by the default time. ***Note:*** For dummy function, this field is RO - zero.
4	RW	0b	Completion Timeout Disable. When set to 1b, this bit disables the completion timeout mechanism. Software is permitted to set or clear this bit at any time. When set, the completion timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued. ***Note:*** For dummy function, this field is RO - zero.
5	RO	0b	ARI Forwarding Enable. Applicable only to switch devices.
7:6	RO	00b	Not supported - hardwired to 00b.
8	RW	0b	IDO Request Enable. If this bit is set, the function is permitted to set the ID-Based Ordering (IDO) bit (Attribute[2]) of Requests it initiates.
9	RW	0b	IDO Completion Enable. If this bit is set, the Function is permitted to set the ID-Based Ordering (IDO) bit (Attribute[2]) of completions it returns.
10	RO / RsvdP	0b	Reserved.
12:11	RO	0x0	Reserved.
14:13	RW / RsvdP	00b	OBFF Enable. 00b = Disabled. 01b = Enabled using message signaling [variation A]. 10b = Enabled using message signaling [variation B]. 11b = Enabled using WAKE# signaling.
15	RsvdP	0b	End-End TLP Prefix Blocking. Not applicable to endpoints (RsvdP).

38.43.5.12 Link Capabilities 2 Register (0xCC)

If the gbe_pci_endpoint_type strap is set to RCIE strap or the gbe_soc strap is set, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
0	RsvdP	0b	Reserved
7:1	RO	0x01	Supported Link Speeds Vector. This field indicates the supported Link speed(s) of the associated port. For each bit, a value of 1b indicates that the corresponding link speed is supported; otherwise, the Link speed is not supported. Bit definitions are: Bit 1 = 2.5 GT/s. Bit 2 = 5.0 GT/s. Bit 3 = 8.0 GT/s. Bits 7:4 = RsvdP. This field is loaded from the NVM and reflected in the GLPCI_LINKCAP register.
8	RO	0b	Crosslink Supported. When set to 1b, this bit indicates that the associated port supports crosslinks. It is recommended that this bit be set in any port that supports crosslinks even though doing so is only required for ports that also support operating at 8.0 GT/s or higher Link speeds.
31:9	RsvdP	0x00	Reserved.

38.43.5.13 Link Control 2 Register (0xD0; RWS)

If the gbe_pci_endpoint_type strap is set to RCIE strap or the gbe_soc strap is set, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
3:0	RWS (func 0) / RsvdP (else)	0011b (func 0) 0000b (else)	Target Link Speed. This field is used to set the target compliance mode speed when software is using the *Enter Compliance* bit to force a link into compliance mode. The encoding is the binary value of the bit in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the desired target Link speed. All other encodings are Reserved. For example, 5.0 GT/s corresponds to bit 1 in the Supported Link Speeds Vector, so the encoding for a 5.0 GT/s target Link speed in this field is 0010b If a value is written to this field that does not correspond to a speed included in the *Supported Link Speeds* field, the result is undefined. The default value of this field is the highest link speed supported by the 10 GbE controller (as reported in the *Supported Link Speeds* field of the Link Capabilities register).
4	RWS (func 0) / RsvdP (else)	0b	Enter Compliance. Software is permitted to force a link to enter compliance mode at the speed indicated in the *Target Link Speed* field by setting this bit to 1b in both components on a link and then initiating a hot reset on the link. The default value of this field following a fundamental reset is 0b.
5	RWS (func 0) / RsvdP (else)	0b	Hardware Autonomous Speed Disable. When set to 1b, this bit disables hardware from changing the link speed for reasons other than attempting to correct unreliable link operation by reducing link speed.
6	RO	0b	Selectable De-Emphasis. This bit is not applicable and reserved for endpoints.

Bits	RW	Default	Description
9:7	RWS (func 0) / RsvdP (else)	000b	Transmit Margin. This field controls the value of the non de emphasized voltage level at the Transmitter pins. Encodings: 000b = Normal operating range. 001b = 800-1200 mV for full swing and 400-700 mV for half-swing. 010b = (n-1) — Values must be monotonic with a non-zero slope. The value of n must be greater than 3 and less than 7. At least two of these must be below the normal operating range of n: 200-400 mV for full-swing and 100-200 mV for half-swing. 111b= (n) reserved.
10	RWS (func 0) / RsvdP (else)	0b	Enter Modified Compliance. When this bit is set to 1b, the device transmits modified compliance pattern if the LTSSM enters Polling.Compliance state. The default value of this bit is 0b.
11	RWS (func 0) / RsvdP (else)	0b	Compliance SOS. When set to 1b, the LTSSM is required to send SOS periodically in between the (modified) compliance patterns. This bit is applicable when the Link is operating at 2.5 GT/s or 5 GT/s data rates only. The default value of this bit is 0b.
15:12	RWS (func 0) / RsvdP (else)	0x0	Compliance Preset/De-emphasis. For 8.0 GT/s Data Rate. This field sets the Transmitter Preset in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. For 5.0 GT/s Data Rate. This field sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. When the link is operating at 2.5 GT/s, the setting of this bit field has no effect. Defined encodings are: 0001b = -3.5 dB. 0000b = -6 dB. The default value of this field is 0000b.

38.43.5.14 Link Status 2 Register (0xD2; RW)

If the gbe_pci_endpoint_type strap is set to RCIE strap or the gbe_soc strap is set, then this register is hardwired to zero, otherwise the description is as follows:

Bits	RW	Default	Description
0	RO	0b	Current De-emphasis Level. When the link is operating at 5 GT/s speed, this bit reflects the level of de-emphasis. it is undefined when the link is not operating at 5.0 GT/s speed. Encodings: 1b = -3.5 dB. 0b = -6 dB. ***Note:*** Same value must be reported for all functions.
1	ROS/RsvdZ	0b	Equalization Complete. When set to 1b, this bit indicates that the transmitter equalization procedure has completed. ***Note:*** This bit must be implemented in function 0 and RsvdZ in other functions.
2	ROS/RsvdZ	0b	Equalization Phase 1 Successful. When set to 1b, this bit indicates that phase 1 of the transmitter equalization procedure has successfully completed. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
3	ROS/RsvdZ	0b	Equalization Phase 2 Successful. When set to 1b, this bit indicates that phase 2 of the transmitter equalization procedure has successfully completed. ***Note:*** This bit must be implemented in function 0 and RsvdZ in other functions.
4	ROS/RsvdZ	0b	Equalization Phase 3 Successful. When set to 1b, this bit indicates that phase 3 of the transmitter equalization procedure has successfully completed. ***Note:*** This bit must be implemented in function 0 and RsvdZ in other functions.

Bits	RW	Default	Description
5	RW1C/ RsvdZ	0b	Link Equalization Request. This bit is set by hardware to request the link equalization process to be performed on the link. ***Note:*** This bit must be implemented in Function 0 and RsvdZ in other Functions.
15:6	RsvdZ	0x00	Reserved.

38.44 PCIe Extended Configuration Space

PCIe configuration space is located in a flat memory-mapped address space. PCIe extends the configuration space beyond the 256 bytes available for PCI to 4096 bytes. The 10 GbE controller decodes an additional four bits (bits 27:24) to provide the additional configuration space as shown. PCIe reserves the remaining four bits (bits 31:28) for future expansion of the configuration space beyond 4096 bytes.

The configuration address for a PCIe device is computed using a PCI-compatible bus, device, and function numbers as follows:

31 28	27 20	19 15	14 12	11 2	1 0
0000b	Bus #	Device #	Fun #	Register Address (offset)	00b

PCIe extended configuration space is allocated using a linked list of optional or required PCIe extended capabilities following a format resembling PCI capability structures. The first PCIe extended capability is located at offset 0x100 in the device configuration space. The first Dword of the capability structure identifies the capability/version and points to the next capability.

The 10 GbE controller supports the following PCIe extended capabilities:

Table 38-627.Extended Capabilities List

Address range	Item	Cases Where Capability Does Not Exist	Next Pointer
0x100 - 0x128	Advanced Error Reporting (AER)	None (always present)	Any of the below / 0x000
0x140 - 0x148	Device Serial Number	NVM is not valid	Any of the below / 0x000
0x150 - 0x154	Alternative RID Interpretation (ARI)	ARI Enabled bit in NVM is set to 0b	Any of the below / 0x000
0x160 - 0x19C	Single Root I/O Virtualization (SR-IOV)	- The global SR-IOV Enable bit in NVM is set to 0b (exposed via the *GLPCI_CAPSUP.IOV_EN* bit) - This is a dummy function - The per-PF SR-IOV Enable bit is set to 0b (*PF_VT_PFALLOC.VALID* is cleared)	Any of the below / 0x000
0x1A0 - 0x1A8	TPH Requester	- TPH Enabled bit in NVM is set to 0b - This is a dummy function	Any of the below / 0x000
0x1B0 - 0x1B4	Access Control Services (ACS)	- ACS Enabled bit in NVM is set to 0b - A single PF is enabled and SR-IOV is disabled	Any of the below / 0x000
0x1D0 - 0x1E8	Secondary PCI Express	- Secondary PCIe Enabled bit in NVM is set to 0b - Function is not function 0	0x000

38.44.1 Advanced Error Reporting Capability (AER)

The PCIe advanced error reporting capability is an optional extended capability to support advanced error reporting. The tables that follow list the PCIe advanced error reporting extended capability structure for PCIe devices.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x100	Next Capability Ptr.	Version (0x1)	AER Capability ID (0x0001)	
0x104	Uncorrectable Error Status			
0x108	Uncorrectable Error Mask			
0x10C	Uncorrectable Error Severity			
0x110	Correctable Error Status			
0x114	Correctable Error Mask			
0x118	Advanced Error Capabilities and Control Register			
0x11C... 0x128	Header Log			

Table 38-628 summarizes configuration sharing of the AER Capability registers among the different PCI functions.

Table 38-628.Configuration Sharing of the AER Capability

Field	Sub-field	Shared?	Replicated?	Comments
Enhanced Capability Header Register	Extended Capability ID	X		
	Capability Version	X		
	Next Capability Offset		X	
Uncorrectable Error Status			X

Uncorrectable Error Severity			X	
Correctable Error Status			X	
Correctable Error Mask			X	
Advanced Error Capabilities and Control	First Error Pointer		X	
	ECRC Generation Capable	X		
	ECRC Generation Enable		X	ECRC insertion is per PF.
	ECRC Check Capable	X		
	ECRC Check Enable		X	
Header Log			X	

38.44.1.1 Advanced Error Reporting Enhanced Capability Header Register (0x100; RO)

Bit Location	Attribute	Default Value	Description
15:0	RO	0x0001	Extended Capability ID. PCIe extended capability ID indicating advanced error reporting capability.
19:16	RO	0x2	Version Number. PCIe advanced error reporting extended capability version number.
31:20	RO	See description	Next Capability Offset. Next PCIe extended capability offset. See Table 38-627 for possible values of the next capability offset.

38.44.1.2 Uncorrectable Error Status Register (0x104; RW1CS)

The Uncorrectable Error Status register reports error status of individual uncorrectable error sources on a PCIe device. An individual error status bit that is set to 1b indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit. Register is cleared by RSMRST#.

Bit Location	Attribute	Default Value	Description
0	RO	0b	Reserved
3:1	RsvdZ	000b	Reserved
4	RW1CS	0b	Data Link Protocol Error Status.
5	RO	0b	Reserved
11:6	RsvdZ	0x00	Reserved
12	RW1CS	0b	Poisoned TLP Status.
13	RW1CS	0b	Flow Control Protocol Error Status.
14	RW1CS	0b	Completion Timeout Status.
15	RW1CS	0b	Completer Abort Status.
16	RW1CS	0b	Unexpected Completion Status.
17	RW1CS	0b	Receiver Overflow Status.
18	RW1CS	0b	Malformed TLP Status.
19	RW1CS	0b	ECRC Error Status.
20	RW1CS	0b	Unsupported Request Error Status.
21	RO	0b	ACS Violation Status. Not supported. Hardwired to 0b.
25:22	RO	0x0	Not supported
31:26	RsvdZ	0b	Reserved

38.44.1.3 Uncorrectable Error Mask Register (0x108; RWS)

The Uncorrectable Error Mask register controls reporting of individual uncorrectable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. Note that there is a mask bit per bit of the Uncorrectable Error Status register.

Bit Location	Attribute	Default Value	Description
0	RO	0b	Reserved
3:1	RsvdP	000b	Reserved
4	RWS	0b	Data Link Protocol Error Mask.
5	RO	0b	Reserved
11:6	RsvdP	0x00	Reserved
12	RWS	0b	Poisoned TLP Mask.
13	RWS	0b	Flow Control Protocol Error Mask.
14	RWS	0b	Completion Timeout Mask.
15	RWS	0b	Completer Abort Mask.
16	RWS	0b	Unexpected Completion Mask.
17	RWS	0b	Receiver Overflow Mask.
18	RWS	0b	Malformed TLP Mask.
19	RWS	0b	ECRC Error Mask.
20	RWS	0b	Unsupported Request Error Mask.
21	RO	0b	ACS Violation Mask. Not supported. Hardwired to 0b.
25:22	RO	0x0	Not supported
31:26	RsvdP	0b	Reserved

38.44.1.4 Uncorrectable Error Severity Register (0x10C; RWS)

The Uncorrectable Error Severity register controls whether an individual uncorrectable error is reported as a fatal error. An uncorrectable error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered non-fatal.

Bit Location	Attribute	Default Value	Description
0	RO	0b	Reserved
3:1	RsvdP	000b	Reserved
4	RWS	1b	Data Link Protocol Error Severity.
5	RO	0b	Reserved
11:6	RsvdP	0x00	Reserved
12	RWS	0b	Poisoned TLP Severity.
13	RWS	1b	Flow Control Protocol Error Severity.
14	RWS	0b	Completion Timeout Severity.
15	RWS	0b	Completer Abort Severity.
16	RWS	0b	Unexpected Completion Severity.

Bit Location	Attribute	Default Value	Description
17	RWS	1b	Receiver Overflow Severity.
18	RWS	1b	Malformed TLP Severity.
19	RWS	0b	ECRC Error Severity.
20	RWS	0b	Unsupported Request Error Severity.
21	RO	0b	ACS Violation Severity. Not supported. Hardwired to 0b.
25:22	RO	0x0	Not supported
31:26	RsvdP	0b	Reserved

38.44.1.5 Correctable Error Status Register (0x110; RW1CS)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit. Register is cleared by RSMRST#.

Bit Location	Attribute	Default Value	Description
0	RW1CS	0b	Receiver Error Status.
5:1	RsvdZ	0b	Reserved
6	RW1CS	0b	Bad TLP Status.
7	RW1CS	0b	Bad DLLP Status.
8	RW1CS	0b	REPLAY_NUM Rollover Status.
11:9	RsvdZ	0b	Reserved
12	RW1CS	0b	Replay Timer Timeout Status.
13	RW1CS	0b	Advisory Non-Fatal Error Status.
15:14	RO	0b	Reserved
31:16	RsvdZ	0x00	Reserved

38.44.1.6 Correctable Error Mask Register (0x114; RWS)

The Correctable Error Mask register controls reporting of individual correctable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. There is a mask bit per bit in the Correctable Error Status register.

Bit Location	Attribute	Default Value	Description
0	RWS	0b	Receiver Error Mask.
5:1	RsvdP	0b	Reserved.
6	RWS	0b	Bad TLP Mask.
7	RWS	0b	Bad DLLP Mask.
8	RWS	0b	REPLAY_NUM Rollover Mask.
11:9	RsvdP	0b	Reserved.
12	RWS	0b	Replay Timer Timeout Mask.
13	RWS	1b	Advisory Non-Fatal Error Mask.

Bit Location	Attribute	Default Value	Description
15:14	RO	0b	Reserved.

38.44.1.7 Advanced Error Capabilities and Control Register (0x118; RO)

Bit Location	Attribute	Default Value	Description
4:0	ROS	0b	Vector pointing to the first recorded error in the Uncorrectable Error Status register. This is a read-only field that identifies the bit position of the first uncorrectable error reported in the Uncorrectable Error Status register.
5	RO	1b	ECRC Generation Capable. If set, this bit indicates that the function is capable of generating ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
6	RWS	0b	ECRC Generation Enable. When set, ECRC generation is enabled.
7	RO	1b	ECRC Check Capable. If set, this bit indicates that the function is capable of checking ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
8	RWS	0b	ECRC Check Enable. When set Set, ECRC checking is enabled.
9	RO	0b	Multiple Header Recording Capable. Not supported. hardwired to 0b
10	RO	0b	Multiple Header Recording Enable Not supported. hardwired to 0b
11	RsvdP	0b	TLP Prefix Log Present Not supported. hardwired to 0b
15:12	RsvdP	0x0	Reserved.

38.44.1.8 Header Log Register (0x11C:0x128; RO)

The header log register captures the header for the transaction that generated an error. This register is 16 bytes.

Bit Location	Attribute	Default Value	Description
127:0	ROS	0b	Header of the packet in error (TLP or DLLP).

38.44.2 Serial Number

The PCIe device serial number capability is an optional extended capability that can be implemented by any PCIe device. The device serial number is a read-only 64-bit value that is unique for a given PCIe device.

Serial Number capability is implemented for function 0; all other functions return the same device serial number value as that reported by function 0.

The capability is disabled when the MAC address in the GLPCI_SERL and GLPCI_SERH registers is 0x00...0 (indicating that the NVM is not valid and a proper MAC address was not loaded).

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x140	Next Capability Ptr.	Version (0x1)	Serial ID Capability ID (0x0003)	
0x144	Serial Number Register (Lower Dword)			
0x148	Serial Number Register (Upper Dword)			

Table 38-629 summarizes configuration sharing of the Serial Number Capability registers among the different PCI functions.

Table 38-629.Configuration Sharing of the Serial Number Capability

Field	Sub-field	Shared?	Replicated?	Comments

	Capability Version	X		
	Next Capability Offset		X	
Serial Number Register		X		See comment above

38.44.2.1 Device Serial Number Enhanced Capability Header Register (0x140; RO)

Bit(s)	Attribute	Default Value	Description
15:0	RO	0x0003	PCIe Extended Capability ID. This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. The extended capability ID for the device serial number capability is 0x0003.
19:16	RO	0x1	Capability Version. This field is a PCI-SIG defined version number that indicates the version of the capability structure present. ***Note:*** Must be set to 0x1 for this version of the specification.
31:20	RO	See description	Next Capability Offset. This field contains the offset to the next PCIe capability structure or 0x000 if no other items exist in the linked list of capabilities. See Table 38-627 for possible values of the next capability offset.

38.44.2.2 Serial Number Registers (0x144:0x148; RO)

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit Extended Unique Identifier (EUI-64*). The register at offset 0x144 holds the higher 32 bits and the register at offset 0x148 holds the lower 32 bits. The following figure details the allocation of register fields in the Serial Number register. The table that follows provides the respective bit definitions.

Bit(s)	Attributes	Description
63:0	RO	PCIe Device Serial Number. This field contains the IEEE defined 64-bit EUI-64*. This identifier includes a 24-bit company ID value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer.

The serial number uses the Ethernet MAC address according to the following definition.

Field	Company ID			Extension Identifier				
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
Most Significant Byte						Least Significant Byte		
Most Significant Bit						Least Significant Bit		

The serial number can be constructed from the 48-bit Ethernet MAC address in the following form.

Field	Company ID			MAC Label		Extension identifier		
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
Most Significant Bytes						Least Significant Byte		
Most Significant Bit						Least Significant Bit		

In this case, the MAC label is 0xFFFF.

For example, assume that the company ID is (Intel) 00-A0-C9 and the extension identifier is 23-45-67 (MAC address of 00-A0-C9-23-45-67). In this case, the 64-bit serial number is:

Field	Company ID			MAC Label		Extension Identifier		
Order	Addr+0	Addr+1	Addr+2	Addr+3	Addr+4	Addr+5	Addr+6	Addr+7
	00	A0	C9	FF	FF	23	45	67
Most Significant Byte						Least Significant Byte		
Most Significant Bit						Least Significant Bit		

The Ethernet MAC address for the serial number capability is loaded from NVM (not the same field that is loaded from NVM into the Station MAC Address registers). It is reflected in the GLPCI_SERL and GLPCI_SERH registers. In the above example:

- GLPCI_SERL = C9-23-45-67
- GLPCI_SERH = 00-00-00-A0

Note: The official document that defines EUI-64* is: http://standards.ieee.org/regauth/oui/tutorials/EUI64.html

38.44.3 Alternate Routing ID Interpretation (ARI) Capability Structure

In order to allow more than eight functions per endpoint without requesting an internal switch, as is usually needed in virtualization scenarios, the PCI-SIG defines a new capability that allows a different interpretation of the *Bus*, *Device*, and *Function* fields. The capability is exposed when the GLPCI_CAPSUP.ARI_EN bit is set from NVM.

Note: This capability should not be exposed in root complex integrated endpoints and the GLPCI_CAPSUP.ARI_EN bit should be set accordingly.

The ARI capability structure is as follows:

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x150	Next Capability Ptr.	Version (0x1)	ARI Capability ID (0x000E)	
0x154	ARI Control Register		ARI Capability Register	

Table 38-630 summarizes configuration sharing of the ARI Capability registers among the different PCI functions.

Table 38-630.Configuration Sharing of the ARI Capability

Field	Sub-Field	Shared?	Replicated?	Comments
Enhanced Capability Header Register	Extended Capability ID	X		
	Capability Version	X		
	Next Capability Offset		X	
ARI capability Register	Next Function Pointer		X	

38.44.3.1 PCIe ARI Header Register (0x150; RO)

Field	Bit(s)	Initial Value	Access	Description
ID	15:0	0x000E	RO	PCIe Extended Capability ID. PCIe extended capability ID for the alternative RID interpretation.
Version	19:16	1b	RO	Capability Version. This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 0x1 for this version of the specification.
Next Capability Offset	31:20	See description	RO	Next Capability Offset.This field contains the offset to the next PCIe extended capability structure. See Table 38-627 for possible values of the next capability offset.

38.44.3.2 PCIe ARI Capability Register (0x154; RO)

Field	Bit(s)	Initial Value	Access	Description
M	0	0b	RO	MFVC Function Groups Capability – Applicable only for Function 0; must be 0b for all other Functions. If 1b, indicates that the ARI Device supports Function Group level arbitration via its Multi-Function Virtual Channel (MFVC) Capability structure. Not supported in the 10 GbE controller.
A	1	0b	RO	ACS Function Groups Capability (A). Applicable only for function 0; must be 0b for all other functions. If 1b, indicates that the ARI device supports function group level granularity for ACS P2P Egress Control via its ACS capability structures. Not supported in the 10 GbE controller.
Reserved	7:2	0b	RsvdP	Reserved
NFN	15:8	See description[1]	RO	Next Function Number. This field contains the pointer to the next physical function configuration space or 0x0000 if no other items exist in the linked list of functions. Function 0 is the start of the link list of functions. Functions may be disabled during the Power-On-Reset flow (through strapping pins, SMASH/CLP commands, NC-SI commands) affecting this field.
M_EN	16	0b	RO	MFVC Function Groups Enable (M) – Applicable only for Function 0; must be hard wired to 0b for all other Functions. When set, the ARI Device must interpret entries in its Function. Arbitration Table as Function Group Numbers rather than Function Numbers. Not supported in the 10 GbE controller.

Field	Bit(s)	Initial Value	Access	Description
A_EN	17	0b	RO	ACS Function Groups Enable (A) – Applicable only for Function 0; must be hard wired to 0b for all other Functions. When set, each Function in the ARI Device must associate bits within its Egress Control Vector with Function Group Numbers rather than Function Numbers. Not supported in the 10 GbE controller.
Reserved	19:18	00b	RO	Reserved
FGN	22:20	0b	RO	Function Group Number. Not supported in the 10 GbE controller.
Reserved	31:23	0b	RsvdP	Reserved

Notes:

1. If function zero is a dummy function, this register should keep its attributes according to the function number. Disabled functions are skipped.

38.44.4 SR-IOV Capability Structure

This is a structure used to support the SR-IOV capabilities reporting and control. The capability is exposed when the GLPCI_CAPSUP.IOV_EN bit is set from NVM and the PF_VT_PFALLOC.VALID is set.

The following tables shows the implementation of this structure in the 10 GbE controller.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x160	Next Capability Offset	Version (0x1)	SR-IOV Capability ID (0x0010)	
0x164	SR-IOV Capabilities			
0x168	SR-IOV Status		SR-IOV Control	
0x16C	TotalVFs (RO)		Initial VF (RO)	
0x170	Reserved	Function Dependency Link (RO)	Num VF (RW)	
0x174	VF Stride (RO)		First VF Offset (RO)	
0x178	VF Device ID		Reserved	
0x17C	Supported Page Size (0x553)			
0x180	system page Size (RW)			
0x184	VF BAR0 — Low (RW)			
0x188	VF BAR0 — High (RW)			
0x18C	VF BAR2 (RO)			
0x190	VF BAR3 — Low (RW)			
0x194	VF BAR3- High (RW)			
0x198	VF BAR5 (RO)			
0x19C	VF Migration State Array Offset (RO)			

Table 38-631 summarizes configuration sharing of the SR-IOV Capability registers among the different PCI functions.

Table 38-631.Configuration Sharing of the SR-IOV Capability

38.44.4.1 PCIe SR-IOV Header Register (0x160; RO)

Field	Bit(s)	Initial Value	Access	Description
ID	15:0	0x0010	RO	PCIe Extended Capability ID. PCIe extended capability ID for the SR-IOV capability.
Version	19:16	0x1	RO	Capability Version. This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 0x1 for this version of the specification.
Next pointer	31:20	0x0	RO	Next Capability Offset. This field contains the offset to the next PCIe extended capability structure or 0x000 if no other items exist in the linked list of capabilities. See Table 38-627 for possible values of the next capability offset.

38.44.4.2 PCIe SR-IOV Capabilities Register (0x164; RO)

Field	Bit(s)	Initial Value	Access	Description
Reserved	0	0b	RO	Reserved.
ARI CHP	1	1b (lowest SR-IOV-enabled function) / 0b (else)	RO	ARI Capable Hierarchy Preserved. If set, the ARI *Capable Hierarchy* bit is preserved across certain power state transitions. Only present in lowest SR-IOV-enabled function. Read only zero in other PFs.
Reserved	31:2	0x0	RO	Reserved.

38.44.4.3 PCIe SR-IOV Control Register (0x168; RW)

Field	Bit(s)	Initial Value	Access	Description
VFE	0	0b	RW	VF Enable. VF Enable manages the assignment of VFs to the associated PF. If *VF Enable* is set to 1b, VFs must be enabled, associated with the PF, and exists in the PCIe fabric. When enabled, VFs must respond to and can issue PCIe transactions following all other rules for PCIe functions. If set to 0b, VFs must be disabled and not visible in the PCIe fabric; VFs cannot respond to or issue PCIe transactions. In addition, if *VF Enable* is cleared after having been set, all of the VFs must no longer: • Issue PCIe transactions • Respond to configuration space or memory space accesses. The behavior must be as if an FLR was issued to each of the VFs. Specifically, VFs must not retain any context after *VF Enable* has been cleared. Any errors already logged via PF error reporting registers, remain logged. However, no new VF errors must be logged after VF Enable is cleared.
VF ME	1	0b	RO	VF Migration Enable. Enables / Disables VF Migration Support. Not supported in the 10 GbE controller.
VF MIE	2	0b	RO	VF Migration Interrupt Enable. Enables / Disables VF Migration State Change Interrupt Not supported in the 10 GbE controller.
VF MSE	3	0b	RW	Memory Space Enable for Virtual Functions. VF MSE controls memory space enable for all VFs associated with this PF as with the Memory Space Enable bit in a functions PCI command register. The default value for this bit is 0b. When VF Enable is 1, virtual function memory space access is permitted only when VF MSE is Set. VFs shall follow the same error reporting rules as defined in the base specification if an attempt is made to access a virtual functions memory space when VF Enable is 1 and VF MSE is zero. **Implementation Note:** Virtual functions memory space cannot be accessed when VF Enable is zero. Thus, VF MSE is "don't care" when VF Enable is zero, however, software may choose to set VF MSE after programming the VF BARn registers, prior to setting VF Enable to 1.
VF ARI	4	0b	RW (lowest SR-IOV-enabled function) RO (else)	ARI Capable Hierarchy. Device can locate VFs in function numbers 8 to 255 of the captured bus number. If either ARI Capable Hierarchy Preserved is Set or No_Soft_Reset is Set, a power state transition of this PF from $D3_{HOT}$ to D0 does not affect the value of this bit
Reserved	15:5	0x0	RO	Reserved.

Field	Bit(s)	Initial Value	Access	Description
VFMIS	16	0b	RO	VF Migration Status. Indicates a VF Migration In or Migration Out Request has been issued by MR-PCIM. To determine the cause of the event, software may scan the VF State Array. Not implemented in the 10 GbE controller.
Reserved	31:17	0b	RO	Reserved

38.44.4.4 PCIe SR-IOV Initial/Total VFs Register (0x16C; RO)

Field	Bit(s)	Initial Value	Access	Description
InitialVFs	15:0	See Section 3 8.45.1.1	RO	InitialVFs indicates the number of VFs that are initially associated with the PF. If *VF Migration Capable* is cleared, this field must contain the same value as TotalVFs. In the 10 GbE controller this parameter is equal to the TotalVFs in this register.
TotalVFs	31:16	See Section 3 8.45.1.1	RO	TotalVFs defines the maximum number of VFs that can be associated with the PF. This field is derived from the PF_VT_PFALLOC.FIRSTVF and PF_VT_PFALLOC register fields loaded from NVM.

38.44.4.5 PCIe SR-IOV Num VFs Register (0x170; RW)

Field	Bit(s)	Initial Value	Access	Description
NumVFs	15:0	0x0	RW	Num VFs defines the number of VFs software has assigned to the PF. Software sets NumVFs to any value between one and the TotalVFs as part of the process of creating VFs. NumVFs VFs must be visible in the PCIe fabric after both NumVFs is set to a valid value and VF Enable is set to 1b.
FDL	23:16	0x0 (func 0)[1] 0x1 (func 1) ... 0xn (func n) ...	RO	Function Dependency Link. Defines dependencies between physical functions allocation. In the 10 GbE controller there are no constraints.
Reserved	31:24	0	RO	Reserved.

Notes:

1. Applies to dummy function as well.

38.44.4.6 PCIe SR-IOV VF RID Mapping Register (0x174; RO)

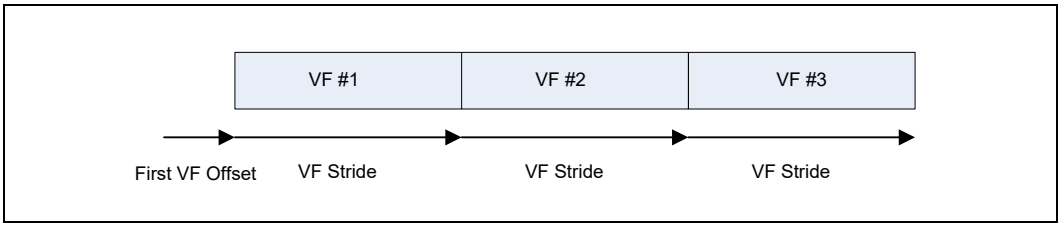
Field	Bit(s)	Initial Value	Access	Description
FVO	15:0	0x100 + 0x10 + FirstVF - PF#	RO	First VF offset defines the requester ID (RID) offset of the first VF that is associated with the PF that contains this capability structure. The first VFs 16-bit RID is calculated by adding the contents of this field to the RID of the PF containing this field. The content of this field is valid only when *VF Enable* is set. If *VF Enable* is 0b, the contents are undefined. If the *VF_ARI Enable* bit is set, this field changes to 0x10 + FirstVF - PF#. This field is derived from the PF_VT_PFALLOC.FIRSTVF register field loaded from NVM

Field	Bit(s)	Initial Value	Access	Description
VFS	31:16	0x1[1]	RO	VF stride defines the requestor ID (RID) offset from one VF to the next one for all VFs associated with the PF that contains this capability structure. The next VFs 16-bit RID is calculated by adding the contents of this field to the RID of the current VF. The contents of this field is valid only when *VF Enable* is set and *NumVFs* is non-zero. If *VF Enable* is 0b or if NumVFs is zero, the contents are undefined.

Notes:

1. See Section 38.45.1.1.

Figure 38-140.VF stride



38.44.4.7 PCIe SR-IOV VF Device ID Register (0x178; RO)

All Virtual functions have the same default value of 0x3A85, and can be auto-loaded from the NVM.

The DevID[15:7] field of a received Set ID Value sideband message is used to change the 9 MSBs of default value, but this value is overridden by the NVM loaded value.

The VF Device ID is loaded from the NVM according to the following rules:

- Device ID is loaded from NVM if the GLPCI_CAPSUP.LOAD_DEV_ID bit is set
- The Device ID value of all VFs associated with a given PF is loaded to the respective *PFPCI_DEVID.VF_DEV_ID* field

38.44.4.8 PCIe SR-IOV Supported Page Size Register (0x17C; RO)

Field	Bit(s)	Initial Value	Access	Description
Supported page Size	31:0	0x553	RO	For PFs that supports the stride-based BAR mechanism, this field defines the supported page sizes. This PF supports a page size of 2^(n+12) if bit n is set. For example, if bit 0 is Set, the Endpoint (EP) supports 4KB page sizes. Endpoints are required to support 4 KB, 8 KB, 64 KB, 256 KB, 1 MB and 4 MB page sizes. All other page sizes are optional.

38.44.4.9 PCIe SR-IOV System Page Size Register (0x180; RW)

Field	Bit(s)	Initial Value	Access	Description
Page size	31:0	0x1	RW	This field defines the page size the system uses to map the VFs' memory addresses. Software must set the value of the *System Page Size* to one of the page sizes set in the *Supported Page Sizes* field. As with *Supported Page Sizes*, if bit n is set in *System Page Size*, the VFs are required to support a page size of 2^(n+12). For example, if bit 1 is set, the system is using an 8 KB page size. The results are undefined if more than one bit is set in *System Page Size*. The results are undefined if a bit is set in *System Page Size* that is not set in *Supported Page Sizes*. When *System Page Size* is set, the VFs are required to align all BAR resources on a *System Page Size* boundary. Each BAR size, including *VF BARn Size* (described later) must be aligned on a *System Page Size* boundary. Each BAR size, including VF *BARn Size* must be sized to consume a multiple of *System Page Size* bytes. All fields requiring page size alignment within a function must be aligned on a *System Page Size* boundary. *VF Enable* must be zero when *System Page Size* is set. The results are undefined if *System Page Size* is set when *VF Enable* is set.

38.44.4.10 PCIe SR-IOV BAR 0 — Low Register (0x184; RW)

Field	Bit(s)	Initial Value	Access	Description
Mem	0	0b	RO	0b indicates memory space.
Mem Type	2:1	10b	RO	Indicates the address space size. 10b = 64-bit. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register
Prefetch Mem	3	0b	RO	0b = Non-prefetchable space. 1b = Prefetchable space. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register
Memory Address Space	31:4	0x0	RW	Which bits are RW bits and which are RO to 0x0 depend on the memory mapping window size.

38.44.4.11 PCIe SR-IOV BAR 0 — High Register (0x188; RW)

Field	Bit(s)	Initial Value	Access	Description
BAR0 — MSB	31:0	0x0	RW	MSB part of BAR0.

38.44.4.12 PCIe SR-IOV BAR 2 Register (0x18C; RO)

Field	Bit(s)	Initial Value	Access	Description
BAR2	31:0	0x0	RO	This BAR is not used.

38.44.4.13 PCIe SR-IOV BAR 3 — Low Register (0x190; RW)

Field	Bit(s)	Initial Value	Access	Description
Mem	0	0b	RO	0b indicates memory space.
Mem Type	2:1	10b	RO	Indicates the address space size. 10b = 64-bit. This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register
Prefetch Mem	3	0b*	RO	0b = Non-prefetchable space 1b = Prefetchable space This bit is loaded from the NVM. It is reflected in the GLPCI_VFSUP register
Memory Address Space	31:4	0x0	RW	Which bits are RW bits and which are RO to 0x0 depend on the memory mapping window size. The size is a maximum between 16 KB and page size.

38.44.4.14 PCIe SR-IOV BAR 3 — High Register (0x194; RW)

Field	Bit(s)	Initial Value	Access	Description
BAR3 — MSB	31:0	0x0	RW	MSB part of BAR3.

38.44.4.15 PCIe SR-IOV BAR 5 Register (0x198; RO)

Field	Bit(s)	Initial Value	Access	Description
BAR5	31:0	0x0	RO	This BAR is not used.

38.44.4.16 PCIe SR-IOV VF Migration State Array Offset Register (0x19C; RO)

Field	Bit(s)	Initial Value	Access	Description
BIR	2:0	0x0	RO	Indicates which PF BAR contains the VF Migration State Array. Not implemented in the 10 GbE controller.
Offset	31:0	0x0	RO	Offset, relative to the beginning of the BAR of the start of the migration array. Not implemented in the 10 GbE controller.

38.44.5 TPH Requester Capability

The TPH Requester capability is an optional extended capability to support TLP Processing Hints. The capability is exposed when the GLPCI_CAPSUP.TPH_EN bit is set from NVM.

The following table lists the TPH extended capability structure for PCIe devices.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1A0	PCI Express Extended Capability Header			
0x1A4	TPH Requester Capability Register			
0x1A8	TPH Requester Control Register			

Table 38-632 summarizes configuration sharing of the TPH Requester Capability registers among the different PCI functions.

Table 38-632.Configuration Sharing of the TPH Requester Capability

Field	Sub-field	Shared?	Replicated?	Comments
Enhanced Capability Header Register	Extended Capability ID	X		
	Capability Version	X		
	Next Capability Offset		X	
TPH Requester Capability		X		
TPH Requester Control			X	
TPH ST Table			X	The steering table upper fields are not supported.

38.44.5.1 TPH Requester Extended Capability Header (0x1A0; RO)

Bit Location	Attribute	Default Value	Description
15:0	RO	0x17	Extended Capability ID. PCIe extended capability ID indicating TPH capability.
19:16	RO	0x1	Capability Version. PCIe TPH extended capability version number.
31:20	RO	See Description	Next Capability Offset.This field contains the offset to the next PCIe capability structure. See Table 38-627 for possible values of the next capability offset.

38.44.5.2 TPH Requester Capability Register (0x1A4; RO)

Bit Location	Attribute	Default Value	Description
0	RO	1	No ST Mode Supported. If set indicates that the Function supports the No ST Mode of operation
1	RO	0	Interrupt Vector Mode Supported. Cleared to indicates that the 10 GbE controller does not support Interrupt Vector Mode of operation
2	RO	1	Device Specific Mode. Set to indicate that the 10 GbE controller supports Device Specific Mode of operation
7:3	RsvdP	0	Reserved.
8	RO	0	Extended TPH Requester Supported. Cleared to indicate that the function is not capable of generating requests with Extended TPH TLP Prefix
10:9	RO	00b	11b = Reserved.
15:11	RsvdP	0x0	Reserved.
26:16	RO	0x0	Reserved.
31:27	RsvdP	0x0	Reserved

38.44.5.3 TPH Requester Control Register (0x1A8; R/W)

Bit Location	Attribute	Default Value	Description
2:0	RW	0x0	Reserved.
7:3	RsvdP	0x0	Reserved
9:8	RW	0x0	TPH Requester Enable – Controls the ability to issue Request TLPs using either TPH or Extended TPH. Defined encodings are: 00b = The 10 GbE controller is not permitted to issue transactions with TPH or extended TPH as requester. 01b = The 10 GbE controller is permitted to issue transactions with TPH as requester and is not permitted to issue transactions with extended TPH as requester. 10b – Reserved. 11b = The 10 GbE controller is permitted to issue transactions with TPH and extended TPH as requester (the 10 GbE controller does not issue transactions with extended TPH). The default value of this field is 00b.
31:10	RsvdP	0x0	Reserved

38.44.6 ACS Extended Capability Structure

The ACS extended capability defines a set of control points within a PCIe topology to determine whether a TLP should be routed normally, blocked, or redirected. The capability is exposed when the GLPCI_CAPSUP.ACS_EN bit is set from NVM.

The ACS capability structure is shared and exposed to all PFs.

The following table lists the PCIe ACS extended capability structure for PCIe devices.

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1B0	PCI Express Extended Capability Header			
0x1B4	ACS Control Register (0x0)		ACS Capability Register (0x0)	

38.44.6.1 ACS Extended Capability Header (0x1B0; RO)

Bit Location	Attribute	Default Value	Description
15:0	RO	0x0D	PCI Express Extended Capability ID - PCIe extended capability ID indicating ACS capability.
19:16	RO	0x1	Capability Version - PCIe ACS extended capability version number.
31:20	RO	See Description	Next Capability Offset - See Table 38-627 for possible values of the next capability offset.

38.45 Virtual Functions

38.45.1 Overview

38.45.1.1 VF to PF Allocation

The 10 GbE controller supports up to 128 VFs. These VFs can be distributed arbitrarily among the different PFs. The distribution is done by NVM settings as the TotalVFs parameter should be stable at enumeration time.

For each of the potential 16 functions the following parameters are defined in the NVM:

- PCIe* Configuration Space Control 1.SR-IOV enable - should SR-IOV be exposed for this function
- SR-IOV configuration.Next PF First VF - what is the first VF allocated to the next function (out of 128). Can be any number between 0 and 127. VF0 is assumed to be assigned to the first function whose Next PF First VF field is not zero. Next PF First VF for the last PF indicates the last VF exposed.

From these parameters the following parameters are derived in the SR-IOV capability structure (see Section 38.44.4 for details):

- The SR-IOV structure is part of the configuration space of a PF only if the GLPCI_CAPSUP.IOV_EN bit is set in the NVM and PF_VT_PFALLOC.VALID field is set for this function.
- InitialVFs = TotalVFs = PF_VT_PFALLOC.LASTVF[n] - PF_VT_PFALLOC.FIRSTVF [n] +1
- First VF Offset = PF_VT_PFALLOC.FIRSTVF [n]+ 16 - PF# for ARI mode and PF_VT_PFALLOC.FIRSTVF [n]+ 272 - PF# for non ARI mode.

Note: The First VF offset formula is defined so that the RID of a VF is fixed no matter which PF it belongs to.

- VF stride = 1

The First VF and last VF allocated to a PF can be read from the *PF_VT_PFALLOC* registers.

The total number of enabled virtual functions is reflected in the GLGEN_PCIFCNCNT register.

38.45.1.2 Bus-Device-Function Layout

The requester ID allocation of the VF is done using the *First VF Offset* field and the *VF stride* in the IOV structure and is used to do the enumeration of the VFs.

38.45.1.2.1 ARI Mode

The ARI capability allows interpretation of the device part of the Requester ID as part of the function part. Thus a single device can span up to 256 functions.

The allocation of VFs to PF is flexible, there is no relationship between the PF RID and the associated VFs RID.

Table 38-633.RID Per VF - ARI Mode

VF#/PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
...	...	...	
PF 15	B,1,7	B,00001,111	PF #15
VF 0	B,2,0	B,00010,000	
VF 1	B,2,1	B,00010,001	
VF 2	B,2,2	B,00010,010	
...	...	...	
VF 127	B,17,7	B,10001,111	Last

38.45.1.2.2 Non-ARI Mode

When ARI is disabled, a non-zero PCI device number in the first bus can not be used, thus a second bus is needed to provide enough requester IDs. In this mode, we support only up to 8 physical functions and the RID layout is as follow:

Table 38-634.RID Per VF - Non ARI Mode

VF#/PF#	B,D,F	Binary	Notes
PF 0	B,0,0	B,00000,000	PF #0
PF 1	B,0,1	B,00000,001	PF #1
PF 2	B,0,2	B,00000,010	PF #2
...	...	...	
PF 7	B,0,7	B,00000,111	PF #7
VF 0	B+1,2,0	B+1,00010,000	
VF 1	B+1,2,1	B+1,00010,001	
VF 2	B+1,2,2	B+1,00010,010	
...	...	...	
VF 127	B+1,17,7	B+1,10001,111	Last

38.45.1.3 Configuration Space Overview

The configuration space reflected to each of the VF is a sparse version of the physical function configuration space. The following table describes the behavior of each register in the VF configuration space.

Table 38-635.VF PCIe Configuration Space (Sheet 1 of 2)

Section	Offset	Name	VF behavior	Notes
PCI Mandatory Registers	0	Vendor ID	RO — 0xFFFF	
	2	Device ID	RO — 0xFFFF	
	4	Command	Per VF	See Section 38.45.2.3.
	6	Status	Per VF	See Section 38.45.2.4.
	8	RevisionID	RO as PF	
	9	Class Code	RO as PF	
	C	Cache Line Size	RO — 0x0	
	D	Latency Timer	RO — 0x0	
	E	Header Type	RO — 0x0	
	F		RO — 0x0	
	10 — 27	BARs	RO — 0x0	Emulated by VMM.
	28	CardBus CIS	RO — 0x0	Not used.
	2C	Sub Vendor ID	RO as PF	
	2E	Sub System	RO.Same value for all VFs of each PF	See Section 38.45.2.5.
	30	Expansion ROM	RO — 0x0	Emulated by VMM.
	34	Cap Pointer	RO — 0x70	Next = MSI-X capability.
	3C	Int Line	RO — 0x0	
	3D	Int Pin	RO — 0x0	
	3E	Max Lat/Min Gnt	RO — 0x0	
MSI-X Capability	70	MSI-X Header	RO — 0xA011	Next = PCIe capability.
	72	MSI-x Message Control	per VF	See Section 38.45.3.1.1.
	74	MSI-X table Address	RO	See Section 38.45.3.1.2
	78	MSI-X PBA Address	RO	See Section 38.45.3.1.3
PCIe Capability	A0	PCIe Header	RO — 0x0010	Next = Last capability.
	A2	PCIe Capabilities	RO — as PF	
	A4	PCIe Dev Cap	RO — as PF	
	A8	PCIe Dev Ctrl	RW	As PF apart from FLR — See Table 38.45.3.2.1.
	AA	PCIe Dev Status	per VF	See Table 38.45.3.2.2.
	AC	PCIe Link Cap	RO — as PF	
	B0	PCIe Link Ctrl	RO — 0x0	
	B2	PCIe Link Status	RO — 0x0	
	C4	PCIe Dev Cap 2	RO — as PF	
	C8	PCIe Dev Ctrl 2	RO — 0x0	
	D0	PCIe Link Ctrl 2	RO — 0x0	
	D2	PCIe Link Status 2	RO — 0x0	

Table 38-635.VF PCIe Configuration Space (Sheet 2 of 2)

Section	Offset	Name	VF behavior	Notes
AER Capability	100	AER — Header	RO — 0x15010002	Next = ARI structure.
	104	AER — Uncorr Status	per VF	See Section 38.45.3.3.1.
	108	AER — Uncorr Mask	RO — 0x0	
	10C	AER — Uncorr Severity	RO — 0x0	
	110	AER — Corr Status	Per VF	See Section 38.45.3.3.2.
	114	AER — Corr Mask	RO — 0x0	
	118	AER — Cap/Ctrl	RO	See Section 38.45.3.3.3
	11C — 128	AER — Error Log	Shared two logs for all VFs	Same structure as in PF. In case of overflow, the header log is filled with ones.
ARI Capability	150	ARI — Header	0x1A01000E	Next = TPH structure.
	154	ARI — Cap/Ctrl	RO — 0X0	
TPH Requester capability	0x1A0	TPH - Header	0x1D010017	Next = ACS Structure.
	0x1A4	TPH - Capability	RO - 0x00000005	No table reported.
	0x1A8	TPH - Control	per VF	Same structure as in PF
ACS capability	0x1D0	ACS - Header	RO - 0x0001000D	Next = Last extended capability.
	0x1D4	ACS - Capability	RO - 0x00000000	

38.45.2 Mandatory Configuration Space

The IOV specification defines the configuration space of the Virtual functions as a mirror of the Physical function configuration space with the exception of some fields which are implemented per VF.

This section describes the expected handling of the different part of the configuration space for virtual functions. It deals only with the parts relevant to the 10 GbE controller and describes only changes which are not a trivial implementation of the specification.

38.45.2.1 Legacy PCI Configuration Space

The legacy configuration space is allocated to the PF only and emulated for the VFs. A separate set of BARs and one Bus master enable bit is allocated to the whole set of VFs.

All the legacy error reporting bits are emulated for the VF.

38.45.2.2 Memory BARs Assignment

The IOV specification defines a fixed stride for all the VF BARs, so that each VF can be allocated part of the memory BARs at a fixed stride from the a basic set of BARs. In this method only two decoders per replicated BAR per PF are required and the BARs reflected to the VF are emulated by the VMM.

The only BARs that are useful for the VFs are BAR0 and BAR3, thus only those are replicated.

The following table describes the BARs and the stride used for the VFs.

Table 38-636.VF BARs in Product Name

BAR	Type	Usage	Requested Size Per VF
0	Mem	CSR space	
1	Mem	High word of CSR space address	N/A
2	N/A	Not used	N/A
3	Mem	MSI-X	max(16K, page size)
4	Mem	High word of MSI-X space address	N/A
5	N/A	Not used	N/A

38.45.2.3 VF Command Register (0x4; RW)

Bit(s)	Initial Value	Rd/Wr	Description
0	0b	RO	IOAE: I/O Access Enable. RO as zero field.
1	0b	RO	MAE: Memory Access Enable. RO as zero field.
2	0b	RW	BME: Bus Master Enable.Disabling this bit prevents the associated VF from issuing any memory or I/O requests. Note that as MSI/MSI-X interrupt messages are in-band memory writes, disabling the bus master enable bit disables MSI/MSI-X interrupt messages as well. Requests other than memory or I/O requests are not controlled by this bit. ***Note:*** The state of active transactions is not specified when this bit is disabled after being enabled. The device can choose how it behaves when this condition occurs. Software cannot count on the device retaining state and resuming without loss of data when the bit is re-enabled. Transactions for a VF that has its *Bus Master Enable* set must not be blocked by transactions for VFs that have their *Bus Master Enable* cleared.
3	0b	RO	SCM: Special Cycle Enable. Hard wired to 0b
4	0b	RO	MWIE: MWI Enable. Hard wired to 0b.
5	0b	RO	PSE: Palette Snoop Enable. Hard wired to 0b.
6	0b	RO	PER: Parity Error Response. Zero for VFs.
7	0b	RO	WCE: Wait Cycle Enable. Hard wired to 0b.
8	0b	RO	SERRE: SERR# Enable. Zero for VFs.
9	0b	RO	FB2BE: Fast Back-to-Back Enable. Hard wired to 0b.
10	0b	RO	INTD: Interrupt Disable. Hard wired to 0b.
15:11	0b	RO	RSV: Reserved

38.45.2.4 VF Status Register (0x6; RW)

Bits	Initial Value	Rd/Wr	Description
2:0	0x0	RO	RSV: Reserved
3	0b	RO	IS: Interrupt Status. Hard wired to 0b.
4	1b	RO	NC: New Capabilities. Indicates that Product Name VFs implement extended capabilities. The 10 GbE controller VFs implement a capabilities list, to indicate that it supports MSI-X and PCIe extensions.
5	0b	RO	66E: 66 MHz Capable. Hard wired to 0b.
6	0b	RO	RSV: Reserved
7	0b	RO	FB2BC: Fast Back-to-Back Capable. Hard wired to 0b.
8	0b	RW1C	MPERR: Data Parity Reported.
10:9	00b	RO	DEVSEL: DEVSEL Timing. Hard wired to 0b.
11	0b	RW1C	STA: Signaled Target Abort.
12	0b	RW1C	RTA: Received Target Abort.
13	0b	RW1C	RMA: Received Master Abort.
14	0b	RW1C	SSERR: Signaled System Error.
15	0b	RW1C	DSERR: Detected Parity Error.

38.45.2.5 VF Subsystem ID (0x2E; RO)

This value is loaded from NVM if the *GLPCI_CAPSUP.LOAD_SUBSYS_ID* bit is set. Each VF is loaded from the respective PF's NVM *PFPCI_SUBSYSID.VF_SUB_ID* field (i.e., all VFs of a specific PF share the same value)

38.45.3 PCI and PCIe Capabilities

The following capability structures are partially replicated in VFs configuration space:

- PCIe capability structure.
- MSI-X capability structure

The following extended capability structures are partially replicated in VFs config space.

Table 38-637.Extended Capabilities List

Address range	Item	Cases where capability does not exist	Next Pointer
0x100 - 0x128	Advanced Error Reporting (AER)	None (always present)	Any of the below / 0x000
0x150 - 0x154	Alternative RID Interpretation (ARI)	ARI Enabled bit in NVM is set to 0b	Any of the below / 0x000
0x1A0 - 0x1A8	TPH Requester	TPH Enabled bit in NVM is set to 0b	Any of the below / 0x000
0x1B0 - 0x1B4	Access Control Services (ACS)	ACS Enabled bit in NVM is set to 0b	0x000

38.45.3.1 MSI-X Capability

The MSI-X BAR size is max(16K, page size).

The location and size of the MSI-X vector table and the MSI-X Pending Bits table are determined as follows:

- MSI-X vector table
  - The MSI-X table structure (Section 38.43.3.5) typically contains multiple entries, each consisting of several fields: *Message Address*, *Message Upper Address*, *Message Data*, and *Vector Control*. Each entry is capable of specifying a unique vector.
  - Starts at offset 0x0000 from start of BAR
  - Contains the MSI-X vectors for the VF as well as the number of entries in table (N). The maximum value of N is 17 per VF (for the case of up to 32 VFs)
  - The vectors start with the Vector 0 (one per VF), followed by the other vectors allocated to the VF
- MSI-X Pending Bits table
  - The PBA structure [Section 38.43.3.5.2] contains the function's pending bits, one per table entry, organized as a packed array of bits within Qwords. The last Qword is not necessarily fully populated
  - Starts at half the BAR size (default is offset 0x2000 - 8KB from start of BAR).
  - Contains the pending bits for the VF. The VF is allocated one 64-bit register for a maximum of 17 bits
  - The bits start with the Vector 0 bit (one per VF), followed by bits for the other vectors allocated to the VF

38.45.3.1.1 VF MSI-X Control Register (0x72; RW)

Bits	Initial Value	Rd/Wr	Description
10:0	0x004	RO	TS: Table Size (N-1). N varies with the number of virtual functions. This field is loaded from NVM. It is reflected in the GLPCI_CNF2.MSI_X_VF_N CSR field
13:11	0x0	RO	RSV: Reserved.
14	0b	RW	Mask: Function Mask.
15	0b	RW	En: MSI-X Enable.

38.45.3.1.2 MSI-X Address Register (0x74; RO)

Bits	Default	Type	Description
2:0	0x3	RO	Table BIR. Indicates which one of a function’s BARs, beginning at 0x10 in the configuration space, is used to map the function’s MSI-X table into the memory space. while BIR values: 0...5 correspond to BARs 0x10…0x 24 respectively.
31:3	0x000	RO	Table offset. Used as an offset from the address contained by one of the function’s BARs to point to the base of the MSI-X vectors address. The lower three BIR bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset.

38.45.3.1.3 MSI-X PBA Register (0x78; RO)

Bits	Default	Type	Description
2:0	0x3	RO	PBA BIR. Indicates which one of a function's BARs, located beginning at 0x10 in configuration space, is used to map the function's MSI-X PBA into memory space. A BIR value of three indicates that the PBA is mapped in BAR 3.
31:3	0x400	RO	PBA Offset. Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X PBA. The lower three PBA BIR bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset. This value is changed by hardware to be half of the requested BAR size.

38.45.3.2 PCIe Capability Registers

The device control and device status registers have some fields which are specific per VF.

38.45.3.2.1 VF Device Control Register (0xA8; RW)

Bits	Rd/Wr	Default	Description
0	RO	0b	Correctable Error Reporting Enable. Zero for VFs.
1	RO	0b	Non-Fatal Error Reporting Enable. Zero for VFs.
2	RO	0b	Fatal Error Reporting Enable. Zero for VFs.
3	RO	0b	Unsupported Request Reporting Enable. Zero for VFs.
4	RO	0b	Enable Relaxed Ordering. Zero for VFs.
7:5	RO	0b	Max Payload Size. Zero for VFs.
8	RO	0b	Extended Tag field Enable.
9	RO	0b	Reserved.
10	RO	0b	Aux Power PM Enable. Zero for VFs.
11	RO	0b	Enable No Snoop. Zero for VFs.
14:12	RO	000b	Max Read Request Size. Zero for VFs.
15	RW	0b	Initiate Function Level Reset. Specific to each VF.

38.45.3.2.2 VF Device Status Register (0xAA; RO)

Bits	Rd/Wr	Default	Description
0	R/W1C	0b	Correctable Detected. Indicates status of correctable error detection.
1	R/W1C	0b	Non-Fatal Error Detected. Indicates status of non-fatal error detection.
2	R/W1C	0b	Fatal Error Detected. Indicates status of fatal error detection.
3	R/W1C	0b	Unsupported Request Detected. Indicates that the 10 GbE controller received an unsupported request. This field is separate per VF. However, in case where an error cannot be associated with a VF, this bit is set in all PFs and VFs.
4	RO	0b	Aux Power Detected. Zero for VFs.
5	RO	0b	Transactions Pending. Specific per VF. When set, indicates that a particular function (PF or VF) has issued non-posted requests that have not been completed. A function reports this bit cleared only when all completions for any outstanding non-posted requests have been received.
15:6	RO	0x00	Reserved

38.45.3.3 AER Registers

The following registers in the AER capability have a different behavior in a VF function.

Note that unlike the PF AER registers, these registers are not sticky since the VF is reset on FLR and on in-band reset.

38.45.3.3.1 Uncorrectable Error Status Register (0x104; RW1C)

Bit Location	Attribute	Default Value	Description
3:0	RO	0x0	Reserved
4	RO	0b	Data Link Protocol Error Status. Hardwired to 0b
5	RO	0b	Surprise Down Error Status. Hardwired to 0b
11:6	RO	0x0	Reserved
12	RW1C	0b	Poisoned TLP Status
13	RO	0b	Flow Control Protocol Error Status. Hardwired to 0b
14	RW1C	0b	Completion Timeout Status.
15	RW1C	0b	Completer Abort Status.
16	RW1C	0b	Unexpected Completion Status.
17	RO	0b	Receiver Overflow Status. Hardwired to 0b
18	RO	0b	Malformed TLP Status. Hardwired to 0b
19	RO	0b	ECRC Error Status. Hardwired to 0b
20	RW1C	0b	Unsupported Request Error Status — when caused by a function that claims a TLP.
21	RO	0b	ACS Violation Status. Hardwired to 0b
31:21	RO	0x0	Reserved

38.45.3.3.2 Correctable Error Status Register (0x110; RW1C)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit.

Bit Location	Attribute	Default Value	Description
0	RO	0b	Receiver Error Status. Hardwired to 0b
5:1	RO	0x0	Reserved
6	RO	0b	Bad TLP Status. Hardwired to 0b
7	RO	0b	Bad DLLP Status. Hardwired to 0b
8	RO	0b	REPLAY_NUM Rollover Status. Hardwired to 0b
11:9	RO	0x0	Reserved
12	RO	0b	Replay Timer Timeout Status. Hardwired to 0b
13	RW1C	0b	Advisory Non-Fatal Error Status.
31:14	RO	0b	Reserved

38.45.3.3.3 Advanced Error Capabilities and Control Register (0x118; RO)

Bit Location	Attribute	Default Value	Description
4:0	ROS	0b	Vector pointing to the first recorded error in the Uncorrectable Error Status register. This is a read-only field that identifies the bit position of the first uncorrectable error reported in the Uncorrectable Error Status register.
5	RO	0b	ECRC Generation Capable. If set, this bit indicates that the function is capable of generating ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register
6	RO	0b	ECRC Generation Enable. When set, ECRC generation is enabled. Hardwired to 0b. The PF setting applies to the VF
7	RO	0b	ECRC Check Capable. If set, this bit indicates that the function is capable of checking ECRC. This bit is loaded from NVM. It is reflected in the GLPCI_CAPSUP register.
8	RO	0b	ECRC Check Enable.When set Set, ECRC checking is enabled. Hardwired to 0b. The PF setting applies to the VF
9	RO	0b	Multiple Header Recording Capable. Not supported. hardwired to 0b
10	RO	0b	Multiple Header Recording Enable Not supported. hardwired to 0b
11	RsvdP	0b	TLP Prefix Log Present Not supported. hardwired to 0b
15:12	RO	0x0	Reserved

38.46 Reliability, Diagnostics and Testability

38.46.1 ECC Support and ECC Error Flow

Memories in the 10 GbE controller are protected by ECC (ECC bits are added to the memory on write and compare on read). There are two types of ECC errors:

- Correctable ECC error — When the memory line has a single bit error, the ECC mechanism corrects it. This is done within the memory shell/wrapper and the flow continues as normal.
- Uncorrectable ECC error — When the memory line read has more than a single ECC error, it cannot be recovered by the ECC mechanism. The text that follows describes how the 10 GbE controller reacts to such an event.

Reporting of ECC errors is as follows:

- The GL_CRITERRMODMASK2 register masks the reporting of ECC errors per block.
  - — If enabled, a correctable error is indicates by the ITR_CAUSE_MEM_0_STATUS.ECC_FIX bit and an uncorrectable error is indicated by the ITR_CAUSE_MEM_0_STATUS.ECC_ERR bit.
- If the ECC_ENA.ECC_ENA is set to 1b, an uncorrectable ECC error sets the ECC_ERR interrupt cause (for all PFs).
- The *_ECC_COR_ERR and *_ECC_UNCOR_ERR per-block registers count the occurrence of correctable and uncorrectable errors, respectively (the * symbol stands for the block name).

Uncorrectable errors are handled as follows:

- Device blocks data from going to an external link and blocks any new PCIe master transaction.
- Recovery then depends on the memory where the error happens:
  - An error takes place in the core or global domains
    - If the GLGEN_RSTCTL.ECC_RST_EN bit is set to 1b, the 10 GbE controller generates a GLOBR reset
  - An error takes place in the EMP
    - If the GLMNG_WD_ENA.ECC_RST_ENA bit is set to 1b, the EMP generates an EMPR reset
  - An error takes place in FLEEP (Shadow RAM)
    - An ECC error check in the shadow RAM is enabled via the *Shadow RAM ECC Enable* bit in the NVM
    - The FLEEP reloads the shadow RAM from the NVM.
    - If the GLGEN_RSTCTL.ECC_RST_EN bit is set to 1b, the 10 GbE controller generates a GLOBR reset (which in turn reloads the relevant sections into hardware)
  - An error takes place in the PCIe domain
    - If an error is in data to be sent out, the TLP is sent with an EDB

    Else, the link goes to a link-down state
    - If the GLMNG_WD_ENA.ECC_RST_ENA bit is set to 1b, the EMP generates an EMPR reset
    - Else, if the GLGEN_RSTCTL.ECC_RST_EN bit is set to 1b, the 10 GbE controller generates a GLOBR reset

38.46.2 Link Loopback Operations

Loopback operations are supported by the 10 GbE controller to assist with system and device debug. Loopback operation can be used to test transmit and receive aspects of software device drivers, as well as to verify electrical integrity of the connections between the 10 GbE controller and the system (such as PCIe bus connections, etc.).

38.46.3 NVM Recovery Mode

NVM recovery mode is intended to recover from a misconfiguration, which can be caused by an interrupted firmware update, power failure, host software access or interrupted BMC configuration access. This misconfiguration prevents firmware from executing successful initialization flows. These flows enable the software device driver/ BMC to fix the misconfiguration and cause firmware to initialize the correct data path.

Note: Device firmware implements a recovery mode that requires driver and firmware update tool software assistance to complete the recovery process. For a full discussion of recovery mode, Refer to the *Intel® Ethernet Connection X722 Feature Support Matrix* Application Note.

38.47 Acronyms

The following table lists the acronyms used in this section.

Acronyms	Description
AEQ	Asynchronous Event Queue
AQP	Admin Queue Pair
ARQ	Admin Receive Queue
ASQ	Admin Send Queue
BAR	Base Address Register
BE	Big Endian
BMC	Baseboard Management Controller
CEQ	Completion Event Queue
CQ	Completion Queue
EMP	Embedded Management Processor
HMC	Host Memory Cache
IRD	Inbound RDMA Read Queue Depth
IRRQ	Inbound RDMA Read Queue
iWARP	Internet Wide Area RDMA Protocol
LE	Little Endian
LED	Light Emitting Diode
LQP	LAN Queue Pair
MAC	Media Access Controller
MDC	Mobile Daughter Card
MDIO	Management Data Input/Output
MPA	Marker PDU Aligned
MSI	Message Signaled Interrupt
MSS	Maximum Segment Size
NC-SI	Network Controlled Side-band Interface
NIC	Network Interface Card
ORD	Outbound RDMA Read Queue Depth
PF	Physical Function (in a virtualization context)
PXE	Pre-boot Execution Environment
QP	Queue Pair
RSS	Receive Side Scaling
SDP	Software Definable Pins
SMBus	System Management Bus
TC	Traffic Class
UDA	User-space Direct Access
VF	Virtual Function – A part of a PF assigned to a VI
VI	Virtual Image – A virtual machine to which a part of the I/O resources is assigned. Also known as a VM

Acronyms	Description
VM	Virtual Machine
VMDq	Virtual Machine Device queue
VMM	Virtual Machine Monitor
VSI	Virtual Station Interfaces
WQ	Work Queues
WQE	Work Queue Element
WSP	Weighted Strict Priority

§

39 Intel® QuickAssist Technology (Intel® QAT)

39.1 Acronyms

Acronyms	Description
3DES	Triple Data Encryption Standard (also TDES)
AES	Advanced Encryption Standard
AES-CCM	Counter Mode Cipher Block Chaining Message Authentication Code. Also CBC-MAC.
AES-GCM	Galois/Counter Mode
AES-XCBC	eXtended Ciphertext Block Chaining
AES-XTS	XEX based (**X**) Tweaked CodeBook mode (**T**CB) with ciphertext stealing (CT**S**) [**X**EX **T**CB CT**S**]
DES	Data Encryption Standard
ECDH	Elliptic Curve Diffie-Hellman
ECDSA	Elliptic Curve Digital Signature Algorithm
EPO	EndPoint Only - A PCH mode where the Intel® QuickAssist Technology and 10 GbE Controller can be used as standalone PCIE endpoints on a non-boot PCH
HMAC	Hash Message Authentication Code
KASUMI*	Block cipher used in UMTS, GSM, and GPRS mobile communication systems.
MD5	Message Digest algorithms: a widely used cryptographic hash function
QAT	Intel® QuickAssist Technology
RC4	Rivest Cipher 4: a software stream cipher
SHA	Secure Hash Algorithm. A cryptographic hash function.
SHA-1	See SHA. SHA-1 produces a 160-bit (20-byte) hash value typically 40 digit long hex number
SHA-2	Six digit hash functions that are 224, 256, 384, or 512 bits.
SHA-3	5x5 array of 64-bit words.
Snow3G	Word based synchronous stream cipher
TDES	Triple Data Encryption Standard (also 3DES)
ZUC	Stream cipher proposed for inclusion in the 4G LTE (Long Term Evolution)
SR-IOV	Single Root - I/O Virtualization
IQIA	Intel QuickAssist Integrated Accelerator
PF	Physical Function
VF	Virtual Function
VM	Virtual Machine
VMM	Virtual Machine Manager
ARI	Alternate Routing ID
MSI	Message Signaled Interrupt
AER	Advanced Error Reporting

39.3 Overview

Intel® QuickAssist Technology consists of an integrated accelerator for offload look-aside cryptographic and compression/decompression co-processing services. These services are accessible via Intel QuickAssist Technology related APIs that communicate via PCI configuration space access and assisted rings stored in system memory.

Intel QuickAssist Technology traffic only traverses across the PCH PCIe Upstream Ports and does not have DMI access. The PCH Upstream Ports are required to be connected to a PCIe Root Port for this feature to function. Refer to Section 39.6 for additional details on Upstream Port requirements.

Note: Intel QuickAssist Technology may not be supported on all PCH SKUs.

Note: The Intel® C620 Series Chipset SKUs that support Intel QuickAssist Technology require an Adaptive Voltage Identification (AVID) compatible VR solution (Vccprim_Avid of 0.85V to 1.0V) to be used.

39.4 Intel QuickAssist Technology Features

- This product contains Intel QuickAssist Technology hardware version 1.7
  - Intel QuickAssist Technology is supported on the boot PCH in normal mode.
  - Intel QuickAssist Technology is supported on a non-boot PCH in EndPoint Only (EPO) mode.
- Cryptographic Functions
  - Cipher Operations
    - Advanced Encryption Standard
    - Data Encryption Standard/Triple DES (3DES/TDES)
    - RC4
  - Hash Operation
    - SHA-1, MD5
    - SHA-2 (SHA-224, SHA-256, SHA-384, SHA-512)
    - SHA-3
    - ZUC
  - Authentication Operation
    - HMAC, AES-XCBC, AES-CCM, AES-GCM, AES-XTS
  - Cipher-Hash Combined Operation
  - Key Derivation Operation
  - Wireless Cryptography
    - KASUMI*, SNOW 3G*, ZUC
- Public Key Functions
  - RSA Operation
  - Diffie-Helman Operation
  - Digital Signature Standard Operation
  - Key Derivation Operation

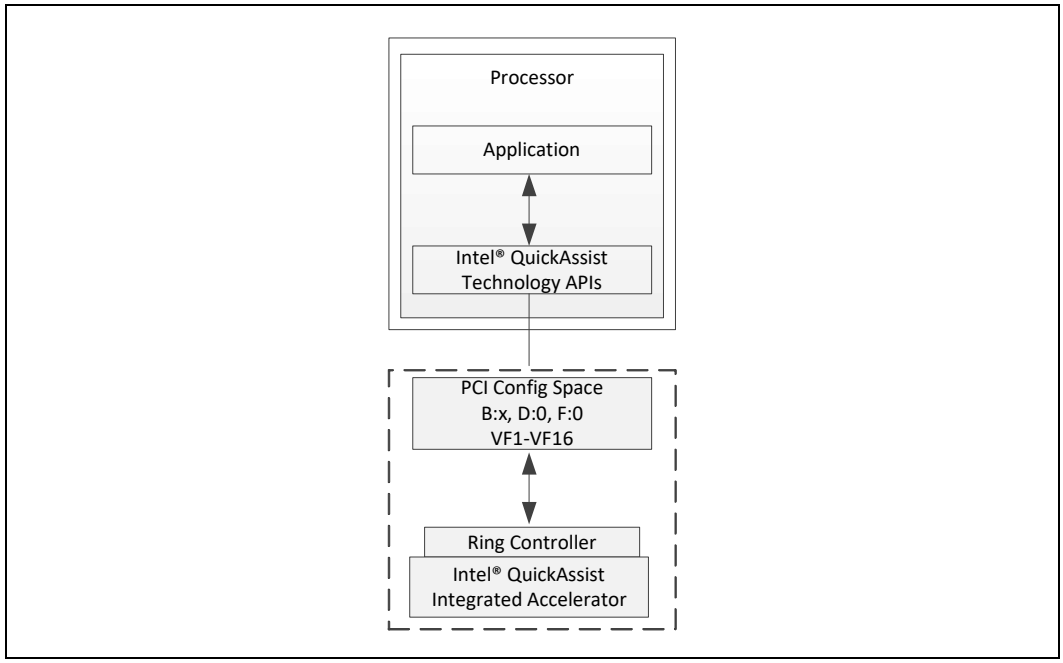
  - — Elliptic Curve Cryptography: ECDSA* and ECDH*
- Compression/Decompression Functions
  - — Deflate

39.5 Intel QuickAssist Integrated Accelerator

The IQIA provides acceleration functions that can be used by the IA cores. The IQIA appears to software as a set of up to three PCIe endpoints and its acceleration services can be accessed by a standard PCIe* driver. To enhance communication between the IA and the IQIA, the IQIA implements rings via a Ring Controller to route messages between them. This allows the IA to efficiently access the Intel QuickAssist Technology services through the Intel QuickAssist Technology APIs. The APIs communicate with the IQIA hardware via PCI configuration space access and assisted rings stored in system memory. Refer to the *Intel® QuickAssist Technology API Programmer's Guide*, incorporated herein by reference, and available at:

https://01.org/packet-processing/intel%C2%AE-quickassist-technology-drivers-and-patches

Figure 39-1. Intel QuickAssist Technology Usage Block Diagram



The following steps list a high-level overview of the usage.

1. The application requires IQIA service (e.g., decrypt a packet using AES). It requests service by calling an API with appropriate parameters.
2. The IQIA device driver formats a request message and places it onto ring-in-host memory, then notifies the IQIA.
3. IQIA reads the request message from the Ring Controller.
4. IQIA carries out the request.
5. When the process is done, write response message to ring-in-host memory.

6. Interrupt the host processor via a Message Signal Interrupt (MSI) or a user application can poll for completions.

Note: See the *Intel® QuickAssist Technology API Programmer's Guide* for information on Intel QuickAssist Technology APIs.

39.5.1 Ring Controller

The Ring Controller provides communication between the IA cores and the Intel QuickAssist Integrated Accelerator.

- Implements 256 rings for communications between the host processor and the IQIA.
- Organized in 16 bundles of 16 rings each.
- Each bundle supports one interrupt to the endpoint.

39.5.2 Single-Root I/O Virtualization

A virtualized platform enables system hardware resources to be shared among multiple guest operating systems. Each guest OS on the virtual platform operates under the assumption that it has complete control of all platform hardware resources. An I/O device that supports I/O virtualization provides the ability for it to be shared simultaneously among multiple guest operating systems.

The Intel QuickAssist Technology endpoint implements support for Single-Root I/O Virtualization for Function 0 and enables a usage model that allows up to 16 guest operating systems simultaneous access to its resources.

SR-IOV is a PCI-SIG* I/O Virtualization specification which in conjunction with system virtualization technologies like Intel® Virtualization Technology (Intel® VT) for Directed I/O (Intel® VT-d) and Intel® Virtualization Technology (Intel® VT) for IA-32, Intel® 64 and Intel® Architecture (Intel® VT-x), allows multiple guest operating systems running simultaneously within a single platform to natively share PCIe devices.

The SR-IOV capability structure is discovered and configured using the well-defined standard PCI enumeration process.

- Implements an SR-IOV extended capability record.
- Up to three Physical Functions available
  - One Physical Function per Intel QuickAssist Technology endpoint
  - Supports INTx, MSI, and MSI-X.
- Up to 48 virtual functions available
  - 16 Virtual Functions per Intel QuickAssist Technology endpoint
  - Supports ARI.
  - Implements MSI only.
  - *Does not* support INTx messages or MSI-X.
- Endpoint *does not* support the following optional IOV features:
  - Multi-root IOV
  - VF migration
- Ring access:
  - Physical Function can access all 16 ring bundles.

— Each Virtual Function can access one bundle.

Note: ARI must be enabled to use all of the Virtual Functions that Intel QuickAssist Technology supports.

39.5.2.1 I/O Virtualization Models

An I/O device such as the Integrated QuickAssist Accelerator can be shared amongst multiple guest operating systems in a virtual platform using several different hardware, software, and a combination of software and hardware techniques.

39.5.2.1.1 Sharing via Virtual Machine Manager

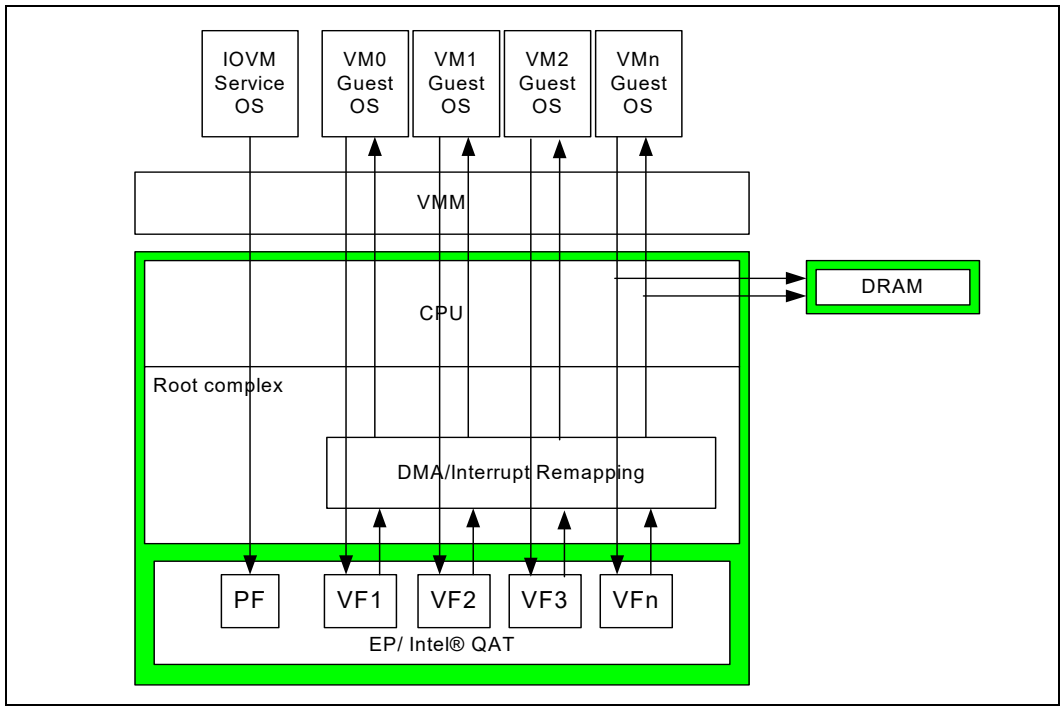
The I/O devices in this mode are assigned to the VMM/hypervisor. The VMM will expose a synthetic device to the Virtual Machines and could provide a paravirtualized driver that will run in the virtual machine. All accesses from the virtual machine using the paravirtualized driver are intercepted by the VMM. The VMM will then use the device driver to access the I/O device on behalf of the virtual machine. In this form of I/O sharing, there is little or no hardware support in the root complex or I/O device for virtualization.

39.5.2.1.2 Direct Assignment of the Endpoint with SR-IOV

The VMM can take advantage of the Intel QuickAssist Technology endpoint with SR-IOV support in the hardware and direct assign up to 16 virtual machines to the 16 virtual functions as shown in Figure 39-2. Each virtual machine can independently access the services of the Intel QuickAssist Technology.

Configuration and initialization of the IQIA will be through the I/O Virtual Machine. All error messages and interrupts not related to the ring status will be directed towards the IOVM (i.e., serviced by the IOVM).

Figure 39-2. Direct I/O Assignment Model with IOV Support



39.5.2.2 Ring Bundle Mapping

Each virtual function will be statically allocated one bundle (16 rings). A guest OS that is directly assigned to a virtual function will have access to only the rings associated with the bundle the virtual function is assigned to as shown in Table 39-1.

All errors and interrupts generated by the rings will use the Ring ID (RID) associated with that bundle.

Table 39-1. Ring Assignment to Intel QuickAssist Technology Virtual Functions

Ring	Virtual Function Assignment	Function Number	Ring CSR PCI Offset Begin
Bundle 0	VF1	8	00000h
Bundle 1	VF2	9	01000h
Bundle 2	VF3	10	02000h
Bundle 3	VF4	11	03000h
Bundle 4	VF5	12	04000h
Bundle 5	VF6	13	05000h
Bundle 6	VF7	14	06000h
Bundle 7	VF8	15	07000h
Bundle 8	VF9	16	08000h
Bundle 9	VF10	17	09000h
Bundle 10	VF11	18	0A000h
Bundle 11	VF12	19	0B000h
Bundle 12	VF13	20	0C000h
Bundle 13	VF14	21	0D000h
Bundle 14	VF15	22	0E000h
Bundle 15	VF16	23	0F000h

Notes:
1. The physical function can view and access all bundles
2. Interrupts and memory accesses generated by each of the bundles via ring commands will use the associated bundle's RID

39.5.2.3 Virtual Function Interrupts

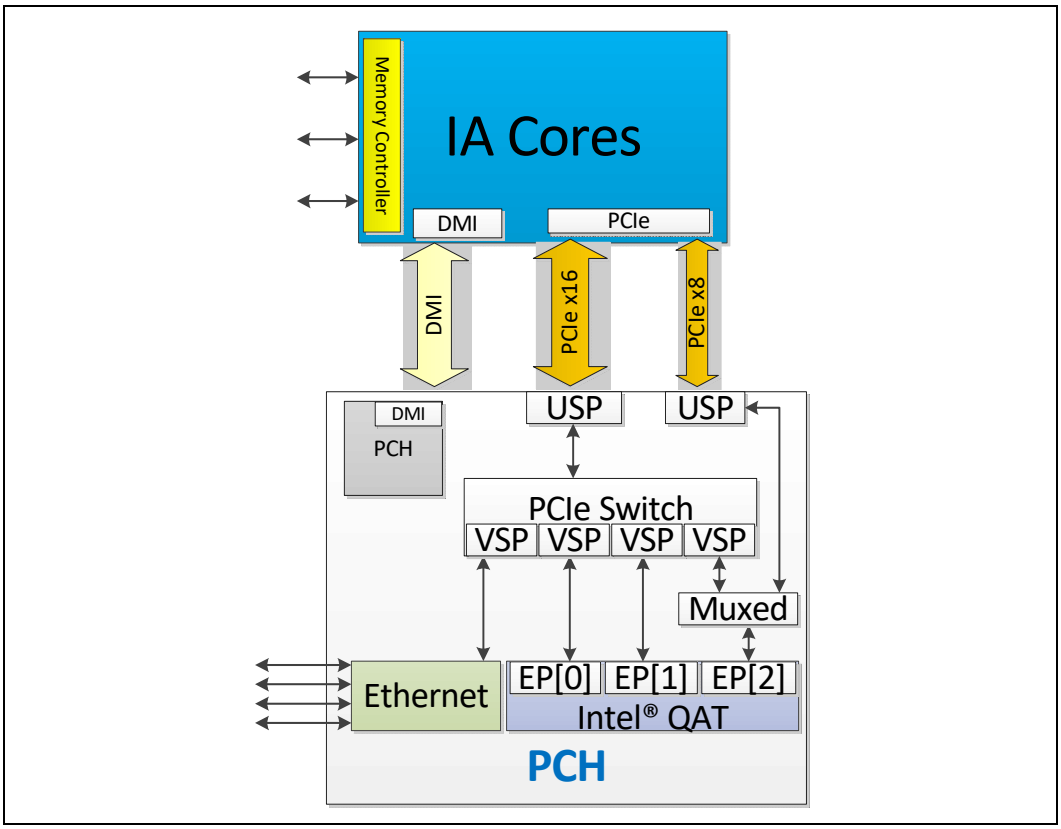
Each virtual function will support only MSI (one vector). A virtual function supports functional interrupts generated by the Ring Controller. INTx is not applicable for a virtual function per the PCI Express* SRIOV specification.

39.6 Intel QuickAssist Technology and PCH Upstream Port Requirements

Intel QuickAssist Technology requires the PCH Upstream Ports (USP) to be connected to a PCIe Root Port. Up to two Upstream Port controllers are supported and each controller consists of multiple lanes. The quantity of controllers and lanes available are SKU dependent. The primary upstream port controller is used by both the Intel QuickAssist Technology and the Integrated 10GbE and will support up to either x16 or x8 lanes depending on the PCH SKU. For PCH SKUs that support a secondary Upstream Port controller, an additional x8 lanes are available that are dedicated to Intel QuickAssist Technology Endpoint 2.

All three Intel QuickAssist Technology endpoints are accessible by the x16 Upstream Port controller via an integrated PCIe Switch and the switch's Virtual Switch Ports (VSP). On PCH SKUs that support the secondary x8 Upstream Port controller, the secondary upstream port controller is muxed with the Intel QuickAssist Technology endpoint 2 (EP[2]) and will have dedicated access to that endpoint (EP[2]) as shown in the following figure.

Figure 39-3. Intel QuickAssist Technology and PCH Upstream Ports



Note: The x8 lanes associated with the second upstream port controller are part of the high speed I/O (HSIO) muxed lanes along with SATA and PCIe Root Ports. When the x8 lanes are used as a second Upstream Port controller, the max number of PCH PCIe RP lanes available will be reduced by eight. Additionally, the PCH SATA ports will not be available. The PCH super speed SATA (sSATA) Ports are muxed separately, and will still be available.

Note: Traditional PCH features and interfaces such as SATA, USB, PCIe RP, and etc. are not accessible via the PCH PCIe Upstream Ports that are connected to a host processor. DMI is required for access to these capabilities.

39.7 Intel QuickAssist Technology Endpoint Only (EPO) Mode

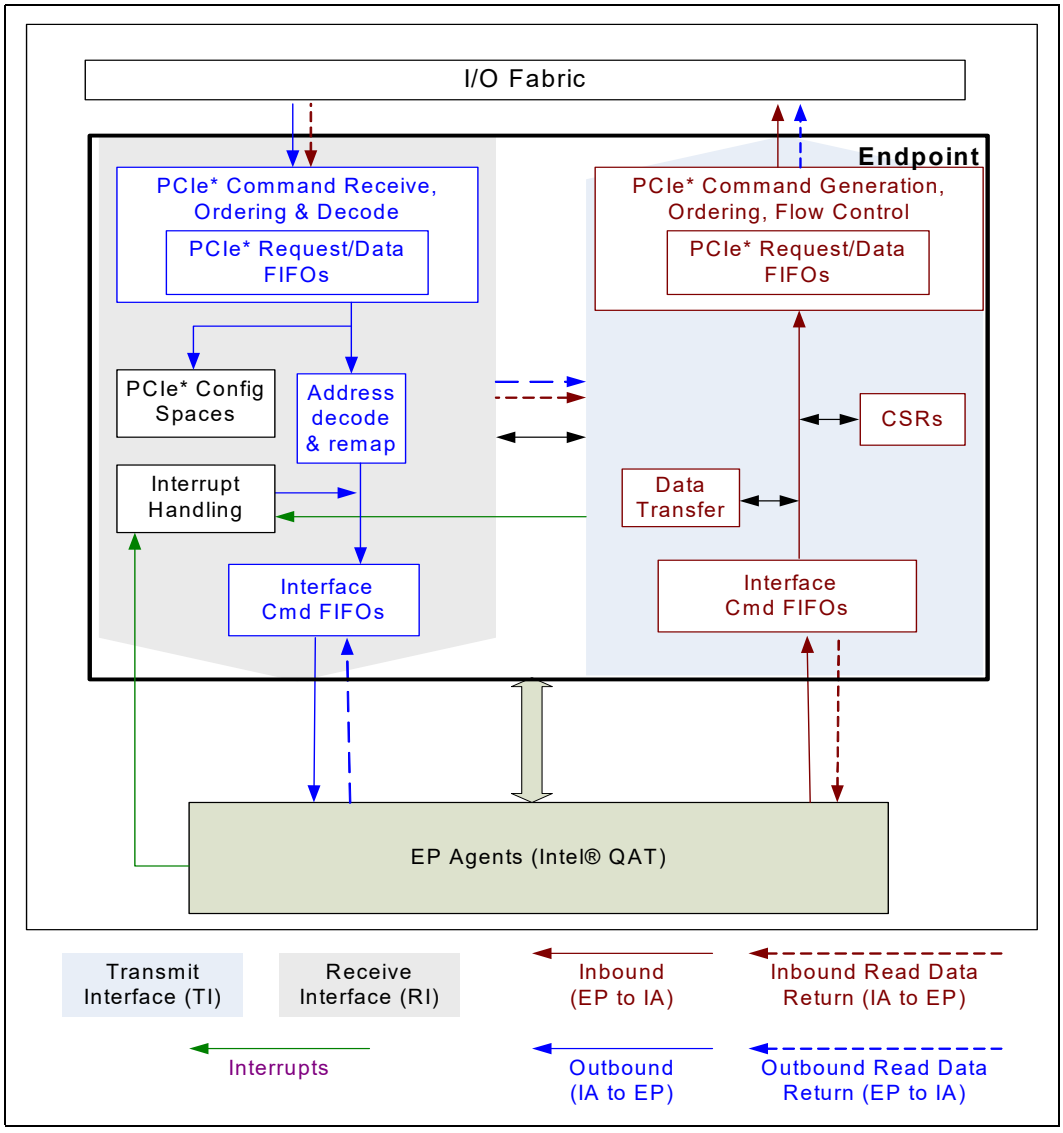
Intel QuickAssist Technology is supported in Endpoint Only Mode. Refer to the Section "PCH EndPoint Only Mode" in this document for additional details.

39.8 Intel QuickAssist Technology PCIe Endpoint Function

Intel QuickAssist Technology will show up as a PCIe device to the software running on the IA cores. The IQIA is integrated/embedded in the Root Complex as the root complex integrated endpoint.

Figure 39-4 shows the functional description block diagram of the PCIe endpoint interface.

Figure 39-4. Endpoint Functional Block Diagram



39.8.1 Transmit Interface

The Transmit Interface is responsible for converting the endpoint agents' commands toward system memory and outbound completions into the PCIe transactions. The Transmit Interface connects to the inbound port of the PCIe root complex.

39.8.2 Receive Interface

The Receive Interface is responsible for converting Outbound PCIe commands from the IA cores into the endpoint agents' commands. Downstream read completions for PCIe commands initiated by the Transmit Interface are also received by the Receive Interface.

39.8.2.1 PCIe Endpoint Functions

The Receive Interface connects to the Outbound port of the PCIe root complex. Table 39-2 lists the Receive Interface supported PCIe transactions. The endpoint only supports requests that are aligned on Dword address boundaries.

Table 39-2. PCIe Commands Supported by the Receive Interface

PCIe* Command	Description	Source	Endpoint Attributes	Comments
MRd32/ MRd64	Memory Read	IA reading EP MMIO region, PCIe* extended configuration space	4B	
MWr32/ MWr64	Memory Write	IA writing to EP MMIO region, PCIe extended configuration space	4-8B	Notes 2
CfgRd0	Type 0 Configuration Read	IA reading EP Configuration register	4B	
CfgWr0	Type 0 Configuration Write	Non-Posted IA writing to EP Configuration register	4B	Note 2
CmplD	Completion with Data	Read completion with data for a read command initiated by TI	4B-256B	Note 3

Notes:
1. Although the endpoint is capable of handling 8B requests, Intel QuickAssist Technology does not support any target that supports 8B requests. Therefore, software should not attempt any 8B requests.
2. This is a non-posted transaction. The Receive Interface will generate a completion without data after the configuration write is completed. The completion will be routed via a RI-TI private bus to the Transmit Interface. The Transmit Interface will initiate the PCIe completion packet.
3. The data will be pushed onto the bus by the Transmit Interface.
4. The Receive Interface will generate an Unsupported Request (UR) completion if it receives PCIe commands from IA that are not listed in this table.

39.8.2.2 Endpoint Function Mapping

The endpoint Receive Interface implements a single PCIe device with SR-IOV, and Table 39-3 shows the mapping of the endpoint functionality. When SR-IOV is enabled, the Receive Interface exposes additional virtual functions.

Table 39-3. PCIe Endpoint Function Mapping

Endpoint	Functional Blocks	PCIe Function Number (Note 1 and 2)	BARs	Interrupt Capability (Note 4)	PCIe Extended / PCI Capabilities (Note 2)
Intel QuickAssist Technology	Intel QuickAssist Technology	0	PMISCBAR, PETRINGCSRBAR	INTA, MSI, MSI-X with 16 vectors	MSI, MSI-X, PM, PCIe, AER, SR-IOV, ARI
VF[1:16]		8-23 Note 1	SRIOVBAR0, SRIOVBAR1	MSI only	MSI, PCIe, AER, ARI, ACS

Notes:
1. ARI must be enabled to view function numbers > 7, which are Virtual Functions.
2. When ARI is disabled, the Bus and Device Number is captured by the Receive Interface on every Type 0 configuration write. When ARI is enabled, the Device Number is implicitly assumed to be 0 and only the bus number is captured by the Receive Interface on every type 0 configuration write.
3. PPETRINGCSRBAR is used for access to registers that configure and access the Ring. PMISCBAR is used for accessing the endpoint and the MSI-X table.

39.8.2.3 Endpoint Mapping of MMIO to BARs

Table 39-4 shows the mapping of the endpoint MMIO regions to the BARs. Host access to the MMIO regions are done via the corresponding BARs. Refer to each PCIe function BAR definition for more details.

Table 39-4. Endpoint Mapping of MMIOs to BARs

Function #	BAR Name (Size)	Region Size	Functionality	Comments
0	PMISCBAR (256 KB)	248 KB	EP, Intel QuickAssist Technology	This region is mapped to the EP and Intel QuickAssist Technology CSRs
0		4 KB	EP MMIO CSRs	The EP CSRs are located in the EP.
0		4 KB	MSI-X Tables	The MSI-X tables are located in the EP
0	PETRINGCSRBAR	256 KB	16 Bundles of Ring CSRs	128 KB for all 16 bundles of CSRs and Intel QuickAssist Technology CSRs. Each bundle requires 4KB. ***Note:*** This space is allocated for 32 bundles. Only the lower 16 bundles are used and the upper 16 are memory holes in this region.
8-23 (VF[1-16])	SRIOVBAR0	MIN (4 KB, System Page Size) (Note 2)	One Ring Bundle per VF[x]	Each bundle requires 512B, but are mapped in a 4 KB window by default or the system page size.
	SRIOVBAR1	MIN (4 KB, System Page Size) (Note 2)	VF Messaging Registers	There is only one register per VF but is mapped in a 4 KB window by default or the system page size.

Notes:
1. Accesses to the MMIO region that are not implemented within the regions defined in this table will return zeros (0s). Accesses to MMIO regions that are not claimed by any of the BARs will return Unsupported Request (UR).
2. The SRIOVBAR0 size is dependent on the value programmed in the system page size.
3. The SRIOVBAR1 size is dependent on the value programmed in the system page size.

39.8.2.4 Alternate Routing-ID

The Receive Interface provides support for the Alternate Routing-ID Interpretation. When enabled, ARI allows the PCIe device to implement more than eight functions.

An ARI device interprets the Routing, Requester, and Completer IDs as having an 8-bit function number instead of the traditional 3-bit function number. An ARI device has its associated device number implied to be 0 rather than specified by an ID field. The Receive Interface supports ARI for Function 0 when SR-IOV is enabled.

Note: ARI must be enabled to use all of the Virtual Functions that Intel QuickAssist Technology supports.

Table 39-5. ARI: Bus, Device and Function Interpretation

ARI Disabled	**Bus Number**	**Device Number**	**Function Number**
	[7:0]	[4:0]	[2:0]
ARI Enabled	**Bus Number**	**Function Number**	
	[7:0]	[7:0]	

39.9 Interrupts

The Receive Interface is responsible for collating interrupts and errors from the endpoint and taking the appropriate actions based on the PCIe configurations status.

Interrupts from the endpoint can be configured in the Receive Interface to be routed to the IA cores. The interrupts can be sent upstream as either an MSI, MSI-X, or by using INTx virtual wire interrupt signaling mechanism (which are messages on PCIe).

39.9.1 INTx

PCIe supports devices that need to use the PCI compatible legacy interrupt signaling: INT[A, B, C, D]. Instead of dedicated pins for this functionality, PCIe supports in-band virtual wires.

The endpoint supports the generation of INTx virtual wire interrupt signaling based on internal generated interrupts. The INTx notification is accomplished using PCIe messages.

The Receive Interface is responsible for collating interrupt sources from the endpoint agents and generating the transaction that is translated to a PCIe interrupt message to the IA. Upon detecting an interrupt from an internal source, the Receive Interface first determines whether to generate an MSI, MSI-X, or INTx message.

39.9.2 Message Signaled Interrupt

Message Signaled Interrupts are an optional feature that enables a device function to request service by writing a system-specified data value to a system specified address (using a PCI Dword memory write transaction). System software initializes the message address and message data during device configuration. Each function in the endpoint supports the MSI capability. All the interrupts per function share one vector.

39.9.3 MSI-X

MSI-X defines a separate optional extension to the basic MSI functionality. Compared to MSI, MSI-X supports a larger number of vectors per function, the ability for the OS to program independent address and data values for each vector. The address and data values for each vector is specified by a table that resides in the memory space. MSI-X is supported only for the physical function.

Once an MSI has been generated using MSI-X, its characteristics are similar to an MSI that was generated using an MSI capability record. However, MSI-X supports per-vector masking that is optional for MSI. MSI-X also supports a Function Mask bit, which when set, masks all of the vectors associated with a function. Per-vector masking is managed through a Mask and Pending bit pair per the MSI vector or MSI-X table entry. An MSI vector is masked when its associated Mask bit is set. An MSI-X vector is masked when its associated MSI-X Table Entry Mask bit or the MSI-X Function Mask bit is set. While a vector is masked, the function is prohibited from sending the associated message, and the function must set the associated Pending bit whenever the function would otherwise send the message. When software unmasks a vector whose associated Pending bit is set, the function must schedule sending the associated message, and clear the Pending bit as soon as the message has been sent.

When MSI-X is enabled, the endpoint generates an interrupt using a PCIe posted memory write transaction. The address and data of that transaction are determined by the system and programmed in the PCI MSI-X table entry.

39.10 Endpoint Errors

There are two classes of errors that the endpoint will encounter:

- Errors that occur due to PCIe transactions
  - PCIe error management defines the scope of these kinds of errors including how they are reported and handled.
- Other errors not directly related to PCIe transactions
  - This class of errors are reported via interrupts and do not fall under the scope of PCIe error management mechanisms.

39.10.1 PCIe Error Management

PCIe error management focuses on errors associated with the PCIe interface and the transactions between the transaction layers of the transmitting and the receiving PCIe ports.

39.10.2 PCIe Error Reporting Mechanisms

The PCIe specification provides three mechanisms for reporting errors that occur while servicing to PCIe transactions.

1. PCI
   a. This mechanism provides backward compatibility with legacy PCI compatible software and is required per the PCIe specification. Legacy compatible PCI software will use this mechanism and control this feature via the PCI configuration Command register. When this mechanism is enabled, the endpoint will also log error status information in the PCI Configuration Status register.
   b. The endpoint will support the legacy PCI compatible error mechanism.

2. PCIe
   a. This is the baseline PCIe mechanism for software that understands PCIe devices. The mechanism can be enabled via the PCIe Device Control register. Error status is logged in the PCIe Device Status register.
   b. Supported error classifications: unsupported request type, fatal error, non-fatal error, and correctable error.
   c. The endpoint will support the baseline PCIe error reporting mechanism.
3. PCIe Advanced Error Reporting
   a. The optional advanced error reporting registers can be implemented by PCIe devices. This mechanism is defined using a PCIe extended capability structure.
   b. All endpoint Functions will support AER.

39.10.3 PCIe Error Handling and Signaling

The endpoint will classify errors in the following three PCIe specification-defined buckets:

1. Correctable errors: These errors are handled by the Hardware.
2. Uncorrectable errors (non-fatal): These errors are handled by device-specific software.
3. Uncorrectable errors (fatal): These errors are handled by system software.

The endpoint will use three different mechanisms to signal errors that occur when processing PCIe commands.

1. Completion status
2. Error forwarding or data poisoning
3. Error messages

39.10.4 PCIe Error Sources

Table 39-6 defines the standard PCIe defined error sources. The following sections describe each of the PCIe error types, and describe how the endpoint handles the PCIe errors.

Table 39-6. PCIe Error Sources

	Type of Error	Report Using	Comment
TL	ECRC Check	Uncorrectable Non-Fatal Message	
	Malformed TLP	Uncorrectable Fatal Message	Receive Interface will perform checks on the PCIe transactions received from IA.
	Completion Timeout	Uncorrectable Non-Fatal Message	Receive Interface will generate these split transaction errors. Completer abort is supported in the Receive Interface.
	Unsupported Requests	Completion Status	
	Completer Abort (optional)		
	Unexpected Completion	Uncorrectable Non-Fatal Message	
	Data Corruption / Poisoning	PCIe Header	Transmit Interface will set the endpoint bit in the3 header based on the data error. Writes that terminate in the Receive Interface get dropped and the status logged. Writes that target an endpoint function will be sent with a data error and logged in the Receive Interface.

39.10.4.1 Role-Based Error Reporting

In earlier versions of the PCI Express Specification, errors were reported by the agent that detected the error. The *PCI Express Base Specification,* Rev. 1.1 implements a role-based error reporting where the response to the errors is based on the components role in the transaction. In general, errors detected in non-posted transactions are handled by the initial requester and the completer may optionally send an advisory message to the root complex as an ERR_COR message. Errors in posted transactions are still logged and reported by the target device.

Note: If the severity for the error is programmed to fatal in the PCI Express Uncorrectable Error Severity register, then it is not an "advisory non-fatal error" and is signaled with an ERR_FATAL message. A fatal severity overrides all other Advisory Error Control bits.

The following errors are considered "advisory non-fatal error" cases and have different handling depending on the transaction type.

- ECRC check failed
- Unexpected completion
- Unsupported request
- Poisoned TLP received
- Completer abort
- Completion timeout

39.10.4.2 Malformed Packets

The following checks are made to detect malformed TLPs.

- Data payload exceeds the length specified by the value in the Max_Payload_Size field of the Device Control register.

When a malformed packet is detected, the packet is dropped and the error is logged. No flow control information is updated for malformed packets.

39.10.4.3 ECRC Check Failed

The endpoint does not calculate for ECRC but will report the ecrc_error signal that it receives. The endpoint reports by sending an ERR_NONFATAL message to the root complex.

39.10.4.4 Unsupported Request

Unsupported requests are detected by the address decode and translation logic. A TLP is treated as unsupported in the following cases:

- The TLP fails to match any of the active memory or I/O windows.
- A configuration TLP that targets an invalid function number.
- A receipt of a Vendor_Defined Type 0 message.
- A message request with an undefined or unsupported message code.
- A poisoned I/O or configuration request.
- A receipt of a memory or I/O transaction while in a non-D0 power state.
- A receipt of a Memory Read Lock (MRdLk).

No checks are made for the address plus the length crossing a window boundary.

For posted transactions, this is **not** an advisory error, and an ERR_NONFATAL is sent to the root complex.

For non-posted transactions, this is considered an advisory error. An ERR_COR is sent to the root complex and a completion with Unsupported Request status is returned to the requester.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error, and an ERR_FATAL will be sent to the root complex.

39.10.4.5 Completer Abort

Requests that target abort or master abort on the internal bus are treated as a completer abort.

These requests must have passed the malformed TLP checks as well as the unsupported request checks before they are issued on the internal bus.

For posted transactions, an ERR_NONFATAL is sent to the root complex.

For non-posted transactions, an ERR_COR is sent to the root complex and a completion with Completer Abort status is returned to the requester.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal this is not an advisory error and an ERR_FATAL will be sent to the root complex.

39.10.4.6 Unexpected Completions

Unexpected completions occur when a completion transaction ID does not match an outstanding request. If the Requester ID of the completion matches a valid function, the error will get logged in that function. Otherwise, the error will get logged against all functions.

This is an advisory non-fatal error and an ERR_COR will be sent to the root complex.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error and an ERR_FATAL will be sent to the root complex.

39.10.4.7 Poisoned TLP Received

Poisoned TLPs can be received for both inbound posted (write/message) and inbound completions. The two TLP types can be handled differently.

Poisoned completions are passed through to the target agent with the error bit set. The error is logged in the corresponding function. This is an advisory error and an ERR_COR will be issued.

Poisoned memory writes that are MMIO-mapped are passed through to the intended target. Depending on the register target, the MMIO-mapped register may get updated with the poisoned data, whereas in some cases the register will not be updated as the byte-enable signals will be disabled. The error is logged in the corresponding function. This is a non-fatal error and an ERR_NONFATAL will be issued.

Writes to configuration registers will not complete to the target. Since configuration writes are non-posted writes, a completion with Unsupported Request is returned to the host.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not a non-fatal error, and an ERR_FATAL will be sent to the root complex. Auto-recovery is discouraged as the ERR_FATAL message will likely bring down the hierarchy.

39.10.4.8 Completion Timeout

When an out-bound, non-posted request results in a completion timeout, the advanced error registers are updated in the corresponding function. This will be treated as an advisory error, and an ERR_COR will be sent to the root complex.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error, and an ERR_FATAL will be sent to the root complex. Auto-recovery is discouraged as the ERR_FATAL message will likely bring down the hierarchy.

39.10.4.9 Non-Function Specific Errors

The PCI Express Specification lists the following errors as non-function specific:

- Transaction layer errors
  - — ECRC fail
  - — Unsupported Request, when caused by no function claiming a TLP
  - — Receiver overflow
  - — Flow control protocol error
  - — Malformed TLP
  - — Unexpected completion, when caused by no function claiming a completion

On the detection of one of these errors, a multi-function device should generate at most one error reporting message of a given severity, where the message must report the Requester ID of a function of the device that is enabled to report that specific type of error. If no function is enabled to send a reporting message, the device does not send a reporting message. If all reporting-enabled functions have the same severity level set for the error, only one error message is sent. If all reporting-enabled functions do not have the same severity level set for the error, one error message for each severity level is sent. Software is responsible for scanning all functions in a multifunction device when it detects one of those errors.

39.10.5 Device-Specific Error Management

The endpoint will report device-specific errors using interrupts—INTx or MSI based on the PCIe configuration settings.

Table 39-7. Device Specific Errors

Function	Description
Function 0	The endpoint implements error source and mask registers. When detecting an assertion on an unmasked error, the Receive Interface will generate either an INTA or MSI.

39.10.5.1 Memory Error Poisoning

The Transmit Interface also tracks data errors for all transactions that flow through the Transaction Interface, including accesses to PCIe and CSRs.

39.10.5.2 Memory Write Poisoning

For a PCIe memory write (including memory writes triggered by the Ring Controller), the Transmit Interface pulls data from the endpoint master. If the internal bus indicates an error, then the Transmit Interface logs the error, but it does not abort the write transaction. Instead, the Transmit Interface passes along the data error notification along with the data. On PCIe, the Transmit Interface will set the appropriate bit in the header of the packet.

39.11 Error Handling with SR-IOV

The endpoint ring-related errors that are associated with a given Virtual Function are handled by the given VF itself. For example, the VF would report and log the errors. Each VF supports the legacy PCI (PCI Command and Status registers) and PCIe reporting mechanism (ERR_COR, ERR_NONFATAL, ERR_FATAL messages). The VF also supports PCIe extended capability - AER. Errors that are not directly related to the ring associated with a given VF are handled by the PF. For example, errors such as endpoint parity errors, etc.

39.12 PCIe Endpoint Function 0 Registers (Intel QuickAssist Technology) - EndPoint (EP) Physical Function (PF) PCI Configuration Space

Table 39-8. Register Attributes / Modifiers

Attribute	Description
RO	**Read Only:** These bits can be read by Software, but writes have no effect. The value of the bit is determined by hardware only.
RW	**Read/Write:** These register bits can be read by software and modified by software
RW/1C	**Read/Write 1Clear**. These bits can be read from and written to by software. Writing a "0" to these bits has no effect. Writing a "1" clears the bit.
RV	**Reserved**: These bits are reserved. Their value must be maintained by software. When writing these bits, software must preserve the value read.
Modifier	**Description**
-O	**Once:** After reset, these bits can only be written to once. After that they are read only.
-V	**Variant:** The value of the bit can be updated by hardware.

The EP Physical Function implement Type 0 PCIe configuration space that is compliant with PCIe 3.0 Specification.

The Endpoint is a single-function device designated as: Bus (M) = 0xM, Device (D) = 0xD, and Function = 0x0.

39.12.2 PCI Standard Header Registers

39.12.2.1 PVID - PF Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

Table 39-10. PVID - PF Vendor Identification Register

Description: PF Vendor Identification Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 00h **Offset End:** 01h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 00h **Offset End:** 01h	
Size: 16 bit	**Default:** 8086h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	VID	**Vendor Identification:** This register field contains the PCI standard identification for Intel, 8086h.		8086h	RO

39.12.2.2 PDID - PF Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Writes to this register have no effect.

Table 39-11. PDID - PF Device Identification Register

Description: PF Device Identification Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 02h **Offset End:** 03h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 02h **Offset End:** 03h	
Size: 16 bit	**Default:** 37C8h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	DIDLOW	**Device Identification Number:** DID = 37C8h		37C8h	RO

39.12.2.3 PPCICMD - PF Device Command Register

Table 39-12. PPCICMD - PF Device Command Register

Description: PF Device Command Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 04h **Offset End:** 05h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 04h **Offset End:** 05h	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :11	Reserved	Reserved		0h	RO
10	INTD	**Interrupt Disable:** Setting this bit disables generation of INTX messages by the EP. Default value is 0 which enables the INTX message generation.		0h	RW
09	FBTB	**Fast Back-to-Back Enable:** EP does not implement this functionality and it is not applicable to PCIe devices. The bit is hardwired to 0.		0h	RO
08	SER	**SERR# Enable:** When set, this bit enables the non-fatal and fatal errors detected by the EP to be reported to the RC. Note that the error reporting can also be enabled via the PCIe specific bits in the PCIe device control register (Section 39.12.5.5, "PPDCNTL - PF PCI Express Device Control Register") The default value of this bit is 0.		0h	RW
07	Reserved1	Reserved/Does not apply to PCIe.		0h	RO
06	PER	**Parity Error Enable:** Controls the setting of the Master Data Parity Error bit in the Device Status Register (Section 39.12.2.4, "PPCISTS - PF Device Status Register") The Master Data Parity Error bit is set by the EP if its Parity Error Enable bit is set and either of the following two conditions occurs: • If the EP receives a poisoned Completion from the RC • If the EP poisons a write request. If the Parity Error Enable bit is cleared, the Master Data Parity Error status bit is never set The default value of this bit is 0.		0h	RW
05	VPS	**VGA Palette Snoop Enable:** The device does not implement this functionality/Does not apply to PCIe. The bit is hardwired to 0.		0h	RO
04	MWE	**Memory Write and Invalidate Enable:** The device does not implement this functionality/Does not apply to PCIe. The bit is hardwired to 0.		0h	RO
03	SS	**Special Cycle Enable:** The device does not implement this functionality/Does not apply to PCIe. The bit is hardwired to 0.		0h	RO
02	BM	**Bus Master Enable:** Controls the ability of EP to issue Memory Read/Write Requests. Clearing (0) this bit prevents EP from issuing any Memory Requests. Note that as MSI's are in-band memory writes, disabling the bus master enable bit disables MSI as well. PCIe messages are not affected by this bit.		0h	RW
01	MEM	**Memory Space Enable**: Setting this bit enables access to the memory regions the device claims through its BARs. EP will return "unsupported request" completion status and error message in response to memory transactions it receives when this bit is clear.		0h	RW
00	IO	**I/O Space Enable:** The device does not implement this functionality since it claims no I/O regions. The bit is hardwired to 0.		0h	RO

39.12.2.4 PPCISTS - PF Device Status Register

Table 39-13. PPCISTS - PF PCI Device Status Register

Description: PF device status register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 06h **Offset End:** 07h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 06h **Offset End:** 07h	
Size: 16 bit	**Default:** 0010h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	DPE	**Detected Parity Error:** This bit is set by EP whenever it receives a Poisoned TLP, regardless of the state the Parity Error Enable bit in the Command register. Default value of this field is 0.		0h	RW/1C/V
14	SSE	**Signaled System Error:** This bit is set by the EP when it sends a ERR_FATAL or ERR_NONFATAL message and the SERR bit in the Device Command register bit is set. Default value of this field is 0.		0h	RW/1C/V
13	RMA	**Received Master Abort Status:** This bit is set when EP, as a Requester receives a Completion with Unsupported Request Completion Status. Default value of this field is 0.		0h	RW/1C/V
12	RTA	**Received Target Abort Status:** This bit is set when EP, as a Requester receives a Completion with Completer Abort Completion Status. Default value of this field is 0.		0h	RW/1C/V
11	STA	**Signaled Target Abort Status:** This bit is set when EP completes a Request using Completer Abort Completion Status. Default value of this field is 0.		0h	RW/1C/V
10 :09	DST	**DEVSEL Timing:** Does not apply to PCI Express. These bits are hardwired to 0.		00b	RO
08	MDPE	**Master Data Parity Error Detected:** This bit is set by EP, as a Requester if the Parity Error Enable bit in the Command register is 1b and either of the following two conditions occurs: • Requester receives a Completion marked poisoned • Requester poisons a write Request If the Parity Error Enable bit is 0b, this bit is never set. Default value of this field is 0.		0h	RW/1C/V
07	FB2B	**Fast Back-to-Back Capable:** Does not apply to PCI Express. The bit is hardwired to 0.		0h	RO
06	Reserved1	Reserved1		0h	RO
05	MC66	**66 MHz Capable:** Does not apply to PCI Express. The bit is hardwired to 0.		0h	RO
04	CL	**Capabilities List:** This bit is hardwired to 1 to indicate that EP has a capabilities list.		1h	RO
03	INTSTS	**Interrupt Status:** Indicates that the EP has transmitted a INTX message and is awaiting servicing. This bit does not includes MSI's generated by the EP.		0h	RO/V
02 :00	Reserved2	Reserved2		0h	RO

39.12.2.5 PRID - PF Revision ID Register

The value of this register indicates the chip stepping. It is hardwired on chip and reflects the latest revision.

Table 39-14. PRID - PF Revision ID and Class Code Register

Description: PF revision ID register and PF class code Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 08h **Offset End:** 0Bh	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 08h **Offset End:** 0Bh	
Size: 32 bit	**Default:** 0B400000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :8	CC	**Class Code:** This value indicates the base class, subclass, and interface. 0B4000h = Base class: Processor, Sub-class Co-processor, no specific register level programming interfaces are defined.		0B4000h	RW/O
07 :4	RIDU	Major Revision: Steppings which require all masks to be regenerated. 00b: A stepping (Current Stepping) 01b: B stepping 10b: C stepping 11b: D stepping		0000b	RO
03 :0	RIDL	Minor Revision: Incremented for each stepping which does not modify all masks. Reset for each major revision. 00b: x0 stepping (Current Stepping) 01b: x1 stepping 10b: x2 stepping 11b: x3 stepping		0000b	RO

39.12.2.6 PCLS - PF Cache Line Size Register

Table 39-15. PCLS - PF Cache Line Size Register

Description: PF Cache Line size Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 0Ch **Offset End:** 0Ch	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 0Ch **Offset End:** 0Ch	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	CLS	**Cache Line Size:** Not used by PCI Express Endpoint. Left for compatibility reason only.		00h	RW

39.12.2.7 PHDR - PF Header Type Register

Table 39-16. PHDR - PF Header Type Register

Description: PF Header type Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 0Eh **Offset End:** 0Eh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 0Eh **Offset End:** 0Eh	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	HDR	**PCI Header Type:** The header type of the EP device. 00h (Bit 7 = 0b) indicates a single-function device with standard header layout.		00h	RO

39.12.2.8 PMISCLBAR - PF Miscellaneous Lower Base Address Register

The BAR is used to access EP and MSI-X registers.

Table 39-17. PMISCLBAR - PF Miscellaneous Lower Base Address Register

Description: PF Miscellaneous Lower Base Address Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 18h **Offset End:** 1Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 18h **Offset End:** 1Bh	
Size: 32 bit	**Default:** 00000004h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :18	ADDR	**Lower Programmable Base Address:** These bits are set by BIOS to locate the base address of the region.		0h	RW
17 :04	ZERO	**Lower Bits:** Hardwired to 0 (256KB region).		0h	RO
03	PREF	**Prefetchable:** Hardwired to 0 to indicate that the region is non-prefetchable.		0b	RO
02 :01	TYP	**Addressing Type:** Hardwired to indicate a 64-bit region.		10b	RO
00	MEM	**Memory Space Indicator:** Hardwired to 0 to identify the region as in memory space.		0b	RO

39.12.2.9 PMISCUBAR - PF Miscellaneous Upper Base Address Register

This BAR is used to access EP MMIO space.

Table 39-18. PMISCUBAR - PF Miscellaneous Upper Base Address Register

Description: PF Miscellaneous Upper Base Address Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 1Ch **Offset End:** 1Fh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 1Ch **Offset End:** 1Fh	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :00	ADDR	**Upper Programmable Base Address:** These bits are set by BIOS to locate the base address of the region.		0h	RW

39.12.2.10 PETRINGCSRLBAR - PF Ring CSR Lower Base Address Register

This BAR points to the Ring Controller rings.

Table 39-19. PETRINGCSRLBAR - PF Ring CSR Lower Base Address Register

Description: PF Ring CSR Lower Base Address Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 20h **Offset End:** 23h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 20h **Offset End:** 23h	
Size: 32 bit	**Default:** 00000004h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :18	ADDR	**Lower Programmable Base Address:** These bits are set by BIOS to locate the base address of the region.		0h	RW
17 :04	ZERO	**Lower Bits:** Hardwired to 0 (256KB region).		0h	RO
03	PREF	**Prefetchable:** Hardwired to 0 to indicate that the region is non-prefetchable.		0b	RO
02 :01	TYP	**Addressing Type:** Hardwired to indicate a 64-bit region.		10b	RO
00	MEM	**Memory Space Indicator:** Hardwired to 0 to identify the region as in memory space.		0b	RO

39.12.2.11 PETRINGCSRUBAR - PF Ring CSR Upper Base Address Register

This BAR points to the Ring controller rings.

Table 39-20. PETRINGCSRUBAR - PF Ring CSR Upper Base Address Register

Description: PF Ring CSR Upper Base Address Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 24h **Offset End:** 27h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 24h **Offset End:** 27h	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :00	ADDR	**Upper Programmable Base Address:** These bits are set by BIOS to locate the base address of the region.		0h	RW

39.12.2.12 PSVID - PF Subsystem Vendor ID Register

This register is a write-once register. Once any byte in the register has been written, the register locks against further writes until reset.

Table 39-21. PSVID - PF Subsystem Vendor ID Register

Description: PF Subsystem Vendor ID Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 2Ch **Offset End:** 2Dh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 2Ch **Offset End:** 2Dh	
Size: 16 bit	**Default:** 8086h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	SVID	**Subsystem Vendor ID:** This field is hardwired to ID assigned to Intel.		8086h	RO

39.12.2.13 PSID - PF Subsystem ID Register

This register is a write-once register. Once any byte in the register has been written, the register locks against further writes until reset.

Table 39-22. PSID - PF Subsystem ID Register

Description: PF Subsystem ID Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 2Eh **Offset End:** 2Fh	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 2Eh **Offset End:** 2Fh	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	SID	**Subsystem ID:** Vendor supplied device ID. Default is 0h.		0h	RW/O

39.12.2.14 PCP - PF Capabilities Pointer Register

The Capabilities Pointer Register provides the offset in configuration space to the location where the first set of capabilities registers is located.

Table 39-23. PCP - PF Capabilities Pointer Register

Description: PF Capabilities Pointer Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 34h **Offset End:** 34h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 34h **Offset End:** 34h	
Size: 8 bit	**Default:** B0h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	CP	**Pointer to First Capability Structure:** Value points to the configuration space offset of the first capability structure (MSI).		B0h	RO

39.12.2.15 PIRQL - PF Interrupt Line Register

Table 39-24. PIRQL - PF Interrupt Line Register

Description: PF Interrupt Line Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 3Ch **Offset End:** 3Ch	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 3Ch **Offset End:** 3Ch	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	IRQL	**Interrupt Line:** BIOS writes the interrupt routing information to this register to indicate which input of the interrupt controller this device is connected to. The device itself does not use this information.		0h	RW

39.12.2.16 PIRQP - PF Interrupt Pin Register

Table 39-25. PIRQP - PF Interrupt Pin Register

Description: PF Interrupt Pin Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 3Dh **Offset End:** 3Dh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 3Dh **Offset End:** 3Dh	
Size: 8 bit	**Default:** 01h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	IRQP	**Interrupt Pin:** Set to 01h to indicate that EP uses INTA# as its interrupt pin.		01h	RO

39.12.3 MSI-X Capability Structure

39.12.3.1 PMSIX - PF Message Signaled Interrupt X Capability ID Register

MSI-X Capability ID Register indicates that the device is capable of generating MSI-X Interrupts.

Table 39-26. PMSIX - PF Message Signaled Interrupt X Capability ID Register

Description: PF Message Signaled Interrupt X Capability ID Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 60h **Offset End:** 60h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 60h **Offset End:** 60h	
Size: 8 bit	**Default:** 11h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	MSIX	**Capability ID:** PCI SIG assigned capability record ID (11h, MSI-X capability). 11h identifies the EP as a device that is MSI-X capable.		11h	RO

39.12.3.2 PMSIXNCP - PF MSIX Next Capability Pointer Register

Table 39-27. PMSIXNCP - PF MSIX Next Capability Pointer Register

Description: PF MSIX Next Capability Pointer Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 61h **Offset End:** 61h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 61h **Offset End:** 61h	
Size: 8 bit	**Default:** 6Ch			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	MCP	**Next Capability Pointer:** Power Management Capability		6Ch	RO

39.12.3.3 PMSIXCNTL - PF Message Signaled Interrupt X Control Register

Table 39-28. PMSIXCNTL - PF Message Signaled Interrupt X Control Register

Description: PF Message Signaled Interrupt X Control Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 62h **Offset End:** 63h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 62h **Offset End:** 63h	
Size: 16 bit	**Default:** 0010h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	MSIXEN	MSI-X Enable: This bit enables the EP to generates interrupts using the MSI-X tables instead of the legacy INTx messages. When this bit is set to 1, the EP will not generate INTx messages and must use the MSI-X to signal interrupts. The device driver should not clear this bit to mask interrupts. This bit will be set by the system PCI device manager.		0h	RW
14	FM	Function Mask: This bit controls the masking of all vectors implemented in the EP. When this bit is 0, each vectors mask bit determines whether the vector is masked or not. When this bit is 1, all vectors are masked regardless of the per vector masking bit.		0h	RW
13 :11	Reserved	Always returns 0's when read.		0h	RO
10 :00	TS	MSI-X Table Size: Number of vectors (encoded as N-1) supported by the EP. The EP supports 17 vectors.		10h	RO

39.12.3.4 PMSIXTBIR - PF MSI-X Table Offset and Table BIR Register

Table 39-29. PMSIXTBIR - PF MSI-X Table Offset and Table BIR Register

Description: PF MSI-X Table Offset and Table BIR Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 64h **Offset End:** 67h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 64h **Offset End:** 67h	
Size: 32 bit	**Default:** 0003B002h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :3	TO	Table Offset: Offset to a location in one of the EP's BAR's (indicated by TBIR) that points to the location of the base of the MSI-X Table. The EP MSI-X Table maps to an offset of 236KB in PMISCBAR.		00000000000001110110000000000b	RO
2 :0	TBIR	Table BAR Indicator Register: The BIR points to the EP PMISCBAR register (18h)		010b	RO

39.12.3.5 PMSIXPBABIR - PF MSI-X Pending Bit Array and BIR Offset Register

Table 39-30. PMSIXPBABIR - PF MSI-X Pending Bit Array and BIR Offset Register

Description: PF MSI-X Pending Bit Array and BIR Offset Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 68h **Offset End:** 6Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 68h **Offset End:** 6Bh	
Size: 32 bit	**Default:** 0003B802h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :3	PBAO	Pending Bit Array Offset: Offset to a location in one of the EP BAR's (indicated by PBABIR) that points to the location of the base of the MSI-X PBA. The EP MSI-X PBA maps to an offset of 238KB in PMISCBAR.		000000000000001110111000 00000b	RO
2 :00	PBABIR	Pending Bit Array BAR Indicator Register: The PBABIR points to the EP PMISCBAR register (18h)		010b	RO

39.12.4 Power Management Capability Structure

39.12.4.1 PPMCAP - PF Power Management Capabilities ID Register

EP supports the PCI bus Power Management Interface Specification Rev 1.2 based PCIe Power Management. The specification requires the implementation of the PCI Power Management Capabilities Register.

Table 39-31. PPMCAP - PF Power Management Capabilities ID Register

Description: PF Power Management Capabilities ID Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 6Ch **Offset End:** 6Ch	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 6Ch **Offset End:** 6Ch	
Size: 8 bit	**Default:** 01h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	PMID	**Capability ID:** PCI SIG assigned capability record ID (01h, Power Management capability)		01h	RO

39.12.4.2 PPMCP - PF Power Management Next Capability Pointer Register

Table 39-32. PPMCP - PF Power Management Next Capability Pointer Register

Description: PF Power Management Next Capability Pointer Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 6Dh **Offset End:** 6Dh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 6Dh **Offset End:** 6Dh	
Size: 8 bit	**Default:** 74h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	PMCP	**Next Capability Pointer:** PCI Express Capability.		74h	RO

39.12.4.3 PPMC - PF Power Management Capabilities Register

EP supports the PCI bus Power Management Interface Specification Rev 1.2 based PCIe Power Management. The specification requires the implementation of the PCI Power Management Capabilities Register.

Table 39-33. PPMC - PF Power Management Capabilities Register

Description: PF Power Management Capabilities Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 6Eh **Offset End:** 6Fh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 6Eh **Offset End:** 6Fh	
Size: 16 bit	**Default:** 0023h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :11	PME	**PME Support**: Set to indicate that the EP will not assert PME# in any state.		00000b	RO
10	D2	**D2 Support**. EP does not support D2 state.		0b	RO
9	D1	**D1 Support**. EP does not support D1 state.		0b	RO
8 :6	AC	**Aux current**: Not relevant for EP.		000b	RO
5	DSI	**Device specific initialization**: A one in this bit indicates that immediately after entry into the D0 Uninitialized state, the function requires additional configuration above and beyond setup of its PCI configuration Header registers before the Class driver can use the function. For the EP this bit is set to 1.		1b	RO
4	Reserved	Reserved		0b	RO
3	PMC	**PME clock**. Does not apply to PCIe.		0b	RO
2 :0	PMV	**Version**. This field is set to 3 to indicate that the EP is compliant with the PCI bus Power Management Interface Specification Rev 1.2.		011b	RO

39.12.4.4 PPMCSR - PF Power Management Control and Status Register

EP supports the PCI bus Power Management Interface Specification Rev 1.2 based PCIe Power Management. The specification requires the implementation of the PCI Power Management Capabilities Register.

Table 39-34. PPMCSR - PF Power Management Control and Status Register (Sheet 1 of 2)

Description: PF Power Management Control and Status Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 70h **Offset End:** 73h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 70h **Offset End:** 73h	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :16	Reserved	Reserved: Not Supported for EP.		0000h	RO
15	PMS	**PME Status**: Hardwired to 0 since EP will not generate PME.		0b	RO
14 :13	DSC	**Data Scale**: Set to 0 because the EP does not implement the Data register. If the Data register has not been implemented, this field must return "00b" when the PMCSR is read.		00b	RO
12 :9	DSEL	**Data Select**: Set to 0 for EP because the EP does not implement the Data register (The Data register is an optional, 8-bit read-only register that provides a mechanism for the function to report state dependent operating data such as power consumed or heat dissipation) If the Data register is not implemented, this field should be read only and return "0000b" when the PMCSR is read.		0000b	RO
8	PME	**PME Enable**: Hardwired to 0 since EP does not generate a PME.		0b	RO
7 :4	Reserved1	Reserved1		0000b	RO

Table 39-34. PPMCSR - PF Power Management Control and Status Register (Sheet 2 of 2)

Description: PF Power Management Control and Status Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 70h **Offset End:** 73h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 70h **Offset End:** 73h	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
3	NSR	**No_Soft_Reset**: Set to 0. The EP will not maintain functional context in the D3_hot state. So when the EP is transitioned from D3_hot to D0 it will be in the D0_uniniitialized state and therefore would require software to initialize it before it can transition to the D0_initialized state. When set (“1”), this bit indicates that devices transitioning from $D3_{HOT}$ to D0 because of Power State commands do not perform an internal reset. Configuration Context is preserved. Upon transition from the D3_hot to the D0_Initialized state, no additional operating system intervention is required to preserve Configuration Context beyond writing the PowerState bits. When clear (“0”), devices do perform an internal reset upon transitioning from D3_hot to D0 via software control of the Power State bits. Configuration Context is lost when performing the soft reset. Upon transition from the D3_hot to the D0 state, full reinitialization sequence is needed to return the device to D0_initialized state		0b	RO
2	Reserved2	Reserved2		0b	RO
1 :0	PS	**Power State**. This field is used to determine the current power state of EP and to set a new power state. • 00: D0 • 01: D1 (Not supported by EP, ignore writes with this value) • 10: D2 (Not supported by EP, ignore writes with this value) • 11: D3_hot If software selects a Power state that is not supported by the EP (D2/D1), the writes must complete normally on PCIe, but the write data is discarded and no state change occurs.		00b	RW

39.12.5 PCI Express Capability Structure

39.12.5.1 PPCID - PF PCI Express Capability ID Register

The PCI Express Capability List register enumerates the PCI Express Capability structure in the PCI 3.0 configuration space capability list.

Table 39-35. PPCID - PF PCI Express Capability Register

Description: PF PCI Express Capability Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 74h **Offset End:** 74h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 74h **Offset End:** 74h	
Size: 8 bit	**Default:** 10h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	PCIECID	**Capability ID:** PCI SIG assigned capability record ID (10h, PCI Express capability)		10h	RO

39.12.5.2 PPCP - PF PCI Express Next Capability Pointer Register

Table 39-36. PPCP - PF PCI Express Next Capability Pointer Register

Description: PF PCI Express Next Capability Pointer Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 75h **Offset End:** 75h	
View: PCI PF	**BAR:** Configuration	**Bus:Device:Function:** M:0		**Offset Start:** 75h **Offset End:** 75h	
Size: 8 bit	**Default:** 0h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	PCIENP	**Next Capability Pointer:** Last Capability.		00h	RO

39.12.5.3 PPCR - PF PCI Express Capabilities Register

Table 39-37. PPCR - PF PCI Express Capabilities Register

Description: PF PCI Express Capabilities Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 76h **Offset End:** 77h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 76h **Offset End:** 77h	
Size: 16 bit	**Default:** 0002h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :14	Reserved	Reserved		00b	RO
13 :9	IMN	**Interrupt Message Number:** This field indicates which MSI vector is used for the interrupt message generated in association with the status bits in either the Slot Status field of this capability structure (applies to only RC or Switch) Not applicable to EP.		00000b	RO
8 8	SI	**Slot Implemented:** This bit when set indicates that the PCI Express Link associated with this port is connected to a slot. Hardwired to 0 for EP.		0b	RO
7 :4	DPT	**Device/Port Type:** Indicates the type of PCI Express logical device. Hardwired to 0000b (PCIe Endpoint)		0000b	RO
3 :0	CV	**Capability Version:** Indicates PCI-SIG defined PCI Express capability structure version number. EP is PCIe 3.0 Specification Compliant.		0010b	RO

39.12.5.4 PPDCAP - PF PCI Express Device Capabilities Register

Table 39-38. PPDCAP - PF PCI Express Device Capabilities Register (Sheet 1 of 2)

Description: PF PCI Express Device Capabilities Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 78h **Offset End:** 7Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 78h **Offset End:** 7Bh	
Size: 32 bit	**Default:** 10008061h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :29	Reserved0	Reserved0		0h	RO
28	FLR	**Function level reset**: When set indicates that the device supports the FLR feature.		1b	RO
27 :26	CSPS	**Captured Slot Power Limit Scale:** Does not apply to EP.		00b	RO
25 :18	CSPV	**Captured Slot Power Limit Value:** Does not apply to EP.		0h	RO
17 :16	Reserved1	Reserved1		0h	RO
15	RBEP	**Role-Based Error Reporting:** Indicates that EP conforms to Role based error reporting ECN for PCIe 1.0a and which was subsequently rolled in PCIe 1.1 and future revisions.		1b	RO
14 :12	ATTN	**Attention Button/Indicator Present and Power Indicator Present**. None of these are implemented in the EP.		000b	RO

Table 39-38. PPDCAP - PF PCI Express Device Capabilities Register (Sheet 2 of 2)

Description: PF PCI Express Device Capabilities Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 78h **Offset End:** 7Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 78h **Offset End:** 7Bh	
Size: 32 bit	**Default:** 10008061h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
11 :9	EL1L	**Endpoint L1 Acceptable Latency:** This field indicates the acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. Hardcoded to the lowest value of 1us. Since EP does not have a physical layer, this functionality is not implemented.		000b	RO
8 :6	EL0L	**Endpoint L0s Acceptable Latency:** This field indicates the acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. This value is hardcoded to the latency of 64-128ns. Since EP does not have a physical layer, this functionality is not implemented.		001b	RO
5	ETFS	**Extended Tag Field Supported:** This field indicates the maximum supported size of the Tag field as a Requester. When Clear indicates 5-bit Tag field is supported. When set 8-bit Tag field is supported. Supports 96 outstanding requests.		1b	RO
4 :3	PFS	**Phantom Functions Supported:** This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed. EP does not use this capability.		00b	RO
2 :0	MPS	**Max_Payload_Size Supported:** This field indicates the maximum payload size that EP can support for TLPs. This value is set to indicate 256B. The defined encodings are: • 000b = 128B max payload size • 001b = 256B max payload size (Max supported) • 010b - 111b = Reserved		001b	RO

39.12.5.5 PPDCNTL - PF PCI Express Device Control Register

Table 39-39. PPDCNTL - PF PCI Express Device Control Register (Sheet 1 of 2)

Description: PF PCI Express Device Control Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 7Ch **Offset End:** 7Dh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 7Ch **Offset End:** 7Dh

Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	STARTFLR	**Initiate FLR** - Used to initiate FLR transition. A write of 1 initiates FLR transition. Since hardware must not respond to any cycles till FLR completion, the value read by software from this bit is 0.		0b	RW
14 :12	MRS	**Max_Read_Request_Size:** This field sets the maximum Read Request size for the EP as a Requester. The EP is capable for generating up to 2kB read requests. However requests generated by the EP will be limited by the programmed value in this field. Defined encodings for this field are: 000b = 128B max read request size 001b = 256B max read request size 010b = 512B max read request size (Default) 011b = 1024B max read request size 100b - 111b = Reserved		010b	RW
11	ENS	**Enable No Snoop (NS):** If this bit is set to 1, EP is permitted to set the No Snoop bit in the Requester Attributes of transactions it initiates. When clear all transactions will have the No Snoop bit clear. Note that setting this bit will not cause the EP to set the No Snoop attribute on every memory requests that it initiates.		1b	RW
10	APME	**Auxiliary (AUX) Power PM Enable:** This bit when set enables a device to draw AUX power independent of PME AUX power. Does not apply to EP		0b	RO
9	PFE	**Phantom Functions Enable:** When set, this bit enables a device to use unclaimed functions as Phantom Functions. Does not apply to EP.		0b	RO
8	ETFE	**Extended Tag Field Enable:** When set, this bit enables a device to use an 8-bit Tag field as a requester. Supports 96 outstanding requests.		0b	RW
7 :5	MPS	**Max_Payload_Size (MPS):** This field sets maximum TLP payload for EP. As a Receiver, the EP must handle TLPs as large as the set value; as a Transmitter, the EP must not generate TLPs exceeding the set value. 000b = 128B(Default) 001b = 256B Others values not supported by EP		000b	RW
4	ERO	**Enable Relaxed Ordering:** If this bit is set, EP is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates. Note that setting this bit does not cause the EP to set the RO on every transaction it issues.		1b	RW
3	URRO	**Unsupported Request Reporting Enable**: This bit, in conjunction with other bits, controls the signaling of Unsupported Requests by sending Error Messages to the root port. When clear it disables sending of error messages.		0b	RW

View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 80h **Offset End:** 83h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 80h **Offset End:** 83h	
Size: 32 bit	**Default:** 00400D02h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
17 :15	L1EL	**L1 Exit Latency**- Indicates the exit latency from L1 to L0 state. 000b - Less than 1 ìs 001b - 1 ìs - 2 ìs 010b - 2 ìs - 4 ìs 011b - 4 ìs - 8 ìs 100b - 8 ìs - 16 ìs 101b - 16 ìs - 32 ìs 110b - 32 ìs - 64 ìs 111b - L1 transition not supported ***Note:*** EP does not support ASPM L1 transition		000b	RO
14 :12	L0EL	**L0s Exit Latency**- Indicates the exit latency from L0s to L0 state. 000b - Less than 64ns 001b - 64ns - 128ns 010b - 128ns - 256ns 011b - 256ns - 512ns 100b - 512ns - 1 ìs 101b - 1 ìs - 2 ìs 110b - 2 ìs - 4 ìs 111b - Reserved		000b	RO
11 :10	ASLPM	**Active State Link PM Support** - Indicates the level of active state power management supported in EP. Defined encodings are: 00b - Reserved 01b - L0s Entry Supported 10b - Reserved 11b - L0s and L1 Supported		11b	RO
9 :4	LINKW	Max Link Width- Indicates the max link width. Relevant encoding: 000000b - Reserved 000001b - x1 000010b - x2 000100b - x4 001000b - x8 001100b - x12 010000b - x16 100000b - x32 EP value depends on SKU. However the max link width is x16.		010000b	RO
3 :0	MAXSPEED	Max Link Speed - Indicates Maximum supported Link Speed. Defined encodings are: 0001b - 2.5Gbs Link speed supported (Gen 1) 0010b - 5.0Gbs Link speed supported (Gen 2) EP indicates a max Link Speed of 5.0 Gbs.		0010b	RO

39.12.5.8 PLCNTLR - PF Link Control Register

Not supported in EP.

Table 39-42. PLCNTLR - PF Link Control Register (Sheet 1 of 2)

Description: Link Control Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 84h **Offset End:** 85h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 84h **Offset End:** 85h	
Size: 16 bit	**Default:** 0h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :12	Reserved	Reserved		0000b	RO
11	LBWINTE	**Link Autonomous Bandwidth Interrupt Enable** - When set to 1b this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been set. ***Note:*** Defined for PCIe Compliance		0b	RO
10	LBWMINTE	**Link Bandwidth Management Interrupt Enable** - When set to 1b this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been set. ***Note:*** Defined for PCIe Compliance		0b	RO
9	WD	**Hardware Autonomous Width Disable** - When set to 1b this bit disables hardware from changing the link width for reasons other than attempting to correct unreliable link operation by reducing link width. ***Note:*** Defined for PCIe Compliance		0b	RO
8	ECLKPM	**Enable Clock Power Management** - Defined for PCIe Compliance		0b	RO
7	EXTSYNC	**Extended Sync**. When set to one, this bit forces the transmission of: - 4096 FTS ordered sets during the L0s state - followed by a single SKP ordered set prior to entering the L0 state, - as well as the transmission of 1024 TS1 ordered sets in the L1 state prior to entering the Recovery state. This mode gives external devices (e.g., logic analyzers) that may be monitoring Link activity time to achieve bit and symbol lock before the Link enters the L0 or Recovery state and resumes communication. Defined for PCIe Compliance		0b	RW
6	CCLKCFG	**Common Clock Configuration** - when set indicates that EP and the root port at the other end of the link are operating with a common reference clock. A value of 0 indicates that they operating with an asynchronous clock. This parameter affects the L0s Exit Latencies. After changing the value in this bit in both components on a Link, software must trigger the Link to retrain by writing a 1b to the Retrain Link bit. Defined for PCIe Compliance		0b	RW
5	RETRAIN	**Retrain Link**: A write of 1b to this bit initiates Link retraining by directing the Physical Layer LTSSM to the Recovery state. ***Note:*** Defined for PCIe Compliance. Does not apply to endpoint		0b	RO

Table 39-42. PLCNTLR - PF Link Control Register (Sheet 2 of 2)

Description: Link Control Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 84h **Offset End:** 85h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 84h **Offset End:** 85h	
Size: 16 bit	**Default:** 0h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
4	LINKDIS	**Link Disable**: This bit disables the Link by directing the LTSSM to the Disabled state when set to 1b. ***Note:*** Defined for PCIe Compliance. Does not apply to endpoint		0b	RO
3	RCB	**Read Completion Boundary (RCB)**: For PCIe Endpoints this field is set optionally by configuration software to indicate the RCB value of the Root Port upstream from the Endpoint. – 0b = 64B – 1b = 128 byte ***Note:*** Defined for PCIe Compliance		0b	RW
2	Reserved2	Reserved		0b	RO
1 :0	ASPMC	**Active State Link PM Control** - this field controls the active state PM supported on the link. Link PM functionality is determined by the lowest common denominator of all functions. Defined encodings are: 00b - PM Disabled 01b - L0s Entry Supported 10b - Reserved 11b - L0s and L1 Supported Defined for PCIe Compliance		00b	RW

39.12.5.9 PLSR– PF Link Status Register

Not supported in EP

Table 39-43. PLSR - PF Link Status Register

Description: Link Status Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 86h **Offset End:** 87h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 86h **Offset End:** 87h

Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	Reserved	Reserved		0b	RO
14	LBWMS	**Link Bandwidth Management Status** ***Note:*** Defined for PCIe Compliance		0b	RO
13	DLACT	**Data Link Layer Link Active** ***Note:*** Defined for PCIe Compliance		0b	RO
12	SCLKCFG	**Slot Clock Configuration** - When set indicates that EP uses the physical reference clock that the platform provides on the connector. This bit must be cleared if EP uses an independent clock. Defined for PCIe Compliance		0b	RW/O
11	LTINPROG	**Link Training** - Indicates that link training is in progress. ***Note:*** Defined for PCIe Compliance, Does not apply to PCIe Endpoints		0b	RO
10	LTE	**Link Training Error** - Indicates that a link training error has occurred. ***Note:*** Defined for PCIe Compliance		0b	RO
9 :4	NLW	**Negotiated Link Width**: Negotiated Link Width - Indicates the negotiated width of the link. Relevant encoding for EP are: 000001b - x1 000010b - x2 000100b - x4 001000b - x8 010000b - x16 Defined for PCIe Compliance		010000b	RO
3 :0	NLS	**Negotiated Link Speed**: The negotiated Link Speed. Defined encodings are: 0001b - 2.5Gbs 0010b - 5.0Gbs Defined for PCIe Compliance		0010b	RO

39.12.5.10 PDCAPR2 - PF Device Capabilities 2 Register

Table 39-44. PDCAPR2 - PF Device Capabilities 2 Register

Description: Device Capabilities 2 Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 98h **Offset End:** 9Bh	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 98h **Offset End:** 9Bh	
Size: 32 bit	**Default:** 00000012h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :5	Reserved	**Reserved**		0h	RO
4	CTODS	Completion Timeout Disable Supported. A value of 1b indicates support for the completion timeout disable mechanism.		1b	RO
3 :0	CTORS	Completion Timeout Ranges Supported: This field indicates support for the optional completion timeout programmability mechanism. This mechanism enables system software to modify the completion timeout value. Four time value ranges are defined: • Range A = 50 us to 10 ms • Range B = 10 ms to 250 ms • Range C = 250 ms to 4 s • Range D = 4 s to 64 s Bits are set according to the following table to show the timeout value ranges that are supported. • 0000b = Completion timeout programming not supported. • 0001b = Range A. • 0010b = Range B. • 0011b = Ranges A and B. • 0110b = Ranges B and C. • 0111b = Ranges A, B and C. • 1110b = Ranges B, C and D. • 1111b = Ranges A, B, C and D. • All other values are reserved. It is strongly recommended that the completion timeout mechanism not expire in less than 10 ms		0010b	RO

39.12.5.11 PDCNTR2 - PF Device Control 2 Register

Table 39-45. PDCNTR2 - PF Device Control 2 Register

Description: Device Control 2 Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 9Ch **Offset End:** 9Dh	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 9Ch **Offset End:** 9Dh	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 5	Reserved0	Reserved0		0h	RO
4	CTODIS	Completion Timeout Disable: When set to 1b, this bit disables the completion timeout mechanism. Software is permitted to set or clear this bit at any time. When set, the completion timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued. The default value for this bit is 0b.		0b	RW
3 :0	CTOV	Completion Timeout Value: In devices that support completion timeout programmability, this field enables system software to modify the completion timeout value. Encoding: • 0000b = Default range: 50 us to 50 ms. It is strongly recommended that the completion timeout mechanism not expire in less than 10 ms. Values available if Range A (50 us to 10 ms) programmability range is supported: • 0001b = 50us to 100 us. • 0010b = 1 ms to 10 ms. Values available if Range B (10 ms to 250 ms) programmability range is supported: • 0101b = 16 ms to 55 ms. • 0110b = 65 ms to 210 ms. Values available if Range C (250 ms to 4 s) programmability range is supported: • 1001b = 260 ms to 900 ms. • 1010b = 1 s to 3.5 s. Values available if the Range D (4 s to 64 s) programmability range is supported: • 1101b = 4 s to 13 s. • 1110b = 17 s to 64 s. Values not defined are reserved. Software is permitted to change the value in this field at any time. For requests already pending when the completion timeout value is changed, hardware is permitted to use either the new or the old value for the outstanding requests and is permitted to base the start time for each request either when this value was changed or when each request was issued. The default value for this field is 0000b.		0000b	RW

31 :01	Reserved	Reserved.		0h	RO
00 :00	PNDB	**Pending Bits.**		0b	RO/V

39.12.7 PF Advanced Error Reporting Capability Structure

39.12.7.1 PPCIEAERCAPID - PF PCI Express AER Capability ID Register

The PCI Express Capability List register enumerates the PCI Express AER Capability structure in the PCI 3.0 configuration space capability list. The AER Capability can be the last capability in the list. Refer to the "PPCIEAERCAPID - PF PCI Express AER Capability ID Register" which describes the next capability pointer value.

Table 39-57. PPCIEAERCAPID - PF PCI Express AER Capability ID Register

Description: PCI Express AER Capability ID Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 100h **Offset End:** 103h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 100h **Offset End:** 103h	
Size: 32 bit	**Default:** 13810001h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :20	PCIEAERNCP	Next PCI Express Extended Capability Pointer		138h	RO
19 :16	PCIEAERCVN	Advanced Error Capability Version Number: PCI Express Advanced Error Reporting Extended Capability Version Number.		1h	RO
15 :00	PCIEAERCID	Advanced Error Capability ID: PCI Express Extended Capability ID indicating Advanced Error Reporting Capability.		1h	RO

39.12.7.2 PPAERUCS - PF PCI Express AER Uncorrectable Error Status Register

03 :00	Reserved2	Reserved2		0h	RO

39.12.7.4 PPAERUCSEV - PF PCI Express AER Uncorrectable Error Severity Register

The Uncorrectable Error Severity register controls whether an individual uncorrectable error is reported as a non-fatal or fatal error. An error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered non-fatal.

Table 39-60. PPAERUCSEV - PF PCI Express AER Uncorrectable Error Severity Register

Description: PCI Express AER Uncorrectable Error Severity Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 10Ch **Offset End:** 10Fh

31 :00	HDRDWLOG3	4th DWord of the Header for the PCI Express packet in error (HDRDWLOG3): Once an error is logged in this register, it remains locked for further error logging until the time the software clears the status bit that cause the header log i.e., the error pointer is rearmed to log again.		0h	RO/V

39.12.8 PF Alternative Routing-ID Extended Capability Structure

This section describes the PCI Express Extended Configuration Space registers that make up the Alternative Routing ID Extended Capability Structure.

Some information from the specification is repeated here as an aid to the reader or to describe implementation choice. Refer to the *PCI Express Base Specification 2.0* for the full register descriptions and additional information regarding their operation.

39.12.8.1 PARIDHDR - PF Alternative Routing ID Capability Header

This register contains information associated with the Alternative Routing ID capability. This is compliant with the *PCI-SIG ECN: Alternatifve Routing-ID Interpretation (ARI)*, Updated June4,2007.

Table 39-68. PARIDHDR - PF Alternative Routing ID Capability Header

Description: Alternative Routing ID Capability Header					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 138h **Offset End:** 13Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 138h **Offset End:** 13Bh	
Size: 32 bit	**Default:** 1401000Eh			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :20	ARINCO	Next Capability Offset - This field contains 140h which points to the next item in the extended capabilities list, the SR-IOV extended capability.		140h	RO
19 :16	ARICV	Capability Version - This is set to 1h for the most current version of the specification.		1h	RO
15 :0	ARIECI	PCI Express Extended Capability ID - The PCI SIG has assigned 000Eh to the ARI extended capability.		000EH	RO

39.12.8.2 PFARICAP - PF ARI Capabilities Register

Table 39-69. PFARICAP - PF ARI Capabilities Register

15 :4	SRIOVNCO	Next Capability Offset.		1B0h	RO
3 :0	SRIOVCV	Capability Version - This is set to 1h for the Single Root I/O Virtualization and Sharing Specification, Revision 1.1.		1h	RO

39.12.9.3 PSRIOVCAP - PF SRIOV Capabilities Register

Table 39-73. PSRIOVCAP - PF SRIOV Capabilities Register

Description: SRIOV Capabilities Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 144h **Offset End:** 147h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 144h **Offset End:** 147h	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :21	VFMINT	VF Migration Interrupt Message Number - Indicates the MSI vector used for migration interrupts. The value in this field has no significance if bit 0 of this capability is Clear. ***Note:*** N/A for EP		0h	RO
20 :1	Reserved	Reserved.		0h	RO
:0	VFMCAP	VF Migration Capable - If Set, the PF is Migration Capable and operating under a Migration Capable MR-PCIM. ***Note:*** EP does not support VF migration		0b	RO

39.12.9.4 PSRIOVCS - PF SRIOV Control and Status Register

Table 39-74. PSRIOVCS - PF SRIOV Control and Status Register

Description: SRIOV Control and Status Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 148h **Offset End:** 14Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 148h **Offset End:** 14Bh	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :5	Reserved	Reserved		0h	RO
4	VFARI	ARI Capable Hierarchy - Device may locate VFs in Function numbers 8 to 255 of the captured Bus number. EP supports ARI and will locate the VF1-VF16 in Function 8 through Function 23.		0b	RW
3	VFMSE	VF MSE - Memory Space Enable for Virtual Functions.		0b	RW
2	VFMIE	VF Migration Interrupt Enable - Enables / Disables VF Migration State Change Interrupt. ***Note:*** EP does not support VF Migration		0b	RO
1	VFME	VF Migration Enable - Enables / Disables VF Migration Support. ***Note:*** EP does not support VF Migration		0b	RO
0	VFE	VF Enable - Enables / Disables VFs. Default value is 0b		0b	RW

39.12.9.5 PSRIOVMTOTINI - PF SRIOV Initial and Total VF's Register

Table 39-75. PSRIOVMTOTINI - PF SRIOV Initial and Total VF's Register

Description: SRIOV Initial and Total VF's Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 14Ch **Offset End:** 14Fh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 14Ch **Offset End:** 14Fh	
Size: 32 bit	**Default:** 00100010h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :16	TOTVF	TotalVFs indicates the maximum number of VFs that could be associated with the PF. Since EP does not support VF migration this field must be equal to the INITVF field		0010h	RO
15 :0	INITVF	InitialVFs indicates the number of VFs that are initially associated with the PF. Since EP does not support VF migration this field must be equal to the TOTVF field		0010h	RO

39.12.9.6 PSRIOVNUMVF - PF SRIOV Number of VF's Register

Table 39-76. PSRIOVNUMVF - PF SRIOV Number of VF's Register

Description: SRIOV Number of VF's Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 150h **Offset End:** 153h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 150h **Offset End:** 153h	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :24	Reserved	Reserved		00h	RO
23 :16	FUNDEP	This field describes dependencies between PFs. VF dependencies are the same as the dependencies of their associated PFs. If a PF is independent from other PFs of a Device, this field shall contain the Function Number of the PF. ***Note:*** EP implements a single PF and therefore this field is N/A to EP.		00h	RO
15 :0	NUMVF	Num VFs defines the number of VFs software has assigned to the PF. Software sets NumVFs to any value between 1 and TotalVFs (16 for EP) as part of the process of creating VFs. NumVFs VFs shall be visible in the PCI-Express fabric after both NumVFs is set to a valid value and VF Enable is set to one. 'Visible in the PCI-Express fabric' means that the VF shall respond to PCI Express transactions targeting the VF, following all other rules defined by this specification and the base specification.		0h	RW

39.12.9.7 PSRIOVFVFO - PF SRIOV First VF Offset Register

Table 39-77. PSRIOVFVFO - PF SRIOV First VF Offset Register

Description: SRIOV First VF Offset Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 154h **Offset End:** 155h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 154h **Offset End:** 155h	
Size: 16 bit	**Default:** 0008h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :0	VFOFFSET	First VF Offset is a constant and defines the Routing ID (RID) offset of the first VF that is associated with the PF that contains this Capability structure. The first VFs 16-bit RID is calculated by adding the contents of this field to the RID of the PF. ***Note:*** For the EP, the RID of the first VF is at an offset of eight from the RID of the Physical Function (PF).		0008h	RO

39.12.9.8 PSRIOVVFS - PF SRIOV VF Stride Register

Table 39-78. PSRIOVVFS - PF SRIOV VF Stride Register

Description: SRIOV VF Stride Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 156h **Offset End:** 157h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 156h **Offset End:** 157h	
Size: 16 bit	**Default:** 0001h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :0	VFSTRIDE	VF Stride is a constant and defines the Routing ID (RID) offset from one VF to the next one for all VFs associated with the PF that contains this Capability structure. The next VFs 16-bit RID is calculated by adding the contents of this field to the RID of the current VF. ***Note:*** For the EP, the stride between the RIDs of subsequent VFs is one.		0001h	RO

39.12.9.9 PSRIOVFDID - PF SRIOV VF Device ID Register

Table 39-79. PSRIOVFDID - PF SRIOV VF Device ID Register

Description: SRIOV VF Device ID Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 158h **Offset End:** 15Bh

Size: 32 bit	**Default:** 37C90000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :23	VFDID151HIGH	VF Device ID - The Device ID that is presented to the OS for every VF. 37C9h for EP		001101111b	RO/V
22 :16	VFDID151LOW	VF Device ID - The Device ID that is presented to the OS for every VF.		1001001b	RO
15 :00	Reserved	Reserved		0h	RO

39.12.9.10 PSRIOVPAGESIZE - PF SRIOV Supported Page size Register

Table 39-80. PSRIOVPAGESIZE - PF SRIOV Supported Page Size Register

Description: SRIOV Supported Page Size Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 15Ch **Offset End:** 15Fh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 15Ch **Offset End:** 15Fh	
Size: 32 bit	**Default:** 00000553h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :00	FIRSTVFO	This field must define the supported page sizes. This PF supports a page size of 2^(n+12) if bit n is Set. For example, if bit 0 is Set, the PF supports 4k byte page sizes. PFs are required to support 4k, 8k, 64k, 256k, 1M and 4M page sizes. All other page sizes are optional. A page size describes the minimum alignment requirements for VF BAR resources as described in "System Page Size".		00000553h	RO

39.12.9.11 PSRIOVSYSPS - PF SRIOV System Page Size Register

Table 39-81. PSRIOVSYSPS - PF SRIOV System Page Size Register

Description: SRIOV System Page Size Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 160h **Offset End:** 163h	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 160h **Offset End:** 163h	
Size: 32 bit	**Default:** 00000001h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :00	SYSPAGSIZ	This field must define the page size the system will use to map the VFs' memory addresses. Software must set the value of the System Page Size to one of the page sizes set in the Supported Page Sizes field. As with Supported Page Sizes, if bit n is Set in System Page Size, the VFs associated with this PF are required to support a page size of 2^(n+12). For example, if bit 1 is Set, the system is using an 8k byte page size. The results are undefined if more than one bit is set in System Page Size. The results are undefined if a bit is Set in System Page Size that is not Set in Supported Page Sizes. When System Page Size is set, the VF associated with this PF is required to align all BAR resources on a System Page Size boundary. Each VF BARn or VF BARn pair (described below) shall be aligned on a System Page Size boundary. Each VF BARn or VF BARn pair defining a non-zero address space shall be sized to consume an integer multiple of System Page Size bytes. All data structures requiring page size alignment within a VF shall be aligned on a System Page Size boundary.		00000001h	RW

39.12.9.12 PSRIOVLBAR0 - SRIOV Lower BAR0 Register

The PSRIOVLBAR0 points to the Ring Controller rings. The base window size of this BAR is dependent on the System Page Size. However, the resulting window size is based on the System Page Size and the Number of VFs supported.

Table 39-82. PSRIOVLBAR0 - SRIOV Lower BAR0 Register

Description: SRIOV Lower BAR0 Register					
View: PCI	**BAR:** Configuration	**Bus:Device:Function:** B:D:0		**Offset Start:** 164h **Offset End:** 167h	
View: PCI PF	**BAR:** Configuration	**Bus:Function:** M:0		**Offset Start:** 164h **Offset End:** 167h	
Size: 32 bit	**Default:** 00000004h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :12	VFBAR0	**Lower SRIOV Base Address 0:** These bits are used to define the memory window for Virtual Functions. This window is used by Virtual Functions to address the Ring bundles. The memory base window size is dependent on the System Page Size as described in Section 39.12.9.11, "PSRIOVSYSPS - PF SRIOV System Page Size Register". As an example, for a System Page Size set at 8KB, and 16 Virtual Functions, this register will be hard-wired to request an 8KB memory window. Since there are 16 Virtual Functions, the resulting window size will be 16*8KB=128KB. Bits Above bit 11 Page Size — Window Size that respond as Reserved Memory 4-KB — None — 128-KB 8-KB — 12:12 — 256-KB 64-KB — 15:12 — 2048-KB 256-KB — 17:12 — 8192-KB 1-MB — 19:12 — 32-MB 4-MB — 21:12 — 128-MB		0h	RW
11 :04	VFZERO	**Lower Bits:** Hardwired to 0 (4KB region).		0h	RO
3	VFPREF	**Prefetchable:** Hardwired to 0 to indicate that the region is not prefetchable.		0h	RO
02 :01	VFTYP	**Addressing Type:** Hardwired to indicate a 64-bit region.		10b	RO
00	VFMEM	**Memory Space Indicator:** Hardwired to 0 to identify the region as in memory space.		0h	RO

39.12.9.13 PSRIOVUBAR0 - SRIOV Upper BAR0 Register

Table 39-83. PSRIOVUBAR0 - SRIOV Upper BAR0 Register

Description: SRIOV Upper BAR0 Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 168h **Offset End:** 16Bh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 168h **Offset End:** 16Bh	
Size: 32 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :00	VFBAR0	Upper SRIOV Base Address 0.		0h	RW

39.12.9.14 PSRIOVLBAR1 - SRIOV Lower BAR1 Register

The base window size of this BAR is dependent on the System Page Size. However, the resulting window size is based on the System Page Size and the Number of VFs supported.

Table 39-84. PSRIOVLBAR1 - SRIOV Lower BAR1 Register (Sheet 1 of 2)

Description: SRIOV Lower BAR1 Register					
View: PCI	**BAR:** Configuration		**Bus:Device:Function:** B:D:0	**Offset Start:** 16Ch **Offset End:** 16Fh	
View: PCI PF	**BAR:** Configuration		**Bus:Function:** M:0	**Offset Start:** 16Ch **Offset End:** 16Fh	
Size: 32 bit	**Default:** 00000004h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :12	VFBAR1	**Lower SRIOV Base Address 1:** These bits are used to define the memory window for Virtual Functions. The memory base window size is dependent on the System Page Size as described in Section 39.12.9.11, "PSRIOVSYSPS - PF SRIOV System Page Size Register". As an example, for a System Page Size set at 8KB, and 32 Virtual Functions, this register will be hardwired to request an 8KB memory window. Since there are 32 Virtual Functions, the resulting window size will be 32*8KB=256KB. Page Size — Bits Above bit 11 that respond as Reserved Memory — Window Size 4-KB — None — 128-KB 8-KB — 12:12 — 256-KB 64-KB — 15:12 — 2048-KB 256-KB — 17:12 — 8192-KB 1-MB — 19:12 — 32-MB 4-MB — 21:12 — 128-MB		0h	RW
11 :04	VFZERO	**Lower Bits:** Hardwired to 0 (4KB region)		0h	RO

31 :00	Reserved	Reserved. ***Note:*** VF Migration not supported in EP.		00000000h	RO

39.12.10 Access Control Services (ACS) Capability

The PCIe ACS defines a set of control points within a PCIe topology to determine whether a TLP should be routed normally, blocked, or redirected. ACS is applicable to RCs, switches, and multifunction devices. The ACS Capability structure is shared and exposed to all PFs.

This section describes the registers for ACS Capability.

39.12.10.1 PACSCAPID - PF - ACS Capability ID Register

Table 39-87. PACSCAPID - PF ACS Capability ID Register

39.13.2 PCI Standard Header Registers

Reflects 16 Virtual Functions.

This section describes the PCI Configuration Space registers that make up the standard Type 0 header. Some information from the specification is repeated here as an aid to the reader or to describe implementation choice. Refer to the *PCI Express Base Specification 2.0* and *PCI Local Bus Specification* for the full register descriptions and additional information regarding their operation.

39.13.2.1 VVID[0:15] - VF Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

Table 39-92. VVID[0:15] - VF Vendor Identification Register

Description: VF Vendor Identification Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 00h **Offset End:** 01h	
Size: 16 bit	**Default:** FFFFh			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	VID	Vendor ID: The Single Root I/O Virtualization and Sharing Specification, Revision 1.1 requires that this field return FFFFH.		FFFFh	RO

39.13.2.2 VDID[0:15] - VF Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Writes to this register have no effect.

Table 39-93. VDID[0:15] - VF Device Identification Register

Description: VF Device Identification Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 02h **Offset End:** 03h	
Size: 16 bit	**Default:** FFFFh			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	DID	Device ID: The Single Root I/O Virtualization and Sharing Specification, Revision 1.1 requires that this field return FFFFH. Software should return the VF Device ID value from the associated PF as the Device ID for the VF.		FFFFh	RO

39.13.2.3 VPCICMD[0:15] - VF Device Command Register

Table 39-94. VPCICMD[0:15] - VF Device Command Register

Description: VF Device Command Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 04h **Offset End:** 05h	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :11	Reserved	Reserved0		0h	RO
10	INTD	Interrupt Disable: The Single Root I/O Virtualization and Sharing Specification, Revision 1.1 requires that this field is hardwired to 0b for all VFs. This bit does not apply to VFs.		0h	RO
9	FBTB	Fast Back to Back Enable: Does not apply to PCI Express. Hardwired to 0		0h	RO
8	SER	**SERR# Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 0b for all VFs. In addition the functionality associated with the setting of this bit in the Section 39.12.2.3, "PPCICMD - PF Device Command Register" will apply to all VFs.		0h	RO
7	Reserved0	Address/Data Stepping Control: Does not apply to PCI Express. Hard-wired to 0.		0h	RO
6	PER	**Parity Error Response**: The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 0b for all VFs. In addition the functionality associated with the setting of this bit in the Section 39.12.2.3, "PPCICMD - PF Device Command Register" will apply to all VFs.		0h	RO
5	VPS	**VGA Palette Snoop Enable:** Does not apply to PCI Express. Hard-wired to 0.		0h	RO
4	MWE	**Memory Write and Invalidate Enable**: Does not apply to PCI Express. Hard-wired to 0.		0h	RO
3	SS	**Special Cycle Enable:** Does not apply to PCI Express. Hard-wired to 0.		0h	RO
2	BM	**Bus Master Enable:** When cleared, the EP is prevented from issuing any memory or I/O read/write requests. Requests other than memory or I/O requests are not controlled by this bit. The EP will initiate a completion transaction regardless of the setting.		0h	RW
1	MEM	**Memory Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 0b for all VFs.		0h	RO
0	IO	**I/O Space Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 0b for all VFs.		0h	RO

39.13.2.4 VPCISTS[0:15] - VF Device Status Register

Table 39-95. VPCISTS[0:15] - VF PCI Device Status Register

Description: VF PCI Device Status Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 06h **Offset End:** 07h	
Size: 16 bit	**Default:** 0010h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	DPE	**Detected Parity Error:** set when the EP receives a poisoned TLP regardless of the state of the Parity Error Response in the VPCICMD register.		0h	RW/1C/V
14	SSE	**SERR# Asserted:** set when the EP sends an ERR_FATAL or ERR_NONFATAL message, and the SERR Enable bit in the VPCICMD register is '1'.		0h	RW/1C/V
13	RMA	**Received Master Abort:** set when the EP receives a completion with Unsupported Request Completion Status.		0h	RW/1C/V
12	RTA	**Received Target Abort:** set when the EP receives a completion with Completer Abort Completion Status.		0h	RW/1C/V
11	STA	**Signaled Target Abort:** set when the EP completes a Request using Completer Abort Completion Status		0h	RW/1C/V
10 :09	DST	DEVSEL# **Timing:** Does not apply to PCI Express. Hard-wired to 0.		00b	RO
8	MDPE	**Master Data Parity Error:** This bit is set by the EP if its Parity Error Enable bit is set and either of the following two conditions occurs: This bit is set under the following conditions. EP receives a Poisoned Completion for an Outbound Read Request EP transmits a Poisoned TLP for an Outbound Write Request. If the Parity Error Response bit is cleared in the Section 39.12.2.3, "PPCICMD - PF Device Command Register", this bit is never set.		0h	RW/1C/V
7	FB2B	**Fast Back-to-Back**: Does not apply to PCI Express.Hard-wired to 0.		0h	RO
6	Reserved1	Reserved1		0h	RO
5	MC66	**66 MHz Capable (C66):** Does not apply to PCI Express. Hard-wired to 0		0h	RO
4	CL	**Capabilities List:** All PCI Express devices are required to implement the PCI Express capability structure. Hard-wired to 1.		1h	RO
3	INTSTS	**Interrupt Status:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 0b for all VFs. This bit does not apply to VFs.		0h	RO
02 : 00	Reserved2	Reserved2		0h	RO

39.13.2.5 VRID[0:15] - Revision ID Register

The value of this register indicates the chip stepping. It is hardwired on chip and reflects the latest revision.

Table 39-96. VRID[0:15] - VF Revision ID Register

Description: VF Revision ID Register and VF Class Code Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 08h **Offset End:** 0Bh	
Size: 32 bit	**Default:** 0B400000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :8	CC	**Class Code:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field return the same value as the Section 39.12.2.6, "PCLS - PF Cache Line Size Register" for all VFs.		0B4000h	RW/O
07 :0	RID	**EP Revision:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field should be viewed as a Vendor Defined Extension to the Device ID. This may be different than the PF's Revision ID, but the same value must be reported by all VFs. Refer to the PF RID for a description.		00h	RO/V

39.13.2.6 VHDR[0:15] - VF Header Type Register

Table 39-97. VHDR[0:15] - VF Header Type Register

Description: VF Header Type Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 0Eh **Offset End:** 0Eh	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	HDR	**Header Type:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field must be set to 00H for VFs.		00h	RO

39.13.2.7 VSVID[0:15] - VF Subsystem Vendor ID Register

Table 39-98. VSVID[0:15] - VF Subsystem Vendor ID Register

Description: VF Subsystem Vendor ID Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 2Ch **Offset End:** 2Dh	
Size: 16 bit	**Default:** 8086h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	SVID	**Subsystem Vendor ID:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that when read, this read only register must return the same value as the Section 39.12.2.12, "PSVID - PF Subsystem Vendor ID Register" for all VFs.		8086h	RO/V

39.13.2.8 VSID[0:15] - VF Subsystem ID Register

This register is a write-once register. Once any byte in the register has been written, the register locks against further writes until reset.

Table 39-99. VSID[0:15] - VF Subsystem ID Register

Description: VF Subsystem ID Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 2Eh **Offset End:** 2Fh	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :00	SID	**Subsystem ID:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this read only register return the same value for all VFs. This may be a different value than that contained in the PF (e.g.,Section 39.12.2.13, "PSID - PF Subsystem ID Register").		0000h	RW/O

39.13.2.9 VCP[0:15] - VF Capabilities Pointer Register

The Capabilities Pointer Register provides the offset in configuration space to the location where the first set of capabilities registers is located.

Table 39-100. VCP[0:15] - VF Capabilities Pointer Register

Description: VF Capabilities Pointer Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 34h **Offset End:** 34h	
Size: 8 bit	**Default:** 90h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	CP	**Capability List Pointer:** This field provides an offset into the configuration space pointing to the first item in the capability list which in the VF is the MSI extended capabilities header.		50h	RO

39.13.2.10 VIRQL[0:15] - VF Interrupt Line Register

Table 39-101. VIRQL[0:15] - VF Interrupt Line Register

Description: VF Interrupt Line Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 3Ch **Offset End:** 3Ch	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	IRQL	**Interrupt Assigned:** This field does not apply to VFs and is hardwired to Zero.		0h	RO

39.13.2.11 VIRQP[0:15] - VF Interrupt Pin Register

Table 39-102.VIRQP[0:15] - VF Interrupt Pin Register

Description: VF Interrupt Pin Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 3Dh **Offset End:** 3Dh	
Size: 8 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	IRQP	**Interrupt Assigned:** This field does not apply to VFs and is hardwired to Zero.		0h	RO

39.13.3 VF PCI Express Capability Structure

39.13.3.1 VPCID[0:15] - VF PCI Express Capability ID Register

The PCI Express Capability List register enumerates the PCI Express Capability structure in the PCI 3.0 configuration space capability list.

Table 39-103.VPCID[0:15] - VF PCI Express Capability ID Register

Description: VF PCI Express Capability ID Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 50h **Offset End:** 50h	
Size: 8 bit	**Default:** 10h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	PCIECID	**Cap Id:** This field identifies this item in the linked list of Extended Capability Headers as being the PCI Express capability registers.		10h	RO

39.13.3.2 VPCP[0:15] - VF PCI Express Next Capability Pointer Register

Table 39-104.VPCP[0:15] - VF PCI Express Next Capability Pointer Register

Description: VF PCI Express Next Capability Pointer Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 51h **Offset End:** 51h	
Size: 8 bit	**Default:** 0h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	MCP	**Next Capability Pointer:** Last capability.		90h	RO

39.13.3.3 VPCR[0:15] - VF PCI Express Capabilities Register

Table 39-105.VPCR[0:15] - VF PCI Express Capabilities Register

Description: VF PCI Express Capabilities Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 52h **Offset End:** 53h	
Size: 16 bit	**Default:** 002h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :14	Reserved	Reserved		00b	RO
13 :9	IMN	**Interrupt Message Number**: This only applies to Root Complex and Switch devices. This register is hardcoded to 0.		00000b	RO
8	SI	**Slot Implemented:** Indicates that the PCI Express Link associated with this port is connected to a slot. Only valid for root complex and switch downstream ports. Hard-wired to 0		0b	RO
7 :4	DPT	**Device/Port Type:** Indicates the type of PCI Express logical device. 0000b - PCI Express Endpoint device		0000b	RO
3 :0	CV	**Capability Version:** Indicates PCI-SIG defined PCI Express capability structure version number EP supports version 2h.		0010b	RO

39.13.3.4 VPDCAP[0:15] - VF PCI Express Device Capabilities Register

Table 39-106.VPDCAP[0:15] - VF PCI Express Device Capabilities Register (Sheet 1 of 2)

Description: VF PCI Express Device Capabilities Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 54h **Offset End:** 57h	
Size: 32 bit	**Default:** 10008061h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :29	Reserved	Reserved		0h	RO
28	FLR	**FLR Cap:** Function Level Reset Capability is required for all VFs and PFs according to the *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1.		1b	RO
27 :26	CSPS	**Captured Slot Power Limit Scale:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field is undefined for all VFs.		00b	RO
25 :18	CSPV	**Captured Slot Power Limit Value**: The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field is undefined for all VFs.		0h	RO
17 :16	Reserved1	Reserved1		0h	RO
15	RBEP	**Role-Based Error Reporting**: this bit is set to indicate that this device implements the Role Base Error Reporting defined in *PCI Express Base Specification*, Revision 2.0.		1b	RO
14 :12	Reserved	**Reserved:** Undefined - Treated as Reserved		000b	RO
11 :9	EL1L	**Endpoint L1 Acceptable Latency:** EP does not support L1 active state power management.		000b	RO

Table 39-106.VPDCAP[0:15] - VF PCI Express Device Capabilities Register (Sheet 2 of 2)

Description: VF PCI Express Device Capabilities Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 54h **Offset End:** 57h	
Size: 32 bit	**Default:** 10008061h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
8 :6	EL0L	**Endpoint L0 Acceptable Latency:** Total acceptable latency that the EP can withstand due to a transition from L0s to L0 state.		001b	RO
5	ETFS	**Extended Tag Field Supported:** Indicates the maximum supported size of the Tag field as a Requester. EP does generate 8-bit Tags and supports 8-bit Tags as a completer. Supports 96 outstanding requests.		1b	RO
4 :3	PFS	**Phantom Functions Supported:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to 00b.		00b	RO
2 :0	MPS	**Max_Payload_Size Supported:** This field indicates the maximum payload size that EP can support for TLPs. This value is set to indicate 256B. The defined encodings are: • 000b = 128B max payload size • 001b = 256 bytes max payload size • 010b = 512 bytes max payload size (Max supported) • 011b - 111b = Reserved		010b	RO

39.13.3.5 VPDC[0:15] - VF PCI Express Device Control Register

Table 39-107.VPDC[0:15] - VF PCI Express Device Control Register (Sheet 1 of 2)

Description: VF PCI Express Device Control Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 58h **Offset End:** 59h	
Size: 16 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15	STARTFLR	**Initiate Function Level Reset:** A write of 1b to this bit initiates Function Level Reset to the VF. The value is always read as 0b.		0b	RW
14 :12	MRS	**Max Read Request Size:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		000b	RO
11	ENS	**Enable No Snoop:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0b	RO
10	APME	**Aux Power PM Enable**: The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0b	RO
9	PFE	**Phantom Functions Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0b	RO
8	ETFE	**Extended Tag Field Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0b	RO
7 :5	MPS	**Max Payload Size:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		000b	RO

Table 39-107.VPDC[0:15] - VF PCI Express Device Control Register (Sheet 2 of 2)

Description: VF PCI Express Device Control Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 58h **Offset End:** 59h	
Size: 16 bit	**Default:** 00h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
4	ERO	**Enable Relaxed Ordering:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0b	RO
3	URRO	**Unsupported Request Reporting Enable (URRE):** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros. In addition the functionality associated with this bit setting is controlled by the corresponding bit in "PPDCNTL - PF PCI Express Device Control Register", and will apply to all VFs.		0b	RO
2	FERE	**Fatal Error Reporting Enable:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros. In addition the functionality associated with this bit setting is controlled by the corresponding bit in "PPDCNTL - PF PCI Express Device Control Register", and will apply to all VFs.		0h	RO
1	NERE	**Non-Fatal Error Reporting Enable**: The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros. In addition the functionality associated with this bit setting is controlled by the corresponding bit in "PPDCNTL - PF PCI Express Device Control Register", and will apply to all VFs.		0h	RO
0	CERE	**Correctable Error Reporting Enable**: The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros. In addition the functionality associated with this bit setting is controlled by the corresponding bit in "PPDCNTL - PF PCI Express Device Control Register", and will apply to all VFs.		0h	RO

39.13.3.6 VPDS[0:15] - VF PCI Express Device Status Register

Table 39-108.VPDS[0:15] - VF PCI Express Device Status Register (Sheet 1 of 2)

Description: VF PCI Express Device Status Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 5Ah **Offset End:** 5Bh	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :6	Reserved	Reserved		0h	RO
5	TP	**Transactions Pending:** This bit when set indicates that a device has issued Non-Posted Requests which have not been completed. A device reports this bit cleared only when all Completions for any outstanding Non-Posted Requests have been received.		0h	RW/1C/V
4	APD	**AUX Power Detected:** The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 requires that this field is hardwired to all zeros.		0h	RO
3	URD	**Unsupported Request Detected:** This bit indicates that the device received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. For a multi-function device, each function indicates status of errors as perceived by the respective function.		0h	RW/1C/V

Table 39-108.VPDS[0:15] - VF PCI Express Device Status Register (Sheet 2 of 2)

Description: VF PCI Express Device Status Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 5Ah **Offset End:** 5Bh	
Size: 16 bit	**Default:** 0000h			**Power Well:** Core

15 :00	Reserved	Reserved		0H	RO

39.13.3.10 VDCAPR2[0:15] - VF Device Capabilities 2 Register

Table 39-112.VDCAPR2[0:15] - VF Device Capabilities 2 Register

Description: Device Capabilities 2 Register					
View: PCI VF	**BAR:** Configuration	**Bus:Device:Function:** M:8 + Index1		**Offset Start:** 74h **Offset End:** 77h	
Size: 32 bit	**Default:** 00000012h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
31 :5	Reserved	Reserved.		0b	RO
4	CTODS	Completion Timeout Disable Supported. A value of 1b indicates support for the completion timeout disable mechanism. The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field value must be identical as the PF value.		1b	RO
3 :0	CTORS	Completion Timeout Ranges Supported: This field indicates support for the optional completion timeout programmability mechanism. This mechanism enables system software to modify the completion timeout value. Four time value ranges are defined: • Range A = 50 us to 10 ms • Range B = 10 ms to 250 ms • Range C = 250 ms to 4 s • Range D = 4 s to 64 s Bits are set according to the following table to show the timeout value ranges that are supported. • 0000b = Completion timeout programming not supported. • 0001b = Range A. • 0010b = Range B. • 0011b = Ranges A and B. • 0110b = Ranges B and C. • 0111b = Ranges A, B and C. • 1110b = Ranges B, C and D. • 1111b = Ranges A, B, C and D. • All other values are reserved. It is strongly recommended that the completion timeout mechanism not expire in less than 10 ms. The *Single Root I/O Virtualization and Sharing Specification*, Revision 1.1 states that this field value must be identical as the PF value.		0010b	RO

15 :00	Reserved	Reserved		0H	RO

39.13.4 VF MSI Capability Structure

39.13.4.1 VMSICID[0:15] - Message Signaled Interrupt Capability ID Register

The Message Signaled Interrupt Capability record defines how the device generates PCI MSI messages. It is a 10B PCI SIG-defined capability record and includes the MCID, MCP, MCTL, MADR, and MDATA fields of the configuration header.

Table 39-116.VMSICID[0:15] - Message Signaled Interrupt Capability ID Register

Description: Message Signaled Interrupt Capability ID Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 90h **Offset End:** 90h	
Size: 8 bit	**Default:** 05h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	MCID	**Capability ID:** PCI SIG assigned capability record ID (05h, MSI capability)		05h	RO

39.13.4.2 VMSINCP[0:15] - Message Signaled Interrupt Next Capability Pointer Register

Table 39-117.VMSINCP[0:15] - Message Signaled Interrupt Next Capability Pointer Register

Description: Message Signaled Interrupt Next Capability Pointer Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 91h **Offset End:** 91h	
Size: 8 bit	**Default:** 50h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
07 :00	MCP	**Next Capability Pointer:** Next Capability is PCI Express.		0h	RO

39.13.4.3 VMSICTL[0:15] - Message Signaled Interrupt Control Register

Table 39-118.VMSICTL[0:15] - Message Signaled Interrupt Control Register

Description: Message Signaled Interrupt Control Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 92h **Offset End:** 93h	
Size: 16 bit	**Default:** 0180h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :09	Reserved	Reserved		0h	RO
08	MC	**Per-Vector Masking Capable:** Per-vector masking capable.		1b	RO
07	C64	**64 bit Address Capable:** Hardwired to 1 to indicate the device does not generate 64b message addresses.		1h	RO
06 :04	MME	**Multiple Message Enable:** System software writes to this field to indicate the number of allocated messages (less than or equal to the number of requested messages in MMC). A value of 0 corresponds to one message.		000h	RW
03 :01	MMC	**Multiple Message Capable:** System software reads this field to determine the number of requested messages. Hardwired to 0 to request one message.		000h	RO
00	MSIE	**MSI Enable:** System software sets this bit to enable MSI signaling. A device driver is prohibited from writing this bit to mask a device's service request. If 1, the device can use an MSI to request service. If 0, the device cannot use an MSI to request service.		0h	RW

39.13.4.4 VMSILADDR[0:15] - Message Signaled Interrupt Lower Address Register

Table 39-119.VMSILADDR[0:15] - Message Signaled Interrupt Lower Address Register

Description: Message Signaled Interrupt Lower Address Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 94h **Offset End:** 97h

31 :00	HDRDWLOG3	4th DWord of the Header for the PCI Express packet in error (HDRDWLOG3): Once an error is logged in this register, it remains locked for further error logging until the time the software clears the status bit that cause the header log i.e., the error pointer is rearmed to log again.		0h	RO/V

39.13.6 VF Alternative Routing ID Extended Capability Structure

This section describes the PCI Express Extended Configuration Space registers that make up the Alternative Routing ID Extended Capability Structure.

Some information from the specification is repeated here as an aid to the reader or to describe implementation choice. Refer to the *PCI Express Base Specification 2.0* for the full register descriptions and additional information regarding their operation.

39.13.6.1 VARIDHDR[0:15]– VF Alternative Routing ID Capability Header

This register contains information associated with the Alternative Routing ID capability. This is compliant with the *PCI-SIG ECN: Alternatifve Routing-ID Interpretation (ARI)*, Updated June4,2007.

Table 39-135.VARIDHDR[0:15] - VF Alternative Routing ID Capability Header

Description: VF Alternative Routing ID Capability Header					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 138h **Offset End:** 13Bh

1	ACS	**ACS Functional Groups Capability**: not supported.		0b	RO
0	MFVC	**MFVC Functional Groups Capability**: not supported.		0b	RO

39.13.6.3 VARIDCTL[0:15] - VF Alternative Routing ID Control Register

This register contains information associated with the Alternative Routing ID capability.

Table 39-137.VARIDCTL[0:15] - VF Alternative Routing ID Control Register

Description: VF Alternative Routing ID Control Register					
View: PCI VF	**BAR:** Configuration		**Bus:Function:** M:8 + Index1	**Offset Start:** 13Eh **Offset End:** 13Fh	
Size: 16 bit	**Default:** 00000000h			**Power Well:** Core	
Bit Range	**Bit Acronym**	**Bit Description**	**Sticky**	**Bit Reset Value**	**Bit Access**
15 :7	Reserved	Reserved		0h	RO
6 :4	FG	**Function Group**: Hardwired to Zero EP does not support Function Groups.		0b	RO
3 :2	Reserved1	Reserved1		0b	RO
1	ACS	**ACS Functional Groups Enable**: Hardwired to Zero as EP does not support.		0b	RO
0	MFVC	**MFVC Functional Groups Enable**: Hardwired to Zero as EP does not support.		0b	RO

39.13.7 VF Access Control Services (ACS) Capability

The PCIe ACS defines a set of control points within a PCIe topology to determine whether a TLP should be routed normally, blocked, or redirected. ACS is applicable to RCs, switches, and multifunction devices. The ACS Capability structure is shared and exposed to all VFs.

This section describes the registers for ACS Capability.

39.13.7.1 VACSCAPPID[0:15] - VF - ACS Capability ID Register

§

40 PCH EndPoint Only (EPO) Mode

40.1 Acronyms

Acronyms	Description
EPO	EndPoint Only Mode - special PCH configuration for standalone Intel® QuickAssist Technology and 10 GbE functionality
PCH EPO	When the PCH is configured to for EndPoint Only Mode
Intel® QAT	Intel® QuickAssist Technology
SPS FW	Server Platform Services is FW required by the PCH and is part of a shared NVM image stored on SPI NVM device.
SPS EPO FW	A version of SPS FW used specifically to support PCH EPO Mode
VSP	Virtual Switch Port

40.2 References

None.

40.3 PCH EndPoint Only (EPO) Mode Overview

The PCH supports an Endpoint Only Mode. In this mode, a non-legacy (non-boot) PCH is configured as a PCIe Endpoint device without support for the legacy PCH I/O capabilities. Up to three endpoints associated with Intel QuickAssist Technology are supported and can be enumerated as well as the integrated 10GbE endpoint.

PCH EndPoint Only Mode is configured via a combination of PCH functions, PCH soft straps, and SPS EPO FW.

Note: EPO / EPO PCH **is not** a unique PCH SKU. Rather it is a configuration where a non-boot PCH gets set to specific mode as described in this section.

Note: Intel QuickAssist Technology may not be supported on all PCH SKUs.

40.4 PCH Endpoint Only (EPO) Mode Features

- Intel QuickAssist Technology
  - — Up to three Intel QAT endpoints
- 10 GbE Controller
  - — Up to four 10/1 GbE ports
- PCH PCI Express Uplink
  - — Up to 24 PCI Express Gen 3 Lanes
    - Primary x16 max. uplink
    - Secondary x8 max. uplink
  - — Two Uplink configuration mapping options
- PCH SPI NVM Flash Interface
- PCH SMLink Interface

- PCH Thermal Sensor Support
- Multiple EPO PCHs supported on a platform
  - — Down on the motherboard
  - — Via PCIe Add-in Card

Note: For more details on the supported features described above, refer to their respective section within this document.

40.5 PCH EPO Mode Considerations

The section contains details and considerations for PCH EPO Mode.

40.5.1 EPO PCH - SPI

In Endpoint Only Mode, the PCH SPI controller is enabled and accessible to support FW requirements for Intel QuickAssist Technology and the integrated 10 GbE endpoint. In this mode, since DMI is unavailable, SPI related cycles that require PCIe Root Port interaction are transacted via the PCIe x16 PCH Upstream Port. This capability is primarily available in order to support in-system updating of the SPI flash device.

40.5.2 EPO PCH - Thermal Sensor and P2SB

The PCH thermal sensor and P2SB are available in EPO mode. Since DMI is not available in EPO mode, transactions are handled via the primary PCIe x16 Uplink and VSP[5:4].

40.5.3 EPO PCH - Additional Considerations

The following are other PCH EPO considerations:

- Endpoint Only Mode requires the use of External clocking mode to support it's input clock requirements. Refer to Section 8.5 for more details on external clocking.
- Intel® C620 Series Chipset SKUs that support Intel QuickAssist Technology require an Adaptive Voltage Identification (AVID) compatible VR solution (Vccprim_Avid of 0.85V to 1.0V) to be used.

40.5.4 EP0 PCH - FW

The EPO PCH utilizes a shared flash image that contains a subset of regions. The supported regions are the Flash Descriptor Region (FDR), the Intel ME Region, and the 10 GbE Region. While the FDR and Intel ME Regions are required the 10 GbE region is only required if the 10 GbE controller will be supported in the EPO Mode.

The EPO PCH uses SPS EPO Intel ME FW. This version of FW is specific for EPO mode. Neither SPS Si Enabling or SPS with Node Manager FW are compatible with EPO mode.

If the 10GbE controller will be supported as part of a EPO PCH implementation it's FW must also be used and integrated into the shared SPI NVM flash image.

The EPO PCH shared FW image does not require a BIOS image or any other additional FW aside from what has previously been identified in this section.

40.5.5 EPO PCH - Soft Straps

Setting the PCH into EPO mode requires the use of specific soft strap settings. Refer to the *Intel*® C620 Series Chipset *PCH-Server SPI Programmings Guide* (RDC document number 559021) for soft strap setting details.

Note: The SPS EPO FW package must be used as it works in conjunction with soft strap settings to ensure proper configuration for EPO mode.

40.5.6 EPO PCH - Unused PCH Functions / Interfaces

In PCH EPO mode the PCH Upstream Port(s) are connected to a PCIe root port; however DMI is not connected nor utilized. Since DMI is not available, the following tables lists PCH capabilities that **are not supported**, not functional, and cannot be enumerated or used in PCH EPO Mode. Many of these functions will either be power gated or held in reset in PCH EPO mode.

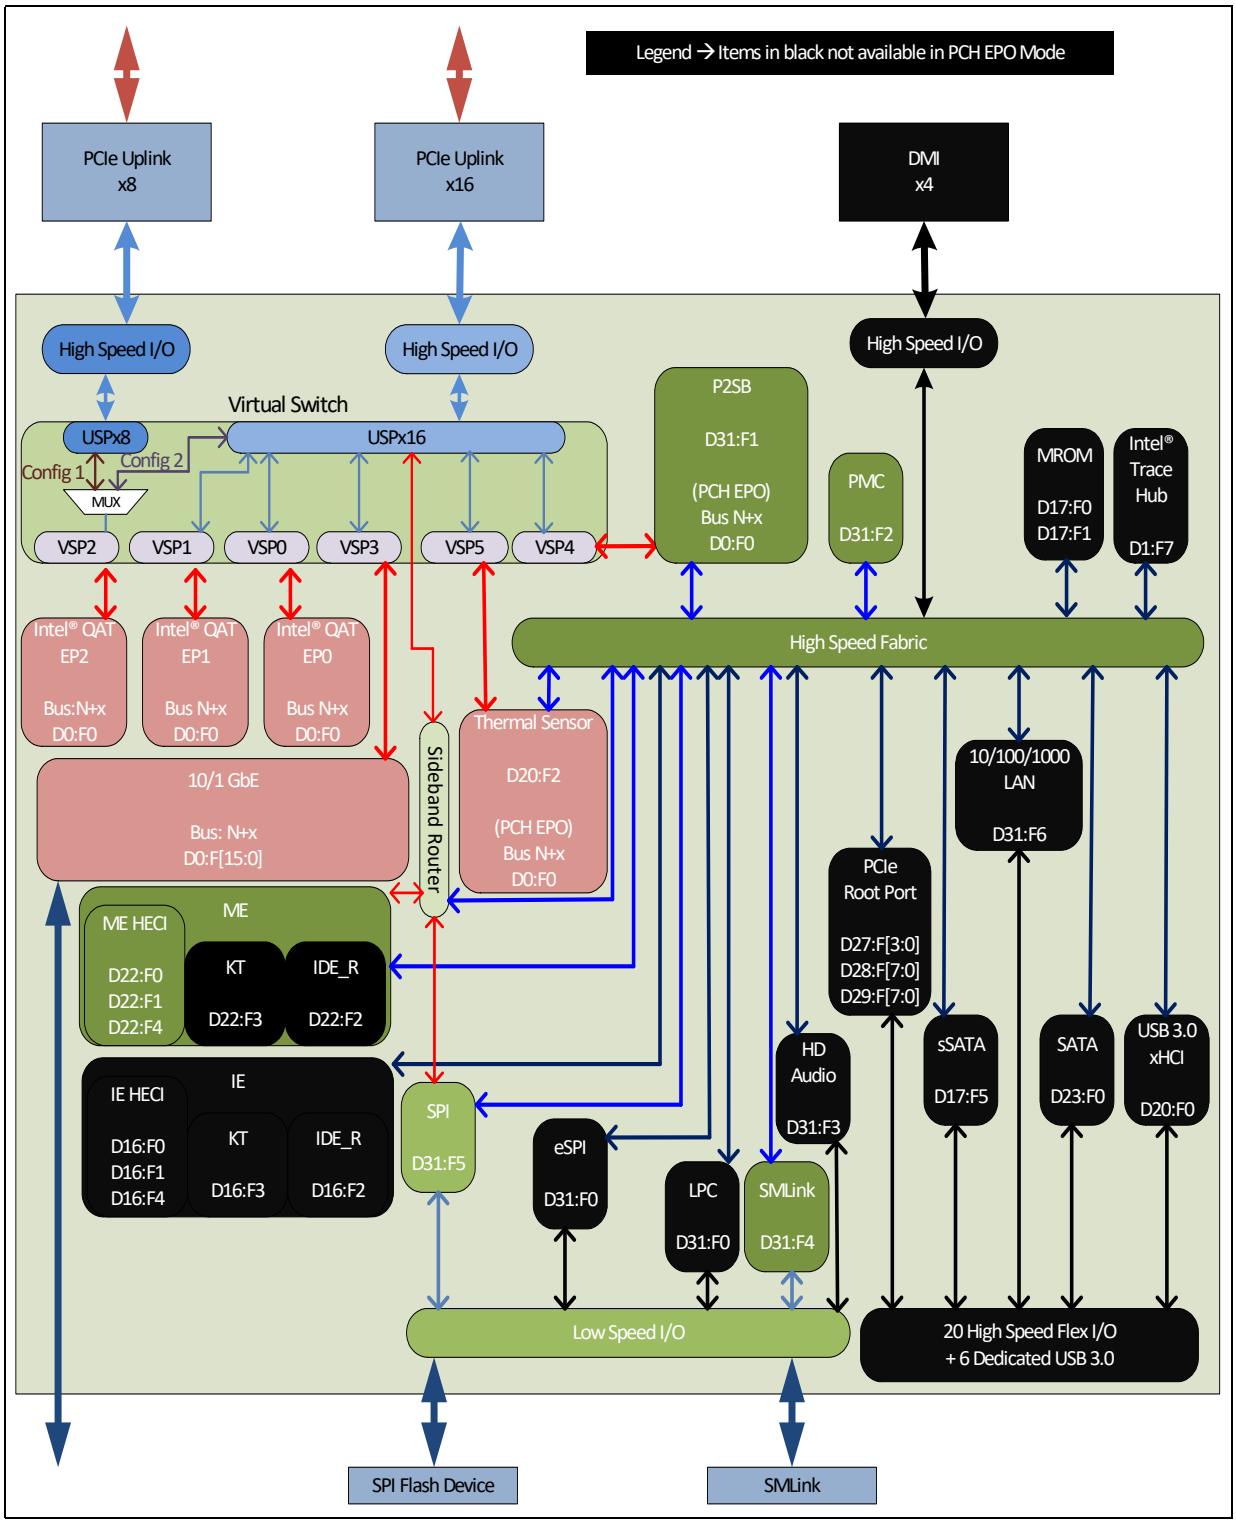
Table 40-1. EPO PCH - Functions Not Supported

DMI	PCI Express Root Ports	xHCI USB
SATA	sSATA	eSPI
LPC	Intel HD Audio	Host SMBus
10/100/1000 GbE	Fan Speed Controller	Pulse Width Modulation
Innovation Engine	Manageability: KT or IDE-R	MROM
Any function that requires DMI Access		Intel Trace Hub

40.5.7 PCH EPO - Block Diagram

The following is a block diagram reflecting a PCH in EPO mode. The blocks represented in black are not available in PCH EPO mode.

Figure 40-1. PCH in EndPoint Only (EPO) Mode Block Diagram



40.6 EPO PCH - PCIe Uplink

40.6.1 PCIe Uplink Overview

The EPO PCH has up to two PCIe Uplinks. The primary PCIe Gen 3 Uplink has a max width of 16 lanes and is required to be connected. The primary upstream port controller is used by both the Intel QuickAssist Technology and the Integrated 10GbE Controller. The max width of the primary Uplink is PCH SKU dependent.

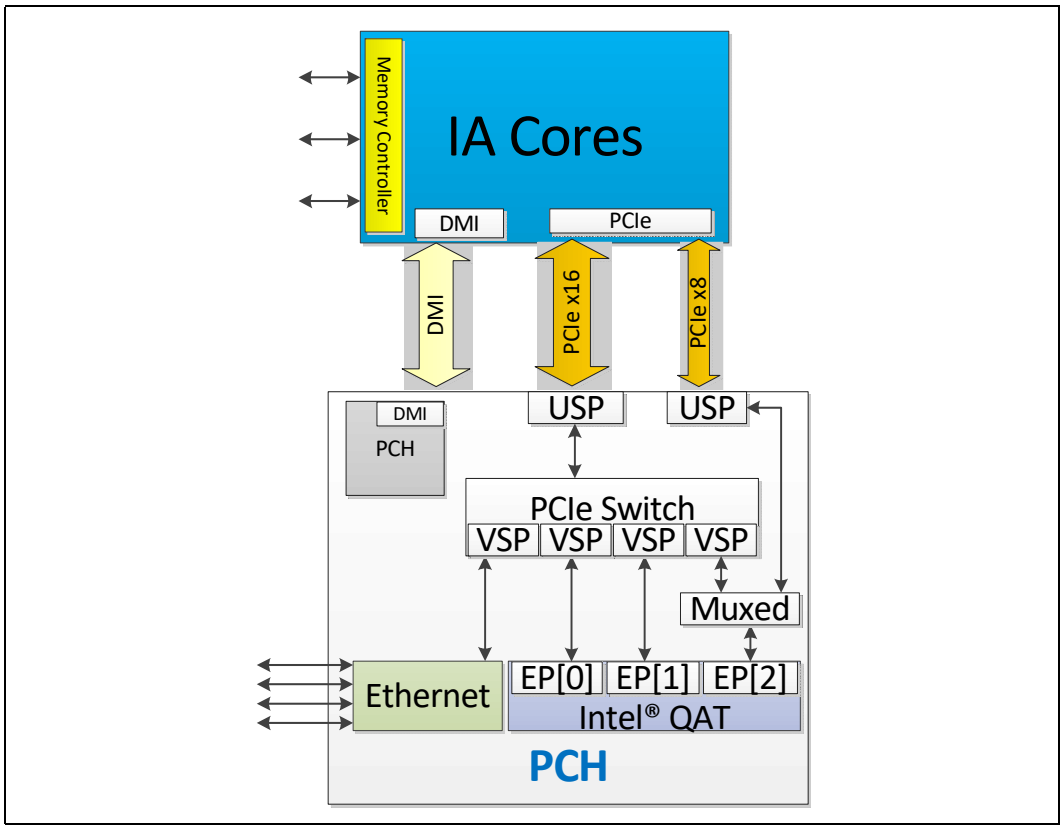
For PCH SKUs that support a second Upstream Port controller, an additional x8 lanes are available that are dedicated to Intel QuickAssist Technology. The secondary PCIe Gen 3 Uplink has a max width of 8 lanes, is optional, and requires the use of Configuration 2 described later in this section.

All three Intel QuickAssist Technology endpoints are accessible via an integrated PCIe Switch and the switch's Virtual Switch Ports (VSP). On PCH SKUs that support the secondary x8 Upstream Port controller, the secondary upstream port controller is muxed with the Intel QuickAssist Technology endpoint 2 (EP[2]) and will have dedicated access to that endpoint (EP[2]) as shown in the following figure.

The PCH has two PCIe Uplink Configurations: Configuration 1 and Configuration 2. These configuration are controlled via softstraps.

Note: Not all PCH SKUs support the secondary PCIe x8 Uplink. On those SKUs that do not support the secondary Uplink, the Uplink has been fused to Configuration 2.

Figure 40-2. Intel QuickAssist Technology and PCH Upstream Ports

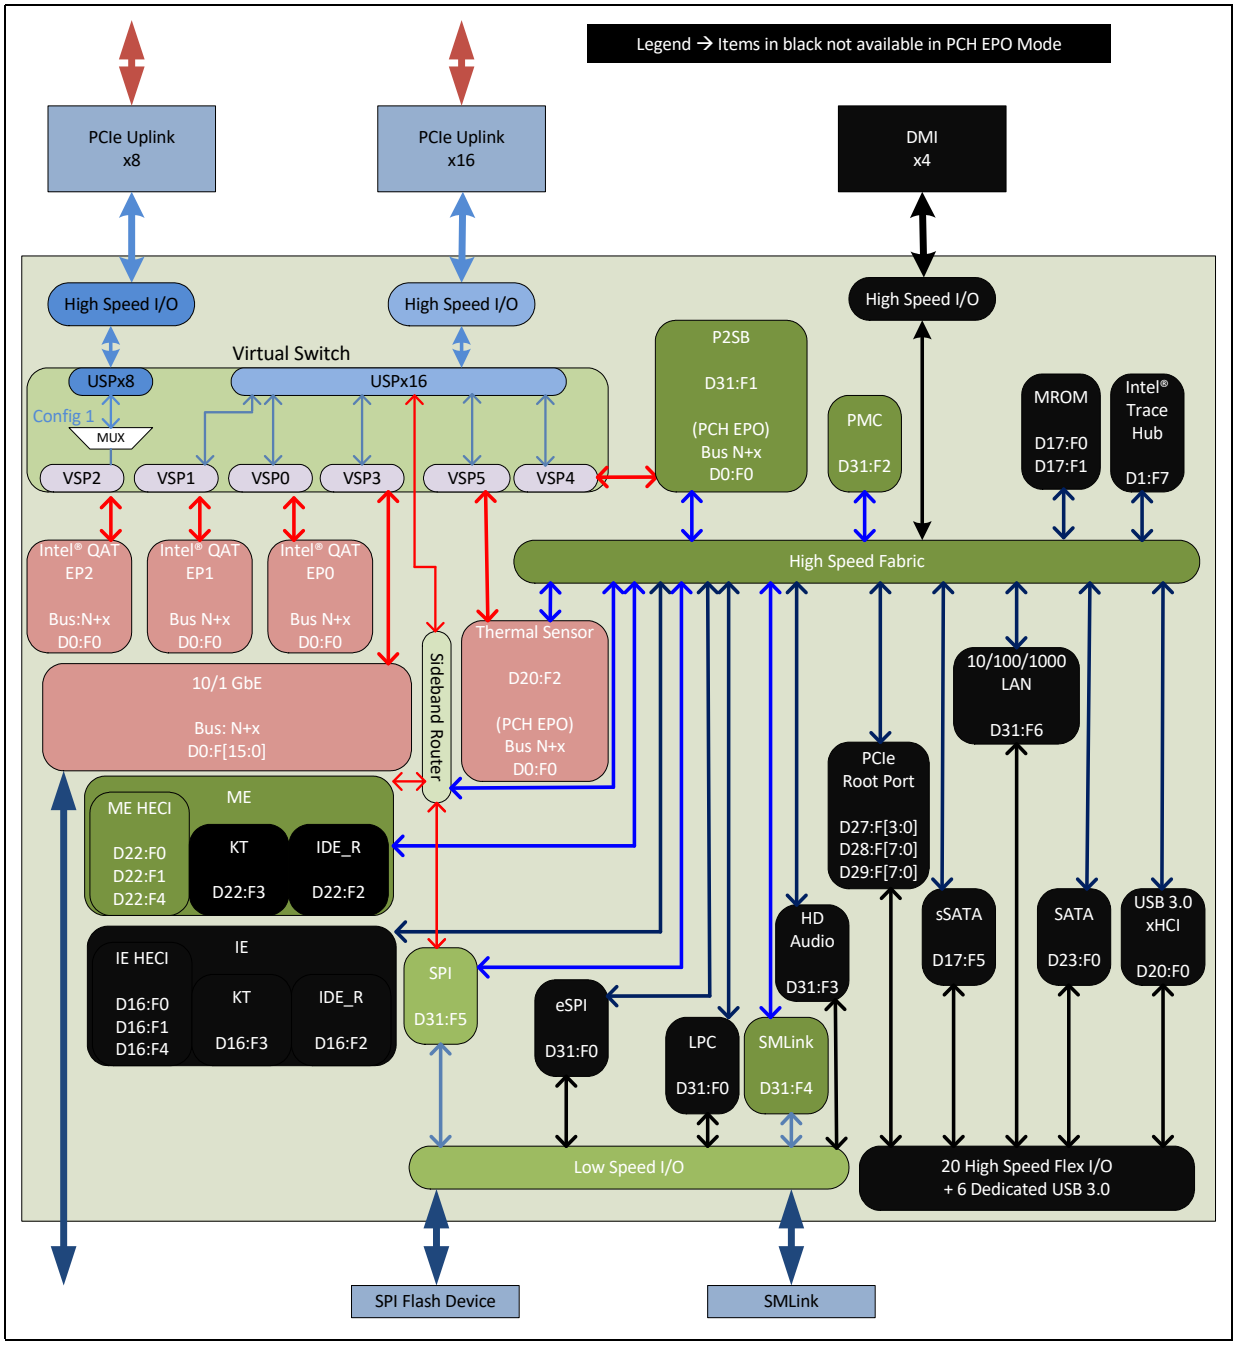


40.6.2 EPO PCH - PCI Uplink Configuration 1

In PCIe Uplink Configuration 1, the primary PCIe x16 Uplink is used for transactions to the 10 GbE controller, Intel QAT Endpoints [1:0], P2SB, and the PCH thermal sensor via the Virtual Switch Ports [5:3,1:0]. The secondary PCIe x8 Uplink is connected and dedicated to Intel QAT Endpoint 2 via Virtual Switch Port 2.

The following is a block diagram of PCH EPO Mode Uplink configuration #1.

Figure 40-3. EPO PCH with Uplink Configuration 1



40.6.3 EPO PCH - PCI Uplink Configuration 2

In PCIe Uplink Configuration 2, the primary PCIe x16 Uplink is used for transactions to the 10 GbE controller, Intel QAT Endpoints [2:0], P2SB, and the PCH thermal sensor via the Virtual Switch Ports [5:0]. The secondary PCIe x8 Uplink is unused and is power gated.

The following is a block diagram of PCH EPO Mode Uplink configuration #2.
