1 Instruction Encoding	1
1.1 Instruction Encoding Overview	1
1.1.1 Encoding Syntax	1
1.1.2 Representation in Memory	4
1.2 Instruction Prefixes	5
1.2.1 Summary of Legacy Prefixes	6
1.2.2 Operand-Size Override Prefix	7
1.2.3 Address-Size Override Prefix	9
1.2.4 Segment-Override Prefixes	10
1.2.5 Lock Prefix	11
1.2.6 Repeat Prefixes	12
1.2.7 REX Prefix	14
1.2.8 VEX and XOP Prefixes	16
1.3 Opcode	16
1.4 ModRM and SIB Bytes	17
1.4.1 ModRM Byte Format	17
1.4.2 SIB Byte Format	18
1.4.3 Operand Addressing in Legacy 32-bit and Compatibility Modes	20
1.4.4 Operand Addressing in 64-bit Mode	23
1.5 Displacement Bytes	24
1.6 Immediate Bytes	24
1.7 RIP-Relative Addressing	24
1.7.1 Encoding	25
1.7.2 REX Prefix and RIP-Relative Addressing	25
1.7.3 Address-Size Prefix and RIP-Relative Addressing	25
1.8 Encoding Considerations Using REX	26
1.8.1 Byte-Register Addressing	26
1.8.2 Special Encodings for Registers	26
1.9 Encoding Using the VEX and XOP Prefixes	29
1.9.1 Three-Byte Escape Sequences	29
1.9.2 Two-Byte Escape Sequence	32

B.7	Segment Override Prefixes in 64-Bit Mode 516
Appendix C	Differences Between Long Mode and Legacy Mode 517
Appendix D	Instruction Subsets and CPUID Feature Flags 519
D.1	Instruction Set Overview 520

D.2	CPUID Feature Flags Related to Instruction Support	522
D.3	Instruction List	524
Appendix E	Obtaining Processor Information Via the CPUID Instruction	589
E.1	Special Notational Conventions	589
E.2	Standard and Extended Function Numbers	590
E.3	Standard Feature Function Numbers	590
	Function 0h—Maximum Standard Function Number and Vendor String	590
	Function 1h—Processor and Processor Feature Identifiers	591
	Functions 2h–4h—Reserved	594
	Function 5h—Monitor and MWait Features	594
	Function 6h—Power Management Related Features	595
	Function 7h—Structured Extended Feature Identifiers	596
	Functions 8h–Ch—Reserved	597
	Function Dh—Processor Extended State Enumeration	597
	Functions 4000_0000h–4000_FFh—Reserved for Hypervisor Use	600
E.4	Extended Feature Function Numbers	600
	Function 8000_0000h—Maximum Extended Function Number and Vendor String	600
	Function 8000_0001h—Extended Processor and Processor Feature Identifiers	601
	Functions 8000_0002h–8000_0004h—Extended Processor Name String	604
	Function 8000_0005h—L1 Cache and TLB Information	604
	Function 8000_0006h—L2 Cache and TLB and L3 Cache Information	606
	Function 8000_0007h—Processor Power Management and RAS Capabilities	608
	Function 8000_0008h—Processor Capacity Parameters	610
	Function 8000_0009h—Reserved	611
	Function 8000_000Ah—SVM Features	611
	Functions 8000_000Bh–8000_0018h—Reserved	613
	Function 8000_0019h—TLB Characteristics for 1GB pages	613
	Function 8000_001Ah—Instruction Optimizations	614
	Function 8000_001Bh—Instruction-Based Sampling Capabilities	614
	Function 8000_001Ch—Lightweight Profiling Capabilities	615
	Function 8000_001Dh—Cache Topology Information	617
	Function 8000_001Eh—Processor Topology Information	619
E.5	Multiple Core Calculation	620
	Legacy Method	620
	Extended Method (Recommended)	621
Appendix F	Instruction Effects on RFLAGS	623

Revision History

Date	Revision	Description
October 2013	3.21	<p>Added BMI2 instructions to Chapter 3.</p> <p>Added BZHI to Table F-1 on page 623.</p> <p>Changed CPUID Fn8000_0001_ECX[25] to reserved.</p> <p>Changed CPUID Fn8000_0007_EAX and _EDX[11] to reserved.</p> <p>Added CPUID Fn0000_0006_EDX[ARAT] (bit 2).</p>
May 2013	3.20	<p>Updated Appendix D "Instruction Subsets and CPUID Feature Flags" on page 519 to make instruction list comprehensive.</p> <p>Added a new Appendix E "Obtaining Processor Information Via the CPUID Instruction" on page 589 which describes all defined processor feature bits. Supersedes and replaces the <i>CPUID Specification</i> (PID # 25481).</p> <p>Previous Appendix E "Instruction Effects on RFLAGS" renumbered as Appendix F.</p>
September 2012	3.19	<p>Corrected the value specified for the most significant nibble of the encoding for the VPSHAX instructions in Table A-28 on page 477.</p>
March 2012	3.18	<p>Added MOVBE instruction reference page to Chapter 3 "General-Purpose Instruction Reference" on page 71.</p> <p>Added instruction reference pages for the RDFSBASE/RDGSBASE and WRFSBASE/WRGSBASE instructions to Chapter 3.</p> <p>Added opcodes for the instructions to the opcode maps in Appendix A.</p>

Date	Revision	Description
December 2011	3.17	<p>Corrected second byte of VEX C5 escape sequence in Figure 1-2 on page 5.</p> <p>Made multiple corrections to the description of register-indirect addressing in Section 1.4 on page 17.</p> <p>Corrected <i>mod</i> field value in third row of Figure 1-16 on page 25.</p> <p>Updated pseudocode definition (see Section 2.5.3 on page 57).</p> <p>Corrected exception tables for LZCNT and TZCNT instructions.</p> <p>Added discussion of UD opcodes to introduction of Appendix A.</p> <p>Provided omitted definition of “B” used in the specification of operand types in opcode maps of Appendix A.</p> <p>Provided numerous corrections to instruction entries in opcode maps of Appendix A.</p> <p>Added ymm register mnemonic to Table A-32 on page 479 and Table A-34 on page 481.</p> <p>Changed notational convention for indicating addressing modes in Table A-33 on page 479, Table A-35 on page 482, Table A-36 on page 484, and Table A-37 on page 485; edited footnotes.</p>
September 2011	3.16	<p>Reworked “Instruction Byte Order” section of Chapter 1. See “Instruction Encoding Overview” on page 1.</p> <p>Added clarification: Execution of VMRUN is disallowed while in System Management Mode.</p> <p>Made wording for BMI and TBM feature flag indication consistent with other instructions.</p> <p>Moved BMI and TBM instructions to this volume from Volume 4.</p> <p>Added instruction reference page for CRC32 Instruction.</p> <p>Removed one cause of #GP fault from exception table for LAR and LSL instructions.</p> <p>Added three-byte, VEX, and XOP opcode maps to Appendix A.</p> <p>Revised description of RDPIC instruction.</p> <p>Corrected errors in description of CLFLUSH instruction.</p> <p>Corrected footnote of Table A-35 on page 482.</p>
November 2009	3.15	<p>Clarified MFENCE serializing behavior.</p> <p>Added multibyte variant to “NOP” on page 237.</p> <p>Corrected descriptive text to “CMPXCHG8B CMPXCHG16B” on page 151.</p>
September 2007	3.14	<p>Added minor clarifications and corrected typographical and formatting errors.</p>

Date	Revision	Description
July 2007	3.13	<p>Added the following instructions: LZCNT, POPCNT, MONITOR, and MWAIT.</p> <p>Reformatted information on instruction support indicated by CPUID feature bits into a table.</p> <p>Added minor clarifications and corrected typographical and formatting errors.</p>
September 2006	3.12	<p>Added minor clarifications and corrected typographical and formatting errors.</p>
December 2005	3.11	<p>Added SVM instructions; added PAUSE instructions; made factual changes.</p>
January 2005	3.10	<p>Clarified CPUID information in exception tables on instruction pages. Added information under “CPUID” on page 153. Made numerous small corrections.</p>
September 2003	3.09	<p>Corrected table of valid descriptor types for LAR and LSL instructions and made several minor formatting, stylistic and factual corrections. Clarified several technical definitions.</p>
April 2003	3.08	<p>Corrected description of the operation of flags for RCL, RCR, ROL, and ROR instructions. Clarified description of the MOVSD and IMUL instructions. Corrected operand specification for the STOS instruction. Corrected opcode of SETcc, Jcc, instructions. Added thermal control and thermal monitoring bits to CPUID instruction. Corrected exception tables for POPF, SFENCE, SUB, XLAT, IRET, LSL, MOV(CRn), SGDT/SIDT, SMSW, and STI instructions. Corrected many small typos and incorporated branding terminology.</p>

Preface

About This Book

This book is part of a multivolume work entitled the *AMD64 Architecture Programmer's Manual*. This table lists each volume and its order number.

Title	Order No.
<i>Volume 1: Application Programming</i>	24592
<i>Volume 2: System Programming</i>	24593
<i>Volume 3: General-Purpose and System Instructions</i>	24594
<i>Volume 4: 128-Bit and 256-Bit Media Instructions</i>	26568
<i>Volume 5: 64-Bit Media and x87 Floating-Point Instructions</i>	26569

Audience

This volume (Volume 3) is intended for all programmers writing application or system software for a processor that implements the AMD64 architecture. Descriptions of general-purpose instructions assume an understanding of the application-level programming topics described in Volume 1. Descriptions of system instructions assume an understanding of the system-level programming topics described in Volume 2.

Organization

Volumes 3, 4, and 5 describe the AMD64 architecture's instruction set in detail. Together, they cover each instruction's mnemonic syntax, opcodes, functions, affected flags, and possible exceptions.

The AMD64 instruction set is divided into five subsets:

- General-purpose instructions
- System instructions
- Streaming SIMD Extensions—SSE (includes 128-bit and 256-bit media instructions)
- 64-bit media instructions (MMX™)
- x87 floating-point instructions

Several instructions belong to—and are described identically in—multiple instruction subsets.

This volume describes the general-purpose and system instructions. The index at the end cross-references topics within this volume. For other topics relating to the AMD64 architecture, and for

information on instructions in other subsets, see the tables of contents and indexes of the other volumes.

Conventions and Definitions

The following section **Notational Conventions** describes notational conventions used in this volume and in the remaining volumes of this *AMD64 Architecture Programmer's Manual*. This is followed by a **Definitions** section which lists a number of terms used in the manual along with their technical definitions. Finally, the **Registers** section lists the registers which are a part of the application programming model.

Notational Conventions

#GP(0)

An instruction exception—in this example, a general-protection exception with error code of 0.

1011b

A binary value—in this example, a 4-bit value.

FOEA_0B02h

A hexadecimal value. Underscore characters may be inserted to improve readability.

128

Numbers without an alpha suffix are decimal unless the context indicates otherwise.

7:4

A bit range, from bit 7 to 4, inclusive. The high-order bit is shown first. Commas may be inserted to indicate gaps.

CPUID FnXXXX_XXXX_RRR[*FieldName*]

Support for optional features or the value of an implementation-specific parameter of a processor can be discovered by executing the CPUID instruction on that processor. To obtain this value, software must execute the CPUID instruction with the function code *XXXX_XXXXh* in EAX and then examine the field *FieldName* returned in register *RRR*. If the “_RRR” notation is followed by “_xYYY”, register ECX must be set to the value *YYYh* before executing CPUID. When *FieldName* is not given, the entire contents of register *RRR* contains the desired value. When determining optional feature support, if the bit identified by *FieldName* is set to a one, the feature is supported on that processor.

CR0–CR4

A register range, from register CR0 through CR4, inclusive, with the low-order register first.

CR0[PE]

Notation for referring to a field within a register—in this case, the PE field of the CR0 register.

CR0[PE] = 1

Notation indicating that the PE bit of the CR0 register has a value of 1.

DS:rSI

The contents of a memory location whose segment address is in the DS register and whose offset relative to that segment is in the rSI register.

EFER[LME] = 0

Notation indicating that the LME bit of the EFER register has a value of 0.

RFLAGS[13:12]

A field within a register identified by its bit range. In this example, corresponding to the IOPL field.

Definitions

Many of the following definitions assume an in-depth knowledge of the legacy x86 architecture. See “Related Documents” on page xxx for descriptions of the legacy x86 architecture.

128-bit media instructions

Instructions that operate on the various 128-bit vector data types. Supported within both the legacy SSE and extended SSE instruction sets.

256-bit media instructions

Instructions that operate on the various 256-bit vector data types. Supported within the extended SSE instruction set.

64-bit media instructions

Instructions that operate on the 64-bit vector data types. These are primarily a combination of MMX™ and 3DNow!™ instruction sets, with some additional instructions from the SSE1 and SSE2 instruction sets.

16-bit mode

Legacy mode or compatibility mode in which a 16-bit address size is active. See *legacy mode* and *compatibility mode*.

32-bit mode

Legacy mode or compatibility mode in which a 32-bit address size is active. See *legacy mode* and *compatibility mode*.

64-bit mode

A submode of *long mode*. In 64-bit mode, the default address size is 64 bits and new features, such as register extensions, are supported for system and application software.

absolute

Said of a displacement that references the base of a code segment rather than an instruction pointer. Contrast with *relative*.

biased exponent

The sum of a floating-point value's exponent and a constant bias for a particular floating-point data type. The bias makes the range of the biased exponent always positive, which allows reciprocation without overflow.

byte

Eight bits.

clear

To write a bit value of 0. Compare *set*.

compatibility mode

A submode of *long mode*. In compatibility mode, the default address size is 32 bits, and legacy 16-bit and 32-bit applications run without modification.

commit

To irreversibly write, in program order, an instruction's result to software-visible storage, such as a register (including flags), the data cache, an internal write buffer, or memory.

CPL

Current privilege level.

direct

Referencing a memory location whose address is included in the instruction's syntax as an immediate operand. The address may be an absolute or relative address. Compare *indirect*.

dirty data

Data held in the processor's caches or internal buffers that is more recent than the copy held in main memory.

displacement

A signed value that is added to the base of a segment (absolute addressing) or an instruction pointer (relative addressing). Same as *offset*.

doubleword

Two words, or four bytes, or 32 bits.

double quadword

Eight words, or 16 bytes, or 128 bits. Also called *octword*.

effective address size

The address size for the current instruction after accounting for the default address size and any address-size override prefix.

effective operand size

The operand size for the current instruction after accounting for the default operand size and any operand-size override prefix.

element

See *vector*.

exception

An abnormal condition that occurs as the result of executing an instruction. The processor's response to an exception depends on the type of the exception. For all exceptions except 128-bit media SIMD floating-point exceptions and x87 floating-point exceptions, control is transferred to the handler (or service routine) for that exception, as defined by the exception's vector. For floating-point exceptions defined by the IEEE 754 standard, there are both masked and unmasked responses. When unmasked, the exception handler is called, and when masked, a default response is provided instead of calling the handler.

flush

An often ambiguous term meaning (1) writeback, if modified, and invalidate, as in “flush the cache line,” or (2) invalidate, as in “flush the pipeline,” or (3) change a value, as in “flush to zero.”

GDT

Global descriptor table.

IDT

Interrupt descriptor table.

IGN

Ignored. Value written is ignored by hardware. Value returned on a read is indeterminate. See *reserved*.

indirect

Referencing a memory location whose address is in a register or other memory location. The address may be an absolute or relative address. Compare *direct*.

IRB

The virtual-8086 mode interrupt-redirection bitmap.

IST

The long-mode interrupt-stack table.

IVT

The real-address mode interrupt-vector table.

LDT

Local descriptor table.

legacy x86

The legacy x86 architecture. See “Related Documents” on page xxx for descriptions of the legacy x86 architecture.

legacy mode

An operating mode of the AMD64 architecture in which existing 16-bit and 32-bit applications and operating systems run without modification. A processor implementation of the AMD64 architecture can run in either *long mode* or *legacy mode*. Legacy mode has three submodes, *real mode*, *protected mode*, and *virtual-8086 mode*.

long mode

An operating mode unique to the AMD64 architecture. A processor implementation of the AMD64 architecture can run in either *long mode* or *legacy mode*. Long mode has two submodes, *64-bit mode* and *compatibility mode*.

lsb

Least-significant bit.

LSB

Least-significant byte.

main memory

Physical memory, such as RAM and ROM (but not cache memory) that is installed in a particular computer system.

mask

(1) A control bit that prevents the occurrence of a floating-point exception from invoking an exception-handling routine. (2) A field of bits used for a control purpose.

MBZ

Must be zero. If software attempts to set an MBZ bit to 1, a general-protection exception (#GP) occurs.

memory

Unless otherwise specified, *main memory*.

ModRM

A byte following an instruction opcode that specifies address calculation based on mode (Mod), register (R), and memory (M) variables.

moffset

A 16, 32, or 64-bit offset that specifies a memory operand directly, without using a ModRM or SIB byte.

msb

Most-significant bit.

MSB

Most-significant byte.

multimedia instructions

A combination of *128-bit media instructions* and *64-bit media instructions*.

octword

Same as *double quadword*.

offset

Same as *displacement*.

overflow

The condition in which a floating-point number is larger in magnitude than the largest, finite, positive or negative number that can be represented in the data-type format being used.

packed

See *vector*.

PAE

Physical-address extensions.

physical memory

Actual memory, consisting of *main memory* and cache.

probe

A check for an address in a processor's caches or internal buffers. *External probes* originate outside the processor, and *internal probes* originate within the processor.

protected mode

A submode of *legacy mode*.

quadword

Four words, or eight bytes, or 64 bits.

RAZ

Read as zero. Value returned on a read is always zero (0) regardless of what was previously written. See *reserved*.

real-address mode

See *real mode*.

real mode

A short name for *real-address mode*, a submode of *legacy mode*.

relative

Referencing with a displacement (also called offset) from an instruction pointer rather than the base of a code segment. Contrast with *absolute*.

reserved

Fields marked as reserved may be used at some future time.

To preserve compatibility with future processors, reserved fields require special handling when read or written by software. Software must not depend on the state of a reserved field (unless qualified as RAZ), nor upon the ability of such fields to return a previously written state.

If a field is marked reserved without qualification, software must not change the state of that field; it must reload that field with the same value returned from a prior read.

Reserved fields may be qualified as IGN, MBZ, RAZ, or SBZ (see definitions).

REX

An instruction prefix that specifies a 64-bit operand size and provides access to additional registers.

RIP-relative addressing

Addressing relative to the 64-bit RIP instruction pointer.

SBZ

Should be zero. An attempt by software to set an SBZ bit to 1 results in undefined behavior.

set

To write a bit value of 1. Compare *clear*.

SIB

A byte following an instruction opcode that specifies address calculation based on scale (S), index (I), and base (B).

SIMD

Single instruction, multiple data. See *vector*.

SSE

Streaming SIMD extensions instruction set. See *128-bit media instructions* and *64-bit media instructions*.

SSE2

Extensions to the SSE instruction set. See *128-bit media instructions* and *64-bit media instructions*.

SSE3

Further extensions to the SSE instruction set. See *128-bit media instructions*.

sticky bit

A bit that is set or cleared by hardware and that remains in that state until explicitly changed by software.

TOP

The x87 top-of-stack pointer.

TPR

Task-priority register (CR8).

TSS

Task-state segment.

underflow

The condition in which a floating-point number is smaller in magnitude than the smallest nonzero, positive or negative number that can be represented in the data-type format being used.

vector

(1) A set of integer or floating-point values, called *elements*, that are packed into a single operand. Most of the 128-bit and 64-bit media instructions use vectors as operands. Vectors are also called *packed* or *SIMD* (single-instruction multiple-data) operands.

(2) An index into an interrupt descriptor table (IDT), used to access exception handlers. Compare *exception*.

virtual-8086 mode

A submode of *legacy mode*.

word

Two bytes, or 16 bits.

x86

See *legacy x86*.

Registers

In the following list of registers, the names are used to refer either to a given register or to the contents of that register:

AH–DH

The high 8-bit AH, BH, CH, and DH registers. Compare *AL–DL*.

AL–DL

The low 8-bit AL, BL, CL, and DL registers. Compare *AH–DH*.

AL–r15B

The low 8-bit AL, BL, CL, DL, SIL, DIL, BPL, SPL, and R8B–R15B registers, available in 64-bit mode.

BP

Base pointer register.

CR_n

Control register number *n*.

CS

Code segment register.

eAX–eSP

The 16-bit AX, BX, CX, DX, DI, SI, BP, and SP registers or the 32-bit EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP registers. Compare *rAX–rSP*.

EFER

Extended features enable register.

eFLAGS

16-bit or 32-bit flags register. Compare *rFLAGS*.

EFLAGS

32-bit (extended) flags register.

eIP

16-bit or 32-bit instruction-pointer register. Compare *rIP*.

EIP

32-bit (extended) instruction-pointer register.

FLAGS

16-bit flags register.

GDTR

Global descriptor table register.

GPRs

General-purpose registers. For the 16-bit data size, these are AX, BX, CX, DX, DI, SI, BP, and SP. For the 32-bit data size, these are EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP. For the 64-bit data size, these include RAX, RBX, RCX, RDX, RDI, RSI, RBP, RSP, and R8–R15.

IDTR

Interrupt descriptor table register.

IP

16-bit instruction-pointer register.

LDTR

Local descriptor table register.

MSR

Model-specific register.

r8–r15

The 8-bit R8B–R15B registers, or the 16-bit R8W–R15W registers, or the 32-bit R8D–R15D registers, or the 64-bit R8–R15 registers.

rAX–rSP

The 16-bit AX, BX, CX, DX, DI, SI, BP, and SP registers, or the 32-bit EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP registers, or the 64-bit RAX, RBX, RCX, RDX, RDI, RSI, RBP, and RSP registers. Replace the placeholder *r* with nothing for 16-bit size, “E” for 32-bit size, or “R” for 64-bit size.

RAX

64-bit version of the EAX register.

RBP

64-bit version of the EBP register.

RBX

64-bit version of the EBX register.

RCX

64-bit version of the ECX register.

RDI

64-bit version of the EDI register.

RDX

64-bit version of the EDX register.

rFLAGS

16-bit, 32-bit, or 64-bit flags register. Compare *RFLAGS*.

RFLAGS

64-bit flags register. Compare *rFLAGS*.

rIP

16-bit, 32-bit, or 64-bit instruction-pointer register. Compare *RIP*.

RIP

64-bit instruction-pointer register.

RSI

64-bit version of the ESI register.

RSP

64-bit version of the ESP register.

SP

Stack pointer register.

SS

Stack segment register.

TPR

Task priority register, a new register introduced in the AMD64 architecture to speed interrupt management.

TR

Task register.

Endian Order

The x86 and AMD64 architectures address memory using little-endian byte-ordering. Multibyte values are stored with their least-significant byte at the lowest byte address, and they are illustrated with their least significant byte at the right side. Strings are illustrated in reverse order, because the addresses of their bytes increase from right to left.

1 Instruction Encoding

AMD64 technology instructions are encoded as byte strings of variable length. The order and meaning of each byte of an instruction's encoding is specified by the architecture. Fields within the encoding specify the instruction's basic operation, the location of the one or more source operands, and the destination of the result of the operation. Data to be used in the execution of the instruction or the computation of addresses for memory-based operands may also be included. This section describes the general format and parameters used by all instructions.

For information on the specific encoding(s) for each instruction, see:

- Chapter 3, “General-Purpose Instruction Reference.”
- Chapter 4, “System Instruction Reference.”
- “SSE Instruction Reference” in Volume 4.
- “64-Bit Media Instruction Reference” in Volume 5.
- “x87 Floating-Point Instruction Reference” in Volume 5.

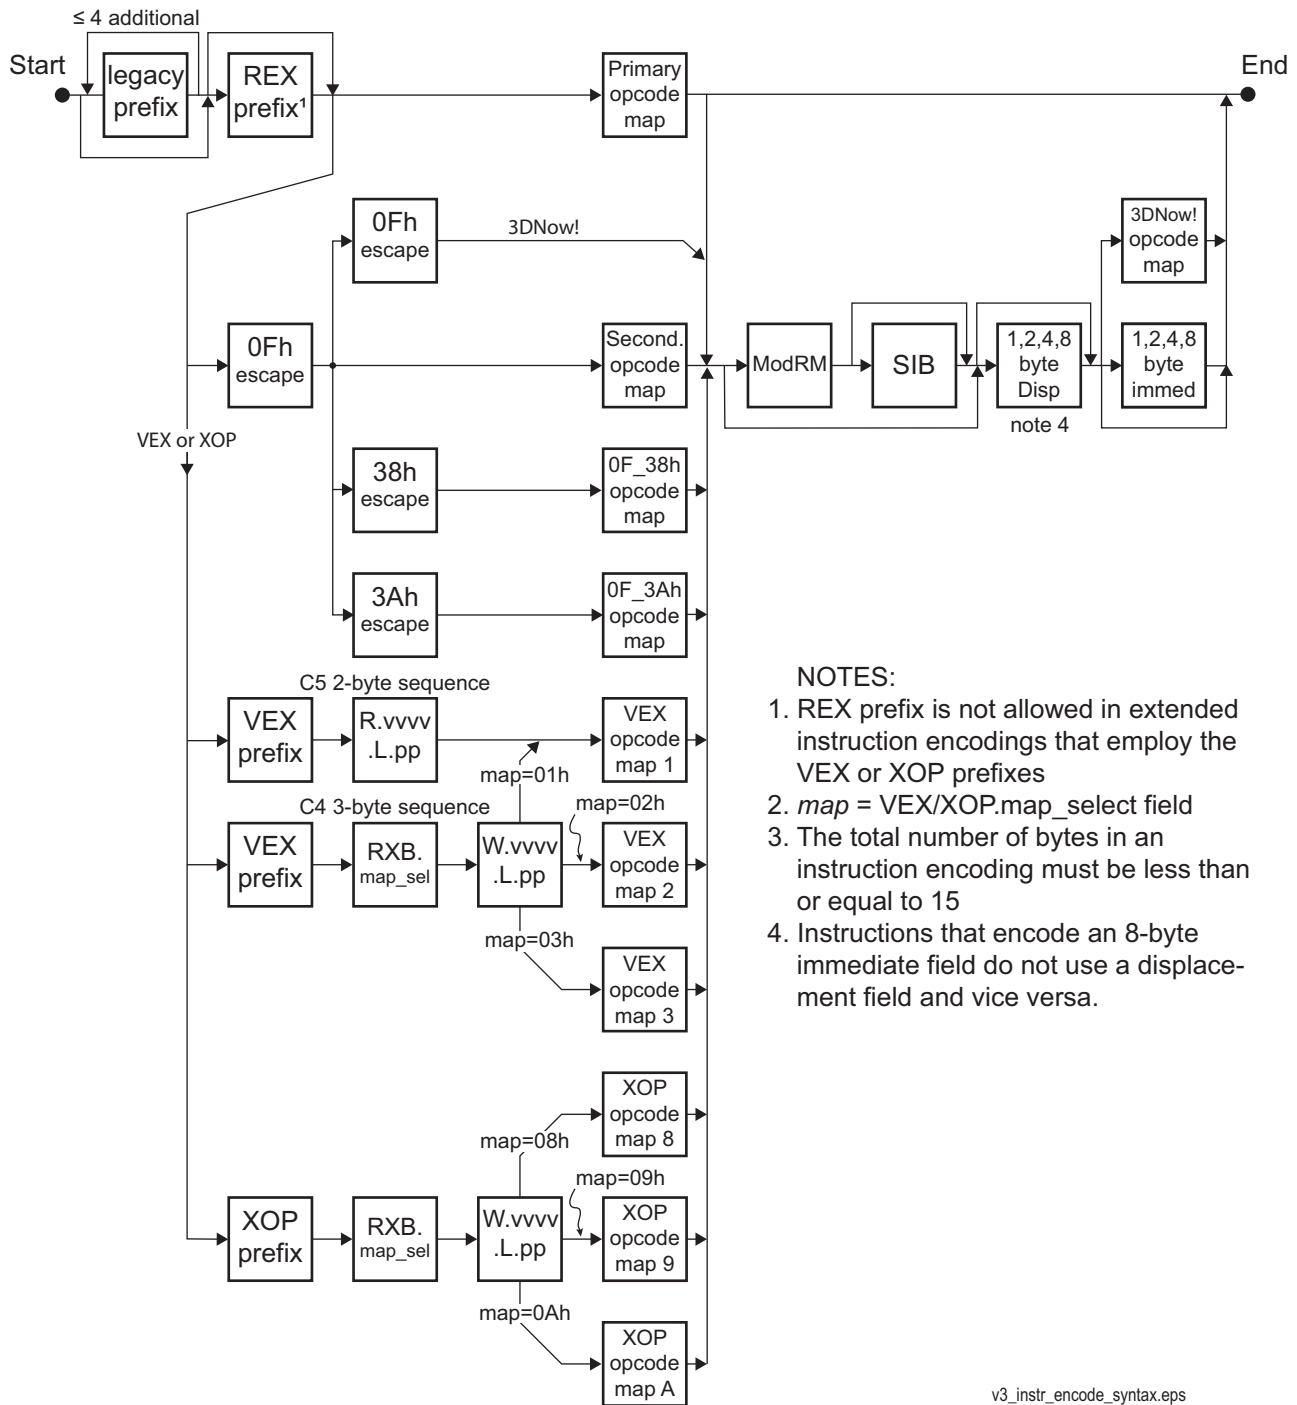

For information on determining the instruction form and operands specified by a given binary encoding, see Appendix A.

1.1 Instruction Encoding Overview

An instruction is encoded as a string between one and 15 bytes in length. The entire sequence of bytes that represents an instruction, including the basic operation, the location of source and destination operands, any operation modifiers, and any immediate and/or displacement values, is called the instruction encoding. The following sections discuss instruction encoding syntax and representation in memory.

1.1.1 Encoding Syntax

Figure 1-1 provides a schematic representation of the encoding syntax of an instruction.

- NOTES:
1. REX prefix is not allowed in extended instruction encodings that employ the VEX or XOP prefixes
 2. *map* = VEX/XOP.map_select field
 3. The total number of bytes in an instruction encoding must be less than or equal to 15
 4. Instructions that encode an 8-byte immediate field do not use a displacement field and vice versa.

v3_instr_encode_syntax.eps

Figure 1-1. Instruction Encoding Syntax

Each square in this diagram represents an instruction byte of a particular type and function. To understand the diagram, follow the connecting paths in the direction indicated by the arrows from “Start” to “End.” The squares passed through as the graph is traversed indicate the order and number of

bytes used to encode the instruction. Note that the path shown above the legacy prefix byte loops back indicating that up to four additional prefix bytes may be used in the encoding of a single instruction. Branches indicate points in the syntax where alternate semantics are employed based on the instruction being encoded. The “VEX or XOP” gate across the path leading down to the VEX prefix and XOP prefix blocks means that only extended instructions employing the VEX or XOP prefixes use this particular branch of the syntax diagram. This diagram will be further explained in the sections that follow.

1.1.1.1 Legacy Prefixes

As shown in the figure, an instruction optionally begins with up to five *legacy prefixes*. These prefixes are described in “Summary of Legacy Prefixes” on page 6. The legacy prefixes modify an instruction’s default address size, operand size, or segment, or they invoke a special function such as modification of the opcode, atomic bus-locking, or repetition.

In the encoding of most SSE instructions, a legacy operand-size or repeat prefix is repurposed to modify the opcode. For the extended encodings utilizing the XOP or VEX prefixes, these prefixes are not allowed.

1.1.1.2 REX Prefix

Following the optional legacy prefix or prefixes, the REX prefix can be used in 64-bit mode to access the AMD64 register number and size extensions. Refer to the diagram in “Application-Programming Register Set” in Volume 1 for an illustration of these facilities. If a REX prefix is used, it must immediately precede the opcode byte or the first byte of a legacy *escape sequence*. The REX prefix is not allowed in extended instruction encodings using the VEX or XOP encoding escape prefixes. Violating this restriction results in an #UD exception.

1.1.1.3 Opcode

The *opcode* is a single byte that specifies the basic operation of an instruction. Every instruction requires an opcode. The correspondence between the binary value of an opcode and the operation it represents is presented in a table called an *opcode map*. Because it is indexed by an 8-bit value, an opcode map has 256 entries. Since there are more than 256 instructions defined by the architecture, multiple different opcode maps must be defined and the selection of these alternate opcode maps must be encoded in the instruction. Escape sequences provide this access to alternate opcode maps.

If there are no opcode escapes, the primary (“one-byte”) opcode map is used. In the figure this is the path pointing from the REX Prefix block to the Primary opcode map block.

Section , “Primary Opcode Map” of Appendix A provides details concerning this opcode map.

1.1.1.4 Escape Sequences

Escape sequences allow access to alternate opcode maps that are distinct from the primary opcode map. Escape sequences may be one, two, or three bytes in length and begin with a unique byte value designated for this purpose in the primary opcode map. Escape sequences are of two distinct types:

legacy escape sequences and extended escape sequences. The legacy escape sequences will be covered here. For more details on the extended escape sequences, see “VEX and XOP Prefixes” on page 16.

Legacy Escape Sequences

The legacy syntax allows one 1-byte escape sequence (0Fh), and three 2-byte escape sequences (0Fh, 0Fh; 0Fh, 38h; and 0Fh, 3Ah). The 1-byte legacy escape sequence 0Fh selects the secondary (“two-byte”) opcode map. In legacy terminology, the sequence [0Fh, *opcode*] is called a two-byte opcode. See Section , “Secondary Opcode Map” of Appendix A for details concerning this opcode map.

The 2-byte escape sequence 0F, 0Fh selects the 3DNow! opcode map which is indexed using an immediate byte rather than an opcode byte. In this case, the byte following the escape sequence is the ModRM byte instead of the opcode byte. In Figure 1-1 this is indicated by the path labeled “3DNow!” leaving the second 0Fh escape block. Details concerning the 3DNow! opcode map are presented in Section A.1.2, “3DNow!™ Opcodes” of Appendix A.

The 2-byte escape sequences [0Fh, 38h] and [0Fh, 3Ah] respectively select the 0F_38h opcode map and the 0F_3Ah opcode map. These are used primarily to encode SSE instructions and are described in Section , “0F_38h and 0F_3Ah Opcode Maps” of Appendix A.

1.1.1.5 ModRM and SIB Bytes

The opcode can be followed by a *mode-register-memory* (ModRM) byte, which further describes the operation and/or operands. The ModRM byte may also be followed by a *scale-index-base* (SIB) byte, which is used to specify indexed register-indirect forms of memory addressing. The ModRM and SIB bytes are described in “ModRM and SIB Bytes” on page 17. Their legacy functions can be augmented by the REX prefix (see “REX Prefix” on page 14) or the VEX and XOP escape sequences (See “VEX and XOP Prefixes” on page 16).

1.1.1.6 Displacement and Immediate Fields

The instruction encoding may end with a 1-, 2-, or 4-byte *displacement* field and/or a 1-, 2-, or 4-byte *immediate* field depending on the instruction and/or the addressing mode. Specific instructions also allow either an 8-byte immediate field or an 8-byte displacement field.

1.1.2 Representation in Memory

Instructions are stored in memory in little-endian order. The first byte of an instruction is stored at the lowest memory address, as shown in Figure 1-2 below. Since instructions are strings of bytes, they may start at any memory address. The total instruction length must be less than or equal to 15. If this limit is exceeded, a general-protection exception results.

Notes:

¹ Available only in 64-Bit Mode

² Available only in Long or Protected Mode

³ F0, F2, F3, and 66 prefixes not allowed

⁴ Instructions that specify an 8-byte immediate field do not include a displacement field and vice versa.

v3_instruct_mem.eps

Figure 1-2. An Instruction as Stored in Memory

1.2 Instruction Prefixes

Instruction prefixes are of two types: *instruction modifier* prefixes and *encoding escape* prefixes. Instruction modifier prefixes can change the operation of the instruction (including causing its execution to repeat), change its operand types, specify an alternate operand size, augment register specification, or even change the interpretation of the opcode byte.

The instruction modifier prefixes comprise the legacy prefixes and the REX prefix. The legacy prefixes are discussed in the next section. The REX prefix is discussed in “REX Prefix” on page 14.

Encoding escape prefixes, on the other hand, signal that the two or three bytes that follow obey a different encoding syntax. As a group, the encoding escape prefix and its subsequent bytes constitute a multi-byte escape sequence. These multi-byte escape sequences perform functions similar to that of

the instruction modifier prefixes, but they also provide a means to directly specify alternate opcode maps.

The currently defined encoding escape prefixes are the VEX and XOP prefixes. They are discussed further in the section entitled “VEX and XOP Prefixes” on page 16.

1.2.1 Summary of Legacy Prefixes

Table 1-1 on page 7 shows the legacy prefixes. The legacy prefixes are organized into five groups, as shown in the left-most column of Table 1-1. An instruction encoding may include a maximum of one prefix from each of the five groups. The legacy prefixes can appear in any order within the position shown in Figure 1-1 for legacy prefixes. The result of using multiple prefixes from a single group is undefined.

Some of the restrictions on legacy prefixes are:

- *Operand-Size Override*—This prefix only affects the operand size for general-purpose instructions or for other instructions whose source or destination is a general-purpose register. When used in the encoding of SIMD and some other instructions, this prefix is repurposed to modify the opcode.
- *Address-Size Override*—This prefix only affects the address size of memory operands.
- *Segment Override*—In 64-bit mode, the CS, DS, ES, and SS segment override prefixes are ignored.
- *LOCK Prefix*—This prefix is allowed only with certain instructions that modify memory.
- *Repeat Prefixes*—These prefixes affect only certain string instructions. When used in the encoding of SIMD and some other instructions, these prefixes are repurposed to modify the opcode.

Table 1-1. Legacy Instruction Prefixes

Prefix Group ¹	Mnemonic	Prefix Byte (Hex)	Description
Operand-Size Override	none	66 ²	Changes the default operand size of a memory or register operand, as shown in Table 1-2 on page 8.
Address-Size Override	none	67 ³	Changes the default address size of a memory operand, as shown in Table 1-3 on page 9.
Segment Override	CS	2E ⁴	Forces use of the current CS segment for memory operands.
	DS	3E ⁴	Forces use of the current DS segment for memory operands.
	ES	26 ⁴	Forces use of the current ES segment for memory operands.
	FS	64	Forces use of the current FS segment for memory operands.
	GS	65	Forces use of the current GS segment for memory operands.
	SS	36 ⁴	Forces use of the current SS segment for memory operands.
Lock	LOCK	F0 ⁵	Causes certain kinds of memory read-modify-write instructions to occur atomically.
Repeat	REP	F3 ⁶	Repeats a string operation (INS, MOVS, OUTS, LODS, and STOS) until the rCX register equals 0.
	REPE or REPZ		Repeats a compare-string or scan-string operation (CMPSx and SCASx) until the rCX register equals 0 or the zero flag (ZF) is cleared to 0.
	REPNE or REPNZ	F2 ⁶	Repeats a compare-string or scan-string operation (CMPSx and SCASx) until the rCX register equals 0 or the zero flag (ZF) is set to 1.

Notes:

1. A single instruction should include a maximum of one prefix from each of the five groups.
2. When used in the encoding of SIMD instructions, this prefix is repurposed to modify the opcode. The prefix is ignored by 64-bit media floating-point (3DNow!™) instructions. See "Instructions that Cannot Use the Operand-Size Prefix" on page 8.
3. This prefix also changes the size of the RCX register when used as an implied count register.
4. In 64-bit mode, the CS, DS, ES, and SS segment overrides are ignored.
5. The LOCK prefix should not be used for instructions other than those listed in "Lock Prefix" on page 11.
6. This prefix should be used only with compare-string and scan-string instructions. When used in the encoding of SIMD instructions, the prefix is repurposed to modify the opcode.

1.2.2 Operand-Size Override Prefix

The default operand size for an instruction is determined by a combination of its opcode, the D (default) bit in the current code-segment descriptor, and the current operating mode, as shown in Table 1-2. The operand-size override prefix (66h) selects the non-default operand size. The prefix can

be used with any general-purpose instruction that accesses non-fixed-size operands in memory or general-purpose registers (GPRs), and it can also be used with the x87 FLDENV, FNSTENV, FNSAVE, and FRSTOR instructions.

In 64-bit mode, the prefix allows mixing of 16-bit, 32-bit, and 64-bit data on an instruction-by-instruction basis. In compatibility and legacy modes, the prefix allows mixing of 16-bit and 32-bit operands on an instruction-by-instruction basis.

Table 1-2. Operand-Size Overrides

Operating Mode		Default Operand Size (Bits)	Effective Operand Size (Bits)	Instruction Prefix ¹	
				66h	REX.W ³
Long Mode	64-Bit Mode	32 ²	64	don't care	yes
			32	no	no
			16	yes	no
	Compatibility Mode	32	32	no	Not Applicable
			16	yes	
			16	yes	
			16	no	
	Legacy Mode (Protected, Virtual-8086, or Real Mode)	32	32	no	
16			yes		
16		32	yes		
		16	no		

Notes:

1. A "no" indicates that the default operand size is used.
2. This is the typical default, although some instructions default to other operand sizes. See Appendix B, "General-Purpose Instructions in 64-Bit Mode," for details.
3. See "REX Prefix" on page 14.

In 64-bit mode, most instructions default to a 32-bit operand size. For these instructions, a REX prefix (page 14) can specify a 64-bit operand size, and a 66h prefix specifies a 16-bit operand size. The REX prefix takes precedence over the 66h prefix. However, if an instruction defaults to a 64-bit operand size, it does not need a REX prefix and it can only be overridden to a 16-bit operand size. It cannot be overridden to a 32-bit operand size, because there is no 32-bit operand-size override prefix in 64-bit mode. Two groups of instructions have a default 64-bit operand size in 64-bit mode:

- Near branches. For details, see "Near Branches in 64-Bit Mode" in Volume 1.
- All instructions, except far branches, that implicitly reference the RSP. For details, see "Stack Operation" in Volume 1.

Instructions that Cannot Use the Operand-Size Prefix. The operand-size prefix should be used only with general-purpose instructions and the x87 FLDENV, FNSTENV, FNSAVE, and FRSTOR

instructions, in which the prefix selects between 16-bit and 32-bit operand size. The prefix is ignored by all other x87 instructions and by 64-bit media floating-point (3DNow!™) instructions.

For other instructions (mostly SIMD instructions) the 66h, F2h, and F3h prefixes are used as instruction modifiers to extend the instruction encoding space in the 0Fh, 0F_38h, and 0F_3Ah opcode maps.

Operand-Size and REX Prefixes. The W bit field of the REX prefix takes precedence over the 66h prefix. See “REX.W: Operand width (Bit 3)” on page 23 for details.

1.2.3 Address-Size Override Prefix

The default address size for instructions that access non-stack memory is determined by the current operating mode, as shown in Table 1-3. The address-size override prefix (67h) selects the non-default address size. Depending on the operating mode, this prefix allows mixing of 16-bit and 32-bit, or of 32-bit and 64-bit addresses, on an instruction-by-instruction basis. The prefix changes the address size for memory operands. It also changes the size of the RCX register for instructions that use RCX implicitly.

For instructions that implicitly access the stack segment (SS), the address size for stack accesses is determined by the D (default) bit in the stack-segment descriptor. In 64-bit mode, the D bit is ignored, and all stack references have a 64-bit address size. However, if an instruction accesses both stack and non-stack memory, the address size of the non-stack access is determined as shown in Table 1-3.

Table 1-3. Address-Size Overrides

Operating Mode		Default Address Size (Bits)	Effective Address Size (Bits)	Address-Size Prefix (67h) ¹ Required?	
Long Mode	64-Bit Mode	64	64	no	
			32	yes	
	Compatibility Mode	32	32	no	
			16	yes	
			16	32	yes
				16	no
Legacy Mode (Protected, Virtual-8086, or Real Mode)	32	32	no		
		16	yes		
	16	32	yes		
		16	no		
Notes:					
1. A “no” indicates that the default address size is used.					

As Table 1-3 shows, the default address size is 64 bits in 64-bit mode. The size can be overridden to 32 bits, but 16-bit addresses are not supported in 64-bit mode. In compatibility and legacy modes, the

default address size is 16 bits or 32 bits, depending on the operating mode (see “Processor Initialization and Long Mode Activation” in Volume 2 for details). In these modes, the address-size prefix selects the non-default size, but the 64-bit address size is not available.

Certain instructions reference pointer registers or count registers implicitly, rather than explicitly. In such instructions, the address-size prefix affects the size of such addressing and count registers, just as it does when such registers are explicitly referenced. Table 1-4 lists all such instructions and the registers referenced using the three possible address sizes.

Table 1-4. Pointer and Count Registers and the Address-Size Prefix

Instruction	Pointer or Count Register		
	16-Bit Address Size	32-Bit Address Size	64-Bit Address Size
CMPS, CMPSB, CMPSW, CMPSD, CMPSQ —Compare Strings	SI, DI, CX	ESI, EDI, ECX	RSI, RDI, RCX
INS, INSB, INSW, INSD —Input String	DI, CX	EDI, ECX	RDI, RCX
JCXZ, JECXZ, JRCXZ —Jump on CX/ECX/RCX Zero	CX	ECX	RCX
LODS, LODSB, LODSW, LODSD, LODSQ —Load String	SI, CX	ESI, ECX	RSI, RCX
LOOP, LOOPE, LOOPNZ, LOOPNE, LOOPZ —Loop	CX	ECX	RCX
MOVS, MOVSB, MOVSW, MOVSD, MOVSQ —Move String	SI, DI, CX	ESI, EDI, ECX	RSI, RDI, RCX
OUTS, OUTSB, OUTSW, OUTSD —Output String	SI, CX	ESI, ECX	RSI, RCX
REP, REPE, REPNE, REPNZ, REPZ —Repeat Prefixes	CX	ECX	RCX
SCAS, SCASB, SCASW, SCASD, SCASQ —Scan String	DI, CX	EDI, ECX	RDI, RCX
STOS, STOSB, STOSW, STOSD, STOSQ —Store String	DI, CX	EDI, ECX	RDI, RCX
XLAT, XLATB —Table Look-up Translation	BX	EBX	RBX

1.2.4 Segment-Override Prefixes

Segment overrides can be used only with instructions that reference non-stack memory. Most instructions that reference memory are encoded with a ModRM byte (page 17). The default segment

for such memory-referencing instructions is implied by the base register indicated in its ModRM byte, as follows:

- *Instructions that Reference a Non-Stack Segment*—If an instruction encoding references any base register other than rBP or rSP, or if an instruction contains an immediate offset, the default segment is the data segment (DS). These instructions can use the segment-override prefix to select one of the non-default segments, as shown in Table 1-5.
- *String Instructions*—String instructions reference two memory operands. By default, they reference both the DS and ES segments (DS:rSI and ES:rDI). These instructions can override their DS-segment reference, as shown in Table 1-5, but they cannot override their ES-segment reference.
- *Instructions that Reference the Stack Segment*—If an instruction’s encoding references the rBP or rSP base register, the default segment is the stack segment (SS). All instructions that reference the stack (push, pop, call, interrupt, return from interrupt) use SS by default. These instructions cannot use the segment-override prefix.

Table 1-5. Segment-Override Prefixes

Mnemonic	Prefix Byte (Hex)	Description
CS ¹	2E	Forces use of current CS segment for memory operands.
DS ¹	3E	Forces use of current DS segment for memory operands.
ES ¹	26	Forces use of current ES segment for memory operands.
FS	64	Forces use of current FS segment for memory operands.
GS	65	Forces use of current GS segment for memory operands.
SS ¹	36	Forces use of current SS segment for memory operands.
Notes:		
1. In 64-bit mode, the CS, DS, ES, and SS segment overrides are ignored.		

Segment Overrides in 64-Bit Mode. In 64-bit mode, the CS, DS, ES, and SS segment-override prefixes have no effect. These four prefixes are not treated as segment-override prefixes for the purposes of multiple-prefix rules. Instead, they are treated as null prefixes.

The FS and GS segment-override prefixes are treated as true segment-override prefixes in 64-bit mode. Use of the FS or GS prefix causes their respective segment bases to be added to the effective address calculation. See “FS and GS Registers in 64-Bit Mode” in Volume 2 for details.

1.2.5 Lock Prefix

The LOCK prefix causes certain kinds of memory read-modify-write instructions to occur atomically. The mechanism for doing so is implementation-dependent (for example, the mechanism may involve bus signaling or packet messaging between the processor and a memory controller). The prefix is intended to give the processor exclusive use of shared memory in a multiprocessor system.

The LOCK prefix can only be used with forms of the following instructions that write a memory operand: ADC, ADD, AND, BTC, BTR, BTS, CMPXCHG, CMPXCHG8B, CMPXCHG16B, DEC, INC, NEG, NOT, OR, SBB, SUB, XADD, XCHG, and XOR. An invalid-opcode exception occurs if the LOCK prefix is used with any other instruction.

1.2.6 Repeat Prefixes

The repeat prefixes cause repetition of certain instructions that load, store, move, input, or output strings. The prefixes should only be used with such string instructions. Two pairs of repeat prefixes, REPE/REPZ and REPNE/REPNZ, perform the same repeat functions for certain compare-string and scan-string instructions. The repeat function uses rCX as a count register. The size of rCX is based on address size, as shown in Table 1-4 on page 10.

REP. The REP prefix repeats its associated string instruction the number of times specified in the counter register (rCX). It terminates the repetition when the value in rCX reaches 0. The prefix can be used with the INS, LODS, MOVS, OUTS, and STOS instructions. Table 1-6 shows the valid REP prefix opcodes.

Table 1-6. REP Prefix Opcodes

Mnemonic	Opcode
REP INS <i>reg/mem8</i> , DX REP INSB	F3 6C
REP INS <i>reg/mem16/32</i> , DX REP INSW REP INSD	F3 6D
REP LODS <i>mem8</i> REP LODSB	F3 AC
REP LODS <i>mem16/32/64</i> REP LODSW REP LODSD REP LODSQ	F3 AD
REP MOVS <i>mem8</i> , <i>mem8</i> REP MOVSB	F3 A4
REP MOVS <i>mem16/32/64</i> , <i>mem16/32/64</i> REP MOVSW REP MOVSD REP MOVSQ	F3 A5
REP OUTS DX, <i>reg/mem8</i> REP OUTSB	F3 6E

Table 1-6. REP Prefix Opcodes (continued)

Mnemonic	Opcode
REP OUTS <i>DX, reg/mem16/32</i> REP OUTSW REP OUTSD	F3 6F
REP STOS <i>mem8</i> REP STOSB	F3 AA
REP STOS <i>mem16/32/64</i> REP STOSW REP STOSD REP STOSQ	F3 AB

REPE and REPZ. REPE and REPZ are synonyms and have identical opcodes. These prefixes repeat their associated string instruction the number of times specified in the counter register (rCX). The repetition terminates when the value in rCX reaches 0 or when the zero flag (ZF) is cleared to 0. The REPE and REPZ prefixes can be used with the CMPS, CMPSB, CMPSD, CMPSW, SCAS, SCASB, SCASD, and SCASW instructions. Table 1-7 shows the valid REPE and REPZ prefix opcodes.

Table 1-7. REPE and REPZ Prefix Opcodes

Mnemonic	Opcode
REPx CMPS <i>mem8, mem8</i> REPx CMPSB	F3 A6
REPx CMPS <i>mem16/32/64, mem16/32/64</i> REPx CMPSW REPx CMPSD REPx CMPSQ	F3 A7
REPx SCAS <i>mem8</i> REPx SCASB	F3 AE
REPx SCAS <i>mem16/32/64</i> REPx SCASW REPx SCASD REPx SCASQ	F3 AF

REPNE and REPNZ. REPNE and REPNZ are synonyms and have identical opcodes. These prefixes repeat their associated string instruction the number of times specified in the counter register (rCX). The repetition terminates when the value in rCX reaches 0 or when the zero flag (ZF) is set to 1. The REPNE and REPNZ prefixes can be used with the CMPS, CMPSB, CMPSD, CMPSW, SCAS, SCASB, SCASD, and SCASW instructions. Table 1-8 on page 14 shows the valid REPNE and REPNZ prefix opcodes.

Table 1-8. REPNE and REPNZ Prefix Opcodes

Mnemonic	Opcode
REPNe CMPS <i>mem8, mem8</i> REPNe CMPSB	F2 A6
REPNe CMPS <i>mem16/32/64, mem16/32/64</i> REPNe CMPSW REPNe CMPSD REPNe CMPSQ	F2 A7
REPNe SCAS <i>mem8</i> REPNe SCASB	F2 AE
REPNe SCAS <i>mem16/32/64</i> REPNe SCASW REPNe SCASD REPNe SCASQ	F2 AF

Instructions that Cannot Use Repeat Prefixes. In general, the repeat prefixes should only be used in the string instructions listed in tables 1-6, 1-7, and 1-8 above. For other instructions (mostly SIMD instructions) the 66h, F2h, and F3h prefixes are used as instruction modifiers to extend the instruction encoding space in the 0Fh, 0F_38h, and 0F_3Ah opcode maps.

Optimization of Repeats. Depending on the hardware implementation, the repeat prefixes can have a setup overhead. If the repeated count is variable, the overhead can sometimes be avoided by substituting a simple loop to move or store the data. Repeated string instructions can be expanded into equivalent sequences of inline loads and stores or a sequence of stores can be used to emulate a REP STOS.

For repeated string moves, performance can be maximized by moving the largest possible operand size. For example, use REP MOVSD rather than REP MOVSW and REP MOVSW rather than REP MOVSB. Use REP STOSD rather than REP STOSW and REP STOSW rather than REP MOVSB.

Depending on the hardware implementation, string moves with the direction flag (DF) cleared to 0 (up) may be faster than string moves with DF set to 1 (down). DF = 1 is only needed for certain cases of overlapping REP MOVS, such as when the source and the destination overlap.

1.2.7 REX Prefix

The REX prefix, available in 64-bit mode, enables use of the AMD64 register and operand size extensions. Unlike the legacy instruction modification prefixes, REX is not a single unique value, but occupies a range (40h to 4Fh). Figure 1-1 on page 2 shows how the REX prefix fits within the encoding syntax of instructions.

The REX prefix enables the following features in 64-bit mode:

- Use of the extended GPR (Figure 2-3 on page 39) and YMM/XMM registers (Figure 2-8 on page 44).

- Use of the 64-bit operand size when accessing GPRs.
- Use of the extended control and debug registers, as described in Section 2.4 “Registers” in Volume 2.
- Use of the uniform byte registers (AL–R15).

REX contains five fields. The upper nibble is unique to the REX prefix and identifies it as such. The lower nibble is divided into four 1-bit fields (W, R, X, and B). See below for a discussion of these fields. Figure 1-3 below shows the format of the REX prefix. Since each bit of the lower nibble can be a 1 or a 0, REX spans one full row of the primary opcode map occupying entries 40h through 4Fh.

v3_REX_byte_format.eps

Figure 1-3. REX Prefix Format

A REX prefix is normally required with an instruction that accesses a 64-bit GPR or one of the extended GPR or YMM/XMM registers. A few instructions have an operand size that defaults to (or is fixed at) 64 bits in 64-bit mode, and thus do not need a REX prefix. These instructions are listed in Table 1-9 below.

Table 1-9. Instructions Not Requiring REX Prefix in 64-Bit Mode

CALL (Near)	POP reg/mem
ENTER	POP reg
Jcc	POP FS
JrCXZ	POP GS
JMP (Near)	POPF, POPFD, POPFQ
LEAVE	PUSH imm8
LGDT	PUSH imm32
LIDT	PUSH reg/mem
LLDT	PUSH reg
LOOP	PUSH FS
LOOPcc	PUSH GS
LTR	PUSHF, PUSHFD, PUSHFQ
MOV CR _n	RET (Near)
MOV DR _n	

An instruction may have only one REX prefix which must immediately precede the opcode or first escape byte in the instruction encoding. The use of a REX prefix in an instruction that does not access an extended register is ignored. The instruction-size limit of 15 bytes applies to instructions that contain a REX prefix.

Implications for INC and DEC Instructions

The REX prefix values are taken from the 16 single-byte INC and DEC instructions, one for each of the eight legacy GPRs. Therefore, these single-byte opcodes for INC and DEC are not available in 64-bit mode, although they are available in legacy and compatibility modes. The functionality of these INC and DEC instructions is still available in 64-bit mode, however, using the ModRM forms of those instructions (opcodes FF /0 and FF /1).

1.2.8 VEX and XOP Prefixes

The extended instruction encoding syntax, available in protected and long modes, provides one 2-byte and three 3-byte escape sequences introduced by either the VEX or XOP prefixes. These multi-byte sequences not only select opcode maps, they also provide instruction modifiers similar to, but in lieu of, the REX prefix.

The 2-byte escape sequence initiated by the VEX C5h prefix implies a map_select encoding of 1. The three-byte escape sequences, initiated by the VEX C4h prefix or the XOP (8Fh) prefix, select the target opcode map explicitly via the VEX/XOP.map_select field. The five-bit VEX.map_select field allows the selection of one of 31 different opcode maps (opcode map 00h is reserved). The XOP.map_select field is restricted to the range 08h – 1Fh and thus can only select one of 24 different opcode maps.

The VEX and XOP escape sequences contain fields that extend register addressing to a total of 16, increase the operand specification capability to four operands, and modify the instruction operation.

The extended SSE instruction subsets AVX, AES, CLMU, FMA, FMA4, and XOP and a few non-SSE instructions utilize the extended encoding syntax. See “Encoding Using the VEX and XOP Prefixes” on page 29 for details on the encoding of the two- and three-byte extended escape sequences.

1.3 Opcode

The *opcode* is a single byte that specifies the basic operation of an instruction. In some cases, it also specifies the operands for the instruction. Every instruction requires an opcode. The correspondence between the binary value of the opcode and the operation it represents is defined by a table called an *opcode map*. As discussed in the previous sections, the legacy prefixes 66h, F2h, and F3h and other fields within the instruction encoding may be used to modify the operation encoded by the opcode.

The affect of the presence of a 66h, F2h, or F3h prefix on the operation performed by the opcode is represented in the opcode map by additional rows in the table indexed by the applicable prefix. The 3-bit reg and r/m fields of the ModRM byte (“ModRM and SIB Bytes” on page 17) are used as well in the encoding of certain instructions. This is represented in the opcode maps via instruction group tables that detail the modifications represented via the extra encoding bits. See Section A.1, “Opcode Maps” of Appendix A for examples.

Even though each instruction has a unique opcode map and opcode, assemblers often support multiple alternate mnemonics for the same instruction to improve the readability of assembly language code.

The 64-bit floating-point 3DNow! instructions utilize the two-byte escape sequence 0Fh, 0Fh to select the 3DNow! opcode map. For these instructions the opcode is encoded in the immediate field at the end of the instruction encoding.

For details on how the opcode byte encodes the basic operation for specific instructions, see Section A.1, “Opcode Maps” of Appendix A

1.4 ModRM and SIB Bytes

The ModRM byte is optional depending on the instruction. When present, it follows the opcode and is used to specify:

- two register-based operands, or
- one register-based operand and a second memory-based operand and an addressing mode.

In the encoding of some instructions, fields within the ModRM byte are repurposed to provide additional opcode bits used to define the instruction’s function.

The ModRM byte is partitioned into three fields—*mod*, *reg*, and *r/m*. Normally the *reg* field specifies a register-based operand and the *mod* and *r/m* fields used together specify a second operand that is either register-based or memory-based. The addressing mode is also specified when the operand is memory-based.

In 64-bit mode, the REX.R and REX.B bits augment the *reg* and *r/m* fields respectively allowing the specification of twice the number of registers.

1.4.1 ModRM Byte Format

Figure 1-4 below shows the format of a ModRM byte.

Figure 1-4. ModRM-Byte Format

Depending on the addressing mode, the SIB byte may appear after the ModRM byte. SIB is used in the specification of various forms of indexed register-indirect addressing. See the following section for details.

ModRM.mod (Bits[7:6]). The mod field is used with the r/m field to specify the addressing mode for an operand. ModRM.mod = 11b specifies the register-direct addressing mode. In the register-direct mode, the operand is held in the specified register. ModRM.mod values less than 11b specify register-indirect addressing modes. In register-indirect addressing modes, values held in registers along with an optional displacement specified in the instruction encoding are used to calculate the address of a memory-based operand. Other encodings of the 5 bits {mod, r/m} are discussed below.

ModRM.reg (Bits[5:3]). The reg field is used to specify a register-based operand, although for some instructions, this field is used to extend the operation encoding. The encodings for this field are shown in Table 1-10 below.

ModRM.r/m (Bits[2:0]). As stated above, the r/m field is used in combination with the mod field to encode 32 different operand specifications (See Table 1-14 on page 21). The encodings for this field are shown in Table 1-10 below.

Table 1-10. ModRM.reg and .r/m Field Encodings

Encoded value (binary)	ModRM.reg ¹	ModRM.r/m (mod = 11b) ¹	ModRM.r/m (mod ≠ 11b) ²
000	rAX, MMX0, XMM0, YMM0	rAX, MMX0, XMM0, YMM0	[rAX]
001	rCX, MMX1, XMM1, YMM1	rCX, MMX1, XMM1, YMM1	[rCX]
010	rDX, MMX2, XMM2, YMM2	rDX, MMX2, XMM2, YMM2	[rDX]
011	rBX, MMX3, XMM3, YMM3	rBX, MMX3, XMM3, YMM3	[rBX]
100	AH, rSP, MMX4, XMM4, YMM4	AH, rSP, MMX4, XMM4, YMM4	SIB ³
101	CH, rBP, MMX5, XMM5, YMM5	CH, rBP, MMX5, XMM5, YMM5	[rBP] ⁴
110	DH, rSI, MMX6, XMM6, YMM6	DH, rSI, MMX6, XMM6, YMM6	[rSI]
111	BH, rDI, MMX7, XMM7, YMM7	BH, rDI, MMX7, XMM7, YMM7	[rDI]

Notes:

1. Specific register used is instruction-dependent.
2. mod = 01 and mod = 10 include an offset specified by the instruction displacement field. The notation [*] signifies that the specified register holds the address of the operand.
3. Indexed register-indirect addressing. SIB byte follows ModRM byte. See following section for SIB encoding.
4. For mod = 00b and r/m = 101b, the ModRM byte is followed by a SIB byte and the contents of the SIB base field is used to specify eight different addressing modes. See Table Table 1-13 on page 20. For mod = [01b, 10b], r/m = 101b specifies the base + offset addressing mode with [rBP] as the base.

Similar to the reg field, r/m is used in some instructions to extend the operation encoding.

1.4.2 SIB Byte Format

The SIB byte has three fields—*scale*, *index*, and *base*—that define the scale factor, index-register number, and base-register number for the 32-bit and 64-bit indexed register-indirect addressing modes.

The basic formula for computing the effective address of a memory-based operand using the indexed register-indirect address modes is:

$$\text{effective_address} = \text{scale} * \text{index} + \text{base} + \text{offset}$$

Specific variants of this addressing mode set one or more elements of the sum to zero.

Figure 1-5 below shows the format of the SIB byte.

Figure 1-5. SIB Byte Format

SIB.scale (Bits[7:6]). The scale field is used to specify the scale factor used in computing the $\text{scale} * \text{index}$ portion of the effective address. In normal usage scale represents the size of data elements in an array expressed in number of bytes. SIB.scale is encoded as shown in Table 1-11 below.

Table 1-11. SIB.scale Field Encodings

Encoded value (binary)	scale factor
00	1
01	2
10	4
11	8

SIB.index (Bits[5:3]). The index field is used to specify the register containing the index portion of the indexed register-indirect effective address. SIB.index is encoded as shown in Table 1-12 below.

SIB.base (Bits[2:0]). The base field is used to specify the register containing the base address portion of the indexed register-indirect effective address. SIB.base is encoded as shown in Table 1-12 below.

Table 1-12. SIB.index and .base Field Encodings

Encoded value (binary)	SIB.index	SIB.base
000	[rAX]	[rAX]
001	[rCX]	[rCX]
010	[rDX]	[rDX]
011	[rBX]	[rBX]
100	(none) ¹	[rSP]
101	[rBP]	[rBP], (none) ²
110	[rSI]	DH, [rSI]
111	[rDI]	BH, [rDI]

Notes:

1. Register specification is null. The scale*index portion of the indexed register-indirect effective address is set to 0.
2. If ModRM.mod = 00b, the register specification is null. The base portion of the indexed register-indirect effective address is set to 0. Otherwise, base encodes the rBP register as the source of the base address used in the effective address calculation.

Table 1-13. SIB.base encodings for ModRM.r/m = 100b

mod	SIB base Field							
	000	001	010	011	100	101	110	111
00						disp32		
01	[rAX]	[rCX]	[rDX]	[rBX]	[rSP]	[rBP]+disp8	[rSI]	[rDI]
10						[rBP]+disp32		
11	(not applicable)							

More discussion of operand addressing follows in the next two sections.

1.4.3 Operand Addressing in Legacy 32-bit and Compatibility Modes

The mod and r/m fields of the ModRM byte provide a total of five bits used to encode 32 operand specification and memory addressing modes. Table 1-14 below shows these encodings.

Table 1-14. Operand Addressing Using ModRM and SIB Bytes

ModRM.mod	ModRM.r/m	Register / Effective Address
00	000	[rAX]
	001	[rCX]
	010	[rDX]
	011	[rBX]
	100	SIB ¹
	101	<i>disp32</i>
	110	[rSI]
	111	[rDI]
01	000	[rAX]+ <i>disp8</i>
	001	[rCX]+ <i>disp8</i>
	010	[rDX]+ <i>disp8</i>
	011	[rBX]+ <i>disp8</i>
	100	SIB+ <i>disp8</i> ²
	101	[rBP]+ <i>disp8</i>
	110	[rSI]+ <i>disp8</i>
	111	[rDI]+ <i>disp8</i>
10	000	[rAX]+ <i>disp32</i>
	001	[rCX]+ <i>disp32</i>
	010	[rDX]+ <i>disp32</i>
	011	[rBX]+ <i>disp32</i>
	100	SIB+ <i>disp32</i> ³
	101	[rBP]+ <i>disp32</i>
	110	[rSI]+ <i>disp32</i>
	111	[rDI]+ <i>disp32</i>
Notes:		
0. In the following notes, <i>scaled_index</i> = SIB.index * (1 << SIB.scale).		
1. SIB byte follows ModRM byte. Effective address is calculated using <i>scaled_index</i> +base. When SIB.base = 101b, addressing mode depends on ModRM.mod. See Table 1-13 above.		
2. SIB byte follows ModRM byte. Effective address is calculated using <i>scaled_index</i> +base+8-bit_offset. One-byte Displacement field provides the offset.		
3. SIB byte follows ModRM byte. Effective address is calculated using <i>scaled_index</i> +base+32-bit_offset. Four-byte Displacement field provides the offset.		

Table 1-14. Operand Addressing Using ModRM and SIB Bytes (continued)

ModRM.mod	ModRM.r/m	Register / Effective Address
11	000	AL/rAX/MMX0/XMM0/YMM0
	001	CL/rCX/MMX1/XMM1/YMM1
	010	DL/rDX/MMX2/XMM2/YMM2
	011	BL/rBX/MMX3/XMM3/YMM3
	100	AH/SPL/rSP/MMX4/XMM4/YMM4
	101	CH/BPL/rBP/MMX5/XMM5/YMM5
	110	DH/SIL/rSI/MMX6/XMM6/YMM6
	111	BH/DIL/rDI/MMX7/XMM7/YMM7
Notes: <ol style="list-style-type: none"> 0. In the following notes, $\text{scaled_index} = \text{SIB.index} * (1 \ll \text{SIB.scale})$. 1. SIB byte follows ModRM byte. Effective address is calculated using $\text{scaled_index} + \text{base}$. When $\text{SIB.base} = 101\text{b}$, addressing mode depends on ModRM.mod. See Table 1-13 above. 2. SIB byte follows ModRM byte. Effective address is calculated using $\text{scaled_index} + \text{base} + 8\text{-bit_offset}$. One-byte Displacement field provides the offset. 3. SIB byte follows ModRM byte. Effective address is calculated using $\text{scaled_index} + \text{base} + 32\text{-bit_offset}$. Four-byte Displacement field provides the offset. 		

Note that the addressing mode $\text{mod} = 11\text{b}$ is a register-direct mode, that is, the operand is contained in the specified register, while the modes $\text{mod} = [00\text{b}:10\text{b}]$ specify different addressing modes for a memory-based operand.

For $\text{mod} = 11\text{b}$, the register containing the operand is specified by the r/m field. For the other modes ($\text{mod} = [00\text{b}:10\text{b}]$), the mod and r/m fields are combined to specify the addressing mode for the memory-based operand. Most are register-indirect addressing modes meaning that the address of the memory-based operand is contained in the register specified by r/m. For these register-indirect modes, $\text{mod} = 01\text{b}$ and $\text{mod} = 10\text{b}$ include an offset encoded in the displacement field of the instruction.

The encodings $\{\text{mod} \neq 11\text{b}, \text{r/m} = 100\text{b}\}$ specify the *indexed register-indirect* addressing mode in which the target address is computed using a combination of values stored in registers and a scale factor encoded directly in the SIB byte. For these addressing modes the effective address is given by the formula:

$$\text{effective_address} = \text{scale} * \text{index} + \text{base} + \text{offset}$$

Scale is encoded in SIB.scale field. Index is contained in the register specified by SIB.index field and base is contained in the register specified by SIB.base field. Offset is encoded in the displacement field of the instruction using either one or four bytes.

If $\{\text{mod}, \text{r/m}\} = 00100\text{b}$, the offset portion of the formula is set to 0. For $\{\text{mod}, \text{r/m}\} = 01100\text{b}$ and $\{\text{mod}, \text{r/m}\} = 10100\text{b}$, offset is encoded in the one- or 4-byte displacement field of the instruction.

Finally, the encoding {mod, r/m} = 00101b specifies an absolute addressing mode. In this mode, the address is provided directly in the instruction encoding using a 4-byte displacement field. In 64-bit mode this addressing mode is changed to RIP-relative (see “RIP-Relative Addressing” on page 24).

1.4.4 Operand Addressing in 64-bit Mode

AMD64 architecture doubles the number of GPRs and increases their width to 64-bits. It also doubles the number of YMM/XMM registers. In order to support the specification of register operands contained in the eight additional GPRs or YMM/XMM registers and to make the additional GPRs available to hold addresses to be used in the addressing modes, the REX prefix provides the R, X, and B bit fields to extend the reg, r/m, index, and base fields of the ModRM and SIB bytes in the various operand addressing modes to four bits. A fourth REX bit field (W) allows instruction encodings to specify a 64-bit operand size.

Table 1-15 below and the sections that follow describe each of these bit fields.

Table 1-15. REX Prefix-Byte Fields

Mnemonic	Bit Position(s)	Definition
—	7:4	0100 (4h)
REX.W	3	0 = Default operand size 1 = 64-bit operand size
REX.R	2	1-bit (msb) extension of the ModRM <i>reg</i> field ¹ , permitting access to 16 registers.
REX.X	1	1-bit (msb) extension of the SIB <i>index</i> field ¹ , permitting access to 16 registers.
REX.B	0	1-bit (msb) extension of the ModRM <i>r/m</i> field ¹ , SIB <i>base</i> field ¹ , or opcode <i>reg</i> field, permitting access to 16 registers.
Notes:		
1. For a description of the ModRM and SIB bytes, see “ModRM and SIB Bytes” on page 17.		

REX.W: Operand width (Bit 3). Setting the REX.W bit to 1 specifies a 64-bit operand size. Like the existing 66h operand-size override prefix, the REX 64-bit operand-size override has no effect on byte operations. For non-byte operations, the REX operand-size override takes precedence over the 66h prefix. If a 66h prefix is used together with a REX prefix that has the W bit set to 1, the 66h prefix is ignored. However, if a 66h prefix is used together with a REX prefix that has the W bit cleared to 0, the 66h prefix is not ignored and the operand size becomes 16 bits.

REX.R: Register field extension (Bit 2). The REX.R bit adds a 1-bit extension (in the most significant bit position) to the ModRM.reg field when that field encodes a GPR, YMM/XMM, control, or debug register. REX.R does not modify ModRM.reg when that field specifies other registers or is used to extend the opcode. REX.R is ignored in such cases.

REX.X: Index field extension (Bit 1). The REX.X bit adds a 1-bit (msb) extension to the SIB.index field. See “ModRM and SIB Bytes” on page 17.

REX.B: Base field extension (Bit 0). The REX.B bit adds a 1-bit (msb) extension to either the ModRM.r/m field to specify a GPR or XMM register, or to the SIB.base field to specify a GPR. (See Table 2-2 on page 56 for more about the B bit.)

1.5 Displacement Bytes

A *displacement* (also called an *offset*) is a signed value that is added to the base of a code segment (absolute addressing) or to an instruction pointer (relative addressing), depending on the addressing mode. The size of a displacement is 1, 2, or 4 bytes. If an addressing mode requires a displacement, the bytes (1, 2, or 4) for the displacement follow the opcode, ModRM, or SIB byte (whichever comes last) in the instruction encoding.

In 64-bit mode, the same ModRM and SIB encodings are used to specify displacement sizes as those used in legacy and compatibility modes. However, the displacement is sign-extended to 64 bits during effective-address calculations. Also, in 64-bit mode, support is provided for some 64-bit displacement and immediate forms of the MOV instruction. See “Immediate Operand Size” in Volume 1 for more information on this.

1.6 Immediate Bytes

An *immediate* is a value—typically an operand value—encoded directly into the instruction. Depending on the opcode and the operating mode, the size of an immediate operand can be 1, 2, 4, or 8 bytes. 64-bit immediates are allowed in 64-bit mode on MOV instructions that load GPRs, otherwise they are limited to 4 bytes. See “Immediate Operand Size” in Volume 1 for more information.

If an instruction takes an immediate operand, the bytes (1, 2, 4, or 8) for the immediate follow the opcode, ModRM, SIB, or displacement bytes (whichever come last) in the instruction encoding. Some 128-bit media instructions use the immediate byte as a condition code.

1.7 RIP-Relative Addressing

In 64-bit mode, addressing relative to the contents of the 64-bit instruction pointer (program counter)—called RIP-relative addressing or PC-relative addressing—is implemented for certain instructions. In such cases, the effective address is formed by adding the displacement to the 64-bit RIP of the next instruction.

In the legacy x86 architecture, addressing relative to the instruction pointer is available only in control-transfer instructions. In the 64-bit mode, any instruction that uses ModRM addressing can use RIP-relative addressing. This feature is particularly useful for addressing data in position-independent code and for code that addresses global data.

Without RIP-relative addressing, ModRM instructions address memory relative to zero. With RIP-relative addressing, ModRM instructions can address memory relative to the 64-bit RIP using a signed 32-bit displacement. This provides an offset range of ± 2 Gbytes from the RIP.

Programs usually have many references to data, especially global data, that are not register-based. To load such a program, the loader typically selects a location for the program in memory and then adjusts program references to global data based on the load location. RIP-relative addressing of data makes this adjustment unnecessary.

1.7.1 Encoding

Table 1-16 shows the ModRM and SIB encodings for RIP-relative addressing. Redundant forms of 32-bit displacement-only addressing exist in the current ModRM and SIB encodings. There is one ModRM encoding with several SIB encodings. RIP-relative addressing is encoded using one of the redundant forms. In 64-bit mode, the ModRM *disp32* (32-bit displacement) encoding ($\{\text{mod}, r/m\} = 00101\text{b}$) is redefined to be $RIP + \text{disp32}$ rather than displacement-only.

Table 1-16. Encoding for RIP-Relative Addressing

ModRM	SIB	Legacy and Compatibility Modes	64-bit Mode	Additional 64-bit Implications
<ul style="list-style-type: none"> • mod = 00 • r/m = 101 	not present	disp32	RIP + disp32	Zero-based (normal) displacement addressing must use SIB form (see next row).
<ul style="list-style-type: none"> • mod = 00 • r/m = 100¹ 	<ul style="list-style-type: none"> • base = 101² • index = 100³ • scale = xx 	disp32	Same as Legacy	None
<p>Notes:</p> <ol style="list-style-type: none"> 1. Encodes the indexed register-indirect addressing mode with 32-bit offset. 2. Base register specification is null (base portion of effective address calculation is set to 0) 3. index register specification is null (scale*index portion of effective address calculation is set to 0) 				

1.7.2 REX Prefix and RIP-Relative Addressing

ModRM encoding for RIP-relative addressing does not depend on a REX prefix. In particular, the *r/m* encoding of 101, used to select RIP-relative addressing, is not affected by the REX prefix. For example, selecting R13 (REX.B = 1, *r/m* = 101) with mod = 00 still results in RIP-relative addressing.

The four-bit *r/m* field of ModRM is not fully decoded. Therefore, in order to address R13 with no displacement, software must encode it as $R13 + 0$ using a one-byte displacement of zero.

1.7.3 Address-Size Prefix and RIP-Relative Addressing

RIP-relative addressing is enabled by 64-bit mode, not by a 64-bit address-size. Conversely, use of the address-size prefix (“Address-Size Override Prefix” on page 9) does not disable RIP-relative

addressing. The effect of the address-size prefix is to truncate and zero-extend the computed effective address to 32 bits, like any other addressing mode.

1.8 Encoding Considerations Using REX

Figure 1-6 on page 28 shows four examples of how the R, X, and B bits of the REX prefix are concatenated with fields from the ModRM byte, SIB byte, and opcode to specify register and memory addressing.

1.8.1 Byte-Register Addressing

In the legacy architecture, the byte registers (AH, AL, BH, BL, CH, CL, DH, and DL, shown in Figure 2-2 on page 38) are encoded in the ModRM *reg* or *r/m* field or in the opcode *reg* field as registers 0 through 7. The REX prefix provides an additional byte-register addressing capability that makes the least-significant byte of any GPR available for byte operations (Figure 2-3 on page 39). This provides a uniform set of byte, word, doubleword, and quadword registers better suited for register allocation by compilers.

1.8.2 Special Encodings for Registers

Readers who need to know the details of instruction encodings should be aware that certain combinations of the ModRM and SIB fields have special meaning for register encodings. For some of these combinations, the instruction fields expanded by the REX prefix are not decoded (treated as don't cares), thereby creating aliases of these encodings in the extended registers. Table 1-17 on page 27 describes how each of these cases behaves.

Table 1-17. Special REX Encodings for Registers

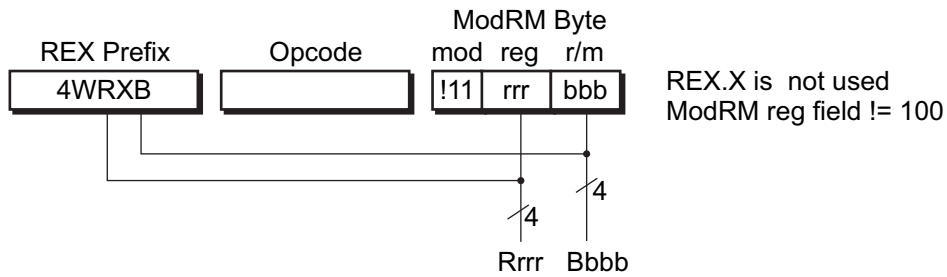

ModRM and SIB Encodings ²	Meaning in Legacy and Compatibility Modes	Implications in Legacy and Compatibility Modes	Additional REX Implications
ModRM Byte: <ul style="list-style-type: none"> • mod ≠ 11 • r/m¹ = 100 (ESP) 	SIB byte is present.	SIB byte is required for ESP-based addressing.	REX prefix adds a fourth bit (b), which is decoded and modifies the base register in the SIB byte. Therefore, the SIB byte is also required for R12-based addressing.
ModRM Byte: <ul style="list-style-type: none"> • mod = 00 • r/m¹ = x101 (EBP) 	Base register is not used.	Using EBP without a displacement must be done by setting mod = 01 with a displacement of 0 (with or without an index register).	REX prefix adds a fourth bit (x), which is not decoded (don't care). Therefore, using RBP or R13 without a displacement must be done via mod = 01 with a displacement of 0.
SIB Byte: <ul style="list-style-type: none"> • index¹ = x100 (ESP) 	Index register is not used.	ESP cannot be used as an index register.	REX prefix adds a fourth bit (x), which is decoded. Therefore, there are no additional implications. The expanded index field is used to distinguish RSP from R12, allowing R12 to be used as an index.
SIB Byte: <ul style="list-style-type: none"> • base = b101 (EBP) • ModRM.mod = 00 	Base register is not used if ModRM.mod = 00.	Base register depends on mod encoding. Using EBP with a scaled index and without a displacement must be done by setting mod = 01 with a displacement of 0.	REX prefix adds a fourth bit (b), which is not decoded (don't care). Therefore, using RBP or R13 without a displacement must be done via mod = 01 with a displacement of 0 (with or without an index register).
Notes: <ol style="list-style-type: none"> 1. The REX-prefix bit is shown in the fourth (most-significant) bit position of the encodings for the ModRM r/m, SIB index, and SIB base fields. The lower-case “x” for ModRM r/m (rather than the upper-case “B” shown in Figure 1-6 on page 28) indicates that the REX-prefix bit is not decoded (don't care). 2. For a description of the ModRM and SIB bytes, see “ModRM and SIB Bytes” on page 17. 			

Examples of Operand Addressing Extension Using REX

Case 1: Register-Register Addressing (No Memory Operand)

Case 2: Memory Addressing Without an SIB Byte

Case 3: Memory Addressing With an SIB Byte

Case 4: Register Operand Coded in Opcode Byte

v3_REX_reg_addr.eps

Figure 1-6. Encoding Examples Using REX R, X, and B Bits

1.9 Encoding Using the VEX and XOP Prefixes

An extended escape sequence is introduced by an encoding escape prefix which establishes the context and the format of the bytes that follow. The currently defined prefixes fall in two classes: the XOP and the VEX prefixes (of which there are two). The XOP prefix and the VEX C4h prefix introduce a three-byte sequence with identical syntax, while the VEX C5h prefix introduces a two-byte escape sequence with a different syntax.

These escape sequences supply fields used to extend operand specification as well as provide for the selection of alternate opcode maps. Encodings support up to two additional operands and the addressing of the extended (beyond 7) registers. The specification of two of the operands is accomplished using the legacy ModRM and optional SIB bytes with the reg, r/m, index, and base fields extended by one bit in a manner analogous to the REX prefix.

The encoding of the extended SSE instructions utilize extended escape sequences. XOP instructions use three-byte escape sequences introduced by the XOP prefix. The AVX, FMA, FMA4, and CLMUL instruction subsets use three-byte or two-byte escape sequences introduced by the VEX prefixes.

1.9.1 Three-Byte Escape Sequences

All the extended instructions can be encoded using a three-byte escape sequence, but certain VEX-encoded instructions that comply with the constraints described below in Section 1.9.2, “Two-Byte Escape Sequence” can also utilize a two-byte escape sequence. Figure 1-7 below shows the format of the three-byte escape sequence which is common to the XOP and VEX-based encodings.

Figure 1-7. VEX/XOP Three-byte Escape Sequence Format

Byte	Bit	Mnemonic	Description
0	[7:0]	VEX, XOP	Value specific to the extended instruction set
1	[7]	R	Inverted one-bit extension of ModRM <i>reg</i> field
	[6]	X	Inverted one-bit extension of SIB <i>index</i> field
	[5]	B	Inverted one-bit extension, <i>r/m</i> field or SIB <i>base</i> field
	[4:0]	map_select	Opcode map select

Byte	Bit	Mnemonic	Description
2	[7]	W	Default operand size override for a general purpose register to 64-bit size in 64-bit mode; operand configuration specifier for certain YMM/XMM-based operations.
	[6:3]	vvv	Source or destination register selector, in ones' complement format
	[2]	L	Vector length specifier
	[1:0]	pp	Implied 66, F2, or F3 opcode extension

Table 1-18. Three-byte Escape Sequence Field Definitions

Byte 0 (VEX/XOP Prefix)

Byte 0 is the encoding escape prefix byte which introduces the encoding escape sequence and establishes the context for the bytes that follow. The VEX and XOP prefixes have the following encodings:

- VEX prefix is encoded as C4h
- XOP prefix is encoded as 8Fh

Byte 1

VEX/XOP.R (Bit 7). The bit-inverted equivalent of the REX.R bit. A one-bit extension of the ModRM.reg field in 64-bit mode, permitting access to 16 YMM/XMM and GPR registers. In 32-bit protected and compatibility modes, the value must be 1.

VEX/XOP.X (Bit 6). The bit-inverted equivalent of the REX.X bit. A one-bit extension of the SIB.index field in 64-bit mode, permitting access to 16 YMM/XMM and GPR registers. In 32-bit protected and compatibility modes, this value must be 1.

VEX/XOP.B (Bit 5). The bit-inverted equivalent of the REX.B bit, available only in the 3-byte prefix format. A one-bit extension of either the ModRM.r/m field, to specify a GPR or XMM register, or of the SIB base field, to specify a GPR. This permits access to all 16 GPR and YMM/XMM registers. In 32-bit protected and compatibility modes, this bit is ignored.

VEX/XOP.map_select (Bits [4:0]). The five-bit map_select field is used to select an alternate opcode map. The map_select encoding spaces for VEX and XOP are disjoint. Table 1-19 below lists the encodings for VEX.map_select and Table 1-20 lists the encodings for XOP.map_select.

Table 1-19. VEX.map_select Encoding

Binary Value	Opcode Map	Analogous Legacy Opcode Map
00000	Reserved	–
00001	VEX opcode map 1	Secondary (“two-byte”) opcode map

Table 1-19. VEX.map_select Encoding

Binary Value	Opcode Map	Analogous Legacy Opcode Map
00010	VEX opcode map 2	0F_38h (“three-byte”) opcode map
00011	VEX opcode map 3	0F_3Ah (“three-byte”) opcode map
00100 – 11111	Reserved	–

Table 1-20. XOP.map_select Encoding

Binary Value	Opcode Map
00000 – 00111	Reserved
01000	XOP opcode map 8
01001	XOP opcode map 9
01010	XOP opcode map 10 (Ah)
01011 – 11111	Reserved

AVX instructions are encoded using the VEX opcode maps 1–3. The AVX instruction set includes instructions that provide operations similar to most legacy SSE instructions. For those AVX instructions that have an analogous legacy SSE instruction, the VEX opcode maps use the same binary opcode value and modifiers as the legacy version. The correspondence between the VEX opcode maps and the legacy opcode maps are shown in Table 1-19 above.

VEX opcode maps 1–3 are also used to encode the FMA4 and FMA instructions. In addition, not all legacy SSE instructions have AVX equivalents. Therefore, the VEX opcode maps are not the same as the legacy opcode maps.

The XOP opcode maps are unique to the XOP instructions. The XOP.map_select value is restricted to the range [08h:1Fh]. If the value of the XOP.map_select field is less than 8, the first two bytes of the three-byte XOP escape sequence are interpreted as a form of the POP instruction.

Both legacy and extended opcode maps are covered in detail in Appendix A.

Byte 2

VEX/XOP.W (Bit 7). Function is instruction-specific. The bit is often used to configure source operand order.

VEX/XOP.vvvv (Bits [6:3]). Used to specify an additional operand for three and four operand instructions. Encodes an XMM or YMM register in inverted ones’ complement form, as shown in Table 1-21.

Table 1-21. VEX/XOP.vvvv Encoding

Binary Value	Register	Binary Value	Register
0000	XMM15/YMM15	1000	XMM07/YMM07
0001	XMM14/YMM14	1001	XMM06/YMM06
0010	XMM13/YMM13	1010	XMM05/YMM05
0011	XMM12/YMM12	1011	XMM04/YMM04
0100	XMM11/YMM11	1100	XMM03/YMM03
0101	XMM10/YMM10	1101	XMM02/YMM02
0110	XMM09/YMM09	1110	XMM01/YMM01
0111	XMM08/YMM08	1111	XMM00/YMM00

Values 0000h to 0111h are not valid in 32-bit modes. *vvvv* is typically used to encode the first source operand, but for the *VPSLLDQ*, *VPSRLDQ*, *VPSRLW*, *VPSRLD*, *VPSRLQ*, *VPSRAW*, *VPSRAD*, *VPSLLW*, *VPSLLD*, and *VPSLLQ* shift instructions, the field specifies the destination register.

VEX/XOP.L (Bit 2). L = 0 specifies 128-bit vector length (XMM registers/128-bit memory locations). L=1 specifies 256-bit vector length (YMM registers/256-bit memory locations). For SSE or XOP instructions with scalar operands, the L bit is ignored. Some vector SSE instructions support only the 128 bit vector size. For these instructions, L is cleared to 0.

VEX/XOP.pp (Bits [1:0]). Specifies an implied 66h, F2h, or F3h opcode extension which is used in a way analogous to the legacy instruction encodings to extend the opcode encoding space. The correspondence between the encoding of the *VEX/XOP.pp* field and its function as an opcode modifier is shown in Table 1-22. The legacy prefixes 66h, F2h, and F3h are not allowed in the encoding of extended instructions.

Table 1-22. VEX/XOP.pp Encoding

Binary Value	Implied Prefix
00	None
01	66h
10	F3h
11	F2h

1.9.2 Two-Byte Escape Sequence

All VEX-encoded instructions can be encoded using the three-byte escape sequence, but certain instructions can also be encoded utilizing a more compact, two-byte VEX escape sequence. The format of the two-byte escape sequence is shown in Figure 1-8 below.

Figure 1-8. VEX Two-byte Escape Sequence Format

Prefix Byte	Bit	Mnemonic	Description
0	[7:0]	VEX	VEX 2-byte encoding escape prefix
1	[7]	R	Inverted one-bit extension of ModRM.reg field
	[6:3]	vvvv	Source or destination register selector, in ones' complement format.
	[2]	L	Vector length specifier
	[1:0]	pp	Implied 66, F2, or F3 opcode extension.

Table 1-23. VEX Two-byte Escape Sequence Field Definitions

Byte 0 (VEX Prefix)

The VEX prefix for the two-byte escape sequence is encoded as C5h.

Byte 1

Note that the bit 7 of this byte is used to encode VEX.R instead of VEX.W as in the three-byte escape sequence form. The R, vvvv, L, and pp fields are defined as in the three-byte escape sequence.

When the two-byte escape sequence is used, specific fields from the three-byte format take on fixed values as shown in Table 1-24 below.

Table 1-24. Fixed Field Values for VEX 2-Byte Format

VEX Field	Value
X	1
B	1
W	0
map_select	00001b

Although they may be encoded using the VEX three-byte escape sequence, all instructions that conform with the constraints listed in Table 1-24 may be encoded using the two-byte escape sequence. Note that the implied value of map_select is 00001b, which means that only instructions included in the VEX opcode map 1 may be encoded using this format.

VEX-encoded instructions that use the other defined values of map_select (00010b and 00011b) cannot be encoded using this a two-byte escape sequence format. Note that the VEX.pp field value is

explicitly encoded in this form and can be used to specify any of the implied legacy prefixes as defined in Table 1-22.

2 Instruction Overview

2.1 Instruction Groups

For easier reference, the instruction descriptions are divided into five groups based on usage. The following sections describe the function, mnemonic syntax, opcodes, affected flags, and possible exceptions generated by all instructions in the AMD64 architecture:

- *Chapter 3, “General-Purpose Instruction Reference”*—The general-purpose instructions are used in basic software execution. Most of these load, store, or operate on data in the general-purpose registers (GPRs), in memory, or in both. Other instructions are used to alter sequential program flow by branching to other locations within the program or to entirely different programs.
- *Chapter 4, “System Instruction Reference”*—The system instructions establish the processor operating mode, access processor resources, handle program and system errors, and manage memory.
- *“SSE Instruction Reference” in Volume 4*—The Streaming SIMD Extensions (SSE) instructions load, store, or operate on data located in the YMM/XMM registers. These instructions define both vector and scalar operations on floating-point and integer data types. They include the SSE and SSE2 instructions that operate on the YMM/XMM registers. Some of these instructions convert source operands in YMM/XMM registers to destination operands in GPR, MMX, or x87 registers or otherwise affect YMM/XMM state.
- *“64-Bit Media Instruction Reference” in Volume 5*—The 64-bit media instructions load, store, or operate on data located in the 64-bit MMX registers. These instructions define both vector and scalar operations on integer and floating-point data types. They include the legacy MMX™ instructions, the 3DNow!™ instructions, and the AMD extensions to the MMX and 3DNow! instruction sets. Some of these instructions convert source operands in MMX registers to destination operands in GPR, YMM/XMM, or x87 registers or otherwise affect MMX state.
- *“x87 Floating-Point Instruction Reference” in Volume 5*—The x87 instructions are used in legacy floating-point applications. Most of these instructions load, store, or operate on data located in the x87 ST(0)–ST(7) stack registers (the FPR0–FPR7 physical registers). The remaining instructions within this category are used to manage the x87 floating-point environment.

The description of each instruction covers its behavior in all operating modes, including legacy mode (real, virtual-8086, and protected modes) and long mode (compatibility and 64-bit modes). Details of certain kinds of complex behavior—such as control-flow changes in CALL, INT, or FXSAVE instructions—have cross-references in the instruction-detail pages to detailed descriptions in volumes 1 and 2.

Two instructions—CMPSD and MOVSD—use the same mnemonic for different instructions. Assemblers can distinguish them on the basis of the number and type of operands with which they are used.

2.2 Reference-Page Format

Figure 2-1 on page 37 shows the format of an instruction-detail page. The instruction mnemonic is shown in bold at the top-left, along with its name. In this example, **POPFD** is the mnemonic and *POP to EFLAGS Doubleword* is the name. Next, there is a general description of the instruction's operation. Many descriptions have cross-references to more detail in other parts of the manual.

Beneath the general description, the mnemonic is shown again, together with the related opcode(s) and a description summary. Related instructions are listed below this, followed by a table showing the flags that the instruction can affect. Finally, each instruction has a summary of the possible exceptions that can occur when executing the instruction. The columns labeled “Real” and “Virtual-8086” apply only to execution in legacy mode. The column labeled “Protected” applies both to legacy mode and long mode, because long mode is a superset of legacy protected mode.

The 128-bit and 64-bit media instructions also have diagrams illustrating the operation. A few instructions have examples or pseudocode describing the action.

Figure 2-1. Format of Instruction-Detail Pages

2.3 Summary of Registers and Data Types

This section summarizes the registers available to software using the five instruction subsets described in “Instruction Groups” on page 35. For details on the organization and use of these registers, see their respective chapters in volumes 1 and 2.

2.3.1 General-Purpose Instructions

Registers. The size and number of general-purpose registers (GPRs) depends on the operating mode, as do the size of the flags and instruction-pointer registers. Figure 2-2 shows the registers available in legacy and compatibility modes.

register encoding	high 8-bit	low 8-bit	16-bit	32-bit
0	AH (4)	AL	AX	EAX
3	BH (7)	BL	BX	EBX
1	CH (5)	CL	CX	ECX
2	DH (6)	DL	DX	EDX
6	SI		SI	ESI
7	DI		DI	EDI
5	BP		BP	EBP
4	SP		SP	ESP
	31	16 15		
	31		FLAGS	FLAGS EFLAGS
	31		IP	IP EIP
		0		

513-311.eps

Figure 2-2. General Registers in Legacy and Compatibility Modes

Figure 2-3 on page 39 shows the registers accessible in 64-bit mode. Compared with legacy mode, registers become 64 bits wide, eight new data registers (R8–R15) are added and the low byte of all 16 GPRs is available for byte operations, and the four high-byte registers of legacy mode (AH, BH, CH, and DH) are not available if the REX prefix is used. The high 32 bits of doubleword operands are zero-extended to 64 bits, but the high bits of word and byte operands are not modified by operations in 64-

bit mode. The RFLAGS register is 64 bits wide, but the high 32 bits are reserved. They can be written with anything but they read as zeros (RAZ).

* Not addressable in REX prefix instruction forms
 ** Only addressable in REX prefix instruction forms

GPRs_64b_mode.eps

Figure 2-3. General Registers in 64-Bit Mode

For most instructions running in 64-bit mode, access to the extended GPRs requires a either a REX instruction modification prefix or extended encoding encoding using the VEX or XOP sequences (page 14).

Figure 2-4 shows the segment registers which, like the instruction pointer, are used by all instructions. In legacy and compatibility modes, all segments are accessible. In 64-bit mode, which uses the flat (non-segmented) memory model, only the CS, FS, and GS segments are recognized, whereas the contents of the DS, ES, and SS segment registers are ignored (the base for each of these segments is assumed to be zero, and neither their segment limit nor attributes are checked). For details, see “Segmented Virtual Memory” in Volume 2.

Figure 2-4. Segment Registers

Data Types. Figure 2-5 on page 41 shows the general-purpose data types. They are all scalar, integer data types. The 64-bit (quadword) data types are only available in 64-bit mode, and for most instructions they require a REX instruction prefix.

Figure 2-5. General-Purpose Data Types

2.3.2 System Instructions

Registers. The system instructions use several specialized registers shown in Figure 2-6 on page 42. System software uses these registers to, among other things, manage the processor’s operating environment, define system resource characteristics, and monitor software execution. With the exception of the RFLAGS register, system registers can be read and written only from privileged software.

All system registers are 64 bits wide, except for the descriptor-table registers and the task register, which include 64-bit base-address fields and other fields.

System_Registers_Diag.eps

Figure 2-6. System Registers

Data Structures. Figure 2-7 on page 43 shows the system data structures. These are created and maintained by system software for use in protected mode. A processor running in protected mode uses these data structures to manage memory and protection, and to store program-state information when an interrupt or task switch occurs.

Figure 2-7. System Data Structures

2.3.3 SSE Instructions

Registers. The SSE instructions operate primarily on 128-bit and 256-bit floating-point vector operands located in the 256-bit YMM/XMM registers. Each 128-bit XMM register is defined as the lower octword of the corresponding YMM register. The number of available YMM/XMM data registers depends on the operating mode, as shown in Figure 2-8 below. In legacy and compatibility modes, eight YMM/XMM registers (YMM/XMM0–7) are available. In 64-bit mode, eight additional YMM/XMM data registers (YMM/XMM8–15) are available. These eight additional registers are addressed via the encoding extensions provided by the REX, VEX, and XOP prefixes.

The MXCSR register contains floating-point and other control and status flags used by the 128-bit media instructions. Some 128-bit media instructions also use the GPR (Figure 2-2 and Figure 2-3) and the MMX registers (Figure 2-12 on page 48) or set or clear flags in the rFLAGS register (see Figure 2-2 and Figure 2-3).

255	127	0
	XMM0	YMM0
	XMM1	YMM1
	XMM2	YMM2
	XMM3	YMM3
	XMM4	YMM4
	XMM5	YMM5
	XMM6	YMM6
	XMM7	YMM7
	XMM8	YMM8
	XMM9	YMM9
	XMM10	YMM10
	XMM11	YMM11
	XMM12	YMM12
	XMM13	YMM13
	XMM14	YMM14
	XMM15	YMM15

Figure 2-8. SSE Registers

Data Types. The SSE instruction set architecture provides support for 128-bit and 256-bit packed floating-point and integer data types as well as integer and floating-point scalars. Figure 2-9 below shows the 128-bit data types. Figure 2-10 on page 46 and Figure 2-11 on page 47 show the 256-bit data types. The floating-point data types include IEEE-754 single precision and double precision types.

Vector (Packed) Floating-Point – Double Precision and Single Precision

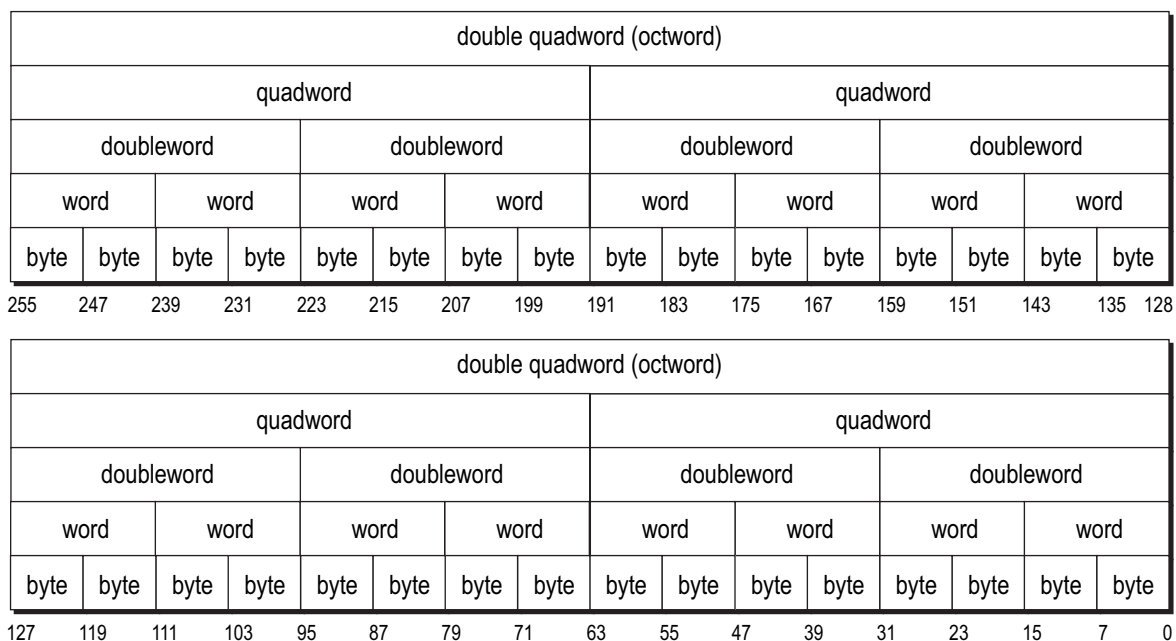

Vector (Packed) Signed Integer – Double Quadword, Quadword, Doubleword, Word, Byte

Scalar Floating-Point – Double Precision and Single Precision¹

Scalar Signed Integers

Scalar Unsigned Integers

Note: 1) A 16 bit Half-Precision Floating-Point Scalar is also defined.

256-bit datatypes_b.eps

Figure 2-11. SSE 256-Bit Data Types (Continued)

2.3.4 64-Bit Media Instructions

Registers. The 64-bit media instructions use the eight 64-bit MMX registers, as shown in Figure 2-12. These registers are mapped onto the x87 floating-point registers, and 64-bit media instructions write the x87 tag word in a way that prevents an x87 instruction from using MMX data.

Some 64-bit media instructions also use the GPR (Figure 2-2 and Figure 2-3) and the XMM registers (Figure 2-8).

513-327eps

Figure 2-12. 64-Bit Media Registers

Data Types. Figure 2-13 on page 49 shows the 64-bit media data types. They include floating-point and integer vectors and integer scalars. The floating-point data type, used by 3DNow! instructions, consists of a packed vector or two IEEE-754 32-bit single-precision data types. Unlike other kinds of floating-point instructions, however, the 3DNow!™ instructions do not generate floating-point exceptions. For this reason, there is no register for reporting or controlling the status of exceptions in the 64-bit-media instruction subset.

2.3.5 x87 Floating-Point Instructions

Registers. The x87 floating-point instructions use the x87 registers shown in Figure 2-14. There are eight 80-bit data registers, three 16-bit registers that hold the x87 control word, status word, and tag word, and three registers (last instruction pointer, last opcode, last data pointer) that hold information about the last x87 operation.

The physical data registers are named FPR0–FPR7, although x87 software references these registers as a stack of registers, named ST(0)–ST(7). The x87 instructions store operands only in their own 80-bit floating-point registers or in memory. They do not access the GPR or XMM registers.

Figure 2-14. x87 Registers

Data Types. Figure 2-15 on page 51 shows all x87 data types. They include three floating-point formats (80-bit double-extended precision, 64-bit double precision, and 32-bit single precision), three signed-integer formats (quadword, doubleword, and word), and an 80-bit packed binary-coded decimal (BCD) format.

513-317eps

Figure 2-15. x87 Data Types

2.4 Summary of Exceptions

Table 2-1 on page 52 lists all possible exceptions. The table shows the interrupt-vector numbers, names, mnemonics, source, and possible causes. Exceptions that apply to specific instructions are documented with each instruction in the instruction-detail pages that follow.

Table 2-1. Interrupt-Vector Source and Cause

Vector	Interrupt (Exception)	Mnemonic	Source	Cause
0	Divide-By-Zero-Error	#DE	Software	DIV, IDIV, AAM instructions
1	Debug	#DB	Internal	Instruction accesses and data accesses
2	Non-Maskable-Interrupt	#NMI	External	External NMI signal
3	Breakpoint	#BP	Software	INT3 instruction
4	Overflow	#OF	Software	INTO instruction
5	Bound-Range	#BR	Software	BOUND instruction
6	Invalid-Opcode	#UD	Internal	Invalid instructions
7	Device-Not-Available	#NM	Internal	x87 instructions
8	Double-Fault	#DF	Internal	Interrupt during an interrupt
9	Coprocessor-Segment-Overrun	—	External	Unsupported (reserved)
10	Invalid-TSS	#TS	Internal	Task-state segment access and task switch
11	Segment-Not-Present	#NP	Internal	Segment access through a descriptor
12	Stack	#SS	Internal	SS register loads and stack references
13	General-Protection	#GP	Internal	Memory accesses and protection checks
14	Page-Fault	#PF	Internal	Memory accesses when paging enabled
15	Reserved	—	—	—
16	Floating-Point Exception-Pending	#MF	Software	x87 floating-point and 64-bit media floating-point instructions
17	Alignment-Check	#AC	Internal	Memory accesses
18	Machine-Check	#MC	Internal External	Model specific
19	SIMD Floating-Point	#XF	Internal	128-bit media floating-point instructions
20—29	Reserved (Internal and External)	—	—	—
30	SVM Security Exception	#SX	External	Security-Sensitive Events
31	Reserved (Internal and External)	—	—	—
0—255	External Interrupts (Maskable)	#INTR	External	External interrupt signal
0—255	Software Interrupts	—	Software	INT n instruction

2.5 Notation

2.5.1 Mnemonic Syntax

Each instruction has a syntax that includes the mnemonic and any operands that the instruction can take. Figure 2-16 shows an example of a syntax in which the instruction takes two operands. In most

instructions that take two operands, the first (left-most) operand is both a source operand (the first source operand) and the destination operand. The second (right-most) operand serves only as a source, not a destination.

Figure 2-16. Syntax for Typical Two-Operand Instruction

The following notation is used to denote the size and type of source and destination operands:

- *cReg*—Control register.
- *dReg*—Debug register.
- *imm8*—Byte (8-bit) immediate.
- *imm16*—Word (16-bit) immediate.
- *imm16/32*—Word (16-bit) or doubleword (32-bit) immediate.
- *imm32*—Doubleword (32-bit) immediate.
- *imm32/64*—Doubleword (32-bit) or quadword (64-bit) immediate.
- *imm64*—Quadword (64-bit) immediate.
- *mem*—An operand of unspecified size in memory.
- *mem8*—Byte (8-bit) operand in memory.
- *mem16*—Word (16-bit) operand in memory.
- *mem16/32*—Word (16-bit) or doubleword (32-bit) operand in memory.
- *mem32*—Doubleword (32-bit) operand in memory.
- *mem32/48*—Doubleword (32-bit) or 48-bit operand in memory.
- *mem48*—48-bit operand in memory.
- *mem64*—Quadword (64-bit) operand in memory.
- *mem128*—Double quadword (128-bit) operand in memory.
- *mem16:16*—Two sequential word (16-bit) operands in memory.
- *mem16:32*—A doubleword (32-bit) operand followed by a word (16-bit) operand in memory.
- *mem32real*—Single-precision (32-bit) floating-point operand in memory.

- *mem32int*—Doubleword (32-bit) integer operand in memory.
- *mem64real*—Double-precision (64-bit) floating-point operand in memory.
- *mem64int*—Quadword (64-bit) integer operand in memory.
- *mem80real*—Double-extended-precision (80-bit) floating-point operand in memory.
- *mem80dec*—80-bit packed BCD operand in memory, containing 18 4-bit BCD digits.
- *mem2env*—16-bit x87 control word or x87 status word.
- *mem14/28env*—14-byte or 28-byte x87 environment. The x87 environment consists of the x87 control word, x87 status word, x87 tag word, last non-control instruction pointer, last data pointer, and opcode of the last non-control instruction completed.
- *mem94/108env*—94-byte or 108-byte x87 environment and register stack.
- *mem512env*—512-byte environment for 128-bit media, 64-bit media, and x87 instructions.
- *mmx*—Quadword (64-bit) operand in an MMX register.
- *mmx1*—Quadword (64-bit) operand in an MMX register, specified as the left-most (first) operand in the instruction syntax.
- *mmx2*—Quadword (64-bit) operand in an MMX register, specified as the right-most (second) operand in the instruction syntax.
- *mmx/mem32*—Doubleword (32-bit) operand in an MMX register or memory.
- *mmx/mem64*—Quadword (64-bit) operand in an MMX register or memory.
- *mmx1/mem64*—Quadword (64-bit) operand in an MMX register or memory, specified as the left-most (first) operand in the instruction syntax.
- *mmx2/mem64*—Quadword (64-bit) operand in an MMX register or memory, specified as the right-most (second) operand in the instruction syntax.
- *moffset*—Direct memory offset that specifies an operand in memory.
- *moffset8*—Direct memory offset that specifies a byte (8-bit) operand in memory.
- *moffset16*—Direct memory offset that specifies a word (16-bit) operand in memory.
- *moffset32*—Direct memory offset that specifies a doubleword (32-bit) operand in memory.
- *moffset64*—Direct memory offset that specifies a quadword (64-bit) operand in memory.
- *pntr16:16*—Far pointer with 16-bit selector and 16-bit offset.
- *pntr16:32*—Far pointer with 16-bit selector and 32-bit offset.
- *reg*—Operand of unspecified size in a GPR register.
- *reg8*—Byte (8-bit) operand in a GPR register.
- *reg16*—Word (16-bit) operand in a GPR register.
- *reg16/32*—Word (16-bit) or doubleword (32-bit) operand in a GPR register.
- *reg32*—Doubleword (32-bit) operand in a GPR register.
- *reg64*—Quadword (64-bit) operand in a GPR register.
- *reg/mem8*—Byte (8-bit) operand in a GPR register or memory.

- *reg/mem16*—Word (16-bit) operand in a GPR register or memory.
- *reg/mem32*—Doubleword (32-bit) operand in a GPR register or memory.
- *reg/mem64*—Quadword (64-bit) operand in a GPR register or memory.
- *rel8off*—Signed 8-bit offset relative to the instruction pointer.
- *rel16off*—Signed 16-bit offset relative to the instruction pointer.
- *rel32off*—Signed 32-bit offset relative to the instruction pointer.
- *segReg* or *sReg*—Word (16-bit) operand in a segment register.
- *ST(0)*—x87 stack register 0.
- *ST(i)*—x87 stack register *i*, where *i* is between 0 and 7.
- *xmm*—Double quadword (128-bit) operand in an XMM register.
- *xmm1*—Double quadword (128-bit) operand in an XMM register, specified as the left-most (first) operand in the instruction syntax.
- *xmm2*—Double quadword (128-bit) operand in an XMM register, specified as the right-most (second) operand in the instruction syntax.
- *xmm/mem64*—Quadword (64-bit) operand in a 128-bit XMM register or memory.
- *xmm/mem128*—Double quadword (128-bit) operand in an XMM register or memory.
- *xmm1/mem128*—Double quadword (128-bit) operand in an XMM register or memory, specified as the left-most (first) operand in the instruction syntax.
- *xmm2/mem128*—Double quadword (128-bit) operand in an XMM register or memory, specified as the right-most (second) operand in the instruction syntax.
- *ymm*—Double octword (256-bit) operand in an YMM register.
- *ymm1*—Double octword (256-bit) operand in an YMM register, specified as the left-most (first) operand in the instruction syntax.
- *ymm2*—Double octword (256-bit) operand in an YMM register, specified as the right-most (second) operand in the instruction syntax.
- *ymm/mem64*—Quadword (64-bit) operand in a 256-bit YMM register or memory.
- *ymm/mem128*—Double quadword (128-bit) operand in an YMM register or memory.
- *ymm1/mem256*—Double octword (256-bit) operand in an YMM register or memory, specified as the left-most (first) operand in the instruction syntax.
- *ymm2/mem256*—Double octword (256-bit) operand in an YMM register or memory, specified as the right-most (second) operand in the instruction syntax.

2.5.2 Opcode Syntax

In addition to the notation shown above in “Mnemonic Syntax” on page 52, the following notation indicates the size and type of operands in the syntax of an instruction opcode:

- */digit*—Indicates that the ModRM byte specifies only one register or memory (r/m) operand. The digit is specified by the ModRM reg field and is used as an instruction-opcode extension. Valid digit values range from 0 to 7.
- */r*—Indicates that the ModRM byte specifies both a register operand and a reg/mem (register or memory) operand.
- *cb, cw, cd, cp*—Specifies a code-offset value and possibly a new code-segment register value. The value following the opcode is either one byte (*cb*), two bytes (*cw*), four bytes (*cd*), or six bytes (*cp*).
- *ib, iw, id, iq*—Specifies an immediate-operand value. The opcode determines whether the value is signed or unsigned. The value following the opcode, ModRM, or SIB byte is either one byte (*ib*), two bytes (*iw*), or four bytes (*id*). Word and doubleword values start with the low-order byte.
- *+rb, +rw, +rd, +rq*—Specifies a register value that is added to the hexadecimal byte on the left, forming a one-byte opcode. The result is an instruction that operates on the register specified by the register code. Valid register-code values are shown in Table 2-2.
- *m64*—Specifies a quadword (64-bit) operand in memory.
- *+i*—Specifies an x87 floating-point stack operand, *ST(i)*. The value is used only with x87 floating-point instructions. It is added to the hexadecimal byte on the left, forming a one-byte opcode. Valid values range from 0 to 7.

Table 2-2. +rb, +rw, +rd, and +rq Register Value

REX.B Bit ¹	Value	Specified Register			
		+rb	+rw	+rd	+rq
0 or no REX Prefix	0	AL	AX	EAX	RAX
	1	CL	CX	ECX	RCX
	2	DL	DX	EDX	RDX
	3	BL	BX	EBX	RBX
	4	AH, SPL ¹	SP	ESP	RSP
	5	CH, BPL ¹	BP	EBP	RBP
	6	DH, SIL ¹	SI	ESI	RSI
	7	BH, DIL ¹	DI	EDI	RDI
1	0	R8B	R8W	R8D	R8
	1	R9B	R9W	R9D	R9
	2	R10B	R10W	R10D	R10
	3	R11B	R11W	R11D	R11
	4	R12B	R12W	R12D	R12
	5	R13B	R13W	R13D	R13
	6	R14B	R14W	R14D	R14
	7	R15B	R15W	R15D	R15

1. See "REX Prefix" on page 14.

2.5.3 Pseudocode Definition

Pseudocode examples are given for the actions of several complex instructions (for example, see “CALL (Near)” on page 124). The following definitions apply to all such pseudocode examples:

```

/////////////////////////////////////////////////////////////////
// Pseudo Code Definition
/////////////////////////////////////////////////////////////////
//
// Comments start with double slashes.
//
// '=' can mean "is", or assignment based on context
// '==' is the equals comparison operator
//
/////////////////////////////////////////////////////////////////
// Constants
/////////////////////////////////////////////////////////////////

0                // numbers are in base-10 (decimal), unless followed by a suffix
0000_0001b      // a number in binary notation, underbars added for readability
FFEO_0000h      // a number expressed in hexadecimal notation

// in the following, '&&' is the logical AND operator. See "Logical Operators"
// below.
// reg[fld] identifies a field (one or more bits) within architected register
// or within a sub-element of a larger data structure. A dot separates the
// higher-level data structure name from the sub-element name.
//
CS.desc = Code Segment descriptor // CS.desc has sub-elements: base, limit, attr
SS.desc = Stack Segment descriptor // SS.desc has the same sub-elements
CS.desc.base = base subfield of CS.desc
CS = Code Segment Register
SS = Stack Segment Register
CPL = Current Privilege Level (0 <= CPL <= 3)
REAL_MODE = (CR0[PE] == 0)
PROTECTED_MODE = ((CR0[PE] == 1) && (RFLAGS[VM] == 0))
VIRTUAL_MODE = ((CR0[PE] == 1) && (RFLAGS[VM] == 1))
LEGACY_MODE = (EFER[LMA] == 0)
LONG_MODE = (EFER[LMA] == 1)
64BIT_MODE = ((EFER[LMA]==1) && (CS_desc.attr[L] == 1) && (CS_desc.attr[D] == 0))
COMPATIBILITY_MODE = (EFER[LMA] == 1) && (CS_desc.attr[L] == 0)
PAGING_ENABLED = (CR0[PG] == 1)
ALIGNMENT_CHECK_ENABLED = ((CR0[AM] == 1) && (RFLAGS[AC] == 1) && (CPL == 3))

OPERAND_SIZE = 16, 32, or 64 // size, in bits, of an operand
// OPERAND_SIZE depends on processor mode, the current code segment descriptor
// default operand size [D], presence of the operand size override prefix (66h)
// and, in 64-bit mode, the REX prefix.
// NOTE: Specific instructions take 8-bit operands, but for these instructions,
// operand size is fixed and the variable OPERAND_SIZE is not needed.

ADDRESS_SIZE = 16, 32, or 64 // size, in bits, of the effective address for

```

```

// memory reads. ADDRESS_SIZE depends processor mode, the current code segment

            // if IST is selected, read an ISTn stack pointer from the tss
            temp_RSP = READ_MEM.q [tss:ist_index*8+28]
        ELSE // (ist_index==0)
            // otherwise read an RSPn stack pointer from the tss
            temp_RSP = READ_MEM.q [tss:new_cpl*8+4]

        temp_SS_desc.sel = NULL + new_cpl
            // in long mode, changing to lower cpl sets SS.sel to
            // NULL+new_cpl
    }
    ELSE // (LEGACY_MODE)
    {
        temp_RSP = READ_MEM.d [tss:new_cpl*8+4]           // read ESPn from the tss
        temp_sel = READ_MEM.d [tss:new_cpl*8+8]           // read SSn from the tss
        temp_SS_desc = READ_DESCRIPTOR (temp_sel, ss_chk)
    }

    return (temp_RSP:temp_SS_desc)

////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
// READ_BIT_ARRAY // Read 1 bit from a bit array in memory
////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////

usage:
    temp_value = READ_BIT_ARRAY ([mem], bit_number)

definition:

    temp_BYTE = READ_MEM.b [mem + (bit_number SHR 3)]
                // read the byte containing the bit

```

```
temp_BIT = temp_BYTE SHR (bit_number & 7)
           // shift the requested bit position into bit 0

return (temp_BIT & 0x01) // return '0' or '1'
```

3 General-Purpose Instruction Reference

This chapter describes the function, mnemonic syntax, opcodes, affected flags, and possible exceptions generated by the general-purpose instructions. General-purpose instructions are used in basic software execution. Most of these instructions load, store, or operate on data located in the general-purpose registers (GPRs), in memory, or in both. The remaining instructions are used to alter the sequential flow of the program by branching to other locations within the program, or to entirely different programs. With the exception of the MOVD, MOVMSKPD and MOVMSKPS instructions, which operate on MMX/XMM registers, the instructions within the category of general-purpose instructions do not operate on any other register set.

Most general-purpose instructions are supported in all hardware implementations of the AMD64 architecture. However, some instructions in this group are optional and support must be determined by testing processor feature flags using the CPUID instruction. These instructions are listed in Table 3-1, along with the CPUID function, the register and bit used to test for the presence of the instruction.

Table 3-1. Instruction Support Indicated by CPUID Feature Bits

Instruction	CPUID Function(s)	Register[Bit]	Feature Flag
Bit Manipulation Instructions - group 1	0000_0007h (ECX=0)	EBX[3]	BMI1
Bit Manipulation Instructions - group 2	0000_0007h (ECX=0)	EBX[8]	BMI2
CMPXCHG8B	0000_0001h, 8000_0001h	EDX[8]	CMPXCHG8B
CMPXCHG16B	0000_0001h	ECX[13]	CMPXCHG16B
CMOVcc (Conditional Moves)	0000_0001h, 8000_0001h	EDX[15]	CMOV
CLFLUSH	0000_0001h	EDX[19]	CLFSH
CRC32	0000_0001h	ECX[20]	SSE42
LZCNT	8000_0001h	ECX[5]	ABM
Long Mode and Long Mode instructions	8000_0001h	EDX[29]	LM
MFENCE, LFENCE	0000_0001h	EDX[26]	SSE2
MOVBE	0000_0001h	ECX[22]	MOVBE
MOVD ¹	0000_0001h, 8000_0001h	EDX[23]	MMX
	0000_0001h	EDX[26]	SSE2
MOVNTI	0000_0001h	EDX[26]	SSE2
POPCNT	0000_0001h	ECX[23]	POPCNT
PREFETCH / PREFETCHW ²	8000_0001h	ECX[8]	3DNowPrefetch
		EDX[29]	LM
		EDX[31]	3DNow
RDFSBASE, RDGSBASE WRFSBASE, WRGSBASE	0000_0007h (ECX=0)	EBX[0]	FSGSBASE

Table 3-1. Instruction Support Indicated by CPUID Feature Bits

Instruction	CPUID Function(s)	Register[Bit]	Feature Flag
SFENCE	0000_0001h	EDX[25]	SSE
Trailing Bit Manipulation Instructions	8000_0001h	ECX[21]	TBM
Notes:			
1. The MOVD variant that moves values to or from MMX registers is part of the MMX subset; the MOVD variant that moves data to or from XMM registers is part of the SSE2 subset.			
2. Instruction is supported if any one of the listed feature flags is set.			

For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153. For a comprehensive list of all instruction support feature flags, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

The general-purpose instructions can be used in legacy mode or 64-bit long mode. Compilation of general-purpose programs for execution in 64-bit long mode offers three primary advantages: access to the eight extended, 64-bit general-purpose registers (for a register set consisting of GPR0–GPR15), access to the 64-bit virtual address space, and access to the RIP-relative addressing mode.

For further information about the general-purpose instructions and register resources, see:

- “General-Purpose Programming” in Volume 1.
- “Summary of Registers and Data Types” on page 38.
- “Notation” on page 52.
- “Instruction Prefixes” on page 5.
- Appendix B, “General-Purpose Instructions in 64-Bit Mode.” In particular, see “General Rules for 64-Bit Mode” on page 487.

AAA

ASCII Adjust After Addition

Adjusts the value in the AL register to an unpacked BCD value. Use the AAA instruction after using the ADD instruction to add two unpacked BCD numbers.

The instruction is coded without explicit operands:

```
AAA
```

If the value in the lower nibble of AL is greater than 9 or the AF flag is set to 1, the instruction increments the AH register, adds 6 to the AL register, and sets the CF and AF flags to 1. Otherwise, it does not change the AH register and clears the CF and AF flags to 0. In either case, AAA clears bits 7:4 of the AL register, leaving the correct decimal digit in bits 3:0.

This instruction also makes it possible to add ASCII numbers without having to mask off the upper nibble ‘3’.

MXCSR Flags Affected

Using this instruction in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
AAA	37	Create an unpacked BCD number. (Invalid in 64-bit mode.)

Related Instructions

AAD, AAM, AAS

rFLAGS Affected

ID	VIP	VIF	AC	VM	RF	NT	IOPL	OF	DF	IF	TF	SF	ZF	AF	PF	CF
								U				U	U	M	U	M
21	20	19	18	17	16	14	13:12	11	10	9	8	7	6	4	2	0

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to 1 or cleared to 0 is M (modified). Unaffected flags are blank. Undefined flags are U.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD			X	This instruction was executed in 64-bit mode.

AAD**ASCII Adjust Before Division**

Converts two unpacked BCD digits in the AL (least significant) and AH (most significant) registers to a single binary value in the AL register.

The instruction is coded without explicit operands:

AAD

The instruction performs the following operation on the contents of AL and AH using the formula:

$$AL = ((10d * AH) + (AL))$$

After the conversion, AH is cleared to 00h.

In most modern assemblers, the AAD instruction adjusts from base-10 values. However, by coding the instruction directly in binary, it can adjust from any base specified by the immediate byte value (*ib*) suffixed onto the D5h opcode. For example, code D508h for octal, D50Ah for decimal, and D50Ch for duodecimal (base 12).

Using this instruction in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
AAD	D5 0A	Adjust two BCD digits in AL and AH. (Invalid in 64-bit mode.)
(None)	D5 <i>ib</i>	Adjust two BCD digits to the immediate byte base. (Invalid in 64-bit mode.)

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to 1 or cleared to 0 is M (modified). Unaffected flags are blank. Undefined flags are U.																

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD			X	This instruction was executed in 64-bit mode.

AAM

ASCII Adjust After Multiply

Converts the value in the AL register from binary to two unpacked BCD digits in the AH (most significant) and AL (least significant) registers.

The instruction is coded without explicit operands:

AAM

The instruction performs the following operation on the contents of AL and AH using the formula:

$$\begin{aligned} \text{AH} &= (\text{AL}/10\text{d}) \\ \text{AL} &= (\text{AL} \bmod 10\text{d}) \end{aligned}$$

In most modern assemblers, the AAM instruction adjusts to base-10 values. However, by coding the instruction directly in binary, it can adjust to any base specified by the immediate byte value (*ib*) suffixed onto the D4h opcode. For example, code D408h for octal, D40Ah for decimal, and D40Ch for duodecimal (base 12).

Using this instruction in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
AAM	D4 0A	Create a pair of unpacked BCD values in AH and AL. (Invalid in 64-bit mode.)
(None)	D4 <i>ib</i>	Create a pair of unpacked values to the immediate byte base. (Invalid in 64-bit mode.)

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Divide by zero, #DE	X	X	X	8-bit immediate value was 0.
Invalid opcode, #UD			X	This instruction was executed in 64-bit mode.

AAS

ASCII Adjust After Subtraction

Adjusts the value in the AL register to an unpacked BCD value. Use the AAS instruction after using the SUB instruction to subtract two unpacked BCD numbers.

The instruction is coded without explicit operands:

AAS

If the value in AL is greater than 9 or the AF flag is set to 1, the instruction decrements the value in AH, subtracts 6 from the AL register, and sets the CF and AF flags to 1. Otherwise, it clears the CF and AF flags and the AH register is unchanged. In either case, the instruction clears bits 7:4 of the AL register, leaving the correct decimal digit in bits 3:0.

Using this instruction in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
AAS	3F	Create an unpacked BCD number from the contents of the AL register. (Invalid in 64-bit mode.)

ADC

Add with Carry

Adds the carry flag (CF), the value in a register or memory location (first operand), and an immediate value or the value in a register or memory location (second operand), and stores the result in the first operand location.

The instruction has two operands:

ADC dest, src

The instruction cannot add two memory operands. The CF flag indicates a pending carry from a previous addition operation. The instruction sign-extends an immediate value to the length of the destination register or memory location.

This instruction evaluates the result for both signed and unsigned data types and sets the OF and CF flags to indicate a carry in a signed or unsigned result, respectively. It sets the SF flag to indicate the sign of a signed result.

Use the ADC instruction after an ADD instruction as part of a multibyte or multiword addition.

The forms of the ADC instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
ADC AL, <i>imm8</i>	14 <i>ib</i>	Add <i>imm8</i> to AL + CF.
ADC AX, <i>imm16</i>	15 <i>iw</i>	Add <i>imm16</i> to AX + CF.
ADC EAX, <i>imm32</i>	15 <i>id</i>	Add <i>imm32</i> to EAX + CF.
ADC RAX, <i>imm32</i>	15 <i>id</i>	Add sign-extended <i>imm32</i> to RAX + CF.
ADC <i>reg/mem8, imm8</i>	80 <i>/2 ib</i>	Add <i>imm8</i> to <i>reg/mem8</i> + CF.
ADC <i>reg/mem16, imm16</i>	81 <i>/2 iw</i>	Add <i>imm16</i> to <i>reg/mem16</i> + CF.
ADC <i>reg/mem32, imm32</i>	81 <i>/2 id</i>	Add <i>imm32</i> to <i>reg/mem32</i> + CF.
ADC <i>reg/mem64, imm32</i>	81 <i>/2 id</i>	Add sign-extended <i>imm32</i> to <i>reg/mem64</i> + CF.

AND

Logical AND

Performs a bit-wise logical and operation on the value in a register or memory location (first operand) and an immediate value or the value in a register or memory location (second operand), and stores the result in the first operand location. Both operands cannot be memory locations.

The instruction has two operands:

`AND dest, src`

The instruction sets each bit of the result to 1 if the corresponding bit of both operands is set; otherwise, it clears the bit to 0. The following table shows the truth table for the logical and operation:

X	Y	X and Y
0	0	0
0	1	0
1	0	0
1	1	1

The forms of the AND instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
AND AL, <i>imm8</i>	24 <i>ib</i>	and the contents of AL with an immediate 8-bit value and store the result in AL.
AND AX, <i>imm16</i>	25 <i>iw</i>	and the contents of AX with an immediate 16-bit value and store the result in AX.
AND EAX, <i>imm32</i>	25 <i>id</i>	and the contents of EAX with an immediate 32-bit value and store the result in EAX.

ANDN

Logical And-Not

Performs a bit-wise logical `and` of the second source operand and the one's complement of the first source operand and stores the result into the destination operand.

This instruction has three operands:

`ANDN dest, src1, src2`

In 64-bit mode, the operand size is determined by the value of `VEX.W`. If `VEX.W` is 1, the operand size is 64-bit; if `VEX.W` is 0, the operand size is 32-bit. In 32-bit mode, `VEX.W` is ignored. 16-bit operands are not supported.

The destination operand (*dest*) is always a general purpose register.

The first source operand (*src1*) is a general purpose register and the second source operand (*src2*) is either a general purpose register or a memory operand.

This instruction implements the following operation:

```
not tmp, src1
and dest, tmp, src2
```

The flags are set according to the result of the `and` pseudo-operation.

The `ANDN` instruction is a BMI1 instruction. Support for this instruction is indicated by `CPUID Fn0000_0007_EBX_x0[BMI1] = 1`.

For more information on using the `CPUID` instruction, see the instruction reference page for the `CPUID` instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and `CPUID` Feature Flags,” on page 519.

Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

BEXTR (register form)

Bit Field Extract

Extracts a contiguous field of bits from the first source operand, as specified by the control field setting in the second source operand and puts the extracted field into the least significant bit positions of the destination. The remaining bits in the destination register are cleared to 0.

This instruction has three operands:

BEXTR *dest, src, cntl*

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64-bit; if VEX.W is 0, the operand size is 32-bit. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is either a general purpose register or a memory operand.

The control (*cntl*) operand is a general purpose register that provides two fields describing the range of bits to extract:

- *lsb_index* (in bits 7:0)—specifies the index of the least significant bit of the field
- *length* (in bits 15:8)—specifies the number of bits in the field.

The position of the extracted field can be expressed as:

$$[lsb_index + length - 1] : [lsb_index]$$

For example, if the *lsb_index* is 7 and *length* is 5, then bits 11:7 of the source will be copied to bits 4:0 of the destination, with the rest of the destination being zero-filled. Zeros are provided for any bit positions in the specified range that lie beyond the most significant bit of the source operand. A length value of zero results in all zeros being written to the destination.

This form of the BEXTR instruction is a BMI1 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI1] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BEXTR (immediate form)

Bit Field Extract

Extracts a contiguous field of bits from the first source operand, as specified by the control field setting in the second source operand and puts the extracted field into the least significant bit positions of the destination. The remaining bits in the destination register are cleared to 0.

This instruction has three operands:

BEXTR *dest, src, cntl*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is either a general purpose register or a memory operand.

The control (*cntl*) operand is a 32-bit immediate value that provides two fields describing the range of bits to extract:

- *lsb_index* (in immediate operand bits 7:0)—specifies the index of the least significant bit of the field
- *length* (in immediate operand bits 15:8)—specifies the number of bits in the field.

The position of the extracted field can be expressed as:

$$[lsb_index + length - 1] : [lsb_index]$$

For example, if the *lsb_index* is 7 and *length* is 5, then bits 11:7 of the source will be copied to bits 4:0 of the destination, with the rest of the destination being zero-filled. Zeros are provided for any bit positions in the specified range that lie beyond the most significant bit of the source operand. A length value of zero results in all zeros being written to the destination.

This form of the BEXTR instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM]=1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLCFILL

Fill From Lowest Clear Bit

Finds the least significant zero bit in the source operand, clears all bits below that bit to 0 and writes the result to the destination. If there is no zero bit in the source operand, the destination is written with all zeros.

This instruction has two operands:

`BLCFILL dest, src`

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLCFILL instruction effectively performs a bit-wise logical `and` of the source operand and the result of incrementing the source operand by 1 and stores the result to the destination register:

```
add tmp, src, 1
and dest, tmp, src
```

The value of the carry flag of rFLAGS is generated according to the result of the `add` pseudo-instruction and the remaining arithmetic flags are generated by the `and` pseudo-instruction.

The BLCFILL instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLCI

Isolate Lowest Clear Bit

Finds the least significant zero bit in the source operand, sets all other bits to 1 and writes the result to the destination. If there is no zero bit in the source operand, the destination is written with all ones.

This instruction has two operands:

BLCI *dest, src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLCI instruction effectively performs a bit-wise logical OR of the source operand and the inverse of the result of incrementing the source operand by 1, and stores the result to the destination register:

```
add tmp, src, 1
not tmp, tmp
or dest, tmp, src
```

The value of the carry flag of rFLAGS is generated according to the result of the `add` pseudo-instruction and the remaining arithmetic flags are generated by the `or` pseudo-instruction.

The BLCI instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLCIC Isolate Lowest Clear Bit and Complement

Finds the least significant zero bit in the source operand, sets that bit to 1, clears all other bits to 0 and writes the result to the destination. If there is no zero bit in the source operand, the destination is written with all zeros.

This instruction has two operands:

BLCIC *dest*, *src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLCIC instruction effectively performs a bit-wise logical `and` of the negation of the source operand and the result of incrementing the source operand by 1, and stores the result to the destination register:

```
add tmp1, src, 1
not tmp2, src
and dest, tmp1, tmp2
```

The value of the carry flag of rFLAGS is generated according to the result of the `add` pseudo-instruction and the remaining arithmetic flags are generated by the `and` pseudo-instruction.

The BLCIC instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLCMSK

Mask From Lowest Clear Bit

Finds the least significant zero bit in the source operand, sets that bit to 1, clears all bits above that bit to 0 and writes the result to the destination. If there is no zero bit in the source operand, the destination is written with all ones.

This instruction has two operands:

BLCMSK *dest*, *src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLCMSK instruction effectively performs a bit-wise logical XOR of the source operand and the result of incrementing the source operand by 1 and stores the result to the destination register:

```
add tmp1, src, 1
xor dest, tmp1, src
```

The value of the carry flag of rFLAGS is generated according to the result of the add pseudo-instruction and the remaining arithmetic flags are generated by the xor pseudo-instruction.

If the input is all ones, the output is a value with all bits set to 1.

The BLCMSK instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLCS

Set Lowest Clear Bit

Finds the least significant zero bit in the source operand, sets that bit to 1 and writes the result to the destination. If there is no zero bit in the source operand, the source is copied to the destination (and CF in rFLAGS is set to 1).

This instruction has two operands:

BLCS *dest*, *src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLCS instruction effectively performs a bit-wise logical `OR` of the source operand and the result of incrementing the source operand by 1, and stores the result to the destination register:

```
add tmp, src, 1
or dest, tmp, src
```

The value of the carry flag of rFLAGS is generated by the `add` pseudo-instruction and the remaining arithmetic flags are generated by the `or` pseudo-instruction.

The BLCS instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLSFILL

Fill From Lowest Set Bit

Finds the least significant one bit in the source operand, sets all bits below that bit to 1 and writes the result to the destination. If there is no one bit in the source operand, the destination is written with all ones.

This instruction has two operands:

BLSFILL *dest*, *src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLSFILL instruction effectively performs a bit-wise logical OR of the source operand and the result of subtracting 1 from the source operand, and stores the result to the destination register:

```
sub tmp, src, 1
or dest, tmp, src
```

The value of the carry flag of rFLAGS is generated by the `sub` pseudo-instruction and the remaining arithmetic flags are generated by the `or` pseudo-instruction.

The BLSFILL instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLSI

Isolate Lowest Set Bit

Clears all bits in the source operand except for the least significant bit that is set to 1 and writes the result to the destination. If the source is all zeros, the destination is written with all zeros.

This instruction has two operands:

BLSI *dest*, *src*

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64-bit; if VEX.W is 0, the operand size is 32-bit. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is either a general purpose register or a bit memory operand.

This instruction implements the following operation:

```
neg tmp, src1
and dst, tmp, src1
```

The value of the carry flag is generated by the `neg` pseudo-instruction and the remaining status flags are generated by the `and` pseudo-instruction.

The BLSI instruction is a BMI1 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI1] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLSIC Isolate Lowest Set Bit and Complement

Finds the least significant bit that is set to 1 in the source operand, clears that bit to 0, sets all other bits to 1 and writes the result to the destination. If there is no one bit in the source operand, the destination is written with all ones.

This instruction has two operands:

BLSIC *dest*, *src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The BLSIC instruction effectively performs a bit-wise logical OR of the inverse of the source operand and the result of subtracting 1 from the source operand, and stores the result to the destination register:

```
sub tmp1, src, 1
not tmp2, src
or dest, tmp1, tmp2
```

The value of the carry flag of rFLAGS is generated by the `sub` pseudo-instruction and the remaining arithmetic flags are generated by the `or` pseudo-instruction.

The BLSR instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Encoding

BLSMSK

Mask From Lowest Set Bit

Forms a mask with bits set to 1 from bit 0 up to and including the least significant bit position that is set to 1 in the source operand and writes the mask to the destination. If the value of the source operand is zero, the destination is written with all ones.

This instruction has two operands:

BLSMSK *dest, src*

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64-bit; if VEX.W is 0, the operand size is 32-bit. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is always a general purpose register.

The source operand (*src*) is either a general purpose register or a memory operand and the destination operand (*dest*) is a general purpose register.

This instruction implements the operation:

```
sub tmp, src1, 1
xor dst, tmp, src1
```

The value of the carry flag is generated by the `sub` pseudo-instruction and the remaining status flags are generated by the `xor` pseudo-instruction.

If the input is zero, the output is a value with all bits set to 1. If this is considered a corner case input, software may test the carry flag to detect the zero input value.

The BLSMSK instruction is a BMI1 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI1] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BLSR

Reset Lowest Set Bit

Clears the least-significant bit that is set to 1 in the input operand and writes the modified operand to the destination.

This instruction has two operands:

BLSR *dest, src*

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64-bit; if VEX.W is 0, the operand size is 32-bit. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is always a general purpose register.

The source operand (*src*) is either a general purpose register or a memory operand.

This instruction implements the operation:

```
sub tmp, src1, 1
and dst, tmp, src1
```

The value of the carry flag is generated by the `sub` pseudo-instruction and the remaining status flags are generated by the `and` pseudo-instruction.

The BLSR instruction is a BMI1 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI1] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

BOUND

Check Array Bound

Checks whether an array index (first operand) is within the bounds of an array (second operand). The array index is a signed integer in the specified register. If the operand-size attribute is 16, the array operand is a memory location containing a pair of signed word-integers; if the operand-size attribute is 32, the array operand is a pair of signed doubleword-integers. The first word or doubleword specifies the lower bound of the array and the second word or doubleword specifies the upper bound.

The array index must be greater than or equal to the lower bound and less than or equal to the upper bound. If the index is not within the specified bounds, the processor generates a BOUND range-exceeded exception (#BR).

The bounds of an array, consisting of two words or doublewords containing the lower and upper limits of the array, usually reside in a data structure just before the array itself, making the limits addressable through a constant offset from the beginning of the array. With the address of the array in a register, this practice reduces the number of bus cycles required to determine the effective address of the array bounds.

Using this instruction in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
BOUND <i>reg16, mem16&mem16</i>	62 /r	Test whether a 16-bit array index is within the bounds specified by the two 16-bit values in <i>mem16&mem16</i> . (Invalid in 64-bit mode.)
BOUND <i>reg32, mem32&mem32</i>	62 /r	Test whether a 32-bit array index is within the bounds specified by the two 32-bit values in <i>mem32&mem32</i> . (Invalid in 64-bit mode.)

BSF

Bit Scan Forward

Searches the value in a register or a memory location (second operand) for the least-significant set bit. If a set bit is found, the instruction clears the zero flag (ZF) and stores the index of the least-significant set bit in a destination register (first operand). If the second operand contains 0, the instruction sets ZF to 1 and does not change the contents of the destination register. The bit index is an unsigned offset from bit 0 of the searched value.

Mnemonic	Opcode	Description
BSF <i>reg16, reg/mem16</i>	0F BC /r	Bit scan forward on the contents of <i>reg/mem16</i> .
BSF <i>reg32, reg/mem32</i>	0F BC /r	Bit scan forward on the contents of <i>reg/mem32</i> .

BSR

Bit Scan Reverse

Searches the value in a register or a memory location (second operand) for the most-significant set bit. If a set bit is found, the instruction clears the zero flag (ZF) and stores the index of the most-significant set bit in a destination register (first operand). If the second operand contains 0, the instruction sets ZF to 1 and does not change the contents of the destination register. The bit index is an unsigned offset from bit 0 of the searched value.

Mnemonic	Opcode	Description
BSR <i>reg16, reg/mem16</i>	0F BD /r	Bit scan reverse on the contents of <i>reg/mem16</i> .
BSR <i>reg32, reg/mem32</i>	0F BD /r	Bit scan reverse on the contents of <i>reg/mem32</i> .

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

BSWAP

Byte Swap

Reverses the byte order of the specified register. This action converts the contents of the register from little endian to big endian or vice versa. In a doubleword, bits 7:0 are exchanged with bits 31:24, and bits 15:8 are exchanged with bits 23:16. In a quadword, bits 7:0 are exchanged with bits 63:56, bits 15:8 with bits 55:48, bits 23:16 with bits 47:40, and bits 31:24 with bits 39:32. A subsequent use of the BSWAP instruction with the same operand restores the original value of the operand.

The result of applying the BSWAP instruction to a 16-bit register is undefined. To swap the bytes of a 16-bit register, use the XCHG instruction and specify the respective byte halves of the 16-bit register as the two operands. For example, to swap the bytes of AX, use XCHG AL, AH.

Mnemonic	Opcode	Description
BSWAP <i>reg32</i>	0F C8 <i>rd</i>	Reverse the byte order of <i>reg32</i> .
BSWAP <i>reg64</i>	0F C8 <i>rq</i>	Reverse the byte order of <i>reg64</i> .

BT**Bit Test**

Copies a bit, specified by a bit index in a register or 8-bit immediate value (second operand), from a bit string (first operand), also called the bit base, to the carry flag (CF) of the rFLAGS register.

If the bit base operand is a register, the instruction uses the modulo 16, 32, or 64 (depending on the operand size) of the bit index to select a bit in the register.

If the bit base operand is a memory location, bit 0 of the byte at the specified address is the bit base of the bit string. If the bit index is in a register, the instruction selects a bit position relative to the bit base in the range -2^{63} to $+2^{63} - 1$ if the operand size is 64, -2^{31} to $+2^{31} - 1$, if the operand size is 32, and -2^{15} to $+2^{15} - 1$ if the operand size is 16. If the bit index is in an immediate value, the bit selected is that value modulo 16, 32, or 64, depending on operand size.

When the instruction attempts to copy a bit from memory, it accesses 2, 4, or 8 bytes starting from the specified memory address for 16-bit, 32-bit, or 64-bit operand sizes, respectively, using the following formula:

$$\text{Effective Address} + (\text{NumBytes}_i * (\text{BitOffset} \text{ DIV } \text{NumBits}_i * 8))$$

When using this bit addressing mechanism, avoid referencing areas of memory close to address space holes, such as references to memory-mapped I/O registers. Instead, use a MOV instruction to load a register from such an address and use a register form of the BT instruction to manipulate the data.

Mnemonic	Opcode	Description
BT <i>reg/mem16, reg16</i>	0F A3 /r	Copy the value of the selected bit to the carry flag.
BT <i>reg/mem32, reg32</i>	0F A3 /r	Copy the value of the selected bit to the carry flag.
BT <i>reg/mem64, reg64</i>	0F A3 /r	Copy the value of the selected bit to the carry flag.
BT <i>reg/mem16, imm8</i>	0F BA /4 <i>ib</i>	Copy the value of the selected bit to the carry flag.
BT <i>reg/mem32, imm8</i>	0F BA /4 <i>ib</i>	Copy the value of the selected bit to the carry flag.
BT <i>reg/mem64, imm8</i>	0F BA /4 <i>ib</i>	Copy the value of the selected bit to the carry flag.

BTC

Bit Test and Complement

Copies a bit, specified by a bit index in a register or 8-bit immediate value (second operand), from a bit string (first operand), also called the bit base, to the carry flag (CF) of the rFLAGS register, and then complements (toggles) the bit in the bit string.

If the bit base operand is a register, the instruction uses the modulo 16, 32, or 64 (depending on the operand size) of the bit index to select a bit in the register.

If the bit base operand is a memory location, bit 0 of the byte at the specified address is the bit base of the bit string. If the bit index is in a register, the instruction selects a bit position relative to the bit base in the range -2^{63} to $+2^{63} - 1$ if the operand size is 64, -2^{31} to $+2^{31} - 1$, if the operand size is 32, and -2^{15} to $+2^{15} - 1$ if the operand size is 16. If the bit index is in an immediate value, the bit selected is that value modulo 16, 32, or 64, depending the operand size.

This instruction is useful for implementing semaphores in concurrent operating systems. Such an application should precede this instruction with the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

BTR

Bit Test and Reset

Copies a bit, specified by a bit index in a register or 8-bit immediate value (second operand), from a bit string (first operand), also called the bit base, to the carry flag (CF) of the rFLAGS register, and then clears the bit in the bit string to 0.

If the bit base operand is a register, the instruction uses the modulo 16, 32, or 64 (depending on the operand size) of the bit index to select a bit in the register.

If the bit base operand is a memory location, bit 0 of the byte at the specified address is the bit base of the bit string. If the bit index is in a register, the instruction selects a bit position relative to the bit base in the range -2^{63} to $+2^{63} - 1$ if the operand size is 64, -2^{31} to $+2^{31} - 1$, if the operand size is 32, and -2^{15} to $+2^{15} - 1$ if the operand size is 16. If the bit index is in an immediate value, the bit selected is that value modulo 16, 32, or 64, depending on the operand size.

This instruction is useful for implementing semaphores in concurrent operating systems. Such applications should precede this instruction with the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Bit Test and Set

Copies a bit, specified by bit index in a register or 8-bit immediate value (second operand), from a bit string (first operand), also called the bit base, to the carry flag (CF) of the rFLAGS register, and then sets the bit in the bit string to 1.

If the bit base operand is a register, the instruction uses the modulo 16, 32, or 64 (depending on the operand size) of the bit index to select a bit in the register.

If the bit base operand is a memory location, bit 0 of the byte at the specified address is the bit base of the bit string. If the bit index is in a register, the instruction selects a bit position relative to the bit base in the range -2^{63} to $+2^{63} - 1$ if the operand size is 64, -2^{31} to $+2^{31} - 1$, if the operand size is 32, and -2^{15} to $+2^{15} - 1$ if the operand size is 16. If the bit index is in an immediate value, the bit selected is that value modulo 16, 32, or 64, depending on the operand size.

This instruction is useful for implementing semaphores in concurrent operating systems. Such applications should precede this instruction with the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

BZHI

Zero High Bits

Copies bits, left to right, from the first source operand starting with the bit position specified by the second source operand (*index*), writes these bits to the destination, and clears all the bits in positions greater than *index*.

This instruction has three operands:

BZHI *dest, src, index*

In 64-bit mode, the operand size (*op_size*) is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register. The first source operand (*src*) is either a general purpose register or a memory operand. The second source operand is a general purpose register. Bits [7:0] of this register, treated as an unsigned 8-bit integer, specify the index of the most-significant bit of the first source operand to be copied to the corresponding bit of the destination. Bits [*op_size*-1:*index*+1] of the destination are cleared.

If the value of *index* is greater than or equal to the operand size, *index* is set to (*op_size*-1). In this case, the CF flag is set.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

CALL (Near)

Near Procedure Call

Pushes the offset of the next instruction onto the stack and branches to the target address, which contains the first instruction of the called procedure. The target operand can specify a register, a memory location, or a label. A procedure accessed by a near CALL is located in the same code segment as the CALL instruction.

If the CALL target is specified by a register or memory location, then a 16-, 32-, or 64-bit rIP is read from the operand, depending on the operand size. A 16- or 32-bit rIP is zero-extended to 64 bits.

If the CALL target is specified by a displacement, the signed displacement is added to the rIP (of the following instruction), and the result is truncated to 16, 32, or 64 bits, depending on the operand size. The signed displacement is 16 or 32 bits, depending on the operand size.

In all cases, the rIP of the instruction after the CALL is pushed on the stack, and the size of the stack push (16, 32, or 64 bits) depends on the operand size of the CALL instruction.

For near calls in 64-bit mode, the operand size defaults to 64 bits. The E8 opcode results in $RIP = RIP + 32\text{-bit signed displacement}$ and the FF /2 opcode results in $RIP = 64\text{-bit offset from register or memory}$. No prefix is available to encode a 32-bit operand size in 64-bit mode.

At the end of the called procedure, RET is used to return control to the instruction following the original CALL. When RET is executed, the rIP is popped off the stack, which returns control to the instruction after the CALL.

See CALL (Far) for information on far calls—calls to procedures located outside of the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
CALL <i>rel16off</i>	E8 <i>iw</i>	Near call with the target specified by a 16-bit relative displacement.
CALL <i>rel32off</i>	E8 <i>id</i>	Near call with the target specified by a 32-bit relative displacement.
CALL <i>reg/mem16</i>	FF /2	Near call with the target specified by <i>reg/mem16</i> .
CALL <i>reg/mem32</i>	FF /2	Near call with the target specified by <i>reg/mem32</i> . (There is no prefix for encoding this in 64-bit mode.)
CALL <i>reg/mem64</i>	FF /2	Near call with the target specified by <i>reg/mem64</i> .

For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

CALL (Far)

Far Procedure Call

Pushes procedure linking information onto the stack and branches to the target address, which contains the first instruction of the called procedure. The operand specifies a target selector and offset.

The instruction can specify the target directly, by including the far pointer in the CALL (Far) opcode itself, or indirectly, by referencing a far pointer in memory. In 64-bit mode, only indirect far calls are allowed, executing a direct far call (opcode 9A) generates an undefined opcode exception. For both direct and indirect far calls, if the CALL (Far) operand-size is 16 bits, the instruction's operand is a 16-bit selector followed by a 16-bit offset. If the operand-size is 32 or 64 bits, the operand is a 16-bit selector followed by a 32-bit offset.

The target selector used by the instruction can be a code selector in all modes. Additionally, the target selector can reference a call gate in protected mode, or a task gate or TSS selector in legacy protected mode.

- *Target is a code selector*—The CS:rIP of the next instruction is pushed to the stack, using operand-size stack pushes. Then code is executed from the target CS:rIP. In this case, the target offset can only be a 16- or 32-bit value, depending on operand-size, and is zero-extended to 64 bits. No CPL change is allowed.
- *Target is a call gate*—The call gate specifies the actual target code segment and offset. Call gates allow calls to the same or more privileged code. If the target segment is at the same CPL as the current code segment, the CS:rIP of the next instruction is pushed to the stack.

If the CALL (Far) changes privilege level, then a stack-switch occurs, using an inner-level stack pointer from the TSS. The CS:rIP of the next instruction is pushed to the new stack. If the mode is legacy mode and the param-count field in the call gate is non-zero, then up to 31 operands are copied from the caller's stack to the new stack. Finally, the caller's SS:rSP is pushed to the new stack.

When calling through a call gate, the stack pushes are 16-, 32-, or 64-bits, depending on the size of the call gate. The size of the target rIP is also 16, 32, or 64 bits, depending on the size of the call gate. If the target rIP is less than 64 bits, it is zero-extended to 64 bits. Long mode only allows 64-bit call gates that must point to 64-bit code segments.

- *Target is a task gate or a TSS*—If the mode is legacy protected mode, then a task switch occurs. See “Hardware Task-Management in Legacy Mode” in volume 2 for details about task switches. Hardware task switches are not supported in long mode.

See CALL (Near) for information on near calls—calls to procedures located inside the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
CALL FAR <i>ptr16:16</i>	9A <i>cd</i>	Far call direct, with the target specified by a far pointer contained in the instruction. (Invalid in 64-bit mode.)

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

CBW
CWDE
CDQE**Convert to Sign-Extended**

Copies the sign bit in the AL or eAX register to the upper bits of the rAX register. The effect of this instruction is to convert a signed byte, word, or doubleword in the AL or eAX register into a signed word, doubleword, or quadword in the rAX register. This action helps avoid overflow problems in signed number arithmetic.

The CDQE mnemonic is meaningful only in 64-bit mode.

Mnemonic	Opcode	Description
CBW	98	Sign-extend AL into AX.
CWDE	98	Sign-extend AX into EAX.
CDQE	98	Sign-extend EAX into RAX.

Related Instructions

CWD, CDQ, CQO

CWD
CDQ
CQO**Convert to Sign-Extended**

Copies the sign bit in the rAX register to all bits of the rDX register. The effect of this instruction is to convert a signed word, doubleword, or quadword in the rAX register into a signed doubleword, quadword, or double-quadword in the rDX:rAX registers. This action helps avoid overflow problems in signed number arithmetic.

The CQO mnemonic is meaningful only in 64-bit mode.

Mnemonic	Opcode	Description
CWD	99	Sign-extend AX into DX:AX.
CDQ	99	Sign-extend EAX into EDX:EAX.
CQO	99	Sign-extend RAX into RDX:RAX.

CLD**Clear Direction Flag**

Clears the direction flag (DF) in the rFLAGS register to zero. If the DF flag is 0, each iteration of a string instruction increments the data pointer (index registers rSI or rDI). If the DF flag is 1, the string instruction decrements the pointer. Use the CLD instruction before a string instruction to make the data pointer increment.

Mnemonic	Opcode	Description
CLD	FC	Clear the direction flag (DF) to zero.

CLFLUSH

Cache Line Flush

Flushes the cache line specified by the *mem8* linear-address. The instruction checks all levels of the cache hierarchy—internal caches and external caches—and invalidates the cache line in every cache in which it is found. If a cache contains a dirty copy of the cache line (that is, the cache line is in the *modified* or *owned* MOESI state), the line is written back to memory before it is invalidated. The instruction sets the cache-line MOESI state to *invalid*.

The instruction also checks the physical address corresponding to the linear-address operand against the processor's write-combining buffers. If the write-combining buffer holds data intended for that physical address, the instruction writes the entire contents of the buffer to memory. This occurs even though the data is not cached in the cache hierarchy. In a multiprocessor system, the instruction checks the write-combining buffers only on the processor that executed the CLFLUSH instruction.

The CLFLUSH instruction is weakly-ordered with respect to other instructions that operate on memory. Speculative loads initiated by the processor, or specified explicitly using cache-prefetch instructions, can be reordered around a CLFLUSH instruction. Such reordering can invalidate a speculatively prefetched cache line, unintentionally defeating the prefetch operation. The only way to avoid this situation is to use the MFENCE instruction after the CLFLUSH instruction to force strong-ordering of the CLFLUSH instruction with respect to subsequent memory operations. The CLFLUSH instruction may also take effect on a cache line while stores from previous store instructions are still pending in the store buffer. To ensure that such stores are included in the cache line that is flushed, use an MFENCE instruction ahead of the CLFLUSH instruction. Such stores would otherwise cause the line to be re-cached and modified after the CLFLUSH completed. The LFENCE, SFENCE, and serializing instructions are *not* ordered with respect to CLFLUSH.

The CLFLUSH instruction behaves like a load instruction with respect to setting the page-table accessed and dirty bits. That is, it sets the page-table accessed bit to 1, but does not set the page-table dirty bit.

The CLFLUSH instruction executes at any privilege level. CLFLUSH performs all the segmentation and paging checks that a 1-byte read would perform, except that it also allows references to execute-only segments.

The CLFLUSH instruction is supported if the feature flag CPUID Fn0000_0001_EDX[CLFSH] is set. The 8-bit field CPUID Fn 0000_0001_EBX[CLFlush] returns the size of the cacheline in quadwords.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

CMOVcc**Conditional Move**

Conditionally moves a 16-bit, 32-bit, or 64-bit value in memory or a general-purpose register (second operand) into a register (first operand), depending upon the settings of condition flags in the rFLAGS register. If the condition is not satisfied, the destination register is not modified. For the memory-based forms of CMOVcc, memory-related exceptions may be reported even if the condition is false. In 64-bit mode, CMOVcc with a 32-bit operand size will clear the upper 32 bits of the destination register even if the condition is false.

The mnemonics of CMOVcc instructions denote the condition that must be satisfied. Most assemblers provide instruction mnemonics with A (above) and B (below) tags to supply the semantics for manipulating unsigned integers. Those with G (greater than) and L (less than) tags deal with signed integers. Many opcodes may be represented by synonymous mnemonics. For example, the CMOVL instruction is synonymous with the CMOVNGE instruction and denote the instruction with the opcode 0F 4C.

The feature flag CPUID Fn0000_0001_EDX[CMOV] or CPUID Fn8000_0001_EDX[CMOV] =1 indicates support for CMOVcc instructions on a particular processor implementation.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

CMP

Compare

Compares the contents of a register or memory location (first operand) with an immediate value or the contents of a register or memory location (second operand), and sets or clears the status flags in the rFLAGS register to reflect the results. To perform the comparison, the instruction subtracts the second operand from the first operand and sets the status flags in the same manner as the SUB instruction, but does not alter the first operand. If the second operand is an immediate value, the instruction sign-extends the value to the length of the first operand.

Use the CMP instruction to set the condition codes for a subsequent conditional jump (*Jcc*), conditional move (*CMOVcc*), or conditional SET*cc* instruction. Appendix F, “Instruction Effects on RFLAGS” shows how instructions affect the rFLAGS status flags.

Mnemonic	Opcode	Description
CMP AL, <i>imm8</i>	3C <i>ib</i>	Compare an 8-bit immediate value with the contents of the AL register.
CMP AX, <i>imm16</i>	3D <i>iw</i>	Compare a 16-bit immediate value with the contents of the AX register.
CMP EAX, <i>imm32</i>	3D <i>id</i>	Compare a 32-bit immediate value with the contents of the EAX register.
CMP RAX, <i>imm32</i>	3D <i>id</i>	Compare a 32-bit immediate value with the contents of the RAX register.
CMP <i>reg/mem8</i> , <i>imm8</i>	80 <i>7 ib</i>	Compare an 8-bit immediate value with the contents of an 8-bit register or memory operand.
CMP <i>reg/mem16</i> , <i>imm16</i>	81 <i>7 iw</i>	Compare a 16-bit immediate value with the contents of a 16-bit register or memory operand.
CMP <i>reg/mem32</i> , <i>imm32</i>	81 <i>7 id</i>	Compare a 32-bit immediate value with the contents of a 32-bit register or memory operand.
CMP <i>reg/mem64</i> , <i>imm32</i>	81 <i>7 id</i>	Compare a 32-bit signed immediate value with the contents of a 64-bit register or memory operand.
CMP <i>reg/mem16</i> , <i>imm8</i>	83 <i>7 ib</i>	Compare an 8-bit signed immediate value with the contents of a 16-bit register or memory operand.
CMP <i>reg/mem32</i> , <i>imm8</i>	83 <i>7 ib</i>	Compare an 8-bit signed immediate value with the contents of a 32-bit register or memory operand.
CMP <i>reg/mem64</i> , <i>imm8</i>	83 <i>7 ib</i>	Compare an 8-bit signed immediate value with the contents of a 64-bit register or memory operand.
CMP <i>reg/mem8</i> , <i>reg8</i>	38 <i>r</i>	Compare the contents of an 8-bit register or memory operand with the contents of an 8-bit register.
CMP <i>reg/mem16</i> , <i>reg16</i>	39 <i>r</i>	Compare the contents of a 16-bit register or memory operand with the contents of a 16-bit register.
CMP <i>reg/mem32</i> , <i>reg32</i>	39 <i>r</i>	Compare the contents of a 32-bit register or memory operand with the contents of a 32-bit register.
CMP <i>reg/mem64</i> , <i>reg64</i>	39 <i>r</i>	Compare the contents of a 64-bit register or memory operand with the contents of a 64-bit register.

Mnemonic	Opcode	Description
CMP <i>reg8, reg/mem8</i>	3A /r	Compare the contents of an 8-bit register with the contents of an 8-bit register or memory operand.
CMP <i>reg16, reg/mem16</i>	3B /r	Compare the contents of a 16-bit register with the contents of a 16-bit register or memory operand.
CMP <i>reg32, reg/mem32</i>	3B /r	Compare the contents of a 32-bit register with the contents of a 32-bit register or memory operand.
CMP <i>reg64, reg/mem64</i>	3B /r	Compare the contents of a 64-bit register with the contents of a 64-bit register or memory operand.

When interpreting operands as unsigned, flag settings are as follows:

Operands	CF	ZF
dest > source	0	0
dest = source	0	1
dest < source	1	0

When interpreting operands as signed, flag settings are as follows:

Operands	OF	ZF
dest > source	SF	0
dest = source	0	1
dest < source	NOT SF	0

CMPS

CMPSB

CMPSW

CMPSD

CMPSQ

Compare Strings

Compares the bytes, words, doublewords, or quadwords pointed to by the rSI and rDI registers, sets or clears the status flags of the rFLAGS register to reflect the results, and then increments or decrements the rSI and rDI registers according to the state of the DF flag in the rFLAGS register. To perform the comparison, the instruction subtracts the second operand from the first operand and sets the status flags in the same manner as the SUB instruction, but does not alter the first operand. The two operands must be the same size.

If the DF flag is 0, the instruction increments rSI and rDI; otherwise, it decrements the pointers. It increments or decrements the pointers by 1, 2, 4, or 8, depending on the size of the operands.

The forms of the CMPSx instruction with explicit operands address the first operand at *seg*:[rSI]. The value of *seg* defaults to the DS segment, but may be overridden by a segment prefix. These instructions always address the second operand at ES:[rDI]. ES may not be overridden. The explicit operands serve only to specify the type (size) of the values being compared and the segment used by the first operand.

The no-operands forms of the instruction use the DS:[rSI] and ES:[rDI] registers to point to the values to be compared. The mnemonic determines the size of the operands.

Do not confuse this CMPSD instruction with the same-mnemonic CMPSD (compare scalar double-precision floating-point) instruction in the 128-bit media instruction set. Assemblers can distinguish the instructions by the number and type of operands.

For block comparisons, the CMPS instruction supports the REPE or REPZ prefixes (they are synonyms) and the REPNE or REPNZ prefixes (they are synonyms). For details about the REP prefixes, see “Repeat Prefixes” on page 12. If a conditional jump instruction like JL follows a CMPSx instruction, the jump occurs if the value of the *seg*:[rSI] operand is less than the ES:[rDI] operand. This action allows lexicographical comparisons of string or array elements. A CMPSx instruction can also operate inside a loop controlled by the LOOP_{cc} instruction.

Mnemonic	Opcode	Description
CMPS <i>mem8, mem8</i>	A6	Compare the byte at DS:rSI with the byte at ES:rDI and then increment or decrement rSI and rDI.
CMPS <i>mem16, mem16</i>	A7	Compare the word at DS:rSI with the word at ES:rDI and then increment or decrement rSI and rDI.
CMPS <i>mem32, mem32</i>	A7	Compare the doubleword at DS:rSI with the doubleword at ES:rDI and then increment or decrement rSI and rDI.
CMPS <i>mem64, mem64</i>	A7	Compare the quadword at DS:rSI with the quadword at ES:rDI and then increment or decrement rSI and rDI.

Mnemonic	Opcode	Description
CMPSB	A6	Compare the byte at DS:rSI with the byte at ES:rDI and then increment or decrement rSI and rDI.
CMPSW	A7	Compare the word at DS:rSI with the word at ES:rDI and then increment or decrement rSI and rDI.
CMPSD	A7	Compare the doubleword at DS:rSI with the doubleword at ES:rDI and then increment or decrement rSI and rDI.
CMPSQ	A7	Compare the quadword at DS:rSI with the quadword at ES:rDI and then increment or decrement rSI and rDI.

CMPXCHG

Compare and Exchange

Compares the value in the AL, AX, EAX, or RAX register with the value in a register or a memory location (first operand). If the two values are equal, the instruction copies the value in the second operand to the first operand and sets the ZF flag in the rFLAGS register to 1. Otherwise, it copies the value in the first operand to the AL, AX, EAX, or RAX register and clears the ZF flag to 0.

The OF, SF, AF, PF, and CF flags are set to reflect the results of the compare.

When the first operand is a memory operand, CMPXCHG always does a read-modify-write on the memory operand. If the compared operands were unequal, CMPXCHG writes the same value to the memory operand that was read.

The forms of the CMPXCHG instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
CMPXCHG <i>reg/mem8, reg8</i>	0F B0 /r	Compare AL register with an 8-bit register or memory location. If equal, copy the second operand to the first operand. Otherwise, copy the first operand to AL.
CMPXCHG <i>reg/mem16, reg16</i>	0F B1 /r	Compare AX register with a 16-bit register or memory location. If equal, copy the second operand to the first operand. Otherwise, copy the first operand to AX.
CMPXCHG <i>reg/mem32, reg32</i>	0F B1 /r	Compare EAX register with a 32-bit register or memory location. If equal, copy the second operand to the first operand. Otherwise, copy the first operand to EAX.
CMPXCHG <i>reg/mem64, reg64</i>	0F B1 /r	Compare RAX register with a 64-bit register or memory location. If equal, copy the second operand to the first operand. Otherwise, copy the first operand to RAX.

CMPXCHG8B CMPXCHG16B

Compare and Exchange Eight Bytes Compare and Exchange Sixteen Bytes

Compares the value in the rDX:rAX registers with a 64-bit or 128-bit value in the specified memory location. If the values are equal, the instruction copies the value in the rCX:rBX registers to the memory location and sets the zero flag (ZF) of the rFLAGS register to 1. Otherwise, it copies the value in memory to the rDX:rAX registers and clears ZF to 0.

If the effective operand size is 16-bit or 32-bit, the CMPXCHG8B instruction is used. This instruction uses the EDX:EAX and ECX:EBX register operands and a 64-bit memory operand. If the effective operand size is 64-bit, the CMPXCHG16B instruction is used; this instruction uses RDX:RAX register operands and a 128-bit memory operand.

The CMPXCHG8B and CMPXCHG16B instructions always do a read-modify-write on the memory operand. If the compared operands were unequal, the instructions write the same value to the memory operand that was read.

The CMPXCHG8B and CMPXCHG16B instructions support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Support for the CMPXCHG8B and CMPXCHG16B instructions is implementation dependent. Support for the CMPXCHG8B instruction is indicated by CPUID Fn0000_0001_EDX[CMPXCHG8B] or Fn8000_0001_EDX[CMPXCHG8B] = 1. Support for the CMPXCHG16B instruction is indicated by CPUID Fn0000_0001_ECX[CMPXCHG16B] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

The memory operand used by CMPXCHG16B must be 16-byte aligned or else a general-protection exception is generated.

Mnemonic	Opcode	Description
CMPXCHG8B <i>mem64</i>	0F C7 /1 <i>m64</i>	Compare EDX:EAX register to 64-bit memory location. If equal, set the zero flag (ZF) to 1 and copy the ECX:EBX register to the memory location. Otherwise, copy the memory location to EDX:EAX and clear the zero flag.
CMPXCHG16B <i>mem128</i>	0F C7 /1 <i>m128</i>	Compare RDX:RAX register to 128-bit memory location. If equal, set the zero flag (ZF) to 1 and copy the RCX:RBX register to the memory location. Otherwise, copy the memory location to RDX:RAX and clear the zero flag.

CPUID

Processor Identification

Provides information about the processor and its capabilities through a number of different functions. Software should load the number of the CPUID function to execute into the EAX register before executing the CPUID instruction. The processor returns information in the EAX, EBX, ECX, and EDX registers; the contents and format of these registers depend on the function.

The architecture supports CPUID information about *standard functions* and *extended functions*. The standard functions have numbers in the 0000_XXXXh series (for example, standard function 1). To determine the largest standard function number that a processor supports, execute CPUID function 0.

The extended functions have numbers in the 8000_XXXXh series (for example, extended function 8000_0001h). To determine the largest extended function number that a processor supports, execute CPUID extended function 8000_0000h. If the value returned in EAX is greater than 8000_0000h, the processor supports extended functions.

Software operating at any privilege level can execute the CPUID instruction to collect this information. In 64-bit mode, this instruction works the same as in legacy mode except that it zero-extends 32-bit register results to 64 bits.

CPUID is a serializing instruction.

Mnemonic	Opcode	Description
CPUID	0F A2	Returns information about the processor and its capabilities. EAX specifies the function number, and the data is returned in EAX, EBX, ECX, EDX.

Testing for the CPUID Instruction

To avoid an invalid-opcode exception (#UD) on those processor implementations that do not support the CPUID instruction, software must first test to determine if the CPUID instruction is supported. Support for the CPUID instruction is indicated by the ability to write the ID bit in the rFLAGS register. Normally, 32-bit software uses the PUSHFD and POPFD instructions in an attempt to write rFLAGS.ID. After reading the updated rFLAGS.ID bit, a comparison determines if the operation changed its value. If the value changed, the processor executing the code supports the CPUID instruction. If the value did not change, rFLAGS.ID is not writable, and the processor does not support the CPUID instruction.

The following code sample shows how to test for the presence of the CPUID instruction using 32-bit code.

```

pushfd                ; save EFLAGS
pop    eax            ; store EFLAGS in EAX
mov    ebx, eax       ; save in EBX for later testing
xor    eax, 00200000h ; toggle bit 21
push   eax            ; push to stack
popfd                ; save changed EAX to EFLAGS

```

```

pushfd                ; push EFLAGS to TOS
pop      eax          ; store EFLAGS in EAX
cmp      eax, ebx     ; see if bit 21 has changed
jz      NO_CPUID     ; if no change, no CPUID

```

Standard Function 0 and Extended Function 8000_0000h

CPUID standard function 0 loads the EAX register with the largest CPUID *standard* function number supported by the processor implementation; similarly, CPUID extended function 8000_0000h loads the EAX register with the largest *extended* function number supported.

Standard function 0 and extended function 8000_0000h both load a 12-character string into the EBX, EDX, and ECX registers identifying the processor vendor. For AMD processors, the string is AuthenticAMD. This string informs software that it should follow the AMD CPUID definition for subsequent CPUID function calls. If the function returns another vendor's string, software must use that vendor's CPUID definition when interpreting the results of subsequent CPUID function calls. Table 3-2 shows the contents of the EBX, EDX, and ECX registers after executing function 0 on an AMD processor.

Table 3-2. Processor Vendor Return Values

Register	Return Value	ASCII Characters
EBX	6874_7541h	"h t u A"
EDX	6974_6E65h	"i t n e"
ECX	444D_4163h	"D M A c"

For a description of all feature flags related to instruction subset support, see Appendix D, "Instruction Subsets and CPUID Feature Flags," on page 519. For a description of all defined feature numbers and return values, see Appendix E, "Obtaining Processor Information Via the CPUID Instruction," on page 589.

CRC32

CRC32 Cyclical Redundancy Check

Performs one step of a 32-bit cyclic redundancy check.

The first source, which is also the destination, is a doubleword value in either a 32-bit or 64-bit GPR depending on the presence of a REX prefix and the value of the REX.W bit. The second source is a GPR or memory location of width 8, 16, or 32 bits. A vector of width 40, 48, or 64 bits is derived from the two operands as follows:

1. The low-order 32 bits of the first operand is bit-wise inverted and shifted left by the width of the second operand.
2. The second operand is bit-wise inverted and shifted left by 32 bits
3. The results of steps 1 and 2 are XORed.

This vector is interpreted as a polynomial of degree 40, 48, or 64 over the field of two elements (i.e., bit i is interpreted as the coefficient of X^i). This polynomial is divided by the polynomial of degree 32 that is similarly represented by the vector 11EDC6F41h. (The division admits an efficient iterative implementation based on the XOR operation.) The remainder is encoded as a 32-bit vector, which is bit-wise inverted and written to the destination. In the case of a 64-bit destination, the upper 32 bits are cleared.

In an application of the CRC algorithm, a data block is partitioned into byte, word, or doubleword segments and CRC32 is executed iteratively, once for each segment.

CRC32 is a SSE4.2 instruction. Support for SSE4.2 instructions is indicated by CPUID Fn0000_0001_ECX[SSE42] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Instruction Encoding

Mnemonic	Encoding	Notes
CRC32 <i>reg32, reg/mem8</i>	F2 0F 38 F0 /r	Perform CRC32 operation on 8-bit values

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

DAA

Decimal Adjust after Addition

Adjusts the value in the AL register into a packed BCD result and sets the CF and AF flags in the rFLAGS register to indicate a decimal carry out of either nibble of AL.

Use this instruction to adjust the result of a byte ADD instruction that performed the binary addition of one 2-digit packed BCD values to another.

The instruction performs the adjustment by adding 06h to AL if the lower nibble is greater than 9 or if AF = 1. Then 60h is added to AL if the original AL was greater than 99h or if CF = 1.

If the lower nibble of AL was adjusted, the AF flag is set to 1. Otherwise AF is not modified. If the upper nibble of AL was adjusted, the CF flag is set to 1. Otherwise, CF is not modified. SF, ZF, and PF are set according to the final value of AL.

Using this instruction in 64-bit mode generates an invalid-opcode (#UD) exception.

Mnemonic	Opcode	Description
DAA	27	Decimal adjust AL. (Invalid in 64-bit mode.)

rFLAGS Affected

ID	VIP	VIF	AC	VM	RF	NT	IOPL	OF	DF	IF	TF	SF	ZF	AF	PF	CF

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD			X	This instruction was executed in 64-bit mode.

DAS

Decimal Adjust after Subtraction

Adjusts the value in the AL register into a packed BCD result and sets the CF and AF flags in the rFLAGS register to indicate a decimal borrow.

Use this instruction to adjust the result of a byte SUB instruction that performed a binary subtraction of one 2-digit, packed BCD value from another.

This instruction performs the adjustment by subtracting 06h from AL if the lower nibble is greater than 9 or if AF = 1. Then 60h is subtracted from AL if the original AL was greater than 99h or if CF = 1.

If the adjustment changes the lower nibble of AL, the AF flag is set to 1; otherwise AF is not modified. If the adjustment results in a borrow for either nibble of AL, the CF flag is set to 1; otherwise CF is not modified. The SF, ZF, and PF flags are set according to the final value of AL.

Using this instruction in 64-bit mode generates an invalid-opcode (#UD) exception.

Mnemonic	Opcode	Description
DAS	2F	Decimal adjusts AL after subtraction. (Invalid in 64-bit mode.)

DEC

Decrement by 1

Subtracts 1 from the specified register or memory location. The CF flag is not affected.

The one-byte forms of this instruction (opcodes 48 through 4F) are used as REX prefixes in 64-bit mode. See “REX Prefix” on page 14.

The forms of the DEC instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

To perform a decrement operation that updates the CF flag, use a SUB instruction with an immediate operand of 1.

Mnemonic	Opcode	Description
DEC <i>reg/mem8</i>	FE /1	Decrement the contents of an 8-bit register or memory location by 1.
DEC <i>reg/mem16</i>	FF /1	Decrement the contents of a 16-bit register or memory location by 1.
DEC <i>reg/mem32</i>	FF /1	Decrement the contents of a 32-bit register or memory location by 1.
DEC <i>reg/mem64</i>	FF /1	Decrement the contents of a 64-bit register or memory location by 1.
DEC <i>reg16</i>	48 + <i>rw</i>	Decrement the contents of a 16-bit register by 1. (See “REX Prefix” on page 14.)
DEC <i>reg32</i>	48 + <i>rd</i>	Decrement the contents of a 32-bit register by 1. (See “REX Prefix” on page 14.)

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

DIV

Unsigned Divide

Divides the unsigned value in a register by the unsigned value in the specified register or memory location. The register to be divided depends on the size of the divisor.

When dividing a word, the dividend is in the AX register. The instruction stores the quotient in the AL register and the remainder in the AH register.

When dividing a doubleword, quadword, or double quadword, the most-significant word of the dividend is in the rDX register and the least-significant word is in the rAX register. After the division, the instruction stores the quotient in the rAX register and the remainder in the rDX register.

The following table summarizes the action of this instruction:

Division Size	Dividend	Divisor	Quotient	Remainder	Maximum Quotient
Word/byte	AX	reg/mem8	AL	AH	255
Doubleword/word	DX:AX	reg/mem16	AX	DX	65,535
Quadword/doubleword	EDX:EAX	reg/mem32	EAX	EDX	$2^{32} - 1$
Double quadword/ quadword	RDX:RAX	reg/mem64	RAX	RDX	$2^{64} - 1$

The instruction truncates non-integral results towards 0 and the remainder is always less than the divisor. An overflow generates a #DE (divide error) exception, rather than setting the CF flag.

Division by zero generates a divide-by-zero exception.

Mnemonic	Opcode	Description
DIV <i>reg/mem8</i>	F6 /6	Perform unsigned division of AX by the contents of an 8-bit register or memory location and store the quotient in AL and the remainder in AH.
DIV <i>reg/mem16</i>	F7 /6	Perform unsigned division of DX:AX by the contents of a 16-bit register or memory operand store the quotient in AX and the remainder in DX.
DIV <i>reg/mem32</i>	F7 /6	Perform unsigned division of EDX:EAX by the contents of a 32-bit register or memory location and store the quotient in EAX and the remainder in EDX.
DIV <i>reg/mem64</i>	F7 /6	Perform unsigned division of RDX:RAX by the contents of a 64-bit register or memory location and store the quotient in RAX and the remainder in RDX.

ENTER

Create Procedure Stack Frame

Creates a stack frame for a procedure.

The first operand specifies the size of the stack frame allocated by the instruction.

The second operand specifies the nesting level (0 to 31—the value is automatically masked to 5 bits). For nesting levels of 1 or greater, the processor copies earlier stack frame pointers before adjusting the stack pointer. This action provides a called procedure with access points to other nested stack frames.

The 32-bit `enter N, 0` (a nesting level of 0) instruction is equivalent to the following 32-bit instruction sequence:

```

push  ebp          ; save current EBP
mov   ebp, esp     ; set stack frame pointer value
sub   esp, N       ; allocate space for local variables

```

The ENTER and LEAVE instructions provide support for block structured languages. The LEAVE instruction releases the stack frame on returning from a procedure.

In 64-bit mode, the operand size of ENTER defaults to 64 bits, and there is no prefix available for encoding a 32-bit operand size.

Mnemonic	Opcode	Description
ENTER <i>imm16</i> , 0	C8 <i>iw</i> 00	Create a procedure stack frame.
ENTER <i>imm16</i> , 1	C8 <i>iw</i> 01	Create a nested stack frame for a procedure.
ENTER <i>imm16</i> , <i>imm8</i>	C8 <i>iw</i> <i>ib</i>	Create a nested stack frame for a procedure.

Action

```
// See "Pseudocode Definition" on page 57.
```

```
ENTER_START:
```

```

temp_ALLOC_SPACE = word-sized immediate specified in the instruction
                  (first operand), zero-extended to 64 bits
temp_LEVEL       = byte-sized immediate specified in the instruction
                  (second operand), zero-extended to 64 bits

```

```

temp_LEVEL = temp_LEVEL AND 0x1f
            // only keep 5 bits of level count

```

```
PUSH.v old_RBP
```

```

temp_RBP = RSP // This value of RSP will eventually be loaded
            // into RBP.

```

```

IF (temp_LEVEL>0) // Push "temp_LEVEL" parameters to the stack.
{
    FOR (I=1; I<temp_LEVEL; I++)

```

```

// All but one of the parameters are copied
// from higher up on the stack.
{
    temp_DATA = READ_MEM.v [SS:old_RBP-I*V]
    PUSH.v temp_DATA
}
PUSH.v temp_RBP // The last parameter is the offset of the old
// value of RSP on the stack.
}
RSP.s = RSP - temp_ALLOC_SPACE // Leave "temp_ALLOC_SPACE" free bytes on
// the stack

WRITE_MEM.v [SS:RSP.s] = temp_unused // ENTER finishes with a memory
write // check on the final stack pointer,
// but no write actually occurs.

RBP.v = temp_RBP
EXIT

```

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Stack, #SS	X	X	X	A memory address exceeded the stack-segment limit or was non-canonical.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

IDIV**Signed Divide**

Divides the signed value in a register by the signed value in the specified register or memory location. The register to be divided depends on the size of the divisor.

When dividing a word, the dividend is in the AX register. The instruction stores the quotient in the AL register and the remainder in the AH register.

When dividing a doubleword, quadword, or double quadword, the most-significant word of the dividend is in the rDX register and the least-significant word is in the rAX register. After the division, the instruction stores the quotient in the rAX register and the remainder in the rDX register.

The following table summarizes the action of this instruction:

Division Size	Dividend	Divisor	Quotient	Remainder	Quotient Range
Word/byte	AX	reg/mem8	AL	AH	-128 to +127
Doubleword/word	DX:AX	reg/mem16	AX	DX	-32,768 to +32,767
Quadword/doubleword	EDX:EAX	reg/mem32	EAX	EDX	-2^{31} to $2^{31}-1$
Double quadword/ quadword	RDX:RAX	reg/mem64	RAX	RDX	-2^{63} to $2^{63}-1$

The instruction truncates non-integral results towards 0. The sign of the remainder is always the same as the sign of the dividend, and the absolute value of the remainder is less than the absolute value of the divisor. An overflow generates a #DE (divide error) exception, rather than setting the OF flag.

To avoid overflow problems, precede this instruction with a CBW, CWD, CDQ, or CQO instruction to sign-extend the dividend.

Mnemonic	Opcode	Description
IDIV <i>reg/mem8</i>	F6 /7	Perform signed division of AX by the contents of an 8-bit register or memory location and store the quotient in AL and the remainder in AH.
IDIV <i>reg/mem16</i>	F7 /7	Perform signed division of DX:AX by the contents of a 16-bit register or memory location and store the quotient in AX and the remainder in DX.
IDIV <i>reg/mem32</i>	F7 /7	Perform signed division of EDX:EAX by the contents of a 32-bit register or memory location and store the quotient in EAX and the remainder in EDX.
IDIV <i>reg/mem64</i>	F7 /7	Perform signed division of RDX:RAX by the contents of a 64-bit register or memory location and store the quotient in RAX and the remainder in RDX.

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

IMUL**Signed Multiply**

Multiplies two signed operands. The number of operands determines the form of the instruction.

If a single operand is specified, the instruction multiplies the value in the specified general-purpose register or memory location by the value in the AL, AX, EAX, or RAX register (depending on the operand size) and stores the product in AX, DX:AX, EDX:EAX, or RDX:RAX, respectively.

If two operands are specified, the instruction multiplies the value in a general-purpose register (first operand) by an immediate value or the value in a general-purpose register or memory location (second operand) and stores the product in the first operand location.

If three operands are specified, the instruction multiplies the value in a general-purpose register or memory location (second operand), by an immediate value (third operand) and stores the product in a register (first operand).

The IMUL instruction sign-extends an immediate operand to the length of the other register/memory operand.

The CF and OF flags are set if, due to integer overflow, the double-width multiplication result cannot be represented in the half-width destination register. Otherwise the CF and OF flags are cleared.

Mnemonic	Opcode	Description
IMUL <i>reg/mem8</i>	F6 /5	Multiply the contents of AL by the contents of an 8-bit memory or register operand and put the signed result in AX.
IMUL <i>reg/mem16</i>	F7 /5	Multiply the contents of AX by the contents of a 16-bit memory or register operand and put the signed result in DX:AX.
IMUL <i>reg/mem32</i>	F7 /5	Multiply the contents of EAX by the contents of a 32-bit memory or register operand and put the signed result in EDX:EAX.
IMUL <i>reg/mem64</i>	F7 /5	Multiply the contents of RAX by the contents of a 64-bit memory or register operand and put the signed result in RDX:RAX.
IMUL <i>reg16, reg/mem16</i>	0F AF /r	Multiply the contents of a 16-bit destination register by the contents of a 16-bit register or memory operand and put the signed result in the 16-bit destination register.
IMUL <i>reg32, reg/mem32</i>	0F AF /r	Multiply the contents of a 32-bit destination register by the contents of a 32-bit register or memory operand and put the signed result in the 32-bit destination register.
IMUL <i>reg64, reg/mem64</i>	0F AF /r	Multiply the contents of a 64-bit destination register by the contents of a 64-bit register or memory operand and put the signed result in the 64-bit destination register.
IMUL <i>reg16, reg/mem16, imm8</i>	6B /r ib	Multiply the contents of a 16-bit register or memory operand by a sign-extended immediate byte and put the signed result in the 16-bit destination register.

Mnemonic	Opcode	Description
IMUL <i>reg32, reg/mem32, imm8</i>	6B /r ib	Multiply the contents of a 32-bit register or memory operand by a sign-extended immediate byte and put the signed result in the 32-bit destination register.
IMUL <i>reg64, reg/mem64, imm8</i>	6B /r ib	Multiply the contents of a 64-bit register or memory operand by a sign-extended immediate byte and put the signed result in the 64-bit destination register.
IMUL <i>reg16, reg/mem16, imm16</i>	69 /r iw	Multiply the contents of a 16-bit register or memory operand by a sign-extended immediate word and put the signed result in the 16-bit destination register.
IMUL <i>reg32, reg/mem32, imm32</i>	69 /r id	Multiply the contents of a 32-bit register or memory operand by a sign-extended immediate double and put the signed result in the 32-bit destination register.
IMUL <i>reg64, reg/mem64, imm32</i>	69 /r id	Multiply the contents of a 64-bit register or memory operand by a sign-extended immediate double and put the signed result in the 64-bit destination register.

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

IN**Input from Port**

Transfers a byte, word, or doubleword from an I/O port to the AL, AX, or EAX register. The port address is specified either by an 8-bit immediate value (00h to FFh) encoded in the instruction or a 16-bit value contained in the DX register (0000h to FFFFh). The processor's I/O address space is distinct from system memory addressing.

For two opcodes (E4h and ECh), the data size of the port is fixed at 8 bits. For the other opcodes (E5h and EDh), the effective operand-size determines the port size. If the effective operand size is 64 bits, IN reads only 32 bits from the I/O port.

If the CPL is higher than IOPL, or the mode is virtual mode, IN checks the I/O permission bitmap in the TSS before allowing access to the I/O port. (See Volume 2 for details on the TSS I/O permission bitmap.)

Mnemonic	Opcode	Description
IN AL, <i>imm8</i>	E4 <i>ib</i>	Input a byte from the port at the address specified by <i>imm8</i> and put it into the AL register.
IN AX, <i>imm8</i>	E5 <i>ib</i>	Input a word from the port at the address specified by <i>imm8</i> and put it into the AX register.
IN EAX, <i>imm8</i>	E5 <i>ib</i>	Input a doubleword from the port at the address specified by <i>imm8</i> and put it into the EAX register.
IN AL, DX	EC	Input a byte from the port at the address specified by the DX register and put it into the AL register.
IN AX, DX	ED	Input a word from the port at the address specified by the DX register and put it into the AX register.
IN EAX, DX	ED	Input a doubleword from the port at the address specified by the DX register and put it into the EAX register.

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP		X		One or more I/O permission bits were set in the TSS for the accessed port.
			X	The CPL was greater than the IOPL and one or more I/O permission bits were set in the TSS for the accessed port.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.

INC

Increment by 1

Adds 1 to the specified register or memory location. The CF flag is not affected, even if the operand is incremented to 0000.

The one-byte forms of this instruction (opcodes 40 through 47) are used as REX prefixes in 64-bit mode. See “REX Prefix” on page 14.

The forms of the INC instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

To perform an increment operation that updates the CF flag, use an ADD instruction with an immediate operand of 1.

Mnemonic	Opcode	Description
INC <i>reg/mem8</i>	FE /0	Increment the contents of an 8-bit register or memory location by 1.
INC <i>reg/mem16</i>	FF /0	Increment the contents of a 16-bit register or memory location by 1.
INC <i>reg/mem32</i>	FF /0	Increment the contents of a 32-bit register or memory location by 1.
INC <i>reg/mem64</i>	FF /0	Increment the contents of a 64-bit register or memory location by 1.
INC <i>reg16</i>	40 + <i>rw</i>	Increment the contents of a 16-bit register by 1. (These opcodes are used as REX prefixes in 64-bit mode. See “REX Prefix” on page 14.)
INC <i>reg32</i>	40 + <i>rd</i>	Increment the contents of a 32-bit register by 1. (These opcodes are used as REX prefixes in 64-bit mode. See “REX Prefix” on page 14.)

INS

INSB

INSW

INSD

Input String

Transfers data from the I/O port specified in the DX register to an input buffer specified in the rDI register and increments or decrements the rDI register according to the setting of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments rDI by 1, 2, or 4, depending on the number of bytes read. If the DF flag is 1, it decrements the pointer by 1, 2, or 4.

In 16-bit and 32-bit mode, the INS instruction always uses ES as the data segment. The ES segment cannot be overridden with a segment override prefix. In 64-bit mode, INS always uses the unsegmented memory space.

The INS instructions use the explicit memory operand (first operand) to determine the size of the I/O port, but always use ES:[rDI] for the location of the input buffer. The explicit register operand (second operand) specifies the I/O port address and must always be DX.

The INSB, INSW, and INSD instructions copy byte, word, and doubleword data, respectively, from the I/O port (0000h to FFFFh) specified in the DX register to the input buffer specified in the ES:rDI registers.

If the operand size is 64-bits, the instruction behaves as if the operand size were 32-bits.

If the CPL is higher than the IOPL or the mode is virtual mode, INSx checks the I/O permission bitmap in the TSS before allowing access to the I/O port. (See volume 2 for details on the TSS I/O permission bitmap.)

The INSx instructions support the REP prefix for block input of rCX bytes, words, or doublewords. For details about the REP prefix, see “Repeat Prefixes” on page 12.

Mnemonic	Opcode	Description
INS <i>mem8</i> , DX	6C	Input a byte from the port specified by DX, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.
INS <i>mem16</i> , DX	6D	Input a word from the port specified by DX register, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.
INS <i>mem32</i> , DX	6D	Input a doubleword from the port specified by DX, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.
INSB	6C	Input a byte from the port specified by DX, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.

Mnemonic	Opcode	Description
INSW	6D	Input a word from the port specified by DX, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.
INSD	6D	Input a doubleword from the port specified by DX, put it into the memory location specified in ES:rDI, and then increment or decrement rDI.

INT

Interrupt to Vector

Transfers execution to the interrupt handler specified by an 8-bit unsigned immediate value. This value is an interrupt vector number (00h to FFh), which the processor uses as an index into the interrupt-descriptor table (IDT).

For detailed descriptions of the steps performed by `INT n` instructions, see the following:

- *Legacy-Mode Interrupts*: “Virtual-8086 Mode Interrupt Control Transfers” in Volume 2.
- *Long-Mode Interrupts*: “Long-Mode Interrupt Control Transfers” in Volume 2.

See also the descriptions of the `INT3` instruction on page 350 and the `INTO` instruction on page 182.

Invalid TSS, #TS (selector)		X	X	As part of a stack switch, the target stack segment selector or rSP in the TSS was beyond the TSS limit.
		X	X	As part of a stack switch, the target stack segment selector in the TSS was a null selector.
		X	X	As part of a stack switch, the target stack segment selector's TI bit was set, but the LDT selector was a null selector.
		X	X	As part of a stack switch, the target stack segment selector in the TSS was beyond the limit of the GDT or LDT descriptor table.
		X	X	As part of a stack switch, the target stack segment selector in the TSS contained a RPL that was not equal to its DPL.
		X	X	As part of a stack switch, the target stack segment selector in the TSS contained a DPL that was not equal to the CPL of the code segment selector.
Segment not present, #NP (selector)		X	X	The accessed code segment, interrupt gate, trap gate, task gate, or TSS was not present.
Stack, #SS	X	X	X	A memory address exceeded the stack segment limit or was non-canonical, and no stack switch occurred.

Exception	Real	Virtual 8086	Protected	Cause of Exception
Stack, #SS (selector)		X	X	After a stack switch, a memory address exceeded the stack segment limit or was non-canonical.
		X	X	As part of a stack switch, the SS register was loaded with a non-null segment selector and the segment was marked not present.
General protection, #GP	X	X	X	A memory address exceeded a data segment limit or was non-canonical.
	X	X	X	The target offset exceeded the code segment limit or was non-canonical.
		X		The IOPL was less than 3 and CR4.VME was 0.
		X		IOPL was less than 3, CR4.VME was 1, and the corresponding bit in the VME interrupt redirection bitmap was 1.
General protection, #GP (selector)	X	X	X	The interrupt vector was beyond the limit of IDT.
		X	X	The descriptor in the IDT was not an interrupt, trap, or task gate in legacy mode or not a 64-bit interrupt or trap gate in long mode.
		X	X	The DPL of the interrupt, trap, or task gate descriptor was less than the CPL.
		X	X	The segment selector specified by the interrupt or trap gate had its TI bit set, but the LDT selector was a null selector.
		X	X	The segment descriptor specified by the interrupt or trap gate exceeded the descriptor table limit or was a null selector.
		X	X	The segment descriptor specified by the interrupt or trap gate was not a code segment in legacy mode, or not a 64-bit code segment in long mode.
			X	The DPL of the segment specified by the interrupt or trap gate was greater than the CPL.
		X		The DPL of the segment specified by the interrupt or trap gate pointed was not 0 or it was a conforming segment.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

INTO

Interrupt to Overflow Vector

Checks the overflow flag (OF) in the rFLAGS register and calls the overflow exception (#OF) handler if the OF flag is set to 1. This instruction has no effect if the OF flag is cleared to 0. The INTO instruction detects overflow in signed number addition. See *AMD64 Architecture Programmer's Manual Volume 1: Application Programming* for more information on the OF flag.

Using this instruction in 64-bit mode generates an invalid-opcode exception.

For detailed descriptions of the steps performed by INT instructions, see the following:

- *Legacy-Mode Interrupts*: “Legacy Protected-Mode Interrupt Control Transfers” in Volume 2.

rFLAGS Affected

None.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Overflow, #OF	X	X	X	The INTO instruction was executed with OF set to 1.
Invalid opcode, #UD			X	Instruction was executed in 64-bit mode.

Jcc

Jump on Condition

Checks the status flags in the rFLAGS register and, if the flags meet the condition specified by the condition code in the mnemonic (*cc*), jumps to the target instruction located at the specified relative offset. Otherwise, execution continues with the instruction following the *Jcc* instruction.

Unlike the unconditional jump (JMP), conditional jump instructions have only two forms—*short* and *near conditional jumps*. Different opcodes correspond to different forms of one instruction. For example, the JO instruction (jump if overflow) has opcode 0Fh 80h for its near form and 70h for its short form, but the mnemonic is the same for both forms. The only difference is that the near form has a 16- or 32-bit relative displacement, while the short form always has an 8-bit relative displacement.

Mnemonics are provided to deal with the programming semantics of both signed and unsigned numbers. Instructions tagged A (above) and B (below) are intended for use in unsigned integer code; those tagged G (greater) and L (less) are intended for use in signed integer code.

If the jump is taken, the signed displacement is added to the RIP (of the following instruction) and the result is truncated to 16, 32, or 64 bits, depending on operand size.

In 64-bit mode, the operand size defaults to 64 bits. The processor sign-extends the 8-bit or 32-bit displacement value to 64 bits before adding it to the RIP.

These instructions cannot perform far jumps (to other code segments). To create a far-conditional-jump code sequence corresponding to a high-level language statement like:

```
IF A == B THEN GOTO FarLabel
```

where *FarLabel* is located in another code segment, use the opposite condition in a conditional short jump before an unconditional far jump. Such a code sequence might look like:

```
cmp    A,B           ; compare operands
jne    NextInstr     ; continue program if not equal
jmp    far FarLabel  ; far jump if operands are equal

NextInstr:           ; continue program
```

For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP	X	X	X	The target offset exceeded the code segment limit or was non-canonical.

JCXZ

JECXZ

JRCXZ

Jump if rCX Zero

Checks the contents of the count register (rCX) and, if 0, jumps to the target instruction located at the specified 8-bit relative offset. Otherwise, execution continues with the instruction following the *JrCXZ* instruction.

The size of the count register (CX, ECX, or RCX) depends on the address-size attribute of the *JrCXZ* instruction. Therefore, *JRCXZ* can only be executed in 64-bit mode and *JCXZ* cannot be executed in 64-bit mode.

If the jump is taken, the signed displacement is added to the rIP (of the following instruction) and the result is truncated to 16, 32, or 64 bits, depending on operand size.

In 64-bit mode, the operand size defaults to 64 bits. The processor sign-extends the 8-bit displacement value to 64 bits before adding it to the RIP.

For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
<i>JCXZ rel8off</i>	E3 <i>cb</i>	Jump short if the 16-bit count register (CX) is zero.
<i>JECXZ rel8off</i>	E3 <i>cb</i>	Jump short if the 32-bit count register (ECX) is zero.
<i>JRCXZ rel8off</i>	E3 <i>cb</i>	Jump short if the 64-bit count register (RCX) is zero.

General protection, #GP	X	X	X	The target offset exceeded the code segment limit or was non-canonical

JMP (Near)

Near Jump

Unconditionally transfers control to a new address without saving the current rIP value. This form of the instruction jumps to an address in the current code segment and is called a *near jump*. The target operand can specify a register, a memory location, or a label.

If the JMP target is specified in a register or memory location, then a 16-, 32-, or 64-bit rIP is read from the operand, depending on operand size. This rIP is zero-extended to 64 bits.

If the JMP target is specified by a displacement in the instruction, the signed displacement is added to the rIP (of the following instruction), and the result is truncated to 16, 32, or 64 bits depending on operand size. The signed displacement can be 8 bits, 16 bits, or 32 bits, depending on the opcode and the operand size.

For near jumps in 64-bit mode, the operand size defaults to 64 bits. The E9 opcode results in $RIP = RIP + 32\text{-bit signed displacement}$, and the FF /4 opcode results in $RIP = 64\text{-bit offset from register or memory}$. No prefix is available to encode a 32-bit operand size in 64-bit mode.

See JMP (Far) for information on far jumps—jumps to procedures located outside of the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
JMP <i>rel8off</i>	EB <i>cb</i>	Short jump with the target specified by an 8-bit signed displacement.

JMP (Far)

Far Jump

Unconditionally transfers control to a new address without saving the current CS:rIP values. This form of the instruction jumps to an address outside the current code segment and is called a *far jump*. The operand specifies a target selector and offset.

The target operand can be specified by the instruction directly, by containing the far pointer in the jmp far opcode itself, or indirectly, by referencing a far pointer in memory. In 64-bit mode, only indirect far jumps are allowed, executing a direct far jmp (opcode EA) will generate an undefined opcode exception. For both direct and indirect far jumps, if the JMP (Far) operand-size is 16 bits, the instruction's operand is a 16-bit selector followed by a 16-bit offset. If the operand-size is 32 or 64 bits, the operand is a 16-bit selector followed by a 32-bit offset.

In all modes, the target selector used by the instruction can be a code selector. Additionally, the target selector can also be a call gate in protected mode, or a task gate or TSS selector in legacy protected mode.

- *Target is a code segment*—Control is transferred to the target CS:rIP. In this case, the target offset can only be a 16 or 32 bit value, depending on operand-size, and is zero-extended to 64 bits. No CPL change is allowed.
- *Target is a call gate*—The call gate specifies the actual target code segment and offset, and control is transferred to the target CS:rIP. When jumping through a call gate, the size of the target rIP is 16, 32, or 64 bits, depending on the size of the call gate. If the target rIP is less than 64 bits, it's zero-extended to 64 bits. In long mode, only 64-bit call gates are allowed, and they must point to 64-bit code segments. No CPL change is allowed.
- *Target is a task gate or a TSS*—If the mode is legacy protected mode, then a task switch occurs. See “Hardware Task-Management in Legacy Mode” in volume 2 for details about task switches. Hardware task switches are not supported in long mode.

See JMP (Near) for information on near jumps—jumps to procedures located inside the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
JMP FAR <i>pntr</i> 16:16	EA <i>cd</i>	Far jump direct, with the target specified by a far pointer contained in the instruction. (Invalid in 64-bit mode.)

LAHF**Load Status Flags into AH Register**

Loads the lower 8 bits of the rFLAGS register, including sign flag (SF), zero flag (ZF), auxiliary carry flag (AF), parity flag (PF), and carry flag (CF), into the AH register.

The instruction sets the reserved bits 1, 3, and 5 of the rFLAGS register to 1, 0, and 0, respectively, in the AH register.

The LAHF instruction can only be executed in 64-bit mode. Support for the instruction is implementation-dependent and is indicated by CPUID Fn8000_0001_ECX[LahfSahf] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Load Far Pointer

Loads a far pointer from a memory location (second operand) into a segment register (mnemonic) and general-purpose register (first operand). The instruction stores the 16-bit segment selector of the pointer into the segment register and the 16-bit or 32-bit offset portion into the general-purpose register. The operand-size attributes determine whether the pointer loaded is 32, 48 or 80 bits in length.

These instructions load associated segment-descriptor information into the hidden portion of the specified segment register.

Mnemonic	Opcode	Description
LDS <i>reg16, mem16:16</i>	C5 /r	Load DS:reg16 with a far pointer from memory. [Redefined as VEX (2-byte prefix) in 64-bit mode.]

LEA

Load Effective Address

Computes the effective address of a memory location (second operand) and stores it in a general-purpose register (first operand).

The address size of the memory location and the size of the register determine the specific action taken by the instruction, as follows:

- If the address size and the register size are the same, the instruction stores the effective address as computed.
- If the address size is longer than the register size, the instruction truncates the effective address to the size of the register.
- If the address size is shorter than the register size, the instruction zero-extends the effective address to the size of the register.

If the second operand is a register, an undefined-opcode exception occurs.

The LEA instruction is related to the MOV instruction, which copies data from a memory location to a register, but LEA takes the address of the source operand, whereas MOV takes the contents of the memory location specified by the source operand. In the simplest cases, LEA can be replaced with MOV. For example:

```
lea eax, [ebx]
```

has the same effect as:

```
mov eax, ebx
```

However, LEA allows software to use any valid ModRM and SIB addressing mode for the source operand. For example:

```
lea eax, [ebx+edi]
```

loads the sum of the EBX and EDI registers into the EAX register. This could not be accomplished by a single MOV instruction.

The LEA instruction has a limited capability to perform multiplication of operands in general-purpose registers using scaled-index addressing. For example:

```
lea eax, [ebx+ebx*8]
```

loads the value of the EBX register, multiplied by 9, into the EAX register. Possible values of multipliers are 2, 4, 8, 3, 5, and 9.

The LEA instruction is widely used in string-processing and array-processing to initialize an index register (rSI or rDI) before performing string instructions such as MOVSx. It is also used to initialize the rBX register before performing the XLAT instruction in programs that perform character translations. In data structures, the LEA instruction can calculate addresses of operands stored in memory, and in particular, addresses of array or string elements.

Mnemonic	Opcode	Description
LEA <i>reg16, mem</i>	8D / <i>r</i>	Store effective address in a 16-bit register.
LEA <i>reg32, mem</i>	8D / <i>r</i>	Store effective address in a 32-bit register.
LEA <i>reg64, mem</i>	8D / <i>r</i>	Store effective address in a 64-bit register.

Invalid opcode, #UD	X	X	X	The source operand was a register.

LEAVE**Delete Procedure Stack Frame**

Releases a stack frame created by a previous ENTER instruction. To release the frame, it copies the frame pointer (in the rBP register) to the stack pointer register (rSP), and then pops the old frame pointer from the stack into the rBP register, thus restoring the stack frame of the calling procedure.

The 32-bit LEAVE instruction is equivalent to the following 32-bit operation:

```
MOV ESP,EBP
POP EBP
```

To return program control to the calling procedure, execute a RET instruction after the LEAVE instruction.

In 64-bit mode, the LEAVE operand size defaults to 64 bits, and there is no prefix available for encoding a 32-bit operand size.

Mnemonic	Opcode	Description
LEAVE	C9	Set the stack pointer register SP to the value in the BP register and pop BP.
LEAVE	C9	Set the stack pointer register ESP to the value in the EBP register and pop EBP. (No prefix for encoding this in 64-bit mode.)
LEAVE	C9	Set the stack pointer register RSP to the value in the RBP register and pop RBP.

LFENCE

Load Fence

Acts as a barrier to force strong memory ordering (serialization) between load instructions preceding the LFENCE and load instructions that follow the LFENCE. Loads from differing memory types may be performed out of order, in particular between WC/WC+ and other memory types. The LFENCE instruction assures that the system completes all previous loads before executing subsequent loads.

The LFENCE instruction is weakly-ordered with respect to store instructions, data and instruction prefetches, and the SFENCE instruction. Speculative loads initiated by the processor, or specified explicitly using cache-prefetch instructions, can be reordered around an LFENCE.

In addition to load instructions, the LFENCE instruction is strongly ordered with respect to other LFENCE instructions, as well as MFENCE and other serializing instructions. Further details on the use of MFENCE to order accesses among differing memory types may be found in *AMD64 Architecture Programmer's Manual Volume 2: System Programming*, section 7.4 “Memory Types” on page 172.

LFENCE is an SSE2 instruction. Support for SSE2 instructions is indicated by CPUID Fn0000_0001_EDX[SSE2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

LLWPCB Load Lightweight Profiling Control Block Address

Parses the Lightweight Profiling Control Block at the address contained in the specified register. If the LWPCB is valid, writes the address into the LWP_CBADDR MSR and enables Lightweight Profiling.

See Volume 2, Chapter 13, for an overview of the lightweight profiling facility.

The LWPCB must be in memory that is readable and writable in user mode. For better performance, it should be aligned on a 64-byte boundary in memory and placed so that it does not cross a page boundary, though neither of these suggestions is required.

The LWPCB address in the register is truncated to 32 bits if the operand size is 32.

Action

1. If LWP is not available or if the machine is not in protected mode, LLWPCB immediately causes a #UD exception.
2. If LWP is already enabled, the processor flushes the LWP state to memory in the old LWPCB. See description of the SLWPCB instruction on page 316 for details on saving the active LWP state.
If the flush causes a #PF exception, LWP remains enabled with the old LWPCB still active. Note that the flush is done before LWP attempts to access the new LWPCB.
3. If the specified LWPCB address is 0, LWP is disabled and the execution of LLWPCB is complete.
4. The LWPCB address is non-zero. LLWPCB validates it as follows:
 - If any part of the LWPCB or the ring buffer is beyond the data segment limit, LLWPCB causes a #GP exception.
 - If the ring buffer size is below the implementation's minimum ring buffer size, LLWPCB causes a #GP exception.
 - While doing these checks, LWP reads and writes the LWPCB, which may cause a #PF exception.

If any of these exceptions occurs, LLWPCB aborts and LWP is left disabled. Usually, the operating system will handle a #PF exception by making the memory available and returning to retry the LLWPCB instruction. The #GP exceptions indicate application programming errors.

5. LWP converts the LWPCB address and the ring buffer address to linear address form by adding the DS base address and stores the addresses internally.
6. LWP examines the LWPCB.Flags field to determine which events should be enabled and whether threshold interrupts should be taken. It clears the bits for any features that are not available and stores the result back to LWPCB.Flags to inform the application of the actual LWP state.
7. For each event being enabled, LWP examines the EventInterval n value and, if necessary, sets it to an implementation-defined minimum. (The minimum event interval for LWPVAL is zero.) It loads its internal counter for the event from the value in EventCounter n . A zero or negative value

in `EventCounter n` means that the next event of that type will cause an event record to be stored. To count every j^{th} event, a program should set `EventInterval n` to $j-1$ and `EventCounter n` to some starting value (where $j-1$ is a good initial count). If the counter value is larger than the interval, the first event record will be stored after a larger number of events than subsequent records.

8. LWP is started. The execution of LLWPCB is complete.

Notes

If none of the bits in the `LWPCB.Flags` specifies an available event, LLWPCB still enables LWP to allow the use of the LWPINS instruction. However, no other event records will be stored.

A program can temporarily disable LWP by executing SLWPCB to obtain the current LWPCB address, saving that value, and then executing LLWPCB with a register containing 0. It can later re-enable LWP by executing LLWPCB with a register containing the saved address.

When LWP is enabled, it is typically an error to execute LLWPCB with the address of the active LWPCB. When the hardware flushes the existing LWP state into the LWPCB, it may overwrite fields that the application may have set to new LWP parameter values. The flushed values will then be loaded as LWP is restarted. To reuse an LWPCB, an application should stop LWP by passing a zero to LLWPCB, then prepare the LWPCB with new parameters and execute LLWPCB again to restart LWP.

Internally, LWP keeps the linear address of the LWPCB and the ring buffer. If the application changes the value of DS, LWP will continue to collect samples even if the new DS value would no longer allow access the LWPCB or the ring buffer. However, a #GP fault will occur if the application uses XRSTOR to restore LWP state saved by XSAVE. Programs should avoid using XSAVE/XRSTOR on LWP state if DS has changed. This only applies when the `CPL != 0`; kernel mode operation of XRSTOR is unaffected by changes to DS. See instruction listing for XSAVE in Volume 4 for details.

Operating system and hypervisor code that runs when `CPL ≠ 3` should use XSAVE and XRSTOR to control LWP rather than using LLWPCB. Use WRMSR to write 0 to the `LWP_CBADDR` MSR to immediately stop LWP without saving its current state.

It is possible to execute LLWPCB when the `CPL != 3` or when SMM is active, but the system software must ensure that the LWPCB and the entire ring buffer are properly mapped into writable memory in order to avoid a #PF or #GP fault. Furthermore, if LWP is enabled when a kernel executes LLWPCB, both the old and new control blocks and ring buffers must be accessible. Using LLWPCB in these situations is not recommended.

LLWPCB is an LWP instruction. Support for LWP instructions is indicated by `CPUID Fn8000_0001_ECX[LWP] = 1`.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Instruction Encoding

Mnemonic	Encoding			
	XOP	RXB.map_select	W.vvvv.L.pp	Opcode
LLWPCB <i>reg32</i>	8F	$\overline{\text{RXB}}.09$	0.1111.0.00	12 /0
LLWPCB <i>reg64</i>	8F	$\overline{\text{RXB}}.09$	1.1111.0.00	12 /0

ModRM.reg augments the opcode and is assigned the value 0. ModRM.r/m (augmented by XOP.R) specifies the register containing the effective address of the LWPCB. ModRM.mod is 11b.

LODS

LODSB

LODSW

LODSD

LODSQ

Load String

Copies the byte, word, doubleword, or quadword in the memory location pointed to by the DS:rSI registers to the AL, AX, EAX, or RAX register, depending on the size of the operand, and then increments or decrements the rSI register according to the state of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments rSI; otherwise, it decrements rSI. It increments or decrements rSI by 1, 2, 4, or 8, depending on the number of bytes being loaded.

The forms of the LODS instruction with an explicit operand address the operand at *seg*:[rSI]. The value of *seg* defaults to the DS segment, but may be overridden by a segment prefix. The explicit operand serves only to specify the type (size) of the value being copied and the specific registers used.

The no-operands forms of the instruction always use the DS:[rSI] registers to point to the value to be copied (they do not allow a segment prefix). The mnemonic determines the size of the operand and the specific registers used.

The LODSx instructions support the REP prefixes. For details about the REP prefixes, see “Repeat Prefixes” on page 12. More often, software uses the LODSx instruction inside a loop controlled by a LOOPcc instruction as a more efficient replacement for instructions like:

```
mov eax, dword ptr ds:[esi]
add esi, 4
```

The LODSQ instruction can only be used in 64-bit mode.

Mnemonic	Opcode	Description
LODS <i>mem8</i>	AC	Load byte at DS:rSI into AL and then increment or decrement rSI.

LOOP

LOOPE

LOOPNE

LOOPNZ

LOOPZ

Loop

Decrements the count register (rCX) by 1, then, if rCX is not 0 and the ZF flag meets the condition specified by the mnemonic, it jumps to the target instruction specified by the signed 8-bit relative offset. Otherwise, it continues with the next instruction after the `LOOPcc` instruction.

The size of the count register used (CX, ECX, or RCX) depends on the address-size attribute of the `LOOPcc` instruction.

The `LOOP` instruction ignores the state of the ZF flag.

The `LOOPE` and `LOOPZ` instructions jump if rCX is not 0 and the ZF flag is set to 1. In other words, the instruction exits the loop (falls through to the next instruction) if rCX becomes 0 or ZF = 0.

The `LOOPNE` and `LOOPNZ` instructions jump if rCX is not 0 and ZF flag is cleared to 0. In other words, the instruction exits the loop if rCX becomes 0 or ZF = 1.

The `LOOPcc` instruction does not change the state of the ZF flag. Typically, the loop contains a compare instruction to set or clear the ZF flag.

If the jump is taken, the signed displacement is added to the rIP (of the following instruction) and the result is truncated to 16, 32, or 64 bits, depending on operand size.

In 64-bit mode, the operand size defaults to 64 bits without the need for a REX prefix, and the processor sign-extends the 8-bit offset before adding it to the RIP.

Mnemonic	Opcode	Description
<code>LOOP rel8off</code>	<code>E2 cb</code>	Decrement rCX, then jump short if rCX is not 0.
<code>LOOPE rel8off</code>	<code>E1 cb</code>	Decrement rCX, then jump short if rCX is not 0 and ZF is 1.

General protection, #GP	X	X	X	The target offset exceeded the code segment limit or was non-canonical.

LWPINS

Lightweight Profiling Insert Record

Inserts programmed event record into the LWP event ring buffer in memory and advances the ring buffer pointer.

Refer to the description of the programmed event record in Volume 2, Chapter 13. The record has an EventId of 255. The value in the register specified by vvvv (first operand) is stored in the Data2 field at bytes 23–16 (zero extended if the operand size is 32). The value in a register or memory location (second operand) is stored in the Data1 field at bytes 7–4. The immediate value (third operand) is truncated to 16 bits and stored in the Flags field at bytes 3–2.

If the ring buffer is not full, or if LWP is running in Continuous Mode, the head pointer is advanced and the CF flag is cleared. If the ring buffer threshold is exceeded and threshold interrupts are enabled, an interrupt is signaled. If LWP is in Continuous Mode and the new head pointer equals the tail pointer, the MissedEvents counter is incremented to indicate that the buffer wrapped.

If the ring buffer is full and LWP is running in Synchronized Mode, the event record overwrites the last record in the buffer, the MissedEvents counter in the LWPCB is incremented, the head pointer is not advanced, and the CF flag is set.

LWPINS generates an invalid opcode exception (#UD) if the machine is not in protected mode or if LWP is not available.

LWPINS simply clears CF if LWP is not enabled. This allows LWPINS instructions to be harmlessly ignored if profiling is turned off.

It is possible to execute LWPINS when the CPL \neq 3 or when SMM is active, but the system software must ensure that the memory operand (if present), the LWPCB, and the entire ring buffer are properly mapped into writable memory in order to avoid a #PF or #GP fault. Using LWPINS in these situations is not recommended.

LWPINS can be used by a program to mark significant events in the ring buffer as they occur. For instance, a program might capture information on changes in the process' address space such as library loads and unloads, or changes in the execution environment such as a change in the state of a user-mode thread of control.

Note that when the LWPINS instruction finishes writing a event record in the event ring buffer, it counts as an instruction retired. If the Instructions Retired event is active, this might cause that counter to become negative and immediately store another event record with the same instruction address (but different EventId values).

LWPINS is an LWP instruction. Support for LWP instructions is indicated by CPUID Fn8000_0001_ECX[LWP] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Instruction Encoding

Mnemonic	Encoding			
	XOP	RXB.map_select	W.vvvv.L.pp	Opcode
LWPINS <i>reg32.vvvv, reg/mem32, imm32</i>	8F	$\overline{\text{RXB}}.0A$	$0.\overline{\text{src}}1.0.00$	12 /0 /imm32
LWPINS <i>reg64.vvvv, reg/mem32, imm32</i>	8F	$\overline{\text{RXB}}.0A$	$1.\overline{\text{src}}1.0.00$	12 /0 /imm32

ModRM.reg augments the opcode and is assigned the value 0. The {mod, r/m} field of the ModRM byte (augmented by XOP.R) encodes the second operand. A 4-byte immediate field follows ModRM.

			X	A page fault resulted from writing the event to the ring buffer.
			X	A page fault resulted from reading a modrm operand from memory.
General protection, #GP			X	A modrm operand in memory exceeded the segment limit.

LWPVAL

Lightweight Profiling Insert Value

Decrements the event counter associated with the programmed value sample event (see “Programmed Value Sample” in Volume 2, Chapter 13). If the resulting counter value is negative, inserts an event record into the LWP event ring buffer in memory and advances the ring buffer pointer.

Refer to the description of the programmed value sample record in Volume 2, Chapter 13. The event record has an EventId of 1. The value in the register specified by *vvvv* (first operand) is stored in the Data2 field at bytes 23–16 (zero extended if the operand size is 32). The value in a register or memory location (second operand) is stored in the Data1 field at bytes 7–4. The immediate value (third operand) is truncated to 16 bits and stored in the Flags field at bytes 3–2.

If the programmed value sample record is not written to the event ring buffer, the memory location of the second operand (assuming it is memory-based) is not accessed.

If the ring buffer is not full or if LWP is running in continuous mode, the head pointer is advanced and the event counter is reset to the interval for the event (subject to randomization). If the ring buffer threshold is exceeded and threshold interrupts are enabled, an interrupt is signaled. If LWP is in Continuous Mode and the new head pointer equals the tail pointer, the MissedEvents counter is incremented to indicate that the buffer wrapped.

If the ring buffer is full and LWP is running in Synchronized Mode, the event record overwrites the last record in the buffer, the MissedEvents counter in the LWPCB is incremented, and the head pointer is not advanced.

LWPVAL generates an invalid opcode exception (#UD) if the machine is not in protected mode or if LWP is not available.

LWPVAL does nothing if LWP is not enabled or if the Programmed Value Sample event is not enabled in LWPCB.Flags. This allows LWPVAL instructions to be harmlessly ignored if profiling is turned off.

It is possible to execute LWPVAL when the CPL \neq 3 or when SMM is active, but the system software must ensure that the memory operand (if present), the LWPCB, and the entire ring buffer are properly mapped into writable memory in order to avoid a #PF or #GP fault. Using LWPVAL in these situations is not recommended.

LWPVAL can be used by a program to perform value profiling. This is the technique of sampling the value of some program variable at a predetermined frequency. For example, a managed runtime might use LWPVAL to sample the value of the divisor for a frequently executed divide instruction in order to determine whether to generate specialized code for a common division. It might sample the target location of an indirect branch or call to see if one destination is more frequent than others. Since LWPVAL does not modify any registers or condition codes, it can be inserted harmlessly between any instructions.

Note

When LWPVAL completes (whether or not it stored an event record in the event ring buffer), it counts as an instruction retired. If the Instructions Retired event is active, this might cause that counter to become negative and immediately store an event record. If LWPVAL also stored an event record, the buffer will contain two records with the same instruction address (but different EventId values).

LWPVAL is an LWP instruction. Support for LWP instructions is indicated by CPUID Fn8000_0001_ECX[LWP] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Instruction Encoding

Mnemonic	Encoding			
	XOP	RXB.map_select	W.vvvv.L.pp	Opcode
LWPVAL <i>reg32.vvvv, reg/mem32, imm32</i>	8F	$\overline{\text{RXB}}.0A$	$0.\overline{\text{src}}1.0.00$	12 /1 /imm32
LWPVAL <i>reg64.vvvv, reg/mem32, imm32</i>	8F	$\overline{\text{RXB}}.0A$	$1.\overline{\text{src}}1.0.00$	12 /1 /imm32

ModRM.reg augments the opcode and is assigned the value 001b. The {mod, r/m} field of the ModRM byte (augmented by XOP.R) encodes the second operand. A four-byte immediate field follows ModRM.

LZCNT

Count Leading Zeros

Counts the number of leading zero bits in the 16-, 32-, or 64-bit general purpose register or memory source operand. Counting starts downward from the most significant bit and stops when the highest bit having a value of 1 is encountered or when the least significant bit is encountered. The count is written to the destination register.

This instruction has two operands:

LZCNT dest, src

If the input operand is zero, CF is set to 1 and the size (in bits) of the input operand is written to the destination register. Otherwise, CF is cleared.

If the most significant bit is a one, the ZF flag is set to 1, zero is written to the destination register. Otherwise, ZF is cleared.

LZCNT is an Advanced Bit Manipulation (ABM) instruction. Support for the LZCNT instruction is indicated by CPUID Fn8000_0001_ECX[ABM] = 1. If the LZCNT instruction is not available, the encoding is interpreted as the BSR instruction. Software MUST check the CPUID bit once per program or library initialization before using the LZCNT instruction, or inconsistent behavior may result.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
LZCNT <i>reg16, reg/mem16</i>	F3 0F BD /r	Count the number of leading zeros in reg/mem16.
LZCNT <i>reg32, reg/mem32</i>	F3 0F BD /r	Count the number of leading zeros in reg/mem32.
LZCNT <i>reg64, reg/mem64</i>	F3 0F BD /r	Count the number of leading zeros in reg/mem64.

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

MFENCE

Memory Fence

Acts as a barrier to force strong memory ordering (serialization) between load and store instructions preceding the MFENCE, and load and store instructions that follow the MFENCE. The processor may perform loads out of program order with respect to non-conflicting stores for certain memory types. The MFENCE instruction guarantees that the system completes all previous memory accesses before executing subsequent accesses.

The MFENCE instruction is weakly-ordered with respect to data and instruction prefetches. Speculative loads initiated by the processor, or specified explicitly using cache-prefetch instructions, can be reordered around an MFENCE.

In addition to load and store instructions, the MFENCE instruction is strongly ordered with respect to other MFENCE instructions, LFENCE instructions, SFENCE instructions, serializing instructions, and CLFLUSH instructions. Further details on the use of MFENCE to order accesses among differing memory types may be found in *AMD64 Architecture Programmer's Manual Volume 2: System Programming*, section 7.4 “Memory Types” on page 172.

The MFENCE instruction is a serializing instruction.

MFENCE is an SSE2 instruction. Support for SSE2 instructions is indicated by CPUID Fn0000_0001_EDX[SSE2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Invalid opcode, #UD	X	X	X	SSE2 instructions are not supported, as indicated by CPUID Fn0000_0001_EDX[SSE2] = 0.

MOV

Move

Copies an immediate value or the value in a general-purpose register, segment register, or memory location (second operand) to a general-purpose register, segment register, or memory location. The source and destination must be the same size (byte, word, doubleword, or quadword) and cannot both be memory locations.

In opcodes A0 through A3, the memory offsets (called *moffsets*) are address sized. In 64-bit mode, memory offsets default to 64 bits. Opcodes A0–A3, in 64-bit mode, are the only cases that support a 64-bit offset value. (In all other cases, offsets and displacements are a maximum of 32 bits.) The B8 through BF (B8 +*rq*) opcodes, in 64-bit mode, are the only cases that support a 64-bit immediate value (in all other cases, immediate values are a maximum of 32 bits).

When reading segment-registers with a 32-bit operand size, the processor zero-extends the 16-bit selector results to 32 bits. When reading segment-registers with a 64-bit operand size, the processor zero-extends the 16-bit selector to 64 bits. If the destination operand specifies a segment register (DS, ES, FS, GS, or SS), the source operand must be a valid segment selector.

It is possible to move a null segment selector value (0000–0003h) into the DS, ES, FS, or GS register. This action does not cause a general protection fault, but a subsequent reference to such a segment *does* cause a #GP exception. For more information about segment selectors, see “Segment Selectors and Registers” in Volume 2.

When the MOV instruction is used to load the SS register, the processor blocks external interrupts until after the execution of the following instruction. This action allows the following instruction to be a MOV instruction to load a stack pointer into the ESP register (MOV ESP, val) before an interrupt occurs. However, the LSS instruction provides a more efficient method of loading SS and ESP.

Attempting to use the MOV instruction to load the CS register generates an invalid opcode exception (#UD). Use the far JMP, CALL, or RET instructions to load the CS register.

To initialize a register to 0, rather than using a MOV instruction, it may be more efficient to use the XOR instruction with identical destination and source operands.

Mnemonic	Opcode	Description
MOV <i>reg/mem8, reg8</i>	88 /r	Move the contents of an 8-bit register to an 8-bit destination register or memory operand.
MOV <i>reg/mem16, reg16</i>	89 /r	Move the contents of a 16-bit register to a 16-bit destination register or memory operand.
MOV <i>reg/mem32, reg32</i>	89 /r	Move the contents of a 32-bit register to a 32-bit destination register or memory operand.
MOV <i>reg/mem64, reg64</i>	89 /r	Move the contents of a 64-bit register to a 64-bit destination register or memory operand.
MOV <i>reg8, reg/mem8</i>	8A /r	Move the contents of an 8-bit register or memory operand to an 8-bit destination register.

Mnemonic	Opcode	Description
MOV <i>reg16, reg/mem16</i>	8B /r	Move the contents of a 16-bit register or memory operand to a 16-bit destination register.
MOV <i>reg32, reg/mem32</i>	8B /r	Move the contents of a 32-bit register or memory operand to a 32-bit destination register.
MOV <i>reg64, reg/mem64</i>	8B /r	Move the contents of a 64-bit register or memory operand to a 64-bit destination register.
MOV <i>reg16/32/64/mem16, segReg</i>	8C /r	Move the contents of a segment register to a 16-bit, 32-bit, or 64-bit destination register or to a 16-bit memory operand.
MOV <i>segReg, reg/mem16</i>	8E /r	Move the contents of a 16-bit register or memory operand to a segment register.
MOV AL, <i>moffset8</i>	A0	Move 8-bit data at a specified memory offset to the AL register.
MOV AX, <i>moffset16</i>	A1	Move 16-bit data at a specified memory offset to the AX register.
MOV EAX, <i>moffset32</i>	A1	Move 32-bit data at a specified memory offset to the EAX register.
MOV RAX, <i>moffset64</i>	A1	Move 64-bit data at a specified memory offset to the RAX register.
MOV <i>moffset8, AL</i>	A2	Move the contents of the AL register to an 8-bit memory offset.
MOV <i>moffset16, AX</i>	A3	Move the contents of the AX register to a 16-bit memory offset.
MOV <i>moffset32, EAX</i>	A3	Move the contents of the EAX register to a 32-bit memory offset.
MOV <i>moffset64, RAX</i>	A3	Move the contents of the RAX register to a 64-bit memory offset.
MOV <i>reg8, imm8</i>	B0 +rb <i>ib</i>	Move an 8-bit immediate value into an 8-bit register.
MOV <i>reg16, imm16</i>	B8 +rw <i>iw</i>	Move a 16-bit immediate value into a 16-bit register.
MOV <i>reg32, imm32</i>	B8 +rd <i>id</i>	Move a 32-bit immediate value into a 32-bit register.
MOV <i>reg64, imm64</i>	B8 +rq <i>iq</i>	Move a 64-bit immediate value into a 64-bit register.
MOV <i>reg/mem8, imm8</i>	C6 /0 <i>ib</i>	Move an 8-bit immediate value to an 8-bit register or memory operand.
MOV <i>reg/mem16, imm16</i>	C7 /0 <i>iw</i>	Move a 16-bit immediate value to a 16-bit register or memory operand.
MOV <i>reg/mem32, imm32</i>	C7 /0 <i>id</i>	Move a 32-bit immediate value to a 32-bit register or memory operand.
MOV <i>reg/mem64, imm32</i>	C7 /0 <i>id</i>	Move a 32-bit signed immediate value to a 64-bit register or memory operand.

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

MOVBE

Move Big Endian

Loads or stores a general purpose register while swapping the byte order. Operates on 16-bit, 32-bit, or 64-bit values. Converts big-endian formatted memory data to little-endian format when loading a register and reverses the conversion when storing a GPR to memory.

The load form reads a 16-, 32-, or 64-bit value from memory, swaps the byte order, and places the reordered value in a general-purpose register. When the operand size is 16 bits, the upper word of the destination register remains unchanged. In 64-bit mode, when the operand size is 32 bits, the upper doubleword of the destination register is cleared.

The store form takes a 16-, 32-, or 64-bit value from a general-purpose register, swaps the byte order, and stores the reordered value in the specified memory location. The contents of the source GPR remains unchanged.

In the 16-bit swap, the upper and lower bytes are exchanged. In the doubleword swap operation, bits 7:0 are exchanged with bits 31:24 and bits 15:8 are exchanged with bits 23:16. In the quadword swap operation, bits 7:0 are exchanged with bits 63:56, bits 15:8 with bits 55:48, bits 23:16 with bits 47:40, and bits 31:24 with bits 39:32.

Support for the MOVBE instruction is indicated by CPUID Fn0000_0001_ECX[MOVBE] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

MOVD

Move Doubleword or Quadword

Moves a 32-bit or 64-bit value in one of the following ways:

- from a 32-bit or 64-bit general-purpose register or memory location to the low-order 32 or 64 bits of an XMM register, with zero-extension to 128 bits
- from the low-order 32 or 64 bits of an XMM to a 32-bit or 64-bit general-purpose register or memory location
- from a 32-bit or 64-bit general-purpose register or memory location to the low-order 32 bits (with zero-extension to 64 bits) or the full 64 bits of an MMX register
- from the low-order 32 or the full 64 bits of an MMX register to a 32-bit or 64-bit general-purpose register or memory location

Figure 3-1 on page 223 illustrates the operation of the MOVD instruction.

The MOVD instruction form that moves data to or from MMX registers is part of the MMX instruction subset. Support for MMX instructions is indicated by CPUID Fn0000_0001_EDX[MMX] or Fn0000_0001_EDX[MMX] = 1.

The MOVD instruction form that moves data to or from XMM registers is part of the SSE2 instruction subset. Support for SSE2 instructions is indicated by CPUID Fn0000_0001_EDX[SSE2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

MOVNTI Move Non-Temporal Doubleword or Quadword

Stores a value in a 32-bit or 64-bit general-purpose register (second operand) in a memory location (first operand). This instruction indicates to the processor that the data is non-temporal and is unlikely to be used again soon. The processor treats the store as a write-combining (WC) memory write, which minimizes cache pollution. The exact method by which cache pollution is minimized depends on the hardware implementation of the instruction. For further information, see “Memory Optimization” in Volume 1.

The MOVNTI instruction is weakly-ordered with respect to other instructions that operate on memory. Software should use an SFENCE instruction to force strong memory ordering of MOVNTI with respect to other stores.

The MOVNTI instruction is an SSE2 instruction. Support for SSE2 instructions is indicated by CPUID Fn0000_0001_EDX[SSE2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
MOVNTI <i>mem32, reg32</i>	0F C3 /r	Stores a 32-bit general-purpose register value into a 32-bit memory location, minimizing cache pollution.
MOVNTI <i>mem64, reg64</i>	0F C3 /r	Stores a 64-bit general-purpose register value into a 64-bit memory location, minimizing cache pollution.

MOVS

MOVSB

MOVSW

MOVSD

MOVSQ

Move String

Moves a byte, word, doubleword, or quadword from the memory location pointed to by DS:rSI to the memory location pointed to by ES:rDI, and then increments or decrements the rSI and rDI registers according to the state of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments both pointers; otherwise, it decrements them. It increments or decrements the pointers by 1, 2, 4, or 8, depending on the size of the operands.

The forms of the MOV S_x instruction with explicit operands address the first operand at *seg*:[rSI]. The value of *seg* defaults to the DS segment, but can be overridden by a segment prefix. These instructions always address the second operand at ES:[rDI] (ES may not be overridden). The explicit operands serve only to specify the type (size) of the value being moved.

The no-operands forms of the instruction use the DS:[rSI] and ES:[rDI] registers to point to the value to be moved (they do not allow a segment prefix). The mnemonic determines the size of the operands.

Do not confuse this MOVSD instruction with the same-mnemonic MOVSD (move scalar double-precision floating-point) instruction in the 128-bit media instruction set. Assemblers can distinguish the instructions by the number and type of operands.

The MOV S_x instructions support the REP prefixes. For details about the REP prefixes, see “Repeat Prefixes” on page 12.

Mnemonic	Opcode	Description
MOVS <i>mem8, mem8</i>	A4	Move byte at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVS <i>mem16, mem16</i>	A5	Move word at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVS <i>mem32, mem32</i>	A5	Move doubleword at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVS <i>mem64, mem64</i>	A5	Move quadword at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVSB	A4	Move byte at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVSW	A5	Move word at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.

Mnemonic	Opcode	Description
MOVSD	A5	Move doubleword at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.
MOVSQ	A5	Move quadword at DS:rSI to ES:rDI, and then increment or decrement rSI and rDI.

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

MOVSXD

Move with Sign-Extend Doubleword

Copies the 32-bit value in a register or memory location (second operand) into a 64-bit register (first operand), extending the most significant bit of the 32-bit value into all higher bits of the 64-bit register.

This instruction requires the REX prefix 64-bit operand size bit (REX.W) to be set to 1 to sign-extend a 32-bit source operand to a 64-bit result. Without the REX operand-size prefix, the operand size will be 32 bits, the default for 64-bit mode, and the source is zero-extended into a 64-bit register. With a 16-bit operand size, only 16 bits are copied, without modifying the upper 48 bits in the destination.

This instruction is available only in 64-bit mode. In legacy or compatibility mode this opcode is interpreted as ARPL.

Mnemonic	Opcode	Description
MOVSXD <i>reg64, reg/mem32</i>	63 /r	Move the contents of a 32-bit register or memory operand to a 64-bit register with sign extension.

MOVZX

Move with Zero-Extension

Copies the value in a register or memory location (second operand) into a register (first operand), zero-extending the value to fit in the destination register. The operand-size attribute determines the size of the zero-extended value.

Mnemonic	Opcode	Description
MOVZX <i>reg16, reg/mem8</i>	0F B6 /r	Move the contents of an 8-bit register or memory operand to a 16-bit register with zero-extension.
MOVZX <i>reg32, reg/mem8</i>	0F B6 /r	Move the contents of an 8-bit register or memory operand to a 32-bit register with zero-extension.

MUL

Unsigned Multiply

Multiplies the unsigned byte, word, doubleword, or quadword value in the specified register or memory location by the value in AL, AX, EAX, or RAX and stores the result in AX, DX:AX, EDX:EAX, or RDX:RAX (depending on the operand size). It puts the high-order bits of the product in AH, DX, EDX, or RDX.

If the upper half of the product is non-zero, the instruction sets the carry flag (CF) and overflow flag (OF) both to 1. Otherwise, it clears CF and OF to 0. The other arithmetic flags (SF, ZF, AF, PF) are undefined.

Mnemonic	Opcode	Description
MUL <i>reg/mem8</i>	F6 /4	Multiplies an 8-bit register or memory operand by the contents of the AL register and stores the result in the AX register.
MUL <i>reg/mem16</i>	F7 /4	Multiplies a 16-bit register or memory operand by the contents of the AX register and stores the result in the DX:AX register.
MUL <i>reg/mem32</i>	F7 /4	Multiplies a 32-bit register or memory operand by the contents of the EAX register and stores the result in the EDX:EAX register.
MUL <i>reg/mem64</i>	F7 /4	Multiplies a 64-bit register or memory operand by the contents of the RAX register and stores the result in the RDX:RAX register.

MULX

Multiply Unsigned

Computes the unsigned product of the specified source operand and the implicit source operand rDX. Writes the upper half of the product to the first destination and the lower half to the second. Does not affect the arithmetic flags.

This instruction has three operands:

`MULX dest1, dest2, src`

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The first and second operands (*dest1* and *dest2*) are general purpose registers. The specified source operand (*src*) is either a general purpose register or a memory operand. If the first and second operands specify the same register, the register receives the upper half of the product.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

NEG

Two's Complement Negation

Performs the two's complement negation of the value in the specified register or memory location by subtracting the value from 0. Use this instruction only on signed integer numbers.

If the value is 0, the instruction clears the CF flag to 0; otherwise, it sets CF to 1. The OF, SF, ZF, AF, and PF flag settings depend on the result of the operation.

The forms of the NEG instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
NEG <i>reg/mem8</i>	F6 /3	Performs a two's complement negation on an 8-bit register or memory operand.
NEG <i>reg/mem16</i>	F7 /3	Performs a two's complement negation on a 16-bit register or memory operand.
NEG <i>reg/mem32</i>	F7 /3	Performs a two's complement negation on a 32-bit register or memory operand.
NEG <i>reg/mem64</i>	F7 /3	Performs a two's complement negation on a 64-bit register or memory operand.

Exceptions

None

NOT

One's Complement Negation

Performs the one's complement negation of the value in the specified register or memory location by inverting each bit of the value.

The memory-operand forms of the NOT instruction support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
NOT <i>reg/mem8</i>	F6 /2	Complements the bits in an 8-bit register or memory operand.
NOT <i>reg/mem16</i>	F7 /2	Complements the bits in a 16-bit register or memory operand.
NOT <i>reg/mem32</i>	F7 /2	Complements the bits in a 32-bit register or memory operand.
NOT <i>reg/mem64</i>	F7 /2	Complements the bits in a 64-bit register or memory operand.

			X	A null data segment was used to reference memory.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference is performed while alignment checking was enabled.

OR

Logical OR

Performs a logical `or` on the bits in a register, memory location, or immediate value (second operand) and a register or memory location (first operand) and stores the result in the first operand location. The two operands cannot both be memory locations.

If both corresponding bits are 0, the corresponding bit of the result is 0; otherwise, the corresponding result bit is 1.

The forms of the OR instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
OR AL, <i>imm8</i>	0C <i>ib</i>	<code>or</code> the contents of AL with an immediate 8-bit value.
OR AX, <i>imm16</i>	0D <i>iw</i>	<code>or</code> the contents of AX with an immediate 16-bit value.
OR EAX, <i>imm32</i>	0D <i>id</i>	<code>or</code> the contents of EAX with an immediate 32-bit value.

OUT

Output to Port

Copies the value from the AL, AX, or EAX register (second operand) to an I/O port (first operand). The port address can be a byte-immediate value (00h to FFh) or the value in the DX register (0000h to FFFFh). The source register used determines the size of the port (8, 16, or 32 bits).

If the operand size is 64 bits, OUT only writes to a 32-bit I/O port.

If the CPL is higher than the IOPL or the mode is virtual mode, OUT checks the I/O permission bitmap in the TSS before allowing access to the I/O port. See Volume 2 for details on the TSS I/O permission bitmap.

Mnemonic	Opcode	Description
OUT <i>imm8</i> , AL	E6 <i>ib</i>	Output the byte in the AL register to the port specified by an 8-bit immediate value.
OUT <i>imm8</i> , AX	E7 <i>ib</i>	Output the word in the AX register to the port specified by an 8-bit immediate value.
OUT <i>imm8</i> , EAX	E7 <i>ib</i>	Output the doubleword in the EAX register to the port specified by an 8-bit immediate value.
OUT DX, AL	EE	Output byte in AL to the output port specified in DX.
OUT DX, AX	EF	Output word in AX to the output port specified in DX.
OUT DX, EAX	EF	Output doubleword in EAX to the output port specified in DX.

			X	The CPL was greater than the IOPL and one or more I/O permission bits were set in the TSS for the accessed port.
Page fault (#PF)		X	X	A page fault resulted from the execution of the instruction.

OUTS

OUTSB

OUTSW

OUTSD

Output String

Copies data from the memory location pointed to by DS:rSI to the I/O port address (0000h to FFFFh) specified in the DX register, and then increments or decrements the rSI register according to the setting of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments rSI; otherwise, it decrements rSI. It increments or decrements the pointer by 1, 2, or 4, depending on the size of the value being copied.

The OUTS DX mnemonic uses an explicit memory operand (second operand) to determine the type (size) of the value being copied, but always uses DS:rSI for the location of the value to copy. The explicit register operand (first operand) specifies the I/O port address and must always be DX.

The no-operands forms of the mnemonic use the DS:rSI register pair to point to the memory data to be copied and the contents of the DX register as the destination I/O port address. The mnemonic specifies the size of the I/O port and the type (size) of the value being copied.

The OUTSx instruction supports the REP prefix. For details about the REP prefix, see “Repeat Prefixes” on page 12.

If the effective operand size is 64-bits, the instruction behaves as if the operand size were 32 bits.

If the CPL is higher than the IOPL or the mode is virtual mode, OUTSx checks the I/O permission bitmap in the TSS before allowing access to the I/O port. See Volume 2 for details on the TSS I/O permission bitmap.

Mnemonic	Opcode	Description
OUTS DX, <i>mem8</i>	6E	Output the byte in DS:rSI to the port specified in DX, then increment or decrement rSI.
OUTS DX, <i>mem16</i>	6F	Output the word in DS:rSI to the port specified in DX, then increment or decrement rSI.
OUTS DX, <i>mem32</i>	6F	Output the doubleword in DS:rSI to the port specified in DX, then increment or decrement rSI.
OUTSB	6E	Output the byte in DS:rSI to the port specified in DX, then increment or decrement rSI.
OUTSW	6F	Output the word in DS:rSI to the port specified in DX, then increment or decrement rSI.
OUTSD	6F	Output the doubleword in DS:rSI to the port specified in DX, then increment or decrement rSI.

PAUSE

Pause

Improves the performance of spin loops, by providing a hint to the processor that the current code is in a spin loop. The processor may use this to optimize power consumption while in the spin loop.

Architecturally, this instruction behaves like a NOP instruction.

Processors that do not support PAUSE treat this opcode as a NOP instruction.

Mnemonic	Opcode	Description
PAUSE	F3 90	Provides a hint to processor that a spin loop is being executed.

PDEP

Parallel Deposit Bits

Scatters consecutive bits of the first source operand, starting at the least significant bit, to bit positions in the destination as specified by 1 bits in the second source operand (*mask*). Bit positions in the destination corresponding to 0 bits in the mask are cleared.

This instruction has three operands:

PDEP *dest, src, mask*

The following diagram illustrates the operation of this instruction.

v3_PDEP_instruct.eps

If the mask is all ones, the execution of this instruction effectively copies the source to the destination.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) and the source (*src*) are general-purpose registers. The second source operand (*mask*) is either a general-purpose register or a memory operand.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

PEXT

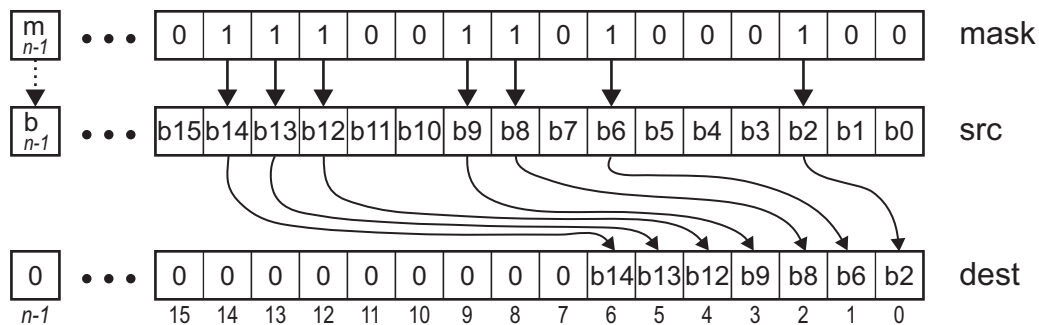

Parallel Extract Bits

Copies bits from the source operand, based on a mask, and packs them into the low-order bits of the destination. Clears all bits in the destination to the left of the most-significant bit copied.

This instruction has three operands:

PEXT *dest, src, mask*

The following diagram illustrates the operation of this instruction.

v3_PEXT_instruct.eps

If the mask is all ones, the execution of this instruction effectively copies the source to the destination.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) and the source (*src*) are general-purpose registers. The second source operand (*mask*) is either a general-purpose register or a memory operand.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

POP

Pop Stack

Copies the value pointed to by the stack pointer (SS:rSP) to the specified register or memory location and then increments the rSP by 2 for a 16-bit pop, 4 for a 32-bit pop, or 8 for a 64-bit pop.

The operand-size attribute determines the amount by which the stack pointer is incremented (2, 4 or 8 bytes). The stack-size attribute determines whether SP, ESP, or RSP is incremented.

For forms of the instruction that load a segment register (POP DS, POP ES, POP FS, POP GS, POP SS), the source operand must be a valid segment selector. When a segment selector is popped into a segment register, the processor also loads all associated descriptor information into the hidden part of the register and validates it.

It is possible to pop a null segment selector value (0000–0003h) into the DS, ES, FS, or GS register. This action does not cause a general protection fault, but a subsequent reference to such a segment *does* cause a #GP exception. For more information about segment selectors, see "Segment Selectors and Registers" in *Volume 2: System Programming*.

In 64-bit mode, the POP operand size defaults to 64 bits and there is no prefix available to encode a 32-bit operand size. Using POP DS, POP ES, or POP SS instruction in 64-bit mode generates an invalid-opcode exception.

This instruction cannot pop a value into the CS register. The RET (Far) instruction performs this function.

Mnemonic	Opcode	Description
POP <i>reg/mem16</i>	8F /0	Pop the top of the stack into a 16-bit register or memory location.
POP <i>reg/mem32</i>	8F /0	Pop the top of the stack into a 32-bit register or memory location. (No prefix for encoding this in 64-bit mode.)
POP <i>reg/mem64</i>	8F /0	Pop the top of the stack into a 64-bit register or memory location.
POP <i>reg16</i>	58 + <i>rw</i>	Pop the top of the stack into a 16-bit register.
POP <i>reg32</i>	58 + <i>rd</i>	Pop the top of the stack into a 32-bit register. (No prefix for encoding this in 64-bit mode.)
POP <i>reg64</i>	58 + <i>rq</i>	Pop the top of the stack into a 64-bit register.
POP DS	1F	Pop the top of the stack into the DS register. (Invalid in 64-bit mode.)
POP ES	07	Pop the top of the stack into the ES register. (Invalid in 64-bit mode.)
POP SS	17	Pop the top of the stack into the SS register. (Invalid in 64-bit mode.)

Mnemonic	Opcode	Description
POP FS	0F A1	Pop the top of the stack into the FS register.
POP GS	0F A9	Pop the top of the stack into the GS register.

			X	The SS register was loaded and the segment pointed to was not a writable data segment.
			X	The DS, ES, FS, or GS register was loaded and the segment pointed to was a data or non-conforming code segment, but the RPL or the CPL was greater than the DPL.
			X	The DS, ES, FS, or GS register was loaded and the segment pointed to was not a data segment or readable code segment.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

POPA POPAD

POP All GPRs

Pops words or doublewords from the stack into the general-purpose registers in the following order: eDI, eSI, eBP, eSP (image is popped and discarded), eBX, eDX, eCX, and eAX. The instruction increments the stack pointer by 16 or 32, depending on the operand size.

Using the POPA or POPAD instructions in 64-bit mode generates an invalid-opcode exception.

Mnemonic	Opcode	Description
POPA	61	Pop the DI, SI, BP, SP, BX, DX, CX, and AX registers. (Invalid in 64-bit mode.)
POPAD	61	Pop the EDI, ESI, EBP, ESP, EBX, EDX, ECX, and EAX registers. (Invalid in 64-bit mode.)

Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

POPCNT

Bit Population Count

Counts the number of bits having a value of 1 in the source operand and places the result in the destination register. The source operand is a 16-, 32-, or 64-bit general purpose register or memory operand; the destination operand is a general purpose register of the same size as the source operand register.

If the input operand is zero, the ZF flag is set to 1 and zero is written to the destination register. Otherwise, the ZF flag is cleared. The other flags are cleared.

Support for the POPCNT instruction is indicated by CPUID Fn0000_0001_ECX[POPCNT] = 1. Software **MUST** check the CPUID bit once per program or library initialization before using the POPCNT instruction, or inconsistent behavior may result.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
POPCNT <i>reg16, reg/mem16</i>	F3 0F B8 /r	Count the 1s in reg/mem16.
POPCNT <i>reg32, reg/mem32</i>	F3 0F B8 /r	Count the 1s in reg/mem32.
POPCNT <i>reg64, reg/mem64</i>	F3 0F B8 /r	Count the 1s in reg/mem64.

POPF

POPFD

POPFQ

POP to rFLAGS

Pops a word, doubleword, or quadword from the stack into the rFLAGS register and then increments the stack pointer by 2, 4, or 8, depending on the operand size.

In protected or real mode, all the non-reserved flags in the rFLAGS register can be modified, except the VIP, VIF, and VM flags, which are unchanged. In protected mode, at a privilege level greater than 0 the IOPL is also unchanged. The instruction alters the interrupt flag (IF) only when the CPL is less than or equal to the IOPL.

In virtual-8086 mode, if IOPL field is less than 3, attempting to execute a POPF_x or PUSHF_x instruction while VME is not enabled, or the operand size is not 16-bit, generates a #GP exception.

In 64-bit mode, this instruction defaults to a 64-bit operand size; there is no prefix available to encode a 32-bit operand size.

Mnemonic	Opcode	Description
POPF	9D	Pop a word from the stack into the FLAGS register.
POPFD	9D	Pop a double word from the stack into the EFLAGS register. (No prefix for encoding this in 64-bit mode.)
POPFQ	9D	Pop a quadword from the stack to the RFLAGS register.

PREFETCH PREFETCHW

Prefetch L1 Data-Cache Line

Loads the entire 64-byte aligned memory sequence *containing* the specified memory address into the L1 data cache. The position of the specified memory address within the 64-byte cache line is irrelevant. If a cache hit occurs, or if a memory fault is detected, no bus cycle is initiated and the instruction is treated as a NOP.

The PREFETCHW instruction loads the prefetched line and sets the cache-line state to Modified, in anticipation of subsequent data writes to the line. The PREFETCH instruction, by contrast, typically sets the cache-line state to Exclusive (depending on the hardware implementation).

The opcodes for the PREFETCH/PREFETCHW instructions include the ModRM byte; however, only the memory form of ModRM is valid. The register form of ModRM causes an invalid-opcode exception. Because there is no destination register, the three destination register field bits of the ModRM byte define the type of prefetch to be performed. The bit patterns 000b and 001b define the PREFETCH and PREFETCHW instructions, respectively. All other bit patterns are reserved for future use.

The *reserved* PREFETCH types do not result in an invalid-opcode exception if executed. Instead, for forward compatibility with future processors that may implement additional forms of the PREFETCH instruction, all reserved PREFETCH types are implemented as synonyms of the basic PREFETCH type (the PREFETCH instruction with type 000b).

The operation of these instructions is implementation-dependent. The processor implementation can ignore or change these instructions. The size of the cache line also depends on the implementation, with a minimum size of 32 bytes. For details on the use of this instruction, see the processor data sheets or other software-optimization documentation relating to particular hardware implementations.

When paging is enabled and PREFETCHW performs a prefetch from a writable page, it may set the PTE Dirty bit to 1.

Support for the PREFETCH and PREFETCHW instructions is indicated by CPUID Fn8000_0001_ECX[3DNowPrefetch] OR Fn8000_0001_EDX[LM] OR Fn8000_0001_EDX[3DNow] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
PREFETCH <i>mem8</i>	0F 0D /0	Prefetch processor cache line into L1 data cache.
PREFETCHW <i>mem8</i>	0F 0D /1	Prefetch processor cache line into L1 data cache and mark it modified.

Invalid opcode, #UD	X	X	X	PREFETCH and PREFETCHW instructions are not supported, as indicated by CPUID Fn8000_0001_ECX[3DNowPrefetch] AND Fn8000_0001_EDX[LM] AND Fn8000_0001_EDX[3DNow] = 0.
	X	X	X	The operand was a register.

PREFETCH/level**Prefetch Data to Cache Level *level***

Loads a cache line from the specified memory address into the data-cache level specified by the locality reference bits 5:3 of the ModRM byte. Table 3-3 on page 266 lists the locality reference options for the instruction.

This instruction loads a cache line even if the *mem8* address is not aligned with the start of the line. If the cache line is already contained in a cache level that is lower than the specified locality reference, or if a memory fault is detected, a bus cycle is not initiated and the instruction is treated as a NOP.

The operation of this instruction is implementation-dependent. The processor implementation can ignore or change this instruction. The size of the cache line also depends on the implementation, with a minimum size of 32 bytes. AMD processors alias PREFETCH1 and PREFETCH2 to PREFETCH0. For details on the use of this instruction, see the software-optimization documentation relating to particular hardware implementations.

Mnemonic	Opcode	Description
PREFETCHNTA <i>mem8</i>	0F 18 /0	Move data closer to the processor using the NTA reference.
PREFETCHT0 <i>mem8</i>	0F 18 /1	Move data closer to the processor using the T0 reference.
PREFETCHT1 <i>mem8</i>	0F 18 /2	Move data closer to the processor using the T1 reference.
PREFETCHT2 <i>mem8</i>	0F 18 /3	Move data closer to the processor using the T2 reference.

Table 3-3. Locality References for the Prefetch Instructions

Locality Reference	Description
NTA	Non-Temporal Access—Move the specified data into the processor with minimum cache pollution. This is intended for data that will be used only once, rather than repeatedly. The specific technique for minimizing cache pollution is implementation-dependent and may include such techniques as allocating space in a software-invisible buffer, allocating a cache line in only a single way, etc. For details, see the software-optimization documentation for a particular hardware implementation.
T0	All Cache Levels—Move the specified data into all cache levels.
T1	Level 2 and Higher—Move the specified data into all cache levels except 0th level (L1) cache.
T2	Level 3 and Higher—Move the specified data into all cache levels except 0th level (L1) and 1st level (L2) caches.

PUSH

Push onto Stack

Decrements the stack pointer and then copies the specified immediate value or the value in the specified register or memory location to the top of the stack (the memory location pointed to by SS:rSP).

The operand-size attribute determines the number of bytes pushed to the stack. The stack-size attribute determines whether SP, ESP, or RSP is the stack pointer. The address-size attribute is used only to locate the memory operand when pushing a memory operand to the stack.

If the instruction pushes the stack pointer (rSP), the resulting value on the stack is that of rSP before execution of the instruction.

There is a PUSH CS instruction but no corresponding POP CS. The RET (Far) instruction pops a value from the top of stack into the CS register as part of its operation.

In 64-bit mode, the operand size of all PUSH instructions defaults to 64 bits, and there is no prefix available to encode a 32-bit operand size. Using the PUSH CS, PUSH DS, PUSH ES, or PUSH SS instructions in 64-bit mode generates an invalid-opcode exception.

Pushing an odd number of 16-bit operands when the stack address-size attribute is 32 results in a misaligned stack pointer.

Mnemonic	Opcode	Description
PUSH <i>reg/mem16</i>	FF /6	Push the contents of a 16-bit register or memory operand onto the stack.
PUSH <i>reg/mem32</i>	FF /6	Push the contents of a 32-bit register or memory operand onto the stack. (No prefix for encoding this in 64-bit mode.)
PUSH <i>reg/mem64</i>	FF /6	Push the contents of a 64-bit register or memory operand onto the stack.
PUSH <i>reg16</i>	50 + <i>rw</i>	Push the contents of a 16-bit register onto the stack.
PUSH <i>reg32</i>	50 + <i>rd</i>	Push the contents of a 32-bit register onto the stack. (No prefix for encoding this in 64-bit mode.)
PUSH <i>reg64</i>	50 + <i>rq</i>	Push the contents of a 64-bit register onto the stack.
PUSH <i>imm8</i>	6A <i>ib</i>	Push an 8-bit immediate value (sign-extended to 16, 32, or 64 bits) onto the stack.
PUSH <i>imm16</i>	68 <i>iw</i>	Push a 16-bit immediate value onto the stack.
PUSH <i>imm32</i>	68 <i>id</i>	Push a 32-bit immediate value onto the stack. (No prefix for encoding this in 64-bit mode.)
PUSH <i>imm64</i>	68 <i>id</i>	Push a sign-extended 32-bit immediate value onto the stack.
PUSH CS	0E	Push the CS selector onto the stack. (Invalid in 64-bit mode.)

Mnemonic	Opcode	Description
PUSH SS	16	Push the SS selector onto the stack. (Invalid in 64-bit mode.)
PUSH DS	1E	Push the DS selector onto the stack. (Invalid in 64-bit mode.)
PUSH ES	06	Push the ES selector onto the stack. (Invalid in 64-bit mode.)
PUSH FS	0F A0	Push the FS selector onto the stack.
PUSH GS	0F A8	Push the GS selector onto the stack.

PUSHF

PUSHFD

PUSHFQ

Push rFLAGS onto Stack

Decrements the rSP register and copies the rFLAGS register (except for the VM and RF flags) onto the stack. The instruction clears the VM and RF flags in the rFLAGS image before putting it on the stack.

The instruction pushes 2, 4, or 8 bytes, depending on the operand size.

In 64-bit mode, this instruction defaults to a 64-bit operand size and there is no prefix available to encode a 32-bit operand size.

In virtual-8086 mode, if system software has set the IOPL field to a value less than 3, a general-protection exception occurs if application software attempts to execute PUSHF_x or POPF_x while VME is not enabled or the operand size is not 16-bit.

Mnemonic	Opcode	Description
PUSHF	9C	Push the FLAGS word onto the stack.
PUSHFD	9C	Push the EFLAGS doubleword onto stack. (No prefix encoding this in 64-bit mode.)
PUSHFQ	9C	Push the RFLAGS quadword onto stack.

RCL**Rotate Through Carry Left**

Rotates the bits of a register or memory location (first operand) to the left (more significant bit positions) and through the carry flag by the number of bit positions in an unsigned immediate value or the CL register (second operand). The bits rotated through the carry flag are rotated back in at the right end (lsb) of the first operand location.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

For 1-bit rotates, the instruction sets the OF flag to the logical `xor` of the CF bit (after the rotate) and the most significant bit of the result. When the rotate count is greater than 1, the OF flag is undefined. When the rotate count is 0, no flags are affected.

Mnemonic	Opcode	Description
RCL <i>reg/mem8</i> , 1	D0 /2	Rotate the 9 bits consisting of the carry flag and an 8-bit register or memory location left 1 bit.
RCL <i>reg/mem8</i> , CL	D2 /2	Rotate the 9 bits consisting of the carry flag and an 8-bit register or memory location left the number of bits specified in the CL register.

RCR**Rotate Through Carry Right**

Rotates the bits of a register or memory location (first operand) to the right (toward the less significant bit positions) and through the carry flag by the number of bit positions in an unsigned immediate value or the CL register (second operand). The bits rotated through the carry flag are rotated back in at the left end (msb) of the first operand location.

The processor masks the upper three bits in the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

For 1-bit rotates, the instruction sets the OF flag to the logical `xor` of the CF flag (before the rotate) and the most significant bit of the original value. When the rotate count is greater than 1, the OF flag is undefined. When the rotate count is 0, no flags are affected.

Mnemonic	Opcode	Description
<code>RCR reg/mem8, 1</code>	<code>D0 /3</code>	Rotate the 9 bits consisting of the carry flag and an 8-bit register or memory location right 1 bit.

RDFSBASE RDGSBASE

Read FS.base Read GS.base

Copies the base field of the FS or GS segment descriptor to the specified register. When supported and enabled, these instructions can be executed at any processor privilege level. The RDFSBASE and RDGSBASE instructions are only defined in 64-bit mode.

System software must set the FSGSBASE bit (bit 16) of CR4 to enable the RDFSBASE and RDGSBASE instructions.

Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[FSGSBASE] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
RDFSBASE <i>reg32</i>	F3 0F AE /0	Copy the lower 32 bits of FS.base to the specified general-purpose register.
RDFSBASE <i>reg64</i>	F3 0F AE /0	Copy the entire 64-bit contents of FS.base to the specified general-purpose register.
RDGSBASE <i>reg32</i>	F3 0F AE /1	Copy the lower 32 bits of GS.base to the specified general-purpose register.
RDGSBASE <i>reg64</i>	F3 0F AE /1	Copy the entire 64-bit contents of GS.base to the specified general-purpose register.

RDRAND

Read Random

Loads the destination register with a hardware-generated random value.

The size of the returned value in bits is determined by the size of the destination register.

Hardware modifies the CF flag to indicate whether the value returned in the destination register is valid. If CF = 1, the value is valid. If CF = 0, the value is invalid. Software must test the state of the CF flag prior to using the value returned in the destination register to determine if the value is valid. If the returned value is invalid, software must execute the instruction again. Software should implement a retry limit to insure forward progress of code.

The execution of RDRAND clears the OF, SF, ZF, AF, and PF flags.

Support for the RDRAND instruction is optional. On processors that support the instruction, CPUID Fn0000_0001_ECX[RDRAND] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
RDRAND <i>reg16</i>	0F C7 /6	Load the destination register with a 16-bit random number.
RDRAND <i>reg32</i>	0F C7 /6	Load the destination register with a 32-bit random number.

RET (Near)

Near Return from Called Procedure

Returns from a procedure previously entered by a CALL near instruction. This form of the RET instruction returns to a calling procedure within the current code segment.

This instruction pops the rIP from the stack, with the size of the pop determined by the operand size. The new rIP is then zero-extended to 64 bits. The RET instruction can accept an immediate value operand that it adds to the rSP after it pops the target rIP. This action skips over any parameters previously passed back to the subroutine that are no longer needed.

In 64-bit mode, the operand size defaults to 64 bits (eight bytes) without the need for a REX prefix. No prefix is available to encode a 32-bit operand size in 64-bit mode.

See RET (Far) for information on far returns—returns to procedures located outside of the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
RET	C3	Near return to the calling procedure.
RET <i>imm16</i>	C2 <i>iw</i>	Near return to the calling procedure then pop the specified number of bytes from the stack.

RET (Far) Far Return from Called Procedure

Returns from a procedure previously entered by a CALL Far instruction. This form of the RET instruction returns to a calling procedure in a different segment than the current code segment. It can return to the same CPL or to a less privileged CPL.

RET Far pops a target CS and rIP from the stack. If the new code segment is less privileged than the current code segment, the stack pointer is incremented by the number of bytes indicated by the immediate operand, if present; then a new SS and rSP are also popped from the stack.

The final value of rSP is incremented by the number of bytes indicated by the immediate operand, if present. This action skips over the parameters (previously passed to the subroutine) that are no longer needed.

All stack pops are determined by the operand size. If necessary, the target rIP is zero-extended to 64 bits before assuming program control.

If the CPL changes, the data segment selectors are set to NULL for any of the data segments (DS, ES, FS, GS) not accessible at the new CPL.

See RET (Near) for information on near returns—returns to procedures located inside the current code segment. For details about control-flow instructions, see “Control Transfers” in Volume 1, and “Control-Transfer Privilege Checks” in Volume 2.

Mnemonic	Opcode	Description
RET	CB	Far return to the calling procedure.
RET <i>imm16</i>	CA <i>iw</i>	Far return to the calling procedure, then pop the specified number of bytes from the stack.

ROL

Rotate Left

Rotates the bits of a register or memory location (first operand) to the left (toward the more significant bit positions) by the number of bit positions in an unsigned immediate value or the CL register (second operand). The bits rotated out left are rotated back in at the right end (lsb) of the first operand location.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, it masks the upper two bits of the count, providing a count in the range of 0 to 63.

After completing the rotation, the instruction sets the CF flag to the last bit rotated out (the lsb of the result). For 1-bit rotates, the instruction sets the OF flag to the logical `XOR` of the CF bit (after the rotate) and the most significant bit of the result. When the rotate count is greater than 1, the OF flag is undefined. When the rotate count is 0, no flags are affected.

ROR

Rotate Right

Rotates the bits of a register or memory location (first operand) to the right (toward the less significant bit positions) by the number of bit positions in an unsigned immediate value or the CL register (second operand). The bits rotated out right are rotated back in at the left end (the most significant bit) of the first operand location.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

After completing the rotation, the instruction sets the CF flag to the last bit rotated out (the most significant bit of the result). For 1-bit rotates, the instruction sets the OF flag to the logical `XOR` of the two most significant bits of the result. When the rotate count is greater than 1, the OF flag is undefined. When the rotate count is 0, no flags are affected.

RORX

Rotate Right Extended

Rotates the bits of the source operand right (toward the least-significant bit) by the number of bit positions specified in an immediate operand and writes the result to the destination. Does not affect the arithmetic flags.

This instruction has three operands:

RORX *dest, src, rot_cnt*

On each right-shift, the bit shifted out of the least-significant bit position is copied to the most-significant bit. This instruction performs a non-destructive operation; that is, the contents of the source operand are unaffected by the operation, unless the destination and source are the same general-purpose register.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general-purpose register and the source (*src*) is either a general-purpose register or a memory operand. The rotate count *rot_cnt* is encoded in an immediate byte. When the operand size is 32, bits [7:5] of the immediate byte are ignored; when the operand size is 64, bits [7:6] of the immediate byte are ignored.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

SAHF

Store AH into Flags

Loads the SF, ZF, AF, PF, and CF flags of the EFLAGS register with values from the corresponding bits in the AH register (bits 7, 6, 4, 2, and 0, respectively). The instruction ignores bits 1, 3, and 5 of register AH; it sets those bits in the EFLAGS register to 1, 0, and 0, respectively.

The SAHF instruction can only be executed in 64-bit mode. Support for the instruction is implementation-dependent and is indicated by CPUID Fn8000_0001_ECX[LahfSahf] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
SAHF	9E	Loads the sign flag, the zero flag, the auxiliary flag, the parity flag, and the carry flag from the AH register into the lower 8 bits of the EFLAGS register.

SAL SHL

Shift Left

Shifts the bits of a register or memory location (first operand) to the left through the CF bit by the number of bit positions in an unsigned immediate value or the CL register (second operand). The instruction discards bits shifted out of the CF flag. For each bit shift, the SAL instruction clears the least-significant bit to 0. At the end of the shift operation, the CF flag contains the last bit shifted out of the first operand.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

The effect of this instruction is multiplication by powers of two.

For 1-bit shifts, the instruction sets the OF flag to the logical `xor` of the CF bit (after the shift) and the most significant bit of the result. When the shift count is greater than 1, the OF flag is undefined.

If the shift count is 0, no flags are modified.

SHL is an alias to the SAL instruction.

Mnemonic	Opcode	Description

SAR

Shift Arithmetic Right

Shifts the bits of a register or memory location (first operand) to the right through the CF bit by the number of bit positions in an unsigned immediate value or the CL register (second operand). The instruction discards bits shifted out of the CF flag. At the end of the shift operation, the CF flag contains the last bit shifted out of the first operand.

The SAR instruction does not change the sign bit of the target operand. For each bit shift, it copies the sign bit to the next bit, preserving the sign of the result.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

For 1-bit shifts, the instruction clears the OF flag to 0. When the shift count is greater than 1, the OF flag is undefined.

If the shift count is 0, no flags are modified.

Although the SAR instruction effectively divides the operand by a power of 2, the behavior is different from the IDIV instruction. For example, shifting -11 (FFFFFFF5h) by two bits to the right (that is, divide -11 by 4), gives a result of FFFFFFFDh, or -3 , whereas the IDIV instruction for dividing -11 by 4 gives a result of -2 . This is because the IDIV instruction rounds off the quotient to zero, whereas the SAR instruction rounds off the remainder to zero for positive dividends and to negative infinity for negative dividends. So, for positive operands, SAR behaves like the corresponding IDIV instruction. For negative operands, it gives the same result if and only if all the shifted-out bits are zeroes; otherwise, the result is smaller by 1.

Mnemonic	Opcode	Description
SAR <i>reg/mem8</i> , 1	D0 /7	Shift a signed 8-bit register or memory operand right 1 bit.

SARX**Shift Right Arithmetic Extended**

Shifts the bits of the first source operand right (toward the least-significant bit) arithmetically by the number of bit positions specified in the second source operand and writes the result to the destination. Does not affect the arithmetic flags.

This instruction has three operands:

SARX *dest, src, shft_cnt*

On each right-shift, the most-significant bit (the sign bit) is replicated. This instruction performs a non-destructive operation; that is, the contents of the source operand are unaffected by the operation, unless the destination and source are the same general-purpose register.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general-purpose register and the first source (*src*) is either a general-purpose register or a memory operand. The second source operand *shft_cnt* is a general-purpose register. When the operand size is 32, bits [31:5] of *shft_cnt* are ignored; when the operand size is 64, bits [63:6] of *shft_cnt* are ignored.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

SBB**Subtract with Borrow**

Subtracts an immediate value or the value in a register or a memory location (second operand) from a register or a memory location (first operand), and stores the result in the first operand location. If the carry flag (CF) is 1, the instruction subtracts 1 from the result. Otherwise, it operates like SUB.

The SBB instruction sign-extends immediate value operands to the length of the first operand size.

This instruction evaluates the result for both signed and unsigned data types and sets the OF and CF flags to indicate a borrow in a signed or unsigned result, respectively. It sets the SF flag to indicate the sign of a signed result.

This instruction is useful for multibyte (multiword) numbers because it takes into account the borrow from a previous SUB instruction.

The forms of the SBB instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
SBB AL, <i>imm8</i>	1C <i>ib</i>	Subtract an immediate 8-bit value from the AL register with borrow.
SBB AX, <i>imm16</i>	1D <i>iw</i>	Subtract an immediate 16-bit value from the AX register with borrow.
SBB EAX, <i>imm32</i>	1D <i>id</i>	Subtract an immediate 32-bit value from the EAX register with borrow.

SCAS

SCASB

SCASW

SCASD

SCASQ

Scan String

Compares the AL, AX, EAX, or RAX register with the byte, word, doubleword, or quadword pointed to by ES:rDI, sets the status flags in the rFLAGS register according to the results, and then increments or decrements the rDI register according to the state of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments the rDI register; otherwise, it decrements it. The instruction increments or decrements the rDI register by 1, 2, 4, or 8, depending on the size of the operands.

The forms of the SCASx instruction with an explicit operand address the operand at ES:rDI. The explicit operand serves only to specify the size of the values being compared.

The no-operands forms of the instruction use the ES:rDI registers to point to the value to be compared. The mnemonic determines the size of the operands and the specific register containing the other comparison value.

For block comparisons, the SCASx instructions support the REPE or REPZ prefixes (they are synonyms) and the REPNE or REPNZ prefixes (they are synonyms). For details about the REP prefixes, see “Repeat Prefixes” on page 12. A SCASx instruction can also operate inside a loop controlled by the LOOPcc instruction.

Mnemonic	Opcode	Description
SCAS <i>mem8</i>	AE	Compare the contents of the AL register with the byte at ES:rDI, and then increment or decrement rDI.
SCAS <i>mem16</i>	AF	Compare the contents of the AX register with the word at ES:rDI, and then increment or decrement rDI.
SCAS <i>mem32</i>	AF	Compare the contents of the EAX register with the doubleword at ES:rDI, and then increment or decrement rDI.

SETcc**Set Byte on Condition**

Checks the status flags in the rFLAGS register and, if the flags meet the condition specified in the mnemonic (*cc*), sets the value in the specified 8-bit memory location or register to 1. If the flags do not meet the specified condition, SETcc clears the memory location or register to 0.

Mnemonics with the A (above) and B (below) tags are intended for use when performing unsigned integer comparisons; those with G (greater) and L (less) tags are intended for use with signed integer comparisons.

Software typically uses the SETcc instructions to set logical indicators. Like the CMOVcc instructions (page 140), the SETcc instructions can replace two instructions—a conditional jump and a move. Replacing conditional jumps with conditional sets can help avoid branch-prediction penalties that may result from conditional jumps.

If the logical value “true” (logical one) is represented in a high-level language as an integer with all bits set to 1, software can accomplish such representation by first executing the opposite SETcc instruction—for example, the opposite of SETZ is SETNZ—and then decrementing the result.

A ModR/M byte is used to identify the operand. The *reg* field in the ModR/M byte is unused.

Mnemonic	Opcode	Description
SETO <i>reg/mem8</i>	0F 90 /0	Set byte if overflow (OF = 1).
SETNO <i>reg/mem8</i>	0F 91 /0	Set byte if not overflow (OF = 0).

SFENCE

Store Fence

Acts as a barrier to force strong memory ordering (serialization) between store instructions preceding the SFENCE and store instructions that follow the SFENCE. Stores to differing memory types, or within the WC memory type, may become visible out of program order; the SFENCE instruction ensures that the system completes all previous stores in such a way that they are globally visible before executing subsequent stores. This includes emptying the store buffer and all write-combining buffers.

The SFENCE instruction is weakly-ordered with respect to load instructions, data and instruction prefetches, and the LFENCE instruction. Speculative loads initiated by the processor, or specified explicitly using cache-prefetch instructions, can be reordered around an SFENCE.

In addition to store instructions, SFENCE is strongly ordered with respect to other SFENCE instructions, MFENCE instructions, and serializing instructions. Further details on the use of MFENCE to order accesses among differing memory types may be found in *AMD64 Architecture Programmer's Manual Volume 2: System Programming*, section 7.4 “Memory Types” on page 172.

The SFENCE instruction is an SSE1 instruction. Support for SSE1 instructions is indicated by CPUID Fn0000_0001_EDX[SSE] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
SFENCE	0F AE F8	Force strong ordering of (serialized) store operations.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid Opcode, #UD	X	X	X	The SSE instructions are not supported, as indicated by EDX bit 25 of CPUID function 0000_0001h; and the AMD extensions to MMX are not supported, as indicated by EDX bit 22 of CPUID function 8000_0001h.

SHL**Shift Left**

This instruction is synonymous with the SAL instruction. For information, see “SAL SHL” on page 291.

SHLD**Shift Left Double**

Shifts the bits of a register or memory location (first operand) to the left by the number of bit positions in an unsigned immediate value or the CL register (third operand), and shifts in a bit pattern (second operand) from the right. At the end of the shift operation, the CF flag contains the last bit shifted out of the first operand.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63. If the masked count is greater than the operand size, the result in the destination register is undefined.

If the shift count is 0, no flags are modified.

If the count is 1 and the sign of the operand being shifted changes, the instruction sets the OF flag to 1. If the count is greater than 1, OF is undefined.

Mnemonic	Opcode	Description
SHLD <i>reg/mem16, reg16, imm8</i>	0F A4 /r ib	Shift bits of a 16-bit destination register or memory operand to the left the number of bits specified in an 8-bit immediate value, while shifting in bits from the second operand.

SHLX

Shift Left Logical Extended

Shifts the bits of the first source operand left (toward the most-significant bit) by the number of bit positions specified in the second source operand and writes the result to the destination. Does not affect the arithmetic flags.

This instruction has three operands:

SHLX *dest, src, shft_cnt*

On each left-shift, a zero is shifted into the least-significant bit position. This instruction performs a non-destructive operation; that is, the contents of the source operand are unaffected by the operation, unless the destination and source are the same general-purpose register.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general-purpose register and the first source (*src*) is either a general-purpose register or a memory operand. The second source operand *shft_cnt* is a general-purpose register. When the operand size is 32, bits [31:5] of *shft_cnt* are ignored; when the operand size is 64, bits [63:6] of *shft_cnt* are ignored.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

SHR

Shift Right

Shifts the bits of a register or memory location (first operand) to the right through the CF bit by the number of bit positions in an unsigned immediate value or the CL register (second operand). The instruction discards bits shifted out of the CF flag. At the end of the shift operation, the CF flag contains the last bit shifted out of the first operand.

For each bit shift, the instruction clears the most-significant bit to 0.

The effect of this instruction is unsigned division by powers of two.

The processor masks the upper three bits of the count operand, thus restricting the count to a number between 0 and 31. When the destination is 64 bits wide, the processor masks the upper two bits of the count, providing a count in the range of 0 to 63.

For 1-bit shifts, the instruction sets the OF flag to the most-significant bit of the original value. If the count is greater than 1, the OF flag is undefined.

If the shift count is 0, no flags are modified.

Mnemonic	Opcode	Description
SHR <i>reg/mem8</i> , 1	D0 /5	Shift an 8-bit register or memory operand right 1 bit.

SHRX**Shift Right Logical Extended**

Shifts the bits of the first source operand right (toward the least-significant bit) by the number of bit positions specified in the second source operand and writes the result to the destination. Does not affect the arithmetic flags.

This instruction has three operands:

SHRX *dest, src, shft_cnt*

On each right-shift, a zero is shifted into the most-significant bit position. This instruction performs a non-destructive operation; that is, the contents of the source operand are unaffected by the operation, unless the destination and source are the same general-purpose register.

In 64-bit mode, the operand size is determined by the value of VEX.W. If VEX.W is 1, the operand size is 64 bits; if VEX.W is 0, the operand size is 32 bits. In 32-bit mode, VEX.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general-purpose register and the first source (*src*) is either a general-purpose register or a memory operand. The second source operand *shft_cnt* is a general-purpose register. When the operand size is 32, bits [31:5] of *shft_cnt* are ignored; when the operand size is 64, bits [63:6] of *shft_cnt* are ignored.

This instruction is a BMI2 instruction. Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[BMI2] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

SLWPCB Store Lightweight Profiling Control Block Address

Flushes Lightweight Profiling (LWP) state to memory and returns the current effective address of the Lightweight Profiling Control Block (LWPCB) in the specified register. The LWPCB address returned is truncated to 32 bits if the operand size is 32.

If LWP is not currently enabled, SLWPCB sets the specified register to zero.

The flush operation stores the internal event counters for active events and the current ring buffer head pointer into the LWPCB. If there is an unwritten event record pending, it is written to the event ring buffer.

The LWP_CBADDR MSR holds the linear address of the current LWPCB. If the contents of LWP_CBADDR is not zero, the value returned in the specified register is an effective address that is calculated by subtracting the current DS.Base address from the linear address kept in LWP_CBADDR. Note that if DS has changed between the time LLWPCB was executed and the time SLWPCB is executed, this might result in an address that is not currently accessible by the application.

SLWPCB generates an invalid opcode exception (#UD) if the machine is not in protected mode or if LWP is not available.

It is possible to execute SLWPCB when the CPL != 3 or when SMM is active, but if the LWPCB pointer is not zero, system software must ensure that the LWPCB and the entire ring buffer are properly mapped into writable memory in order to avoid a #PF fault. Using SLWPCB in these situations is not recommended.

See the discussion of lightweight profiling in Volume 2, Chapter 13 for more information on the use of the LLWPCB, SLWPCB, LWPINS, and LWPVAL instructions.

The SLWPCB instruction is implemented if LWP is supported on a processor. Support for LWP is indicated by CPUID Fn8000_0001_ECX[LWP] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Instruction Encoding

Mnemonic	Encoding			
	XOP	RXB.map_select	W.vvvv.L.pp	Opcode
SLWPCB <i>reg32</i>	8F	$\overline{\text{RXB}}.09$	0.1111.0.00	12 /1
SLWPCB <i>reg64</i>	8F	$\overline{\text{RXB}}.09$	1.1111.0.00	12 /1

ModRM.reg augments the opcode and is assigned the value 001b. ModRM.r/m (augmented by XOP.R) specifies the register in which to put the LWPCB address. ModRM.mod must be 11b.

STOS

STOSB

STOSW

STOSD

STOSQ

Store String

Copies a byte, word, doubleword, or quadword from the AL, AX, EAX, or RAX registers to the memory location pointed to by ES:rDI and increments or decrements the rDI register according to the state of the DF flag in the rFLAGS register.

If the DF flag is 0, the instruction increments the pointer; otherwise, it decrements the pointer. It increments or decrements the pointer by 1, 2, 4, or 8, depending on the size of the value being copied.

The forms of the STOSx instruction with an explicit operand use the operand only to specify the type (size) of the value being copied.

The no-operands forms specify the type (size) of the value being copied with the mnemonic.

The STOSx instructions support the REP prefixes. For details about the REP prefixes, see “Repeat Prefixes” on page 12. The STOSx instructions can also operate inside a LOOPcc instruction.

Mnemonic	Opcode	Description
STOS <i>mem8</i>	AA	Store the contents of the AL register to ES:rDI, and then increment or decrement rDI.
STOS <i>mem16</i>	AB	Store the contents of the AX register to ES:rDI, and then increment or decrement rDI.
STOS <i>mem32</i>	AB	Store the contents of the EAX register to ES:rDI, and then increment or decrement rDI.
STOS <i>mem64</i>	AB	Store the contents of the RAX register to ES:rDI, and then increment or decrement rDI.
STOSB	AA	Store the contents of the AL register to ES:rDI, and then increment or decrement rDI.
STOSW	AB	Store the contents of the AX register to ES:rDI, and then increment or decrement rDI.
STOSD	AB	Store the contents of the EAX register to ES:rDI, and then increment or decrement rDI.

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

SUB**Subtract**

Subtracts an immediate value or the value in a register or memory location (second operand) from a register or a memory location (first operand) and stores the result in the first operand location. An immediate value is sign-extended to the length of the first operand.

This instruction evaluates the result for both signed and unsigned data types and sets the OF and CF flags to indicate a borrow in a signed or unsigned result, respectively. It sets the SF flag to indicate the sign of a signed result.

The forms of the SUB instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
SUB AL, <i>imm8</i>	2C <i>ib</i>	Subtract an immediate 8-bit value from the AL register and store the result in AL.
SUB AX, <i>imm16</i>	2D <i>iw</i>	Subtract an immediate 16-bit value from the AX register and store the result in AX.
SUB EAX, <i>imm32</i>	2D <i>id</i>	Subtract an immediate 32-bit value from the EAX register and store the result in EAX.
SUB RAX, <i>imm32</i>	2D <i>id</i>	Subtract a sign-extended immediate 32-bit value from the RAX register and store the result in RAX.
SUB <i>reg/mem8</i> , <i>imm8</i>	80 <i>/5 ib</i>	Subtract an immediate 8-bit value from an 8-bit destination register or memory location.
SUB <i>reg/mem16</i> , <i>imm16</i>	81 <i>/5 iw</i>	Subtract an immediate 16-bit value from a 16-bit destination register or memory location.
SUB <i>reg/mem32</i> , <i>imm32</i>	81 <i>/5 id</i>	Subtract an immediate 32-bit value from a 32-bit destination register or memory location.
SUB <i>reg/mem64</i> , <i>imm32</i>	81 <i>/5 id</i>	Subtract a sign-extended immediate 32-bit value from a 64-bit destination register or memory location.
SUB <i>reg/mem16</i> , <i>imm8</i>	83 <i>/5 ib</i>	Subtract a sign-extended immediate 8-bit value from a 16-bit register or memory location.

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

T1MSKC Inverse Mask From Trailing Ones

Finds the least significant zero bit in the source operand, clears all bits below that bit to 0, sets all other bits to 1 (including the found bit) and writes the result to the destination. If the least significant bit of the source operand is 0, the destination is written with all ones.

This instruction has two operands:

T1MSKC *dest, src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The T1MSKC instruction effectively performs a bit-wise logical OR of the inverse of the source operand and the result of incrementing the source operand by 1 and stores the result to the destination register:

```
add tmp1, src, 1
not tmp2, src
or dest, tmp1, tmp2
```

The value of the carry flag of rFLAGS is generated by the `add` pseudo-instruction and the remaining arithmetic flags are generated by the `or` pseudo-instruction.

The T1MSKC instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

TEST

Test Bits

Performs a bit-wise logical `and` on the value in a register or memory location (first operand) with an immediate value or the value in a register (second operand) and sets the flags in the `rFLAGS` register based on the result.

This instruction has two operands:

`TEST dest, src`

While the `AND` instruction changes the contents of the destination and the flag bits, the `TEST` instruction changes only the flag bits.

Mnemonic	Opcode	Description
<code>TEST AL, imm8</code>	<code>A8 ib</code>	<code>and</code> an immediate 8-bit value with the contents of the <code>AL</code> register and set <code>rFLAGS</code> to reflect the result.
<code>TEST AX, imm16</code>	<code>A9 iw</code>	<code>and</code> an immediate 16-bit value with the contents of the <code>AX</code> register and set <code>rFLAGS</code> to reflect the result.
<code>TEST EAX, imm32</code>	<code>A9 id</code>	<code>and</code> an immediate 32-bit value with the contents of the <code>EAX</code> register and set <code>rFLAGS</code> to reflect the result.
<code>TEST RAX, imm32</code>	<code>A9 id</code>	<code>and</code> a sign-extended immediate 32-bit value with the contents of the <code>RAX</code> register and set <code>rFLAGS</code> to reflect the result.
<code>TEST reg/mem8, imm8</code>	<code>F6 /0 ib</code>	<code>and</code> an immediate 8-bit value with the contents of an 8-bit register or memory operand and set <code>rFLAGS</code> to reflect the result.

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

TZCNT

Count Trailing Zeros

Counts the number of trailing zero bits in the 16-, 32-, or 64-bit general purpose register or memory source operand. Counting starts upward from the least significant bit and stops when the lowest bit having a value of 1 is encountered or when the most significant bit is encountered. The count is written to the destination register.

If the input operand is zero, CF is set to 1 and the size (in bits) of the input operand is written to the destination register. Otherwise, CF is cleared.

If the least significant bit is a one, the ZF flag is set to 1 and zero is written to the destination register. Otherwise, ZF is cleared.

TZCNT is a BMI instruction. Support for BMI instructions is indicated by CPUID Fn0000_0007_EBX_x0[BMI] = 1. If the TZCNT instruction is not available, the encoding is treated as the BSF instruction. Software *must* check the CPUID bit once per program or library initialization before using the TZCNT instruction or inconsistent behavior may result.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
TZCNT <i>reg16, reg/mem16</i>	F3 0F BC /r	Count the number of trailing zeros in reg/mem16.
TZCNT <i>reg32, reg/mem32</i>	F3 0F BC /r	Count the number of trailing zeros in reg/mem32.
TZCNT <i>reg64, reg/mem64</i>	F3 0F BC /r	Count the number of trailing zeros in reg/mem64.

TZMSK

Mask From Trailing Zeros

Finds the least significant one bit in the source operand, sets all bits below that bit to 1, clears all other bits to 0 (including the found bit) and writes the result to the destination. If the least significant bit of the source operand is 1, the destination is written with all zeros.

This instruction has two operands:

TZMSK *dest, src*

In 64-bit mode, the operand size is determined by the value of XOP.W. If XOP.W is 1, the operand size is 64-bit; if XOP.W is 0, the operand size is 32-bit. In 32-bit mode, XOP.W is ignored. 16-bit operands are not supported.

The destination (*dest*) is a general purpose register.

The source operand (*src*) is a general purpose register or a memory operand.

The TZMSK instruction effectively performs a bit-wise logical `and` of the negation of the source operand and the result of subtracting 1 from the source operand, and stores the result to the destination register:

```
sub tmp1, src, 1
not tmp2, src
and dest, tmp1, tmp2
```

The value of the carry flag of rFLAGS is generated by the `sub` pseudo-instruction and the remaining arithmetic flags are generated by the `and` pseudo-instruction.

The TZMSK instruction is a TBM instruction. Support for this instruction is indicated by CPUID Fn8000_0001_ECX[TBM] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

WRFSBASE WRGSBASE

Write FS.base Write GS.base

Writes the base field of the FS or GS segment descriptor with the value contained in the register operand. When supported and enabled, these instructions can be executed at any processor privilege level. Instructions are only defined in 64-bit mode. The address written to the base field must be in canonical form or a #GP fault will occur.

System software must set the FSGSBASE bit (bit 16) of CR4 to enable the WRFSBASE and WRGSBASE instructions.

Support for this instruction is indicated by CPUID Fn0000_0007_EBX_x0[FSGSBASE] = 1.

For more information on using the CPUID instruction, see the instruction reference page for the CPUID instruction on page 153. For a description of all feature flags related to instruction subset support, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519.

Mnemonic	Opcode	Description
WRFSBASE <i>reg32</i>	F3 0F AE /2	Copy the contents of the specified 32-bit general-purpose register to the lower 32 bits of FS.base.
WRFSBASE <i>reg64</i>	F3 0F AE /2	Copy the contents of the specified 64-bit general-purpose register to FS.base.
WRGSBASE <i>reg32</i>	F3 0F AE /3	Copy the contents of the specified 32-bit general-purpose register to the lower 32 bits of GS.base.

#GP			X	Attempt to write non-canonical address to segment base address.

XADD

Exchange and Add

Exchanges the contents of a register (second operand) with the contents of a register or memory location (first operand), computes the sum of the two values, and stores the result in the first operand location.

The forms of the XADD instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

Mnemonic	Opcode	Description
XADD <i>reg/mem8, reg8</i>	0F C0 /r	Exchange the contents of an 8-bit register with the contents of an 8-bit destination register or memory operand and load their sum into the destination.
XADD <i>reg/mem16, reg16</i>	0F C1 /r	Exchange the contents of a 16-bit register with the contents of a 16-bit destination register or memory operand and load their sum into the destination.
XADD <i>reg/mem32, reg32</i>	0F C1 /r	Exchange the contents of a 32-bit register with the contents of a 32-bit destination register or memory operand and load their sum into the destination.
XADD <i>reg/mem64, reg64</i>	0F C1 /r	Exchange the contents of a 64-bit register with the contents of a 64-bit destination register or memory operand and load their sum into the destination.

XCHG

Exchange

Exchanges the contents of the two operands. The operands can be two general-purpose registers or a register and a memory location. If either operand references memory, the processor locks automatically, whether or not the LOCK prefix is used and independently of the value of IOPL. For details about the LOCK prefix, see “Lock Prefix” on page 11.

The x86 architecture commonly uses the XCHG EAX, EAX instruction (opcode 90h) as a one-byte NOP. In 64-bit mode, the processor treats opcode 90h as a true NOP only if it would exchange rAX with itself. Without this special handling, the instruction would zero-extend the upper 32 bits of RAX, and thus it would not be a true no-operation. Opcode 90h can still be used to exchange rAX and r8 if the appropriate REX prefix is used.

This special handling does not apply to the two-byte ModRM form of the XCHG instruction.

Mnemonic	Opcode	Description
XCHG AX, <i>reg16</i>	90 <i>+rw</i>	Exchange the contents of the AX register with the contents of a 16-bit register.
XCHG <i>reg16</i> , AX	90 <i>+rw</i>	Exchange the contents of a 16-bit register with the contents of the AX register.
XCHG EAX, <i>reg32</i>	90 <i>+rd</i>	Exchange the contents of the EAX register with the contents of a 32-bit register.
XCHG <i>reg32</i> , EAX	90 <i>+rd</i>	Exchange the contents of a 32-bit register with the contents of the EAX register.
XCHG RAX, <i>reg64</i>	90 <i>+rq</i>	Exchange the contents of the RAX register with the contents of a 64-bit register.
XCHG <i>reg64</i> , RAX	90 <i>+rq</i>	Exchange the contents of a 64-bit register with the contents of the RAX register.

XLAT XLATB

Translate Table Index

Uses the unsigned integer in the AL register as an offset into a table and copies the contents of the table entry at that location to the AL register.

The instruction uses *seg*:*[rBX]* as the base address of the table. The value of *seg* defaults to the DS segment, but may be overridden by a segment prefix.

This instruction writes AL without changing RAX[63:8]. This instruction ignores operand size.

The single-operand form of the XLAT instruction uses the operand to document the segment and address size attribute, but it uses the base address specified by the rBX register.

This instruction is often used to translate data from one format (such as ASCII) to another (such as EBCDIC).

Mnemonic	Opcode	Description
XLAT <i>mem8</i>	D7	Set AL to the contents of DS:[rBX + unsigned AL].
XLATB	D7	Set AL to the contents of DS:[rBX + unsigned AL].

			X	A null data segment was used to reference memory.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.

XOR**Logical Exclusive OR**

Performs a bit-wise logical `xor` operation on both operands and stores the result in the first operand location. The first operand can be a register or memory location. The second operand can be an immediate value, a register, or a memory location. XOR-ing a register with itself clears the register.

The forms of the XOR instruction that write to memory support the LOCK prefix. For details about the LOCK prefix, see “Lock Prefix” on page 11.

The instruction performs the following operation for each bit:

X	Y	X <code>xor</code> Y
0	0	0
0	1	1
1	0	1
1	1	0

Mnemonic	Opcode	Description
XOR AL, <i>imm8</i>	34 <i>ib</i>	<code>xor</code> the contents of AL with an immediate 8-bit operand and store the result in AL.
XOR AX, <i>imm16</i>	35 <i>iw</i>	<code>xor</code> the contents of AX with an immediate 16-bit operand and store the result in AX.
XOR EAX, <i>imm32</i>	35 <i>id</i>	<code>xor</code> the contents of EAX with an immediate 32-bit operand and store the result in EAX.
XOR RAX, <i>imm32</i>	35 <i>id</i>	<code>xor</code> the contents of RAX with a sign-extended immediate 32-bit operand and store the result in RAX.
XOR <i>reg/mem8, imm8</i>	80 <i>/6 ib</i>	<code>xor</code> the contents of an 8-bit destination register or memory operand with an 8-bit immediate value and store the result in the destination.
XOR <i>reg/mem16, imm16</i>	81 <i>/6 iw</i>	<code>xor</code> the contents of a 16-bit destination register or memory operand with a 16-bit immediate value and store the result in the destination.
XOR <i>reg/mem32, imm32</i>	81 <i>/6 id</i>	<code>xor</code> the contents of a 32-bit destination register or memory operand with a 32-bit immediate value and store the result in the destination.
XOR <i>reg/mem64, imm32</i>	81 <i>/6 id</i>	<code>xor</code> the contents of a 64-bit destination register or memory operand with a sign-extended 32-bit immediate value and store the result in the destination.
XOR <i>reg/mem16, imm8</i>	83 <i>/6 ib</i>	<code>xor</code> the contents of a 16-bit destination register or memory operand with a sign-extended 8-bit immediate value and store the result in the destination.

Mnemonic	Opcode	Description
XOR <i>reg/mem32, imm8</i>	83 /6 <i>ib</i>	xor the contents of a 32-bit destination register or memory operand with a sign-extended 8-bit immediate value and store the result in the destination.
XOR <i>reg/mem64, imm8</i>	83 /6 <i>ib</i>	xor the contents of a 64-bit destination register or memory operand with a sign-extended 8-bit immediate value and store the result in the destination.
XOR <i>reg/mem8, reg8</i>	30 / <i>r</i>	xor the contents of an 8-bit destination register or memory operand with the contents of an 8-bit register and store the result in the destination.
XOR <i>reg/mem16, reg16</i>	31 / <i>r</i>	xor the contents of a 16-bit destination register or memory operand with the contents of a 16-bit register and store the result in the destination.
XOR <i>reg/mem32, reg32</i>	31 / <i>r</i>	xor the contents of a 32-bit destination register or memory operand with the contents of a 32-bit register and store the result in the destination.
XOR <i>reg/mem64, reg64</i>	31 / <i>r</i>	xor the contents of a 64-bit destination register or memory operand with the contents of a 64-bit register and store the result in the destination.
XOR <i>reg8, reg/mem8</i>	32 / <i>r</i>	xor the contents of an 8-bit destination register with the contents of an 8-bit register or memory operand and store the results in the destination.
XOR <i>reg16, reg/mem16</i>	33 / <i>r</i>	xor the contents of a 16-bit destination register with the contents of a 16-bit register or memory operand and store the results in the destination.
XOR <i>reg32, reg/mem32</i>	33 / <i>r</i>	xor the contents of a 32-bit destination register with the contents of a 32-bit register or memory operand and store the results in the destination.
XOR <i>reg64, reg/mem64</i>	33 / <i>r</i>	xor the contents of a 64-bit destination register with the contents of a 64-bit register or memory operand and store the results in the destination.

4 System Instruction Reference

This chapter describes the function, mnemonic syntax, opcodes, affected flags, and possible exceptions generated by the system instructions. System instructions are used to establish the processor operating mode, access processor resources, handle program and system errors, manage memory, and instantiate a virtual machine. Most of these instructions can only be executed by privileged software, such as the operating system or a Virtual Machine Monitor (VMM), also known as a hypervisor. Only system instructions can access certain processor resources, such as the control registers, model-specific registers, and debug registers.

Most system instructions are supported in all hardware implementations of the AMD64 architecture. The table below lists instructions that may not be supported on a given processor implementation. System software must execute the CPUID instruction using the function number listed to determine support prior to using these instructions.

Table 4-1. System Instruction Support Indicated by CPUID Feature Bits

Instruction	CPUID Feature Bit	Register[Bit]
Long Mode and Long Mode instructions	CPUID Fn8000_0001_EDX[LM]	EDX[29]
MONITOR, MWAIT	CPUID Fn0000_0001_ECX[MONITOR]	ECX[3]
RDMSR, WRMSR	CPUID Fn0000_0001_EDX[MSR]	EDX[5]
RDTSCP	CPUID Fn8000_0001_EDX[RDTSCP]	EDX[27]
SKINIT, STGI	CPUID Fn8000_0001_ECX[SKINIT]	ECX[12]
SVM Architecture and instructions	CPUID Fn8000_0001_ECX[SVM]	ECX[2]
SYSCALL, SYSRET	CPUID Fn8000_0001_EDX[SysCallSysRet]	EDX[11]
SYSENTER, SYSEXIT	CPUID Fn0000_0001_EDX[SysEnterSysExit]	EDX[11]

There are also several other CPUID feature bits that indicate support for certain paging functions, virtual-mode extensions, machine-check exceptions, advanced programmable interrupt control (APIC), memory-type range registers (MTRRs), etc.

For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153. For a comprehensive list of all instruction support feature flags, see Appendix D, “Instruction Subsets and CPUID Feature Flags,” on page 519. For a comprehensive list of all defined CPUID feature numbers and return values, see Appendix E, “Obtaining Processor Information Via the CPUID Instruction,” on page 589.

For further information about the system instructions and register resources, see:

- “System-Management Instructions” in Volume 2.
- “Summary of Registers and Data Types” on page 38.

- “Notation” on page 52.
- “Instruction Prefixes” on page 5.

ARPL

Adjust Requestor Privilege Level

Compares the requestor privilege level (RPL) fields of two segment selectors in the source and destination operands of the instruction. If the RPL field of the destination operand is less than the RPL field of the segment selector in the source register, then the zero flag is set and the RPL field of the destination operand is increased to match that of the source operand. Otherwise, the destination operand remains unchanged and the zero flag is cleared.

The destination operand can be either a 16-bit register or memory location; the source operand must be a 16-bit register.

The ARPL instruction is intended for use by operating-system procedures to adjust the RPL of a segment selector that has been passed to the operating system by an application program to match the privilege level of the application program. The segment selector passed to the operating system is placed in the destination operand and the segment selector for the code segment of the application program is placed in the source operand. The RPL field in the source operand represents the privilege level of the application program. The ARPL instruction then insures that the RPL of the segment selector received by the operating system is no lower than the privilege level of the application program.

See “Adjusting Access Rights” in Volume 2, for more information on access rights.

In 64-bit mode, this opcode (63H) is used for the MOVSSXD instruction.

Mnemonic	Opcode	Description
ARPL <i>reg/mem16, reg16</i>	63 /r	Adjust the RPL of a destination segment selector to a level not less than the RPL of the segment selector specified in the 16-bit source register. (Invalid in 64-bit mode.)

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to one or cleared to zero is M (modified). Unaffected flags are blank. Undefined flags are U.																

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Invalid opcode, #UD	X	X		This instruction is only recognized in protected legacy and compatibility mode.
Stack, #SS			X	A memory address exceeded the stack segment limit.
General protection, #GP			X	A memory address exceeded a data segment limit.
			X	The destination operand was in a non-writable segment.
			X	A null segment selector was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.
Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

CLGI**Clear Global Interrupt Flag**

Clears the global interrupt flag (GIF). While GIF is zero, all external interrupts are disabled.

This is a Secure Virtual Machine instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume-2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description
CLGI	0F 01 DD	Clears the global interrupt flag (GIF).

Related Instructions

STGI

rFLAGS Affected

None.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SVM instructions are not supported as indicated by CPUID Fn8000_0001_ECX[SVM] = 0.
			X	Secure Virtual Machine was not enabled (EFER.SVME=0).
	X	X		Instruction is only recognized in protected mode.
General protection, #GP			X	CPL was not zero.

CLI**Clear Interrupt Flag**

Clears the interrupt flag (IF) in the rFLAGS register to zero, thereby masking external interrupts received on the INTR input. Interrupts received on the non-maskable interrupt (NMI) input are not affected by this instruction.

In real mode, this instruction clears IF to 0.

In protected mode and virtual-8086-mode, this instruction is IOPL-sensitive. If the CPL is less than or equal to the rFLAGS.IOPL field, the instruction clears IF to 0.

In protected mode, if $IOPL < 3$, $CPL = 3$, and protected mode virtual interrupts are enabled ($CR4.PVI = 1$), then the instruction instead clears rFLAGS.VIF to 0. If none of these conditions apply, the processor raises a general-purpose exception (#GP). For more information, see “Protected Mode Virtual Interrupts” in Volume 2.

In virtual-8086 mode, if $IOPL < 3$ and the virtual-8086-mode extensions are enabled ($CR4.VME = 1$), the CLI instruction clears the virtual interrupt flag (rFLAGS.VIF) to 0 instead.

See “Virtual-8086 Mode Extensions” in Volume 2 for more information about IOPL-sensitive instructions.

Mnemonic	Opcode	Description
CLI	FA	Clear the interrupt flag (IF) to zero.

Action

```
IF (CPL <= IOPL)
    RFLAGS.IF = 0

ELSEIF (((VIRTUAL_MODE) && (CR4.VME == 1))
        || ((PROTECTED_MODE) && (CR4.PVI == 1) && (CPL == 3)))
    RFLAGS.VIF = 0;

ELSE
    EXCEPTION[#GP(0)]
```

General protection, #GP		X		The CPL was greater than the IOPL and virtual mode extensions are not enabled (CR4.VME = 0).
			X	The CPL was greater than the IOPL and either the CPL was not 3 or protected mode virtual interrupts were not enabled (CR4.PVI = 0).

CLTS**Clear Task-Switched Flag in CR0**

Clears the task-switched (TS) flag in the CR0 register to 0. The processor sets the TS flag on each task switch. The CLTS instruction is intended to facilitate the synchronization of FPU context saves during multitasking operations.

This instruction can only be used if the current privilege level is 0.

See “System-Control Registers” in Volume 2 for more information on FPU synchronization and the TS flag.

Mnemonic	Opcode	Description
CLTS	0F 06	Clear the task-switched (TS) flag in CR0 to 0.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
General protection, #GP		X	X	CPL was not 0.

HLT

Halt

Causes the microprocessor to halt instruction execution and enter the HALT state. Entering the HALT state puts the processor in low-power mode. Execution resumes when an unmasked hardware interrupt (INTR), non-maskable interrupt (NMI), system management interrupt (SMI), RESET, or INIT occurs.

If an INTR, NMI, or SMI is used to resume execution after a HLT instruction, the saved instruction pointer points to the instruction following the HLT instruction.

Before executing a HLT instruction, hardware interrupts should be enabled. If rFLAGS.IF = 0, the system will remain in a HALT state until an NMI, SMI, RESET, or INIT occurs.

If an SMI brings the processor out of the HALT state, the SMI handler can decide whether to return to the HALT state or not. See *Volume 2: System Programming*, for information on SMIs.

Current privilege level must be 0 to execute this instruction.

Mnemonic	Opcode	Description
HLT	F4	Halt instruction execution.

Exception	Real	Virtual 8086	Protected	Cause of Exception
General protection, #GP		X	X	CPL was not 0.

INT 3

Interrupt to Debug Vector

Calls the debug exception handler. This instruction maps to a 1-byte opcode (CC) that raises a #BP exception. The INT 3 instruction is normally used by debug software to set instruction breakpoints by replacing the first byte of the instruction opcode bytes with the INT 3 opcode.

This one-byte INT 3 instruction behaves differently from the two-byte INT 3 instruction (opcode CD 03) (see “INT” in Chapter 3 “General Purpose Instructions” for further information) in two ways:

The #BP exception is handled without any IOPL checking in virtual x86 mode. (IOPL mismatches will not trigger an exception.)

- In VME mode, the #BP exception is not redirected via the interrupt redirection table. (Instead, it is handled by a protected mode handler.)

Mnemonic	Opcode	Description
INT 3	CC	Trap to debugger at Interrupt 3.

For complete descriptions of the steps performed by INT instructions, see the following:

- *Legacy-Mode Interrupts*: “Legacy Protected-Mode Interrupt Control Transfers” in Volume 2.
- *Long-Mode Interrupts*: “Long-Mode Interrupt Control Transfers” in Volume 2.

Action

```
// Refer to INT instruction's Action section for the details on INT_N_REAL,
// INT_N_PROTECTED, and INT_N_VIRTUAL_TO_PROTECTED.
INT3_START:
```

```
If (REAL_MODE)
    INT_N_REAL //N = 3

ELSEIF (PROTECTED_MODE)
    INT_N_PROTECTED //N = 3

ELSE // VIRTUAL_MODE
    INT_N_VIRTUAL_TO_PROTECTED //N = 3
```

Related Instructions

INT, INTO, IRET

rFLAGS Affected

If a task switch occurs, all flags are modified; otherwise, settings are as follows:

ID	VIP	VIF	AC	VM	RF	NT	IOPL	OF	DF	IF	TF	SF	ZF	AF	PF	CF
			M	0	0	M				M	0					
21	20	19	18	17	16	14	13:12	11	10	9	8	7	6	4	2	0

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to one or cleared to zero is M (modified). Unaffected flags are blank. Undefined flags are U.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Breakpoint, #BP	X	X	X	INT 3 instruction was executed.
Invalid TSS, #TS (selector)		X	X	As part of a stack switch, the target stack segment selector or rSP in the TSS that was beyond the TSS limit.
		X	X	As part of a stack switch, the target stack segment selector in the TSS was beyond the limit of the GDT or LDT descriptor table.
		X	X	As part of a stack switch, the target stack segment selector in the TSS was a null selector.
		X	X	As part of a stack switch, the target stack segment selector's TI bit was set, but the LDT selector was a null selector.
		X	X	As part of a stack switch, the target stack segment selector in the TSS contained a RPL that was not equal to its DPL.
		X	X	As part of a stack switch, the target stack segment selector in the TSS contained a DPL that was not equal to the CPL of the code segment selector.
Segment not present, #NP (selector)		X	X	The accessed code segment, interrupt gate, trap gate, task gate, or TSS was not present.
Stack, #SS	X	X	X	A memory address exceeded the stack segment limit or was non-canonical.
Stack, #SS (selector)		X	X	After a stack switch, a memory address exceeded the stack segment limit or was non-canonical and a stack switch occurred.
		X	X	As part of a stack switch, the SS register was loaded with a non-null segment selector and the segment was marked not present.
General protection, #GP	X	X	X	A memory address exceeded the data segment limit or was non-canonical.
	X	X	X	The target offset exceeded the code segment limit or was non-canonical.

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP (selector)	X	X	X	The interrupt vector was beyond the limit of IDT.
		X	X	The descriptor in the IDT was not an interrupt, trap, or task gate in legacy mode or not a 64-bit interrupt or trap gate in long mode.
		X	X	The DPL of the interrupt, trap, or task gate descriptor was less than the CPL.
		X	X	The segment selector specified by the interrupt or trap gate had its TI bit set, but the LDT selector was a null selector.
		X	X	The segment descriptor specified by the interrupt or trap gate exceeded the descriptor table limit or was a null selector.
		X	X	The segment descriptor specified by the interrupt or trap gate was not a code segment in legacy mode, or not a 64-bit code segment in long mode.
			X	The DPL of the segment specified by the interrupt or trap gate was greater than the CPL.
		X		The DPL of the segment specified by the interrupt or trap gate pointed was not 0 or it was a conforming segment.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

INVD**Invalidate Caches**

Invalidates all levels of cache associated with this processor. This may or may not include lower level caches associated with another processor that shares any level of this processor's cache hierarchy.

No data is written back to main memory from invalidating the caches.

CPUID Fn8000_001D_EDX[WBINVD]_xN indicates the behavior of the processor at various levels of the cache hierarchy. If the feature bit is 0, the instruction causes the invalidation of all lower level caches of other processors sharing the designated level of cache. If the feature bit is 1, the instruction does not necessarily cause the invalidation of all lower level caches of other processors sharing the designated level of cache. See Appendix E, “Obtaining Processor Information Via the CPUID Instruction,” on page 589 for more information on using the CPUID function.

This is a privileged instruction. The current privilege level (CPL) of a procedure invalidating the processor's internal caches must be 0.

To insure that data is written back to memory prior to invalidating caches, use the WBINVD instruction.

This instruction does not invalidate TLB caches.

INVD is a serializing instruction.

Mnemonic	Opcode	Description
INVD	0F 08	Invalidate internal caches and trigger external cache invalidations.

Related Instructions

WBINVD, CLFLUSH

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP		X	X	CPL was not 0.

INVLPG**Invalidate TLB Entry**

Invalidates the TLB entry that would be used for the 1-byte memory operand.

This instruction invalidates the TLB entry, regardless of the G (Global) bit setting in the associated PDE or PTE entry and regardless of the page size (4 Kbytes, 2 Mbytes, 4 Mbytes, or 1 Gbyte). It may invalidate any number of additional TLB entries, in addition to the targeted entry.

INVLPG is a serializing instruction and a privileged instruction. The current privilege level must be to execute this instruction.

See “Page Translation and Protection” in Volume 2 for more information on page translation.

Mnemonic	Opcode	Description
INVLPG <i>mem8</i>	0F 01 17	Invalidate the TLB entry for the page containing a specified memory location.

Related Instructions

INVLPGA, MOV CR_n (CR3 and CR4)

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP		X	X	CPL was not 0.

INVLPGA Invalidate TLB Entry in a Specified ASID

Invalidates the TLB mapping for a given virtual page and a given ASID. The virtual address is specified in the implicit register operand rAX. The portion of RAX used to form the address is determined by the effective address size. The ASID is taken from ECX.

The INVLPGA instruction may invalidate any number of additional TLB entries, in addition to the targeted entry.

The INVLPGA instruction is a serializing instruction and a privileged instruction. The current privilege level must be 0 to execute this instruction.

This is a Secure Virtual Machine (SVM) instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume-2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description
INVLPGA rAX, ECX	0F 01 DF	Invalidates the TLB mapping for the virtual page specified in rAX and the ASID specified in ECX.

Related Instructions

INVLPG.

rFLAGS Affected

None.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SVM instructions are not supported as indicated by CPUID Fn8000_0001_ECX[SVM] = 0.
			X	Secure Virtual Machine was not enabled (EFER.SVME=0).
	X	X		Instruction is only recognized in protected mode.
General protection, #GP			X	CPL was not zero.

IRET

IRETD

IRETQ

Return from Interrupt

Returns program control from an exception or interrupt handler to a program or procedure previously interrupted by an exception, an external interrupt, or a software-generated interrupt. These instructions also perform a return from a nested task. All flags, CS, and RIP are restored to the values they had before the interrupt so that execution may continue at the next instruction following the interrupt or exception. In 64-bit mode or if the CPL changes, SS and RSP are also restored.

IRET, IRETD, and IRETQ are synonyms mapping to the same opcode. They are intended to provide semantically distinct forms for various opcode sizes. The IRET instruction is used for 16-bit operand size; IRETD is used for 32-bit operand sizes; IRETQ is used for 64-bit operands. The latter form is only meaningful in 64-bit mode.

IRET, IRETD, or IRETQ must be used to terminate the exception or interrupt handler associated with the exception, external interrupt, or software-generated interrupt.

IRETx is a serializing instruction.

For detailed descriptions of the steps performed by IRETx instructions, see the following:

- *Legacy-Mode Interrupts*: “Legacy Protected-Mode Interrupt Control Transfers” in Volume 2.
- *Long-Mode Interrupts*: “Long-Mode Interrupt Control Transfers” in Volume 2.

Mnemonic	Opcode	Description
IRET	CF	Return from interrupt (16-bit operand size).
IRETD	CF	Return from interrupt (32-bit operand size).
IRETQ	CF	Return from interrupt (64-bit operand size).

Stack, #SS (selector)			X	The SS register was loaded with a non-null segment selector and the segment was marked not present.
General protection, #GP	X	X	X	The target offset exceeded the code segment limit or was non-canonical.
		X		IOPL was less than 3 and one of the following conditions was true: <ul style="list-style-type: none"> CR4.VME was 0. The effective operand size was 32-bit. Both the original EFLAGS.VIP and the new EFLAGS.IF were set. The new EFLAGS.TF was set.
			X	IRET _x was executed in long mode while EFLAGS.NT=1.

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP (selector)			X	The return code selector was a null selector.
			X	The return stack selector was a null selector and the return mode was non-64-bit mode or CPL was 3.
			X	The return code or stack descriptor exceeded the descriptor table limit.
			X	The return code or stack selector's TI bit was set but the LDT selector was a null selector.
			X	The segment descriptor for the return code was not a code segment.
			X	The RPL of the return code segment selector was less than the CPL.
			X	The return code segment was non-conforming and the segment selector's DPL was not equal to the RPL of the code segment's segment selector.
			X	The return code segment was conforming and the segment selector's DPL was greater than the RPL of the code segment's segment selector.
			X	The segment descriptor for the return stack was not a writable data segment.
			X	The stack segment descriptor DPL was not equal to the RPL of the return code segment selector.
		X	The stack segment selector RPL was not equal to the RPL of the return code segment selector.	
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

LAR**Load Access Rights Byte**

Loads the access rights from the segment descriptor specified by a 16-bit source register or memory operand into a specified 16-bit, 32-bit, or 64-bit general-purpose register and sets the zero (ZF) flag in the rFLAGS register if successful. LAR clears the zero flag if the descriptor is invalid for any reason.

The LAR instruction checks that:

- the segment selector is not a null selector.
- the descriptor is within the GDT or LDT limit.
- the descriptor DPL is greater than or equal to both the CPL and RPL, or the segment is a conforming code segment.
- the descriptor type is valid for the LAR instruction. Valid descriptor types are shown in the following table. LDT and TSS descriptors in 64-bit mode, and call-gate descriptors in long mode, are only valid if bits 12:8 of doubleword +12 are zero.

See Volume 2, Section 6.4 for more information on checking access rights using LAR.

Valid Descriptor Type		Description
Legacy Mode	Long Mode	
All	All	All code and data descriptors
1	—	Available 16-bit TSS
2	2	LDT
3	—	Busy 16-bit TSS
4	—	16-bit call gate
5	—	Task gate
9	9	Available 32-bit or 64-bit TSS
B	B	Busy 32-bit or 64-bit TSS
C	C	32-bit or 64-bit call gate

If the segment descriptor passes these checks, the attributes are loaded into the destination general-purpose register. If it does not, then the zero flag is cleared and the destination register is not modified.

When the operand size is 16 bits, access rights include the DPL and Type fields located in bytes 4 and 5 of the descriptor table entry. Before loading the access rights into the destination operand, the low order word is masked with FF00H.

When the operand size is 32 or 64 bits, access rights include the DPL and type as well as the descriptor type (S field), segment present (P flag), available to system (AVL flag), default operation size (D/B

flag), and granularity flags located in bytes 4–7 of the descriptor. Before being loaded into the destination operand, the doubleword is masked with 00FF_FF00H.

In 64-bit mode, for both 32-bit and 64-bit operand sizes, 32-bit register results are zero-extended to 64 bits.

This instruction can only be executed in protected mode.

Mnemonic	Opcode	Description
LAR <i>reg16, reg/mem16</i>	0F 02 /r	Reads the GDT/LDT descriptor referenced by the 16-bit source operand, masks the attributes with FF00h and saves the result in the 16-bit destination register.
LAR <i>reg32, reg/mem16</i>	0F 02 /r	Reads the GDT/LDT descriptor referenced by the 16-bit source operand, masks the attributes with 00FFFF00h and saves the result in the 32-bit destination register.
LAR <i>reg64, reg/mem16</i>	0F 02 /r	Reads the GDT/LDT descriptor referenced by the 16-bit source operand, masks the attributes with 00FFFF00h and saves the result in the 64-bit destination register.

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to one or zero is M (modified). Unaffected flags are blank. Undefined flags are U.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X		This instruction is only recognized in protected mode.
Stack, #SS			X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP			X	A memory address exceeded the data segment limit or was non-canonical.
			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.
Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

LGDT**Load Global Descriptor Table Register**

Loads the pseudo-descriptor specified by the source operand into the global descriptor table register (GDTR). The pseudo-descriptor is a memory location containing the GDTR base and limit. In legacy and compatibility mode, the pseudo-descriptor is 6 bytes; in 64-bit mode, it is 10 bytes.

If the operand size is 16 bits, the high-order byte of the 6-byte pseudo-descriptor is not used. The lower two bytes specify the 16-bit limit and the third, fourth, and fifth bytes specify the 24-bit base address. The high-order byte of the GDTR is filled with zeros.

If the operand size is 32 bits, the lower two bytes specify the 16-bit limit and the upper four bytes specify a 32-bit base address.

In 64-bit mode, the lower two bytes specify the 16-bit limit and the upper eight bytes specify a 64-bit base address. In 64-bit mode, operand-size prefixes are ignored and the operand size is forced to 64-bits; therefore, the pseudo-descriptor is always 10 bytes.

This instruction is only used in operating system software and must be executed at CPL 0. It is typically executed once in real mode to initialize the processor before switching to protected mode.

LGDT is a serializing instruction.

Mnemonic	Opcode	Description
LGDT <i>mem16:32</i>	0F 01 /2	Loads <i>mem16:32</i> into the global descriptor table register.
LGDT <i>mem16:64</i>	0F 01 /2	Loads <i>mem16:64</i> into the global descriptor table register.

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General protection, #GP	X		X	A memory address exceeded the data segment limit or was non-canonical.
		X	X	CPL was not 0.
			X	The new GDT base address was non-canonical.
			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.

LIDT**Load Interrupt Descriptor Table Register**

Loads the pseudo-descriptor specified by the source operand into the interrupt descriptor table register (IDTR). The pseudo-descriptor is a memory location containing the IDTR base and limit. In legacy and compatibility mode, the pseudo-descriptor is six bytes; in 64-bit mode, it is 10 bytes.

If the operand size is 16 bits, the high-order byte of the 6-byte pseudo-descriptor is not used. The lower two bytes specify the 16-bit limit and the third, fourth, and fifth bytes specify the 24-bit base address. The high-order byte of the IDTR is filled with zeros.

If the operand size is 32 bits, the lower two bytes specify the 16-bit limit and the upper four bytes specify a 32-bit base address.

In 64-bit mode, the lower two bytes specify the 16-bit limit, and the upper eight bytes specify a 64-bit base address. In 64-bit mode, operand-size prefixes are ignored and the operand size is forced to 64-bits; therefore, the pseudo-descriptor is always 10 bytes.

This instruction is only used in operating system software and must be executed at CPL 0. It is normally executed once in real mode to initialize the processor before switching to protected mode.

LIDT is a serializing instruction.

Mnemonic	Opcode	Description
LIDT <i>mem16:32</i>	0F 01 /3	Loads <i>mem16:32</i> into the interrupt descriptor table register.
LIDT <i>mem16:64</i>	0F 01 /3	Loads <i>mem16:64</i> into the interrupt descriptor table register.

			X	The new IDT base address was non-canonical.
			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.

LLDT**Load Local Descriptor Table Register**

Loads the specified segment selector into the visible portion of the local descriptor table (LDT). The processor uses the selector to locate the descriptor for the LDT in the global descriptor table. It then loads this descriptor into the hidden portion of the LDTR.

If the source operand is a null selector, the LDTR is marked invalid and all references to descriptors in the LDT will generate a general protection exception (#GP), except for the LAR, VERR, VERW or LSL instructions.

In legacy and compatibility modes, the LDT descriptor is 8 bytes long and contains a 32-bit base address.

In 64-bit mode, the LDT descriptor is 16-bytes long and contains a 64-bit base address. The LDT descriptor type (02h) is redefined in 64-bit mode for use as the 16-byte LDT descriptor.

This instruction must be executed in protected mode. It is only provided for use by operating system software at CPL 0.

LLDT is a serializing instruction.

Mnemonic	Opcode	Description
LLDT <i>reg/mem16</i>	0F 00 /2	Load the 16-bit segment selector into the local descriptor table register and load the LDT descriptor from the GDT.

			X	The descriptor was not an LDT descriptor.
			X	The descriptor's extended attribute bits were not zero in 64-bit mode.
			X	The new LDT base address was non-canonical.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.

LMSW**Load Machine Status Word**

Loads the lower four bits of the 16-bit register or memory operand into bits 3:0 of the machine status word in register CR0. Only the protection enabled (PE), monitor coprocessor (MP), emulation (EM), and task switched (TS) bits of CR0 are modified. Additionally, LMSW can set CR0.PE, but cannot clear it.

The LMSW instruction can be used only when the current privilege level is 0. It is only provided for compatibility with early processors.

Use the MOV CR0 instruction to load all 32 or 64 bits of CR0.

Mnemonic	Opcode	Description
LMSW <i>reg/mem16</i>	0F 01 /6	Load the lower 4 bits of the source into the lower 4 bits of CR0.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Stack, #SS	X		X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP	X		X	A memory address exceeded a data segment limit or was non-canonical.
		X	X	CPL was not 0.
			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.

LSL

Load Segment Limit

Loads the segment limit from the segment descriptor specified by a 16-bit source register or memory operand into a specified 16-bit, 32-bit, or 64-bit general-purpose register and sets the zero (ZF) flag in the rFLAGS register if successful. LSL clears the zero flag if the descriptor is invalid for any reason.

In 64-bit mode, for both 32-bit and 64-bit operand sizes, 32-bit register results are zero-extended to 64 bits.

The LSL instruction checks that:

- the segment selector is not a null selector.
- the descriptor is within the GDT or LDT limit.
- the descriptor DPL is greater than or equal to both the CPL and RPL, or the segment is a conforming code segment.
- the descriptor type is valid for the LAR instruction. Valid descriptor types are shown in the following table. LDT and TSS descriptors in 64-bit mode are only valid if bits 12:8 of doubleword +12 are zero, as described in “System Descriptors” in Volume 2.

Valid Descriptor Type		Description
Legacy Mode	Long Mode	
—	—	All code and data descriptors
1	—	Available 16-bit TSS
2	2	LDT
3	—	Busy 16-bit TSS
9	9	Available 32-bit or 64-bit TSS
B	B	Busy 32-bit or 64-bit TSS

If the segment selector passes these checks and the segment limit is loaded into the destination general-purpose register, the instruction sets the zero flag of the rFLAGS register to 1. If the selector does not pass the checks, then LSL clears the zero flag to 0 and does not modify the destination.

The instruction calculates the segment limit to 32 bits, taking the 20-bit limit and the granularity bit into account. When the operand size is 16 bits, it truncates the upper 16 bits of the 32-bit adjusted segment limit and loads the lower 16-bits into the target register.

Mnemonic	Opcode	Description
LSL <i>reg16, reg/mem16</i>	0F 03 /r	Loads a 16-bit general-purpose register with the segment limit for a selector specified in a 16-bit memory or register operand.

LSL <i>reg32, reg/mem16</i>	OF 03 /r	Loads a 32-bit general-purpose register with the segment limit for a selector specified in a 16-bit memory or register operand.
LSL <i>reg64, reg/mem16</i>	OF 03 /r	Loads a 64-bit general-purpose register with the segment limit for a selector specified in a 16-bit memory or register operand.

			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.
Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

LTR

Load Task Register

Loads the specified segment selector into the visible portion of the task register (TR). The processor uses the selector to locate the descriptor for the TSS in the global descriptor table. It then loads this descriptor into the hidden portion of TR. The TSS descriptor in the GDT is marked busy, but no task switch is made.

If the source operand is null, a general protection exception (#GP) is generated.

In legacy and compatibility modes, the TSS descriptor is 8 bytes long and contains a 32-bit base address.

In 64-bit mode, the instruction references a 64-bit descriptor to load a 64-bit base address. The TSS type (09H) is redefined in 64-bit mode for use as the 16-byte TSS descriptor.

This instruction must be executed in protected mode when the current privilege level is 0. It is only provided for use by operating system software.

The operand size attribute has no effect on this instruction.

LTR is a serializing instruction.

Mnemonic	Opcode	Description
LTR <i>reg/mem16</i>	0F 00 /3	Load the 16-bit segment selector into the task register and load the TSS descriptor from the GDT.

MONITOR

Setup Monitor Address

Establishes a linear address range of memory for hardware to monitor and puts the processor in the monitor event pending state. When in the monitor event pending state, the monitoring hardware detects stores to the specified linear address range and causes the processor to exit the monitor event pending state. The MWAIT instruction uses the state of the monitor hardware.

The address range should be a write-back memory type. Executing MONITOR on an address range for a non-write-back memory type is not guaranteed to cause the processor to enter the monitor event pending state. The size of the linear address range that is established by the MONITOR instruction can be determined by CPUID function 0000_0005h.

The [rAX] register provides the effective address. The DS segment is the default segment used to create the linear address. Segment overrides may be used with the MONITOR instruction.

The ECX register specifies optional extensions for the MONITOR instruction. There are currently no extensions defined and setting any bits in ECX will result in a #GP exception. The ECX register operand is implicitly 32-bits.

The EDX register specifies optional hints for the MONITOR instruction. There are currently no hints defined and EDX is ignored by the processor. The EDX register operand is implicitly 32-bits.

The MONITOR instruction can be executed at CPL 0 and is allowed at CPL > 0 only if MSR C001_0015h[MonMwaitUserEn] = 1. When MSR C001_0015h[MonMwaitUserEn] = 0, MONITOR generates #UD at CPL > 0. (See the *BIOS and Kernel Developer's Guide* applicable to your product for specific details on MSR C001_0015h.)

MONITOR performs the same segmentation and paging checks as a 1-byte read.

Support for the MONITOR instruction is indicated by CPUID Fn0000_0001_ECX[MONITOR] = 1. Software must check the CPUID bit once per program or library initialization before using the MONITOR instruction, or inconsistent behavior may result. Software designed to run at CPL greater than 0 must also check for availability by testing whether executing MONITOR causes a #UD exception.

The following pseudo-code shows typical usage of a MONITOR/MWAIT pair:

```
EAX = Linear_Address_to_Monitor;
ECX = 0; // Extensions
EDX = 0; // Hints

while (!matching_store_done){
    MONITOR EAX, ECX, EDX
    IF (!matching_store_done) {
        MWAIT EAX, ECX
    }
}
```

Mnemonic	Opcode	Description
MONITOR	0F 01 C8	Establishes a linear address range to be monitored by hardware and activates the monitor hardware.

MOV CR n

Move to/from Control Registers

Moves the contents of a 32-bit or 64-bit general-purpose register to a control register or vice versa.

In 64-bit mode, the operand size is fixed at 64 bits without the need for a REX prefix. In non-64-bit mode, the operand size is fixed at 32 bits and the upper 32 bits of the destination are forced to 0.

CR0 maintains the state of various control bits. CR2 and CR3 are used for page translation. CR4 holds various feature enable bits. CR8 is used to prioritize external interrupts. CR1, CR5, CR6, CR7, and CR9 through CR15 are all reserved and raise an undefined opcode exception (#UD) if referenced.

CR8 can be read and written in 64-bit mode, using a REX prefix. CR8 can be read and written in all modes using a LOCK prefix instead of a REX prefix to specify the additional opcode bit. To verify whether the LOCK prefix can be used in this way, check for support of this feature. CPUID Fn8000_0001_ECX[AltMovCr8] = 1, indicates that this feature is supported.

For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

CR8 can also be read and modified using the task priority register described in “System-Control Registers” in Volume 2.

This instruction is always treated as a register-to-register (MOD = 11) instruction, regardless of the encoding of the MOD field in the MODR/M byte.

MOV CR n is a privileged instruction and must always be executed at CPL = 0.

MOV CR n is a serializing instruction.

Mnemonic	Opcode	Description
MOV CR n , <i>reg32</i>	0F 22 /r	Move the contents of a 32-bit register to CR n
MOV CR n , <i>reg64</i>	0F 22 /r	Move the contents of a 64-bit register to CR n
MOV <i>reg32</i> , CR n	0F 20 /r	Move the contents of CR n to a 32-bit register.
MOV <i>reg64</i> , CR n	0F 20 /r	Move the contents of CR n to a 64-bit register.
MOV CR8, <i>reg32</i>	F0 0F 22/r	Move the contents of a 32-bit register to CR8.
MOV CR8, <i>reg64</i>	F0 0F 22/r	Move the contents of a 64-bit register to CR8.
MOV <i>reg32</i> , CR8	F0 0F 20/r	Move the contents of CR8 into a 32-bit register.
MOV <i>reg64</i> , CR8	F0 0F 20/r	Move the contents of CR8 into a 64-bit register.

	X		X	An attempt was made to set CR0.PG while long mode was enabled (EFER.LME = 1), but paging address extensions were disabled (CR4.PAE = 0).
				X

MOV DRn

Move to/from Debug Registers

Moves the contents of a debug register into a 32-bit or 64-bit general-purpose register or vice versa.

In 64-bit mode, the operand size is fixed at 64 bits without the need for a REX prefix. In non-64-bit mode, the operand size is fixed at 32-bits and the upper 32 bits of the destination are forced to 0.

DR0 through DR3 are linear breakpoint address registers. DR6 is the debug status register and DR7 is the debug control register. DR4 and DR5 are aliased to DR6 and DR7 if CR4.DE = 0, and are reserved if CR4.DE = 1.

DR8 through DR15 are reserved and generate an undefined opcode exception if referenced.

These instructions are privileged and must be executed at CPL 0.

The `MOV DRn, reg32` and `MOV DRn, reg64` instructions are serializing instructions.

The MOV(DR) instruction is always treated as a register-to-register (MOD = 11) instruction, regardless of the encoding of the MOD field in the MODR/M byte.

See “Debug and Performance Resources” in Volume 2 for details.

Mnemonic	Opcode	Description
<code>MOV reg32, DRn</code>	0F 21 /r	Move the contents of DRn to a 32-bit register.
<code>MOV reg64, DRn</code>	0F 21 /r	Move the contents of DRn to a 64-bit register.
<code>MOV DRn, reg32</code>	0F 23 /r	Move the contents of a 32-bit register to DRn.
<code>MOV DRn, reg64</code>	0F 23 /r	Move the contents of a 64-bit register to DRn.

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Debug, #DB	X		X	A debug register was referenced while the general detect (GD) bit in DR7 was set.
Invalid opcode, #UD	X		X	DR4 or DR5 was referenced while the debug extensions (DE) bit in CR4 was set.
			X	An illegal debug register (DR8–DR15) was referenced.
General protection, #GP		X	X	CPL was not 0.
			X	A 1 was written to any of the upper 32 bits of DR6 or DR7 in 64-bit mode.

MWAIT

Monitor Wait

Used in conjunction with the MONITOR instruction to cause a processor to wait until a store occurs to a specific linear address range from another processor. The previously executed MONITOR instruction causes the processor to enter the monitor event pending state. The MWAIT instruction may enter an implementation dependent power state until the monitor event pending state is exited. The MWAIT instruction has the same effect on architectural state as the NOP instruction.

Events that cause an exit from the monitor event pending state include:

- A store from another processor matches the address range established by the MONITOR instruction.
- Any unmasked interrupt, including INTR, NMI, SMI, INIT.
- RESET.
- Any far control transfer that occurs between the MONITOR and the MWAIT.

EAX specifies optional hints for the MWAIT instruction. There are currently no hints defined and all bits should be 0. Setting a reserved bit in EAX is ignored by the processor.

ECX specifies optional extensions for the MWAIT instruction. The only extension currently defined is ECX bit 0, which allows interrupts to wake MWAIT, even when eFLAGS.IF = 0. Support for this extension is indicated by a feature flag returned by the CPUID instruction. Setting any unsupported bit in ECX results in a #GP exception.

CPUID Function 0000_0005h indicates support for extended features of MONITOR/MWAIT:

- CPUID Fn0000_0005_ECX[EMX] = 1 indicates support for enumeration of MONITOR/MWAIT extensions.
- CPUID Fn0000_0005_ECX[IBE] = 1 indicates that MWAIT can set ECX[0] to allow interrupts to cause an exit from the monitor event pending state even when eFLAGS.IF = 0.

The MWAIT instruction can be executed at CPL 0 and is allowed at CPL > 0 only if MSR C001_0015h[MonMwaitUserEn] = 1. When MSR C001_0015h[MonMwaitUserEn] is 0, MWAIT generates #UD at CPL > 0. (See the *BIOS and Kernel Developer's Guide* applicable to your product for specific details on MSR C001_0015h.)

Support for the MWAIT instruction is indicated by CPUID Fn0000_0001_ECX[MONITOR] = 1. Software MUST check the CPUID bit once per program or library initialization before using the MWAIT instruction, or inconsistent behavior may result. Software designed to run at CPL greater than 0 must also check for availability by testing whether executing MWAIT causes a #UD exception.

The use of the MWAIT instruction is contingent upon the satisfaction of the following coding requirements:

- MONITOR must precede the MWAIT and occur in the same loop.

- MWAIT must be conditionally executed only if the awaited store has not already occurred. (This prevents a race condition between the MONITOR instruction arming the monitoring hardware and the store intended to trigger the monitoring hardware.)

The following pseudo-code shows typical usage of a MONITOR/MWAIT pair:

```
EAX = Linear_Address_to_Monitor;
ECX = 0; // Extensions
EDX = 0; // Hints

WHILE (!matching_store_done ){
    MONITOR EAX, ECX, EDX
    IF ( !matching_store_done ) {
        MWAIT EAX, ECX
    }
}
```

Mnemonic	Opcode	Description
MWAIT	0F 01 C9	Causes the processor to stop instruction execution and enter an implementation-dependent optimized state until occurrence of a class of events.

		X	X	CPL was not zero and MSRC001_0015[MonMwaitUserEn] = 0.
General protection, #GP	X	X	X	Unsupported extension bits were set in ECX

RDMSR

Read Model-Specific Register

Loads the contents of a 64-bit model-specific register (MSR) specified in the ECX register into registers EDX:EAX. The EDX register receives the high-order 32 bits and the EAX register receives the low order bits. The RDMSR instruction ignores operand size; ECX always holds the MSR number, and EDX:EAX holds the data. If a model-specific register has fewer than 64 bits, the unimplemented bit positions loaded into the destination registers are undefined.

This instruction must be executed at a privilege level of 0 or a general protection exception (#GP) will be raised. This exception is also generated if a reserved or unimplemented model-specific register is specified in ECX.

Support for the RDMSR instruction is indicated by CPUID Fn0000_0001_EDX[MSR] = 1 OR CPUID Fn8000_0001_EDX[MSR] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

For more information about model-specific registers, see the documentation for various hardware implementations and “Model-Specific Registers (MSRs)” in *Volume 2: System Programming*.

Mnemonic	Opcode	Description
RDMSR	0F 32	Copy MSR specified by ECX into EDX:EAX.

Related Instructions

WRMSR, RDTSC, RDPMC

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The RDMSR instruction is not supported, as indicated by CPUID Fn0000_0001_EDX[MSR] = 0 or CPUID Fn8000_0001_EDX[MSR] = 0.
General protection, #GP		X	X	CPL was not 0.
	X		X	The value in ECX specifies a reserved or unimplemented MSR address.

RDPMC

Read Performance-Monitoring Counter

Reads the contents of a 64-bit performance counter and returns it in the registers EDX:EAX. The ECX register is used to specify the index of the performance counter to be read. The EDX register receives the high-order 32 bits and the EAX register receives the low order 32 bits of the counter. The RDPMC instruction ignores operand size; the index and the return values are all 32 bits.

The base architecture supports four core performance counters: PerfCtr0–3. An extension to the architecture increases the number of core performance counters to 6 (PerfCtr0–5). Other extensions add four northbridge performance counters NB_PerfCtr0–3 and four L2 cache performance counters L2I_PerfCtr0–3.

To select the core performance counter to be read, specify the counter index, rather than the performance counter MSR address. To access the northbridge performance counters, specify the index of the counter plus 6. To access the L2 cache performance counters, specify the index of the counter plus 10.

Programs running at any privilege level can read performance monitor counters if the PCE flag in CR4 is set to 1; otherwise this instruction must be executed at a privilege level of 0.

This instruction is not serializing. Therefore, there is no guarantee that all instructions have completed at the time the performance counter is read.

For more information about performance-counter registers, see the documentation for various hardware implementations and “Performance Counters” in Volume 2.

Support for the core performance counters PerfCtr4–5 is indicated by CPUID Fn8000_0001_ECX[PerfCtrExtCore] = 1. CPUID Fn8000_0001_ECX[PerfCtrExtNB] = 1 indicates support for the four architecturally defined northbridge performance counters and CPUID Fn8000_0001_ECX[PerfCtrExtL2I] = 1 indicates support for the L2 cache performance counters.

For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

Instruction Encoding

Mnemonic	Opcode	Description
RDPMC	0F 33	Copy the performance monitor counter specified by ECX into EDX:EAX.

Related Instructions

RDMSR, WRMSR

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
General Protection, #GP	X	X	X	The value in ECX specified an unimplemented performance counter number.
		X	X	CPL was not 0 and CR4.PCE = 0.

RDTSC

Read Time-Stamp Counter

Loads the value of the processor's 64-bit time-stamp counter into registers EDX:EAX.

The time-stamp counter (TSC) is contained in a 64-bit model-specific register (MSR). The processor sets the counter to 0 upon reset and increments the counter every clock cycle. INIT does not modify the TSC.

The high-order 32 bits are loaded into EDX, and the low-order 32 bits are loaded into the EAX register. This instruction ignores operand size.

When the time-stamp disable flag (TSD) in CR4 is set to 1, the RDTSC instruction can only be used at privilege level 0. If the TSD flag is 0, this instruction can be used at any privilege level.

This instruction is not serializing. Therefore, there is no guarantee that all instructions have completed at the time the time-stamp counter is read.

The behavior of the RDTSC instruction is implementation dependent. The TSC counts at a constant rate, but may be affected by power management events (such as frequency changes), depending on the processor implementation. If CPUID Fn8000_0007_EDX[TscInvariant] = 1, then the TSC rate is ensured to be invariant across all P-States, C-States, and stop-grant transitions (such as STPCLK Throttling); therefore, the TSC is suitable for use as a source of time. Consult the *BIOS and Kernel Developer's Guide* applicable to your product for information concerning the effect of power management on the TSC.

Support for the RDTSC instruction is indicated by CPUID Fn0000_0001_EDX[TSC] = 1 OR CPUID Fn8000_0001_EDX[TSC] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

Instruction Encoding

Mnemonic	Opcode	Description
RDTSC	0F 31	Copy the time-stamp counter into EDX:EAX.

Related Instructions

RDTSCP, RDMSR, WRMSR

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Invalid opcode, #UD	X	X	X	The RDTSC instruction is not supported, as indicated by CPUID Fn0000_0001_EDX[TSC] = 0 OR CPUID Fn8000_0001_EDX[TSC] = 0.
General protection, #GP		X	X	CPL was not 0 and CR4.TSD = 1.

RDTSCP

Read Time-Stamp Counter and Processor ID

Loads the value of the processor's 64-bit time-stamp counter into registers EDX:EAX, and loads the value of TSC_AUX into ECX. This instruction ignores operand size.

The time-stamp counter is contained in a 64-bit model-specific register (MSR). The processor sets the counter to 0 upon reset and increments the counter every clock cycle. INIT does not modify the TSC.

The high-order 32 bits are loaded into EDX, and the low-order 32 bits are loaded into the EAX register.

The TSC_AUX value is contained in the low-order 32 bits of the TSC_AUX register (MSR address C000_0103h). This MSR is initialized by privileged software to any meaningful value, such as a processor ID, that software wants to associate with the returned TSC value.

When the time-stamp disable flag (TSD) in CR4 is set to 1, the RDTSCP instruction can only be used at privilege level 0. If the TSD flag is 0, this instruction can be used at any privilege level.

Unlike the RDTSC instruction, RDTSCP forces all older instructions to retire before reading the time-stamp counter.

The behavior of the RDTSCP instruction is implementation dependent. The TSC counts at a constant rate, but may be affected by power management events (such as frequency changes), depending on the processor implementation. If CPUID Fn8000_0007_EDX[TscInvariant] = 1, then the TSC rate is ensured to be invariant across all P-States, C-States, and stop-grant transitions (such as STPCLK Throttling); therefore, the TSC is suitable for use as a source of time. Consult the *BIOS and Kernel Developer's Guide* applicable to your product for information concerning the effect of power management on the TSC.

Support for the RDTSCP instruction is indicated by CPUID Fn8000_0001_EDX[RDTSCP] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

Exceptions

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Invalid opcode, #UD	X	X	X	The RDTSCP instruction is not supported, as indicated by CPUID Fn8000_0001_EDX[RDTSCP] = 0.
General protection, #GP		X	X	CPL was not 0 and CR4.TSD = 1.

RSM**Resume from System Management Mode**

Resumes an operating system or application procedure previously interrupted by a system management interrupt (SMI). The processor state is restored from the information saved when the SMI was taken. The processor goes into a shutdown state if it detects invalid state information in the system management mode (SMM) save area during RSM.

RSM will shut down if any of the following conditions are found in the save map (SSM):

- An illegal combination of flags in CR0 (CR0.PG = 1 and CR0.PE = 0, or CR0.NW = 1 and CR0.CD = 0).
- A reserved bit in CR0, CR3, CR4, DR6, DR7, or the extended feature enable register (EFER) is set to 1.
- The following bit combination occurs: EFER.LME = 1, CR0.PG = 1, CR4.PAE = 0.
- The following bit combination occurs: EFER.LME = 1, CR0.PG = 1, CR4.PAE = 1, CS.D = 1, CS.L = 1.
- SMM revision field has been modified.

RSM cannot modify EFER.SVME. Attempts to do so are ignored.

When EFER.SVME is 1, RSM reloads the four PDPEs (through the incoming CR3) when returning to a mode that has legacy PAE mode paging enabled.

When EFER.SVME is 1, the RSM instruction is permitted to return to paged real mode (i.e., CR0.PE=0 and CR0.PG=1).

The AMD64 architecture uses a new 64-bit SMM state-save memory image. This 64-bit save-state map is used in all modes, regardless of mode. See “System-Management Mode” in Volume 2 for details.

Mnemonic	Opcode	Description
RSM	0F AA	Resume operation of an interrupted program.

Related Instructions

None

rFLAGS Affected

All flags are restored from the state-save map (SSM).

Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

SKINIT**Secure Init and Jump with Attestation**

Securely reinitializes the cpu, allowing for the startup of trusted software (such as a VMM). The code to be executed after reinitialization can be verified based on a secure hash comparison. SKINIT takes the physical base address of the SLB as its only input operand, in EAX. The SLB must be structured as described in “Secure Loader Block” on page 499 of the *AMD64 Architecture Programmer’s Manual Volume 2: System Programming*, order# 24593, and is assumed to contain the code for a Secure Loader (SL).

This is a Secure Virtual Machine (SVM) instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume 2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description
SKINIT EAX	0F 01 DE	Secure initialization and jump, with attestation.

Action

			X	The destination operand was in a non-writable segment.
			X	A null data segment was used to reference memory.
Page fault, #PF		X	X	A page fault resulted from the execution of the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

STI**Set Interrupt Flag**

Sets the interrupt flag (IF) in the rFLAGS register to 1, thereby allowing external interrupts received on the INTR input. Interrupts received on the non-maskable interrupt (NMI) input are not affected by this instruction.

In real mode, this instruction sets IF to 1.

In protected mode and virtual-8086-mode, this instruction is IOPL-sensitive. If the CPL is less than or equal to the rFLAGS.IOPL field, the instruction sets IF to 1.

In protected mode, if $IOPL < 3$, $CPL = 3$, and protected mode virtual interrupts are enabled ($CR4.PVI = 1$), then the instruction instead sets rFLAGS.VIF to 1. If none of these conditions apply, the processor raises a general protection exception (#GP). For more information, see “Protected Mode Virtual Interrupts” in Volume 2.

In virtual-8086 mode, if $IOPL < 3$ and the virtual-8086-mode extensions are enabled ($CR4.VME = 1$), the STI instruction instead sets the virtual interrupt flag (rFLAGS.VIF) to 1.

If STI sets the IF flag and IF was initially clear, then interrupts are not enabled until after the instruction following STI. Thus, if IF is 0, this code will not allow an INTR to happen:

```
STI
CLI
```

In the following sequence, INTR will be allowed to happen only after the NOP.

```
STI
NOP
CLI
```

If STI sets the VIF flag and VIP is already set, a #GP fault will be generated.

See “Virtual-8086 Mode Extensions” in Volume 2 for more information about IOPL-sensitive instructions.

Mnemonic	Opcode	Description
STI	FB	Set interrupt flag (IF) to 1.

Action

```

IF (CPL <= IOPL)
    RFLAGS.IF = 1

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. M (modified) is either set to one or cleared to zero. Unaffected flags are blank. Undefined flags are U.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
General protection, #GP		X		The CPL was greater than the IOPL and virtual-mode extensions were not enabled (CR4.VME = 0).
			X	The CPL was greater than the IOPL and either the CPL was not 3 or protected-mode virtual interrupts were not enabled (CR4.PVI = 0).
		X	X	This instruction would set RFLAGS.VIF to 1 and RFLAGS.VIP was already 1.

STGI**Set Global Interrupt Flag**

Sets the global interrupt flag (GIF) to 1. While GIF is zero, all external interrupts are disabled.

This is a Secure Virtual Machine (SVM) instruction.

Attempted execution of this instruction causes a #UD exception if SVM is not enabled and neither SVM Lock nor the device exclusion vector (DEV) are supported. Support for SVM Lock is indicated by CPUID Fn8000_000A_EDX[SVML] = 1. Support for DEV is part of the SKINIT architecture and is indicated by CPUID Fn8000_0001_ECX[SKINIT] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

For information on enabling SVM, see “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume-2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description
STGI	0F 01 DC	Sets the global interrupt flag (GIF).

Invalid opcode, #UD			X	Secure Virtual Machine was not enabled (EFER.SVME=0) and both of the following conditions were true: <ul style="list-style-type: none"> SVM Lock is not available, as indicated by CPUID Fn8000_000A_EDX[SVML] = 0. DEV is not available, as indicated by CPUID Fn8000_0001_ECX[SKINIT] = 0.
	X	X		Instruction is only recognized in protected mode.
General protection, #GP			X	CPL was not zero.

STR

Store Task Register

Stores the task register (TR) selector to a register or memory destination operand.

If the destination is a register, the selector is zero-extended into a 16-, 32-, or 64-bit general purpose register, depending on the operand size.

If the destination is a memory location, the segment selector is written to memory as a 16-bit value, regardless of operand size.

The STR instruction can only be used in protected mode, but it can be used at any privilege level.

Mnemonic	Opcode	Description
STR <i>reg16</i>	0F 00 /1	Store the segment selector from the task register to a 16-bit general-purpose register.
STR <i>reg32</i>	0F 00 /1	Store the segment selector from the task register to a 32-bit general-purpose register.
STR <i>reg64</i>	0F 00 /1	Store the segment selector from the task register to a 64-bit general-purpose register.
STR <i>mem16</i>	0F 00 /1	Store the segment selector from the task register to a 16-bit memory location.

Stack, #SS			X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP			X	A memory address exceeded a data segment limit or was non-canonical.
			X	The destination operand was in a non-writable segment.
			X	A null data segment was used to reference memory.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.
Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

SWAPGS Swap GS Register with KernelGSbase MSR

Provides a fast method for system software to load a pointer to system data structures. SWAPGS can be used upon entering system-software routines as a result of a SYSCALL instruction, an interrupt or an exception. Prior to returning to application software, SWAPGS can be used to restore the application data pointer that was replaced by the system data-structure pointer.

This instruction can only be executed in 64-bit mode. Executing SWAPGS in any other mode generates an undefined opcode exception.

The SWAPGS instruction only exchanges the base-address value located in the KernelGSbase model-specific register (MSR address C000_0102h) with the base-address value located in the hidden-portion of the GS selector register (GS.base). This allows the system-kernel software to access kernel data structures by using the GS segment-override prefix during memory references.

The address stored in the KernelGSbase MSR must be in canonical form. The WRMSR instruction used to load the KernelGSbase MSR causes a general-protection exception if the address loaded is not in canonical form. The SWAPGS instruction itself does not perform a canonical check.

This instruction is only valid in 64-bit mode at CPL 0. A general protection exception (#GP) is generated if this instruction is executed at any other privilege level.

For additional information about this instruction, refer to “System-Management Instructions” in Volume 2.

Examples

At a kernel entry point, the OS uses SwapGS to obtain a pointer to kernel data structures and simultaneously save the user's GS base. Upon exit, it uses SwapGS to restore the user's GS base:

```
SystemCallEntryPoint:
SwapGS                ; get kernel pointer, save user GSbase
mov gs:[SavedUserRSP], rsp    ; save user's stack pointer
mov rsp, gs:[KernelStackPtr] ; set up kernel stack
push rax                 ; now save user GPRs on kernel stack
    .                   ; perform system service
    .
SwapGS                ; restore user GS, save kernel pointer
```

Mnemonic	Opcode	Description
SWAPGS	0F 01 F8	Exchange GS base with KernelGSBase MSR. (Invalid in legacy and compatibility modes.)

SYSCALL

Fast System Call

Transfers control to a fixed entry point in an operating system. It is designed for use by system and application software implementing a flat-segment memory model.

The SYSCALL and SYSRET instructions are low-latency system call and return control-transfer instructions, which assume that the operating system implements a flat-segment memory model. By eliminating unneeded checks, and by loading pre-determined values into the CS and SS segment registers (both visible and hidden portions), calls to and returns from the operating system are greatly simplified. These instructions can be used in protected mode and are particularly well-suited for use in 64-bit mode, which requires implementation of a paged, flat-segment memory model.

This instruction has been optimized by reducing the number of checks and memory references that are normally made so that a call or return takes considerably fewer clock cycles than the CALL FAR /RET FAR instruction method.

It is assumed that the base, limit, and attributes of the Code Segment will remain flat for all processes and for the operating system, and that only the current privilege level for the selector of the calling process should be changed from a current privilege level of 3 to a new privilege level of 0. It is also assumed (but not checked) that the RPL of the SYSCALL and SYSRET target selectors are set to 0 and 3, respectively.

SYSCALL sets the CPL to 0, regardless of the values of bits 33:32 of the STAR register. There are no permission checks based on the CPL, real mode, or virtual-8086 mode. SYSCALL and SYSRET must be enabled by setting EFER.SCE to 1.

It is the responsibility of the operating system to keep the descriptors in memory that correspond to the CS and SS selectors loaded by the SYSCALL and SYSRET instructions consistent with the segment base, limit, and attribute values forced by these instructions.

Legacy x86 Mode. In legacy x86 mode, when SYSCALL is executed, the EIP of the instruction following the SYSCALL is copied into the ECX register. Bits 31:0 of the SYSCALL/SYSRET target address register (STAR) are copied into the EIP register. (The STAR register is model-specific register C000_0081h.)

New selectors are loaded, without permission checking (see above), as follows:

- Bits 47:32 of the STAR register specify the selector that is copied into the CS register.
- Bits 47:32 of the STAR register + 8 specify the selector that is copied into the SS register.
- The CS_base and the SS_base are both forced to zero.
- The CS_limit and the SS_limit are both forced to 4 Gbyte.
- The CS segment attributes are set to execute/read 32-bit code with a CPL of zero.
- The SS segment attributes are set to read/write and expand-up with a 32-bit stack referenced by ESP.

Long Mode. When long mode is activated, the behavior of the SYSCALL instruction depends on whether the calling software is in 64-bit mode or compatibility mode. In 64-bit mode, SYSCALL saves the RIP of the instruction following the SYSCALL into RCX and loads the new RIP from LSTAR bits 63:0. (The LSTAR register is model-specific register C000_0082h.) In compatibility mode, SYSCALL saves the RIP of the instruction following the SYSCALL into RCX and loads the new RIP from CSTAR bits 63:0. (The CSTAR register is model-specific register C000_0083h.)

New selectors are loaded, without permission checking (see above), as follows:

- Bits 47:32 of the STAR register specify the selector that is copied into the CS register.
- Bits 47:32 of the STAR register + 8 specify the selector that is copied into the SS register.
- The CS_base and the SS_base are both forced to zero.
- The CS_limit and the SS_limit are both forced to 4 Gbyte.
- The CS segment attributes are set to execute/read 64-bit code with a CPL of zero.
- The SS segment attributes are set to read/write and expand-up with a 64-bit stack referenced by RSP.

The WRMSR instruction loads the target RIP into the LSTAR and CSTAR registers. If an RIP written by WRMSR is not in canonical form, a general-protection exception (#GP) occurs.

How SYSCALL and SYSRET handle rFLAGS, depends on the processor's operating mode.

In legacy mode, SYSCALL treats EFLAGS as follows:

- EFLAGS.IF is cleared to 0.
- EFLAGS.RF is cleared to 0.
- EFLAGS.VM is cleared to 0.

In long mode, SYSCALL treats RFLAGS as follows:

- The current value of RFLAGS is saved in R11.
- RFLAGS is masked using the value stored in SYSCALL_FLAG_MASK.
- RFLAGS.RF is cleared to 0.

For further details on the SYSCALL and SYSRET instructions and their associated MSR registers (STAR, LSTAR, CSTAR, and SYSCALL_FLAG_MASK), see “Fast System Call and Return” in Volume 2.

Support for the SYSCALL instruction is indicated by CPUID Fn8000_0001_EDX[SysCallSysRet] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

Note: Bits 31:22, 15, 5, 3, and 1 are reserved. A flag set to one or cleared to zero is M (modified). Unaffected flags are blank. Undefined flags are U.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SYSCALL and SYSRET instructions are not supported, as indicated by CPUID Fn8000_0001_EDX[SysCallSysRet] = 0.
	X	X	X	The system call extension bit (SCE) of the extended feature enable register (EFER) is set to 0. (The EFER register is MSR C000_0080h.)

SYSENTER

System Call

Transfers control to a fixed entry point in an operating system. It is designed for use by system and application software implementing a flat-segment memory model. This instruction is valid only in legacy mode.

Three model-specific registers (MSRs) are used to specify the target address and stack pointers for the SYSENTER instruction, as well as the CS and SS selectors of the called and returned procedures:

- **MSR_SYSENTER_CS**: Contains the CS selector of the called procedure. The SS selector is set to **MSR_SYSENTER_CS + 8**.
- **MSR_SYSENTER_ESP**: Contains the called procedure's stack pointer.
- **MSR_SYSENTER_EIP**: Contains the offset into the CS of the called procedure.

The hidden portions of the CS and SS segment registers are not loaded from the descriptor table as they would be using a legacy x86 CALL instruction. Instead, the hidden portions are forced by the processor to the following values:

- The CS and SS base values are forced to 0.
- The CS and SS limit values are forced to 4 Gbytes.
- The CS segment attributes are set to execute/read 32-bit code with a CPL of zero.
- The SS segment attributes are set to read/write and expand-up with a 32-bit stack referenced by ESP.

System software must create corresponding descriptor-table entries referenced by the new CS and SS selectors that match the values described above.

The return EIP and application stack are not saved by this instruction. System software must explicitly save that information.

An invalid-opcode exception occurs if this instruction is used in long mode. Software should use the SYSCALL (and SYSRET) instructions in long mode. If SYSENTER is used in real mode, a #GP is raised.

For additional information on this instruction, see “SYSENTER and SYSEXIT (Legacy Mode Only)” in Volume 2.

Support for the SYSENTER instruction is indicated by CPUID Fn0000_0001_EDX[SysEnterSysExit] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

Instruction Encoding

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SYSENTER and SYSEXIT instructions are not supported, as indicated by CPUID Fn0000_0001_EDX[SysEnterSysExit] = 0.
			X	This instruction is not recognized in long mode.
General protection, #GP	X			This instruction is not recognized in real mode.
		X	X	MSR_SYSENTER_CS was a null selector.

SYSEXIT

System Return

Returns from the operating system to an application. It is a low-latency system return instruction designed for use by system and application software implementing a flat-segment memory model.

This is a privileged instruction. The current privilege level must be zero to execute this instruction. An invalid-opcode exception occurs if this instruction is used in long mode. Software should use the SYSRET (and SYSCALL) instructions when running in long mode.

When a system procedure performs a SYSEXIT back to application software, the CS selector is updated to point to the second descriptor entry after the SYSENTER CS value (MSR SYSENTER_CS+16). The SS selector is updated to point to the third descriptor entry after the SYSENTER CS value (MSR SYSENTER_CS+24). The CPL is forced to 3, as are the descriptor privilege levels.

The hidden portions of the CS and SS segment registers are not loaded from the descriptor table as they would be using a legacy x86 RET instruction. Instead, the hidden portions are forced by the processor to the following values:

- The CS and SS base values are forced to 0.
- The CS and SS limit values are forced to 4 Gbytes.
- The CS segment attributes are set to 32-bit read/execute at CPL 3.
- The SS segment attributes are set to read/write and expand-up with a 32-bit stack referenced by ESP.

System software must create corresponding descriptor-table entries referenced by the new CS and SS selectors that match the values described above.

The following additional actions result from executing SYSEXIT:

- EIP is loaded from EDX.
- ESP is loaded from ECX.

System software must explicitly load the return address and application software-stack pointer into the EDX and ECX registers prior to executing SYSEXIT.

For additional information on this instruction, see “SYSENTER and SYSEXIT (Legacy Mode Only)” in Volume 2.

Support for the SYSEXIT instruction is indicated by CPUID Fn0000_0001_EDX[SysEnterSysExit] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

			X	MSR_SYSENTER_CS was a null selector.

SYSRET

Fast System Return

Returns from the operating system to an application. It is a low-latency system return instruction designed for use by system and application software implementing a flat segmentation memory model.

The SYSCALL and SYSRET instructions are low-latency system call and return control-transfer instructions that assume that the operating system implements a flat-segment memory model. By eliminating unneeded checks, and by loading pre-determined values into the CS and SS segment registers (both visible and hidden portions), calls to and returns from the operating system are greatly simplified. These instructions can be used in protected mode and are particularly well-suited for use in 64-bit mode, which requires implementation of a paged, flat-segment memory model.

This instruction has been optimized by reducing the number of checks and memory references that are normally made so that a call or return takes substantially fewer internal clock cycles when compared to the CALL/RET instruction method.

It is assumed that the base, limit, and attributes of the Code Segment will remain flat for all processes and for the operating system, and that only the current privilege level for the selector of the calling process should be changed from a current privilege level of 0 to a new privilege level of 3. It is also assumed (but not checked) that the RPL of the SYSCALL and SYSRET target selectors are set to 0 and 3, respectively.

SYSRET sets the CPL to 3, regardless of the values of bits 49:48 of the star register. SYSRET can only be executed in protected mode at CPL 0. SYSCALL and SYSRET must be enabled by setting EFER.SCE to 1.

It is the responsibility of the operating system to keep the descriptors in memory that correspond to the CS and SS selectors loaded by the SYSCALL and SYSRET instructions consistent with the segment base, limit, and attribute values forced by these instructions.

When a system procedure performs a SYSRET back to application software, the CS selector is updated from bits 63:50 of the STAR register (STAR.SYSRET_CS) as follows:

- If the return is to 32-bit mode (legacy or compatibility), CS is updated with the value of STAR.SYSRET_CS.
- If the return is to 64-bit mode, CS is updated with the value of STAR.SYSRET_CS + 16.

In both cases, the CPL is forced to 3, effectively ignoring STAR bits 49:48. The SS selector is updated to point to the next descriptor-table entry after the CS descriptor (STAR.SYSRET_CS + 8), and its RPL is not forced to 3.

The hidden portions of the CS and SS segment registers are not loaded from the descriptor table as they would be using a legacy x86 RET instruction. Instead, the hidden portions are forced by the processor to the following values:

- The CS base value is forced to 0.
- The CS limit value is forced to 4 Gbytes.

- The CS segment attributes are set to execute-read 32 bits or 64 bits (see below).
- The SS segment base, limit, and attributes are not modified.

When SYSCALLed system software is running in 64-bit mode, it has been entered from either 64-bit mode or compatibility mode. The corresponding SYSRET needs to know the mode to which it must return. Executing SYSRET in non-64-bit mode or with a 16- or 32-bit operand size returns to 32-bit mode with a 32-bit stack pointer. Executing SYSRET in 64-bit mode with a 64-bit operand size returns to 64-bit mode with a 64-bit stack pointer.

The instruction pointer is updated with the return address based on the operating mode in which SYSRET is executed:

- If returning to 64-bit mode, SYSRET loads RIP with the value of RCX.
- If returning to 32-bit mode, SYSRET loads EIP with the value of ECX.

How SYSRET handles RFLAGS depends on the processor's operating mode:

- If executed in 64-bit mode, SYSRET loads the lower-32 RFLAGS bits from R11[31:0] and clears the upper 32 RFLAGS bits.
- If executed in legacy mode or compatibility mode, SYSRET sets EFLAGS.IF.

For further details on the SYSCALL and SYSRET instructions and their associated MSR registers (STAR, LSTAR, and CSTAR), see “Fast System Call and Return” in Volume 2.

Support for the SYSRET instruction is indicated by CPUID Fn8000_0001_EDX[SysCallSysRet] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

VERR**Verify Segment for Reads**

Verifies whether a code or data segment specified by the segment selector in the 16-bit register or memory operand is readable from the current privilege level. The zero flag (ZF) is set to 1 if the specified segment is readable. Otherwise, ZF is cleared.

A segment is readable if all of the following apply:

- the selector is not a null selector.
- the descriptor is within the GDT or LDT limit.
- the segment is a data segment or readable code segment.
- the descriptor DPL is greater than or equal to both the CPL and RPL, or the segment is a conforming code segment.

The processor does not recognize the VERR instruction in real or virtual-8086 mode.

Mnemonic	Opcode	Description
VERR <i>reg/mem16</i>	0F 00 /4	Set the zero flag (ZF) to 1 if the segment selected can be read.

			X	A null data segment was used to reference memory.

Exception	Real	Virtual 8086	Protecte d	Cause of Exception
Page fault, #PF			X	A page fault resulted from the execution of the instruction.
Alignment check, #AC			X	An unaligned memory reference was performed while alignment checking was enabled.

VERW

Verify Segment for Write

Verifies whether a data segment specified by the segment selector in the 16-bit register or memory operand is writable from the current privilege level. The zero flag (ZF) is set to 1 if the specified segment is writable. Otherwise, ZF is cleared.

A segment is writable if all of the following apply:

- the selector is not a null selector.
- the descriptor is within the GDT or LDT limit.
- the segment is a writable data segment.
- the descriptor DPL is greater than or equal to both the CPL and RPL.

The processor does not recognize the VERW instruction in real or virtual-8086 mode.

Mnemonic	Opcode	Description
VERW <i>reg/mem16</i>	0F 00 /5	Set the zero flag (ZF) to 1 if the segment selected can be written.

VMLOAD

Load State from VMCB

Loads a subset of processor state from the VMCB specified by the system-physical address in the rAX register. The portion of RAX used to form the address is determined by the effective address size.

The VMSAVE and VMLOAD instructions complement the state save/restore abilities of VMRUN and #VMEXIT, providing access to hidden state that software is otherwise unable to access, plus some additional commonly-used state.

This is a Secure Virtual Machine (SVM) instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume 2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description
VMLOAD rAX	0F 01 DA	Load additional state from VMCB.

Action

```
IF ((MSR_EFER.SVME == 0) || (!PROTECTED_MODE))
    EXCEPTION [#UD]           // This instruction can only be executed in protected
                             // mode with SVM enabled

IF (CPL != 0)                // This instruction is only allowed at CPL 0
    EXCEPTION [#GP]

IF (rAX contains an unsupported system-physical address)
    EXCEPTION [#GP]

Load from a VMCB at system-physical address rAX:
    FS, GS, TR, LDTR (including all hidden state)
    KernelGsBase
    STAR, LSTAR, CSTAR, SFMASK
    SYSENTER_CS, SYSENTER_ESP, SYSENTER_EIP
```

General protection, #GP			X	CPL was not zero.
			X	rAX referenced a physical address above the maximum supported physical address.
			X	The address in rAX was not aligned on a 4Kbyte boundary.

VMMCALL

Call VMM

Provides a mechanism for a guest to explicitly communicate with the VMM by generating a #VMEXIT.

A non-intercepted VMMCALL unconditionally raises a #UD exception.

VMMCALL is not restricted to either protected mode or CPL zero.

This is a Secure Virtual Machine (SVM) instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume 2: System Instructions*, order# 24593.

Mnemonic	Opcode	Description

	X	X	X	Secure Virtual Machine was not enabled (EFER.SVME=0).
	X	X	X	VMMCALL was not intercepted.

VMRUN

Run Virtual Machine

Starts execution of a guest instruction stream. The physical address of the *virtual machine control block* (VMCB) describing the guest is taken from the rAX register (the portion of RAX used to form the address is determined by the effective address size). The physical address of the VMCB must be aligned on a 4K-byte boundary.

VMRUN saves a subset of host processor state to the host state-save area specified by the physical address in the VM_HSAVE_PA MSR. VMRUN then loads guest processor state (and control information) from the VMCB at the physical address specified in rAX. The processor then executes guest instructions until one of several *intercept* events (specified in the VMCB) is triggered. When an intercept event occurs, the processor stores a snapshot of the guest state back into the VMCB, reloads the host state, and continues execution of host code at the instruction following the VMRUN instruction.

This is a Secure Virtual Machine (SVM) instruction. Support for the SVM architecture and the SVM instructions is indicated by CPUID Fn8000_0001_ECX[SVM] = 1. For more information on using the CPUID instruction, see the reference page for the CPUID instruction on page 153.

This instruction generates a #UD exception if SVM is not enabled. See “Enabling SVM” in *AMD64 Architecture Programmer’s Manual Volume 2: System Instructions*, order# 24593.

The VMRUN instruction is not supported in System Management Mode. Processor behavior resulting from an attempt to execute this instruction from within the SMM handler is undefined.

Instruction Encoding

WBINVD

Writeback and Invalidate Caches

Writes all modified lines in all levels of cache associated with this processor to main memory and invalidates the caches. This may or may not include lower level caches associated with another processor that shares any level of this processor's cache hierarchy.

CPUID Fn8000_001D_EDX[WBINVD]_xN indicates the behavior of the processor at various levels of the cache hierarchy. If the feature bit is 0, the instruction causes the invalidation of all lower level caches of other processors sharing the designated level of cache. If the feature bit is 1, the instruction does not necessarily cause the invalidation of all lower level caches of other processors sharing the designated level of cache. See Appendix E, “Obtaining Processor Information Via the CPUID Instruction,” on page 589 for more information on using the CPUID function.

The INVD instruction can be used when cache coherence with memory is not important.

This instruction does not invalidate TLB caches.

This is a privileged instruction. The current privilege level of a procedure invalidating the processor's internal caches must be zero.

WBINVD is a serializing instruction.

Mnemonic	Opcode	Description
WBINVD	0F 09	Write modified cache lines to main memory, invalidate internal caches, and trigger external cache flushes.

WRMSR

Write to Model-Specific Register

Writes data to 64-bit model-specific registers (MSRs). These registers are widely used in performance-monitoring and debugging applications, as well as testability and program execution tracing.

This instruction writes the contents of the EDX:EAX register pair into a 64-bit model-specific register specified in the ECX register. The 32 bits in the EDX register are mapped into the high-order bits of the model-specific register and the 32 bits in EAX form the low-order 32 bits.

This instruction must be executed at a privilege level of 0 or a general protection fault #GP(0) will be raised. This exception is also generated if an attempt is made to specify a reserved or unimplemented model-specific register in ECX.

WRMSR is a serializing instruction.

Support for the WRMSR instruction is indicated by CPUID Fn0000_0001_EDX[MSR] = 1 OR CPUID Fn8000_0001_EDX[MSR] = 1. For more information on using the CPUID instruction, see the description of the CPUID instruction on page 153.

The CPUID instruction can provide model information useful in determining the existence of a particular MSR.

See “Model-Specific Registers (MSRs)” in *Volume 2: System Programming*, for more information about model-specific registers, machine check architecture, performance monitoring and debug registers.

Mnemonic	Opcode	Description
WRMSR	0F 30	Write EDX:EAX to the MSR specified by ECX.

Appendix A Opcode and Operand Encodings

This appendix specifies the opcode and operand encodings for each instruction in the AMD64 instruction set. As discussed in Chapter 1, “Instruction Encoding,” the basic operation and implied operand type(s) of an instruction are encoded by the binary value of the opcode byte. The correspondence between an opcode binary value and its meaning is provided by the *opcode map*.

Each opcode map has 256 entries and can encode up to 256 different operations. Since the AMD64 instruction set comprises more than 256 instructions, multiple opcode maps are utilized to encode the instruction set. A particular opcode map is selected using the instruction encoding syntax diagrammed in Figure 1-1 on page 2. For each opcode map, values may be reserved or utilized for purposes other than encoding an instruction operation.

To preserve compatibility with future instruction architectural extensions, reserved opcodes should not be used. If a means to reliably cause an invalid-opcode exception (#UD) is required, software should use one of the UDx opcodes. These opcodes are set aside for this purpose and will not be used for future instructions. The UD opcodes are located on the secondary opcode map at code points B9h, 0Bh, and FFh.

The following section provides a key to the notation used in the opcode maps to specify the implied operand types.

Opcode-Syntax Notation

In the opcode maps which follow, each table entry represents a specific form of an instruction, identifying the instruction by its mnemonic and listing the operand or operands peculiar to that opcode. If a register-based operand is specified by the opcode itself, the operand is represented directly using the register mnemonic as defined in “Summary of Registers and Data Types” on page 38. If the operand is encoded in one or more bytes following the opcode byte, the following special notation is used to represent the operand and its encoding in more generic terms.

This special notation, used exclusively in the opcode maps, is composed of three parts:

- an initial capital letter that represents the operand source / destination (register-based, memory-based, or immediate) and how it is encoded in the instruction (either as an immediate, or via the ModRM.reg, ModRM.{mod,r/m}, or VEX/XOP.vvvv fields). For register-based operands, the initial letter also specifies the register type (General-purpose, MMX, YMM/XMM, debug, or control register).
- one, two, or three letter modifier (in lowercase) that represents the data type (for example, byte, word, quadword, packed single-precision floating-point vector).
- *x*, which indicates for an SSE instruction that the instruction supports both vector sizes (128 bits and 256 bits). The specific vector size is encoded in the VEX/XOP.L field. L=0 indicates 128 bits and L=1 indicates 256 bits.

The following list describes the meaning of each letter that is used in the first position of the operand notation:

- A* A far pointer encoded in the instruction. No ModRM byte in the instruction encoding.
- B* General-purpose register specified by the VEX or XOP vvvv field.
- C* Control register specified by the ModRM.reg field.
- D* Debug register specified by the ModRM.reg field.
- E* General purpose register or memory operand specified by the r/m field of the ModRM byte. For memory operands, the ModRM byte may be followed by a SIB byte to specify one of the indexed register-indirect addressing forms.
- F* rFLAGS register.
- G* General purpose register specified by the ModRM.reg field.
- H* YMM or XMM register specified by the VEX/XOP.vvvv field.
- I* Immediate value encoded in the instruction immediate field.
- J* The instruction encoding includes a relative offset that is added to the rIP.
- L* YMM or XMM register specified using the most-significant 4 bits of an 8-bit immediate value. In legacy or compatibility mode the most significant bit is ignored.
- M* A memory operand specified by the {mod, r/m} field of the ModRM byte. ModRM.mod ≠ 11b.
- M** A sparse array of memory operands addressed using the VSIB addressing mode. See “VSIB Addressing” in Volume 4.
- N* 64-bit MMX register specified by the ModRM.r/m field. The ModRM.mod field must be 11b.
- O* The offset of an operand is encoded in the instruction. There is no ModRM byte in the instruction encoding. Indexed register-indirect addressing using the SIB byte is not supported.
- P* 64-bit MMX register specified by the ModRM.reg field.
- Q* 64-bit MMX-register or memory operand specified by the {mod, r/m} field of the ModRM byte. For memory operands, the ModRM byte may be followed by a SIB byte to specify one of the indexed register-indirect addressing forms.
- R* General purpose register specified by the ModRM.r/m field. The ModRM.mod field must be 11b.
- S* Segment register specified by the ModRM.reg field.
- U* YMM/XMM register specified by the ModRM.r/m field. The ModRM.mod field must be 11b.
- V* YMM/XMM register specified by the ModRM.reg field.
- W* YMM/XMM register or memory operand specified by the {mod, r/m} field of the ModRM byte. For memory operands, the ModRM byte may be followed by a SIB byte to specify one of the indexed register-indirect addressing forms.

X A memory operand addressed by the DS.rSI registers. Used in string instructions.

Y A memory operand addressed by the ES.rDI registers. Used in string instructions.

The following list provides the key for the second part of the operand notation:

a Two 16-bit or 32-bit memory operands, depending on the effective operand size. Used in the BOUND instruction.

b A byte, irrespective of the effective operand size.

c A byte or a word, depending on the effective operand size.

d A doubleword (32 bits), irrespective of the effective operand size.

do A double octword (256 bits), irrespective of the effective operand size.

i A 16-bit integer.

j A 32-bit integer.

m A bit mask of size equal to the source operand.

mn Where $n = 2, 4, 8,$ or 16 . A bit mask of size n .

o An octword (128 bits), irrespective of the effective operand size.

o.q Operand is either the upper or lower half of a 128-bit value.

p A 32-, 48-, 80-bit far pointer, depending on the effective operand size.

pb Vector with byte-wide (8-bit) elements (packed byte).

pd A double-precision (64-bit) floating-point vector operand (packed double-precision).

pdw Vector composed of 32-bit doublewords.

ph A half-precision (16-bit) floating-point vector operand (packed half-precision)

pi Vector composed of 16-bit integers (packed integer).

pj Vector composed of 32-bit integers (packed double integer).

pk Vector composed of 8-bit integers (packed half-word integer).

pq Vector composed of 64-bit integers (packed quadword integer).

pqw Vector composed of 64-bit quadwords (packed quadword).

ps A single-precision floating-point vector operand (packed single-precision).

pw Vector composed of 16-bit words (packed word).

q A quadword (64 bits), irrespective of the effective operand size.

s A 6-byte or 10-byte pseudo-descriptor.

sd A scalar double-precision floating-point operand (scalar double).

sj A scalar doubleword (32-bit) integer operand (scalar double integer).

- ss* A scalar single-precision floating-point operand (scalar single).
- v* A word, doubleword, or quadword (in 64-bit mode), depending on the effective operand size.
- w* A word, irrespective of the effective operand size.
- x* Instruction supports both vector sizes (128 bits or 256 bits). Size is encoded using the VEX/XOP.L field. (L=0: 128 bits; L=1: 256 bits). This symbol may be appended to *ps* or *pd* to represent a packed single- or double-precision floating-point vector of either size; or to *pk*, *pi*, *pj*, or *pq*, to represent a packed 8-bit, 16-bit, 32-bit, or 64-bit packed integer vector of either size.
- y* A doubleword or quadword depending on effective operand size.
- z* A word if the effective operand size is 16 bits, or a doubleword if the effective operand size is 32 or 64 bits.

For some instructions, fields in the ModRM or SIB byte are used as encoding extensions. This is indicated using the following notation:

- /n* A ModRM-byte *reg* field or SIB-byte *base* field, where *n* is a value between zero (000b) and 7 (111b).

For SSE instructions that take scalar operands, VEX/XOP.L field is ignored.

For immediates and memory-based operands, only the size and not the datatype is indicated. Operand widths and datatypes are specified based on the source operands. For instructions where the result overwrites one of the source registers, the data width and datatype of the result may not match that of the source register. See individual instruction descriptions for more details.

A.1 Opcode Maps

In all of the following opcode maps, cells shaded grey represent reserved opcodes.

A.1.1 Legacy Opcode Maps

Primary Opcode Map. Tables A-1 and A-2 below show the primary opcode map (known in legacy terminology as one-byte opcodes).

Table A-1 below shows those instructions for which the low nibble is in the range 0–7h. Table A-2 on page 440 shows those instructions for which the low nibble is in the range 8–Fh. In both tables, the rows show the full range (0–Fh) of the high nibble, and the columns show the specified range of the low nibble.

Table A-1. Primary Opcode Map (One-byte Opcodes), Low Nibble 0–7h

Nibble ¹	0	1	2	3	4	5	6	7
0	ADD Eb, Gb Ev, Gv Gb, Eb Gv, Ev AL, Ib rAX, Iz						PUSH ES ³	POP ES ³

Notes:

- Rows in this table show the high opcode nibble, columns show the low opcode nibble (both in hexadecimal).
- An opcode extension is specified using the reg field of the ModRM byte (ModRM bits [5:3]) which follows the opcode. See Table A-6 on page 447 for details.
- Invalid in 64-bit mode.
- Valid only in 64-bit mode.
- Used as REX prefixes in 64-bit mode.
- This is a null prefix in 64-bit mode.

Secondary Opcode Map. As described in “Encoding Syntax” on page 1, the escape code 0Fh indicates the switch from the primary to the secondary opcode map. In legacy terminology, the secondary opcode map is presented as a listing of “two-byte” opcodes where the first byte is 0Fh. Tables A-3 and A-4 show the secondary opcode map.

Table A-3 below shows those instructions for which the low nibble is in the range 0–7h. Table A-4 on page 444 shows those instructions for which the low nibble is in the range 8–Fh. In both tables, the rows show the full range (0–Fh) of the high nibble, and the columns show the specified range of the low nibble. Note the added column labeled “prefix.”

For the secondary opcode map shown below, the legacy prefixes 66h, F2h, and F3 are repurposed to provide additional opcode encoding space. For those rows that utilize them, the presence of a 66h, F2h, or F3h prefix changes the operation or the operand types specified by the corresponding opcode value.

As discussed in “Encoding Extensions Using the ModRM Byte” on page 447, some opcode values represent a group of instructions. This is denoted in the map entry by “Group *n*”, where $n = [1:17,P]$. Instructions within a group are encoded by the reg field of the ModRM byte. These encodings are specified in Table A-7 on page 449. For some opcodes, both the reg and the r/m field of the ModRM byte are used to extend the encoding. See Table A-8 on page 450.

3. This instruction takes a ModRM byte.

rFLAGS Condition Codes for CMOVcc, Jcc, and SETcc Instructions. Table A-5 shows the rFLAGS condition codes specified by the low nibble in the opcode of the CMOVcc, Jcc, and SETcc instructions.

Table A-5. rFLAGS Condition Codes for CMOVcc, Jcc, and SETcc

Low Nibble of Opcode (hex)	rFLAGS Value	cc Mnemonic	Arithmetic Type	Condition(s)
0	OF = 1	O	Signed	Overflow
1	OF = 0	NO		No Overflow
2	CF = 1	B, C, NAE	Unsigned	Below, Carry, Not Above or Equal
3	CF = 0	NB, NC, AE		Not Below, No Carry, Above or Equal
4	ZF = 1	Z, E		Zero, Equal
5	ZF = 0	NZ, NE		Not Zero, Not Equal
6	CF = 1 or ZF = 1	BE, NA		Below or Equal, Not Above
7	CF = 0 and ZF = 0	NBE, A		Not Below or Equal, Above
8	SF = 1	S	Signed	Sign
9	SF = 0	NS		Not Sign
A	PF = 1	P, PE	n/a	Parity, Parity Even
B	PF = 0	NP, PO		Not Parity, Parity Odd
C	(SF xor OF) = 1	L, NGE	Signed	Less than, Not Greater than or Equal to
D	(SF xor OF) = 0	NL, GE		Not Less than, Greater than or Equal to
E	(SF xor OF) = 1 or ZF = 1	LE, NG		Less than or Equal to, Not Greater than
F	(SF xor OF) = 0 and ZF = 0	NLE, G		Not Less than or Equal to, Greater than

Encoding Extensions Using the ModRM Byte. The ModRM byte, which immediately follows the opcode byte, is used in certain instruction encodings to provide additional opcode bits with which to define the function of the instruction. ModRM bytes have three fields—*mod*, *reg*, and *r/m*, as shown in Figure A-1.

Figure A-1. ModRM-Byte Fields

In most cases, the *reg* field (bits [5:3]), and in some cases, the *r/m* field (bits [2:0]) provide the additional bits used to extend the encodings of the opcode byte. In the case of the x87 floating-point instructions, the entire ModRM byte is used to extend the opcode encodings.

Table A-6 shows how the ModRM.*reg* field is used to extend the range of opcodes in the primary opcode map. The opcode ranges are organized into *groups* of opcode extensions. The group number is shown in the left-most column. These groups are referenced in the primary opcode map shown in Table A-1 on page 439 and Table A-2 on page 440. An entry of “n.a.” in the Prefix column means that prefixes are not applicable to the opcodes in that row. Prefixes only apply to certain 64-bit media and SSE instructions.

Table A-7 on page 449 shows how the ModRM.*reg* field is used to extend the range of the opcodes in the secondary opcode map.

The /0 through /7 notation for the ModRM *reg* field (bits [5:3]) in the tables below means that the three-bit field contains a value from zero (000b) to 7 (111b).

Table A-6. ModRM.reg Extensions for the Primary Opcode Map¹

Group Number	Prefix	Opcode	ModRM <i>reg</i> Field							
			/0	/1	/2	/3	/4	/5	/6	/7
Group 1	n/a	80	ADD Eb, Ib	OR Eb, Ib	ADC Eb, Ib	SBB Eb, Ib	AND Eb, Ib	SUB Eb, Ib	XOR Eb, Ib	CMP Eb, Ib
		81	ADD Ev, Iz	OR Ev, Iz	ADC Ev, Iz	SBB Ev, Iz	AND Ev, Iz	SUB Ev, Iz	XOR Ev, Iz	CMP Ev, Iz
		82	ADD Eb, Ib ²	OR Eb, Ib ²	ADC Eb, Ib ²	SBB Eb, Ib ²	AND Eb, Ib ²	SUB Eb, Ib ²	XOR Eb, Ib ²	CMP Eb, Ib ²
		83	ADD Ev, Ib	OR Ev, Ib	ADC Ev, Ib	SBB Ev, Ib	AND Ev, Ib	SUB Ev, Ib	XOR Ev, Ib	CMP Ev, Ib

Notes:

1. See Table A-7 on page 449 for ModRM extensions for the secondary (two-byte) opcode map.
2. Invalid in 64-bit mode.
3. This instruction takes a ModRM byte.
4. Reserved prefetch encodings are aliased to the /0 encoding (PREFETCH Exclusive) for future compatibility.

Table A-6. ModRM.reg Extensions for the Primary Opcode Map¹ (continued)

Group Number	Prefix	Opcode	ModRM reg Field

Notes:

1. Opcode is extended further using the r/m field of the ModRM byte in conjunction with the reg field. See Table A-8 on page 450 for ModRM.r/m extensions of this opcode.
2. Invalid in 64-bit mode.
3. This instruction takes a ModRM byte.
4. Reserved prefetch encodings are aliased to the /0 encoding (PREFETCH Exclusive) for future compatibility.
5. ModRM.mod = 11b.
6. ModRM.mod ≠ 11b.
7. ModRM.mod ≠ 11b, ModRM.mod = 11b is an invalid encoding.

Secondary Opcode Map, ModRM Extensions for Opcode 01h . Table A-8 below shows the ModRM byte encodings for the 01h opcode. In the table the full ModRM byte is listed below the instruction in hexadecimal. For all instructions shown, the ModRM byte is immediately preceded by the byte string {0Fh, 01h} in the instruction encoding.

Table A-8. Opcode 01h ModRM Extensions

0F_38h and 0F_3Ah Opcode Maps. The 0F_38h and 0F_3Ah opcode maps are used primarily to encode the legacy SSE instructions. In legacy terminology, these maps are presented as three-byte opcodes where the first two bytes are {0Fh, 38h} and {0Fh, 3Ah} respectively.

In these maps the legacy prefixes F2h and F3h are repurposed to provide additional opcode encoding space. In rows [0:E] the legacy prefix 66h is also used to modify the opcode. However, in row F, 66h is used as an operand-size override. See the CRC32 instruction as an example.

The 0F_38h opcode map is presented below in Tables A-9 and A-10. The 0F_3Ah opcode map is presented in Tables A-11 and A-12.

Table A-9. 0F_38h Opcode Map, Low Nibble = [0h:7h]

A.1.2 3DNow!™ Opcodes

The 64-bit media instructions include the MMX™ instructions and the AMD 3DNow!™ instructions. The MMX instructions are encoded using two opcode bytes, as described in “Secondary Opcode Map” on page 440.

The 3DNow! instructions are encoded using two 0Fh opcode bytes and an immediate byte that is located at the last byte position of the instruction encoding. Thus, the format for 3DNow! instructions is:

```
0Fh 0Fh [ModRM] [SIB] [displacement] imm8_opcode
```

Table A-13 and Table A-14 on page 457 show the immediate byte following the opcode bytes for 3DNow! instructions. In these tables, rows show the high nibble of the immediate byte, and columns show the low nibble of the immediate byte. Table A-13 shows the immediate bytes whose low nibble is in the range 0–7h. Table A-14 shows the same for immediate bytes whose low nibble is in the range 8–Fh.

Byte values shown as *reserved* in these tables have implementation-specific functions, which can include an invalid-opcode exception.

Notes:

1. All 3DNow!™ opcodes consist of two 0Fh bytes. This table shows the immediate byte for 3DNow! opcodes. Rows show the high nibble of the immediate byte. Columns show the low nibble of the immediate byte.

A.1.3 x87 Encodings

All x87 instructions begin with an opcode byte in the range D8h to DFh, as shown in Table A-2 on page 440. These opcodes are followed by a ModRM byte that further defines the opcode. Table A-15 shows both the opcode byte and the ModRM byte for each x87 instruction.

There are two significant ranges for the ModRM byte for x87 opcodes: 00–BFh and C0–FFh. When the value of the ModRM byte falls within the first range, 00–BFh, the opcode uses only the *reg* field to further define the opcode. When the value of the ModRM byte falls within the second range, C0–FFh, the opcode uses the entire ModRM byte to further define the opcode.

Byte values shown as *reserved* or *invalid* in Table A-15 have implementation-specific functions, which can include an invalid-opcode exception.

The basic instructions FNSTENV, FNSTCW, FNCLEX, FNINIT, FNSAVE, FNSTSW, and FNSTSW do not check for possible floating point exceptions before operating. Utility versions of these mnemonics are provided that insert an FWAIT (opcode 9B) before the corresponding non-waiting instruction. These are FSTENV, FSTCW, FCLEX, FINIT, FSAVE, and FSTSW. For further information on wait and non-waiting versions of these instructions, see their corresponding pages in Volume 5.

A.1.4 rFLAGS Condition Codes for x87 Opcodes

Table A-16 shows the rFLAGS condition codes specified by the opcode and ModRM bytes of the FCMOV cc instructions.

Table A-16. rFLAGS Condition Codes for FCMOV cc

Opcode (hex)	ModRM <i>mod</i> Field	ModRM <i>reg</i> Field	rFLAGS Value	cc Mnemonic	Condition
DA	11	000	CF = 1	B	Below
		001	ZF = 1	E	Equal
		010	CF = 1 or ZF = 1	BE	Below or Equal
		011	PF = 1	U	Unordered
DB		000	CF = 0	NB	Not Below
		001	ZF = 0	NE	Not Equal
		010	CF = 0 and ZF = 0	NBE	Not Below or Equal
		011	PF = 0	NU	Not Unordered

A.1.5 Extended Instruction Opcode Maps

The following sections present the VEX and the XOP extended instruction opcode maps. The VEX.map_select field of the three-byte VEX encoding escape sequence selects VEX opcode maps: 01h, 02h, or 03h. The two-byte VEX encoding escape sequence implicitly selects the VEX map 01h.

The XOP.map_select field selects between the three XOP maps: 08h, 09h or 0Ah.

VEX Opcode Maps. Tables A-17 – A-23 below present the VEX opcode maps and Table A-24 on page 475 presents the VEX opcode groups.

Note 1: The condition codes are: EQ, LT, LE, UNORD, NEQ, NLT, NLE, and ORD; encoded as [00:07h] using lb.

VEX encoding adds: EQ_UQ, NGE, NGT, FALSE, NEQ_OQ, GE, GT, TRUE [08:0fh];
EQ_OS, LT_OQ, LE_OQ, UNORD_S, NEQ_US, NLT_UQ, NLE_UQ, ORD_S [10h:17h]; and
EQ_US, NGE_UQ, NGT_UQ, FALSE_OS, NEQ_OS, GE_OQ, GT_OQ, TRUE_US [18:1Fh].

Note 2: Supports both 128 bit and 256 bit vector sizes. Vector size is specified using the VEX.L bit. When L = 0, size is 128 bits; when L = 1, size is 256 bits.

Note 3: Operands are scalars. VEX.L bit is ignored.

A.2 Operand Encodings

An operand is data that affects or is affected by the execution of an instruction. Operands may be located in registers, memory, or I/O ports. For some instructions, the location of one or more operands is implicitly specified based on the opcode alone. However, for most instructions, operands are specified using bytes that immediately follow the opcode byte. These bytes are designated the *mode-register-memory* (ModRM) byte, the *scale-index-base* (SIB) byte, the displacement byte(s), and the immediate byte(s). The presence of the SIB, displacement, and immediate bytes are optional depending on the instruction, and, for instructions that reference memory, the memory addressing mode.

The following sections describe the encoding of the ModRM and SIB bytes in various processor modes.

A.2.1 ModRM Operand References

Figure A-2 below shows the format of the ModRM byte. There are three fields—*mod*, *reg*, and *r/m*. The *reg* field is normally used to specify a register-based operand. The *mod* and *r/m* fields together provide a 5-bit field, augmented in 64-bit mode by the R and B bits of a REX, VEX, or XOP prefix, normally used to specify the location of a second memory- or register-based operand and, for a memory-based operand, the addressing mode.

As described in “Encoding Extensions Using the ModRM Byte” on page 447, certain instructions use either the *reg* field, the *r/m* field, or the entire ModRM byte to extend the opcode byte in the encoding of the instruction operation.

Figure A-2. ModRM-Byte Format

The two sections below describe the ModRM operand encodings, first for 16-bit references and then for 32-bit and 64-bit references.

16-Bit Register and Memory References. Table A-32 shows the notation and encoding conventions for register references using the ModRM *reg* field. This table is comparable to Table A-34 on page 481 but applies only when the address-size is 16-bit. Table A-33 on page 479 shows the

notation and encoding conventions for 16-bit memory references using the ModRM byte. This table is comparable to Table A-35 on page 482.

Table A-32. ModRM reg Field Encoding, 16-Bit Addressing

Mnemonic Notation	ModRM reg Field							
	/0	/1	/2	/3	/4	/5	/6	/7

Notes:
1. See Table A-32 for complete specification of ModRM “reg” field.

Register and Memory References for 32-Bit and 64-Bit Addressing. Table A-34 on page 481 shows the encoding for register references using the ModRM *reg* field. The first ten rows of Table A-34 show references when the REX.R bit is cleared to 0, and the last ten rows show references when the REX.R bit is set to 1. In this table, entries under the *Mnemonic Notation* heading correspond

to register notation described in “Mnemonic Syntax” on page 52, and the */r* notation under the *ModRM reg Field* heading corresponds to that described in “Opcode Syntax” on page 55.

Table A-34. ModRM *reg* Field Encoding, 32-Bit and 64-Bit Addressing

Mnemonic Notation	REX.R Bit	ModRM <i>reg</i> Field

Table A-35 on page 482 shows the encoding for 32-bit and 64-bit memory references using the ModRM byte. This table describes 32-bit and 64-bit addressing, with the REX.B bit set or cleared. The *Effective Address* is shown in the two left-most columns, followed by the binary encoding of the ModRM-byte *mod* field, followed by the eight possible hex values of the complete ModRM byte (one value for each binary encoding of the ModRM-byte *reg* field), followed by the binary encoding of the ModRM *r/m* field.

The */0* through */7* notation for the ModRM *reg* field (bits [5:3]) means that the three-bit field contains a value from zero (binary 000) to 7 (binary 111).

Table A-35. ModRM Byte Encoding, 32-Bit and 64-Bit Addressing

Effective Address		ModRM mod Field (binary)	ModRM reg Field ¹								ModRM r/m Field (binary)
			/0	/1	/2	/3	/4	/5	/6	/7

[rBP] + disp32	[r13] + disp32		85	8D	95	9D	A5	AD	B5	BD	101
[rSI] + disp32	[r14] + disp32		86	8E	96	9E	A6	AE	B6	BE	110
[rDI] + disp32	[r15] + disp32		87	8F	97	9F	A7	AF	B7	BF	111

Notes:

1. See Table A-34 for complete specification of ModRM "reg" field.
2. If SIB.base = 5, the SIB byte is followed by four-byte disp32 field and addressing mode is absolute.
3. In 64-bit mode, the effective address is [rIP]+disp32. In all other modes, the effective address is disp32. If the address-size prefix is used in 64-bit mode to override 64-bit addressing, the [RIP]+disp32 effective address is truncated after computation to 32 bits.

Table A-35. ModRM Byte Encoding, 32-Bit and 64-Bit Addressing (continued)

Effective Address		ModRM mod Field (binary)	ModRM reg Field ¹								ModRM r/m Field (binary)
REX.B = 0	REX.B = 1		/0	/1	/2	/3	/4	/5	/6	/7

BH/DIL/rDI/MMX7/ XMM7/YMM7	r15/MMX7/XMM15/ YMM15		C7	CF	D7	DF	E7	EF	F7	FF	111
Notes:											
1. See Table A-34 for complete specification of ModRM “reg” field.											
2. If <i>SIB.base</i> = 5, the SIB byte is followed by four-byte <i>disp32</i> field and addressing mode is absolute.											
3. In 64-bit mode, the effective address is $[RIP]+disp32$. In all other modes, the effective address is <i>disp32</i> . If the address-size prefix is used in 64-bit mode to override 64-bit addressing, the $[RIP]+disp32$ effective address is truncated after computation to 32 bits.											

A.2.2 SIB Operand References

Figure A-3 on page 484 shows the format of a scale-index-base (SIB) byte. Some instructions have an SIB byte following their ModRM byte to define memory addressing for the complex-addressing modes described in “Effective Addresses” in Volume 1. The SIB byte has three fields—*scale*, *index*, and *base*—that define the scale factor, index-register number, and base-register number for 32-bit and 64-bit complex addressing modes. In 64-bit mode, the REX.B and REX.X bits extend the encoding of the SIB byte’s *base* and *index* fields.

Figure A-3. SIB Byte Format

Table A-36 shows the encodings for the SIB byte’s *base* field, which specifies the base register for addressing. Table A-37 on page 485 shows the encodings for the effective address referenced by a complete SIB byte, including its *scale* and *index* fields. The /0 through /7 notation for the SIB *base* field means that the three-bit field contains a value between zero (binary 000) and 7 (binary 111).

Table A-36. Addressing Modes: SIB *base* Field Encoding

REX.B Bit	ModRM <i>mod</i> Field	SIB <i>base</i> Field							
		/0	/1	/2	/3	/4	/5	/6	/7

Notes:
 1. See Table A-36 on page 484 for complete specification of SIB base field.

Appendix B General-Purpose Instructions in 64-Bit Mode

This appendix provides details of the general-purpose instructions in 64-bit mode and its differences from legacy and compatibility modes. The appendix covers only the general-purpose instructions (those described in *Chapter 3, “General-Purpose Instruction Reference”*). It does not cover the 128-bit media, 64-bit media, or x87 floating-point instructions because those instructions are not affected by 64-bit mode, other than in the access by such instructions to extended GPR and XMM registers when using a REX prefix.

B.1 General Rules for 64-Bit Mode

In 64-bit mode, the following general rules apply to instructions and their operands:

- **“Promoted to 64 Bit”**: If an instruction’s operand size (16-bit or 32-bit) in legacy and compatibility modes depends on the CS.D bit and the operand-size override prefix, then the operand-size choices in 64-bit mode are extended from 16-bit and 32-bit to include 64 bits (with a REX prefix), or the operand size is fixed at 64 bits. Such instructions are said to be “*Promoted to 64 bits*” in Table B-1. However, byte-operand opcodes of such instructions are not promoted.
- **Byte-Operand Opcodes Not Promoted**: As stated above in “Promoted to 64 Bit”, byte-operand opcodes of promoted instructions are not promoted. Those opcodes continue to operate only on bytes.
- **Fixed Operand Size**: If an instruction’s operand size is fixed in legacy mode (thus, independent of CS.D and prefix overrides), that operand size is usually fixed at the same size in 64-bit mode. For example, CPUID operates on 32-bit operands, irrespective of attempts to override the operand size.
- **Default Operand Size**: The default operand size for most instructions is 32 bits, and a REX prefix must be used to change the operand size to 64 bits. However, two groups of instructions default to 64-bit operand size and do not need a REX prefix: (1) near branches and (2) all instructions, except far branches, that implicitly reference the RSP. See Table B-5 on page 515 for a list of all instructions that default to 64-bit operand size.
- **Zero-Extension of 32-Bit Results**: Operations on 32-bit operands in 64-bit mode zero-extend the high 32 bits of 64-bit GPR destination registers.
- **No Extension of 8-Bit and 16-Bit Results**: Operations on 8-bit and 16-bit operands in 64-bit mode leave the high 56 or 48 bits, respectively, of 64-bit GPR destination registers unchanged.
- **Shift and Rotate Counts**: When the operand size is 64 bits, shifts and rotates use one additional bit (6 bits total) to specify shift-count or rotate-count, allowing 64-bit shifts and rotates.
- **Immediates**: The maximum size of immediate operands is 32 bits, except that 64-bit immediates can be MOVED into 64-bit GPRs. Immediates that are less than 64 bits are a maximum of 32 bits, and are sign-extended to 64 bits during use.

- **Displacements and Offsets:** The maximum size of an address displacement or offset is 32 bits, except that 64-bit offsets can be used by specific MOV opcodes that read or write AL or rAX. Displacements and offsets that are less than 64 bits are a maximum of 32 bits, and are sign-extended to 64 bits during use.
- **Undefined High 32 Bits After Mode Change:** The processor does not preserve the upper 32 bits of the 64-bit GPRs across switches from 64-bit mode to compatibility or legacy modes. In compatibility or legacy mode, the upper 32 bits of the GPRs are undefined and not accessible to software.

B.2 Operation and Operand Size in 64-Bit Mode

Table B-1 lists the integer instructions, showing operand size in 64-bit mode and the state of the high 32 bits of destination registers when 32-bit operands are used. Opcodes, such as byte-operand versions of several instructions, that do not appear in Table B-1 are covered by the general rules described in “General Rules for 64-Bit Mode” on page 487.

Table B-1. Operations and Operands in 64-Bit Mode

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
AAA - ASCII Adjust after Addition 37	INVALID IN 64-BIT MODE (invalid-opcode exception)			
AAD - ASCII Adjust AX before Division D5	INVALID IN 64-BIT MODE (invalid-opcode exception)			
AAM - ASCII Adjust AX after Multiply D4	INVALID IN 64-BIT MODE (invalid-opcode exception)			
AAS - ASCII Adjust AL after Subtraction 3F	INVALID IN 64-BIT MODE (invalid-opcode exception)			

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
ADC —Add with Carry 11 13 15 81 /2 83 /2	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
ADD —Signed or Unsigned Add 01 03 05 81 /0 83 /0	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
AND —Logical AND 21 23 25 81 /4 83 /4	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
ARPL - Adjust Requestor Privilege Level 63	OPCODE USED as MOVSLD in 64-BIT MODE			
BOUND - Check Array Against Bounds 62	INVALID IN 64-BIT MODE (invalid-opcode exception)			
BSF —Bit Scan Forward 0F BC	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (RDI, RSI) or count registers (RCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
BSR —Bit Scan Reverse 0F BD	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
BSWAP —Byte Swap 0F C8 through 0F CF	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Swap all 8 bytes of a 64-bit GPR.
BT —Bit Test 0F A3 0F BA /4	Promoted to 64 bits.	32 bits	No GPR register results.	
BTC —Bit Test and Complement 0F BB 0F BA /7	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
BTR —Bit Test and Reset 0F B3 0F BA /6	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
BTS —Bit Test and Set 0F AB 0F BA /5	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
CALL —Procedure Call Near	See “Near Branches in 64-Bit Mode” in Volume 1.			
E8	Promoted to 64 bits.	64 bits	Can't encode. ⁶	RIP = RIP + 32-bit displacement sign-extended to 64 bits.
FF /2	Promoted to 64 bits.	64 bits	Can't encode. ⁶	RIP = 64-bit offset from register or memory.
Notes:				
<ol style="list-style-type: none"> See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode. 				

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
CALL —Procedure Call Far 9A	See “Branches to 64-Bit Offsets” in Volume 1.			
	INVALID IN 64-BIT MODE (invalid-opcode exception)			
FF /3	Promoted to 64 bits.	32 bits	If selector points to a gate, then RIP = 64-bit offset from gate, else RIP = zero-extended 32-bit offset from far pointer referenced in instruction.	
CBW, CWDE, CDQE —Convert Byte to Word, Convert Word to Doubleword, Convert Doubleword to Quadword 98	Promoted to 64 bits.	32 bits (size of destination register)	CWDE: Converts word to doubleword. Zero-extends EAX to RAX.	CDQE (new mnemonic): Converts doubleword to quadword. RAX = sign-extended EAX.
CDQ	see CWD, CDQ, CQO			
CDQE (new mnemonic)	see CBW, CWDE, CDQE			
CDWE	see CBW, CWDE, CDQE			
CLC —Clear Carry Flag F8	Same as legacy mode.	Not relevant.	No GPR register results.	
CLD —Clear Direction Flag FC	Same as legacy mode.	Not relevant.	No GPR register results.	
CLFLUSH —Cache Line Invalidate 0F AE /7	Same as legacy mode.	Not relevant.	No GPR register results.	
CLGI —Clear Global Interrupt 0F 01 DD	Same as legacy mode	Not relevant	No GPR register results.	
CLI —Clear Interrupt Flag FA	Same as legacy mode.	Not relevant.	No GPR register results.

Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. Immediates and branch displacements are sign-extended to 64 bits.				
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.				
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.				

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
LEA —Load Effective Address 8D	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
LEAVE —Delete Procedure Stack Frame C9	Promoted to 64 bits.	64 bits	Can't encode ⁶	
LES - Load ES Far Pointer C4	INVALID IN 64-BIT MODE (invalid-opcode exception)			
LFENCE —Load Fence 0F AE /5	Same as legacy mode.	Not relevant.	No GPR register results.	
LFS —Load FS Far Pointer 0F B4	Same as legacy mode.	32 bits	Zero-extends 32-bit register results to 64 bits.	
LGDT —Load Global Descriptor Table Register 0F 01 /2	Promoted to 64 bits.	Operand size fixed at 64 bits.	No GPR register results. Loads 8-byte base and 2-byte limit.	
LGS —Load GS Far Pointer 0F B5	Same as legacy mode.	32 bits	Zero-extends 32-bit register results to 64 bits.	
LIDT —Load Interrupt Descriptor Table Register 0F 01 /3	Promoted to 64 bits.	Operand size fixed at 64 bits.	No GPR register results. Loads 8-byte base and 2-byte limit.	
LLDT —Load Local Descriptor Table Register 0F 00 /2	Promoted to 64 bits.	Operand size fixed at 16 bits.	No GPR register results. References 16-byte descriptor to load 64-bit base.	
LMSW —Load Machine Status Word 0F 01 /6	Same as legacy mode.	Operand size fixed at 16 bits.	No GPR register results.	
Notes:				
1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.				
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.				
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.				
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.				
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.				
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.				

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
LODS, LODSW, LODSD, LODSQ — Load String AD	Promoted to 64 bits.	32 bits	LODSD: Load String Doublewords. Zero-extends 32-bit register results to 64 bits. See footnote ⁵	LODSQ (new mnemonic): Load String Quadwords. See footnote ⁵
LOOP —Loop E2	Promoted to 64 bits.	64 bits	Can't encode. ⁶	RIP = RIP + 8-bit displacement sign-extended to 64 bits. See footnote ⁵
LOOPZ, LOOPE —Loop if Zero/Equal E1				
LOOPNZ, LOOPNE —Loop if Not Zero/Equal E0				
LSL —Load Segment Limit 0F 03	Same as legacy mode.	32 bits	Zero-extends 32-bit register results to 64 bits.	
LSS —Load SS Segment Register 0F B2	Same as legacy mode.	32 bits	Zero-extends 32-bit register results to 64 bits.	
LTR —Load Task Register 0F 00 /3	Promoted to 64 bits.	Operand size fixed at 16 bits.	No GPR register results. References 16-byte descriptor to load 64-bit base.	
LZCNT —Count Leading Zeros F3 0F BD	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
MFENCE —Memory Fence 0F AE /6	Same as legacy mode.	Not relevant.	No GPR register results.	
MONITOR —Setup Monitor Address 0F 01 C8	Same as legacy mode.	Operand size fixed at 32 bits.	No GPR register results.	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
MOV —Move 89 8B C7 B8 through BF A1 (moffset) A3 (moffset)	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	32-bit immediate is sign-extended to 64 bits.
			Zero-extends 32-bit register results to 64 bits. Memory offsets are address-sized and default to 64 bits.	64-bit immediate.
			Zero-extends 32-bit register results to 64 bits. Memory offsets are address-sized and default to 64 bits.	Memory offsets are address-sized and default to 64 bits.
MOV —Move to/from Segment Registers 8C 8E	Same as legacy mode.	32 bits	Zero-extends 32-bit register results to 64 bits.	
		Operand size fixed at 16 bits.	No GPR register results.	
MOV(CRn) —Move to/from Control Registers 0F 22 0F 20	Promoted to 64 bits.	Operand size fixed at 64 bits.	The high 32 bits of control registers differ in their writability and reserved status. See “System Resources” in Volume 2 for details.	
MOV(DRn) —Move to/from Debug Registers 0F 21 0F 23	Promoted to 64 bits.	Operand size fixed at 64 bits.	The high 32 bits of debug registers differ in their writability and reserved status. See “Debug and Performance Resources” in Volume 2 for details.	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
MOVD —Move Doubleword or Quadword 0F 6E 0F 7E 66 0F 6E 66 0F 7E	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
			Zero-extends 32-bit register results to 128 bits.	Zero-extends 64-bit register results to 128 bits.
MOVNTI —Move Non-Temporal Doubleword 0F C3	Promoted to 64 bits.	32 bits	No GPR register results.	
MOVS, MOVSW, MOVSD, MOVSQ —Move String A5	Promoted to 64 bits.	32 bits	MOVSD: Move String Doublewords. See footnote ⁵	MOVSQ (new mnemonic): Move String Quadwords. See footnote ⁵
MOVSX —Move with Sign-Extend 0F BE 0F BF	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Sign-extends byte to quadword.
				Sign-extends word to quadword.
Notes:				
1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.				
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.				
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.				
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.				
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.				
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.				

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
MOVSXD —Move with Sign-Extend Doubleword 63	New instruction, available only in 64-bit mode. (In other modes, this opcode is ARPL instruction.)	32 bits	Zero-extends 32-bit register results to 64 bits.	Sign-extends doubleword to quadword.
MOVZX —Move with Zero-Extend 0F B6 0F B7	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Zero-extends byte to quadword. Zero-extends word to quadword.
MUL —Multiply Unsigned F7 /4	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	RDX:RAX=RAX* quadword in register or memory.
MWAIT —Monitor Wait 0F 01 C9	Same as legacy mode.	Operand size fixed at 32 bits.	No GPR register results.	
NEG —Negate Two's Complement F7 /3	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
NOP —No Operation 90	Same as legacy mode.	Not relevant.	No GPR register results.	
NOT —Negate One's Complement F7 /2	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
OR —Logical OR 09 0B 0D 81 /1 83 /1	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
OUT —Output to Port E7 EF	Same as legacy mode.	32 bits	No GPR register results.	
OUTS, OUTSW, OUTSD —Output String 6F	Same as legacy mode.	32 bits	Writes doubleword to I/O port. No GPR register results. See footnote ⁵	
PAUSE —Pause F3 90	Same as legacy mode.	Not relevant.	No GPR register results.	
POP —Pop Stack 8F /0 58 through 5F	Promoted to 64 bits.	64 bits	Cannot encode ⁶	No GPR register results.
POP —Pop (segment register from) Stack 0F A1 (POP FS) 0F A9 (POP GS) 1F (POP DS) 07 (POP ES) 17 (POP SS)	Same as legacy mode.	64 bits	Cannot encode ⁶	No GPR register results.
INVALID IN 64-BIT MODE (invalid-opcode exception)				

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
POPA, POPAD —Pop All to GPR Words or Doublewords 61	INVALID IN 64-BIT MODE (invalid-opcode exception)			
POPCNT —Bit Population Count F3 0F B8	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
POPF, POPFD, POPFQ —Pop to rFLAGS Word, Doubleword, or Quadword 9D	Promoted to 64 bits.	64 bits	Cannot encode ⁶	POPFQ (new mnemonic): Pops 64 bits off stack, writes low 32 bits into EFLAGS and zero-extends the high 32 bits of RFLAGS.
PREFETCH —Prefetch L1 Data-Cache Line 0F 0D /0	Same as legacy mode.	Not relevant.	No GPR register results.	
PREFETCH/level —Prefetch Data to Cache Level <i>level</i> 0F 18 /0-3	Same as legacy mode.	Not relevant.	No GPR register results.	
PREFETCHW —Prefetch L1 Data-Cache Line for Write 0F 0D /1	Same as legacy mode.	Not relevant.	No GPR register results.	
PUSH —Push onto Stack FF /6 50 through 57 6A 68	Promoted to 64 bits.	64 bits	Cannot encode ⁶	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
PUSH —Push (segment register) onto Stack 0F A0 (PUSH FS) 0F A8 (PUSH GS) 0E (PUSH CS) 1E (PUSH DS) 06 (PUSH ES) 16 (PUSH SS)	Promoted to 64 bits.	64 bits	Cannot encode ⁶	
	INVALID IN 64-BIT MODE (invalid-opcode exception)			
PUSHA, PUSHAD - Push All to GPR Words or Doublewords 60	INVALID IN 64-BIT MODE (invalid-opcode exception)			
PUSHF, PUSHFD, PUSHFQ —Push rFLAGS Word, Doubleword, or Quadword onto Stack 9C	Promoted to 64 bits.	64 bits	Cannot encode ⁶	PUSHFQ (new mnemonic): Pushes the 64-bit RFLAGS register.
RCL —Rotate Through Carry Left D1 /2 D3 /2 C1 /2	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
RCR —Rotate Through Carry Right D1 /3 D3 /3 C1 /3	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
RDMSR —Read Model-Specific Register 0F 32	Same as legacy mode.	Not relevant.	RDX[31:0] contains MSR[63:32], RAX[31:0] contains MSR[31:0]. Zero-extends 32-bit register results to 64 bits.	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
RDPMC —Read Performance-Monitoring Counters 0F 33	Same as legacy mode.	Not relevant.	RDX[31:0] contains PMC[63:32], RAX[31:0] contains PMC[31:0]. Zero-extends 32-bit register results to 64 bits.	
RDTSC —Read Time-Stamp Counter 0F 31	Same as legacy mode.	Not relevant.	RDX[31:0] contains TSC[63:32], RAX[31:0] contains TSC[31:0]. Zero-extends 32-bit register results to 64 bits.	
RDTSCP —Read Time-Stamp Counter and Processor ID 0F 01 F9	Same as legacy mode.	Not relevant.	RDX[31:0] contains TSC[63:32], RAX[31:0] contains TSC[31:0]. RCX[31:0] contains the TSC_AUX MSR C000_0103h[31:0]. Zero-extends 32-bit register results to 64 bits.	
REP INS —Repeat Input String F3 6D	Same as legacy mode.	32 bits	Reads doubleword I/O port. See footnote ⁵	
REP LODS —Repeat Load String F3 AD	Promoted to 64 bits.	32 bits	Zero-extends EAX to 64 bits. See footnote ⁵	See footnote ⁵
REP MOVS —Repeat Move String F3 A5	Promoted to 64 bits.	32 bits	No GPR register results. See footnote ⁵	
REP OUTS —Repeat Output String to Port F3 6F	Same as legacy mode.	32 bits	Writes doubleword to I/O port. No GPR register results. See footnote ⁵	
REP STOS —Repeat Store String F3 AB	Promoted to 64 bits.	32 bits	No GPR register results. See footnote ⁵	
REPx CMPS —Repeat Compare String F3 A7	Promoted to 64 bits.	32 bits	No GPR register results. See footnote ⁵	

Notes:

1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
REPx SCAS —Repeat Scan String F3 AF	Promoted to 64 bits.	32 bits	No GPR register results. See footnote ⁵	
RET —Return from Call Near C2 C3	See “Near Branches in 64-Bit Mode” in Volume 1.			
	Promoted to 64 bits.	64 bits	Cannot encode. ⁶	No GPR register results.
RET —Return from Call Far CB CA	Promoted to 64 bits.	32 bits	See “Control Transfers” in Volume 1 and “Control-Transfer Privilege Checks” in Volume 2.	
ROL —Rotate Left D1 /0 D3 /0 C1 /0	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
ROR —Rotate Right D1 /1 D3 /1 C1 /1	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
RSM —Resume from System Management Mode 0F AA	New SMM state-save area.	Not relevant.	See “System-Management Mode” in Volume 2.	
SAHF —Store AH into Flags 9E	Same as legacy mode.	Not relevant.	No GPR register results.	
SAL —Shift Arithmetic Left D1 /4 D3 /4 C1 /4	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
Notes:				
1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table.				
2. The type of operation, excluding considerations of operand size or extension of results. See “General Rules for 64-Bit Mode” on page 487 for definitions of “Promoted to 64 bits” and related topics.				
3. If “Type of Operation” is 64 bits, a REX prefix is needed for 64-bit operand size, unless the instruction size defaults to 64 bits. If the operand size is fixed, operand-size overrides are silently ignored.				
4. Special actions in 64-bit mode, in addition to legacy-mode actions. Zero or sign extensions apply only to result operands, not source operands. Unless otherwise stated, 8-bit and 16-bit results leave the high 56 or 48 bits, respectively, of 64-bit destination registers unchanged. immediates and branch displacements are sign-extended to 64 bits.				
5. Any pointer registers (rDI, rSI) or count registers (rCX) are address-sized and default to 64 bits. For 32-bit address size, any pointer and count registers are zero-extended to 64 bits.				
6. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode.				

Table B-1. Operations and Operands in 64-Bit Mode (continued)

Instruction and Opcode (hex) ¹	Type of Operation ²	Default Operand Size ³	For 32-Bit Operand Size ⁴	For 64-Bit Operand Size ⁴
SAR —Shift Arithmetic Right D1 /7 D3 /7 C1 /7	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
SBB —Subtract with Borrow 19 1B 1D 81 /3 83 /3	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	
SCAS, SCASW, SCASD, SCASQ —Scan String AF	Promoted to 64 bits.	32 bits	SCASD: Scan String Doublewords. Zero-extends 32-bit register results to 64 bits. See footnote ⁵	SCASQ (new mnemonic): Scan String Quadwords. See footnote ⁵
SFENCE —Store Fence 0F AE /7	Same as legacy mode.	Not relevant.	No GPR register results.	
SGDT —Store Global Descriptor Table Register 0F 01 /0	Promoted to 64 bits.	Operand size fixed at 64 bits.	No GPR register results. Stores 8-byte base and 2-byte limit.	
SHL —Shift Left D1 /4 D3 /4 C1 /4	Promoted to 64 bits.	32 bits	Zero-extends 32-bit register results to 64 bits.	Uses 6-bit count.
Notes:				
<ol style="list-style-type: none"> 1. See “General Rules for 64-Bit Mode” on page 487, for opcodes that do not appear in this table. 2. The default operand size can be overridden to 16 bits with 66h prefix, but there is no 32-bit operand-size override in 64-bit mode. 				

B.3 Invalid and Reassigned Instructions in 64-Bit Mode

Table B-2 lists instructions that are illegal in 64-bit mode. Attempted use of these instructions generates an invalid-opcode exception (#UD).

Table B-2. Invalid Instructions in 64-Bit Mode

Mnemonic	Opcode (hex)	Description
AAA	37	ASCII Adjust After Addition
AAD	D5	ASCII Adjust Before Division
AAM	D4	ASCII Adjust After Multiply
AAS	3F	ASCII Adjust After Subtraction
BOUND	62	Check Array Bounds
CALL (far)	9A	Procedure Call Far (far absolute)
DAA	27	Decimal Adjust after Addition
DAS	2F	Decimal Adjust after Subtraction
INTO	CE	Interrupt to Overflow Vector
JMP (far)	EA	Jump Far (absolute)
LDS	C5	Load DS Far Pointer
LES	C4	Load ES Far Pointer
POP DS	1F	Pop Stack into DS Segment
POP ES	07	Pop Stack into ES Segment
POP SS	17	Pop Stack into SS Segment
POPA, POPAD	61	Pop All to GPR Words or Doublewords
PUSH CS	0E	Push CS Segment Selector onto Stack
PUSH DS	1E	Push DS Segment Selector onto Stack
PUSH ES	06	Push ES Segment Selector onto Stack
PUSH SS	16	Push SS Segment Selector onto Stack
PUSHA, PUSHAD	60	Push All to GPR Words or Doublewords
Redundant Grp1	82 /2	Redundant encoding of group1 Eb,lb opcodes
SALC	D6	Set AL According to CF

Table B-3 lists instructions that are reassigned to different functions in 64-bit mode. Attempted use of these instructions generates the reassigned function.

Table B-3. Reassigned Instructions in 64-Bit Mode

Mnemonic	Opcode (hex)	Description
ARPL	63	Opcode for MOVSD instruction in 64-bit mode. In all other modes, this is the Adjust Requestor Privilege Level instruction opcode.
DEC and INC	40-4F	REX prefixes in 64-bit mode. In all other modes, decrement by 1 and increment by 1.
LDS	C5	VEX Prefix. Introduces the VEX two-byte instruction encoding escape sequence.
LES	C4	VEX Prefix. Introduces the VEX three-byte instruction encoding escape sequence.

Table B-4 lists instructions that are illegal in long mode. Attempted use of these instructions generates an invalid-opcode exception (#UD).

Table B-4. Invalid Instructions in Long Mode

Mnemonic	Opcode (hex)	Description
SYSENTER	0F 34	System Call
SYSEXIT	0F 35	System Return

B.4 Instructions with 64-Bit Default Operand Size

In 64-bit mode, two groups of instructions default to 64-bit operand size without the need for a REX prefix:

- *Near branches* —CALL, Jcc, JrcX, JMP, LOOP, and RET.
- *All instructions, except far branches, that implicitly reference the RSP*—CALL, ENTER, LEAVE, POP, PUSH, and RET (CALL and RET are in both groups of instructions).

Table B-5 lists these instructions.

Table B-5. Instructions Defaulting to 64-Bit Operand Size

Mnemonic	Opcode (hex)	Implicitly Reference RSP	Description
CALL	E8, FF /2	yes	Call Procedure Near
ENTER	C8	yes	Create Procedure Stack Frame
Jcc	many	no	Jump Conditional Near
JMP	E9, EB, FF /4	no	Jump Near
LEAVE	C9	yes	Delete Procedure Stack Frame
LOOP	E2	no	Loop
LOOPcc	E0, E1	no	Loop Conditional
POP reg/mem	8F /0	yes	Pop Stack (register or memory)
POP reg	58-5F	yes	Pop Stack (register)
POP FS	0F A1	yes	Pop Stack into FS Segment Register
POP GS	0F A9	yes	Pop Stack into GS Segment Register
POPF, POPFD, POPFQ	9D	yes	Pop to rFLAGS Word, Doubleword, or Quadword
PUSH imm8	6A	yes	Push onto Stack (sign-extended byte)
PUSH imm32	68	yes	Push onto Stack (sign-extended doubleword)
PUSH reg/mem	FF /6	yes	Push onto Stack (register or memory)
PUSH reg	50-57	yes	Push onto Stack (register)
PUSH FS	0F A0	yes	Push FS Segment Register onto Stack
PUSH GS	0F A8	yes	Push GS Segment Register onto Stack
PUSHF, PUSHFD, PUSHFQ	9C	yes	Push rFLAGS Word, Doubleword, or Quadword onto Stack
RET	C2, C3	yes	Return From Call (near)

The 64-bit default operand size can be overridden to 16 bits using the 66h operand-size override. However, it is not possible to override the operand size to 32 bits because there is no 32-bit operand-size override prefix for 64-bit mode. See “Operand-Size Override Prefix” on page 7 for details.

B.5 Single-Byte INC and DEC Instructions in 64-Bit Mode

In 64-bit mode, the legacy encodings for the 16 single-byte INC and DEC instructions (one for each of the eight GPRs) are used to encode the REX prefix values, as described in “REX Prefix” on page 14. Therefore, these single-byte opcodes for INC and DEC are not available in 64-bit mode, although they are available in legacy and compatibility modes. The functionality of these INC and DEC instructions is still available in 64-bit mode, however, using the ModRM forms of those instructions (opcodes FF/0 and FF/1).

B.6 NOP in 64-Bit Mode

Programs written for the legacy x86 architecture commonly use opcode 90h (the XCHG EAX, EAX instruction) as a one-byte NOP. In 64-bit mode, the processor treats opcode 90h specially in order to preserve this legacy NOP use. Without special handling in 64-bit mode, the instruction would not be a true no-operation. Therefore, in 64-bit mode the processor treats XCHG EAX, EAX as a true NOP, regardless of operand size.

This special handling does not apply to the two-byte ModRM form of the XCHG instruction. Unless a 64-bit operand size is specified using a REX prefix byte, using the two byte form of XCHG to exchange a register with itself will not result in a no-operation because the default operation size is 32 bits in 64-bit mode.

B.7 Segment Override Prefixes in 64-Bit Mode

In 64-bit mode, the CS, DS, ES, SS segment-override prefixes have no effect. These four prefixes are no longer treated as segment-override prefixes in the context of multiple-prefix rules. Instead, they are treated as null prefixes.

The FS and GS segment-override prefixes are treated as true segment-override prefixes in 64-bit mode. Use of the FS and GS prefixes cause their respective segment bases to be added to the effective address calculation. See “FS and GS Registers in 64-Bit Mode” in Volume 2 for details.

Appendix C Differences Between Long Mode and Legacy Mode

Table C-1 summarizes the major differences between 64-bit mode and legacy protected mode. The third column indicates differences between 64-bit mode and legacy mode. The fourth column indicates whether that difference also applies to compatibility mode.

Table C-1. Differences Between Long Mode and Legacy Mode

Type	Subject	64-Bit Mode Difference	Applies To Compatibility Mode?
Application Programming	Addressing	RIP-relative addressing available	no
	Data and Address Sizes	Default data size is 32 bits	
		REX Prefix toggles data size to 64 bits	
		Default address size is 64 bits	
	Instruction Differences	Address size prefix toggles address size to 32 bits	no
		Various opcodes are invalid or changed in 64-bit mode (see Table B-2 on page 513 and Table B-3 on page 514)	
		Various opcodes are invalid in long mode (see Table B-4 on page 514)	yes
		MOV reg,imm32 becomes MOV reg,imm64 (with REX operand size prefix)	no
		REX is always enabled	
	Direct-offset forms of MOV to or from accumulator become 64-bit offsets		
	MOVD extended to MOV 64 bits between MMX registers and long GPRs (with REX operand-size prefix)		

Table C-1. Differences Between Long Mode and Legacy Mode (continued)

Type	Subject	64-Bit Mode Difference	Applies To Compatibility Mode?
System Programming	x86 Modes	Real and virtual-8086 modes not supported	yes
	Task Switching	Task switching not supported	yes
	Addressing	64-bit virtual addresses	yes
		4-level paging structures	
		PAE must always be enabled	
	Segmentation	CS, DS, ES, SS segment bases are ignored	no
		CS, DS, ES, FS, GS, SS segment limits are ignored	
		CS, DS, ES, SS Segment prefixes are ignored	
	Exception and Interrupt Handling	All pushes are 8 bytes	yes
		16-bit interrupt and trap gates are illegal	
		32-bit interrupt and trap gates are redefined as 64-bit gates and are expanded to 16 bytes	
		SS is set to null on stack switch	
		SS:RSP is pushed unconditionally	
	Call Gates	All pushes are 8 bytes	yes
		16-bit call gates are illegal	
32-bit call gate type is redefined as 64-bit call gate and is expanded to 16 bytes.			
SS is set to null on stack switch			
System-Descriptor Registers	GDT, IDT, LDT, TR base registers expanded to 64 bits	yes	
System-Descriptor Table Entries and Pseudo-descriptors	LGDT and LIDT use expanded 10-byte pseudo-descriptors.	no	
	LLDT and LTR use expanded 16-byte table entries.		

Appendix D Instruction Subsets and CUID Feature Flags

This appendix provides information that can be used to determine if a specific instruction within the AMD64 instruction-set architecture (ISA) is supported on a processor.

Originally the x86 ISA was composed of a set of instructions from the general-purpose and system instruction groups. This set forms the base of the AMD64 ISA. As the ISA expanded over time, new instructions were added. Each addition constituted either a single instruction or a set of instructions and each addition was assigned a specific processor feature flag.

Although most current processor products support the entire ISA, support for each added instruction or instruction subset is optional and must be confirmed by testing the corresponding feature flag. The presence of a particular instruction or subset is indicated by the corresponding feature flag being set. A feature flag is a single bit value located at a specific bit position within the 32-bit value returned in a register as a result of executing the CUID instruction.

For more information on using the CUID instruction, see the instruction reference page for CUID on page 153. For a comprehensive list of processor feature flags accessed using the CUID instruction, see Appendix E, “Obtaining Processor Information Via the CUID Instruction” on page 589.

D.1 Instruction Set Overview

The AMD64 ISA can be organized into five instruction groups:

1. General-purpose instructions

These instructions operate on the general-purpose registers (GP registers) and can be used at all privilege levels. This group includes instructions to load and store the contents of a GP register to and from memory, move values between the GP registers, and perform arithmetic and logical operations on the contents of the registers.

2. System instructions

These instructions provide the means to manipulate the processor operating mode, access processor resources, handle program and system errors, and manage system memory. Many of these instructions require privilege level 0 to execute.

3. x87 instructions

These instructions are available at all privilege levels and include legacy floating-point instructions that use the ST(0)–ST(7) stack registers (FPR0–FPR7 physical registers) and internally use extended precision (80-bit) binary floating-point representation and operations.

4. 64-bit media Instructions

These instructions are available at all privilege levels and perform vector operations on packed integer and floating-point values held in the 64-bit MMX™ registers. The MMX register set overlays the FPR0–FPR7 physical registers. This group is composed of the MMX and 3DNow!™ instruction subsets and was subsequently expanded by the MMX and 3DNow! extensions subsets.

5. SSE instructions

The SSE instructions operate on packed integer and floating-point values held in the XMM / YMM registers. SSE includes the original Streaming SIMD Extensions, all the subsequent named SSE subsets, and the AVX, XOP, and AES instructions.

Figure D-1 on page 521 represents the relationship between the five major instruction groups and the named instruction subsets. Circles represent the instruction subsets. These include the base instruction set labeled “Base Instructions” in the diagram and the named subsets. The diagram omits individual optional instructions and some of the minor named instruction subsets. Dashed-line polygons represent the instruction groups.

Note that the 128-bit and 256-bit media instructions are referred to collectively as the Streaming SIMD Extensions (SSE). This is also the name of the original SSE subset. In the diagram the original SSE subset is labeled “SSE1 Instructions.” Collectively the 64-bit media and the SSE instructions make up the single instruction / multiple data (SIMD) group (labeled “SIMD Instructions” in the diagram).

The overlapping of the SSE and 64-bit media instruction subsets indicates that these subsets share some common mnemonics. However, these common mnemonics either have distinct opcodes for each subset or they take operands in both the MMX and XMM register sets.

The horizontal axis of Figure D-1 shows how the subsets have evolved over time.

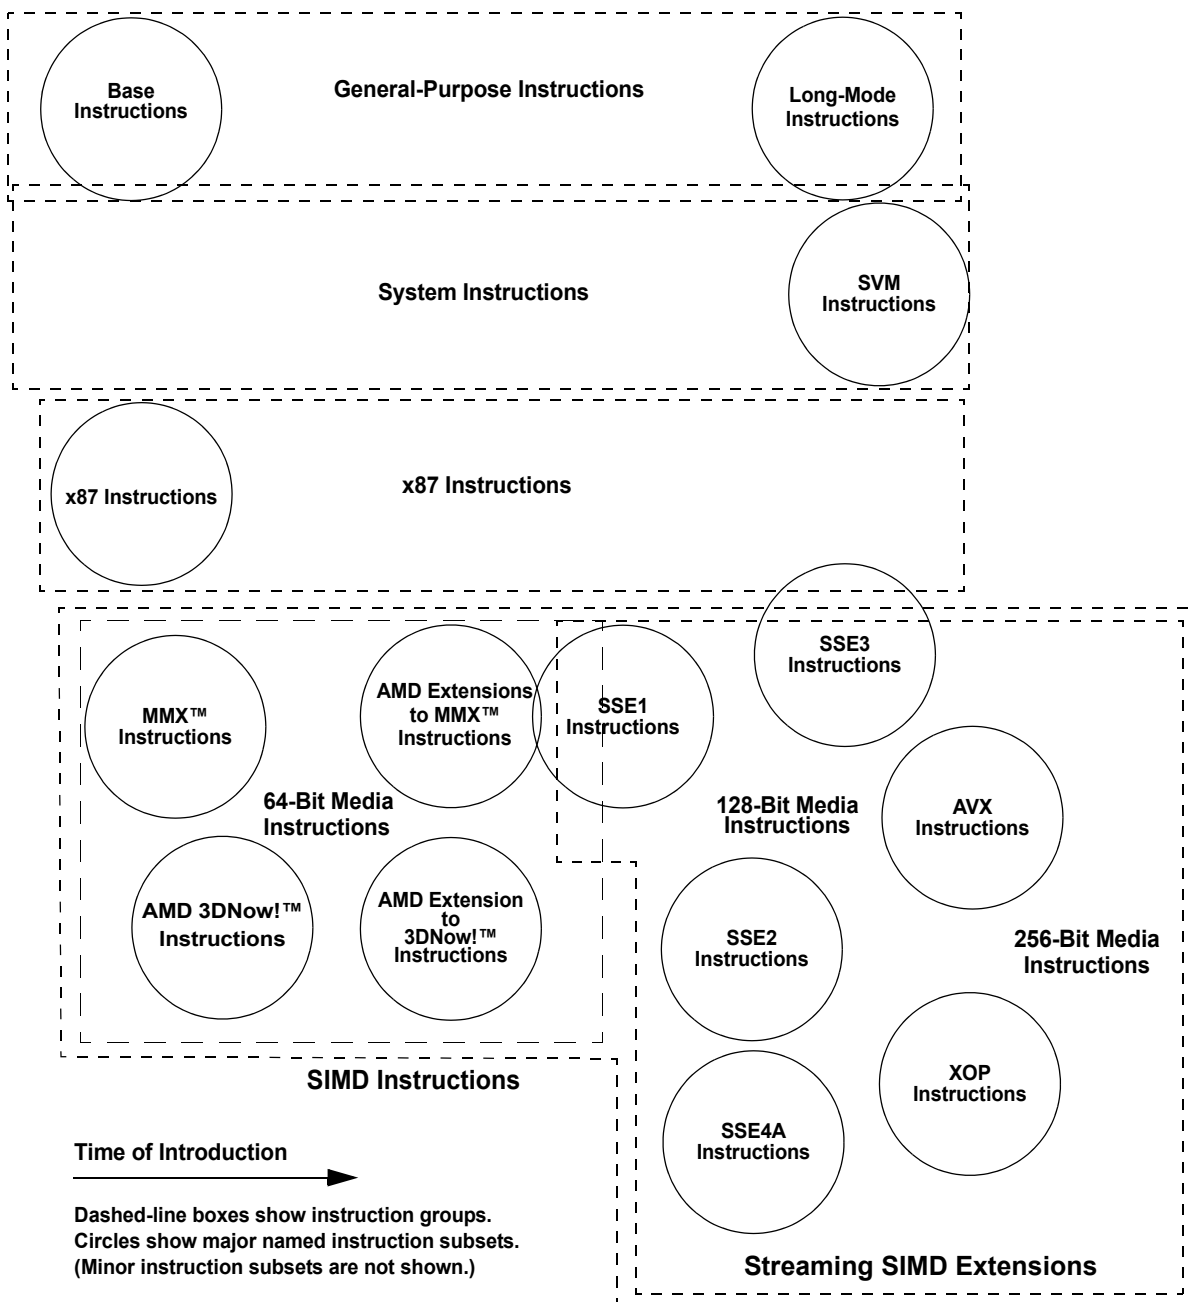

Figure D-1. AMD64 ISA Instruction Subsets

D.2 CPUID Feature Flags Related to Instruction Support

Only a subset of the CPUID feature flags provides information related to instruction support.

The feature flags related to supported instruction subsets are accessed via the *standard* function number 0000_0001h, the *extended* function number 8000_0001h, and the *structured extended* function number 0000_0007h.

The following table lists all flags related to instruction support. Entries for each flag provide the instruction or instruction subset corresponding to the flag, the CPUID function that must be executed to access the flag, and the bit position of the flag in the return value. The feature flags listed are used in Table D-2 on page 524:

Table D-1. Feature Flags for Instruction / Instruction Subset Support

Feature Flag	Instruction or Subset	CPUID Function ¹	Feature Flag Bit Position ²
BASE	Base Instruction set	—	—
CLFSH	CLFLUSH	standard	EDX[19]
CMPXCHG8B	CMPXCHG8B	both	EDX[8]
CMPXCHG16B	CMPXCHG16B	standard	ECX[13]
CMOV	CMOV _{cc}	both	EDX[15]
MSR	RDMSR / WRMSR	both	EDX[5]
TSC	RDTSC / RDTSCP	both	EDX[4]
RDTSCP	RDTSCP	extended	EDX[27]
SysCallSysRet	SYSCALL / SYSRET	extended	EDX[11]
SysEnterSysExit	SYSENTER / SYSEXIT	standard	EDX[11]
FPU	x87	both	EDX[0]
x87 && CMOV	FCMOV _{cc} ³	both	EDX[0] && EDX[15]
MMX	MMX	both	EDX[23]
3DNow	3DNow!	extended	EDX[31]
MmxExt	MMX Extensions	extended	EDX[22]
3DNowExt	3DNow! Extensions	extended	EDX[30]
3DNowPrefetch	PREFETCH / PREFETCHW	extended	ECX[8]
SSE	SSE1	standard	EDX[25]
SSE2	SSE2	standard	EDX[26]
Notes:			
<ol style="list-style-type: none"> 1. <i>standard</i> = Fn 0000_0001h; <i>extended</i> = Fn 8000_0001h; both means that both standard and extended CPUID functions return the same feature flag in the same bit position of the return value. <i>structured extended</i> = Fn 0000_0007h, with input argument ECX = 0. 2. Register and bit position of the return value that corresponds to the feature flag. 3. FCMOV_{cc} instruction is supported if x87 and CMOV_{cc} instructions are both supported. 4. XSAVE (and related) instructions require separate enablement. 			

Table D-1. Feature Flags for Instruction / Instruction Subset Support

Feature Flag	Instruction or Subset	CPUID Function ¹	Feature Flag Bit Position ²
SSE3	SSE3	standard	ECX[0]
SSSE3	SSSE3	standard	ECX[9]
SSE4A	SSE4A	extended	ECX[6]
SSE41	SSE4.1	standard	ECX[19]
SSE42	SSE4.2	standard	ECX[20]
LM	Long Mode	extended	EDX[29]
SVM	Secure Virtual Machine	extended	ECX[2]
AVX	AVX	standard	ECX[28]
AVX2	AVX2	structured extended	EBX[5]
XOP	XOP	extended	ECX[11]
AES	AES	standard	ECX[25]
FMA	FMA	standard	ECX[12]
FMA4	FMA4	extended	ECX[16]
F16C	16-bit floating-point conversion	standard	ECX[29]
RDRAND	RDRAND	standard	ECX[30]
ABM	LZCNT	extended	ECX[5]
BMI1	Bit Manipulation, group 1	structured extended	EBX[3]
BMI2	Bit Manipulation, group 2	structured extended	EBX[8]
POPCNT	POPCNT	standard	ECX[23]
TBM	Trailing bit manipulation	extended	ECX[21]
MOVBE	MOVBE	standard	ECX[22]
MONITOR	MONITOR / MWAIT	standard	ECX[3]
PCLMULQDQ	PCLMULQDQ	standard	ECX[1]
FXSR	FXSAVE / FXRSTOR	both	EDX[24]
SKINIT	SKINIT / STGI	extended	ECX[12]
LahfSahf	LAHF / SAHF	extended	ECX[0]
FSGSBASE	FS and GS base read and write	structured extended	EBX[0]
XSAVE	XSAVE / XRSTOR ⁴	standard	ECX[26]
Notes:			
<ol style="list-style-type: none"> 1. <i>standard</i> = Fn 0000_0001h; <i>extended</i> = Fn 8000_0001h; both means that both standard and extended CPUID functions return the same feature flag in the same bit position of the return value. <i>structured extended</i> = Fn 0000_0007h, with input argument ECX = 0. 2. Register and bit position of the return value that corresponds to the feature flag. 3. FCMOVcc instruction is supported if x87 and CMOVcc instructions are both supported. 4. XSAVE (and related) instructions require separate enablement. 			

D.3 Instruction List

Table D-2 shows the minimum current privilege level (CPL) required to execute each instruction and the feature flag or flags that indicates support for that instruction. Each flag is listed in the column corresponding to the instruction group to which it belongs. Note that some instructions span groups.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
AAA	ASCII Adjust After Addition	3	Base				
AAD	ASCII Adjust Before Division	3	Base				
AAM	ASCII Adjust After Multiply	3	Base				
AAS	ASCII Adjust After Subtraction	3	Base				
ADC	Add with Carry	3	Base				
ADD	Signed or Unsigned Add	3	Base				
ADDPD	Add Packed Double-Precision Floating-Point	3		SSE2			
ADDPS	Add Packed Single-Precision Floating-Point	3		SSE			
ADDSD	Add Scalar Double-Precision Floating-Point	3		SSE2			
ADDSS	Add Scalar Single-Precision Floating-Point	3		SSE			
ADDSUBPD	Add and Subtract Double-Precision	3		SSE3			
ADDSUBPS	Add and Subtract Single-Precision	3		SSE3			
AESDEC	AES Decryption Round	3		AES			
AESDECLAST	AES Last Decryption Round	3		AES			
AESENC	AES Encryption Round	3		AES			
AESENCLAST	AES Last Encryption Round	3		AES			
AESIMC	AES InvMixColumn Transformation	3		AES			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
AESKEYGENASSIST	AES Assist Round Key Generation	3		AES			
AND	Logical AND	3	Base				
ANDN	Logical And-Not	3	BMI1				
ANDNPD	AND NOT Packed Double-Precision Floating-Point	3		SSE2			
ANDNPS	AND NOT Packed Single-Precision Floating-Point	3		SSE			
ANDPD	AND Packed Double-Precision Floating-Point	3		SSE2			
ANDPS	AND Packed Single-Precision Floating-Point	3		SSE			
ARPL	Adjust Requestor Privilege Level	3					Base
BEXTR (immediate form)	Bit Field Extract	3	TBM				
BEXTR (register form)	Bit Field Extract	3	BMI1				
BLCFILL	Fill From Lowest Clear Bit	3	TBM				
BLCI	Isolate Lowest Clear Bit	3	TBM				
BLSI	Isolate Lowest Set Bit	3	BMI1				
BLCIC	Isolate Lowest Clear Bit and Complement	3	TBM				
BLCMSK	Mask From Lowest Clear Bit	3	TBM				
BLCS	Set Lowest Clear Bit	3	TBM				
BLENDDP	Blend Packed Double-Precision Floating-Point	3		SSE41			
BLENDPS	Blend Packed Single-Precision Floating-Point	3		SSE41			
BLENDVPD	Variable Blend Packed Double-Precision Floating-Point	3		SSE41			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
BLENDVPS	Variable Blend Packed Single-Precision Floating-Point	3		SSE41			
BLSMSK	Mask From Lowest Set Bit	3	BMI1				
BLSFILL	Fill From Lowest Set Bit	3	TBM				
BLSIC	Isolate Lowest Set Bit and Complement	3	TBM				
BLSR	Reset Lowest Set Bit	3	BMI1				
BOUND	Check Array Bounds	3	Base				
BSF	Bit Scan Forward	3	Base				
BSR	Bit Scan Reverse	3	Base				
BSWAP	Byte Swap	3	Base				
BT	Bit Test	3	Base				
BTC	Bit Test and Complement	3	Base				
BTR	Bit Test and Reset	3	Base				
BTS	Bit Test and Set	3	Base				
BZHI	Zero High Bits	3	BMI2				
CALL	Procedure Call	3	Base				
CBW	Convert Byte to Word	3	Base				
CDQ	Convert Doubleword to Quadword	3	Base				
CDQE	Convert Doubleword to Quadword	3	LM				
CLC	Clear Carry Flag	3	Base				
CLD	Clear Direction Flag	3	Base				
CLFLUSH	Cache Line Flush	3	CLFSH				
CLGI	Clear Global Interrupt Flag	0					SVM
CLI	Clear Interrupt Flag	3					Base
CLTS	Clear Task-Switched Flag in CR0	0					Base
CMC	Complement Carry Flag	3	Base				
CMOVcc	Conditional Move	3	CMOV				
CMP	Compare	3	Base				

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
CMPPD	Compare Packed Double-Precision Floating-Point	3		SSE2			
CMPPS	Compare Packed Single-Precision Floating-Point	3		SSE			
CMPS	Compare Strings	3	Base				
CMPSB	Compare Strings by Byte	3	Base				
CMPSD	Compare Strings by Doubleword	3	Base ²				
CMPSD	Compare Scalar Double-Precision Floating-Point	3		SSE2 ²			
CMPSQ	Compare Strings by Quadword	3	LM				
CMPSS	Compare Scalar Single-Precision Floating-Point	3		SSE			
CMPSW	Compare Strings by Word	3	Base				
CMPXCHG	Compare and Exchange	3	Base				
CMPXCHG8B	Compare and Exchange Eight Bytes	3	CMPXCHG8B				
CMPXCHG16B	Compare and Exchange Sixteen Bytes	3	CMPXCHG16B				
COMISD	Compare Ordered Scalar Double-Precision Floating-Point	3		SSE2			
COMISS	Compare Ordered Scalar Single-Precision Floating-Point	3		SSE			
CPUID	Processor Identification	3	Base				
CQO	Convert Quadword to Double Quadword	3	LM				
CRC32	32-bit Cyclical Redundancy Check	3	SSE42				
CVTDQ2PD	Convert Packed Doubleword Integers to Packed Double-Precision Floating-Point	3		SSE2			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
CVTDQ2PS	Convert Packed Doubleword Integers to Packed Single-Precision Floating-Point	3		SSE2			
CVTPD2DQ	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers	3		SSE2			
CVTPD2PI	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers	3		SSE2	SSE2		
CVTPD2PS	Convert Packed Double-Precision Floating-Point to Packed Single-Precision Floating-Point	3		SSE2			
CVTPI2PD	Convert Packed Doubleword Integers to Packed Double-Precision Floating-Point	3		SSE2	SSE2		
CVTPI2PS	Convert Packed Doubleword Integers to Packed Single-Precision Floating-Point	3		SSE	SSE		
CVTPS2DQ	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers	3		SSE2			
CVTPS2PD	Convert Packed Single-Precision Floating-Point to Packed Double-Precision Floating-Point	3		SSE2			
CVTPS2PI	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers	3		SSE	SSE		

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
CVTSD2SI	Convert Scalar Double-Precision Floating-Point to Signed Doubleword or Quadword Integer	3		SSE2			
CVTSD2SS	Convert Scalar Double-Precision Floating-Point to Scalar Single-Precision Floating-Point	3		SSE2			
CVTSI2SD	Convert Signed Doubleword or Quadword Integer to Scalar Double-Precision Floating-Point	3		SSE2			
CVTSI2SS	Convert Signed Doubleword or Quadword Integer to Scalar Single-Precision Floating-Point	3		SSE			
CVTSS2SD	Convert Scalar Single-Precision Floating-Point to Scalar Double-Precision Floating-Point	3		SSE2			
CVTSS2SI	Convert Scalar Single-Precision Floating-Point to Signed Doubleword or Quadword Integer	3		SSE			
CVTTPD2DQ	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		SSE2			
CVTTPD2PI	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		SSE2	SSE2		
CVTTPS2DQ	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
CVTTPS2PI	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		SSE	SSE		
CVTTSD2SI	Convert Scalar Double-Precision Floating-Point to Signed Doubleword or Quadword Integer, Truncated	3		SSE2			
CVTTSS2SI	Convert Scalar Single-Precision Floating-Point to Signed Doubleword or Quadword Integer, Truncated	3		SSE			
CWD	Convert Word to Doubleword	3	Base				
CWDE	Convert Word to Doubleword	3	Base				
DAA	Decimal Adjust after Addition	3	Base				
DAS	Decimal Adjust after Subtraction	3	Base				
DEC	Decrement by 1	3	Base				
DIV	Unsigned Divide	3	Base				
DIVPD	Divide Packed Double-Precision Floating-Point	3		SSE2			
DIVPS	Divide Packed Single-Precision Floating-Point	3		SSE			
DIVSD	Divide Scalar Double-Precision Floating-Point	3		SSE2			
DIVSS	Divide Scalar Single-Precision Floating-Point	3		SSE			
DPPD	Dot Product Packed Double-Precision Floating-Point	3		SSE41			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
DPPS	Dot Product Packed Single-Precision Floating-Point	3		SSE41			
EMMS	Enter/Exit Multimedia State	3			MMX	MMX	
ENTER	Create Procedure Stack Frame	3	Base				
EXTRACTPS	Extract Packed Single-Precision Floating-Point	3		SSE41			
EXTRQ	Extract Field From Register	3		SSE4A			
F2XM1	Floating-Point Compute 2x-1	3				X87	
FABS	Floating-Point Absolute Value	3				X87	
FADD	Floating-Point Add	3				X87	
FADDP	Floating-Point Add and Pop	3				X87	
FBLD	Floating-Point Load Binary-Coded Decimal	3				X87	
FBSTP	Floating-Point Store Binary-Coded Decimal Integer and Pop	3				X87	
FCHS	Floating-Point Change Sign	3				X87	
FCLEX	Floating-Point Clear Flags	3				X87	
FCMOVB	Floating-Point Conditional Move If Below	3				X87 && CMOV	
FCMOVBE	Floating-Point Conditional Move If Below or Equal	3				X87 && CMOV	
FCMOVE	Floating-Point Conditional Move If Equal	3				X87 && CMOV	
FCMOVNB	Floating-Point Conditional Move If Not Below	3				X87 && CMOV	
FCMOVNBE	Floating-Point Conditional Move If Not Below or Equal	3				X87 && CMOV	

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
FCMOVNE	Floating-Point Conditional Move If Not Equal	3				X87 && CMOV	
FCMOVNU	Floating-Point Conditional Move If Not Unordered	3				X87 && CMOV	
FCMOVU	Floating-Point Conditional Move If Unordered	3				X87 && CMOV	
FCOM	Floating-Point Compare	3				X87	
FCOMI	Floating-Point Compare and Set Flags	3				X87	
FCOMIP	Floating-Point Compare and Set Flags and Pop	3				X87	
FCOMP	Floating-Point Compare and Pop	3				X87	
FCOMPP	Floating-Point Compare and Pop Twice	3				X87	
FCOS	Floating-Point Cosine	3				X87	
FDECSTP	Floating-Point Decrement Stack-Top Pointer	3				X87	
FDIV	Floating-Point Divide	3				X87	
FDIVP	Floating-Point Divide and Pop	3				X87	
FDIVR	Floating-Point Divide Reverse	3				X87	
FDIVRP	Floating-Point Divide Reverse and Pop	3				X87	
FEMMS	Fast Enter/Exit Multimedia State	3			3DNow	3DNow	
FFREE	Free Floating-Point Register	3				X87	
FIADD	Floating-Point Add Integer to Stack Top	3				X87	
FICOM	Floating-Point Integer Compare	3				X87	
FICOMP	Floating-Point Integer Compare and Pop	3				X87	

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
FIDIV	Floating-Point Integer Divide	3				X87	
FIDIVR	Floating-Point Integer Divide Reverse	3				X87	
FILD	Floating-Point Load Integer	3				X87	
FIMUL	Floating-Point Integer Multiply	3				X87	
FINCSTP	Floating-Point Increment Stack-Top Pointer	3				X87	
FINIT	Floating-Point Initialize	3				X87	
FIST	Floating-Point Integer Store	3				X87	
FISTP	Floating-Point Integer Store and Pop	3				X87	
FISTTP	Floating-Point Integer Truncate and Store	3				SSE3	
FISUB	Floating-Point Integer Subtract	3				X87	
FISUBR	Floating-Point Integer Subtract Reverse	3				X87	
FLD	Floating-Point Load	3				X87	
FLD1	Floating-Point Load +1.0	3				X87	
FLDCW	Floating-Point Load x87 Control Word	3				X87	
FLDENV	Floating-Point Load x87 Environment	3				X87	
FLDL2E	Floating-Point Load $\log_2 e$	3				X87	
FLDL2T	Floating-Point Load $\log_2 10$	3				X87	
FLDLG2	Floating-Point Load $\log_{10} 2$	3				X87	
FLDLN2	Floating-Point Load Ln 2	3				X87	
FLDPI	Floating-Point Load Pi	3				X87	

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
FLDZ	Floating-Point Load +0.0	3				X87	
FMUL	Floating-Point Multiply	3				X87	
FMULP	Floating-Point Multiply and Pop	3				X87	
FNCLEX	Floating-Point No-Wait Clear Flags	3				X87	
FNINIT	Floating-Point No-Wait Initialize	3				X87	
FNOP	Floating-Point No Operation	3				X87	
FNSAVE	Save No-Wait x87 and MMX State	3			X87	X87	
FNSTCW	Floating-Point No-Wait Store x87 Control Word	3				X87	
FNSTENV	Floating-Point No-Wait Store x87 Environment	3				X87	
FNSTSW	Floating-Point No-Wait Store x87 Status Word	3				X87	
FPATAN	Floating-Point Partial Arctangent	3				X87	
FPREM	Floating-Point Partial Remainder	3				X87	
FPREM1	Floating-Point Partial Remainder	3				X87	
FPTAN	Floating-Point Partial Tangent	3				X87	
FRNDINT	Floating-Point Round to Integer	3				X87	
FRSTOR	Restore x87 and MMX State	3			X87	X87	
FSAVE	Save x87 and MMX State	3			X87	X87	
FSCALE	Floating-Point Scale	3				X87	
FSIN	Floating-Point Sine	3				X87	
FSINCOS	Floating-Point Sine and Cosine	3				X87	

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
FSQRT	Floating-Point Square Root	3				X87	
FST	Floating-Point Store Stack Top	3				X87	
FSTCW	Floating-Point Store x87 Control Word	3				X87	
FSTENV	Floating-Point Store x87 Environment	3				X87	
FSTP	Floating-Point Store Stack Top and Pop	3				X87	
FSTSW	Floating-Point Store x87 Status Word	3				X87	
FSUB	Floating-Point Subtract	3				X87	
FSUBP	Floating-Point Subtract and Pop	3				X87	
FSUBR	Floating-Point Subtract Reverse	3				X87	
FSUBRP	Floating-Point Subtract Reverse and Pop	3				X87	
FTST	Floating-Point Test with Zero	3				X87	
FUCOM	Floating-Point Unordered Compare	3				X87	
FUCOMI	Floating-Point Unordered Compare and Set Flags	3				X87	
FUCOMIP	Floating-Point Unordered Compare and Set Flags and Pop	3				X87	
FUCOMP	Floating-Point Unordered Compare and Pop	3				X87	
FUCOMPP	Floating-Point Unordered Compare and Pop Twice	3				X87	
FWAIT	Wait for x87 Floating-Point Exceptions	3				X87	
FXAM	Floating-Point Examine	3				X87	
FXCH	Floating-Point Exchange	3				X87	

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
FXRSTOR	Restore XMM, MMX, and x87 State	3		FXSR	FXSR	FXSR	
FXSAVE	Save XMM, MMX, and x87 State	3		FXSR	FXSR	FXSR	
FXTRACT	Floating-Point Extract Exponent and Significand	3				X87	
FYL2X	Floating-Point $y * \log_2 x$	3				X87	
FYL2XP1	Floating-Point $y * \log_2(x + 1)$	3				X87	
HADDPD	Horizontal Add Packed Double	3		SSE3			
HADDPS	Horizontal Add Packed Single	3		SSE3			
HLT	Halt	0					Base
HSUBPD	Horizontal Subtract Packed Double	3		SSE3			
HSUBPS	Horizontal Subtract Packed Single	3		SSE3			
IDIV	Signed Divide	3	Base				
IMUL	Signed Multiply	3	Base				
IN	Input from Port	3	Base				
INC	Increment by 1	3	Base				
INS	Input String	3	Base				
INSB	Input String Byte	3	Base				
INSD	Input String Doubleword	3	Base				
INSERTPS	Insert Packed Single-Precision Floating-Point	3		SSE41			
INSERTQ	Insert Field	3		SSE4A			
INSW	Input String Word	3	Base				
INT	Interrupt to Vector	3	Base				
INT 3	Interrupt to Debug Vector	3					Base
INTO	Interrupt to Overflow Vector	3	Base				
INVD	Invalidate Caches	0					Base

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
INVLPG	Invalidate TLB Entry	0					Base
INVLPGA	Invalidate TLB Entry in a Specified ASID	0					SVM
IRET	Interrupt Return Word	3					Base
IRETD	Interrupt Return Doubleword	3					Base
IRETQ	Interrupt Return Quadword	3					LM
Jcc	Jump Condition	3	Base				
JCXZ	Jump if CX Zero	3	Base				
JECXZ	Jump if ECX Zero	3	Base				
JMP	Jump	3	Base				
JRCXZ	Jump if RCX Zero	3	Base				
LAHF	Load Status Flags into AH Register	3	LahfSahf				
LAR	Load Access Rights Byte	3					Base
LDDQU	Load Unaligned Double Quadword	3		SSE3			
LDMXCSR	Load MXCSR Control/Status Register	3		SSE			
LDS	Load DS Far Pointer	3	Base				
LEA	Load Effective Address	3	Base				
LEAVE	Delete Procedure Stack Frame	3	Base				
LES	Load ES Far Pointer	3	Base				
LFENCE	Load Fence	3	SSE2				
LFS	Load FS Far Pointer	3	Base				
LGDT	Load Global Descriptor Table Register	0					Base
LGS	Load GS Far Pointer	3	Base				
LIDT	Load Interrupt Descriptor Table Register	0					Base
LLDT	Load Local Descriptor Table Register	0					Base
LMSW	Load Machine Status Word	0					Base

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
LODS	Load String	3	Base				
LODSB	Load String Byte	3	Base				
LODSD	Load String Doubleword	3	Base				
LODSQ	Load String Quadword	3	LM				
LODSW	Load String Word	3	Base				
LOOP	Loop	3	Base				
LOOPE	Loop if Equal	3	Base				
LOOPNE	Loop if Not Equal	3	Base				
LOOPNZ	Loop if Not Zero	3	Base				
LOOPZ	Loop if Zero	3	Base				
LSL	Load Segment Limit	3	Base				
LSS	Load SS Segment Register	3	Base				
LTR	Load Task Register	0					Base
LZCNT	Count Leading Zeros	3	ABM				
MASKMOVDQU	Masked Move Double Quadword Unaligned	3		SSE2			
MASKMOVQ	Masked Move Quadword	3			SSE MmxExt		
MAXPD	Maximum Packed Double-Precision Floating-Point	3		SSE2			
MAXPS	Maximum Packed Single-Precision Floating-Point	3		SSE			
MAXSD	Maximum Scalar Double-Precision Floating-Point	3		SSE2			
MAXSS	Maximum Scalar Single-Precision Floating-Point	3		SSE			
MFENCE	Memory Fence	3	SSE2				
MINPD	Minimum Packed Double-Precision Floating-Point	3		SSE2			
MINPS	Minimum Packed Single-Precision Floating-Point	3		SSE			
MINSD	Minimum Scalar Double-Precision Floating-Point	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
MINSS	Minimum Scalar Single-Precision Floating-Point	3		SSE			
MONITOR	Setup Monitor Address ³	0					MONITOR
MOV	Move	3	Base				
MOV CR _n	Move to/from Control Registers	0					Base
MOV DR _n	Move to/from Debug Registers	0					Base
MOVAPD	Move Aligned Packed Double-Precision Floating-Point	3		SSE2			
MOVAPS	Move Aligned Packed Single-Precision Floating-Point	3		SSE			
MOVBE	Move Big Endian	3	MOVBE				
MOVD	Move Doubleword or Quadword	3	MMX, SSE2	SSE2	MMX		
MOVDDUP	Move Double-Precision and Duplicate	3		SSE3			
MOVDQ2Q	Move Quadword to Quadword	3		SSE2	SSE2		
MOVDQA	Move Aligned Double Quadword	3		SSE2			
MOVDQU	Move Unaligned Double Quadword	3		SSE2			
MOVHLP	Move Packed Single-Precision Floating-Point High to Low	3		SSE			
MOVHPD	Move High Packed Double-Precision Floating-Point	3		SSE2			
MOVHPS	Move High Packed Single-Precision Floating-Point	3		SSE			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
MOVLHPS	Move Packed Single-Precision Floating-Point Low to High	3		SSE			
MOVLPD	Move Low Packed Double-Precision Floating-Point	3		SSE2			
MOVLPS	Move Low Packed Single-Precision Floating-Point	3		SSE			
MOVMSKPD	Extract Packed Double-Precision Floating-Point Sign Mask	3	SSE2	SSE2			
MOVMSKPS	Extract Packed Single-Precision Floating-Point Sign Mask	3	SSE	SSE			
MOVNTDQ	Move Non-Temporal Double Quadword	3		SSE2			
MOVNTDQA	Move Non-Temporal Double Quadword Aligned	3		SSE41			
MOVNTI	Move Non-Temporal Doubleword or Quadword	3	SSE2				
MOVNTPD	Move Non-Temporal Packed Double-Precision Floating-Point	3		SSE2			
MOVNTPS	Move Non-Temporal Packed Single-Precision Floating-Point	3		SSE			
MOVNTSD	Move Non-Temporal Scalar Double-Precision Floating-Point	3		SSE4A			
MOVNTSS	Move Non-Temporal Scalar Single-Precision Floating-Point	3		SSE4A			
MOVNTQ	Move Non-Temporal Quadword	3			SSE MmxExt		
MOVQ	Move Quadword	3		SSE2	MMX		

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
MOVQ2DQ	Move Quadword to Quadword	3		SSE2	SSE2		
MOVS	Move String	3	Base				
MOVSB	Move String Byte	3	Base				
MOVSD	Move String Doubleword	3	Base ²				
MOVSD	Move Scalar Double-Precision Floating-Point	3		SSE2 ²			
MOVSHDUP	Move Single-Precision High and Duplicate	3		SSE3			
MOVSLDUP	Move Single-Precision Low and Duplicate	3		SSE3			
MOVSQ	Move String Quadword	3	LM				
MOVSS	Move Scalar Single-Precision Floating-Point	3		SSE			
MOVSW	Move String Word	3	Base				
MOVSX	Move with Sign-Extend	3	Base				
MOVSLD	Move with Sign-Extend Doubleword	3	LM				
MOVUPD	Move Unaligned Packed Double-Precision Floating-Point	3		SSE2			
MOVUPS	Move Unaligned Packed Single-Precision Floating-Point	3		SSE			
MOVZX	Move with Zero-Extend	3	Base				
MPSADBW	Multiple Sum of Absolute Differences	3		SSE41			
MUL	Multiply Unsigned	3	Base				
MULPD	Multiply Packed Double-Precision Floating-Point	3		SSE2			
MULPS	Multiply Packed Single-Precision Floating-Point	3		SSE			
MULSD	Multiply Scalar Double-Precision Floating-Point	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
MULSS	Multiply Scalar Single-Precision Floating-Point	3		SSE			
MULX	Multiply Unsigned	3	BMI2				
MWAIT	Monitor Wait ³	0					MONITOR
NEG	Two's Complement Negation	3	Base				
NOP	No Operation	3	Base				
NOT	One's Complement Negation	3	Base				
OR	Logical OR	3	Base				
ORPD	Logical Bitwise OR Packed Double-Precision Floating-Point	3		SSE2			
ORPS	Logical Bitwise OR Packed Single-Precision Floating-Point	3		SSE			
OUT	Output to Port	3	Base				
OUTS	Output String	3	Base				
OUTSB	Output String Byte	3	Base				
OUTSD	Output String Doubleword	3	Base				
OUTSW	Output String Word	3	Base				
PABSB	Packed Absolute Value Signed Byte	3		SSSE3			
PABSD	Packed Absolute Value Signed Doubleword	3		SSSE3			
PABSW	Packed Absolute Value Signed Word	3		SSSE3			
PACKSSDW	Pack with Saturation Signed Doubleword to Word	3		SSE2	MMX		
PACKSSWB	Pack with Saturation Signed Word to Byte	3		SSE2	MMX		

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PACKUSDW	Pack with Unsigned Saturation Doubleword to Word	3		SSE41			
PACKUSWB	Pack with Saturation Signed Word to Unsigned Byte	3		SSE2	MMX		
PADDB	Packed Add Bytes	3		SSE2	MMX		
PADD	Packed Add Doublewords	3		SSE2	MMX		
PADDQ	Packed Add Quadwords	3		SSE2	SSE2		
PADDSB	Packed Add Signed with Saturation Bytes	3		SSE2	MMX		
PADDSW	Packed Add Signed with Saturation Words	3		SSE2	MMX		
PADDUSB	Packed Add Unsigned with Saturation Bytes	3		SSE2	MMX		
PADDUSW	Packed Add Unsigned with Saturation Words	3		SSE2	MMX		
PADDW	Packed Add Words	3		SSE2	MMX		
PALIGNR	Packed Align Right	3		SSSE3			
PAND	Packed Logical Bitwise AND	3		SSE2	MMX		
PANDN	Packed Logical Bitwise AND NOT	3		SSE2	MMX		
PAUSE	Pause	3	BASE				
PAVGB	Packed Average Unsigned Bytes	3		SSE2	SSE MmxExt		
PAVGUSB	Packed Average Unsigned Bytes	3			3DNow		
PAVGW	Packed Average Unsigned Words	3		SSE2	SSE MmxExt		
PBLENDVB	Variable Blend Packed Bytes	3		SSE41			
PBLENDW	Blend Packed Words	3		SSE41			
PCLMULQDQ	Carry-less Multiply Quadwords	3		CLMUL			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PCMPEQB	Packed Compare Equal Bytes	3		SSE2	MMX		
PCMPEQD	Packed Compare Equal Doublewords	3		SSE2	MMX		
PCMPEQQ	Packed Compare Equal Quadwords	3		SSE41			
PCMPEQW	Packed Compare Equal Words	3		SSE2	MMX		
PCMPESTRI	Packed Compare Explicit Length Strings Return Index	3		SSE42			
PCMPESTRM	Packed Compare Explicit Length Strings Return Mask	3		SSE42			
PCMPGTB	Packed Compare Greater Than Signed Bytes	3		SSE2	MMX		
PCMPGTD	Packed Compare Greater Than Signed Doublewords	3		SSE2	MMX		
PCMPGTQ	Packed Compare Greater Than Signed Quadwords	3		SSE42			
PCMPGTW	Packed Compare Greater Than Signed Words	3		SSE2	MMX		
PCMPISTRI	Packed Compare Implicit Length Strings Return Index	3		SSE42			
PCMPISTRM	Packed Compare Implicit Length Strings Return Mask	3		SSE42			
PDEP	Parallel Deposit Bits	3	BMI2				
PEXT	Parallel Extract Bits	3	BMI2				
PEXTRB	Extract Packed Byte	3		SSE41			
PEXTRD	Extract Packed Doubleword	3		SSE41			
PEXTRQ	Extract Packed Quadword	3		SSE41			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PEXTRW	Packed Extract Word	3		SSE41 SSE2	SSE MmxExt		
PF2ID	Packed Floating-Point to Integer Doubleword Conversion	3			3DNow		
PF2IW	Packed Floating-Point to Integer Word Conversion	3			3DNow! Extensions		
PFACC	Packed Floating-Point Accumulate	3			3DNow		
PFADD	Packed Floating-Point Add	3			3DNow		
PFCMPEQ	Packed Floating-Point Compare Equal	3			3DNow		
PFCMPGE	Packed Floating-Point Compare Greater or Equal	3			3DNow		
PFCMPGT	Packed Floating-Point Compare Greater Than	3			3DNow		
PFMAX	Packed Floating-Point Maximum	3			3DNow		
PFCMPGT	Packed Floating-Point Minimum	3			3DNow		
PFMIN	Packed Floating-Point Minimum	3			3DNow		
PFMUL	Packed Floating-Point Multiply	3			3DNow		
PFNACC	Packed Floating-Point Negative Accumulate	3			3DNowExt		
PFPNACC	Packed Floating-Point Positive-Negative Accumulate	3			3DNowExt		
PFRCPP	Packed Floating-Point Reciprocal Approximation	3			3DNow		
PFRCPP1	Packed Floating-Point Reciprocal, Iteration 1	3			3DNow		
PFRCPP2	Packed Floating-Point Reciprocal or Reciprocal Square Root, Iteration 2	3			3DNow		

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PFRSQIT1	Packed Floating-Point Reciprocal Square Root, Iteration 1	3			3DNow		
PFRSQRT	Packed Floating-Point Reciprocal Square Root Approximation	3			3DNow		
PFSUB	Packed Floating-Point Subtract	3			3DNow		
PFSUBR	Packed Floating-Point Subtract Reverse	3			3DNow		
PHADDD	Packed Horizontal Add Doubleword	3		SSSE3			
PHADDSW	Packed Horizontal Add with Saturation Word	3		SSSE3			
PHADDW	Packed Horizontal Add Word	3		SSSE3			
PHMINPOSUW	Horizontal Minimum and Position	3		SSE41			
PHSUBD	Packed Horizontal Subtract Doubleword	3		SSSE3			
PHSUBSW	Packed Horizontal Subtract with Saturation Word	3		SSSE3			
PHSUBW	Packed Horizontal Subtract Word	3		SSSE3			
PI2FD	Packed Integer to Floating-Point Doubleword Conversion	3			3DNow		
PI2FW	Packed Integer To Floating-Point Word Conversion	3			3DNowExt		
PINSRB	Packed Insert Byte	3		SSE41			
PINSRD	Packed Insert Doubleword	3		SSE41			
PINSRQ	Packed Insert Quadword	3		SSE41			
PINSRW	Packed Insert Word	3		SSE2	SSE MmxExt		

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PMADDUBSW	Packed Multiply and Add Unsigned Byte to Signed Word,	3		SSSE3			
PMADDWD	Packed Multiply Words and Add Doublewords	3		SSE2	MMX		
PMAXSB	Packed Maximum Signed Bytes	3		SSE41			
PMAXSD	Packed Maximum Signed Doublewords	3		SSE41			
PMAXSW	Packed Maximum Signed Words	3		SSE2	SSE MmxExt		
PMAXUB	Packed Maximum Unsigned Bytes	3		SSE2	SSE MmxExt		
PMAXUD	Packed Maximum Unsigned Doublewords	3		SSE41			
PMAXUW	Packed Maximum Unsigned Words	3		SSE41			
PMINSB	Packed Minimum Signed Bytes	3		SSE41			
PMINSD	Packed Minimum Signed Doublewords	3		SSE41			
PMINSW	Packed Minimum Signed Words	3		SSE2	SSE MmxExt		
PMINUB	Packed Minimum Unsigned Bytes	3		SSE2	SSE MmxExt		
PMINUD	Packed Minimum Unsigned Doublewords	3		SSE41			
PMINUW	Packed Minimum Unsigned Words	3		SSE41			
PMOVMKB	Packed Move Mask Byte	3		SSE2	SSE MmxExt		
PMOVXBD	Packed Move with Sign-Extension Byte to Doubleword	3		SSE41			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PMOVSBQ	Packed Move with Sign Extension Byte to Quadword	3		SSE41			
PMOVSBW	Packed Move with Sign Extension Byte to Word	3		SSE41			
PMOVSDQ	Packed Move with Sign-Extension Doubleword to Quadword	3		SSE41			
PMOVSWD	Packed Move with Sign-Extension Word to Doubleword	3		SSE41			
PMOVXWQ	Packed Move with Sign-Extension Word to Quadword	3		SSE41			
PMOVZBD	Packed Move with Zero-Extension Byte to Doubleword	3		SSE41			
PMOVZBQ	Packed Move Byte to Quadword with Zero-Extension	3		SSE41			
PMOVZBW	Packed Move Byte to Word with Zero-Extension	3		SSE41			
PMOVZDQ	Packed Move with Zero-Extension Doubleword to Quadword	3		SSE41			
PMOVZWD	Packed Move Word to Doubleword with Zero-Extension	3		SSE41			
PMOVZXWQ	Packed Move with Zero-Extension Word to Quadword	3		SSE41			
PMULDQ	Packed Multiply Signed Doubleword to Quadword	3		SSE41			
PMULHSW	Packed Multiply High with Round and Scale Words	3		SSSE3			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PMULHRW	Packed Multiply High Rounded Word	3			3DNow		
PMULHUW	Packed Multiply High Unsigned Word	3		SSE2	SSE MmxExt		
PMULHW	Packed Multiply High Signed Word	3		SSE2	MMX		
PMULLD	Packed Multiply and Store Low Signed Doubleword	3		SSE41			
PMULLW	Packed Multiply Low Signed Word	3		SSE2	MMX		
PMULUDQ	Packed Multiply Unsigned Doubleword and Store Quadword	3		SSE2	SSE2		
POP	Pop Stack	3	Base				
POPA	Pop All to GPR Words	3	Base				
POPAD	Pop All to GPR Doublewords	3	Base				
POPCNT	Bit Population Count	3	Base				
POPF	Pop to FLAGS Word	3	Base				
POPFD	Pop to EFLAGS Doubleword	3	Base				
POPFQ	Pop to RFLAGS Quadword	3	LM				
POR	Packed Logical Bitwise OR	3		SSE2	MMX		
PREFETCH	Prefetch L1 Data-Cache Line	3	3DNow 3DNowPrefetch LM				
PREFETCH $_{level}$	Prefetch Data to Cache Level $_{level}$	3	SSE MmxExt				
PREFETCHW	Prefetch L1 Data-Cache Line for Write	3	3DNow 3DNowPrefetch LM				
PSADBW	Packed Sum of Absolute Differences of Bytes into a Word	3		SSE2	SSE MmxExt		
PSHUFB	Packed Shuffle Byte	3		SSSE3			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PSHUFD	Packed Shuffle Doublewords	3		SSE2			
PSHUFHW	Packed Shuffle High Words	3		SSE2			
PSHUFLW	Packed Shuffle Low Words	3		SSE2			
PSHUFW	Packed Shuffle Words	3			SSE MmxExt		
PSIGNB	Packed Sign Byte	3		SSSE3			
PSIGND	Packed Sign Doubleword	3		SSSE3			
PSIGNW	Packed Sign Word	3		SSSE3			
PSLLD	Packed Shift Left Logical Doublewords	3		SSE2	MMX		
PSLLDQ	Packed Shift Left Logical Double Quadword	3		SSE2			
PSLLQ	Packed Shift Left Logical Quadwords	3		SSE2	MMX		
PSLLW	Packed Shift Left Logical Words	3		SSE2	MMX		
PSRAD	Packed Shift Right Arithmetic Doublewords	3		SSE2	MMX		
PSRAW	Packed Shift Right Arithmetic Words	3		SSE2	MMX		
PSRLD	Packed Shift Right Logical Doublewords	3		SSE2	MMX		
PSRLDQ	Packed Shift Right Logical Double Quadword	3		SSE2			
PSRLQ	Packed Shift Right Logical Quadwords	3		SSE2	MMX		
PSRLW	Packed Shift Right Logical Words	3		SSE2	MMX		
PSUBB	Packed Subtract Bytes	3		SSE2	MMX		
PSUBD	Packed Subtract Doublewords	3		SSE2	MMX		
PSUBQ	Packed Subtract Quadword	3		SSE2	SSE2		

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PSUBSB	Packed Subtract Signed With Saturation Bytes	3		SSE2	MMX		
PSUBSW	Packed Subtract Signed with Saturation Words	3		SSE2	MMX		
PSUBUSB	Packed Subtract Unsigned and Saturate Bytes	3		SSE2	MMX		
PSUBUSW	Packed Subtract Unsigned and Saturate Words	3		SSE2	MMX		
PSUBW	Packed Subtract Words	3		SSE2	MMX		
PSWAPD	Packed Swap Doubleword	3			3DNowExt		
PTEST	Packed Bit Test	3		SSE41			
PUNPCKHBW	Unpack and Interleave High Bytes	3		SSE2	MMX		
PUNPCKHDQ	Unpack and Interleave High Doublewords	3		SSE2	MMX		
PUNPCKHQDQ	Unpack and Interleave High Quadwords	3		SSE2			
PUNPCKHWD	Unpack and Interleave High Words	3		SSE2	MMX		
PUNPCKLBW	Unpack and Interleave Low Bytes	3		SSE2	MMX		
PUNPCKLDQ	Unpack and Interleave Low Doublewords	3		SSE2	MMX		
PUNPCKLQDQ	Unpack and Interleave Low Quadwords	3		SSE2			
PUNPCKLWD	Unpack and Interleave Low Words	3		SSE2	3DNow		
PUSH	Push onto Stack	3	Base				
PUSHA	Push All GPR Words onto Stack	3	Base				
PUSHAD	Push All GPR Doublewords onto Stack	3	Base				
PUSHF	Push EFLAGS Word onto Stack	3	Base				

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
PUSHFD	Push EFLAGS Doubleword onto Stack	3	Base				
PUSHFQ	Push RFLAGS Quadword onto Stack	3	LM				
PXOR	Packed Logical Bitwise Exclusive OR	3		SSE2	MMX		
RCL	Rotate Through Carry Left	3	Base				
RCPPS	Reciprocal Packed Single-Precision Floating-Point	3		SSE			
RCPSS	Reciprocal Scalar Single-Precision Floating-Point	3		SSE			
RCR	Rotate Through Carry Right	3	Base				
RDFSBASE	Read FS.base	3					FSGSBASE
RDGSBASE	Read GS.base	3					FSGSBASE
RDMSR	Read Model-Specific Register	0					MSR
RDPMC	Read Performance-Monitoring Counter	3					Base
RDTSC	Read Time-Stamp Counter	3					TSC
RDTSCP	Read Time-Stamp Counter and Processor ID	3					TSC RDTSCP
RET	Return from Call	3	Base				
ROL	Rotate Left	3	Base				
ROR	Rotate Right	3	Base				
RORX	Rotate Right Extended	3	BMI2				
ROUNDPD	Round Packed Double-Precision Floating-Point	3		SSE41			
ROUNDPS	Round Packed Single-Precision Floating-Point	3		SSE41			
ROUNDSD	Round Scalar Double-Precision Floating-Point	3		SSE41			
ROUNDSS	Round Scalar Single-Precision Floating-Point	3		SSE41			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
RSM	Resume from System Management Mode	3					Base
RSQRTPS	Reciprocal Square Root Packed Single-Precision Floating-Point	3		SSE			
RSQRTSS	Reciprocal Square Root Scalar Single-Precision Floating-Point	3		SSE			
SAHF	Store AH into Flags	3	LahfSahf				
SAL	Shift Arithmetic Left	3	Base				
SAR	Shift Arithmetic Right	3	Base				
SARX	Shift Right Arithmetic Extended	3	BMI2				
SBB	Subtract with Borrow	3	Base				
SCAS	Scan String	3	Base				
SCASB	Scan String as Bytes	3	Base				
SCASD	Scan String as Doubleword	3	Base				
SCASQ	Scan String as Quadword	3	LM				
SCASW	Scan String as Words	3	Base				
SETcc	Set Byte if Condition	3	Base				
SFENCE	Store Fence	3	SSE MmxExt				
SGDT	Store Global Descriptor Table Register	3					Base
SHL	Shift Left	3	Base				
SHLD	Shift Left Double	3	Base				
SHLX	Shift Left Logical Extended	3	BMI2				
SHR	Shift Right	3	Base				
SHRD	Shift Right Double	3	Base				
SHRX	Shift Right Logical Extended	3	BMI2				
SHUFPD	Shuffle Packed Double-Precision Floating-Point	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
SHUFPS	Shuffle Packed Single-Precision Floating-Point	3		SSE			
SIDT	Store Interrupt Descriptor Table Register	3					Base
SKINIT	Secure Init and Jump with Attestation	0					SKINIT
SLDT	Store Local Descriptor Table Register	3					Base
SMSW	Store Machine Status Word	3					Base
SQRTPD	Square Root Packed Double-Precision Floating-Point	3		SSE2			
SQRTPS	Square Root Packed Single-Precision Floating-Point	3		SSE			
SQRTSD	Square Root Scalar Double-Precision Floating-Point	3		SSE2			
SQRTSS	Square Root Scalar Single-Precision Floating-Point	3		SSE			
STC	Set Carry Flag	3	Base				
STD	Set Direction Flag	3	Base				
STGI	Set Global Interrupt Flag	0					SKINIT
STI	Set Interrupt Flag	3					Base
STMXCSR	Store MXCSR Control/Status Register	3		SSE			
STOS	Store String	3	Base				
STOSB	Store String Bytes	3	Base				
STOSD	Store String Doublewords	3	Base				
STOSQ	Store String Quadwords	3	LM				
STOSW	Store String Words	3	Base				
STR	Store Task Register	3					Base
SUB	Subtract	3	Base				

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
SUBPD	Subtract Packed Double-Precision Floating-Point	3		SSE2			
SUBPS	Subtract Packed Single-Precision Floating-Point	3		SSE			
SUBSD	Subtract Scalar Double-Precision Floating-Point	3		SSE2			
SUBSS	Subtract Scalar Single-Precision Floating-Point	3		SSE			
SWAPGS	Swap GS Register with KernelGSbase MSR	0					LM
SYSCALL	Fast System Call	3					SYSCALL, SYSRET
SYSENTER	System Call	3					SYS-ENTER, SYSEXIT
SYSEXIT	System Return	0					SYS-ENTER, SYSEXIT
SYSRET	Fast System Return	0					SYSCALL, SYSRET
T1MSKC	Inverse Mask From Trailing Ones	3	TBM				
TEST	Test Bits	3	Base				
TZCNT	Count Trailing Zeros	3	BMI1				
TZMSK	Mask From Trailing Zeros	3	TBM				
UCOMISD	Unordered Compare Scalar Double-Precision Floating-Point	3		SSE2			
UCOMISS	Unordered Compare Scalar Single-Precision Floating-Point	3		SSE			
UD2	Undefined Operation	3					Base
UNPCKHPD	Unpack High Double-Precision Floating-Point	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
UNPCKHPS	Unpack High Single-Precision Floating-Point	3		SSE			
UNPCKLPD	Unpack Low Double-Precision Floating-Point	3		SSE2			
UNPCKLPS	Unpack Low Single-Precision Floating-Point	3		SSE			
VADDPD	Add Packed Double-Precision Floating-Point	3		AVX			
VADDPS	Add Packed Single-Precision Floating-Point	3		AVX			
VADDSD	Add Scalar Double-Precision Floating-Point	3		AVX			
VADDSS	Add Scalar Single-Precision Floating-Point	3		AVX			
VADDSUBPD	Add and Subtract Double-Precision	3		AVX			
VADDSUBPS	Add and Subtract Single-Precision	3		AVX			
VAESDEC	AES Decryption Round	3		AVX			
VAESDECLAST	AES Last Decryption Round	3		AVX			
VAESEC	AES Encryption Round	3		AVX			
VAESENCLAST	AES Last Encryption Round	3		AVX			
VAESIMC	AES InvMixColumn Transformation	3		AVX			
VAESKEYGENASSIST	AES Assist Round Key Generation	3		AVX			
VANDNPD	AND NOT Packed Double-Precision Floating-Point	3		AVX			
VANDNPS	AND NOT Packed Single-Precision Floating-Point	3		AVX			
VANDPD	AND Packed Double-Precision Floating-Point	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VANDPS	AND Packed Single-Precision Floating-Point	3		AVX			
VBLENDPD	Blend Packed Double-Precision Floating-Point	3		AVX			
VBLENDPS	Blend Packed Single-Precision Floating-Point	3		AVX			
VBLENDVPD	Variable Blend Packed Double-Precision Floating-Point	3		AVX			
VBLENDVPS	Variable Blend Packed Single-Precision Floating-Point	3		AVX			
VBROADCASTF128	Load With Broadcast From 128-bit Memory Location	3		AVX			
VBROADCASTI128	Load With Broadcast Integer From 128-bit Memory Location	3		AVX2			
VBROADCASTSD	Load With Broadcast From 64-Bit Memory Location	3		AVX, AVX2 ⁴			
VBROADCASTSS	Load With Broadcast From 32-Bit Memory Location	3		AVX, AVX2 ⁴			
VCMPDPD	Compare Packed Double-Precision Floating-Point	3		AVX			
VCMPDPS	Compare Packed Single-Precision Floating-Point	3		AVX			
VCMPDSD	Compare Scalar Double-Precision Floating-Point	3		AVX			
VCMPDSS	Compare Scalar Single-Precision Floating-Point	3		AVX			
VCOMISD	Compare Ordered Scalar Double-Precision Floating-Point	3		AVX			
VCOMISS	Compare Ordered Scalar Single-Precision Floating-Point	3		AVX			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VCVTDQ2PD	Convert Packed Doubleword Integers to Packed Double-Precision Floating-Point	3		AVX			
VCVTDQ2PS	Convert Packed Doubleword Integers to Packed Single-Precision Floating-Point	3		AVX			
VCVTPD2DQ	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers	3		AVX			
VCVTPD2PS	Convert Packed Double-Precision Floating-Point to Packed Single-Precision Floating-Point	3		AVX			
VCVTPH2PS	Convert Packed 16-Bit Floating-Point to Single-Precision Floating-Point	3		AVX			
VCVTPS2DQ	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers	3		AVX			
VCVTPS2PD	Convert Packed Single-Precision Floating-Point to Packed Double-Precision Floating-Point	3		AVX			
VCVTPS2PH	Convert Packed Single-Precision Floating-Point to 16-Bit Floating-Point	3		AVX			
VCVTSD2SI	Convert Scalar Double-Precision Floating-Point to Signed Doubleword or Quadword Integer	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VCVTSD2SS	Convert Scalar Double-Precision Floating-Point to Scalar Single-Precision Floating-Point	3		AVX			
VCVTSI2SD	Convert Signed Doubleword or Quadword Integer to Scalar Double-Precision Floating-Point	3		AVX			
VCVTSI2SS	Convert Signed Doubleword or Quadword Integer to Scalar Single-Precision Floating-Point	3		AVX			
VCVTSS2SD	Convert Scalar Single-Precision Floating-Point to Scalar Double-Precision Floating-Point	3		AVX			
VCVTSS2SI	Convert Scalar Single-Precision Floating-Point to Signed Doubleword or Quadword Integer	3		AVX			
VCVTTPD2DQ	Convert Packed Double-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		AVX			
VCVTTPS2DQ	Convert Packed Single-Precision Floating-Point to Packed Doubleword Integers, Truncated	3		AVX			
VCVTTSD2SI	Convert Scalar Double-Precision Floating-Point to Signed Doubleword or Quadword Integer, Truncated	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VCVTSS2SI	Convert Scalar Single-Precision Floating-Point to Signed Doubleword or Quadword Integer, Truncated	3		AVX			
VDIVPD	Divide Packed Double-Precision Floating-Point	3		AVX			
VDIVPS	Divide Packed Single-Precision Floating-Point	3		AVX			
VDIVSD	Divide Scalar Double-Precision Floating-Point	3		AVX			
VDIVSS	Divide Scalar Single-Precision Floating-Point	3		AVX			
VDPPD	Dot Product Packed Double-Precision Floating-Point	3		AVX			
VDPPS	Dot Product Packed Single-Precision Floating-Point	3		AVX			
VERR	Verify Segment for Reads	3					Base
VERW	Verify Segment for Writes	3					Base
VEXTRACTF128	Extract Packed Values from 128-bit Memory Location	3		AVX			
VEXTRACTI128	Extract 128-bit Integer	3		AVX2			
VEXTRACTPS	Extract Packed Single-Precision Floating-Point	3		AVX			
VFMADDPD	Multiply and Add Packed Double-Precision Floating-Point	3		FMA4			
VFMADD132PD	Multiply and Add Packed Double-Precision Floating-Point	3		FMA			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VFMADD213PD	Multiply and Add Packed Double-Precision Floating-Point	3		FMA			
VFMADD231PD	Multiply and Add Packed Double-Precision Floating-Point	3		FMA

Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VMOVNTDQA	Move Non-Temporal Double Quadword Aligned	3		AVX, AVX2 ⁴			
VMOVNTPD	Move Non-Temporal Packed Double-Precision Floating-Point	3		AVX			
VMOVNTPS	Move Non-Temporal Packed Single-Precision Floating-Point	3		AVX			
VMOVQ	Move Quadword	3		AVX			
VMOVSD	Move Scalar Double-Precision Floating-Point	3		AVX			
VMOVSHDUP	Move Single-Precision High and Duplicate	3		AVX			
VMOVSLDUP	Move Single-Precision Low and Duplicate	3		AVX			
VMOVSS	Move Scalar Single-Precision Floating-Point	3		AVX			
VMOVUPD	Move Unaligned Packed Double-Precision Floating-Point	3		AVX			
VMOVUPS	Move Unaligned Packed Single-Precision Floating-Point	3		AVX			
VMPSADBW	Multiple Sum of Absolute Differences	3		AVX, AVX2 ⁴			
VMULPD	Multiply Packed Double-Precision Floating-Point	3		AVX			
VMULPS	Multiply Packed Single-Precision Floating-Point	3		AVX			
VMULSD	Multiply Scalar Double-Precision Floating-Point	3		AVX			
VMULSS	Multiply Scalar Single-Precision Floating-Point	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VORPD	Logical Bitwise OR Packed Double-Precision Floating-Point	3		AVX			
VORPS	Logical Bitwise OR Packed Single-Precision Floating-Point	3		AVX			
VPABSB	Packed Absolute Value Signed Byte	3		AVX, AVX2 ⁴			
VPABSD	Packed Absolute Value Signed Doubleword	3		AVX, AVX2 ⁴			
VPABSW	Packed Absolute Value Signed Word	3		AVX, AVX2 ⁴			
VPACKSSDW	Pack with Saturation Signed Doubleword to Word	3		AVX, AVX2 ⁴			
VPACKSSWB	Pack with Saturation Signed Word to Byte	3		AVX, AVX2 ⁴			
VPACKUSDW	Pack with Unsigned Saturation Doubleword to Word	3		AVX, AVX2 ⁴			
VPACKUSWB	Pack with Saturation Signed Word to Unsigned Byte	3		AVX, AVX2 ⁴			
VPADDB	Packed Add Bytes	3		AVX, AVX2 ⁴			
VPADDD	Packed Add Doublewords	3		AVX, AVX2 ⁴			
VPADDQ	Packed Add Quadwords	3		AVX, AVX2 ⁴			
VPADDSB	Packed Add Signed with Saturation Bytes	3		AVX, AVX2 ⁴			
VPADDSW	Packed Add Signed with Saturation Words	3		AVX, AVX2 ⁴			
VPADDUSB	Packed Add Unsigned with Saturation Bytes	3		AVX, AVX2 ⁴			
VPADDUSW	Packed Add Unsigned with Saturation Words	3		AVX, AVX2 ⁴			
VPADDW	Packed Add Words	3		AVX, AVX2 ⁴			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPALIGNR	Packed Align Right	3		AVX, AVX2 ⁴			
VPAND	Packed Logical Bitwise AND	3		AVX, AVX2 ⁴			
VPANDN	Packed Logical Bitwise AND NOT	3		AVX, AVX2 ⁴			
VPAVGB	Packed Average Unsigned Bytes	3		AVX, AVX2 ⁴			
VPAVGW	Packed Average Unsigned Words	3		AVX, AVX2 ⁴			
VPBLENDQ	Blend Packed Doublewords	3		AVX2			
VPBLENDVB	Variable Blend Packed Bytes	3		AVX, AVX2 ⁴			
VPBLENDW	Blend Packed Words	3		AVX, AVX2 ⁴			
VPBROADCASTB	Broadcast Packed Byte	3		AVX2			
VPBROADCASTD	Broadcast Packed Doubleword	3		AVX2			
VPBROADCASTQ	Broadcast Packed Quadword	3		AVX2			
VPBROADCASTW	Broadcast Packed Word	3		AVX2			
VPCLMULQDQ	Carry-less Multiply Quadwords	3		CLMUL AVX			
VPCMOV	Vector Conditional Move	3		XOP			
VPCMPEQB	Packed Compare Equal Bytes	3		AVX, AVX2 ⁴			
VPCMPEQD	Packed Compare Equal Doublewords	3		AVX, AVX2 ⁴			
VPCMPEQQ	Packed Compare Equal Quadwords	3		AVX, AVX2 ⁴			
VPCMPEQW	Packed Compare Equal Words	3		AVX, AVX2 ⁴			
VPCMPESTRI	Packed Compare Explicit Length Strings Return Index	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPCMPESTRM	Packed Compare Explicit Length Strings Return Mask	3		AVX			
VPCMPGTB	Packed Compare Greater Than Signed Bytes	3		AVX, AVX2 ⁴			
VPCMPGTD	Packed Compare Greater Than Signed Doublewords	3		AVX, AVX2 ⁴			
VPCMPGTQ	Packed Compare Greater Than Signed Quadwords	3		AVX, AVX2 ⁴			
VPCMPGTW	Packed Compare Greater Than Signed Words	3		AVX, AVX2 ⁴			
VPCMPISTRM	Packed Compare Implicit Length Strings Return Mask	3		AVX			
VPCMPISTRM	Packed Compare Implicit Length Strings Return Mask	3		AVX			
VPCOMB	Compare Vector Signed Bytes	3		XOP			
VPCOMD	Compare Vector Signed Doublewords	3		XOP			
VPCOMQ	Compare Vector Signed Quadwords	3		XOP			
VPCOMUB	Compare Vector Unsigned Bytes	3		XOP			
VPCOMUD	Compare Vector Unsigned Doublewords	3		XOP			
VPCOMUQ	Compare Vector Unsigned Quadwords	3		XOP			
VPCOMUW	Compare Vector Unsigned Words	3		XOP			
VPCOMW	Compare Vector Signed Words	3		XOP			
VPERM2F128	Permute Floating-Point 128-bit	3		AVX			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPERM2I128	Permute Integer 128-bit	3		AVX2			
VPERMD	Packed Permute Doubleword	3		AVX2			
VPERMIL2PD	Permute Two-Source Double-Precision Floating-Point	3		XOP			
VPERMIL2PS	Permute Two-Source Single-Precision Floating-Point	3		XOP			
VPERMILPD	Permute Double-Precision	3		AVX			
VPERMILPS	Permute Single-Precision	3		AVX			
VPERMPD	Packed Permute Double-Precision Floating-Point	3		AVX2			
VPERMPS	Packed Permute Single-Precision Floating-Point	3		AVX2			
VPERMQ	Packed Permute Quadword	3		AVX2			
VPEXTRB	Extract Packed Byte	3		AVX			
VPEXTRD	Extract Packed Doubleword	3		AVX

VPEXTRW	Packed Extract Word	3		AVX			
VPGATHERDD	Conditionally Gather Doublewords, Doubleword Indices	3		AVX2			
VPGATHERDQ	Conditionally Gather Quadwords, Doubleword Indices	3		AVX2			
VPGATHERQD	Conditionally Gather Doublewords, Quadword Indices	3		AVX2			
VPGATHERQQ	Conditionally Gather Quadwords, Quadword Indices	3		AVX2			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPHADDBD	Packed Horizontal Add Signed Byte to Signed Doubleword	3		XOP			
VPHADDBQ	Packed Horizontal Add Signed Byte to Signed Quadword	3		XOP			
VPHADDBW	Packed Horizontal Add Signed Byte to Signed Word	3		XOP			
VPHADDD	Packed Horizontal Add Doubleword	3		AVX, AVX2 ⁴			
VPHADDDQ	Packed Horizontal Add Signed Doubleword to Signed Quadword	3		XOP			
VPHADDSW	Packed Horizontal Add with Saturation Word	3		AVX, AVX2 ⁴			
VPHADDUBD	Packed Horizontal Add Unsigned Byte to Doubleword	3		XOP			
VPHADDUBQ	Packed Horizontal Add Unsigned Byte to Quadword	3		XOP			
VPHADDUBW	Packed Horizontal Add Unsigned Byte to Word	3		XOP			
VPHADDUDQ	Packed Horizontal Add Unsigned Doubleword to Quadword	3		XOP			
VPHADDUWD	Packed Horizontal Add Unsigned Word to Doubleword	3		XOP			
VPHADDUWQ	Packed Horizontal Add Unsigned Word to Quadword	3		XOP			
VPHADDW	Packed Horizontal Add Word	3		AVX, AVX2 ⁴			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPHADDWD	Packed Horizontal Add Signed Word to Signed Doubleword	3		XOP			
VPHADDWQ	Packed Horizontal Add Signed Word to Signed Quadword	3		XOP			
VPHMINPOSUW	Horizontal Minimum and Position	3		AVX			
VPHSUBBW	Packed Horizontal Subtract Signed Byte to Signed Word	3		XOP			
VPHSUBD	Packed Horizontal Subtract Doubleword	3		AVX, AVX2 ⁴			
VPHSUBDQ	Packed Horizontal Subtract Signed Doubleword to Signed Quadword	3		XOP			
VPHSUBSW	Packed Horizontal Subtract with Saturation Word	3		AVX, AVX2 ⁴			
VPHSUBW	Packed Horizontal Subtract Word	3		AVX, AVX2 ⁴			
VPHSUBWD	Packed Horizontal Subtract Signed Word to Signed Doubleword	3		XOP			
VPINSRB	Packed Insert Byte	3		AVX			
VPINSRD	Packed Insert Doubleword	3		AVX			
VPINSRQ	Packed Insert Quadword	3		AVX			
VPINSRW	Packed Insert Word	3		AVX			
VPMACSDD	Packed Multiply Accumulate Signed Doubleword to Signed Doubleword	3		XOP			
VPMACSDQH	Packed Multiply Accumulate Signed High Doubleword to Signed Quadword	3		XOP			

Notes:

1. Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
2. Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
3. MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
4. One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
VPMACSDQL	Packed Multiply Accumulate Signed Low Doubleword to Signed Quadword	3		XOP			
VPMACSSDD	Packed Multiply Accumulate with Saturation Signed Doubleword to Signed Doubleword	3		XOP			
VPMACSSDQH	Packed Multiply Accumulate with Saturation Signed High Doubleword to Signed Quadword	3		XOP			
VPMACSSDQL	Packed Multiply Accumulate with Saturation Signed Low Doubleword to Signed Quadword	3		XOP			
VPMACSSWD	Packed Multiply Accumulate with Saturation Signed Word to Signed Doubleword	3		XOP

VUNPCKHPS	Unpack High Single-Precision Floating-Point	3		AVX			
VUNPCKLPD	Unpack Low Double-Precision Floating-Point	3		AVX			
VUNPCKLPS	Unpack Low Single-Precision Floating-Point	3		AVX			
VXORPD	Logical Bitwise Exclusive OR Packed Double-Precision Floating-Point	3		AVX			
VXORPS	Logical Bitwise Exclusive OR Packed Single-Precision Floating-Point	3		AVX			
VZEROALL	Zero All YMM Registers	3		AVX			
VZERoupper	Zero All YMM Registers Upper	3		AVX			
WAIT	Wait for x87 Floating-Point Exceptions	3				X87	
WBINVD	Writeback and Invalidate Caches	0					Base
WRFSBASE	Write FS.base	3					FSGSBASE
WRGSBASE	Write GS.base	3					FSGSBASE
WRMSR	Write to Model-Specific Register	0					MSR
XADD	Exchange and Add	3	Base				
XCHG	Exchange	3	Base				
XGETBV	Get Extended Control Register Value	3		XSAVE			
XLAT	Translate Table Index	3	Base				
XLATB	Translate Table Index (No Operands)	3	Base				
XOR	Exclusive OR	3	Base				
XORPD	Logical Bitwise Exclusive OR Packed Double-Precision Floating-Point	3		SSE2			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. "Base" indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Table D-2. Instruction Groups and CPUID Feature Flags

Instruction			Instruction Group and CPUID Feature Flag(s) ¹				
Mnemonic	Description	CPL	General-Purpose	SSE	64-Bit Media	x87	System
XORPS	Logical Bitwise Exclusive OR Packed Single-Precision Floating-Point	3		SSE			
XRSTOR	Restore Extended States	3		XSAVE			
XSAVE	Save Extended States	3		XSAVE			
XSAVEOPT	Save Extended States Performance Optimized	3		XSAVEOPT			
XSETBV	Set Extended Control Register Value	3		XSAVE			

Notes:

- Columns indicate the instruction groups. Entries indicate the CPUID feature flags(s) indicating support for that instruction. “Base” indicates that no feature flag exists and all processors support this instruction.
- Mnemonic is used for two different instructions. Assemblers can distinguish them by the number and type of operands.
- MONITOR/MWAIT can execute at privilege level >0 if enabled. See instruction description.
- One or more features of the instruction (usually support for 256-bit operands) are only available if AVX2 is supported.

Appendix E Obtaining Processor Information Via the CPUID Instruction

This appendix specifies the information that software can obtain about the processor on which it is running by executing the CPUID instruction. The information in this appendix supersedes the contents of the *CPUID Specification*, order #25481, which is now obsolete.

The CPUID instruction is described on page 153. This appendix does not replace the CPUID instruction reference information presented there.

The CPUID instruction behaves much like a function call. Parameters are passed to the instruction via registers and on execution the instruction loads specific registers with return values. These return values can be interpreted by software based on the field definitions and their assigned meanings.

The first input parameter is the *function number* which is passed to the instruction via the EAX register. Some functions also accept a second input parameter passed via the ECX register. Values are returned via the EAX, EBX, ECX, and EDX registers. Software should not assume that any values written to these registers prior to the execution of CPUID instruction will be retained after the instruction executes (even those that are marked reserved).

The description of each return value breaks the value down into one or more named *fields* which represent a bit position or contiguous range of bits. All bit positions that are not defined as fields are reserved. The value of bits within reserved ranges cannot be relied upon to be zero. Software must mask off all reserved bits in the return value prior to making any value comparisons of represented information.

This appendix applies to all AMD processors with a family designation of 0Fh or greater.

E.1 Special Notational Conventions

The following special notation conventions are used in this appendix:

- The notation (standard throughout this APM) for representing the function number, optional input parameter, and the information returned is as follows:

CPUID FnXXXX_XXXX_RRR[FieldName]_xYYY.

Where:

- XXXX_XXXX is the function number represented in hexadecimal (passed to the instruction in EAX).
- RRR is one of {EDX, ECX, EBX, EAX} and represents a register holding a return value.
- YYY represents the optional input parameter passed in the ECX register expressed as a hexadecimal number. If this parameter is not used, the characters represented by _xYYY are omitted from the notation.

- *FieldName* identifies a specific named element of processor information represented by a specific bit range (1 or more bits wide) within the *RRR* register.
- The notation CPUID FnXXXX_XXXX_RRR is used when referring to one of the registers that holds information returned by the instruction.
- The notation CPUID FnXXXX_XXXX or FnXXXX_XXXX is used to refer to a specific function number.
- Most one-bit fields indicate support or non-support of a specific processor feature. By convention, (unless otherwise noted) a value of 1 means that the feature is supported by the processor and a value of 0 means that the feature is not supported by the processor.

E.2 Standard and Extended Function Numbers

The CPUID instruction supports two sets or ranges of function numbers: standard and extended.

- The smallest function number of the standard function range is Fn0000_0000. The largest function number of the standard function range, for a particular implementation, is returned in CPUID Fn0000_0000_EAX.
- The smallest function number of the extended function range is Fn8000_0000. The largest function number of the extended function range, for a particular implementation, is returned in CPUID Fn8000_0000_EAX.

E.3 Standard Feature Function Numbers

This section describes each of the defined CPUID functions in the standard range.

E.3.1 Function 0h—Maximum Standard Function Number and Vendor String

This function number provides information about the maximum standard function number supported on this processor and a string that identifies the vendor of the product.

CPUID Fn0000_0000_EAX Largest Standard Function Number

The value returned in EAX provides the largest standard function number supported by this processor.

Bits	Field Name	Description
31:0	LFuncStd	Largest standard function. The largest CPUID standard function input value supported by the processor implementation.

CPUID Fn0000_0000_E[D,C,B]X Processor Vendor

The values returned in EBX, EDX, and ECX together provide a 12-character string identifying the vendor of this processor. Each register supplies 4 characters. The leftmost character of each substring

is stored in the least significant bit position in the register. The string is the concatenation of the contents of EBX, EDX, and ECX in left to right order. No null terminator is included in the string.

`CPUID Fn8000_0000_E[D,C,B]X` return the same values as this function.

Bits	Field Name	Description
31:0	Vendor	Four characters of the 12-byte character string (encoded in ASCII) "AuthenticAMD". See Table E-1 below.

Table E-1. CPUID Fn0000_0000_E[D,C,B]X values

Register	Value	Description
CPUID Fn0000_0000_EBX	6874_7541h	The ASCII characters "h t u A".
CPUID Fn0000_0000_ECX	444D_4163h	The ASCII characters "D M A c".
CPUID Fn0000_0000_EDX	6974_6E65h	The ASCII characters "i t n e".

E.3.2 Function 1h—Processor and Processor Feature Identifiers

This function number identifies the processor family, model, and stepping and provides feature support information.

CPUID Fn0000_0001_EAX Family, Model, Stepping Identifiers

The value returned in EAX provides the family, model, and stepping identifiers. Three values are used by software to identify a processor: Family, Model, and Stepping.

Bits	Field Name	Description
31:28	—	Reserved.
27:20	ExtFamily	Processor extended family. See above for definition of Family[7:0].
19:16	ExtModel	Processor extended model. See above for definition of Model[7:0].
15:12	—	Reserved.
11:8	BaseFamily	Base processor family. See above for definition of Family[7:0].
7:4	BaseModel	Base processor model. See above for definition of Model[7:0].
3:0	Stepping	Processor stepping. Processor stepping (revision) for a specific model.

The processor *Family* identifies one or more processors as belonging to a group that possesses some common definition for software or hardware purposes. The *Model* specifies one instance of a processor family. The *Stepping* identifies a particular version of a specific model. Therefore, Family, Model and Stepping, when taken together, form a unique identification or signature for a processor.

The **Family** is an 8-bit value and is defined as: **Family[7:0]** = ({0000b,BaseFamily[3:0]} + ExtFamily[7:0]). For example, if BaseFamily[3:0] = Fh and ExtFamily[7:0] = 01h, then Family[7:0] =

10h. If BaseFamily[3:0] is less than Fh, then ExtFamily is reserved and Family is equal to BaseFamily[3:0].

Model is an 8-bit value and is defined as: **Model[7:0]** = {ExtModel[3:0],BaseModel[3:0]}. For example, if ExtModel[3:0] = Eh and BaseModel[3:0] = 8h, then Model[7:0] = E8h. If BaseFamily[3:0] is less than 0Fh, then ExtModel is reserved and Model is equal to BaseModel[3:0].

The value returned by [CPUID Fn8000_0001_EAX](#) is equivalent to [CPUID Fn0000_0001_EAX](#).

CPUID Fn0000_0001_EBX LocalApicId, LogicalProcessorCount, CLFlush

The value returned in EBX provides miscellaneous information regarding the processor brand, the number of logical threads per processor socket, the CLFLUSH instruction, and APIC.

Bits	Field Name	Description
31:24	LocalApicId	Initial local APIC physical ID. The 8-bit value assigned to the local APIC physical ID register at power-up. Some of the bits of LocalApicId represent the core within a processor and other bits represent the processor ID. See the APIC20 “APIC ID” register in the processor BKDG for details.
23:16	LogicalProcessorCount	Logical processor count. If CPUID Fn0000_0001_EDX[HTT] = 1 then LogicalProcessorCount is the number of cores per processor. If CPUID Fn0000_0001_EDX[HTT] = 0 then LogicalProcessorCount is reserved. See E.5.1 [Legacy Method].
15:8	CLFlush	CLFLUSH size. Specifies the size of a cache line in quadwords flushed by the CLFLUSH instruction. See “CLFLUSH” in APM3.
7:0	8BitBrandId	8-bit brand ID. This field, in conjunction with CPUID Fn8000_0001_EBX[BrandId] , is used by the system firmware to generate the processor name string. See the appropriate processor revision guide for how to program the processor name string.

CPUID Fn0000_0001_ECX Feature Identifiers

The value returned in ECX contains the following miscellaneous feature identifiers:

Bits	Field Name	Description
31	—	RAZ. Reserved for use by hypervisor to indicate guest status.
30	RDRAND	RDRAND instruction support.
29	F16C	Half-precision convert instruction support. See “Half-Precision Floating-Point Conversion” in APM1 and listings for individual F16C instructions in APM4.
28	AVX	AVX instruction support. See APM4.
27	OSXSAVE	XSAVE (and related) instructions are enabled. See “OSXSAVE” in APM2. .
26	XSAVE	XSAVE (and related) instructions are supported by hardware. See “XSAVE/XRSTOR Instructions” in APM2.

Bits	Field Name	Description
25	AES	AES instruction support. See “AES Instructions” in APM4.
24	—	Reserved.
23	POPCNT	POPCNT instruction. See “POPCNT” in APM3.
22		MOVBE: MOVBE instruction support.
21	—	Reserved.
20	SSE42	SSE4.2 instruction support. "Determining Media and x87 Feature Supprt" in APM2 and individual SSE4.2 instruction listings in APM4.
19	SSE41	SSE4.1 instruction support. See individual instruction listings in APM4. .
18:14	—	Reserved.
13	CMPXCHG16B	CMPXCHG16B instruction support. See “CMPXCHG16B” in APM3.
12	FMA	FMA instruction support.
11:10	—	Reserved.
9	SSSE3	Supplemental SSE3 instruction support.
8:4	—	Reserved.
3	MONITOR	MONITOR/MWAIT instructions. See “MONITOR” and “MWAIT” in APM3.
2	—	Reserved.
1	PCLMULQDQ	PCLMULQDQ instruction support. See instruction reference page for the PCLMULQDQ / VPCLMULQDQ instruction in APM4.
0	SSE3	SSE3 instruction support. See Appendix D “Instruction Subsets and CPUID Feature Sets” in APM3 for the list of instructions covered by the SSE3 feature bit. See APM4 for the definition of the SSE3 instructions.

CPUID Fn0000_0001_EDX Feature Identifiers

The value returned in EDX contains the following miscellaneous feature identifiers:

Bits	Field Name	Description
31:29	—	Reserved.
28	HTT	Hyper-threading technology. Indicates either that there is more than one thread per core or more than one core per processor. See “Legacy Method” on page 620.
27	—	Reserved.
26	SSE2	SSE2 instruction support. See Appendix D “CPUID Feature Sets” in APM3.
25	SSE	SSE instruction support. See Appendix D “CPUID Feature Sets” in APM3 appendix and “64-Bit Media Programming” in APM1.
24	FXSR	FXSAVE and FXRSTOR instructions. See “FXSAVE” and “FXRSTOR” in APM4.
23	MMX	MMX™ instructions. See Appendix D “CPUID Feature Sets” in APM3 and “128-Bit Media and Scientific Programming” in APM1.
22:20	—	Reserved.
19	CLFSH	CLFLUSH instruction support. See “CLFLUSH” in APM3.

Bits	Field Name	Description
18	—	Reserved.
17	PSE36	Page-size extensions. The PDE[20:13] supplies physical address [39:32]. See “Page Translation and Protection” in APM2.
16	PAT	Page attribute table. See “Page-Attribute Table Mechanism” in APM2.
15	CMOV	Conditional move instructions. See “CMOV”, “FCMOV” in APM3.
14	MCA	Machine check architecture. See “Machine Check Mechanism” in APM2.
13	PGE	Page global extension. See “Page Translation and Protection” in APM2.
12	MTRR	Memory-type range registers. See “Page Translation and Protection” in APM2.
11	SysEnterSysExit	SYSENTER and SYSEXIT instructions. See “SYSENTER”, “SYSEXIT” in APM3.
10	—	Reserved.
9	APIC	Advanced programmable interrupt controller. Indicates APIC exists and is enabled. See “Exceptions and Interrupts” in APM2.
8	CMPXCHG8B	CMPXCHG8B instruction. See “CMPXCHG8B” in APM3.
7	MCE	Machine check exception. See “Machine Check Mechanism” in APM2.
6	PAE	Physical-address extensions. Indicates support for physical addresses ³ 32b. Number of physical address bits above 32b is implementation specific. See “Page Translation and Protection” in APM2.
5	MSR	AMD model-specific registers. Indicates support for AMD model-specific registers (MSRs), with RDMSR and WRMSR instructions. See “Model Specific Registers” in APM2.
4	TSC	Time stamp counter. RDTSC and RDTSCP instruction support. See “Debug and Performance Resources” in APM2.
3	PSE	Page-size extensions. See “Page Translation and Protection” in APM2.
2	DE	Debugging extensions. See “Debug and Performance Resources” in APM2.
1	VME	Virtual-mode enhancements. CR4.VME, CR4.PVI, software interrupt indirection, expansion of the TSS with the software, indirection bitmap, EFLAGS.VIF, EFLAGS.VIP. See “System Resources” in APM2.
0	FPU	x87 floating point unit on-chip. See “x87 Floating Point Programming” in APM1.

E.3.3 Functions 2h–4h—Reserved

CPUID Fn0000_000[4:2] Reserved

These function numbers are reserved.

E.3.4 Function 5h—Monitor and MWait Features

This function provides feature identifiers for the MONITOR and MWAIT instructions. For more information see the description of the MONITOR instruction on page 375 and the MWAIT instruction on page 381.

CPUID Fn0000_0005_EAX Monitor/MWait

The value returned in EAX provides the following information:

Bits	Field Name	Description
31:16	—	Reserved.
15:0	MonLineSizeMin	Smallest monitor-line size in bytes.

CPUID Fn0000_0005_EBX Monitor/MWait

The value returned in EBX provides the following information:

Bits	Field Name	Description
31:16	—	Reserved.
15:0	MonLineSizeMax	Largest monitor-line size in bytes.

CPUID Fn0000_0005_ECX Monitor/MWait

The value returned in ECX provides the following information:

Bits	Field Name	Description
31:2	—	Reserved.
1	IBE	Interrupt break-event. Indicates MWAIT can use ECX bit 0 to allow interrupts to cause an exit from the monitor event pending state, even if EFLAGS.IF=0.
0	EMX	Enumerate MONITOR/MWAIT extensions: Indicates enumeration MONITOR/MWAIT extensions are supported.

CPUID Fn0000_0005_EDX Monitor/MWait

The value returned in EDX is undefined and is reserved.

E.3.5 Function 6h—Power Management Related Features

This function provides information about the local APIC timer timebase and the effective frequency interface for the processor.

CPUID Fn0000_0006_EAX Local APIC Timer Invariance

The value returned in EAX is undefined and is reserved.

Bits	Field Name	Description
31:3	—	Reserved.
2	ARAT	If set, indicates that the timebase for the local APIC timer is not affected by processor p-state.
1:0	—	Reserved.

CPUID Fn0000_0006_EBX Reserved

The value returned in EBX is undefined and is reserved.

CPUID Fn0000_0006_ECX Effective Processor Frequency Interface

The value returned in ECX indicates support of the processor effective frequency interface. For more information on this feature, see "Determining Processor Effective Frequency" in APM2.

Bits	Field Name	Description
31:1	—	Reserved.
0	EffFreq	Effective frequency interface support. If set, indicates presence of MSR0000_00E7 (MPERF) and MSR0000_00E8 (APERF).

CPUID Fn0000_0006_EDX Reserved

The value returned in EDX is undefined and is reserved.

E.3.6 Function 7h—Structured Extended Feature Identifiers

CPUID Fn0000_0007_EAX_x0 Structured Extended Feature Identifiers (ECX=0)

Bits	Field Name	Description
31:0	MaxSubFn	Returns the number of subfunctions supported. Currently equal to 1.

CPUID Fn0000_0007_EBX_x0 Structured Extended Feature Identifiers (ECX=0)

Bits	Field Name	Description
31:9	—	Reserved.
8	BMI2	Bit manipulation group 2 instruction support.
7	SMEP	Supervisor mode execution protection.
6	—	Reserved.
5	AVX2	AVX2 instruction subset support.
4	—	Reserved.
3	BMI1	Bit manipulation group 1 instruction support.

Bits	Field Name	Description
2:1	—	Reserved.
0	FSGSBASE	FS and GS base read write instruction support.

CPUID Fn0000_0007_ECX_x0 Structured Extended Feature Identifiers (ECX=0)

Bits	Field Name	Description
31:0	—	Reserved.

CPUID Fn0000_0007_EDX_x0 Structured Extended Feature Identifiers (ECX=0)

Bits	Field Name	Description
31:0	—	Reserved.

E.3.7 Functions 8h–Ch—Reserved

CPUID Fn0000_000[C:8] Reserved

These function numbers are reserved.

E.3.8 Function Dh—Processor Extended State Enumeration

The XSAVE / XRSTOR instructions are used to save and restore x87/MMX FPU and SSE processor state. These instructions allow processor state associated with specific architected features to be selectively saved and restored. This function provides information about extended state support and save area size requirements.

The function has a number of subfunctions specified by the input value passed to the CPUID instruction in the ECX register.

Subfunction 0 of Fn0000_000D

Subfunction 0 provides information about features within the extended processor state management architecture that are supported by the processor.

CPUID Fn0000_000D_EAX_x0 Processor Extended State Enumeration (ECX=0)

The value returned in EAX provides a bit mask specifying which of the features defined by the extended processor state architecture are supported by the processor.

Bits	Field Name	Description
31:0	XFeatureSupportedMask[31:0]	Reports the valid bit positions for the lower 32 bits of the XFeatureEnabledMask register. If a bit is set, the corresponding feature is supported. See “XSAVE/XRSTOR Instructions” in APM2.

CPUID Fn0000_000D_EBX_x0 Processor Extended State Enumeration (ECX=0)

The value returned in EBX gives the save area size requirement in bytes based on the features currently enabled in the XFEATURE_ENABLED_MASK (XCR0).

Bits	Field Name	Description
31:0	XFeatureEnabledSizeMax	Size in bytes of XSAVE/XRSTOR area for the currently enabled features in XCR0.

CPUID Fn0000_000D_ECX_x0 Processor Extended State Enumeration (ECX=0)

The value returned in ECX gives the save area size requirement in bytes for all extended state management features supported by the processor (whether enabled or not).

Bits	Field Name	Description
31:0	XFeatureSupportedSizeMax	Size in bytes of XSAVE/XRSTOR area for all features that the core supports. See XFeatureEnabledSizeMax.

CPUID Fn0000_000D_EDX_x0 Processor Extended State Enumeration (ECX=0)

The value returned in EDX provides a bit mask specifying which of the features defined by the extended processor state architecture are supported by the processor.

Bits	Field Name	Description
31:0	XFeatureSupportedMask[63:32]	Reports the valid bit positions for the upper 32 bits of the XFeatureEnabledMask register. If a bit is set, the corresponding feature is supported.

See “XSAVE/XRSTOR Instructions” in APM2 and reference pages for the individual instructions in APM4.

Subfunction 1 of Fn0000_000D

Subfunction 1 provides additional information about features within the extended processor state management architecture that are supported by the processor.

CPUID Fn0000_000D_EAX_x1 Processor Extended State Enumeration (ECX=1)

Bits	Field Name	Description
31:1		Reserved.
0	XSAVEOPT	XSAVEOPT is available.

CPUID Fn0000_000D_E[D,C,B]X_x1 Processor Extended State Enumeration (ECX=1)

The values returned in EBX, ECX, and EDX for subfunction 1 are undefined and are reserved.

Subfunction 2 of Fn0000_000D

Subfunction 2 provides information about the size and offset of the 256-bit SSE vector floating point processor unit state save area.

CPUID Fn0000_000D_EAX_x2 Processor Extended State Enumeration (ECX=2)

The value returned in EAX provides information about the size of the 256-bit SSE vector floating point processor unit state save area.

Bits	Field Name	Description
31:0	YmmSaveStateSize	YMM state save size. The state save area size in bytes for The YMM registers.

CPUID Fn0000_000D_EBX_x2 Processor Extended State Enumeration (ECX=2)

The value returned in EBX provides information about the offset of the 256-bit SSE vector floating point processor unit state save area from the base of the extended state (XSAVE/XRSTOR) save area.

Bits	Field Name	Description
31:0	YmmSaveStateOffset	YMM state save offset. The offset in bytes from the base of the extended state save area of the YMM register state save area.

CPUID Fn0000_000D_E[D,C]X_x2 Processor Extended State Enumeration (ECX=2)

The values returned in ECX and EDX for subfunction 2 are undefined and are reserved.

If CPUID Fn0000_000D is executed with a subfunction (passed in ECX) greater than 2 but less than 3Eh, the instruction returns all zeros in the EAX, EBX, ECX, and EDX registers.

Subfunction 3Eh of Fn0000_000D

Subfunction 3Eh provides information about the size and offset of the Lightweight Profiling (LWP) unit state save area.

CPUID Fn0000_000D_EAX_x3E Processor Extended State Enumeration (ECX=62)

The value returned in EAX provides the size of the Lightweight Profiling (LWP) unit state save area.

Bits	Field Name	Description
31:0	LwpSaveStateSize	LWP state save area size. The size of the save area for LWP state in bytes. See “Lightweight Profiling” in APM2.

CPUID Fn0000_000D_EBX_x3E Processor Extended State Enumeration (ECX=62)

The value returned in EBX provides the offset of the Lightweight Profiling (LWP) unit state save area from the base of the extended state (XSAVE/XRSTOR) save area.

Bits	Field Name	Description
31:0	LwpSaveStateOffset	LWP state save byte offset. The offset in bytes from the base of the extended state save area of the state save area for LWP. See “Lightweight Profiling” in APM2.

CPUID Fn0000_000D_E[D,C]X_x3E Processor Extended State Enumeration (ECX=62)

The values returned in ECX and EDX for subfunction 3Eh are undefined and are reserved.

Subfunctions of Fn0000_000D greater than 3Eh

For CPUID Fn0000_000D, if the subfunction (specified by contents of ECX) passed as input to the instruction is greater than 3Eh, the instruction returns zero in the EAX, EBX, ECX, and EDX registers.

E.3.9 Functions 4000_0000h–4000_FFh—Reserved for Hypervisor Use**CPUID Fn4000_00[FF:00] Reserved**

These function numbers are reserved for use by the virtual machine monitor.

E.4 Extended Feature Function Numbers

This section describes each of the defined CPUID functions in the extended range.

E.4.1 Function 8000_0000h—Maximum Extended Function Number and Vendor String

This function provides information about the maximum extended function number supported on this processor and a string that identifies the vendor of the product.

CPUID Fn8000_0000_EAX Largest Extended Function Number

The value returned in EAX provides the largest extended function number supported by the processor.

Bits	Field Name	Description
31:0	LFuncExt	Largest extended function. The largest CPUID extended function input value supported by the processor implementation.

CPUID Fn8000_0000_E[D,C,B]X Processor Vendor

The values returned in EBX, ECX, and EDX together provide a 12-character string identifying the vendor of this processor. The output string is the same as the one returned by Fn0000_0000. See [CPUID Fn0000_0000_E\[D,C,B\]X](#) on page 590 for more details.

Bits	Field Name	Description
31:0	Vendor	Four characters of the 12-byte character string (encoded in ASCII) “AuthenticAMD”. See Table E-2 below.

Table E-2. CPUID Fn8000_0000_E[D,C,B]X values

Register	Value	Description
CPUID Fn8000_0000_EBX	6874_7541h	The ASCII characters “h t u A”.
CPUID Fn8000_0000_ECX	444D_4163h	The ASCII characters “D M A c”.
CPUID Fn8000_0000_EDX	6974_6E65h	The ASCII characters “i t n e”.

E.4.2 Function 8000_0001h—Extended Processor and Processor Feature Identifiers

CPUID Fn8000_0001_EAX AMD Family, Model, Stepping

The value returned in EAX provides the family, model, and stepping identifiers. Three values are used by software to identify a processor: Family, Model, and Stepping. The value returned in EAX is the same as the value returned in EAX for Fn0000_0001. See [CPUID Fn0000_0001_EAX](#) on page 591 for more details on the field definitions.

Bits	Field Names	Description
31:0	Family, Model, Stepping	See: CPUID Fn0000_0001_EAX .

CPUID Fn8000_0001_EBX BrandId Identifier

The value returned in EBX provides package type and a 16-bit processor name string identifiers.

Bits	Field Name	Description
31:28	PkgType	Package type. If (Family[7:0] >= 10h), this field is valid. If (Family[7:0] < 10h), this field is reserved.
27:16	—	Reserved.
15:0	BrandId	Brand ID. This field, in conjunction with CPUID Fn0000_0001_EBX[8BitBrandId] , is used by system firmware to generate the processor name string. See your processor revision guide for how to program the processor name string.

For processor families 10h and greater, PkgType is described in the *BIOS and Kernel Developer's Guide* for the product.

CPUID Fn8000_0001_ECX Feature Identifiers

This function contains the following miscellaneous feature identifiers:

Bits	Field Name	Description
31:28	—	Reserved.
27	PerfTsc	Performance time-stamp counter. Indicates support for MSRC001_0280 [Performance Time Stamp Counter].
26	DataBreakpointExtension	Data access breakpoint extension. Indicates support for MSRC001_1027 and MSRC001_101[B:9].
25	—	Reserved
24	PerfCtrExtNB	NB performance counter extensions support. Indicates support for MSRC001_024[6,4,2,0] and MSRC001_024[7,5,3,1].
23	PerfCtrExtCore	Processor performance counter extensions support. Indicates support for MSRC001_020[A,8,6,4,2,0] and MSRC001_020[B,9,7,5,3,1].
22	TopologyExtensions	Topology extensions support. Indicates support for CPUID Fn8000_001D_EAX_x[N:0] - CPUID Fn8000_001E_EDX .
21	TBM	Trailing bit manipulation instruction support.
20	—	Reserved.
19	—	Reserved.
18	—	Reserved.
17	—	Reserved.
16	FMA4	Four-operand FMA instruction support.
15	LWP	Lightweight profiling support. See “Lightweight Profiling” in APM2 and reference pages for individual LWP instructions in APM3.
14	—	Reserved.
13	WDT	Watchdog timer support. See APM2 and APM3. Indicates support for MSRC001_0074.
12	SKINIT	SKINIT and STGI are supported. Indicates support for SKINIT and STGI, independent of the value of MSRC000_0080[SVME]. See APM2 and APM3.
11	XOP	Extended operation support.
10	IBS	Instruction based sampling. See “Instruction Based Sampling” in APM2.
9	OSVW	OS visible workaround. Indicates OS-visible workaround support. See “OS Visible Work-around (OSVW) Information” in APM2.
8	3DNowPrefetch	PREFETCH and PREFETCHW instruction support. See “PREFETCH” and “PREFETCHW” in APM3.
7	MisAlignSse	Misaligned SSE mode. See “Misaligned Access Support Added for SSE Instructions” in APM1.
6	SSE4A	EXTRQ, INSERTQ, MOVNTSS, and MOVNTSD instruction support. See “EXTRQ”, “INSERTQ”, “MOVNTSS”, and “MOVNTSD” in APM4.

Bits	Field Name	Description
5	ABM	Advanced bit manipulation. LZCNT instruction support. See “LZCNT” in APM3.
4	AltMovCr8	LOCK MOV CR0 means MOV CR8. See “MOV(CRn)” in APM3.
3	ExtApicSpace	Extended APIC space. This bit indicates the presence of extended APIC register space starting at offset 400h from the “APIC Base Address Register,” as specified in the BKDG.
2	SVM	Secure virtual machine. See “Secure Virtual Machine” in APM2.
1	CmpLegacy	Core multi-processing legacy mode. See “Legacy Method” on page 620.
0	LahfSahf	LAHF and SAHF instruction support in 64-bit mode. See “LAHF” and “SAHF” in APM3.

CPUID Fn8000_0001_EDX Feature Identifiers

This function contains the following miscellaneous feature identifiers:

Bits	Field Name	Description
31	3DNow	3DNow!™ instructions. See Appendix D “Instruction Subsets and CPUID Feature Sets” in APM3.
30	3DNowExt	AMD extensions to 3DNow! instructions. See Appendix D “Instruction Subsets and CPUID Feature Sets” in APM3.
29	LM	Long mode. See “Processor Initialization and Long-Mode Activation” in APM2.
28	—	Reserved.
27	RDTSCP	RDTSCP instruction. See “RDTSCP” in APM3.
26	Page1GB	1-GB large page support. See “1-GB Paging Support” in APM2.
25	FXSR	FXSAVE and FXRSTOR instruction optimizations. See “FXSAVE” and “FXRSTOR” in APM4.
24	FXSR	FXSAVE and FXRSTOR instructions. Same as CPUID Fn0000_0001_EDX[FXSR] .
23	MMX	MMX™ instructions. Same as CPUID Fn0000_0001_EDX[MMX] .
22	MmxExt	AMD extensions to MMX instructions. See Appendix D “Instruction Subsets and CPUID Feature Sets” in APM3 and “128-Bit Media and Scientific Programming” in APM1.
21	—	Reserved.
20	NX	No-execute page protection. See “Page Translation and Protection” in APM2.
19:18	—	Reserved.
17	PSE36	Page-size extensions. Same as CPUID Fn0000_0001_EDX[PSE36] .
16	PAT	Page attribute table. Same as CPUID Fn0000_0001_EDX[PAT] .
15	CMOV	Conditional move instructions. Same as CPUID Fn0000_0001_EDX[CMOV] .
14	MCA	Machine check architecture. Same as CPUID Fn0000_0001_EDX[MCA] .
13	PGE	Page global extension. Same as CPUID Fn0000_0001_EDX[PGE] .
12	MTRR	Memory-type range registers. Same as CPUID Fn0000_0001_EDX[MTRR] .
11	SysCallSysRet	SYSCALL and SYSRET instructions. See “SYSCALL” and “SYSRET” in APM3.

Bits	Field Name	Description
10	—	Reserved.
9	APIC	Advanced programmable interrupt controller. Same as CPUID Fn0000_0001_EDX[APIC] .
8	CMPXCHG8B	CMPXCHG8B instruction. Same as CPUID Fn0000_0001_EDX[CMPXCHG8B] .
7	MCE	Machine check exception. Same as CPUID Fn0000_0001_EDX[MCE] .
6	PAE	Physical-address extensions. Same as CPUID Fn0000_0001_EDX[PAE] .
5	MSR	AMD model-specific registers. Same as CPUID Fn0000_0001_EDX[MSR] .
4	TSC	Time stamp counter. Same as CPUID Fn0000_0001_EDX[TSC] .
3	PSE	Page-size extensions. Same as CPUID Fn0000_0001_EDX[PSE] .
2	DE	Debugging extensions. Same as CPUID Fn0000_0001_EDX[DE] .
1	VME	Virtual-mode enhancements. Same as CPUID Fn0000_0001_EDX[VME] .
0	FPU	x87 floating-point unit on-chip. Same as CPUID Fn0000_0001_EDX[FPU] .

E.4.3 Functions 8000_0002h–8000_0004h—Extended Processor Name String

CPUID Fn8000_000[4:2]_E[D,C,B,A]X Processor Name String Identifier

The three extended functions from Fn8000_0002 to Fn8000_0004 are programmed to return a null terminated ASCII string up to 48 characters in length corresponding to the processor name.

Bits	Field Name	Description
31:0	ProcName	Four characters of the extended processor name string.

The 48 character maximum includes the terminating null character. The 48 character string is ordered first to last (left to right) as follows:

```
Fn8000_0002[EAX[7:0],..., EAX[31:24], EBX[7:0],..., EBX[31:24], ECX[7:0],...,
ECX[31:24], EDX[7:0],..., EDX[31:24]],
Fn8000_0003[EAX[7:0],..., EAX[31:24], EBX[7:0],..., EBX[31:24], ECX[7:0],..., ECX[31:24],
EDX[7:0],..., EDX[31:24]],
Fn8000_0004[EAX[7:0],..., EAX[31:24], EBX[7:0],..., EBX[31:24], ECX[7:0],..., ECX[31:24],
EDX[7:0],..., EDX[31:24]].
```

The extended processor name string is programmed by system firmware. See your processor revision guide for information about how to display the extended processor name string.

E.4.4 Function 8000_0005h—L1 Cache and TLB Information

This function provides first level cache TLB characteristics for the processor that executes the instruction.

CPUID Fn8000_0005_EAX L1 TLB 2M/4M Information

The value returned in EAX provides information about the L1 TLB for 2-MB and 4-MB pages.

Bits	Field Name	Description
31:24	L1DTlb2and4MAssoc	Data TLB associativity for 2-MB and 4-MB pages. Encoding is per Table E-3 below.
23:16	L1DTlb2and4MSize	Data TLB number of entries for 2-MB and 4-MB pages. The value returned is for the number of entries available for the 2-MB page size; 4-MB pages require two 2-MB entries, so the number of entries available for the 4-MB page size is one-half the returned value.
15:8	L1ITlb2and4MAssoc	Instruction TLB associativity for 2-MB and 4-MB pages. Encoding is per Table E-3 below.
7:0	L1ITlb2and4MSize	Instruction TLB number of entries for 2-MB and 4-MB pages. The value returned is for the number of entries available for the 2-MB page size; 4-MB pages require two 2-MB entries, so the number of entries available for the 4-MB page size is one-half the returned value.

The associativity fields (L1DTlb2and4MAssoc and L1ITlb2and4MAssoc) are encoded as follows:

Table E-3. L1 Cache and TLB Associativity Field Encodings

Associativity [7:0]	Definition
00h	Reserved
01h	1 way (direct mapped)
02h–FEh	n -way associative. (field encodes n)
FFh	Fully associative

CPUID Fn8000_0005_EBX L1 TLB 4K Information

The value returned in EBX provides information about the L1 TLB for 4-KB pages.

Bits	Field Name	Description
31:24	L1DTlb4KAssoc	Data TLB associativity for 4 KB pages. Encoding is per Table E-3 above.
23:16	L1DTlb4KSize	Data TLB number of entries for 4 KB pages.
15:8	L1ITlb4KAssoc	Instruction TLB associativity for 4 KB pages. Encoding is per Table E-3 above.
7:0	L1ITlb4KSize	Instruction TLB number of entries for 4 KB pages.

The associativity fields (L1DTlb4KAssoc and L1ITlb4KAssoc) are encoded as specified in Table E-3 on page 605.

CPUID Fn8000_0005_ECX L1 Data Cache Information

The value returned in ECX provides information about the first level data cache.

Bits	Field Name	Description
31:24	L1DcSize	L1 data cache size in KB.
23:16	L1DcAssoc	L1 data cache associativity. Encoding is per Table E-3.
15:8	L1DcLinesPerTag	L1 data cache lines per tag.
7:0	L1DcLineSize	L1 data cache line size in bytes.

The associativity field (L1DcAssoc) is encoded as specified in Table E-3 on page 605.

CPUID Fn8000_0005_EDX L1 Instruction Cache Information

The value returned in EDX provides information about the first level instruction cache.

Bits	Field Name	Description
31:24	L1IcSize	L1 instruction cache size KB.
23:16	L1IcAssoc	L1 instruction cache associativity. Encoding is per Table E-3.
15:8	L1IcLinesPerTag	L1 instruction cache lines per tag.
7:0	L1IcLineSize	L1 instruction cache line size in bytes.

The associativity field (L1IcAssoc) is encoded as specified in Table E-3 on page 605.

E.4.5 Function 8000_0006h—L2 Cache and TLB and L3 Cache Information

This function provides the second level cache and TLB characteristics for the processor that executes the instruction. The EDX register returns the processor's third level cache characteristics that are shared by all cores of the processor.

CPUID Fn8000_0006_EAX L2 TLB 2M/4M Information

The value returned in EAX provides information about the L2 TLB for 2-MB and 4-MB pages.

Bits	Field Name	Description
31:28	L2DTIb2and4MAssoc	L2 data TLB associativity for 2-MB and 4-MB pages. Encoding is per Table E-4 below.
27:16	L2DTIb2and4MSize	L2 data TLB number of entries for 2-MB and 4-MB pages. The value returned is for the number of entries available for the 2 MB page size; 4 MB pages require two 2 MB entries, so the number of entries available for the 4 MB page size is one-half the returned value.
15:12	L2ITIb2and4MAssoc	L2 instruction TLB associativity for 2-MB and 4-MB pages. Encoding is per Table E-4 below.
11:0	L2ITIb2and4MSize	L2 instruction TLB number of entries for 2-MB and 4-MB pages. The value returned is for the number of entries available for the 2 MB page size; 4 MB pages require two 2 MB entries, so the number of entries available for the 4 MB page size is one-half the returned value.

The associativity fields (L2DTlb2and4MAssoc and L2ITlb2and4MAssoc) are encoded as follows:

Table E-4. L2/L3 Cache and TLB Associativity Field Encoding

Associativity [3:0]	Definition
0h	L2/L3 cache or TLB is disabled.
1h	Direct mapped.
2h	2-way associative.
4h	4-way associative.
6h	8-way associative.
8h	16-way associative.
Ah	32-way associative.
Bh	48-way associative.
Ch	64-way associative.
Dh	96-way associative.
Eh	128-way associative.
Fh	Fully associative.
All other encodings are reserved.	

CPUID Fn8000_0006_EBX L2 TLB 4K Information

The value returned in EBX provides information about the L2 TLB for 4-KB pages.

Bits	Field Name	Description
31:28	L2DTlb4KAssoc	L2 data TLB associativity for 4-KB pages. Encoding is per Table E-4 above.
27:16	L2DTlb4KSize	L2 data TLB number of entries for 4-KB pages.
15:12	L2ITlb4KAssoc	L2 instruction TLB associativity for 4-KB pages. Encoding is per Table E-4 above.
11:0	L2ITlb4KSize	L2 instruction TLB number of entries for 4-KB pages.

The associativity fields (L2DTlb4KAssoc and L2ITlb4KAssoc) are encoded per Table E-4 above.

CPUID Fn8000_0006_ECX L2 Cache Information

The value returned in ECX provides information about the L2 cache.

Bits	Field Name	Description
31:16	L2Size	L2 cache size in KB.
15:12	L2Assoc	L2 cache associativity. Encoding is per Table E-4 on page 607.
11:8	L2LinesPerTag	L2 cache lines per tag.
7:0	L2LineSize	L2 cache line size in bytes.

The associativity field (L2Assoc) is encoded per Table E-4 on page 607.

CPUID Fn8000_0006_EDX L3 Cache Information

The value returned in EDX provides the third level cache characteristics shared by all cores of a physical processor.

Bits	Field Name	Description
31:18	L3Size	Specifies the L3 cache size range: (L3Size[31:18] * 512KB) ≤ L3 cache size < ((L3Size[31:18]+1) * 512KB).
17:16	—	Reserved.
15:12	L3Assoc	L3 cache associativity. Encoded per Table E-4 on page 607.
11:8	L3LinesPerTag	L3 cache lines per tag.
7:0	L3LineSize	L3 cache line size in bytes.

The associativity field (L3Assoc) is encoded per Table E-4 on page 607.

E.4.6 Function 8000_0007h—Processor Power Management and RAS Capabilities

This function provides information about the power management, power reporting, and RAS capabilities of the processor that executes the instruction. There may be other processor-specific features and reporting capabilities not covered here. Refer to the *BIOS and Kernel Developer's Guide* for your specific product to obtain more information.

CPUID Fn8000_0007_EAX Reserved

Bits	Field Name	Description
31:0	—	Reserved.

CPUID Fn8000_0007_EBX RAS Capabilities

The value returned in EBX provides information about RAS features that allow system software to detect specific hardware errors.

Bits	Field Name	Description
31:3	—	Reserved.
2	HWA	Hardware assert supported. Indicates support for MSRC001_10[DF:C0].

1	SUCCOR	Software uncorrectable error containment and recovery capability. The processor supports software containment of uncorrectable errors through context synchronizing data poisoning and deferred error interrupts; see APM2, Chapter 9, “Determining Machine-Check Architecture Support.”
0	McaOverflowRecov	MCA overflow recovery support. If set, indicates that MCA overflow conditions (MCI_STATUS[Overflow]=1) are not fatal; software may safely ignore such conditions. If clear, MCA overflow conditions require software to shut down the system. See APM2, Chapter 9, “Handling Machine Check Exceptions.”

CPUID Fn8000_0007_ECX Processor Power Monitoring Interface

The value returned in ECX provides information about the implementation of the processor power monitoring interface.

Bits	Field Name	Description
31:0	CpuPwrSampleTimeRatio	Specifies the ratio of the compute unit power accumulator sample period to the TSC counter period.

CPUID Fn8000_0007_EDX Advanced Power Management Features

The value returned in EDX provides information about the advanced power management and power reporting features available. Refer to the *BIOS and Kernel Developer's Guide* for your specific product for a detailed description of the definition of each power management feature.

Bits	Field Name	Description
31:13	—	Reserved.
12	ProcPowerReporting	Core power reporting interface supported.
11	ProcFeedbackInterface	Processor feedback interface. Value: 1. 1=Indicates support for processor feedback interface. Note: This feature is deprecated.
10	EffFreqRO	Read-only effective frequency interface. 1=Indicates presence of MSRC000_00E7 [Read-Only Max Performance Frequency Clock Count (MPerfReadOnly)] and MSRC000_00E8 [Read-Only Actual Performance Frequency Clock Count (APerfReadOnly)].
9	CPB	Core performance boost.
8	TscInvariant	TSC invariant. The TSC rate is ensured to be invariant across all P-States, C-States, and stop grant transitions (such as STPCLK Throttling); therefore the TSC is suitable for use as a source of time. 0 = No such guarantee is made and software should avoid attempting to use the TSC as a source of time.
7	HwpPstate	Hardware P-state control. MSRC001_0061 [P-state Current Limit], MSRC001_0062 [P-state Control] and MSRC001_0063 [P-state Status] exist.
6	100MHzSteps	100 MHz multiplier Control.
5	—	Reserved.
4	TM	Hardware thermal control (HTC).
3	TTP	THERMTRIP.

2	VID	Voltage ID control. Function replaced by HwPstate.
1	FID	Frequency ID control. Function replaced by HwPstate.
0	TS	Temperature sensor.

E.4.7 Function 8000_0008h—Processor Capacity Parameters

This function provides the size or capacity of various architectural parameters that vary by implementation.

CPUID Fn8000_0008_EAX Long Mode Size Identifiers

The value returned in EAX provides information about the maximum host and guest physical and linear address width (in bits) supported by the processor.

Bits	Field Name	Description
31:24	—	Reserved.
23:16	GuestPhysAddrSize	Maximum guest physical byte address size in bits. This number applies only to guests using nested paging. When this field is zero, refer to the PhysAddrSize field for the maximum guest physical address size. See “Secure Virtual Machine” in APM2.
15:8	LinAddrSize	Maximum linear byte address size in bits.
7:0	PhysAddrSize	Maximum physical byte address size in bits. When GuestPhysAddrSize is zero, this field also indicates the maximum guest physical address size.

The address width reported is the maximum supported in any mode. For long mode capable processors, the size reported is independent of whether long mode is enabled. See “Processor Initialization and Long-Mode Activation” in APM2.

CPUID Fn8000_0008_EBX Reserved

The value returned in EBX is undefined and reserved for future use.

CPUID Fn8000_0008_ECX Size Identifiers

The value returned in ECX provides information about the number of cores supported by the processor, the width of the APIC ID, and the width of the performance time-stamp counter.

Bits	Field Name	Description										
31:16	—	Reserved.										
17:16	PerfTscSize	Performance time-stamp counter size. Indicates the size of MSRC001_0280[PTSC]. <table border="0"> <tr> <td>Bits</td> <td>Description</td> </tr> <tr> <td>00b</td> <td>40 bits</td> </tr> <tr> <td>01b</td> <td>48 bits</td> </tr> <tr> <td>10b</td> <td>56 bits</td> </tr> <tr> <td>11b</td> <td>64 bits</td> </tr> </table>	Bits	Description	00b	40 bits	01b	48 bits	10b	56 bits	11b	64 bits
Bits	Description											
00b	40 bits											
01b	48 bits											
10b	56 bits											
11b	64 bits											
15:12	ApicIdCoreIdSize	APIC ID size. The number of bits in the initial APIC20[ApicId] value that indicate core ID within a processor. A zero value indicates that legacy methods must be used to derive the maximum number of cores. The size of this field determines the maximum number of cores (MNC) that the processor could theoretically support, not the actual number of cores that are actually implemented or enabled on the processor, as indicated by CPUID Fn8000_0008_ECX[NC]. <pre> if (ApicIdCoreIdSize[3:0] == 0){ // Used by legacy dual-core/single-core processors MNC = CPUID Fn8000_0008_ECX[NC] + 1; } else { // use ApicIdCoreIdSize[3:0] field MNC = (2 ^ ApicIdCoreIdSize[3:0]); } </pre>										
11:8	—	Reserved.										
7:0	NC	Number of physical cores - 1. The number of cores in the processor is NC+1 (e.g., if NC = 0, then there is one core). See “Legacy Method” on page 620.										

CPUID Fn8000_0008_EDX Reserved

The value returned in EDX for this function is undefined and is reserved.

E.4.8 Function 8000_0009h—Reserved

CPUID Fn8000_0009 Reserved

This function is reserved.

E.4.9 Function 8000_000Ah—SVM Features

This function provides information about the SVM features that the processor supports. If SVM is not supported (CPUID Fn8000_0001_ECX[SVM] = 0), this function is reserved.

CPUID Fn8000_000A_EAX SVM Revision and Feature Identification

The value returned in EAX provides the SVM revision number. I

Bits	Field Name	Description
31:8	—	Reserved.
7:0	SvmRev	SVM revision number.

CPUID Fn8000_000A_EBX SVM Revision and Feature Identification

The value returned in EBX provides the number of address space identifiers (ASIDs) that the processor supports.

Bits	Field Name	Description
31:0	NASID	Number of available address space identifiers (ASID).

CPUID Fn8000_000A_ECX Reserved

The value returned in ECX for this function is undefined and is reserved.

CPUID Fn8000_000A_EDX SVM Feature Identification

The value returned in EDX provides Secure Virtual Machine architecture feature information. All cross references in the table below are to sections within the *Secure Virtual Machine* chapter of APM2.

Bits	Field Name	Description
31:14	—	Reserved.
13	AVIC	Support for the AMD advanced virtual interrupt controller. See “Advanced Virtual Interrupt Controller.”
12	PauseFilterThreshold	PAUSE filter threshold. Indicates support for the PAUSE filter cycle count threshold. See “Pause Intercept Filtering.”
11	—	Reserved.
10	PauseFilter	Pause intercept filter. Indicates support for the pause intercept filter. See “Pause Intercept Filtering.”
9:8	—	Reserved.
7	DecodeAssists	Decode assists. Indicates support for the decode assists. See “Decode Assists.”
6	FlushByAsid	Flush by ASID. Indicates that TLB flush events, including CR3 writes and CR4.PGE toggles, flush only the current ASID's TLB entries. Also indicates support for the extended VMCB TLB_Control. See “TLB Control.”
5	VmcbClean	VMCB clean bits. Indicates support for VMCB clean bits. See “VMCB Clean Bits.”
4	TscRateMsr	MSR based TSC rate control. Indicates support for MSR TSC ratio MSRC000_0104. See “TSC Ratio MSR (C000_0104h).”
3	NRIPS	NRIP save. Indicates support for NRIP save on #VMEXIT. See “State Saved on Exit.”

Bits	Field Name	Description
2	SVML	SVM lock. Indicates support for SVM-Lock. See “Enabling SVM.”
1	LbrVirt	LBR virtualization. Indicates support for LBR Virtualization. See “Enabling LBR Virtualization.”
0	NP	Nested paging. Indicates support for nested paging. See “Nested Paging.”

E.4.10 Functions 8000_000Bh–8000_0018h—Reserved

CPUID Fn8000_00[18:0B] Reserved

These functions are reserved.

E.4.11 Function 8000_0019h—TLB Characteristics for 1GB pages

This function provides information about the TLB for 1 GB pages for the processor that executes the instruction.

CPUID Fn8000_0019_EAX L1 TLB 1G Information

The value returned in EAX provides information about the L1 TLB for 1 GB pages.

Bits	Field Name	Description
31:28	L1DTIb1GAssoc	L1 data TLB associativity for 1 GB pages. See Table E-4 on page 607.
27:16	L1DTIb1GSize	L1 data TLB number of entries for 1 GB pages.
15:12	L1ITIb1GAssoc	L1 instruction TLB associativity for 1 GB pages. See Table E-4 on page 607.
11:0	L1ITIb1GSize	L1 instruction TLB number of entries for 1 GB pages.

CPUID Fn8000_0019_EBX L2 TLB 1G Information

The value returned in EBX provides information about the L2 TLB for 1 GB pages.

Bits	Field Name	Description
31:28	L2DTIb1GAssoc	L2 data TLB associativity for 1 GB pages. See Table E-4 on page 607.
27:16	L2DTIb1GSize	L2 data TLB number of entries for 1 GB pages.
15:12	L2ITIb1GAssoc	L2 instruction TLB associativity for 1 GB pages. See Table E-4 on page 607.
11:0	L2ITIb1GSize	L2 instruction TLB number of entries for 1 GB pages.

CPUID Fn8000_0019_E[D,C]X Reserved

The values returned in ECX and EDX for this function are undefined and reserved for future use.

E.4.12 Function 8000_001Ah—Instruction Optimizations

CPUID Fn8000_001A_EAX Performance Optimization Identifiers

This function returns performance related information. For more details on how to use these bits to optimize software, see the *Software Optimization Guide* applicable to your product.

Bits	Field Name	Description
31:3	—	Reserved.
2	FP256	256-bit AVX instructions are executed with full-width internal operations and pipelines rather than decomposing them into internal 128-bit suboperations. This may impact how software performs instruction selection and scheduling.
1	MOVU	MOVU SSE instructions are more efficient and should be preferred to SSE MOVL/MOVH. MOVUPS is more efficient than MOVLPS/MOVHPS. MOVUPD is more efficient than MOVLPD/MOVHPD.
0	FP128	128-bit SSE (multimedia) instructions are executed with full-width internal operations and pipelines rather than decomposing them into internal 64-bit suboperations. This may impact how software performs instruction selection and scheduling.

CPUID Fn8000_001A_E[D,C,B]X Reserved

The values returned in EBX, ECX, and EDX are undefined for this function and are reserved.

E.4.13 Function 8000_001Bh—Instruction-Based Sampling Capabilities

If instruction-based sampling (IBS) is supported (CPUID Fn8000_0001_ECX[IBS] = 1), this CPUID function can be used to obtain IBS feature information. If IBS is not supported (CPUID Fn8000_0001_ECX[IBS] = 0), this function number is reserved. For more information on using IBS, see “Instruction-Based Sampling” in APM2.

CPUID Fn8000_001B_EAX Instruction-Based Sampling Feature Indicators

The value returned in EAX provides the following information about the specific features of IBS that the processor supports:

Bits	Field Name	Description
31:9		Reserved.
8	OpBrnFuse	Fused branch micro-op indication supported.
7	RipInvalidChk	Invalid RIP indication supported.
6	OpCntExt	IbsOpCurCnt and IbsOpMaxCnt extend by 7 bits.
5	BrnTrgt	Branch target address reporting supported.
4	OpCnt	Op counting mode supported.

Bits	Field Name	Description
3	RdWrOpCnt	Read write of op counter supported.
2	OpSam	IBS execution sampling supported.
1	FetchSam	IBS fetch sampling supported.
0	IBSFFV	IBS feature flags valid.

CPUID Fn8000_001B_E[D,C,B]X Reserved

The values returned in EBX, ECX, and EDX are undefined and are reserved.

E.4.14 Function 8000_001Ch—Lightweight Profiling Capabilities

If lightweight profiling (LWP) is supported (CPUID Fn8000_0001_ECX[LWP] = 1), this CPUID function can be used to obtain information about LWP features supported by the processor. If LWP is not supported (CPUID Fn8000_0001_ECX[LWP] = 0), this function number is reserved. For more information on using LWP, see “Lightweight Profiling” in APM2.

CPUID Fn8000_001C_EAX Lightweight Profiling Capabilities 0

The value returned in EAX provides the following information about LWP capabilities supported by the processor:

Bits	Field Name	Description
31	LwpInt	Interrupt on threshold overflow available.
30	LwpPTSC	Performance time stamp counter in event record is available.
29	LwpCont	Sampling in continuous mode is available.
28:7	—	Reserved.
6	LwpRNH	Core reference clocks not halted event available.
5	LwpCNH	Core clocks not halted event available.
4	LwpDME	DC miss event available.
3	LwpBRE	Branch retired event available.
2	LwpIRE	Instructions retired event available.
1	LwpVAL	LWPVAL instruction available.
0	LwpAvail	The LWP feature is available.

CPUID Fn8000_001C_EBX Lightweight Profiling Capabilities 0

The value returned in EBX provides the following additional information about LWP capabilities supported by the processor:

Bits	Field Name	Description
31:24	LwpEventOffset	Offset in bytes from the start of the LWPCB to the EventInterval1 field.
23:16	LwpMaxEvents	Maximum EventId value supported.
15:8	LwpEventSize	Event record size. Size in bytes of an event record in the LWP event ring buffer.
7:0	LwpCbSize	Control block size. Size in quadwords of the LWPCB.

CPUID Fn8000_001C_ECX Lightweight Profiling Capabilities 0

The value returned in ECX provides the following additional information about LWP capabilities supported by the processor:

Bits	Field Name	Description
31	LwpCacheLatency	Cache latency filtering supported. Cache-related events can be filtered by latency.
30	LwpCacheLevels	Cache level filtering supported. Cache-related events can be filtered by the cache level that returned the data.
29	LwpIpFiltering	IP filtering supported.
28	LwpBranchPrediction	Branch prediction filtering supported. Branches Retired events can be filtered based on whether the branch was predicted properly.

Bits	Field Name	Description
27:24	—	Reserved.
23:16	LwpMinBufferSize	Event ring buffer size. Minimum size of the LWP event ring buffer, in units of 32 event records.
15:9	LwpVersion	Version of LWP implementation.
8:6	LwpLatencyRnd	Amount by which cache latency is rounded.
5	LwpDataAddress	Data cache miss address valid. Address is valid for cache miss event records.
4:0	LwpLatencyMax	Latency counter size. Size in bits of the cache latency counters.

CPUID Fn8000_001C_EDX Lightweight Profiling Capabilities 0

The value returned in EDX provides the following additional information about LWP capabilities supported by the processor:

Bits	Field Name	Description
31	LwpInt	Interrupt on threshold overflow supported.
30	LwpPTSC	Performance time stamp counter in event record is supported.
29	LwpCont	Sampling in continuous mode is supported.
28:7	—	Reserved.
6	LwpRNH	Core reference clocks not halted event is supported.
5	LwpCNH	Core clocks not halted event is supported.
4	LwpDME	DC miss event is supported.
3	LwpBRE	Branch retired event is supported.
2	LwpIRE	Instructions retired event is supported.
1	LwpVAL	LWPVAL instruction is supported.
0	LwpAvail	Lightweight profiling is supported.

E.4.15 Function 8000_001Dh—Cache Topology Information

CPUID Fn8000_001D_E[D,C,B,A]X reports cache topology information for the cache enumerated by the value passed to the instruction in ECX, referred to as Cache *n* in the following description. To gather information for all cache levels, software must repeatedly execute CPUID with 8000_001Dh in EAX and ECX set to increasing values beginning with 0 until a value of 00h is returned in the field CacheType (EAX[4:0]) indicating no more cache descriptions are available for this processor.

If CPUID Fn8000_0001_ECX[TopologyExtensions] = 0, then CPUID Fn8000_001Dh is reserved. The value of ECX that returns the null CacheType is represented by *N*. Executing CPUID Fn8000_001D with ECX = *N* + 1 results in an #UD exception. See .

CPUID Fn8000_001D_EAX_x[N:0] Cache Properties

Bits	Field Name	Description												
31:26	—	Reserved.												
25:14	NumSharingCache	Specifies the number of cores sharing the cache enumerated by n , the value passed to the instruction in ECX. The number of cores sharing this cache is the value of this field incremented by 1.												
13:10	—	Reserved.												
9	FullyAssociative	Fully associative cache. When set, indicates that the cache is fully associative. If 0 is returned in this field, the cache is set associative.												
8	SelfInitialization	Self-initializing cache. When set, indicates that the cache is self initializing; software initialization not required. If 0 is returned in this field, hardware does not initialize this cache.												
7:5	CacheLevel	Cache level. Identifies the level of this cache. Note that the enumeration value is not necessarily equal to the cache level. <table border="1"> <thead> <tr> <th>Bits</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>000b</td> <td>Reserved.</td> </tr> <tr> <td>001b</td> <td>Level 1</td> </tr> <tr> <td>010b</td> <td>Level 2</td> </tr> <tr> <td>011b</td> <td>Level 3</td> </tr> <tr> <td>111b-100b</td> <td>Reserved.</td> </tr> </tbody> </table>	Bits	Description	000b	Reserved.	001b	Level 1	010b	Level 2	011b	Level 3	111b-100b	Reserved.
Bits	Description													
000b	Reserved.													
001b	Level 1													
010b	Level 2													
011b	Level 3													
111b-100b	Reserved.													
4:0	CacheType	Cache type. Identifies the type of cache. <table border="1"> <thead> <tr> <th>Bits</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>00h</td> <td>Null; no more caches.</td> </tr> <tr> <td>01h</td> <td>Data cache</td> </tr> <tr> <td>02h</td> <td>Instruction cache</td> </tr> <tr> <td>03h</td> <td>Unified cache</td> </tr> <tr> <td>1Fh-04h</td> <td>Reserved.</td> </tr> </tbody> </table>	Bits	Description	00h	Null; no more caches.	01h	Data cache	02h	Instruction cache	03h	Unified cache	1Fh-04h	Reserved.
Bits	Description													
00h	Null; no more caches.													
01h	Data cache													
02h	Instruction cache													
03h	Unified cache													
1Fh-04h	Reserved.													

CPUID Fn8000_001D_EBX_x[N:0] Cache PropertiesSee [CPUID Fn8000_001D_EAX_x\[N:0\]](#).

Bits	Field Name	Description
31:22	CacheNumWays	Number of ways for this cache. The number of ways is the value returned in this field incremented by 1.
21:12	CachePhysPartitions	Number of physical line partitions. The number of physical line partitions is the value returned in this field incremented by 1.
11:0	CacheLineSize	Cache line size. The cache line size in bytes is the value returned in this field incremented by 1.

CPUID Fn8000_001D_ECX_x[N:0] Cache PropertiesSee [CPUID Fn8000_001D_EAX_x\[N:0\]](#).

Bits	Field Name	Description
31:0	CacheNumSets	Number of ways for set associative cache. Number of ways is the value returned in this field incremented by 1. Only valid for caches that are not fully associative (Fn8000_001D_EAX_xn[FullyAssociative] = 0).

CPUID Fn8000_001D_EDX_x[N:0] Cache Properties

See [CPUID Fn8000_001D_EAX_x\[N:0\]](#).

Bits	Field Name	Description
31:2	—	Reserved.
1	CacheInclusive	Cache inclusivity. A value of 0 indicates that this cache is not inclusive of lower cache levels. A value of 1 indicates that the cache is inclusive of lower cache levels.
0	WBINVD	Write-Back Invalidate/Invalidate execution scope. A value of 0 returned in this field indicates that the WBINVD/INVD instruction invalidates all lower level caches of non-originating cores sharing this cache. When set, this field indicates that the WBINVD/INVD instruction is not guaranteed to invalidate all lower level caches of non-originating cores sharing this cache.

E.4.16 Function 8000_001Eh—Processor Topology Information

CPUID Fn8000_001E_EAX Extended APIC ID

If [CPUID Fn8000_0001_ECX\[TopologyExtensions\]](#) = 0, this function number is reserved.

Bits	Field Name	Description
31:0	ExtendedApicId	Extended APIC ID. If MSR0000_001B[ApicEn] = 0, this field is reserved..

CPUID Fn8000_001E_EBX Compute Unit Identifiers

See [CPUID Fn8000_001E_EAX](#).

Bits	Field Name	Description
31:16	—	Reserved.
15:8	ThreadsPerComputeUnit	Threads per compute unit (zero-based count). The actual number of cores per compute unit is the value of this field + 1.
7:0	ComputeUnitId	Compute unit ID. Identifies the processor compute unit ID.

CPUID Fn8000_001E_ECX Node Identifiers

See [CPUID Fn8000_001E_EAX](#).

Bits	Field Name	Description								
31:0	—	Reserved.								
10:8	NodesPerProcessor	Specifies the number of nodes per processor. Encoding is as follows: <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>000b</td> <td>1 node per processor</td> </tr> <tr> <td>001b</td> <td>2 nodes per processor</td> </tr> <tr> <td>111b-010b</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Description	000b	1 node per processor	001b	2 nodes per processor	111b-010b	Reserved
Value	Description									
000b	1 node per processor									
001b	2 nodes per processor									
111b-010b	Reserved									
7:0	Nodeld	Specifies the node ID.								

CPUID Fn8000_001E_EDX Reserved

The value returned in EDX is undefined and is reserved.

E.5 Multiple Core Calculation

Operating systems use one of two possible methods to calculate the number of cores per processor (NC), and the maximum number of cores per processor (MNC). The extended method is recommended, but a legacy method is also available for existing operating systems.

E.5.1 Legacy Method

The CPUID identification of total number of cores per processor (c) is derived from information returned by the following fields:

- CPUID Fn0000_0001_EBX[LogicalProcessorCount]
- CPUID Fn0000_0001_EDX[HTT] (Hyper-Threading Technology)
- CPUID Fn8000_0001_ECX[CmpLegacy]
- CPUID Fn8000_0008_ECX[NC] (number of cores - 1)

Table E-5 defines LogicalProcessorCount, HTT, CmpLegacy, and NC as a function of the number of cores per processor (c).

When HTT = 0, LogicalProcessorCount is reserved and the processor contains one core.

When HTT = 1 and CmpLegacy = 1, LogicalProcessorCount represents the number of cores per processor (c).

Table E-5. LogicalProcessorCount, CmpLegacy, HTT, and NC

Cores per Processor (c)	CmpLegacy	HTT	LogicalProcessorCount	NC
1	0	0	Reserved	0
2 or more	1	1	c	c-1

The use of CmpLegacy and LogicalProcessorCount for the determination of the number of cores is deprecated.

Instead, use NC to determine the number of cores.

E.5.2 Extended Method (Recommended)

The CPUID identification of total number of cores per processor is derived from information returned by the CPUID Fn8000_0008_ECX[ApicIdCoreIdSize[3:0]]. This field indicates the number of least significant bits in the CPUID Fn0000_0001_EBX[LocalApicId] that indicates core ID within the processor. The size of this field determines the maximum number of cores (MNC) that the processor could theoretically support, not the actual number of cores that are actually implemented or enabled on the processor, as indicated by CPUID Fn8000_0008_ECX[NC].

A value of zero for ApicIdCoreIdSize[3:0] indicates that the legacy method (section 2.1) should be used to derive the maximum number of cores:

$$\text{MNC} = \text{CPUID Fn8000_0008_ECX[NC]} + 1.$$

For non-zero values of ApicIdCoreIdSize[3:0],

$$\text{MNC} = (2 \wedge \text{ApicIdCoreIdSize[3:0]})$$

APIC Enumeration Requirements. System hardware and system firmware must ensure that the maximum number of cores per processor (MNC) exposed to the operating system across all cores and processors in the system is identical.

Local ApicId MNC rule: The ApicId of core j on processor node i must be enumerated/assigned as:

$$\text{LocalApicId[proc=i, core=j]} = (\text{OFFSET_IDX} + i) * \text{MNC} + j$$

Where "OFFSET_IDX" is an integer offset (0 to N) used to shift up the core LocalApicId values to allow room for IOAPIC devices. This assignment allows software to use a simple bitmask in addressing all the cores of a single processor. (The assignment also has the effect of reserving some IDs from use to ensure alignment of the ID of core 0 on each processor.)

For example, consider a 3-processor system where:

processor 0 has 4 cores
 processor 1 has 1 core
 processor 2 has 2 cores
 there are 8 IOAPIC devices
 cpuid.core_id_bits = 2 for all cases, so MNC=4

The LocalApicId and IOAPIC ID spaces cannot be disjointed and must be enumerated in the same ID space in order to support legacy operating systems. Each core can support an 8-bit ApicId. But if each IOAPIC device supports only a 4-bit IOAPIC ID, then the problem can be solved by shifting the LocalApicId space to start at some integer multiple of MNC, such as offset 8 (MNC = 4; OFFSET_IDX=2):

$$\begin{aligned} \text{LocalApicId[proc=0,core=0]} &= (2+0)*4 + 0 = 0x08 \\ \text{LocalApicId[proc=0,core=1]} &= (2+0)*4 + 1 = 0x09 \end{aligned}$$

$\text{LocalApicId}[\text{proc}=0, \text{core}=2] = (2+0)*4 + 2 = 0x0A$

$\text{LocalApicId}[\text{proc}=0, \text{core}=3] = (2+0)*4 + 3 = 0x0B$

$\text{LocalApicId}[\text{proc}=1, \text{core}=0] = (2+1)*4 + 0 = 0x0C$

LocalApicId 0xD to 0xF are reserved

$\text{LocalApicId}[\text{proc}=2, \text{core}=0] = (2+2)*4 + 0 = 0x10$

$\text{LocalApicId}[\text{proc}=2, \text{core}=1] = (2+2)*4 + 1 = 0x11$

LocalApicId 0x12 and 0x13 are reserved

It is recommended that system firmware use the following LocalApicId assignments for the broadest operating system support. Given $N = (\text{Number_Of_Processors} * \text{MNC})$ and $M = \text{Number_Of_IOAPICs}$:

- If $(N+M) < 16$, assign the LocalApicIds for the cores first from 0 to $N-1$, and the IOAPIC IDs from N to $N+(M-1)$.
- If $(N+M) \geq 16$, assign the IOAPIC IDs first from 0 to $M-1$, and the LocalApicIds for the cores from K to $K+(N-1)$, where K is an integer multiple of MNC greater than $M-1$.

Appendix F Instruction Effects on RFLAGS

The flags in the RFLAGS register are described in “Flags Register” in Volume 1 and “RFLAGS Register” in Volume 2. Table F-1 summarizes the effect that instructions have on these flags. The table includes all instructions that affect the flags. Instructions not shown have no effect on RFLAGS.

The following codes are used within the table:

- 0—The flag is always cleared to 0.
- 1—The flag is always set to 1.
- AH—The flag is loaded with value from AH register.
- Mod—The flag is modified, depending on the results of the instruction.
- Pop—The flag is loaded with value popped off of the stack.
- Tst—The flag is tested.
- U—The effect on the flag is undefined.
- Gray shaded cells indicate that the flag is not affected by the instruction.
