1 Introduction	1
1.1 Syntax and Notation	2
1.2 Extended Instruction Encoding	3
1.2.1 Immediate Byte Usage Unique to the SSE instructions	4
1.2.2 Instruction Format Examples	5
1.3 Enabling SSE Instruction Execution	7
1.4 AES Instructions	9
1.4.1 Coding Conventions	9
1.4.2 AES Data Structures	10
1.4.3 Algebraic Preliminaries	10
1.4.4 AES Operations	12
1.4.5 Initializing the Sbox and InvSBox Matrices	15
1.4.6 Encryption and Decryption	19
1.4.7 The Cipher Function	21
1.4.8 The InvCipher Function	24
1.4.9 An Alternative Decryption Procedure	27
1.4.10 Computation of GFInv with Euclidean Greatest Common Divisor	29
1.5 String Compare Instructions	32
1.5.1 Source Data Format	32
1.5.2 Aggregation	33
1.5.3 Valid/Invalid Override of Comparisons	34
1.5.4 Complementation	34
1.5.5 Output Selection	34

Revision History

Date	Revision	Description
September 2011	3.13	<p>Moved discussion of extended instruction encoding; VEX and XOP prefixes to Volume 3.</p> <p>Added FMA instructions. Described on the corresponding FMA4 reference page.</p> <p>Moved BMI and TBM instructions to Volume 3.</p> <p>Added XSAVEOPT instruction.</p> <p>Corrected descriptions of VSQRTSD and VSQRTSS.</p>
May 2011	3.12	Added F16C, BMI, and TBM instructions.
December 2010	3.11	<p>Complete revision and reformat accommodating 128-bit and 256-bit media instructions. Includes revised definitions of legacy SSE, SSE2, SSE3, SSE4.1, SSE4.2, and SSSE3 instructions, as well as new definitions of extended AES, AVX, CLMUL, FMA4, and XOP instructions. Introduction includes supplemental information concerning encoding of extended instructions, enhanced processor state management provided by the XSAVE/XRSTOR instructions, cryptographic capabilities of the AES instructions, and functionality of extended string comparison instructions.</p>
September 2007	3.10	Added minor clarifications and corrected typographical and formatting errors.
July 2007	3.09	<p>Added the following instructions: EXTRQ on page 149, INSERTQ on page 161, MOVNTSD on page 221, and MOVNTSS on page 223.</p> <p>Added misaligned exception mask (MXCSR.MM) information.</p> <p>Added imm8 values with corresponding mnemonics to CMPPD VCMPPD on page 83, CMPPS VCMPPS on page 86, CMPSD VCMPSD on page 89, and CMPSS VCMPS on page 92.</p> <p>Reworded CPUID information in condition tables.</p> <p>Added minor clarifications and corrected typographical and formatting errors.</p>
September 2006	3.08	Made minor corrections.
December 2005	3.07	Made minor editorial and formatting changes.
January 2005	3.06	Added documentation on SSE3 instructions. Corrected numerous minor factual errors and typos.
September 2003	3.05	Made numerous small factual corrections.
April 2003	3.04	Made minor corrections.

Preface

About This Book

This book is part of a multivolume work entitled the *AMD64 Architecture Programmer's Manual*. The complete set includes the following volumes.

Title	Order No.
<i>Volume 1: Application Programming</i>	24592
<i>Volume 2: System Programming</i>	24593
<i>Volume 3: General-Purpose and System Instructions</i>	24594
<i>Volume 4: 128-Bit and 256-Bit Media Instructions</i>	26568
<i>Volume 5: 64-Bit Media and x87 Floating-Point Instructions</i>	26569

Audience

This volume is intended for programmers who develop application or system software.

Organization

Volumes 3, 4, and 5 describe the AMD64 instruction set in detail, providing mnemonic syntax, instruction encoding, functions, affected flags, and possible exceptions.

The AMD64 instruction set is divided into five subsets:

- General-purpose instructions
- System instructions
- Streaming SIMD Extensions (includes 128-bit and 256-bit media instructions)
- 64-bit media instructions (MMX™)
- x87 floating-point instructions

Several instructions belong to, and are described identically in, multiple instruction subsets.

This volume describes the Streaming SIMD Extensions (SSE) instruction set which includes 128-bit and 256-bit media instructions. SSE includes both legacy and extended forms. The index at the end cross-references topics within this volume. For other topics relating to the AMD64 architecture, and for information on instructions in other subsets, see the tables of contents and indexes of the other volumes.

Conventions and Definitions

The section which follows, **Notational Conventions**, describes notational conventions used in this volume. The next section, **Definitions**, lists a number of terms used in this volume along with their technical definitions. Some of these definitions assume knowledge of the legacy x86 architecture. See “Related Documents” on page xxxvii for further information about the legacy x86 architecture. Finally, the **Registers** section lists the registers which are a part of the system programming model.

Notational Conventions

“Syntax and Notation” on page 2 describes notation relating specifically to instruction encoding.

#GP(0)

An instruction exception—in this example, a general-protection exception with error code of 0.

1011b

A binary value, in this example, a 4-bit value.

FOEA_0B40h

A hexadecimal value, in this example a 32-bit value. Underscore characters may be used to improve readability.

128

Numbers without an alpha suffix are decimal unless the context indicates otherwise.

[7:4]

A bit range, from bit 7 to 4, inclusive. The high-order bit is shown first. Commas may be inserted to indicate gaps.

#GP(0)

A general-protection exception (#GP) with error code of 0.

CPUID FnXXXX_XXXX_RRR[*FieldName*]

Support for optional features or the value of an implementation-specific parameter of a processor can be discovered by executing the CPUID instruction on that processor. To obtain this value, software must execute the CPUID instruction with the function code XXXX_XXXXh in EAX and then examine the field *FieldName* returned in register *RRR*. If the “_RRR” notation is followed by “_xYYY”, register ECX must be set to the value YYYh before executing CPUID. When *FieldName* is not given, the entire contents of register *RRR* contains the desired value. When determining optional feature support, if the bit identified by *FieldName* is set to a one, the feature is supported on that processor.

CR0–CR4

A register range, from register CR0 through CR4, inclusive, with the low-order register first.

CR4[OXSAVE]

The OXSAVE bit of the CR4 register.

CR0[PE] = 1

The PE bit of the CR0 register has a value of 1.

EFER[LME] = 0

The LME field of the EFER register is cleared (contains a value of 0).

DS:rSI

The content of a memory location whose segment address is in the DS register and whose offset relative to that segment is in the rSI register.

Definitions**128-bit media instruction**

Instructions that operate on the various 128-bit vector data types. Supported within both the legacy SSE and extended SSE instruction sets.

256-bit media instruction

Instructions that operate on the various 256-bit vector data types. Supported within the extended SSE instruction set.

64-bit media instructions

Instructions that operate on the 64-bit vector data types. These are primarily a combination of MMX and 3DNow!™ instruction sets and their extensions, with some additional instructions from the SSE1 and SSE2 instruction sets.

16-bit mode

Legacy mode or compatibility mode in which a 16-bit address size is active. See *legacy mode* and *compatibility mode*.

32-bit mode

Legacy mode or compatibility mode in which a 32-bit address size is active. See *legacy mode* and *compatibility mode*.

64-bit mode

A submode of *long mode*. In 64-bit mode, the default address size is 64 bits and new features, such as register extensions, are supported for system and application software.

absolute

A displacement that references the base of a code segment rather than an instruction pointer. See *relative*.

AES

Advance Encryption Standard (AES) algorithm acceleration instructions; part of Streaming SIMD Extensions (SSE).

ASID

Address space identifier.

AVX

Extension of the SSE instruction set supporting 256-bit vector (packed) operands. See Streaming SIMD Extensions.

biased exponent

The sum of a floating-point value's exponent and a constant bias for a particular floating-point data type. The bias makes the range of the biased exponent always positive, which allows reciprocation without overflow.

byte

Eight bits.

clear, cleared

To write the value 0 to a bit or a range of bits. See *set*.

compatibility mode

A submode of *long mode*. In compatibility mode, the default address size is 32 bits, and legacy 16-bit and 32-bit applications run without modification.

commit

To irreversibly write, in program order, an instruction's result to software-visible storage, such as a register (including flags), the data cache, an internal write buffer, or memory.

CPL

Current privilege level.

direct

Referencing a memory address included in the instruction syntax as an immediate operand. The address may be an absolute or relative address. See *indirect*.

displacement

A signed value that is added to the base of a segment (absolute addressing) or an instruction pointer (relative addressing). Same as *offset*.

doubleword

Two words, or four bytes, or 32 bits.

double quadword

Eight words, or 16 bytes, or 128 bits. Also called *octword*.

effective address size

The address size for the current instruction after accounting for the default address size and any address-size override prefix.

effective operand size

The operand size for the current instruction after accounting for the default operand size and any operand-size override prefix.

element

See *vector*.

exception

An abnormal condition that occurs as the result of instruction execution. Processor response to an exception depends on the type of exception. For all exceptions except SSE floating-point exceptions and x87 floating-point exceptions, control is transferred to a handler (or service routine) for that exception as defined by the exception's vector. For floating-point exceptions defined by the IEEE 754 standard, there are both masked and unmasked responses. When unmasked, the exception handler is called, and when masked, a default response is provided instead of calling the handler.

extended SSE instructions

Enhanced set of SIMD instructions supporting 256-bit vector data types and allowing the specification of up to four operands. A subset of the *Streaming SIMD Extensions (SSE)*. Includes the AVX, FMA, FMA4, and XOP instructions. Compare *legacy SSE*.

flush

An often ambiguous term meaning (1) writeback, if modified, and invalidate, as in “flush the cache line,” or (2) invalidate, as in “flush the pipeline,” or (3) change a value, as in “flush to zero.”

FMA4

Fused Multiply Add, four operand. Part of the extended SSE instruction set.

FMA

Fused Multiply Add. Part of the extended SSE instruction set.

GDT

Global descriptor table.

GIF

Global interrupt flag.

IDT

Interrupt descriptor table.

IGN

Ignored. Value written is ignored by hardware. Value returned on a read is indeterminate. See *reserved*.

indirect

Referencing a memory location whose address is in a register or other memory location. The address may be an absolute or relative address. See *direct*.

IRB

The virtual-8086 mode interrupt-redirection bitmap.

IST

The long-mode interrupt-stack table.

IVT

The real-address mode interrupt-vector table.

LDT

Local descriptor table.

legacy x86

The legacy x86 architecture.

legacy mode

An operating mode of the AMD64 architecture in which existing 16-bit and 32-bit applications and operating systems run without modification. A processor implementation of the AMD64 architecture can run in either *long mode* or *legacy mode*. Legacy mode has three submodes, *real mode*, *protected mode*, and *virtual-8086 mode*.

legacy SSE instructions

All Streaming SIMD Extensions instructions prior to AVX, XOP, and FMA4. Legacy SSE instructions primarily utilize operands held in XMM registers. The legacy SSE instructions include the original Streaming SIMD Extensions (SSE1) and the subsequent extensions SSE2, SSE3, SSSE3, SSE4, SSE4A, SSE4.1, and SSE4.2. See *Streaming SIMD instructions*.

long mode

An operating mode unique to the AMD64 architecture. A processor implementation of the AMD64 architecture can run in either *long mode* or *legacy mode*. Long mode has two submodes, *64-bit mode* and *compatibility mode*.

lsb

Least-significant bit.

LSB

Least-significant byte.

main memory

Physical memory, such as RAM and ROM (but not cache memory) that is installed in a particular computer system.

mask

(1) A control bit that prevents the occurrence of a floating-point exception from invoking an exception-handling routine. (2) A field of bits used for a control purpose.

MBZ

Must be zero. If software attempts to set an MBZ bit to 1, a general-protection exception (#GP) occurs. See *reserved*.

memory

Unless otherwise specified, *main memory*.

moffset

A 16, 32, or 64-bit offset that specifies a memory operand directly, without using a ModRM or SIB byte.

msb

Most-significant bit.

MSB

Most-significant byte.

octword

Same as *double quadword*.

offset

Same as *displacement*.

overflow

The condition in which a floating-point number is larger in magnitude than the largest, finite, positive or negative number that can be represented in the data-type format being used.

packed

See *vector*.

PAE

Physical-address extensions.

physical memory

Actual memory, consisting of *main memory* and cache.

probe

A check for an address in processor caches or internal buffers. *External probes* originate outside the processor, and *internal probes* originate within the processor.

protected mode

A submode of *legacy mode*.

quadword

Four words, eight bytes, or 64 bits.

RAZ

Read as zero. Value returned on a read is always zero (0) regardless of what was previously written. See *reserved*.

real-address mode, real mode

A short name for *real-address mode*, a submode of *legacy mode*.

relative

Referencing with a *displacement (offset)* from an instruction pointer rather than the base of a code segment. See *absolute*.

reserved

Fields marked as reserved may be used at some future time.

To preserve compatibility with future processors, reserved fields require special handling when read or written by software. Software must not depend on the state of a reserved field (unless qualified as RAZ), nor upon the ability of such fields to return a previously written state.

If a field is marked reserved without qualification, software must not change the state of that field; it must reload that field with the same value returned from a prior read.

Reserved fields may be qualified as IGN, MBZ, RAZ, or SBZ (see definitions).

REX

A legacy instruction modifier prefix that specifies 64-bit operand size and provides access to additional registers.

RIP-relative addressing

Addressing relative to the 64-bit relative instruction pointer.

SBZ

Should be zero. An attempt by software to set an SBZ bit to 1 results in undefined behavior. See *reserved*.

scalar

An atomic value existing independently of any specification of location, direction, etc., as opposed to vectors.

set

To write the value 1 to a bit or a range of bits. See *clear*.

SIMD

Single instruction, multiple data. See *vector*.

Streaming SIMD Extensions (SSE)

Instructions that operate on scalar or vector (packed) integer and floating point numbers. The SSE instruction set comprises the legacy SSE and extended SSE instruction sets.

SSE1

Original SSE instruction set. Includes instructions that operate on vector operands in both the MMX and the XMM registers.

SSE2

Extensions to the SSE instruction set.

SSE3

Further extensions to the SSE instruction set.

SSSE3

Further extensions to the SSE instruction set.

SSE4.1

Further extensions to the SSE instruction set.

SSE4.2

Further extensions to the SSE instruction set.

SSE4A

A minor extension to the SSE instruction set adding the instructions EXTRQ, INSERTQ, MOVNTSS, and MOVNTSD.

sticky bit

A bit that is set or cleared by hardware and that remains in that state until explicitly changed by software.

TSS

Task-state segment.

underflow

The condition in which a floating-point number is smaller in magnitude than the smallest nonzero, positive or negative number that can be represented in the data-type format being used.

vector

- (1) A set of integer or floating-point values, called *elements*, that are packed into a single operand. Most media instructions use vectors as operands. Also called *packed* or *SIMD* operands.
- (2) An *interrupt descriptor table* index, used to access exception handlers. See *exception*.

VEX prefix

Extended instruction encoding escape prefix. Introduces a two- or three-byte encoding escape sequence used in the encoding of AVX instructions. Opens a new extended instruction encoding space. Fields select the opcode map and allow the specification of operand vector length and an additional operand register. See *XOP prefix*.

virtual-8086 mode

A submode of *legacy mode*.

VMCB

Virtual machine control block.

VMM

Virtual machine monitor.

word

Two bytes, or 16 bits.

x86

See *legacy x86*.

XOP instructions

Part of the extended SSE instruction set using the XOP prefix. See Streaming SIMD Extensions.

XOP prefix

Extended instruction encoding escape prefix. Introduces a three-byte escape sequence used in the encoding of XOP instructions. Opens a new extended instruction encoding space distinct from the VEX opcode space. Fields select the opcode map and allow the specification of operand vector length and an additional operand register. See *VEX prefix*.

Registers

In the following list of registers, mnemonics refer either to the register itself or to the register content:

AH–DH

The high 8-bit AH, BH, CH, and DH registers. See *[AL–DL]*.

AL–DL

The low 8-bit AL, BL, CL, and DL registers. See *[AH–DH]*.

AL–r15B

The low 8-bit AL, BL, CL, DL, SIL, DIL, BPL, SPL, and [r8B–r15B] registers, available in 64-bit mode.

BP

Base pointer register.

CR_n

Control register number *n*.

CS

Code segment register.

eAX–eSP

The 16-bit AX, BX, CX, DX, DI, SI, BP, and SP registers or the 32-bit EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP registers. See [rAX–rSP].

EFER

Extended features enable register.

eFLAGS

16-bit or 32-bit flags register. See *rFLAGS*.

EFLAGS

32-bit (extended) flags register.

eIP

16-bit or 32-bit instruction-pointer register. See *rIP*.

EIP

32-bit (extended) instruction-pointer register.

FLAGS

16-bit flags register.

GDTR

Global descriptor table register.

GPRs

General-purpose registers. For the 16-bit data size, these are AX, BX, CX, DX, DI, SI, BP, and SP. For the 32-bit data size, these are EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP. For the 64-bit data size, these include RAX, RBX, RCX, RDX, RDI, RSI, RBP, RSP, and R8–R15.

IDTR

Interrupt descriptor table register.

IP

16-bit instruction-pointer register.

LDTR

Local descriptor table register.

MSR

Model-specific register.

r8–r15

The 8-bit R8B–R15B registers, or the 16-bit R8W–R15W registers, or the 32-bit R8D–R15D registers, or the 64-bit R8–R15 registers.

rAX–rSP

The 16-bit AX, BX, CX, DX, DI, SI, BP, and SP registers, or the 32-bit EAX, EBX, ECX, EDX, EDI, ESI, EBP, and ESP registers, or the 64-bit RAX, RBX, RCX, RDX, RDI, RSI, RBP, and RSP registers. Replace the placeholder *r* with nothing for 16-bit size, “E” for 32-bit size, or “R” for 64-bit size.

RAX

64-bit version of the EAX register.

RBP

64-bit version of the EBP register.

RBX

64-bit version of the EBX register.

RCX

64-bit version of the ECX register.

RDI

64-bit version of the EDI register.

RDX

64-bit version of the EDX register.

rFLAGS

16-bit, 32-bit, or 64-bit flags register. See *RFLAGS*.

RFLAGS

64-bit flags register. See *rFLAGS*.

rIP

16-bit, 32-bit, or 64-bit instruction-pointer register. See *RIP*.

RIP

64-bit instruction-pointer register.

RSI

64-bit version of the ESI register.

RSP

64-bit version of the ESP register.

SP

Stack pointer register.

SS

Stack segment register.

TPR

Task priority register (CR8).

TR

Task register.

YMM/XMM

Set of sixteen (eight accessible in legacy and compatibility modes) 256-bit wide registers that hold scalar and vector operands used by the SSE instructions.

Endian Order

The x86 and AMD64 architectures address memory using little-endian byte-ordering. Multibyte values are stored with the least-significant byte at the lowest byte address, and illustrated with their least significant byte at the right side. Strings are illustrated in reverse order, because the addresses of string bytes increase from right to left.

1 Introduction

Processors capable of performing the same mathematical operation simultaneously on multiple data streams are classified as *single-instruction, multiple-data (SIMD)*. Instructions that utilize this hardware capability are called SIMD instructions.

Software can utilize SIMD instructions to drastically increase the performance of media applications which typically employ algorithms that perform the same mathematical operation on a set of values in parallel. The original SIMD instruction set was called MMX and operated on 64-bit wide vectors of integer and floating-point elements. Subsequently a new SIMD instruction set called the Streaming SIMD Extensions (SSE) was added to the architecture.

The SSE instruction set defines a new programming model with its own array of vector data registers (YMM/XMM registers) and a control and status register (MXCSR). Most SSE instructions pull their operands from one or more YMM/XMM registers and store results in a YMM/XMM register, although some instructions use a GPR as either a source or destination. Most instructions allow one operand to be loaded from memory. The set includes instructions to load a YMM/XMM register from memory (aligned or unaligned) and store the contents of a YMM/XMM register.

An overview of the SSE instruction set is provided in Volume 1, Chapter 4.

This volume provides detailed descriptions of each instruction within the SSE instruction set. The SSE instruction set comprises the *legacy* SSE instructions and the *extended* SSE instructions.

Legacy SSE instructions comprise the following subsets:

- The original Streaming SIMD Extensions (herein referred to as SSE1)
- SSE2
- SSE3
- SSSE3
- SSE4.1
- SSE4.2
- SSE4A
- Advanced Encryption Standard (AES)

Extended SSE instructions comprise the following subsets:

- AVX
- FMA
- FMA4
- XOP

Legacy SSE architecture supports operations involving 128-bit vectors and defines the base programming model including the SSE registers, the Media Control and Status Register (MXCSR), and the instruction exception behavior.

The Streaming SIMD Extensions (SSE) instruction set is extended to include the AVX, FMA, FMA4, and XOP instruction sets. The AVX instruction set provides an extended form for most legacy SSE instructions and several new instructions. Extensions include providing for the specification of a unique destination register for operations with two or more source operands and support for 256-bit wide vectors. Some AVX instructions also provide enhanced functionality compared to their legacy counterparts.

A significant feature of the extended SSE instruction set architecture is the doubling of the width of the XMM registers. These registers are referred to as the YMM registers. The XMM registers overlay the lower octword (128 bits) of the YMM registers. Registers YMM/XMM0–7 are accessible in legacy and compatibility mode. Registers YMM/XMM8–15 are available in 64-bit mode (a subset of long mode). VEX/XOP instruction prefixes allow instruction encodings to address the additional registers.

The SSE instructions can be used in processor legacy mode or long (64-bit) mode. CPUID function 8000_0001h[LM] indicates the availability of long mode.

Compilation for execution in 64-bit mode offers the following advantages:

- Access to an additional eight YMM/XMM registers for a total of 16
- Access to an additional eight 64-bit general-purpose registers for a total of 16
- Access to the 64-bit virtual address space and the RIP-relative addressing mode

Hardware support for each of the subsets of SSE instructions listed above is indicated by CPUID feature bits. Refer to Volume 2, Chapter 11, “Determining Media and x87 Feature Support” for a list of feature bits. The CPUID feature bits that pertain to each instruction are also given in the instruction descriptions below.

The following chapter contains detailed descriptions of each instruction, organized in alphabetic order by mnemonic. In the instruction reference chapter that follows, the extended (AVX) form(s) of each legacy SSE instruction is (are) described together with the legacy instruction in one entry. For these instructions, the instruction reference page is located based on the instruction mnemonic of the legacy SSE and not the extended (AVX) form. Those AVX instructions without a legacy form are listed in order by their AVX mnemonic. The mnemonic for all extended SSE instructions including the FMA and XOP instructions begin with the letter V.

1.1 Syntax and Notation

The descriptive synopsis of opcode syntax for legacy SSE instructions follows the conventions described in *Volume 3: General Purpose and System Instructions*. See Chapter 2 and the section entitled “Notation.”

For general information on the programming model and overview descriptions of the SSE instruction set, see:

- “Streaming SIMD Extensions Media and Scientific Programming” in Volume 1.
- “Summary of Registers and Data Types” in Volume 3.
- “Instruction Prefixes” in Volume 3

The syntax of the extended instruction sets requires an expanded synopsis. The expanded synopsis includes a mnemonic summary and a summary of prefix sequence fields. Figure 1-1 shows the descriptive synopsis of a typical XOP instruction. The synopsis of VEX-encoded instructions have the same format, differing only in regard to the instruction encoding escape prefix, that is, VEX instead of XOP.

Figure 1-1. Typical Descriptive Synopsis - Extended SSE Instructions

1.2 Extended Instruction Encoding

The legacy SSE instructions are encoded using the legacy encoding syntax and the extended instructions are encoded using an enhanced encoding syntax which is compatible with the legacy syntax. Both are described in detail in Chapter 1 of Volume 3.

As described in Volume 3, the extended instruction encoding syntax utilizes multi-byte escape sequences to both select alternate opcode maps as well as augment the encoding of the instruction. Multi-byte escape sequences are introduced by one of the two VEX prefixes or the XOP prefix.

The AVX instructions utilize either the two-byte (introduced by the VEX C5h prefix) or the three-byte (introduced by the VEX C4h prefix) encoding escape sequence. XOP instructions are encoded using a three-byte encoding escape sequence introduced by the XOP prefix (except for the XOP instruction VPERMIL2PS which is encoded using the VEX prefix). The XOP prefix is 8Fh. The three-byte encoding escape sequences utilize the map_select field of the second byte to select the opcode map used to interpret the opcode byte.

The two-byte VEX prefix sequence implicitly selects the secondary (“two-byte”) opcode map.

1.2.1 Immediate Byte Usage Unique to the SSE instructions

An *immediate* is a value, typically an operand, explicitly provided within the instruction encoding. Depending on the opcode and the operating mode, the size of an immediate operand can be 1, 2, 4, or 8 bytes. Legacy and extended media instructions typically use an immediate byte operand (*imm8*).

A one-byte immediate is generally shown in the instruction synopsis as “ib” suffix. For extended SSE instructions with four source operands, the suffix “is4” is used to indicate the presence of the immediate byte used to select the fourth source operand.

The VPERMIL2PD/PS instructions utilize a fifth 2-bit operand which is encoded along with the fourth register select index in an immediate byte. For this special case the immediate byte will be shown in the instruction synopsis as “is5”.

1.2.2 Instruction Format Examples

The following sections provide examples of two-, three-, and four-operand extended instructions. These instructions generally perform *nondestructive-source operations*, meaning that the result of the operation is written to a separately specified destination register rather than overwriting one of the source operands. This preserves the contents of the source registers. Most legacy SSE instructions perform *destructive-source operations*, in which a single register is both source and destination, so source content is lost.

1.2.2.1 XMM Register Destinations

The following general properties apply to YMM/XMM register destination operands.

- For legacy instructions that use XMM registers as a destination: When a result is written to a destination XMM register, bits [255:128] of the corresponding YMM register are not affected.
- For extended instructions that use XMM registers as a destination: When a result is written to a destination XMM register, bits [255:128] of the corresponding YMM register are cleared.

1.2.2.2 Two Operand Instructions

Two-operand instructions use ModRM-based operand assignment. For most instructions, the first operand is the destination, selected by the ModRM.reg field, and the second operand is either a register or a memory source, selected by the ModRM.r/m field.

VCVTDQ2PD is an example of a two-operand AVX instruction.

Mnemonic	Encoding			
	VEX	RXB.map_select	W.vvvv.L.pp	Opcode
VCVTDQ2PD <i>xmm1, xmm2/mem64</i>	C4	$\overline{\text{RXB}}$.01	0.1111.0.10	E6 /r
VCVTDQ2PD <i>ymm1, xmm2/mem128</i>	C4	$\overline{\text{RXB}}$.01	0.1111.1.10	E6 /r

The destination register is selected by ModRM.reg. The size of the destination register is determined by VEX.L. The source is either an YMM/XMM register or a memory location specified by ModRM.r/m. Because this instruction converts packed doubleword integers to double-precision floating-point values, the source data size is smaller than the destination data size.

VEX.vvvv is not used and must be set to 1111b.

1.2.2.3 Three-Operand Instructions

These extended instructions have two source operands and a destination operand.

VPROTB is an example of a three-operand XOP instruction.

There are versions of the instruction for variable-count rotation and for fixed-count rotation.

VPROTB *dest, src, variable-count*

VPROTB *dest, src, fixed-count*

Mnemonic	Encoding			
	XOP	RXB.map_select	W.vvvv.L.pp	Opcode
VPROTB <i>xmm1, xmm2/mem128, xmm3</i>	8F	RXB.09	0. <u>src</u> .0.00	90 /r
VPROTB <i>xmm1, xmm2, xmm3/mem128</i>	8F	RXB.09	1. <u>src</u> .0.00	90 /r
VPROTB <i>xmm1, xmm2/mem128, imm8</i>	8F	RXB.08	0.1111.0.00	90 /r ib

For both versions of the instruction, the destination (*dest*) operand is an XMM register specified by ModRM.reg.

The variable-count version of the instruction rotates each byte of the source as specified by the corresponding byte element *variable-count*.

Selection of *src* and *variable-count* is controlled by XOP.W.

- When XOP.W = 0, *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m, and *variable-count* is an XMM register specified by XOP.vvvv.
- When XOP.W = 1, *src* is an XMM register specified by XOP.vvvv and *variable-count* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.

Table 1-1 summarizes the effect of the XOP.W bit on operand selection.

Table 1-1. Three-Operand Selection

XOP.W	<i>dest</i>	<i>src</i>	<i>variable-count</i>
0	ModRM.reg	ModRM.r/m	XOP.vvvv
1	ModRM.reg	XOP.vvvv	ModRM.r/m

The fixed-count version of the instruction rotates each byte of *src* as specified by the immediate byte operand *fixed-count*. For this version, *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m. Because XOP.vvvv is not used to specify the source register, it must be set to 1111b or execution of the instruction will cause an Invalid Opcode (#UD) exception.

1.2.2.4 Four-Operand Instructions

Some extended instructions have three source operands and a destination operand. This is accomplished by using the VEX/XOP.vvvv field, the ModRM.reg and ModRM.r/m fields, and bits [7:4] of an immediate byte to select the operands. The opcode suffix “is4” is used to identify the immediate byte, and the selected operands are shown in the synopsis.

VFMSUBPD is an example of an four-operand FMA4 instruction.

VFMSUBPD *dest, src1, src2, src3* $dest = src1 * src2 - src3$

Mnemonic	Encoding			Opcode
	VEX	RXB.map_select	W.vvvv.L.pp	
VFMSUBPD <i>xmm1, xmm2, xmm3/mem128, xmm4</i>	C4	$\overline{RXB}.03$	$0.\overline{src}.0.01$	6D /r is4
VFMSUBPD <i>ymm1, ymm2, ymm3/mem256, ymm4</i>	C4	$\overline{RXB}.03$	$0.\overline{src}.1.01$	6D /r is4
VFMSUBPD <i>xmm1, xmm2, xmm3, xmm4/mem128</i>	C4	$\overline{RXB}.03$	$1.\overline{src}.0.01$	6D /r is4
VFMSUBPD <i>ymm1, ymm2, ymm3, ymm4/mem256</i>	C4	$\overline{RXB}.03$	$1.\overline{src}.1.01$	6D /r is4

The first operand, the destination (*dest*), is an XMM register or a YMM register (as determined by VEX.L) selected by ModRM.reg. The following three operands (*src1, src2, src3*) are sources.

The *src1* operand is an XMM or YMM register specified by VEX.vvvv.

VEX.W determines the configuration of the *src2* and *src3* operands.

- When VEX.W = 0, *src2* is either a register or a memory location specified by ModRM.r/m, and *src3* is a register specified by bits [7:4] of the immediate byte.
- When VEX.W = 1, *src2* is a register specified by bits [7:4] of the immediate byte and *src3* is either a register or a memory location specified by ModRM.r/m.

Table 1-1 summarizes the effect of the VEX.W bit on operand selection.

Table 1-2. Four-Operand Selection

VEX.W	<i>dest</i>	<i>src1</i>	<i>src2</i>	<i>src3</i>
0	ModRM.reg	VEX.vvvv	ModRM.r/m	is4[7:4]
1	ModRM.reg	VEX.vvvv	is4[7:4]	ModRM.r/m

1.3 Enabling SSE Instruction Execution

Application software that utilizes the SSE instructions requires support from operating system software.

To enable and support SSE instruction execution, operating system software must:

- enable hardware for supported SSE subsets
- manage the SSE hardware architectural state, saving and restoring it as required during and after task switches

- provide exception handlers for all unmasked SSE exceptions.

See Volume 3, Chapter 11, for details on enabling SSE execution and managing its execution state.

1.4 AES Instructions

This section provides an overview of AMD64 instructions that support AES software implementation.

The U.S. National Institute of Standards and Technology has adopted the Rijndael algorithm, a block cipher that processes 16-byte data blocks using a shared key of variable length, as the Advanced Encryption Standard (AES). The standard is defined in Federal Information Processing Standards Publication 197 (FIPS 197), *Specification for the Advanced Encryption Standard (AES)*. There are three versions of the algorithm, based on key widths of 16 (AES-128), 24 (AES-192), and 32 (AES-256) bytes.

The following AMD64 instructions support AES implementation:

- AESDEC/VAESDEC and AESDECLAST/VAESDECLAST
Perform one round of AES decryption
- AESENC/VAESENC and AESENCLAST/VAESENCLAST
Perform one round of AES encryption
- AESIMC/VAESIMC
Perform the AES InvMixColumn transformation
- AESKEYGENASSIST/VAESKEYGENASSIST
Assist AES round key generation
- PCLMULQDQ, VPCLMULQDQ
Perform carry-less multiplication

See Chapter 1, “Instruction Reference” for detailed descriptions of the instructions.

1.4.1 Coding Conventions

This overview uses descriptive code that has the following basic characteristics.

- Syntax and notation based on the C language
- Four numerical data types:
 - bool: The numbers 0 and 1, the values of the Boolean constants false and true
 - nat: The infinite set of all natural numbers, including bool as a subtype
 - int: The infinite set of all integers, including nat as a subtype
 - rat: The infinite set of all rational numbers, including int as a subtype
- Standard logical and arithmetic operators
- Enumeration (enum) types, arrays, structures (struct), and union types
- Global and local variable and constant declarations, initializations, and assignments
- Standard control constructs (if, then, else, for, while, switch, break, and continue)
- Function subroutines
- Macro definitions (#define)

1.4.2 AES Data Structures

The AES instructions operate on 16-byte blocks of text called the *state*. Each block is represented as a 4×4 matrix of bytes which is assigned the Galois field matrix data type (GFMatrix). In the AMD64 implementation, the matrices are formatted as 16-byte vectors in XMM registers or 128-bit memory locations. This overview represents each matrix as a sequence of 16 bytes in little-endian format (least significant byte on the right and most significant byte on the left).

Figure 1-2 shows a state block in 4×4 matrix representation.

$$GFMatrix = \begin{pmatrix} X_{3,0} & X_{2,0} & X_{1,0} & X_{0,0} \\ X_{3,1} & X_{2,1} & X_{1,1} & X_{0,1} \\ X_{3,2} & X_{2,2} & X_{1,2} & X_{0,2} \\ X_{3,3} & X_{2,3} & X_{1,3} & X_{0,3} \end{pmatrix}$$

Figure 1-2. GFMatrix Representation of 16-byte Block

Figure 1-3 shows the AMD64 AES format, with the corresponding mapping of FIPS 197 AES “words” to operand bytes.

Figure 1-3. GFMatrix to Operand Byte Mappings

1.4.3 Algebraic Preliminaries

AES operations are based on the Galois field $GF = GF(2^8)$, of order 256, constructed by adjoining a root of the irreducible polynomial

$$p(X) = X^8 + X^4 + X^3 + X + 1$$

to the field of two elements, \mathbb{Z}_2 . Equivalently, GF is the quotient field $\mathbb{Z}_2[X]/p(X)$ and thus may be viewed as the set of all polynomials of degree less than 8 in $\mathbb{Z}_2[X]$ with the operations of addition and multiplication modulo $p(X)$. These operations may be implemented efficiently by exploiting the mapping from $\mathbb{Z}_2[X]$ to the natural numbers given by

$$a_n X^n + \dots + a_1 X + a_0 \rightarrow 2^n a_n + \dots + 2 a_1 + a_0 \rightarrow a_n \dots a_1 a_0 b$$

For example:

$$\begin{aligned} 1 &\rightarrow 01\text{h} \\ X &\rightarrow 02\text{h} \\ X^2 &\rightarrow 04\text{h} \\ X^4 + X^3 + 1 &\rightarrow 19\text{h} \\ p(X) &\rightarrow 11\text{Bh} \end{aligned}$$

Thus, each element of GF is identified with a unique byte. This overview uses the data type **GF256** as an alias of **nat**, to identify variables that are to be thought of as elements of GF .

The operations of addition and multiplication in GF are denoted by \oplus and \odot , respectively. Since \mathbb{Z}_2 is of characteristic 2, addition is simply the “exclusive or” operation:

$$x \oplus y = x \wedge y$$

In particular, every element of GF is its own additive inverse.

Multiplication in GF may be computed as a sequence of additions and multiplications by 2. Note that this operation may be viewed as multiplication in $\mathbb{Z}_2[X]$ followed by a possible reduction modulo $p(X)$. Since 2 corresponds to the polynomial X and 11B corresponds to $p(X)$, for any $x \in GF$,

$$2 \odot x = \begin{cases} x \ll 1 & \text{if } x < 80\text{h} \\ (x \ll 1) \oplus 11\text{Bh} & \text{if } x \geq 80\text{h} \end{cases}$$

Now, if $y = b_7 \dots b_1 b_0 b$, then

$$x \odot y = 2 \odot (\dots (2 \odot (2 \odot (b_7 \odot x) \oplus b_6 \odot x) \oplus b_5 \odot x) \dots b_0).$$

This computation is performed by the **GFMul()** function.

1.4.3.1 Multiplication in the Field GF

The **GFMul()** function operates on GF256 elements in SRC1 and SRC2 and returns a GF256 matrix in the destination.

```
GF256 GFMul(GF256 x, GF256 y) {
    nat sum = 0;
    for (int i=7; i>=0; i--) {
        // Multiply sum by 2. This amounts to a shift followed
        // by reduction mod 0x11B:
        sum <<= 1;
        if (sum > 0xFF) {sum = sum ^ 0x11B;}
        // Add y[i]*x:
        if (y[i]) {sum = sum ^ x;}
    }
    return sum;
}
```

Because the multiplicative group GF^* is of order 255, the inverse of an element x of GF may be computed by repeated multiplication as $x^{-1} = x^{254}$. A more efficient computation, however, is performed by the **GFInv()** function as an application of Euclid's greatest common divisor algorithm. See Section 1.4.10, "Computation of GFInv with Euclidean Greatest Common Divisor" for an analysis of this computation and the **GFInv()** function.

The AES algorithms operate on the vector space GF^4 , of dimension 4 over GF , which is represented by the array type **GFWord**. FIPS 197 refers to an object of this type as a *word*. This overview uses the term *GF word* in order to avoid confusion with the AMD64 notion of a 16-bit word.

A **GFMatrix** is an array of four GF words, which are viewed as the rows of a 4×4 matrix over GF .

The field operation symbols \oplus and \odot are used to denote addition and multiplication of matrices over GF as well. The **GFMatrixMul()** function computes the product $A \odot B$ of 4×4 matrices.

1.4.3.2 Multiplication of 4x4 Matrices Over GF

```
, GFMatrix GFMatrixMul(GFMatrix a, GFMatrix b) {
  GFMatrix c;
  for (nat i=0; i<4; i++) {
    for (nat j=0; j<4; j++) {
      c[i][j] = 0;
      for (nat k=0; k<4; k++) {
        c[i][j] = c[i][j] ^ GFMul(a[i][k], b[k][j]);
      }
    }
  }
  return c;
}
```

1.4.4 AES Operations

The AES encryption and decryption procedures may be specified as follows, in terms of a set of basic operations that are defined later in this section. See the alphabetic instruction reference for detailed descriptions of the instructions that are used to implement the procedures.

Call the **Encrypt** or **Decrypt** procedure, which pass the same expanded key to the functions

TextBlock Cipher(TextBlock in, ExpandedKey w, nat Nk)

and

TextBlock InvCipher(TextBlock in, ExpandedKey w, nat Nk)

In both cases, the input text is converted by

GFMatrix Text2Matrix(TextBlock A)

to a matrix, which becomes the initial state of the process. This state is transformed through the sequence of $N_r + 1$ rounds and ultimately converted back to a linear array by

TextBlock Matrix2Text(GFMatrix M).

In each round i , the round key K_i is extracted from the expanded key w and added to the state by

GFMatrix AddRoundKey(GFMatrix state, ExpandedKey w, nat round).

Note that **AddRoundKey** does not explicitly construct K_i , but operates directly on the bytes of w .

The rounds of **Cipher** are numbered $0, \dots, N_r$. Let X be the initial state an an execution, i.e., the input in matrix format, let S_i be the state produced by round i , and let $Y = S_{N_r}$ be the final state. Let Σ , R , and C denote the operations performed by **SubBytes**, **ShiftRows**, **MixColumns**, respectively. Then

The initial round is a simple addition:

$$S_0 = X \oplus K_0;$$

Each of the next $N_r + 1$ rounds is a composition of four operations:

$$S_i = \mathcal{C}(\mathcal{R}(\Sigma(S_{i-1}))) \oplus K_i \quad \text{for } i = 1, \dots, N_r - 1;$$

The **MixColumns** transformation is omitted from the final round:

$$Y = S_{N_r} = \mathcal{R}(\Sigma(S_{N_r-1})) \oplus K_{N_r}.$$

Composing these expressions yields

$$Y = \mathcal{R}(\Sigma(\mathcal{C}(\mathcal{R}(\Sigma(\dots(\mathcal{C}(\mathcal{R}(\Sigma(X \oplus K_0))) \oplus K_1) \dots))) \oplus K_{N_r-1})) \oplus K_{N_r}.$$

Note that the rounds of **InvCipher** are numbered in reverse order, $N_r, \dots, 0$. If X' and Y' are the initial and final states and S'_i is the state following round i , then

$$S'_{N_r} = X' \oplus K_{N_r};$$

$$S'_i = \mathcal{C}^{-1}(\Sigma^{-1}(\mathcal{R}^{-1}(S'_{i+1})) \oplus K_i) \quad \text{for } i = N_r - 1, \dots, 1;$$

$$Y' = \Sigma^{-1}(\mathcal{R}^{-1}(S'_1)) \oplus K_0.$$

Composing these expressions yields

$$Y' = \Sigma^{-1}(\mathcal{R}^{-1}(\mathcal{C}^{-1}(\Sigma^{-1}(\mathcal{R}^{-1}(\dots(\mathcal{C}^{-1}(\Sigma^{-1}(\mathcal{R}^{-1}(X' \oplus K_{N_r}) \oplus K_{N_r-1})) \dots)) \oplus K_1))) \oplus K_0.$$

In order to show that **InvCipher** is the inverse of **Cipher**, it is only necessary to combine these expanded expressions by replacing X' with Y and cancel inverse operations to yield $Y' = X$.

1.4.4.1 Sequence of Operations

- Use predefined **SBox** and **InvSBox** matrices or initialize the matrices using the **ComputeSBox** and **ComputeInvSBox** functions.
- Call the **Encrypt** or **Decrypt** procedure.
 - For the **Encrypt** procedure:
 1. Load the input **TextBlock** and **CipherKey**.
 2. Expand the cipher key using the **KeyExpansion** function.
 3. Call the **Cipher** function to perform the number of rounds determined by the cipher key length.
 4. Perform round entry operations.
 - a. Convert input text block to state matrix using the **Text2Matrix** function.
 - b. Combine state and round key bytes by bitwise XOR using the **AddRoundKey** function.
 5. Perform round iteration operations.
 - a. Replace each state byte with another by non-linear substitution using the **SubBytes** function.
 - b. Shift each row of the state cyclically using the **ShiftRows** function.
 - c. Combine the four bytes in each column of the state using the **MixColumns** function.
 - d. Perform **AddRoundKey**.
 6. Perform round exit operations.
 - a. Perform **SubBytes**.
 - b. Perform **ShiftRows**.
 - c. Perform **AddRoundKey**.
 - d. Convert state matrix to output text block using the **Matrix2Text** function and return **TextBlock**.
 - For the **Decrypt** procedure:
 1. Load the input **TextBlock** and **CipherKey**.
 2. Expand the cipher key using the **KeyExpansion** function.
 3. Call the **InvCipher** function to perform the number of rounds determined by the cipher key length.
 4. Perform round entry operations.
 - a. Convert input text block to state matrix using the **Text2Matrix** function.
 - b. Combine state and round key bytes by bitwise XOR using the **AddRoundKey** function.
 5. Perform round iteration operations.
 - a. Shift each row of the state cyclically using the **InvShiftRows** function.
 - b. Replace each state byte with another by non-linear substitution using the **InvSubBytes** function.
 - c. Perform **AddRoundKey**.
 - d. Combine the four bytes in each column of the state using the **InvMixColumns** function.
 6. Perform round exit operations.
 - a. Perform **InvShiftRows**.
 - b. Perform **InvSubBytes (InvSubWord)**.
 - c. Perform **AddRoundKey**.
 - d. Convert state matrix to output text block using the **Matrix2Text** function and return **TextBlock**.

1.4.5 Initializing the Sbox and InvSBox Matrices

The AES makes use of a bijective mapping $\sigma : GF \rightarrow GF$, which is encoded, along with its inverse mapping, in the 16×16 arrays **SBox** (for encryption) and **InvSBox** (for decryption), as follows:

for all $x \in G$,

$$\sigma(x) = \text{SBox}[x[7:4], x[3:0]]$$

and

$$\sigma^{-1}(x) = \text{InvSBox}[x[7:4], x[3:0]]$$

While the FIPS 197 standard defines the contents of the **SBox**[] and **InvSbox** [] matrices, the matrices may also be initialized algebraically (and algorithmically) by means of the **ComputeSBox()** and **ComputeInvSBox()** functions, discussed below.

The bijective mappings for encryption and decryption are computed by the **SubByte()** and **InvSubByte()** functions, respectively:

SubByte() computation:

```
GF256 SubByte(GF256 x) {
    return SBox[x[7:4]][x[3:0]];
}
```

InvSubByte() computation:

```
GF256 InvSubByte(GF256 x) {
    return InvSBox[x[7:4]][x[3:0]];
}
```

1.4.5.1 Computation of SBox and InvSBox

Computation of SBox and InvSBox elements has a direct relationship to the cryptographic properties of the AES, but not to the algorithms that use the tables. Readers who prefer to view σ as a primitive operation may skip the remainder of this section.

The algorithmic definition of the bijective mapping σ is based on the consideration of GF as an 8-dimensional vector space over the subfield \mathbb{Z}_2 . Let ϕ be a linear operator on this vector space and let $M = [a_{ij}]$ be the matrix representation of ϕ with respect to the ordered basis $\{1, 2, 4, 10, 20, 40, 80\}$. Then ϕ may be encoded concisely as an array of bytes A of dimension 8, each entry of which is the concatenation of the corresponding row of M :

$$A[i] = a_{i8}a_{i7} \dots a_{i0}$$

This expression may be represented algorithmically by means of the **ApplyLinearOp()** function, which applies a linear operator to an element of GF . The **ApplyLinearOp()** function is used in the initialization of both the **sBox**[] and **InvSBox**[] matrices.

// The following function takes the array A representing a linear operator phi and
 // an element x of G and returns phi(x):

```
GF256 ApplyLinearOp(GF256 A[8], GF256 x) {
  GF256 result = 0;
  for (nat i=0; i<8; i++) {
    bool sum = 0;
    for (nat j=0; j<8; j++) {
      sum = sum ^ (A[i][j] & x[j]);
    }
    result[i] = sum;
  }
  return result;
}
```

The definition of σ involves the linear operator ϕ with matrix

$$M = \begin{bmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{bmatrix}$$

In this case,

$$A = \{F1, E3, C7, 8F, 1F, 3E, 7C, F8\}.$$

Initialization of SBox[]

The mapping $\sigma : G \rightarrow G$ is defined by

$$\sigma(x) = \phi(x^{-1}) \oplus 63$$

This computation is performed by **ComputeSBox()**.

ComputeSBox()

```
GF256[16][16] ComputeSBox() {
  GF256 result[16][16];
  GF256 A[8] = {0xF1, 0xE3, 0xC7, 0x8F, 0x1F, 0x3E, 0x7C, 0xF8};
  for (nat i=0; i<16; i++) {
    for (nat j=0; j<16; j++) {
      GF256 x = (i << 4) | j;
      result[i][j] = ApplyLinearOp(A, GFInv(x)) ^ 0x63;
    }
  }
  return result;
}
```

```
const GF256 SBox[16][16] = ComputeSBox();
```

Table 1-3 shows the resulting **SBox**[], as defined in FIPS 197.

Table 1-3. SBox Definition

		S[3:0]															
		0	1	2	3	4	5	6	7	8	9	a	b	c	d	e	f

	f	8c	a1	89	0d	bf	e6	42	68	41	99	2d	0f	b0	54	bb	16

1.4.5.2 Initialization of InvSBox[]

A straightforward calculation confirms that the matrix M is nonsingular with inverse.

Thus, ϕ is invertible and ϕ^{-1} is encoded as the array

$$M^{-1} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \end{bmatrix}$$

$$B = \{A4, 49, 92, 25, 4A, 94, 29, 52\}.$$

If $y = \sigma(x)$, then

$$\begin{aligned} (\phi^{-1}(y) \oplus 5)^{-1} &= (\phi^{-1}(y \oplus \phi(5)))^{-1} \\ &= (\phi^{-1}(y \oplus 63))^{-1} \\ &= (\phi^{-1}(\phi(x^{-1}) \oplus 63 \oplus 63))^{-1} \\ &= (\phi^{-1}(\phi(x^{-1})))^{-1} \\ &= x, \end{aligned}$$

and σ is a permutation of GF with

$$\sigma^{-1}(y) = (\phi^{-1}(y) \oplus 5)^{-1}$$

This computation is performed by **ComputeInvSBox()**.

ComputeInvSBox()

```
GF256 [16] [16] ComputeInvSBox() {
    GF256 result [16] [16];
    GF256 B [8] = {0xA4, 0x49, 0x92, 0x25, 0x4A, 0x94, 0x29, 0x52};
    for (nat i=0; i<16; i++) {
        for (nat j=0; j<16; j++) {
            GF256 y = (i << 4) | j;
            result[i][j] = GFInv(ApplyLinearOp(B, y) ^ 0x5);
        }
    }
    return result;
}
```

```
const GF256 InvSBox [16] [16] = ComputeInvSBox();
```

Table 1-4 shows the resulting **InvSBox[]**, as defined in the FIPS 197.

Table 1-4. InvSBox Definition

		S[3:0]

1.4.6 Encryption and Decryption

The AMD64 architecture implements the AES algorithm by means of an iterative function called a *round* for both encryption and the inverse operation, decryption.

The top-level encryption and decryption procedures **Encrypt()** and **Decrypt()** set up the rounds and invoke the functions that perform them. Each of the procedures takes two 128-bit binary arguments:

- *input data* — a 16-byte block of text stored in a source 128-bit XMM register
- *cipher key* — a 16-, 24-, or 32-byte cipher key stored in either a second 128-bit XMM register or 128-bit memory location

1.4.6.1 The Encrypt() and Decrypt() Procedures

```
TextBlock Encrypt(TextBlock in, CipherKey key, nat Nk) {
    return Cipher(in, ExpandKey(key, Nk), Nk);
}
```

```
TextBlock Decrypt(TextBlock in, CipherKey key, nat Nk) {
    return InvCipher(in, ExpandKey(key, Nk), Nk);
}
```

The array types **TextBlock** and **CipherKey** are introduced to accommodate the text and key parameters. The 16-, 24-, or 32-byte cipher keys correspond to AES-128, AES-192, or AES-256 key sizes. The cipher key is logically partitioned into $N_k = 4, 6,$ or 8 AES 32-bit words. N_k is passed as a parameter to determine the AES version to be executed, and the number of rounds to be performed.

Both the **Encrypt()** and **Decrypt()** procedures invoke the **ExpandKey()** function to expand the cipher key for use in round key generation. When key expansion is complete, either the **Cipher()** or **InvCipher()** functions are invoked.

The **Cipher()** and **InvCipher()** functions are the key components of the encryption and decryption process. See Section 1.4.7, “The Cipher Function” and Section 1.4.8, “The InvCipher Function” for detailed information.

1.4.6.2 Round Sequences and Key Expansion

Encryption and decryption are performed in a sequence of rounds indexed by $0, \dots, N_r$, where N_r is determined by the number N_k of *GF* words in the cipher key. A key matrix called a *round key* is generated for each round. The number of *GF* words required to form $N_r + 1$ round keys is equal to $4(N_r + 1)$. Table 1-5 shows the relationship between cipher key length, round sequence length, and round key length.

Table 1-5. Cipher Key, Round Sequence, and Round Key Length

N_k	N_r	$4(N_r + 1)$
4	10	44
6	12	52
8	14	60

Expanded keys are generated from the cipher key by the **ExpandKey()** function, where the array type **ExpandedKey** is defined to accommodate 60 words (the maximum required) corresponding to $N_k = 8$.

The **ExpandKey()** Function

```
ExpandedKey ExpandKey(CipherKey key, nat Nk) {
  assert((Nk == 4) || (Nk == 6) || (Nk == 8));
  nat Nr = Nk + 6;
  ExpandedKey w;

  // Copy key into first Nk rows of w:
  for (nat i=0; i<Nk; i++) {
    for (nat j=0; j<4; j++) {
      w[i][j] = key[4*i+j];
    }
  }
}
```

```

// Write next row of w:
for (nat i=Nk; i<4*(Nr+1); i++) {

    // Encode preceding row:
    GFWord tmp = w[i-1];
    if (mod(i, Nk) == 0) {
        tmp = SubWord(RotWord(tmp));
        tmp[0] = tmp[0] ^ RCON[i/Nk];
    }
    else if ((Nk == 8) && (mod(i, Nk) == 4)) {
        tmp = SubWord(tmp);
    }

    // XOR tmp with w[i-Nk]:
    for (nat j=0; j<4; j++) {
        w[i][j] = w[i-Nk][j] ^ tmp[j];
    }
}
return w;
}

```

ExpandKey() begins by copying the input cipher key into the first N_k GF words of the expanded key w . The remaining $4(N_r + 1) - N_k$ GF words are computed iteratively. For each $i \geq N_k$, $w[i]$ is derived from the two GF words $w[i - 1]$ and $w[i - N_k]$. In most cases, $w[i]$ is simply the sum $w[i - 1] \oplus w[i - N_k]$. There are two exceptions:

- If i is divisible by N_k , then before adding it to $w[i - N_k]$, $w[i - 1]$ is first rotated by one position to the left by **RotWord()**, then transformed by the substitution **SubWord()**, and an element of the array **RCON** is added to it.

$$\text{RCON}[11] = \{00\text{h}, 01\text{h}, 02\text{h}, 04\text{h}, 08\text{h}, 10\text{h}, 20\text{h}, 40\text{h}, 80\text{h}, 1\text{Bh}, 36\text{h}\}$$

- In the case $N_k = 8$, if i is divisible by 4 but not 8, then $w[i - 1]$ is transformed by the substitution **SubWord()**.

The i^{th} round key K_i comprises the four GF words $w[4i]$, ..., $w[4i + 3]$. More precisely, let W_i be the matrix

$$W = \{w[4i], w[4i + 1], w[4i + 2], w[4i + 3]\}$$

Then $K_i = W_i^t$, the transpose of W_i . Thus, the entries of the array w are the columns of the round keys.

1.4.7 The Cipher Function

This function performs encryption. It converts the input text to matrix form, generates the round key from the expanded key matrix, and iterates through the transforming functions the number of times determined by encryption key size to produce a 128-bit binary cipher matrix. As a final step, it converts the matrix to an output text block.

```

TextBlock Cipher(TextBlock in, ExpandedKey w, nat Nk) {
    assert((Nk == 4) || (Nk == 6) || (Nk == 8));
    nat Nr = Nk + 6;
    GFMatrix state = Text2Matrix(in);
    state = AddRoundKey(state, w, 0);
    for (nat round=1; round<Nr; round++) {
        state = SubBytes(state);
        state = ShiftRows(state);
        state = MixColumns(state);
        state = AddRoundKey(state, w, round);
    }
    state = SubBytes(state);
    state = ShiftRows(state);
    state = AddRoundKey(state, w, Nr);
    return Matrix2Text(state);
}

```

1.4.7.1 Text to Matrix Conversion

Prior to processing, the input text block must be converted to matrix form. The **Text2Matrix()** function stores a **TextBlock** in a **GFMatrix** in column-major order as follows.

```

GFMatrix Text2Matrix(TextBlock A) {
    GFMatrix result;
    for (nat j=0; j<4; j++) {
        for (nat i=0; i<4; i++) {
            result[i][j] = A[4*j+i];
        }
    }
    return result;
}

```

1.4.7.2 Cipher Transformations

The Cipher function employs the following transformations.

SubBytes() — Applies a non-linear substitution table (SBox) to each byte of the state.

SubWord() — Uses a non-linear substitution table (SBox) to produce a four-byte AES output word from the four bytes of an AES input word.

ShiftRows() — Cyclically shifts the last three rows of the state by various offsets.

RotWord() — Rotates an AES (4-byte) word to the right.

MixColumns() — Mixes data in all the state columns independently to produce new columns.

AddRoundKey() — Extracts a 128-bit round key from the expanded key matrix and adds it to the 128-bit state using an XOR operation.

Inverses of **SubBytes()**, **SubWord()**, **ShiftRows()** and **MixColumns()** are used in decryption. See Section 1.4.8, “The InvCipher Function” for more information.

The SubBytes() Function

Performs a byte substitution operation using the invertible substitution table (**SBox**) to convert input text to an intermediate encryption state.

```
GFMMatrix SubBytes(GFMMatrix M) {
    GFMMatrix result;
    for (nat i=0; i<4; i++) {
        result[i] = SubWord(M[i]);
    }
    return result;
}
```

The SubWord() Function

Applies **SubBytes** to each element of a vector or a matrix:

```
GFWord SubWord(GFWord x) {
    GFWord result;
    for (nat i=0; i<4; i++) {
        result[i] = SubByte(x[i]);
    }
    return result;
}
```

The ShiftRows() Function

Cyclically shifts the last three rows of the state by various offsets.

```
GFMMatrix ShiftRows(GFMMatrix M) {
    GFMMatrix result;
    for (nat i=0; i<4; i++) {
        result[i] = RotateLeft(M[i], -i);
    }
    return result;
}
```

The RotWord() Function

Performs byte-wise cyclic permutation of a 32-bit AES word.

```
GFWord RotWord(GFWord x)
{ return RotateLeft(x, 1); }
```

The MixColumns() Function

Performs a byte-oriented column-by-column matrix multiplication

$M \rightarrow C \odot M$, where C is the predefined fixed matrix

$$C = \begin{bmatrix} 2 & 3 & 1 & 1 \\ 1 & 2 & 3 & 1 \\ 1 & 1 & 2 & 3 \\ 3 & 1 & 1 & 2 \end{bmatrix}$$

The function is implemented as follows:

```

GFMatrix MixColumns(GFMatrix M) {
    GFMatrix C = {
        {0x02,0x03,0x01,0x01},
        {0x01,0x02,0x03,0x01},
        {0x01,0x01,0x02,0x03},
        {0x03,0x01,0x01,0x02}
    };
    return GFMatrixMul(C, M);
}

```

The AddRoundKey() Function

Extracts the round key from the expanded key and adds it to the state using a bitwise XOR operation.

```

GFMatrix AddRoundKey(GFMatrix state, ExpandedKey w, nat round) {
    GFMatrix result = state;
    for (nat i=0; i<4; i++) {
        for (nat j=0; j<4; j++) {
            result[i][j] = result[i][j] ^ w[4*round+j][i];
        }
    }
    return result;
}

```

1.4.7.3 Matrix to Text Conversion

After processing, the output matrix must be converted to a text block. The **Matrix2Text()** function converts a **GFMatrix** in column-major order to a **TextBlock** as follows.

```

TextBlock Matrix2Text(GFMatrix M) {
    TextBlock result;
    for (nat j=0; j<4; j++) {
        for (nat i=0; i<4; i++) {
            result[4*j+i] = M[i][j];
        }
    }
    return result;
}

```

1.4.8 The InvCipher Function

This function performs decryption. It iterates through the round function the number of times determined by encryption key size and produces a 128-bit block of text as output.

```

TextBlock InvCipher(TextBlock in, ExpandedKey w, nat Nk) {
    assert((Nk == 4) || (Nk == 6) || (Nk == 8));
    nat Nr = Nk + 6;
    GFMatrix state = Text2Matrix(in);
    state = AddRoundKey(state, w, Nr);
    for (nat round=Nr-1; round>0; round--) {
        state = InvShiftRows(state);
        state = InvSubBytes(state);
        state = AddRoundKey(state, w, round);
        state = InvMixColumns(state);
    }
}

```

```

state = InvShiftRows(state);
state = InvSubBytes(state);
state = AddRoundKey(state, w, 0);
return Matrix2Text(state);
}

```

1.4.8.1 Text to Matrix Conversion

Prior to processing, the input text block must be converted to matrix form. The **Text2Matrix()** function stores a **TextBlock** in a GFMatrix in column-major order as follows.

```

GFMatrix Text2Matrix(TextBlock A) {
    GFMatrix result;
    for (nat j=0; j<4; j++) {
        for (nat i=0; i<4; i++) {
            result[i][j] = A[4*j+i];
        }
    }
    return result;
}

```

1.4.8.2 InvCypher Transformations

The following functions are used in decryption:

InvShiftRows() — The inverse of **ShiftRows()**.

InvSubBytes() — The inverse of **SubBytes()**.

InvSubWord() — The inverse of **SubWord()**.

InvMixColumns() — The inverse of **MixColumns()**.

AddRoundKey() — Is its own inverse.

Decryption is the inverse of encryption and is accomplished by means of the inverses of the, **SubBytes()**, **SubWord()**, **ShiftRows()** and **MixColumns()** transformations used in encryption.

SubWord(), **SubBytes()**, and **ShiftRows()** are injective. This is also the case with **MixColumns()**. A simple computation shows that C is invertible with

$$C^{-1} = \begin{bmatrix} E & B & D & 9 \\ 9 & E & B & D \\ D & 9 & E & B \\ B & D & 9 & E \end{bmatrix}$$

The InvShiftRows() Function

The inverse of **ShiftRows()**.

```

GFMatrix InvShiftRows(GFMatrix M) {
    GFMatrix result;
    for (nat i=0; i<4; i++) {
        result[i] = RotateLeft(M[i], -i);
    }
    return result;
}

```

The InvSubBytes() Function

The inverse of *SubBytes()*.

```
GFMMatrix InvSubBytes(GFMMatrix M) {
    GFMMatrix result;
    for (nat i=0; i<4; i++) {
        result[i] = InvSubWord(M[i]);
    }
    return result;
}
```

The InvSubWord() Function

The inverse of **SubWord()**, **InvSubBytes()** applied to each element of a vector or a matrix.

```
GFWord InvSubWord(GFWord x) {
    GFWord result;
    for (nat i=0; i<4; i++) {
        result[i] = InvSubByte(x[i]);
    }
    return result;
}
```

The InvMixColumns() Function

The inverse of the **MixColumns()** function. Multiplies by the inverse of the predefined fixed matrix, C , C^{-1} , as discussed previously.

```
GFMMatrix InvMixColumns(GFMMatrix M) {
    GFMMatrix D = {
        {0x0e, 0x0b, 0x0d, 0x09},
        {0x09, 0x0e, 0x0b, 0x0d},
        {0x0d, 0x09, 0x0e, 0x0b},
        {0x0b, 0x0d, 0x09, 0x0e}
    };
    return GFMMatrixMul(D, M);
}
```

The AddRoundKey() Function

Extracts the round key from the expanded key and adds it to the state using a bitwise XOR operation.

```
GFMMatrix AddRoundKey(GFMMatrix state, ExpandedKey w, nat round) {
    GFMMatrix result = state;
    for (nat i=0; i<4; i++) {
        for (nat j=0; j<4; j++) {
            result[i][j] = result[i][j] ^ w[4*round+j][i];
        }
    }
    return result;
}
```

1.4.8.3 Matrix to Text Conversion

After processing, the output matrix must be converted to a text block. The **Matrix2Text()** function converts a **GFMatrix** in column-major order to a **TextBlock** as follows.

```
TextBlock Matrix2Text (GFMatrix M) {
    TextBlock result;
    for (nat j=0; j<4; j++) {
        for (nat i=0; i<4; i++) {
            result[4*j+i] = M[i][j];
        }
    }
    return result;
}
```

1.4.9 An Alternative Decryption Procedure

This section outlines an alternative decrypting procedure,

TextBlock EqDecrypt(TextBlock in, CipherKey key, nat Nk):

```
TextBlock EqDecrypt (TextBlock in, CipherKey key, nat Nk) {
    return EqInvCipher (in, MixRoundKeys (ExpandKey (key, Nk), Nk), Nk);
}
```

The procedure is based on a variation of **InvCipher**,

TextBlock EqInvCipher(TextBlock in, ExpandedKey w, nat Nk):

```
TextBlock EqInvCipher (TextBlock in, ExpandedKey dw, nat Nk) {
    assert ((Nk == 4) || (Nk == 6) || (Nk == 8));
    nat Nr = Nk + 6;
    GFMatrix state = Text2Matrix (in);
    state = AddRoundKey (state, dw, Nr);
    for (nat round=Nr-1; round>0; round--) {
        state = InvSubBytes (state);
        state = InvShiftRows (state);
        state = InvMixColumns (state);
        state = AddRoundKey (state, dw, round);
    }
    state = InvSubBytes (state);
    state = InvShiftRows (state);
    state = AddRoundKey (state, dw, 0);
    return Matrix2Text (state);
}
```

The variant structure more closely resembles that of **Cipher**. This requires a modification of the expanded key generated by **ExpandKey**,

ExpandedKey MixRoundKeys(ExpandedKey w, nat Nk):

```

ExpandedKey MixRoundKeys (ExpandedKey w, nat Nk) {
  assert((Nk == 4) || (Nk == 6) || (Nk == 8));
  nat Nr = Nk + 6;
  ExpandedKey result;
  GFMatrix roundKey;
  for (nat round=0; round<Nr+1; round++) {
    for (nat i=0; i<4; i++) {
      roundKey[i] = w[4*round+i];
    }
    if ((round > 0) && (round < Nr)) {
      roundKey = InvMixRows(roundKey);
    }
    for (nat i=0; i<4; i++) {
      result[4*round+i] = roundKey[i];
    }
  }
  return result;
}

```

The transformation **MixRoundKeys** leaves K_0 and K_{N_r} unchanged, but for $i = 1, \dots, N_r - 1$, it replaces W_i with the matrix product $W_i \odot Q$, where

$$Q = \begin{bmatrix} E & 9 & D & B \\ B & E & 9 & D \\ D & B & E & 9 \\ 9 & D & B & E \end{bmatrix} = \begin{bmatrix} E & B & D & 9 \\ 9 & E & B & D \\ D & 9 & E & B \\ B & D & 9 & E \end{bmatrix}^t = (C^{-1})^t.$$

The effect of this is to replace K_i with

$$(W_i \odot Q)^t = Q^t \odot W_i^t = C^{-1} \odot K_i = C^{-1}(K_i)$$

for $i = 1, \dots, N_r - 1$.

The equivalence of **EqDecrypt** and **Decrypt** follows from two properties of the basic operations:

C is a linear transformation and therefore, so is C^{-1} ;

Σ and R commute, and hence so do Σ^{-1} and R^{-1} , for if

$$S = \begin{bmatrix} s_{00} & s_{01} & s_{02} & s_{03} \\ s_{10} & s_{11} & s_{12} & s_{13} \\ s_{20} & s_{21} & s_{22} & s_{23} \\ s_{30} & s_{31} & s_{32} & s_{33} \end{bmatrix},$$

then

$$\Sigma(\mathcal{R}(S)) = \begin{bmatrix} \sigma(s_{00}) & \sigma(s_{01}) & \sigma(s_{02}) & \sigma(s_{03}) \\ \sigma(s_{11}) & \sigma(s_{12}) & \sigma(s_{13}) & \sigma(s_{10}) \\ \sigma(s_{22}) & \sigma(s_{23}) & \sigma(s_{20}) & \sigma(s_{21}) \\ \sigma(s_{33}) & \sigma(s_{30}) & \sigma(s_{31}) & \sigma(s_{32}) \end{bmatrix} = \mathcal{R}(\Sigma(S)).$$

Now let X'' and Y'' be the initial and final states of an execution of **EqDecrypt** and let S''_i be the state following round i . Suppose $X'' = X'$. Appealing to the definitions of **EqDecrypt** and **EqInvCipher**, we have

$$S''_{N_r} = X'' \oplus K_{N_r} = X' \oplus K_{N_r} = S'_{N_r},$$

and for $i = N_r - 1, \dots, 1$, by induction,

$$\begin{aligned} S''_i &= \mathcal{C}^{-1}(\Sigma^{-1}(\mathcal{R}^{-1}(S''_{i+1}))) \oplus \mathcal{C}^{-1}(K_{N_r}) \\ &= \mathcal{C}^{-1}(\Sigma^{-1}(\mathcal{R}^{-1}(S'_{i+1})) \oplus K_{N_r}) \\ &= \mathcal{C}^{-1}(\mathcal{R}^{-1}(\Sigma^{-1}(S'_{i+1})) \oplus K_{N_r}) \\ &= \mathcal{C}^{-1}(\mathcal{R}^{-1}(\Sigma^{-1}(S'_{i+1}))) \oplus K_{N_r} \\ &= S'_i. \end{aligned}$$

Finally,

$$\begin{aligned} Y'' = S''_0 &= \mathcal{R}^{-1}(\Sigma^{-1}(S''_1)) \oplus K_0 \\ &= \Sigma^{-1}(\mathcal{R}^{-1}(S''_1)) \oplus K_0 \\ &= \Sigma^{-1}(\mathcal{R}^{-1}(S'_1)) \oplus K_0 \\ &= S'_0 = Y'. \end{aligned}$$

1.4.10 Computation of GFInv with Euclidean Greatest Common Divisor

Note that the operations performed by **GFInv**() are in the ring $\mathbb{Z}_2[X]$ rather than the quotient field GF .

The initial values of the variables x_1 and x_2 are the inputs x and 11b, the latter representing the polynomial $p(X)$. The variables a_1 and a_2 are initialized to 1 and 0.

On each iteration of the loop, a multiple of the lesser of x_1 and x_2 is added to the other. If $x_1 \leq x_2$, then the values of x_2 and a_2 are adjusted as follows:

$$x_2 \rightarrow x_2 \oplus 2^s \odot x_1$$

$$a_2 \rightarrow a_2 \oplus 2^s \odot a_1$$

where s is the difference in the exponents (*i.e.*, degrees) of x_1 and x_2 . In the remaining case, x_1 and a_1 are similarly adjusted. This step is repeated until either $x_1 = 0$ or $x_2 = 0$.

We make the following observations:

- On each iteration, the value added to x_i has the same exponent as x_i , and hence the sum has lesser exponent. Therefore, termination is guaranteed.
- Since $p(X)$ is irreducible and x is of smaller degree than $p(X)$, the initial values of x_1 and x_2 have no non-trivial common factor. This property is clearly preserved by each step.
- Initially,

$$x_1 \oplus a_1 \odot x = x \oplus x = 0$$

and

$$x_2 \oplus a_2 \odot x = 11b \oplus 0 = 11b$$

are both divisible by $11b$. This property is also invariant, since, for example, the above assignments result in

$$x_2 \oplus a_2 \odot x \rightarrow (x_2 \oplus 2^s \odot x_1) \oplus (a_2 \oplus 2^s \odot a_1) \odot x = (x_2 \oplus a_2 \odot x) \oplus 2^s \odot (x_1 \oplus a_1 \odot x).$$

Now suppose that the loop terminates with $x_2 = 0$. Then x_1 has no non-trivial factor and, hence, $x_1 = 1$. Thus, $1 \oplus a_1 \odot x$ is divisible by $11b$. Since the final result y is derived by reducing a_1 modulo $11b$, it follows that $1 \oplus y \odot x$ is also divisible by $11b$ and, hence, in the quotient field GF , $1 + y \odot x = 0$, which implies $y \odot x = 1$.

The computation of the multiplicative inverse utilizing Euclid's algorithm is as follows:

```

// Computation of multiplicative inverse based on Euclid's algorithm:

GF256 GFInv(GF256 x) {
  if (x == 0) {
    return 0;
  }
  // Initialization:
  nat x1 = x;
  nat x2 = 0x11B; // the irreducible polynomial p(X)
  nat a1 = 1;
  nat a2 = 0;
  nat shift; // difference in exponents
  while ((x1 != 0) && (x2 != 0)) {

    // Termination is guaranteed, since either x1 or x2 decreases on each iteration.
    // We have the following loop invariants, viewing natural numbers as elements of
    // the polynomial ring  $\mathbb{Z}_2[X]$ :
    // (1) x1 and x2 have no common divisor other than 1.
    // (2)  $x1 \wedge \text{GFMul}(a1, x)$  and  $x2 \wedge \text{GFMul}(a2, x)$  are both divisible by p(X).

    if (x1 <= x2) {
      shift = expo(x2) - expo(x1);
      x2 = x2 ^ (x1 << shift);
      a2 = a2 ^ (a1 << shift);
    }
    else {
      shift = expo(x1) - expo(x2);
      x1 = x1 ^ (x2 << shift);
      a1 = a1 ^ (a2 << shift);
    }
  }
  nat y;

  // Since either x1 or x2 is 0, it follows from (1) above that the other is 1.

  if (x1 == 1) { // x2 == 0
    y = a1;
  }
  else if (x2 == 1) { // x1 == 0
    y = a2;
  }
  else {
    assert(false);
  }

  // Now it follows from (2) that  $\text{GFMul}(y, x) \wedge 1$  is divisible by 0x11b.
  // We need only reduce y modulo 0x11b:

  nat e = expo(y);
  while (e >= 8) {
    y = y ^ (0x11B << (e - 8));
    e = expo(y);
  }
  return y;
}

```

1.5 String Compare Instructions

The (V)PCMPESTRI, (V)PCMPESTRM, (V)PCMPISTRI, and (V)PCMPISTRM instructions perform arithmetic comparisons of byte or word elements in two source operands using positive Boolean logic. All possible comparisons are performed, 64 for words, 256 for bytes. Individual comparison results are aggregated and processed to produce final results.

Instruction operation affects the arithmetic status flags (ZF, CF, SF, OF, AF, PF), but the flags are defined to provide additional information.

The instructions have a defined base function and additional functionality controlled by bit fields in an immediate byte operand. The base function determines whether the source strings have implicitly (I) or explicitly (E) defined lengths, and whether the result is an index (I) or a mask (M).

Some immediate operand functions are specific to a particular instruction and others pertain to two or more instructions. This description covers functions that are common to all of the instructions. Individual functional differences are covered in the specific instruction descriptions.

Bit fields of the immediate operand control the following functions:

- Source data format — data element length, signed or unsigned
- Aggregation — comparison type and intermediate result aggregation
- Complementation — intermediate result processing
- Output selection — type of processing performed to produce final result

1.5.1 Source Data Format

Bits [1:0] of the immediate byte operand determine source data format, as shown in Table 1-6.

Table 1-6. Source Data Format

Imm8[1:0]	Source Content
00b	16 packed unsigned bytes
01b	8 packed unsigned words
10b	16 packed signed bytes
11b	8 packed signed words

1.5.2 Aggregation

Bits [3:2] of the immediate byte operand determine comparison type and aggregation method, as shown in Table 1-7. Aggregation results are stored in *IntRes1*. See Section 1.5.3, “Valid/Invalid Override of Comparisons” for more information about the override function.

Table 1-7. Comparison and Aggregation Method

Imm8[3:2]	Comparison	Method
00b	Equal	Equal any
01b	Greater than or equal for even-indexed elements of <i>reg</i> and corresponding elements of <i>reg/mem</i> . Less than or equal for odd-indexed elements of <i>reg</i> and corresponding elements of <i>reg/mem</i> .	Ranges
10b	Equal	Equal each
11b	Equal	Equal ordered

1.5.2.1 Equal Any Aggregation Method

Finds characters in a set.

```
UpperBound = imm8[0] ? 7:15;
IntRes1 = 0;
For j = 0 to UpperBound, j++
For i = 0 to UpperBound, i++
IntRes1[j] OR= overrideIfDataInvalid(BoolRes[j,i])
```

1.5.2.2 Ranges Aggregation Method

Finds characters in ranges.

```
UpperBound = imm8[0]?7:15;
IntRes1 = 0;
For j = 0 to UpperBound, j++
For i = 0 to UpperBound, i+=2
IntRes1[j] OR= (overrideIfDataInvalid(BoolRes[j,i])
AND overrideIfDataInvalid(BoolRes[j,i+1]))
```

1.5.2.3 Equal Each Aggregation Method

Performs string compare.

```
UpperBound = imm8[0]?7:15;
IntRes1 = 0;
For i = 0 to UpperBound, i++
IntRes1[i] = overrideIfDataInvalid(BoolRes[i,i])
```

1.5.2.4 Equal Ordered Aggregation Method

Performs a substring search

```
UpperBound = imm8[0]?7:15;
IntRes1 = imm8[0] ? 0xFF : 0xFFFF
For j = 0 to UpperBound, j++
For i = 0 to UpperBound-j, k=j to UpperBound, k++, i++
IntRes1[j] AND= overrideIfDataInvalid(BoolRes[k,i])
```

1.5.3 Valid/Invalid Override of Comparisons

The string comparison instructions allow for occurrence of an end-of-string (EOS) within the source data. Source data elements that are determined to be past the EOS are considered invalid.

Aggregation method determines how invalid data within a comparison pair are handled. In most cases, the comparison result for each element pair $BoolRes[i,j]$ is forced true or false if one or more elements of the pair are invalid. Table 1-8 summarizes override operation.

Table 1-8. End-of-String Comparison Override

<i>xmm1</i> , byte/word	<i>xmm2/m128</i> , byte/word	<i>Imm8[3:2]=00b</i> , (equal any)	<i>Imm8[3:2]=01b</i> , (ranges)	<i>Imm8[3:2]=10b</i> , (equal each)	<i>Imm8[3:2]=11b</i> , (equal ordered)
Invalid	Invalid	Force false	Force false	Force true	Force true
Invalid	Valid	Force false	Force false	Force false	Force true
Valid	Invalid	Force false	Force false	Force false	Force false
Valid	Valid	Do not force	Do not force	Do not force	Do not force

Bit [7] of the immediate byte operand is reserved.

1.5.4 Complementation

Bit [4] of the immediate operand determines whether a ones'-complement is performed on *IntRes1*; bit [5] of the immediate operand determines whether a complementation mask is used (see Table 1-9). The mask allows complementation only when an *IntRes1* bit corresponds to a valid reg/mem source element. The basic functional definition of each instruction determines the validity of elements.

Table 1-9. Complementation

<i>Imm8[5:4]</i>	Description
x0b	$IntRes2 = IntRes1$
01b	$IntRes2 = IntRes1 \text{ XOR } -1$
11b	$IntRes2[i] = IntRes1[i]$ if reg/mem[i] invalid, else $= \sim IntRes1[i]$

After complementation, the data is stored in a second intermediate result, *IntRes2*.

1.5.5 Output Selection

For (V)PCMPESTRI and (V)PCMPISTRI, bit 6 of the immediate operand determines whether the index of the lowest set bit or the highest set bit of *IntRes2* is written to ECX, as shown in Table 1-10.

Table 1-10. Indexed Comparison Output Selection

<i>Imm8[6]</i>	Description
0b	Return the index of the least significant set bit in <i>IntRes2</i> .
1b	Return the index of the most significant set bit in <i>IntRes2</i> .

For (V)PCMPESTRM and (V)PCMPISTRM, bit [6] of the immediate operand determines whether the mask is a 16-bit or 8-bit mask or an expanded 128-bit byte/word mask, as shown in Table 1-11.

Mask size is determined by *imm8[1]*. The mask is expanded by copying each bit of *IntRes2* to all bits of the element of the same index.

Table 1-11. Masked Comparison Output Selection

Imm8[6]	Description
0b	Return IntRes2 as the mask with zero extension to 128 bits.
1b	Return expanded IntRes2 mask.

1 Instruction Reference

Instructions are listed by mnemonic, in alphabetic order. Each entry describes instruction function, syntax, opcodes, affected flags and exceptions related to the instruction.

Figure 1-1 shows the conventions used in the descriptions. Items that do not pertain to a particular instruction, such as a synopsis of the 256-bit form, may be omitted.

Figure 1-1. Typical Instruction Description

Instruction Exceptions

Under various conditions instructions described below can cause exceptions. The conditions that cause these exceptions can differ based on processor mode and instruction subset. This information is summarized at the end of each instruction reference page in an Exception Table. Rows list the applicable exceptions and the different conditions that trigger each exception for the instruction. For each processor mode (real, virtual, and protected) a symbol in the table indicates whether this exception condition applies.

Each AVX instruction has a legacy form that comes from one of the legacy (SSE1, SSE2, ...) subsets. An “X” at the intersection of a processor mode column and an exception cause row indicates that the causing condition and potential exception applies to both the AVX instruction and the legacy SSE instruction. “A” indicates that the causing condition applies only to the AVX instruction and “S” indicates that the condition applies to the SSE legacy instruction.

Note that XOP and FMA4 instructions do not have corresponding instructions from the SSE legacy subsets. In the exception tables for these instructions, “X” represents the XOP instruction and “F” represents the FMA4 instruction.

ADDPD Add

VADDPD Packed Double-Precision Floating-Point

Adds each packed double-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the result of each addition into the corresponding quadword of the destination.

There are legacy and extended forms of the instruction:

ADDPD

Adds two pairs of values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VADDPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Adds two pairs of values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Adds four pairs of values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

ADDPD is an SSE2 instruction and VADDPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
ADDPD <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F 58 /r	Adds two packed double-precision floating-point values in <i>xmm1</i> to corresponding values in <i>xmm2</i> or <i>mem128</i> . Writes results to <i>xmm1</i> .

ADDPS Add

VADDPS Packed Single-Precision Floating-Point

Adds each packed single-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the result of each addition into the corresponding elements of the destination.

There are legacy and extended forms of the instruction:

ADDPS

Adds four pairs of values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VADDPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Adds four pairs of values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Adds eight pairs of values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

ADDPS is an SSE2 instruction and VADDPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

ADDSD Add

VADDSD Scalar Double-Precision Floating-Point

Adds the double-precision floating-point value in the low-order quadword of the first source operand to the corresponding value in the low-order quadword of the second source operand and writes the result into the low-order quadword of the destination.

There are legacy and extended forms of the instruction:

ADDSD

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The first source register is also the destination register. Bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are not affected.

VADDSD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The destination is a third XMM register. Bits [127:64] of the first source operand are copied to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

ADDSD is an SSE2 instruction and VADDSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

ADDSS Add VADDSS Scalar Single-Precision Floating-Point

Adds the single-precision floating-point value in the low-order doubleword of the first source operand to the corresponding value in the low-order doubleword of the second source operand and writes the result into the low-order doubleword of the destination.

There are legacy and extended forms of the instruction:

ADDSS

The first source operand is an XMM register and the second source operand is either an XMM register or a 32-bit memory location. The first source register is also the destination. Bits [127:32] of the destination register and bits [255:128] of the corresponding YMM register are not affected.

VADDSS

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 32-bit memory location. The destination is a third XMM register. Bits [127:32] of the first source register are copied to bits [127:32] of the of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

ADDSS is an SSE1 instruction and VADDSS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
ADDSS <i>xmm1, xmm2/mem32</i>	F3 0F 58 /r	Adds a single-precision floating-point value in the low-order doubleword of <i>xmm1</i> to a corresponding value in <i>xmm2</i> or <i>mem32</i> . Writes results to <i>xmm1</i> .

Mnemonic	Encoding

ADDSUBPD Alternating Addition and Subtraction VADDSUBPD Packed Double-Precision Floating-Point

Adds the odd-numbered packed double-precision floating-point values of the first source operand to the corresponding values of the second source operand and writes the sum to the corresponding odd-numbered element of the destination; subtracts the even-numbered packed double-precision floating-point values of the second source operand from the corresponding values of the first source operand and writes the differences to the corresponding even-numbered element of the destination.

There are legacy and extended forms of the instruction:

ADDSUBPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VADDSUBPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

ADDSUBPD is an SSE2 instruction and VADDSUBPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

AESDEC VAESDEC

AES Decryption Round

Performs a single round of AES decryption. Transforms a state value specified by the first source operand using a round key value specified by the second source operand, and writes the result to the destination.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

Decryption consists of $1, \dots, N_r - 1$ iterations of sequences of operations called rounds, terminated by a unique final round, N_r . The AESDEC and VAESDEC instructions perform all the rounds except the last; the AESDECLAST and VAESDECLAST instructions perform the final round.

The 128-bit state and round key vectors are interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed state is written to the destination in column-major order. For both instructions, the destination register is the same as the first source register.

There are legacy and extended forms of the instruction:

AESDEC

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESDEC

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESDEC is an AES instruction and VAESDEC is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

AESDECLAST VAESDECLAST

AES Last Decryption Round

Performs the final round of AES decryption. Completes transformation of a state value specified by the first source operand using a round key value specified by the second source operand, and writes the result to the destination.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

Decryption consists of $1, \dots, N_r - 1$ iterations of sequences of operations called rounds, terminated by a unique final round, N_r . The AESDEC and VAESDEC instructions perform all the rounds before the final round; the AESDECLAST and VAESDECLAST instructions perform the final round.

The 128-bit state and round key vectors are interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed state is written to the destination in column-major order. For both instructions, the destination register is the same as the first source register.

There are legacy and extended forms of the instruction:

AESDECLAST

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESDECLAST

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESDECLAST is an AES instruction and VAESDECLAST is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description	
AESDECLAST <i>xmm1, xmm2/mem128</i>	66 0F 38 DF/r	Performs the last decryption round on a state value in <i>xmm1</i> using the key value in <i>xmm2</i> or <i>mem128</i> . Writes results to <i>xmm1</i> .

AESENC VAESENC

AES Encryption Round

Performs a single round of AES encryption. Transforms a state value specified by the first source operand using a round key value specified by the second source operand, and writes the result to the destination.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

Encryption consists of $1, \dots, N_r - 1$ iterations of sequences of operations called rounds, terminated by a unique final round, N_r . The AESENC and VAESENC instructions perform all the rounds before the final round; the AESENCLAST and VAESSENCLAST instructions perform the final round.

The 128-bit state and round key vectors are interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed state is written to the destination in column-major order. For both instructions, the destination register is the same as the first source register.

There are legacy and extended forms of the instruction:

AESENC

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESENC

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESENC is an AES instruction and VAESENC is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

AESENCLAST VAESENCLAST

AES Last Encryption Round

Performs the final round of AES encryption. Completes transformation of a state value specified by the first source operand using a round key value specified by the second source operand, and writes the result to the destination.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

Encryption consists of $1, \dots, N_r - 1$ iterations of sequences of operations called rounds, terminated by a unique final round, N_r . The AESENC and VAESENC instructions perform all the rounds before the final round; the AESENCLAST and VAESENCLAST instructions perform the final round.

The 128-bit state and round key vectors are interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed state is written to the destination in column-major order. For both instructions, the destination register is the same as the first source register.

There are legacy and extended forms of the instruction:

AESENCLAST

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESENCLAST

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESENCLAST is an AES instruction and VAESENCLAST is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description	
AESENCLAST <i>xmm1, xmm2/mem128</i>	66 0F 38 DD /r	Performs the last encryption round on a state value in <i>xmm1</i> using the key value in <i>xmm2</i> or <i>mem128</i> . Writes results to <i>xmm1</i> .

AESIMC VAESIMC

AES

InvMixColumn Transformation

Applies the AES *InvMixColumns*() transformation to expanded round keys in preparation for decryption. Transforms an expanded key specified by the second source operand and writes the result to a destination register.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

The 128-bit round key vector is interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed result is written to the destination in column-major order.

AESIMC and VAESIMC are not used to transform the first and last round key in a decryption sequence.

There are legacy and extended forms of the instruction:

AESIMC

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESIMC

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESIMC is an AES instruction and VAESIMC is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

AESKEYGENASSIST VAESKEYGENASSIST

AES

Assist Round Key Generation

Expands a round key for encryption. Transforms a 128-bit round key operand using an 8-bit round constant and writes the result to a destination register.

See Section 1.4, “AES Instructions” for more information about the operation of the AES instructions.

The round key is provided by the second source operand and the round constant is specified by an immediate operand. The 128-bit round key vector is interpreted as 16-byte column-major entries in a 4-by-4 matrix of bytes. The transformed result is written to the destination in column-major order.

There are legacy and extended forms of the instruction:

AESKEYGENASSIST

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VAESKEYGENASSIST

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

AESKEYGENASSIST is an AES instruction and VAESKEYGENASSIST is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AES] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
AESKEYGENASSIST <i>xmm1, xmm2/mem128, imm8</i>	66 0F 3A DF /r ib	Expands a round key in <i>xmm2</i> or <i>mem128</i> using an immediate round constant. Writes the result to <i>xmm1</i> .

BLENDPD Blend

VBLENDPD Packed Double-Precision Floating-Point

Copies packed double-precision floating-point values from either of two sources to a destination, as specified by an 8-bit mask operand.

Each mask bit specifies a 64-bit element in a source location and a corresponding 64-bit element in the destination register. When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination register. When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination register.

There are legacy and extended forms of the instruction:

BLENDPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Only mask bits [1:0] are used.

VBLENDPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Only mask bits [1:0] are used.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register. Only mask bits [3:0] are used.

BLENDPD is an SSE4.1 instruction and VBLENDPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

BLENDPS VBLENDPS

Blend Packed Single-Precision Floating-Point

Copies packed single-precision floating-point values from either of two sources to a destination, as specified by an 8-bit mask operand.

Each mask bit specifies a 32-bit element in a source location and a corresponding 32-bit element in the destination register. When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination register. When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination register.

There are legacy and extended forms of the instruction:

BLENDPS

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Only mask bits [3:0] are used.

VBLENDPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Only mask bits [3:0] are used.

YMM Encoding

The first operand is a YMM register and the second operand is either another YMM register or a 256-bit memory location. The destination is a third YMM register. Only mask bits [3:0] are used.

BLENDPS is an SSE4.1 instruction and VBLENDPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

BLENDVPD Variable Blend

VBLENDVPD Packed Double-Precision Floating-Point

Copies packed double-precision floating-point values from either of two sources to a destination, as specified by a mask operand.

Each mask bit specifies a 64-bit element of a source location and a corresponding 64-bit element of the destination. The position of a mask bit corresponds to the position of the most significant bit of a copied value. When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination. When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination.

There are legacy and extended forms of the instruction:

BLENDVPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. The mask is defined by bits 127 and 63 of the implicit register XMM0.

VBLENDVPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. The mask is defined by bits 127 and 63 of a fourth XMM register.

YMM Encoding

The first operand is a YMM register and the second operand is either another YMM register or a 256-bit memory location. The destination is a third YMM register. The mask is defined by bits 255, 191, 127, and 63 of a fourth YMM register.

BLENDVPD is an SSE4.1 instruction and VBLENDVPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
BLENDVPD <i>xmm1, xmm2/mem128</i>	66 0F 38 15 /r	Copies values from <i>xmm1</i> or <i>xmm2/mem128</i> to <i>xmm1</i> , as specified by the MSB of corresponding elements of <i>xmm0</i> .

BLENDVPS Variable Blend

VBLENDVPS Packed Single-Precision Floating-Point

Copies packed single-precision floating-point values from either of two sources to a destination, as specified by a mask operand.

Each mask bit specifies a 32-bit element of a source location and a corresponding 32-bit element of the destination register. The position of a mask bits corresponds to the position of the most significant bit of a copied value. When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination. When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination.

There are legacy and extended forms of the instruction:

BLENDVPS

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. The mask is defined by bits 127, 95, 63, and 31 of the implicit register XMM0.

VBLENDVPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. The mask is defined by bits 127, 95, 63, and 31 of a fourth XMM register.

YMM Encoding

The first operand is a YMM register and the second operand is either another YMM register or a 256-bit memory location. The destination is a third YMM register. The mask is defined by bits 255, 223, 191, 159, 127, 95, 63, and 31 of a fourth YMM register.

BLENDVPS is an SSE4.1 instruction and VBLENDVPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CMPPD Compare

VCMPD Packed Double-Precision Floating-Point

Compares each of the two packed double-precision floating-point values of the first source operand to the corresponding values of the second source operand and writes the result of each comparison to the corresponding 64-bit element of the destination. When a comparison is TRUE, all 64 bits of the destination element are set; when a comparison is FALSE, all 64 bits of the destination element are cleared. The type of comparison is specified by an immediate byte operand.

Signed comparisons return TRUE only when both operands are valid numbers and the numbers have the relation specified by the type of comparison operation. Ordered comparison returns TRUE when both operands are valid numbers, or FALSE when either operand is a NaN. Unordered comparison returns TRUE only when one or both operands are NaN and FALSE otherwise.

QNaN operands generate an Invalid Operation Exception (IE) only if the comparison type isn't Equal, Unequal, Ordered, or Unordered. SNaN operands always generate an IE.

There are legacy and extended forms of the instruction:

CMPPD

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Comparison type is specified by bits [2:0] of an immediate byte operand.

VCMPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Comparison type is specified by bits [4:0] of an immediate byte operand.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination operand is a YMM register. Comparison type is specified by bits [4:0] of an immediate byte operand.

Immediate Operand Encoding

CMPPD uses bits [2:0] of the 8-bit immediate operand and VCMPPD uses bits [4:0] of the 8-bit immediate operand. Although VCMPPD supports 20h encoding values, the comparison types echo those of CMPPD on 4-bit boundaries. The following table shows the immediate operand value for CMPPD and each of the VCMPPD echoes.

Some comparison operations that are not directly supported by immediate-byte encodings can be implemented by swapping the contents of the source and destination operands and executing the appropriate comparison of the swapped values. These additional comparison operations are shown with the directly supported comparison operations.

Immediate Operand Value	Compare Operation	Result If NaN Operand	QNaN Operand Causes Invalid Operation Exception
00h, 08h, 10h, 18h	Equal	FALSE	No
01h, 09h, 11h, 19h	Less than	FALSE	Yes
	Greater than (swapped operands)	FALSE	Yes
02h, 0Ah, 12h, 1Ah	Less than or equal	FALSE	Yes
	Greater than or equal (swapped operands)	FALSE	Yes
03h, 0Bh, 13h, 1Bh	Unordered	TRUE	No
04h, 0Ch, 14h, 1Ch	Not equal	TRUE	No
05h, 0Dh, 15h, 1Dh	Not less than	TRUE	Yes
	Not greater than (swapped operands)	TRUE	Yes
06h, 0Eh, 16h, 1Eh	Not less than or equal	TRUE	Yes
	Not greater than or equal (swapped operands)	TRUE	Yes
07h, 0Fh, 17h, 1Fh	Ordered	FALSE	No

The following alias mnemonics for (V)CMPPD with appropriate value of *imm8* are supported.

Mnemonic	Implied Value of <i>imm8</i>

CMPPS VCMPPS

Compare Packed Single-Precision Floating-Point

Compares each of the four packed single-precision floating-point values of the first source operand to the corresponding values of the second source operand and writes the result of each comparison to the corresponding 32-bit element of the destination. When a comparison is TRUE, all 32 bits of the destination element are set; when a comparison is FALSE, all 32 bits of the destination element are cleared. The type of comparison is specified by an immediate byte operand.

Signed comparisons return TRUE only when both operands are valid numbers and the numbers have the relation specified by the type of comparison operation. Ordered comparison returns TRUE when both operands are valid numbers, or FALSE when either operand is a NaN. Unordered comparison returns TRUE only when one or both operands are NaN and FALSE otherwise.

QNaN operands generate an Invalid Operation Exception (IE) only if the comparison type isn't Equal, Unequal, Ordered, or Unordered. SNaN operands always generate an IE.

There are legacy and extended forms of the instruction:

CMPPS

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Comparison type is specified by bits [2:0] of an immediate byte operand.

VCMPPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Comparison type is specified by bits [4:0] of an immediate byte operand.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination operand is a YMM register. Comparison type is specified by bits [4:0] of an immediate byte operand.

Immediate Operand Encoding

CMPPS uses bits [2:0] of the 8-bit immediate operand and VCMPPS uses bits [4:0] of the 8-bit immediate operand. Although VCMPPS supports 20h encoding values, the comparison types echo those of CMPPS on 4-bit boundaries. The following table shows the immediate operand value for CMPPS and each of the VCMPPS echoes.

Some comparison operations that are not directly supported by immediate-byte encodings can be implemented by swapping the contents of the source and destination operands and executing the appropriate comparison of the swapped values. These additional comparison operations are shown in with the directly supported comparison operations.

CMPSD VCMPSD

Compare Scalar Double-Precision Floating-Point

Compares a double-precision floating-point value in the low-order 64 bits of the first source operand with a double-precision floating-point value in the low-order 64 bits of the second source operand and writes the result to the low-order 64 bits of the destination. When a comparison is TRUE, all 64 bits of the destination element are set; when a comparison is FALSE, all 64 bits of the destination element are cleared. Comparison type is specified by an immediate byte operand.

Signed comparisons return TRUE only when both operands are valid numbers and the numbers have the relation specified by the type of comparison operation. Ordered comparison returns TRUE when both operands are valid numbers, or FALSE when either operand is a NaN. Unordered comparison returns TRUE only when one or both operands are NaN and FALSE otherwise.

QNaN operands generate an Invalid Operation Exception (IE) only when the comparison type is not Equal, Unequal, Ordered, or Unordered. SNaN operands always generate an IE.

There are legacy and extended forms of the instruction:

CMPSD

The first source operand is an XMM register. The second source operand is either another XMM register or a 64-bit memory location. The first source register is also the destination. Bits [127:64] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Comparison type is specified by bits [2:0] of an immediate byte operand.

This CMPSD instruction must not be confused with the same-mnemonic CMPSD (compare strings by doubleword) instruction in the general-purpose instruction set. Assemblers can distinguish the instructions by the number and type of operands.

VCMPSD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 64-bit memory location. The destination is a third XMM register. Bits [127:64] of the destination are copied from bits [127:64] of the first source. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Comparison type is specified by bits [4:0] of an immediate byte operand.

Immediate Operand Encoding

CMPSD uses bits [2:0] of the 8-bit immediate operand and VCMPSD uses bits [4:0] of the 8-bit immediate operand. Although VCMPSD supports 20h encoding values, the comparison types echo those of CMPSD on 4-bit boundaries. The following table shows the immediate operand value for CMPSD and each of the VCMPSD echoes.

Some comparison operations that are not directly supported by immediate-byte encodings can be implemented by swapping the contents of the source and destination operands and executing the appropriate comparison of the swapped values. These additional comparison operations are shown with the directly supported comparison operations. When operands are swapped, the first source XMM register is overwritten by the result.

Immediate Operand Value	Compare Operation	Result If NaN Operand	QNaN Operand Causes Invalid Operation Exception
00h, 08h, 10h, 18h	Equal	FALSE	No
01h, 09h, 11h, 19h	Less than	FALSE	Yes
	Greater than (swapped operands)	FALSE	Yes
02h, 0Ah, 12h, 1Ah	Less than or equal	FALSE	Yes
	Greater than or equal (swapped operands)	FALSE	Yes
03h, 0Bh, 13h, 1Bh	Unordered	TRUE	No
04h, 0Ch, 14h, 1Ch	Not equal	TRUE	No
05h, 0Dh, 15h, 1Dh	Not less than	TRUE	Yes
	Not greater than (swapped operands)	TRUE	Yes
06h, 0Eh, 16h, 1Eh	Not less than or equal	TRUE	Yes
	Not greater than or equal (swapped operands)	TRUE	Yes
07h, 0Fh, 17h, 1Fh	Ordered	FALSE	No

The following alias mnemonics for (V)CMPSD with appropriate value of *imm8* are supported.

Mnemonic	Implied Value of <i>imm8</i>
(V)CMPEQSD	00h, 08h, 10h, 18h

CMPSS VCMPSS

Compare Scalar Single-Precision Floating-Point

Compares a single-precision floating-point value in the low-order 32 bits of the first source operand with a single-precision floating-point value in the low-order 32 bits of the second source operand and writes the result to the low-order 32 bits of the destination. When a comparison is TRUE, all 32 bits of the destination element are set; when a comparison is FALSE, all 32 bits of the destination element are cleared. Comparison type is specified by an immediate byte operand.

Signed comparisons return TRUE only when both operands are valid numbers and the numbers have the relation specified by the type of comparison operation. Ordered comparison returns TRUE when both operands are valid numbers, or FALSE when either operand is a NaN. Unordered comparison returns TRUE only when one or both operands are NaN and FALSE otherwise.

QNaN operands generate an Invalid Operation Exception (IE) only if the comparison type isn't Equal, Unequal, Ordered, or Unordered. SNaN operands always generate an IE.

There are legacy and extended forms of the instruction:

CMPSS

The first source operand is an XMM register. The second source operand is either another XMM register or a 32-bit memory location. The first source register is also the destination. Bits [127:32] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected. Comparison type is specified by bits [2:0] of an immediate byte operand.

VCMPSS

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 32-bit memory location. The destination is a third XMM register. Bits [127:32] of the destination are copied from bits [127L32] of the first source. Bits [255:128] of the YMM register that corresponds to the destination are cleared. Comparison type is specified by bits [4:0] of an immediate byte operand.

Immediate Operand Encoding

CMPSS uses bits [2:0] of the 8-bit immediate operand and VCMPS uses bits [4:0] of the 8-bit immediate operand. Although VCMPS supports 20h encoding values, the comparison types echo those of CMPSS on 4-bit boundaries. The following table shows the immediate operand value for CMPSS and each of the VCMPS echoes.

Some comparison operations that are not directly supported by immediate-byte encodings can be implemented by swapping the contents of the source and destination operands and executing the appropriate comparison of the swapped values. These additional comparison operations are shown below with the directly supported comparison operations. When operands are swapped, the first source XMM register is overwritten by the result.

Immediate Operand Value	Compare Operation	Result If NaN Operand	QNaN Operand Causes Invalid Operation Exception
00h, 08h, 10h, 18h	Equal	FALSE	No
01h, 09h, 11h, 19h	Less than	FALSE	Yes
	Greater than (swapped operands)	FALSE	Yes
02h, 0Ah, 12h, 1Ah	Less than or equal	FALSE	Yes
	Greater than or equal (swapped operands)	FALSE	Yes
03h, 0Bh, 13h, 1Bh	Unordered	TRUE	No
04h, 0Ch, 14h, 1Ch	Not equal	TRUE	No
05h, 0Dh, 15h, 1Dh	Not less than	TRUE	Yes
	Not greater than (swapped operands)	TRUE	Yes
06h, 0Eh, 16h, 1Eh	Not less than or equal	TRUE	Yes
	Not greater than or equal (swapped operands)	TRUE	Yes
07h, 0Fh, 17h, 1Fh	Ordered	FALSE	No

The following alias mnemonics for (V)CMPSS with appropriate value of *imm8* are supported.

Mnemonic	Implied Value of <i>imm8</i>
(V)CMPEQSS	00h, 08h, 10h, 18h
(V)CMPLTSS	01h, 09h, 11h, 19h
(V)CMPLESS	02h, 0Ah, 12h, 1Ah
(V)CMPUNORDSS	03h, 0Bh, 13h, 1Bh
(V)CMPNEQSS	04h, 0Ch, 14h, 1Ch
(V)CMPNLTSS	05h, 0Dh, 15h, 1Dh
(V)CMPNLESS	06h, 0Eh, 16h, 1Eh
(V)CMPORDSS	07h, 0Fh, 17h, 1Fh

CMPSS is an SSE1 instruction and VCMPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
CMPSS <i>xmm1</i> , <i>xmm2/mem32</i> , <i>imm8</i>	F3 0F C2 /r ib	Compares single-precision floating-point values in the low-order 32 bits of <i>xmm1</i> with corresponding values in <i>xmm2</i> or <i>mem32</i> . Comparison type is determined by <i>imm8</i> . Writes comparison results to <i>xmm1</i> .

Mnemonic

COMISD VCOMISD

Compare Ordered Scalar Double-Precision Floating-Point

Compares a double-precision floating-point value in the low-order 64 bits of an operand with a double-precision floating-point value in the low-order 64 bits of another operand or a 64-bit memory location and sets rFLAGS.ZF, PF, and CF to show the result of the comparison:

Comparison	ZF	PF	CF
NaN input	1	1	1
operand 1 > operand 2	0	0	0
operand 1 < operand 2	0	0	1
operand 1 = operand 2	1	0	0

The result is unordered if one or both of the operand values is a NaN. The rFLAGS.OF, AF, and SF bits are cleared. If an #XF SIMD floating-point exception occurs the rFLAGS bits are not updated.

There are legacy and extended forms of the instruction:

COMISD

The first source operand is an XMM register and the second source operand is another XMM register or a 64-bit memory location.

VCOMISD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location.

COMISD is an SSE2 instruction and VCOMISD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

CVTDQ2PS Convert Packed Doubleword Integers VCVTDQ2PS to Packed Single-Precision Floating-Point

Converts packed 32-bit signed integer values to packed single-precision floating-point values and writes the converted values to the destination. When the result is an inexact value, it is rounded as specified by MXCSR.RC.

There are legacy and extended forms of the instruction:

CVTDQ2PS

Converts four packed 32-bit signed integer values in an XMM register or a 128-bit memory location to four packed single-precision floating-point values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VCVTDQ2PS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts four packed 32-bit signed integer values in an XMM register or a 128-bit memory location to four packed double-precision floating-point values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts eight packed 32-bit signed integer values in a YMM register or a 256-bit memory location to eight packed double-precision floating-point values and writes the converted values to a YMM register.

CVTDQ2PS is an SSE2 instruction and the VCVTDQ2PS instruction is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
CVTDQ2PS <i>xmm1, xmm2/mem128</i>	0F 5B /r	Converts packed doubleword integer values in <i>xmm2</i> or <i>mem128</i> to packed single-precision floating-point values in <i>xmm2</i> .

CVTPD2DQ Convert Packed Double-Precision Floating-Point VCVTPD2DQ to Packed Doubleword Integer

Converts packed double-precision floating-point values to packed signed doubleword integers and writes the converted values to the destination.

When the result is an inexact value, it is rounded as specified by MXCSR.RC. When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$), the instruction returns the 32-bit indefinite integer value (8000_0000h) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTPD2DQ

Converts two packed double-precision floating-point values in an XMM register or a 128-bit memory location to two packed signed doubleword integers and writes the converted values to the two low-order doublewords of the destination XMM register. Bits [127:64] of the destination are cleared. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VCVTPD2DQ

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts two packed double-precision floating-point values in an XMM register or a 128-bit memory location to two signed doubleword values and writes the converted values to the lower two doubleword elements of the destination XMM register. Bits [127:64] of the destination are cleared. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts four packed double-precision floating-point values in a YMM register or a 256-bit memory location to four signed doubleword values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTPD2DQ is an SSE2 instruction and VCVTPD2DQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts two packed double-precision floating-point values in an XMM register or a 128-bit memory location to two packed single-precision floating-point values and writes the converted values to an XMM register. Bits [127:64] of the destination are cleared. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts four packed double-precision floating-point values in a YMM register or a 256-bit memory location to four packed single-precision floating-point values and writes the converted values to a YMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTPD2PS is an SSE2 instruction and VCVTPD2PS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTTPS2DQ Convert Packed Single-Precision Floating-Point VCVTPS2DQ to Packed Doubleword Integers

Converts packed single-precision floating-point values to packed signed doubleword integer values and writes the converted values to the destination.

When the result is an inexact value, it is rounded as specified by MXCSR.RC. When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$), the instruction returns the 32-bit indefinite integer value (8000_0000h) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTTPS2DQ

Converts four packed single-precision floating-point values in an XMM register or a 128-bit memory location to four packed signed doubleword integer values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VCVTPS2DQ

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts four packed single-precision floating-point values in an XMM register or a 128-bit memory location to four packed signed doubleword integer values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts eight packed single-precision floating-point values in a YMM register or a 256-bit memory location to eight packed signed doubleword integer values and writes the converted values to a YMM register.

CVTTPS2DQ is an SSE2 instruction and VCVTPS2DQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTSD2SI Convert Scalar Double-Precision Floating-Point VCVTSD2SI to Signed Doubleword or Quadword Integer

Converts a scalar double-precision floating-point value to a 32-bit or 64-bit signed integer value and writes the converted value to a general-purpose register.

When the result is an inexact value, it is rounded as specified by MXCSR.RC. When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$) or quadword value (-2^{63} to $+2^{63} - 1$), the instruction returns the indefinite integer value (8000_0000h for 32-bit integers, 8000_0000_0000_0000h for 64-bit integers) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTSD2SI

The legacy form has two encodings:

- When REX.W = 0, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 32-bit signed integer and writes the converted value to a 32-bit general purpose register.
- When REX.W = 1, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 64-bit sign-extended integer and writes the converted value to a 64-bit general purpose register.

VCVTSD2SI

The extended form of the instruction has two 128-bit encodings:

- When VEX.W = 0, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 32-bit signed integer and writes the converted value to a 32-bit general purpose register.
- When VEX.W = 1, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 64-bit sign-extended integer and writes the converted value to a 64-bit general purpose register.

CVTSD2SI is an SSE2 instruction and VCVTSD2SI is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
CVTSD2SI <i>reg32, xmm1/mem64</i>	F2 (W0) 0F 2D /r	Converts a packed double-precision floating-point value in <i>xmm1</i> or <i>mem64</i> to a doubleword integer in <i>reg32</i> .

CVTSD2SS Convert Scalar Double-Precision Floating-Point VCVTSD2SS to Scalar Single-Precision Floating-Point

Converts a scalar double-precision floating-point value to a scalar single-precision floating-point value and writes the converted value to the low-order 32 bits of the destination. When the result is an inexact value, it is rounded as specified by MXCSR.RC.

There are legacy and extended forms of the instruction:

CVTSD2SS

Converts a scalar double-precision floating-point value in the low-order 64 bits of the second source XMM register or a 64-bit memory location to a scalar single-precision floating-point value and writes the converted value to the low-order 32 bits of a destination XMM register. Bits [127:32] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VCVTSD2SS

The extended form of the instruction has a 128-bit encoding only.

Converts a scalar double-precision floating-point value in the low-order 64 bits of a source XMM register or a 64-bit memory location to a scalar single-precision floating-point value and writes the converted value to the low-order 32 bits of the destination XMM register. Bits [127:32] of the destination are copied from the first source XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTSD2SS is an SSE2 instruction and VCVTSD2SS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

CVTSI2SD Convert Signed Doubleword or Quadword Integer VCVTSI2SD to Scalar Double-Precision Floating-Point

Converts a signed integer value to a double-precision floating-point value and writes the converted value to a destination register. When the result of the conversion is an inexact value, the value is rounded as specified by MXCSR.RC.

There are legacy and extended forms of the instruction:

CVTSI2SD

The legacy form has two encodings:

- When REX.W = 0, converts a signed doubleword integer value from a 32-bit source general-purpose register or a 32-bit memory location to a double-precision floating-point value and writes the converted value to the low-order 64 bits of an XMM register. Bits [127:64] of the destination XMM register and bits [255:128] of the corresponding YMM register are not affected.
- When REX.W = 1, converts a signed quadword integer value from a 64-bit source general-purpose register or a 64-bit memory location to a 64-bit double-precision floating-point value and writes the converted value to the low-order 64 bits of an XMM register. Bits [127:64] of the destination XMM register and bits [255:128] of the corresponding YMM register are not affected.

VCVTSI2SD

The extended form of the instruction has two 128-bit encodings:

- When VEX.W = 0, converts a signed doubleword integer value from a 32-bit source general-purpose register or a 32-bit memory location to a double-precision floating-point value and writes the converted value to the low-order 64 bits of the destination XMM register. Bits [127:64] of the first source XMM register are copied to the destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- When VEX.W = 1, converts a signed quadword integer value from a 64-bit source general-purpose register or a 64-bit memory location to a double-precision floating-point value and writes the converted value to the low-order 64 bits of the destination XMM register. Bits [127:64] of the first source XMM register are copied to the destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTSI2SD is an SSE2 instruction and VCVTSI2SD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

CVTSI2SS Convert Signed Doubleword or Quadword Integer VCVTSI2SS to Scalar Single-Precision Floating-Point

Converts a signed integer value to a single-precision floating-point value and writes the converted value to an XMM register. When the result of the conversion is an inexact value, the value is rounded as specified by MXCSR.RC.

There are legacy and extended forms of the instruction:

CVTSI2SS

The legacy form has two encodings:

- When REX.W = 0, converts a signed doubleword integer value from a 32-bit source general-purpose register or a 32-bit memory location to a single-precision floating-point value and writes the converted value to the low-order 32 bits of an XMM register. Bits [127:32] of the destination XMM register and bits [255:128] of the corresponding YMM register are not affected.
- When REX.W = 1, converts a signed quadword integer value from a 64-bit source general-purpose register or a 64-bit memory location to a 64-bit double-precision floating-point value and writes the converted value to the low-order 64 bits of an XMM register. Bits [127:32] of the destination XMM register and bits [255:128] of the corresponding YMM register are not affected.

VCVTSI2SS

The extended form of the instruction has two 128-bit encodings:

- When VEX.W = 0, converts a signed doubleword integer value from a 32-bit source general-purpose register or a 32-bit memory location to a double-precision floating-point value and writes the converted value to the low-order 32 bits of the destination XMM register. Bits [127:32] of the first source XMM register are copied to the destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- When VEX.W = 1, converts a signed quadword integer value from a 64-bit source general-purpose register or a 64-bit memory location to a double-precision floating-point value and writes the converted value to the low-order 32 bits of the destination XMM register. Bits [127:32] of the first source XMM register are copied to the destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTSI2SS is an SSE1 instruction and VCVTSI2SS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTSS2SD Convert Scalar Single-Precision Floating-Point VCVTSS2SD to Scalar Double-Precision Floating-Point

Converts a scalar single-precision floating-point value to a scalar double-precision floating-point value and writes the converted value to the low-order 64 bits of the destination.

There are legacy and extended forms of the instruction:

CVTSS2SD

Converts a scalar single-precision floating-point value in the low-order 32 bits of a source XMM register or a 32-bit memory location to a scalar double-precision floating-point value and writes the converted value to the low-order 64 bits of a destination XMM register. Bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are not affected.

VCVTSS2SD

The extended form of the instruction has a 128-bit encoding only.

Converts a scalar single-precision floating-point value in the low-order 32 bits of the second source XMM register or 32-bit memory location to a scalar double-precision floating-point value and writes the converted value to the low-order 64 bits of the destination XMM register. Bits [127:64] of the destination are copied from the first source XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTSD2SD is an SSE2 instruction and VCVTSD2SD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTSS2SI Convert Scalar Single-Precision Floating-Point VCVTSS2SI to Signed Doubleword or Quadword Integer

Converts a single-precision floating-point value to a signed integer value and writes the converted value to a general-purpose register.

When the result of the conversion is an inexact value, the value is rounded as specified by MXCSR.RC. When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$) or quadword value (-2^{63} to $+2^{63} - 1$), the indefinite integer value (8000_0000h for 32-bit integers, 8000_0000_0000_0000h for 64-bit integers) is returned when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTSS2SI

The legacy form has two encodings:

- When REX.W = 0, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 32-bit signed integer value and writes the converted value to a 32-bit general-purpose register.
- When REX.W = 1, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 64-bit signed integer value and writes the converted value to a 64-bit general-purpose register.

VCVTSS2SI

The extended form of the instruction has two 128-bit encodings:

- When VEX.W = 0, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 32-bit signed integer value and writes the converted value to a 32-bit general-purpose register.
- When VEX.W = 1, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 64-bit signed integer value and writes the converted value to a 64-bit general-purpose register.

CVTSS2SI is an SSE1 instruction and VCVTSS2SI is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTTPD2DQ Convert Packed Double-Precision Floating-Point VCVTPD2DQ to Packed Doubleword Integer, Truncated

Converts packed double-precision floating-point values to packed signed doubleword integer values and writes the converted values to the destination.

When the result is an inexact value, it is truncated (rounded toward zero). When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$), the instruction returns the 32-bit indefinite integer value (8000_0000h) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTTPD2DQ

Converts two packed double-precision floating-point values in an XMM register or a 128-bit memory location to two packed signed doubleword integers and writes the converted values to the two low-order doublewords of the destination XMM register. Bits [127:64] of the destination are cleared. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VCVTPD2DQ

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts two packed double-precision floating-point values in an XMM register or a 128-bit memory location to two signed doubleword values and writes the converted values to the lower two doubleword elements of the destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts four packed double-precision floating-point values in a YMM register or a 256-bit memory location to four signed doubleword integer values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

CVTTPD2DQ is an SSE2 instruction and VCVTPD2DQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTTPS2DQ Convert Packed Single-Precision Floating-Point VCVTTPS2DQ to Packed Doubleword Integers, Truncated

Converts packed single-precision floating-point values to packed signed doubleword integer values and writes the converted values to the destination.

When the result of the conversion is an inexact value, the value is truncated (rounded toward zero). When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$), the instruction returns the 32-bit indefinite integer value (8000_0000h) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTTPS2DQ

Converts four packed single-precision floating-point values in an XMM register or a 128-bit memory location to four packed signed doubleword integer values and writes the converted values to an XMM register. The high-order 128-bits of the corresponding YMM register are not affected.

VCVTTPS2DQ

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts four packed single-precision floating-point values in an XMM register or a 128-bit memory location to four packed signed doubleword integer values and writes the converted values to an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Converts eight packed single-precision floating-point values in a YMM register or a 256-bit memory location to eight packed signed doubleword integer values and writes the converted values to a YMM register.

CVTTPS2DQ is an SSE2 instruction and VCVTTPS2DQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

CVTTSD2SI Convert Scalar Double-Precision Floating-Point VCVTTSD2SI to Signed Double- or Quadword Integer, Truncated

Converts a scalar double-precision floating-point value to a signed integer value and writes the converted value to a general-purpose register.

When the result of the conversion is an inexact value, the value is truncated (rounded toward zero). When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$) or quadword value (-2^{63} to $+2^{63} - 1$), the instruction returns the indefinite integer value (8000_0000h for 32-bit integers, 8000_0000_0000_0000h for 64-bit integers) when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTTSD2SI

The legacy form of the instruction has two encodings:

- When REX.W = 0, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 32-bit signed integer and writes the converted value to a 32-bit general purpose register.
- When REX.W = 1, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 64-bit sign-extended integer and writes the converted value to a 64-bit general purpose register.

VCVTTSD2SI

The extended form of the instruction has two 128-bit encodings.

- When VEX.W = 0, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 32-bit signed integer and writes the converted value to a 32-bit general purpose register.
- When VEX.W = 1, converts a scalar double-precision floating-point value in the low-order 64 bits of an XMM register or a 64-bit memory location to a 64-bit sign-extended integer and writes the converted value to a 64-bit general purpose register.

CVTTSD2SI is an SSE2 instruction and VCVTTSD2SI is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

CVTTSS2SI Convert Scalar Single-Precision Floating-Point VCVTTSS2SI to Signed Double or Quadword Integer, Truncated

Converts a single-precision floating-point value to a signed integer value and writes the converted value to a general-purpose register.

When the result of the conversion is an inexact value, the value is truncated (rounded toward zero). When the floating-point value is a NaN, infinity, or the result of the conversion is larger than the maximum signed doubleword (-2^{31} to $+2^{31} - 1$) or quadword value (-2^{63} to $+2^{63} - 1$), the indefinite integer value (8000_0000h for 32-bit integers, 8000_0000_0000_0000h for 64-bit integers) is returned when the invalid-operation exception (IE) is masked.

There are legacy and extended forms of the instruction:

CVTTSS2SI

The legacy form of the instruction has two encodings:

- When REX.W = 0, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 32-bit signed integer value and writes the converted value to a 32-bit general-purpose register. Bits [255:128] of the YMM register that corresponds to the source are not affected.
- When REX.W = 1, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 64-bit signed integer value and writes the converted value to a 64-bit general-purpose register. Bits [255:128] of the YMM register that corresponds to the source are not affected.

VCVTTSS2SI

The extended form of the instruction has two 128-bit encodings:

- When VEX.W = 0, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 32-bit signed integer value and writes the converted value to a 32-bit general-purpose register. Bits [255:128] of the YMM register that corresponds to the source are cleared.
- When VEX.W = 1, converts a single-precision floating-point value in the low-order 32 bits of an XMM register or a 32-bit memory location to a 64-bit signed integer value and writes the converted value to a 64-bit general-purpose register. Bits [255:128] of the YMM register that corresponds to the source are cleared.

CVTTSS2SI is an SSE1 instruction and VCVTTSS2SI is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

DIVPD**Divide****VDIVPD****Packed Double-Precision Floating-Point**

Divides each of the packed double-precision floating-point values of the first source operand by the corresponding packed double-precision floating-point values of the second source operand and writes the quotients to the destination.

There are legacy and extended forms of the instruction:

DIVPD

Divides two packed double-precision floating-point values in the first source XMM register by the corresponding packed double-precision floating-point values in either a second source XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VDIVPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Divides two packed double-precision floating-point values in the first source XMM register by the corresponding packed double-precision floating-point values in either a second source XMM register or a 128-bit memory location and writes the two results a destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Divides four packed double-precision floating-point values in the first source YMM register by the corresponding packed double-precision floating-point values in either a second source YMM register or a 256-bit memory location and writes the two results a destination YMM register.

DIVPD is an SSE2 instruction and VDIVPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

DIVPS Divide

VDIVPS Packed Single-Precision Floating-Point

Divides each of the packed single-precision floating-point values of the first source operand by the corresponding packed single-precision floating-point values of the second source operand and writes the quotients to the destination.

There are legacy and extended forms of the instruction:

DIVPS

Divides four packed single-precision floating-point values in the first source XMM register by the corresponding packed single-precision floating-point values in either a second source XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VDIVPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Divides four packed single-precision floating-point values in the first source XMM register by the corresponding packed single-precision floating-point values in either a second source XMM register or a 128-bit memory location and writes two results to a third destination XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Divides eight packed single-precision floating-point values in the first source YMM register by the corresponding packed single-precision floating-point values in either a second source YMM register or a 256-bit memory location and writes the two results a destination YMM register.

DIVPS is an SSE1 instruction and VDIVPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

DIVSD Divide

VDIVSD Scalar Double-Precision Floating-Point

Divides the double-precision floating-point value in the low-order quadword of the first source operand by the double-precision floating-point value in the low-order quadword of the second source operand and writes the quotient to the low-order quadword of the destination.

There are legacy and extended forms of the instruction:

DIVSD

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The first source register is also the destination register. Bits [127:64] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VDIVSD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. Bits [127:64] of the first source operand are copied to bits [127:64] of the destination. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

DIVSD is an SSE2 instruction and VDIVSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

DPPD VDPPD

Dot Product Packed Double-Precision Floating-Point

Computes the dot-product of the input operands. An immediate operand specifies both the input values and the destination locations to which the products are written.

Selectively multiplies packed double-precision values in a source operand by the corresponding values in another source operand, writes the results to a temporary location, adds the results, writes the sum to a second temporary location and selectively writes the sum to a destination.

Mask bits [5:4] of an 8-bit immediate operand perform multiplicative selection. Bit 5 selects bits [127:64] of the source operands; bit 4 selects bits [63:0] of the source operands. When a mask bit = 1, the corresponding packed double-precision floating point values are multiplied and the product is written to the corresponding position of a 128-bit temporary location. When a mask bit = 0, the corresponding position of the temporary location is cleared.

After the two 64-bit values in the first temporary location are added and written to the 64-bit second temporary location, mask bits [1:0] of the same 8-bit immediate operand perform write selection. Bit 1 selects bits [127:64] of the destination; bit 0 selects bits [63:0] of the destination. When a mask bit = 1, the 64-bit value of the second temporary location is written to the corresponding position of the destination. When a mask bit = 0, the corresponding position of the destination is cleared.

When the operation produces a NaN, its value is determined as follows.

Source Operands (in either order)		NaN Result ¹
QNaN	Any non-NaN floating-point value (or single-operand instruction)	Value of QNaN
SNaN	Any non-NaN floating-point value (or single-operand instruction)	Value of SNaN, converted to a QNaN ²
QNaN	QNaN	First operand
QNaN	SNaN	First operand (converted to QNaN if SNaN)
SNaN	SNaN	First operand converted to a QNaN ²
Note: 1. A NaN result produced when the floating-point invalid-operation exception is masked. 2. The conversion is done by changing the most-significant fraction bit to 1.		

For each addition occurring in either the second or third step, for the purpose of NaN propagation, the addend of lower bit index is considered to be the first of the two operands. For example, when both multiplications produce NaNs, the one that corresponds to bits [64:0] is written to all indicated fields of the destination, regardless of how those NaNs were generated from the sources. When the high-order multiplication produces NaNs and the low-order multiplication produces infinities of opposite signs, the real indefinite QNaN (produced as the sum of the infinities) is written to the destination.

NaNs in source operands or in computational results result in at least one NaN in the destination. For the 256-bit version, NaNs are propagated within the two independent dot product operations only to their respective 128-bit results.

There are legacy and extended forms of the instruction:

DPPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VDPPD

The extended form of the instruction has a single 128-bit encoding.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

DPPD is an SSE4.1 instruction and VDPPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

DPPS VDPPS

Dot Product Packed Single-Precision Floating-Point

Computes the dot-product of the input operands. An immediate operand specifies both the input values and the destination locations to which the products are written.

Selectively multiplies packed single-precision values in a source operand by corresponding values in another source operand, writes results to a temporary location, adds pairs of results, writes the sums to additional temporary locations, and selectively writes a cumulative sum to a destination.

Mask bits [7:4] of an 8-bit immediate operand perform multiplicative selection. Each bit selects a 32-bit segment of the source operands; bit 7 selects bits [127:96], bit 6 selects bits [95:64], bit 5 selects bits [63:32], and bit 4 selects bits [31:0]. When a mask bit = 1, the corresponding packed single-precision floating point values are multiplied and the product is written to the corresponding position of a 128-bit temporary location. When a mask bit = 0, the corresponding position of the temporary location is cleared.

After multiplication, three pairs of 32-bit values are added and written to temporary locations.

Bits [63:32] and [31:0] of temporary location 1 are added and written to 32-bit temporary location 2; bits [127:96] and [95:64] of temporary location 1 are added and written to 32-bit temporary location 3; then the contents of temporary locations 2 and 3 are added and written to 32-bit temporary location 4.

After addition, mask bits [3:0] of the same 8-bit immediate operand perform write selection. Each bit selects a 32-bit segment of the source operands; bit 3 selects bits [127:96], bit 2 selects bits [95:64], bit 1 selects bits [63:32], and bit 0 selects bits [31:0] of the destination. When a mask bit = 1, the 64-bit value of the fourth temporary location is written to the corresponding position of the destination. When a mask bit = 0, the corresponding position of the destination is cleared.

For the 256-bit extended encoding, this process is performed on the upper and lower 128 bits of the affected YMM registers.

When the operation produces a NaN, its value is determined as follows.

Source Operands (in either order)		NaN Result ¹
QNaN	Any non-NaN floating-point value (or single-operand instruction)	Value of QNaN
SNaN	Any non-NaN floating-point value (or single-operand instruction)	Value of SNaN, converted to a QNaN ²
QNaN	QNaN	First operand
QNaN	SNaN	First operand (converted to QNaN if SNaN)
SNaN	SNaN	First operand converted to a QNaN ²
Note: 1. A NaN result produced when the floating-point invalid-operation exception is masked. 2. The conversion is done by changing the most-significant fraction bit to 1.		

For each addition occurring in either the second or third step, for the purpose of NaN propagation, the addend of lower bit index is considered to be the first of the two operands. For example, when all four multiplications produce NaNs, the one that corresponds to bits [31:0] is written to all indicated fields

of the destination, regardless of how those NaNs were generated from the sources. When the two highest-order multiplications produce NaNs and the two lowest-order multiplications produce infinities of opposite signs, the real indefinite QNaN (produced as the sum of the infinities) is written to the destination.

NaNs in source operands or in computational results result in at least one NaN in the destination. For the 256-bit version, NaNs are propagated within the two independent dot product operations only to their respective 128-bit results.

There are legacy and extended forms of the instruction:

DPPS

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VDPPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

DPPS is an SSE4.1 instruction and VDPPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

EXTRACTPS VEXTRACTPS

Extract Packed Single-Precision Floating-Point

Copies one of four packed single-precision floating-point values from a source XMM register to a general purpose register or a 32-bit memory location.

Bits [1:0] of an immediate byte operand specify the location of the 32-bit value that is copied. 00b corresponds to the low word of the source register and 11b corresponds to the high word of the source register. Bits [7:2] of the immediate operand are ignored.

There are legacy and extended forms of the instruction:

EXTRACTPS

The source operand is an XMM register. The destination can be a general purpose register or a 32-bit memory location. A 32-bit single-precision value extracted to a general purpose register is zero-extended to 64-bits.

VEXTRACTPS

The extended form of the instruction has a single 128-bit encoding.

The source operand is an XMM register. The destination can be a general purpose register or a 32-bit memory location.

EXTRACTPS is an SSE4.1 instruction and VEXTRACTPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

EXTRQ

Extract Field From Register

Extracts specified bits from the lower 64 bits of the first operand (the destination XMM register). The extracted bits are saved in the least-significant bit positions of the lower quadword of the destination; the remaining bits in the lower quadword of the destination register are cleared to 0. The upper quadword of the destination register is undefined.

The portion of the source data being extracted is defined by the bit index and the field length. The bit index defines the least-significant bit of the source operand being extracted. Bits [*bit index* + *length field* – 1]:[*bit index*] are extracted. If the sum of the *bit index* + *length field* is greater than 64, the results are undefined.

For example, if the bit index is 32 (20h) and the field length is 16 (10h), then the result in the destination register will be source [47:32] in bits 15:0, with zeros in bits 63:16.

A value of zero in the field length is defined as a length of 64. If the *length field* is 0 and the *bit index* is 0, bits 63:0 of the source are extracted. For any other value of the *bit index*, the results are undefined.

The *bit index* and *field length* can be specified as immediate values (second and first immediate operands, respectively, in the case of the three argument version of the instruction), or they can both be specified by fields in an XMM source operand. In the latter case, bits [5:0] of the XMM register specify the number of bits to extract (the *field length*) and bits [13:8] of the XMM register specify the index of the first bit in the field to extract. The *bit index* and *field length* are each six bits in length; other bits of the field are ignored.

The diagram below illustrates the operation of this instruction.

EXTRQ is an SSE4A instruction. Support for SSE4A instructions is indicated by CPUID Fn8000_0001_ECX[SSE4A] = 1. Software *must* check the CPUID bit once per program or library initialization before using the EXTRQ instruction, or inconsistent behavior may result.

See the *CPUID Specification*, order# 25481 for more information on feature bits.

Instruction Encoding

Mnemonic	Opcode	Description
EXTRQ <i>xmm1, imm8, imm8</i>	66 0F 78 /0 ib ib	Extract field from <i>xmm1</i> , with the least significant bit of the extracted data starting at the bit index specified by [5:0] of the second immediate byte, with the length specified by [5:0] of the first immediate byte.
EXTRQ <i>xmm1, xmm2</i>	66 0F 79 /r	Extract field from <i>xmm1</i> , with the least significant bit of the extracted data starting at the bit index specified by <i>xmm2</i> [13:8], with the length specified by <i>xmm2</i> [5:0].

HADDPD VHADDPD

Horizontal Add Packed Double-Precision Floating-Point

Adds adjacent pairs of double-precision floating-point values in two source operands and writes the sums to a destination.

There are legacy and extended forms of the instruction:

HADDPD

Adds the packed double-precision values in bits [127:64] and bits [63:0] of the first source XMM register and writes the sum to bits [63:0] of the destination; adds the corresponding doublewords of the second source XMM register or a 128-bit memory location and writes the sum to bits [127:64] of the destination. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VHADDPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Adds the packed double-precision values in bits [127:64] and bits [63:0] of the first source XMM register and writes the sum to bits [63:0] of the destination XMM register; adds the corresponding doublewords of the second source XMM register or a 128-bit memory location and writes the sum to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Adds the packed double-precision values in bits [127:64] and bits [63:0] of the of the first source YMM register and writes the sum to bits [63:0] of the destination YMM register; adds the corresponding doublewords of the second source YMM register or a 256-bit memory location and writes the sum to bits [127:64] of the destination. Performs the same process for the upper 128 bits of the sources and destination.

HADDPD is an SSE3 instruction and VHADDPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

X — AVX and SSE exception A — AVX exception S — SSE exception				

HADDPS VHADDPS

Horizontal Add Packed Single-Precision

Adds adjacent pairs of single-precision floating-point values in two source operands and writes the sums to a destination.

There are legacy and extended forms of the instruction:

HADDPS

Adds the packed single-precision values in bits [63:32] and bits [31:0] of the first source XMM register and writes the sum to bits [31:0] of the destination; adds the packed single-precision values in bits [127:96] and bits [95:64] of the first source register and writes the sum to bits [63:32] of the destination. Adds the corresponding values in the second source XMM register or a 128-bit memory location and writes the sum to bits [95:64] and [127:96] of the destination. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VHADDPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Adds the packed single-precision values in bits [63:32] and bits [31:0] of the first source XMM register and writes the sum to bits [31:0] of the destination XMM register; adds the packed single-precision values in bits [127:96] and bits [95:64] of the first source register and writes the sum to bits [63:32] of the destination. Adds the corresponding values in the second source XMM register or a 128-bit memory location and writes the sum to bits [95:64] and [127:96] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Adds the packed single-precision values in bits [63:32] and bits [31:0] of the first source YMM register and writes the sum to bits [31:0] of the destination YMM register; adds the packed single-precision values in bits [127:96] and bits [95:64] of the first source register and writes the sum to bits [63:32] of the destination. Adds the corresponding values in the second source YMM register or a 256-bit memory location and writes the sums to bits [95:64] and [127:96] of the destination. Performs the same process for the upper 128 bits of the sources and destination.

HADDPS is an SSE3 instruction and VHADDPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

HSUBPD VHSUBPD

Horizontal Subtract Packed Double-Precision

Subtracts adjacent pairs of double-precision floating-point values in two source operands and writes the sums to a destination.

There are legacy and extended forms of the instruction:

HSUBPD

The first source register is also the destination.

Subtracts the packed double-precision value in bits [127:64] from the value in bits [63:0] of the first source XMM register and writes the difference to bits [63:0] of the destination; subtracts the corresponding values of the second source XMM register or a 128-bit memory location and writes the difference to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VHSUBPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Subtracts the packed double-precision values in bits [127:64] from the value in bits [63:0] of the first source XMM register and writes the difference to bits [63:0] of the destination XMM register; subtracts the corresponding values of the second source XMM register or a 128-bit memory location and writes the difference to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Subtracts the packed double-precision values in bits [127:64] from the value in bits [63:0] of the first source YMM register and writes the difference to bits [63:0] of the destination YMM register; subtracts the corresponding values of the second source YMM register or a 256-bit memory location and writes the difference to bits [127:64] of the destination. Performs the same process for the upper 128 bits of the sources and destination.

HSUBPD is an SSE3 instruction and VHSUBPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

INSERTPS VINSERTPS

Insert Packed Single-Precision Floating-Point

Copies a selected single-precision floating-point value from a source operand to a selected location in a destination register and optionally clears selected elements of the destination. The legacy and extended forms of the instruction treat the remaining elements of the destination in different ways.

Selections are specified by three fields of an immediate 8-bit operand:

7	6	5	4	3	2	1	0
COUNT_S		COUNT_D		ZMASK			

COUNT_S — The binary value of the field specifies a 32-bit element of a source register, counting upward from the low-order doubleword. COUNT_S is used only for register source; when the source is a memory operand, COUNT_S = 0.

COUNT_D — The binary value of the field specifies a 32-bit destination element, counting upward from the low-order doubleword.

ZMASK — Set a bit to clear a 32-bit element of the destination.

There are legacy and extended forms of the instruction:

INSERTPS

The source operand is either an XMM register or a 32-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

When the source operand is a register, the instruction copies the 32-bit element of the source specified by Count_S to the location in the destination specified by Count_D, and clears destination elements as specified by ZMask. Elements of the destination that are not cleared are not affected.

When the source operand is a memory location, the instruction copies a 32-bit value from memory, to the location in the destination specified by Count_D, and clears destination elements as specified by ZMask. Elements of the destination that are not cleared are not affected.

VINSERTPS

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either another XMM register or a 32-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

When the second source operand is a register, the instruction copies the 32-bit element of the source specified by Count_S to the location in the destination specified by Count_D. The other elements of the destination are either copied from the first source operand or cleared as specified by ZMask.

When the second source operand is a memory location, the instruction copies a 32-bit value from the source to the location in the destination specified by Count_D. The other elements of the destination are either copied from the first source operand or cleared as specified by ZMask.

INSERTPS is an SSE4.1 instruction and VINSERTPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
INSERTPS <i>xmm1</i> , <i>xmm2/mem32</i> , <i>imm8</i>	66 0F 3A 21 /r ib	Insert a selected single-precision floating-point value from <i>xmm2</i> or from <i>mem32</i> at a selected location in <i>xmm1</i> and clear selected elements of <i>xmm1</i> . Selections specified by <i>imm8</i> .

Mnemonic	Encoding

INSERTQ

Insert Field

Inserts bits from the lower 64 bits of the source operand into the lower 64 bits of the destination operand. No other bits in the lower 64 bits of the destination are modified. The upper 64 bits of the destination are undefined.

The least-significant l bits of the source operand are inserted into the destination, with the least-significant bit of the source operand inserted at bit position n , where l and n are defined as the *field length* and *bit index*, respectively.

Bits $(\text{field length} - 1):0$ of the source operand are inserted into bits $(\text{bit index} + \text{field length} - 1):(\text{bit index})$ of the destination. If the sum of the *bit index* + *length field* is greater than 64, the results are undefined.

For example, if the *bit index* is 32 (20h) and the *field length* is 16 (10h), then the result in the destination register will be *source operand*[15:0] in bits 47:32. Bits 63:48 and bits 31:0 are not modified.

A value of zero in the *field length* is defined as a length of 64. If the *length field* is 0 and the *bit index* is 0, bits 63:0 of the source operand are inserted. For any other value of the *bit index*, the results are undefined.

The bits to insert are located in the XMM2 source operand. The *bit index* and *field length* can be specified as immediate values or can be specified in the XMM source operand. In the immediate form, the *bit index* and the *field length* are specified by the fourth (second immediate byte) and third operands (first immediate byte), respectively. In the register form, the *bit index* and *field length* are specified in bits [77:72] and bits [69:64] of the source XMM register, respectively. The *bit index* and *field length* are each six bits in length; other bits in the field are ignored.

The diagram below illustrates the operation of this instruction.

INSERTQ is an SSE4A instruction. Support for SSE4A instructions is indicated CPUID Fn8000_0001_ECX[SSE4A] = 1. Software *must* check the CPUID bit once per program or library initialization before using the INSERTQ instruction, or inconsistent behavior may result.

See the *CPUID Specification*, order# 25481 for more information about processor feature bits.

Instruction Encoding

Mnemonic	Opcode	Description
INSERTQ <i>xmm1, xmm2, imm8, imm8</i>	F2 0F 78 /r ib ib	Insert field starting at bit 0 of xmm2 with the length specified by [5:0] of the first immediate byte. This field is inserted into xmm1 starting at the bit position specified by [5:0] of the second immediate byte.
INSERTQ <i>xmm1, xmm2</i>	F2 0F 79 /r	Insert field starting at bit 0 of xmm2 with the length specified by xmm2[69:64]. This field is inserted into xmm1 starting at the bit position specified by xmm2[77:72].

	X	X	X	The operating-system FXSAVE/FXRSTOR support bit (OSFXSR) of CR4 is cleared to 0.
Device not available, #NM	X	X	X	The task-switch bit (TS) of CR0 was set to 1.

LDDQU Load

VLDDQU Unaligned Double Quadword

Loads unaligned double quadwords from a memory location to a destination register.

Like the (V)MOVUPD instructions, (V)LDDQU loads a 128-bit or 256-bit operand from an unaligned memory location. However, to improve performance when the memory operand is actually misaligned, (V)LDDQU may read an aligned 16 or 32 bytes to get the first part of the operand, and an aligned 16 or 32 bytes to get the second part of the operand. This behavior is implementation-specific, and (V)LDDQU may only read the exact 16 or 32 bytes needed for the memory operand. If the memory operand is in a memory range where reading extra bytes can cause performance or functional issues, use (V)MOVUPD instead of (V)LDDQU.

Memory operands that are not aligned on 16-byte or 32-byte boundaries do not cause general-protection exceptions.

There are legacy and extended forms of the instruction:

LDDQU

The source operand is an unaligned 128-bit memory location. The destination operand is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination register are not affected.

VLDDQU

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The source operand is an unaligned 128-bit memory location. The destination operand is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination register are cleared.

YMM Encoding

The source operand is an unaligned 256-bit memory location. The destination operand is a YMM register.

LDDQU is an SSE3 instruction and VLDDQU is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

LDMXCSR VLDMXCSR

Load MXCSR Control/Status Register

Loads the MXCSR register with a 32-bit value from memory.

For both legacy LDMXCSR and extended VLDMXCSR forms of the instruction, the source operand is a 32-bit memory location and the destination operand is the MXCSR.

If an MXCSR load clears a SIMD floating-point exception mask bit and sets the corresponding exception flag bit, a SIMD floating-point exception is not generated immediately. An exception is generated only when the next instruction that operates on an XMM or YMM register operand and causes that particular SIMD floating-point exception to be reported executes.

A general protection exception occurs if the instruction attempts to load non-zero values into reserved MXCSR bits. Software can use MXCSR_MASK to determine which bits are reserved. For details, see “128-Bit, 64-Bit, and x87 Programming” in Volume 2.

The MXCSR register is described in “Registers” in Volume 1.

LDMXCSR is an SSE1 instruction and VLDMXCSR is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MASKMOVDQU VMASKMOVDQU

Masked Move Double Quadword Unaligned

Moves bytes from the first source operand to a memory location specified by the DS:rDI register. Bytes are selected by mask bits in the second source operand. The memory location may be unaligned.

The mask consists of the most significant bit of each byte of the second source register. When a mask bit = 1, the corresponding byte of the first source register is written to the destination; when a mask bit = 0, the corresponding byte is not written.

An all-zero mask value results in the following behavior:

- No data is written to memory.
- Code and data breakpoints are not guaranteed to be signaled in all implementations.
- Exceptions associated with memory addressing and page faults are not guaranteed to be signaled in all implementations.

The instruction implicitly uses weakly-ordered, write-combining buffering for the data, as described in “Buffering and Combining Memory Writes” in Volume 2. For data that is shared by multiple processors, this instruction should be used together with a fence instruction in order to ensure data coherency (see “Cache and TLB Management” in Volume 2).

There are legacy and extended forms of the instruction:

MASKMOVDQU

The first source operand is an XMM register and the second source operand is another XMM register. The destination is a 128-bit memory location.

VMASKMOVDQU

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is another XMM register. The destination is a 128-bit memory location.

MASKMOVDQU is an SSE2 instruction and VMASKMOVDQU is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MASKMOVDQU <i>xmm1</i> , <i>xmm2</i>	66 0F F7 /r	Move bytes selected by a mask value in <i>xmm2</i> from <i>xmm1</i> to the memory location specified by DS:rDI.		
Mnemonic	Encoding

MAXPD Maximum

VMAXPD Packed Double-Precision Floating-Point

Compares each packed double-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the numerically greater value into the corresponding location of the destination.

If both source operands are equal to zero, the value of the second source operand is returned. If either operand is a NaN (SNaN or QNaN), and invalid-operation exceptions are masked, the second source operand is written to the destination.

There are legacy and extended forms of the instruction:

MAXPD

Compares two pairs of packed double-precision floating-point values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMAXPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Compares two pairs of packed double-precision floating-point values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Compares four pairs of packed double-precision floating-point values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MAXPD is an SSE2 instruction and VMAXPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MAXPS Maximum

VMAXPS Packed Single-Precision Floating-Point

Compares each packed single-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the numerically greater value into the corresponding location of the destination.

If both source operands are equal to zero, the value of the second source operand is returned. If either operand is a NaN (SNaN or QNaN), and invalid-operation exceptions are masked, the second source operand is written to the destination.

There are legacy and extended forms of the instruction:

MAXPS

Compares four pairs of packed single-precision floating-point values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMAXPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Compares four pairs of packed single-precision floating-point values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Compares eight pairs of packed single-precision floating-point values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MAXPS is an SSE1 instruction and VMAXPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MINPD Minimum

VMINPD Packed Double-Precision Floating-Point

Compares each packed double-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the numerically lesser value into the corresponding location of the destination.

If both source operands are equal to zero, the value of the second source operand is returned. If either operand is a NaN (SNaN or QNaN), and invalid-operation exceptions are masked, the second source operand is written to the destination.

There are legacy and extended forms of the instruction:

MINPD

Compares two pairs of packed double-precision floating-point values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMINPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Compares two pairs of packed double-precision floating-point values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Compares four pairs of packed double-precision floating-point values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MINPD is an SSE2 instruction and VMINPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

MINPS Minimum

VMINPS Packed Single-Precision Floating-Point

Compares each packed single-precision floating-point value of the first source operand to the corresponding value of the second source operand and writes the numerically lesser value into the corresponding location of the destination.

If both source operands are equal to zero, the value of the second source operand is returned. If either operand is a NaN (SNaN or QNaN), and invalid-operation exceptions are masked, the second source operand is written to the destination.

There are legacy and extended forms of the instruction:

MINPS

Compares four pairs of packed single-precision floating-point values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMINPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Compares four pairs of packed single-precision floating-point values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Compares eight pairs of packed single-precision floating-point values.

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MINPS is an SSE1 instruction and VMINPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

MOVAPD VMOVAPD

Move Aligned Packed Double-Precision Floating-Point

Moves packed double-precision floating-point values. Values can be moved from a register or memory location to a register; or from a register to a register or memory location.

A memory operand that is not aligned causes a general-protection exception.

There are legacy and extended forms of the instruction:

MOVAPD

Moves two double-precision floating-point values. There are encodings for each type of move.

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVAPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves two double-precision floating-point values. There are encodings for each type of move:

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves four double-precision floating-point values. There are encodings for each type of move:

- The source operand is either a YMM register or a 256-bit memory location. The destination operand is a YMM register.
- The source operand is a YMM register. The destination operand is either a YMM register or a 256-bit memory location.

MOVAPD is an SSE2 instruction and VMOVAPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVAPS VMOVAPS

Move Aligned Packed Single-Precision Floating-Point

Moves packed single-precision floating-point values. Values can be moved from a register or memory location to a register; or from a register to a register or memory location.

A memory operand that is not aligned causes a general-protection exception.

There are legacy and extended forms of the instruction:

MOVAPS

Moves four single-precision floating-point values.

There are encodings for each type of move.

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVAPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves four single-precision floating-point values. There are encodings for each type of move.

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves eight single-precision floating-point values. There are encodings for each type of move.

- The source operand is either a YMM register or a 256-bit memory location. The destination operand is a YMM register.
- The source operand is a YMM register. The destination operand is either a YMM register or a 256-bit memory location.

MOVAPS is an SSE1 instruction and VMOVAPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVD Move

VMOVD Doubleword or Quadword

Moves 32-bit and 64-bit values. A value can be moved from a general-purpose register or memory location to the corresponding low-order bits of an XMM register, with zero-extension to 128 bits; or from the low-order bits of an XMM register to a general-purpose register or memory location.

The quadword form of this instruction is distinct from the differently-encoded (V)MOVQ instruction. There are legacy and extended forms of the instruction:

MOVD

There are two encodings for 32-bit moves, characterized by REX.W = 0.

- The source operand is either a 32-bit general-purpose register or a 32-bit memory location. The destination is an XMM register. The 32-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either a 32-bit general-purpose register or a 32-bit memory location.

There are two encodings for 64-bit moves, characterized by REX.W = 0.

- The source operand is either a 64-bit general-purpose register or a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either a 64-bit general-purpose register or a 64-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVD

The extended form of the instruction has four 128-bit encodings:

There are two encodings for 32-bit moves, characterized by VEX.W = 0.

- The source operand is either a 32-bit general-purpose register or a 32-bit memory location. The destination is an XMM register. The 32-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either a 32-bit general-purpose register or a 32-bit memory location.

There are two encodings for 64-bit moves, characterized by VEX.W = 1.

- The source operand is either a 64-bit general-purpose register or a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either a 64-bit general-purpose register or a 64-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVD is an SSE2 instruction and VMOVD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
MOVD <i>xmm, reg32/mem32</i>	66 (W0) 0F 6E /r	Move a 32-bit value from <i>reg32/mem32</i> to <i>xmm</i> .
MOVQ <i>xmm, reg64/mem64</i>	66 (W1) 0F 6E /r	Move a 64-bit value from <i>reg64/mem64</i> to <i>xmm</i> .
MOVD <i>reg32/mem32, xmm</i>	66 (W0) 0F 7E /r	Move a 32-bit value from <i>xmm</i> to <i>reg32/mem32</i> .
MOVQ <i>reg64/mem64, xmm</i>	66 (W1) 0F 7E /r	Move a 64-bit value from <i>xmm</i> to <i>reg64/mem64</i> .

Mnemonic	Encoding			
	VEX	RXB.map_select	W.vvvv.L.pp	Opcode
VMOVD <i>xmm, reg32/mem32</i>	C4	$\overline{\text{RXB}}$.00001	0.1111.0.01	6E /r

MOVDDUP VMOVDDUP

Move and Duplicate Double-Precision Floating-Point

Moves and duplicates double-precision floating-point values.

There are legacy and extended forms of the instruction:

MOVDDUP

Moves and duplicates one quadword value.

The source operand is either the low 64 bits of an XMM register or the address of the least-significant byte of 64 bits of data in memory. The destination is another XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVDDUP

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves and duplicates one quadword value.

The source operand is either the low 64 bits of an XMM register or the address of the least-significant byte of 64 bits of data in memory. The destination is another XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves and duplicates two even-indexed quadword values.

The source operand is either a YMM register or the address of the least-significant byte of 256 bits of data in memory. The destination is another YMM register. Bits [63:0] of the source are written to bits [127:64] and [63:0] of the destination; bits [191:128] of the source are written to bits [255:192] and [191:128] of the destination.

MOVDDUP is an SSE3 instruction and VMOVDDUP is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVDDUP <i>xmm1, xmm2/mem64</i>	F2 0F 12 /r	Moves two copies of the low 64 bits of <i>xmm2</i> or <i>mem64</i> to <i>xmm1</i> .

MOVDQA VMOVDQA

Move Aligned Double Quadword

Moves aligned packed integer values. Values can be moved from a register or a memory location to another register, or from a register to another register or a memory location.

A memory operand that is not aligned causes a general-protection exception.

There are legacy and extended forms of the instruction:

MOVDQA

Moves two aligned quadwords (128-bit move). There are two encodings.

- The source operand is an XMM register. The destination is either another XMM register or a 128-bit memory location.
- The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVDQA

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves two aligned quadwords (128-bit move). There are two encodings.

- The source operand is an XMM register. The destination is either another XMM register or a 128-bit memory location.
- The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves four aligned quadwords (256-bit move). There are two encodings.

- The source operand is a YMM register. The destination is either another YMM register or a 256-bit memory location.
- The source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MOVDQA is an SSE2 instruction and VMOVDQA is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
MOVDQA <i>xmm1, xmm2/mem128</i>	66 0F 6F /r	Moves aligned packed integer values from <i>xmm2</i> or <i>mem128</i> to <i>xmm1</i> .
MOVDQA <i>xmm1/mem128, xmm2</i>	66 0F 7F /r	Moves aligned packed integer values from <i>xmm1</i> or <i>mem128</i> to <i>xmm2</i> .

Mnemonic	Encoding

MOVDQU Move

VMOVDQU Unaligned Double Quadword

Moves unaligned packed integer values. Values can be moved from a register or a memory location to another register, or from a register to another register or a memory location.

There are legacy and extended forms of the instruction:

MOVDQU

Moves two unaligned quadwords (128-bit move). There are two encodings.

- The source operand is an XMM register. The destination is either another XMM register or a 128-bit memory location.
- The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVDQU

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves two unaligned quadwords (128-bit move). There are two encodings:

- The source operand is an XMM register. The destination is either another XMM register or a 128-bit memory location.
- The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves four unaligned quadwords (256-bit move). There are two encodings:

- The source operand is a YMM register. The destination is either another YMM register or a 256-bit memory location.
- The source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

MOVDQU is an SSE2 instruction and VMOVDQU is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

MOVHLPS Move High to Low

VMOVHLPS Packed Single-Precision Floating-Point

Moves two packed single-precision floating-point values from the high quadword of an XMM register to the low quadword of another XMM register.

There are legacy and extended forms of the instruction:

MOVHLPS

The source operand is bits [127:64] of an XMM register. The destination is bits [63:0] of another XMM register. Bits [127:64] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVHLPS

The extended form of the instruction has a 128-bit encoding only.

The source operands are bits [127:64] of two XMM registers. The destination is a third XMM register. Bits [127:64] of the first source are moved to bits [127:64] of the destination; bits [127:64] of the second source are moved to bits [63:0] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVHLPS is an SSE1 instruction and VMOVHLPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVHLPS <i>xmm1, xmm2</i>	0F 12 /r	Moves two packed single-precision floating-point values from <i>xmm2</i> [127:64] to <i>xmm1</i> [63:0].

MOVHPD Move High

VMOVHPD Packed Double-Precision Floating-Point

Moves a packed double-precision floating-point value. Values can be moved from a 64-bit memory location to the high-order quadword of an XMM register, or from the high-order quadword of an XMM register to a 64-bit memory location.

There are legacy and extended forms of the instruction:

MOVHPD

There are two encodings.

- The source operand is a 64-bit memory location. The destination is bits [127:64] of an XMM register.
- The source operand is bits [127:64] of an XMM register. The destination is a 64-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVHPD

The extended form of the instruction has two 128-bit encodings:

- There are two source operands. The first source is an XMM register. The second source is a 64-bit memory location. The destination is an XMM register. Bits [63:0] of the source register are written to bits [63:0] of the destination; bits [63:0] of the source memory location are written to bits [127:64] of the destination.
- The source operand is bits [127:64] of an XMM register. The destination is a 64-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVHPD is an SSE2 instruction and VMOVHPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVLHPS Move Low to High VMOVLHPS Packed Single-Precision Floating-Point

Moves two packed single-precision floating-point values from the low quadword of an XMM register to the high quadword of another XMM register.

There are legacy and extended forms of the instruction:

MOVLHPS

The source operand is bits [63:0] of an XMM register. The destination is bits [127:64] of another XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVLHPS

The extended form of the instruction has a 128-bit encoding only.

The source operands are bits [63:0] of two XMM registers. The destination is a third XMM register. Bits [63:0] of the first source are moved to bits [63:0] of the destination; bits [63:0] of the second source are moved to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVLHPS is an SSE1 instruction and VMOVLHPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVLHPS <i>xmm1, xmm2</i>	0F 16 /r	Moves two packed single-precision floating-point values from <i>xmm2</i> [63:0] to <i>xmm1</i> [127:64].		
Mnemonic	Encoding			
	VEX	RXB.map_select	W.vvvv.L.pp	Opcode
VMOVLHPS <i>xmm1, xmm2, xmm3</i>	C4	RXB.00001	X.src.0.00	16 /r

MOVLPD Move Low

VMOVLPD Packed Double-Precision Floating-Point

Moves a packed double-precision floating-point value. Values can be moved from a 64-bit memory location to the low-order quadword of an XMM register, or from the low-order quadword of an XMM register to a 64-bit memory location.

There are legacy and extended forms of the instruction:

MOVLPD

There are two encodings.

- The source operand is a 64-bit memory location. The destination is bits [63:0] of an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.
- The source operand is bits [63:0] of an XMM register. The destination is a 64-bit memory location.

VMOVLPD

The extended form of the instruction has two 128-bit encodings.

- There are two source operands. The first source is an XMM register. The second source is a 64-bit memory location. The destination is an XMM register. Bits [127:64] of the source register are written to bits [127:64] of the destination; bits [63:0] of the source memory location are written to bits [63:0] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- The source operand is bits [63:0] of an XMM register. The destination is a 64-bit memory location.

MOVLPD is an SSE2 instruction and VMOVLPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

MOVMSKPD Extract Sign Mask

VMOVMSKPD Packed Double-Precision Floating-Point

Extracts the sign bits of packed double-precision floating-point values from an XMM register, zero-extends the value, and writes it to the low-order bits of a general-purpose register.

There are legacy and extended forms of the instruction:

MOVMSKPD

Extracts two mask bits.

The source operand is an XMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [1:0] of the destination and clears the remaining bits. Bits [255:128] of the YMM register that corresponds to the source are not affected.

MOVMSKPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Extracts two mask bits.

The source operand is an XMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [1:0] of the destination and clears the remaining bits. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Extracts four mask bits.

The source operand is a YMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [3:0] of the destination and clears the remaining bits.

MOVMSKPD is an SSE2 instruction and VMOVMSKPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVMSKPS Extract Sign Mask

VMOVMSKPS Packed Single-Precision Floating-Point

Extracts the sign bits of packed single-precision floating-point values from an XMM register, zero-extends the value, and writes it to the low-order bits of a general-purpose register.

There are legacy and extended forms of the instruction:

MOVMSKPS

Extracts four mask bits.

The source operand is an XMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [3:0] of the destination and clears the remaining bits.

MOVMSKPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Extracts four mask bits.

The source operand is an XMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [3:0] of the destination and clears the remaining bits.

YMM Encoding

Extracts eight mask bits.

The source operand is a YMM register. The destination can be either a 64-bit or a 32-bit general purpose register. Writes the extracted bits to positions [7:0] of the destination and clears the remaining bits.

MOVMSKPS is an SSE1 instruction and VMOVMSKPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVNTDQ VMOVNTDQ

Move Non-Temporal Double Quadword

Moves double quadword values from a register to a memory location.

Indicates to the processor that the data is non-temporal, and is unlikely to be used again soon. The processor treats the store as a write-combining (WC) memory write, which minimizes cache pollution. The method of minimization depends on the hardware implementation of the instruction. For further information, see “Memory Optimization” in Volume 1.

The instruction is weakly-ordered with respect to other instructions that operate on memory. Software should use an SFENCE or MFENCE instruction to force strong memory ordering of MOVNTDQ with respect to other stores.

There are legacy and extended forms of the instruction:

MOVNTDQ

Moves one 128-bit value.

The source operand is an XMM register. The destination is a 128-bit memory location.

VMOVNTDQ

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves one 128-bit value.

The source operand is an XMM register. The destination is a 128-bit memory location.

YMM Encoding

Moves two 128-bit values.

The source operand is a YMM register. The destination is a 256-bit memory location.

MOVNTDQ is an SSE2 instruction and VMOVNTDQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

MOVNTDQA VMOVNTDQA

Move Non-Temporal Double Quadword Aligned

Moves aligned double quadword values from a register to a memory location.

Indicates to the processor that the data is non-temporal, and is unlikely to be used again soon. The processor treats the store as a write-combining (WC) memory write, which minimizes cache pollution. The method of minimization depends on the hardware implementation of the instruction. For further information, see “Memory Optimization” in Volume 1.

The instruction is weakly-ordered with respect to other instructions that operate on memory. Software should use an MFENCE instruction to force strong memory ordering of MOVNTDQ with respect to other stores.

There are legacy and extended forms of the instruction:

MOVNTDQA

Moves one 128-bit value.

The source operand is an XMM register. The destination is a 128-bit memory location.

VMOVNTDQ

The extended form of the instruction has a 128-bit encodings only.

Moves one 128-bit value.

The source operand is an XMM register. The destination is a 128-bit memory location.

MOVNTDQA is an SSE4.1 instruction and VMOVNTDQA is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MOVNTPS Move Non-Temporal

VMOVNTPS Packed Single-Precision Floating-Point

Moves packed single-precision floating-point values from a register to a memory location.

Indicates to the processor that the data is non-temporal, and is unlikely to be used again soon. The processor treats the store as a write-combining (WC) memory write, which minimizes cache pollution. The method of minimization depends on the hardware implementation of the instruction. For further information, see “Memory Optimization” in Volume 1.

The instruction is weakly-ordered with respect to other instructions that operate on memory. Software should use an SFENCE or MFENCE instruction to force strong memory ordering of MOVNTPS with respect to other stores.

There are legacy and extended forms of the instruction:

MOVNTPS

Moves four values.

The source operand is an XMM register. The destination is a 128-bit memory location.

VMOVNTPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves four values.

The source operand is an XMM register. The destination is a 128-bit memory location.

YMM Encoding

Moves eight values.

The source operand is a YMM register. The destination is a 256-bit memory location.

MOVNTPS is an SSE1 instruction and VMOVNTPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVNTPS <i>mem128, xmm</i>	0F 2B /r	Moves four packed double-precision floating-point values from <i>xmm</i> to <i>mem128</i> , minimizing cache pollution.		
Mnemonic	Encoding			
	VEX	RXB.map_select	W.vvvv.L.pp	Opcode
VMOVNTPS <i>mem128, xmm</i>	C4	$\overline{\text{R}}\text{XB}.00001$	X.1111.0.00	2B /r
VMOVNTPS <i>mem256, ymm</i>	C4	$\overline{\text{R}}\text{XB}.00001$	X.1111.1.00	2B /r

			X	Null data segment used to reference memory.
Page fault, #PF		S	X	Instruction execution caused a page fault.
<i>X — AVX and SSE exception</i> <i>A — AVX exception</i> <i>S — SSE exception</i>				

MOVNTSD

Move Non-Temporal Scalar Double-Precision Floating-Point

Stores one double-precision floating-point value from an XMM register to a 64-bit memory location. This instruction indicates to the processor that the data is non-temporal, and is unlikely to be used again soon. The processor treats the store as a write-combining memory write, which minimizes cache pollution.

The diagram below illustrates the operation of this instruction:

MOVNTSD is an SSE4A instruction. Support for SSE4A instructions is indicated by CPUID Fn8000_0001_ECX[SSE4A] = 1. Software *must* check the CPUID bit once per program or library initialization before using the MOVNTSD instruction or inconsistent behavior may result.

For more information about the CPUID instruction, see instruction listing in Volume 3. For more information on processor feature bits, see the *CPUID Specification*, order# 25481.

Instruction Encoding

Mnemonic	Opcode	Description
MOVNTSD <i>mem64, xmm</i>	F2 0F 2B /r	Stores one double-precision floating-point XMM register value into a 64 bit memory location. Treat as a non-temporal store.

Related Instructions

rFLAGS Affected

None

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SSE4A instructions are not supported, as indicated by CPUID Fn8000_0001_ECX[SSE4A] = 0.
	X	X	X	The emulate bit (CR0.EM) was set to 1.
	X	X	X	The operating-system FXSAVE/FXRSTOR support bit (CR4.OSFXSR) was cleared to 0.
Device not available, #NM	X	X	X	The task-switch bit (CR0.TS) was set to 1.
Stack, #SS	X	X	X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP	X	X	X	A memory address exceeded a data segment limit or was non-canonical.
			X	A null data segment was used to reference memory.
			X	The destination operand was in a non-writable segment.
Page fault, #PF		X	X	A page fault resulted from executing the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

MOVNTSS

Move Non-Temporal Scalar Single-Precision Floating-Point

Stores one single-precision floating-point value from an XMM register to a 32-bit memory location. This instruction indicates to the processor that the data is non-temporal, and is unlikely to be used again soon. The processor treats the store as a write-combining memory write, which minimizes cache pollution.

The diagram below illustrates the operation of this instruction:

Support for the MOVNTSS instruction is indicated by ECX bit 6 (SSE4A) as returned by CPUID function 8000_0001h. Software *must* check the CPUID bit once per program or library initialization before using the MOVNTSS instruction, or inconsistent behavior may result.

Instruction Encoding

Mnemonic	Opcode	Description
MOVNTSS <i>mem32, xmm</i>	F3 0F 2B /r	Stores one single-precision floating-point XMM register value into a 32-bit memory location. Treat as a non-temporal store.

Exceptions

Exception	Real	Virtual 8086	Protected	Cause of Exception
Invalid opcode, #UD	X	X	X	The SSE4A instructions are not supported, as indicated by ECX bit 6 (SSE4A) of CPUID function 8000_0001h.
	X	X	X	The emulate bit (CR0.EM) was set to 1.
	X	X	X	The operating-system FXSAVE/FXRSTOR support bit (CR4.OSFXSR) was cleared to 0.
Device not available, #NM	X	X	X	The task-switch bit (CR0.TS) was set to 1.
Stack, #SS	X	X	X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP	X	X	X	A memory address exceeded a data segment limit or was non-canonical.
			X	A null data segment was used to reference memory.
			X	The destination operand was in a non-writable segment.
Page fault, #PF		X	X	A page fault resulted from executing the instruction.
Alignment check, #AC		X	X	An unaligned memory reference was performed while alignment checking was enabled.

MOVQ VMOVQ

Move Quadword

Moves 64-bit values. The source is either the low-order quadword of an XMM register or a 64-bit memory location. The destination is either the low-order quadword of an XMM register or a 64-bit memory location. When the destination is a register, the 64-bit value is zero-extended to 128 bits.

There are legacy and extended forms of the instruction:

MOVQ

There are two encodings:

- The source operand is either an XMM register or a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either an XMM register or a 64-bit memory location. When the destination is a register, the 64-bit value is zero-extended to 128 bits.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVQ

The extended form of the instruction has three 128-bit encodings:

- The source operand is an XMM register. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either an XMM register or a 64-bit memory location. When the destination is a register, the 64-bit value is zero-extended to 128 bits.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVQ is an SSE2 instruction and VMOVQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVQ <i>xmm1</i> , <i>xmm2/mem64</i>	F3 0F 7E /r	Move a zero-extended 64-bit value from <i>xmm2</i> or <i>mem64</i> to <i>xmm1</i> .		
MOVQ <i>xmm1/mem64</i> , <i>xmm2</i>	66 0F D6 /r	Move a 64-bit value from <i>xmm2</i> to <i>xmm1</i> or <i>mem64</i> . Zero-extends for register destination.		
Mnemonic	Encoding

MOVSD Move

VMOVSD Scalar Double-Precision Floating-Point

Moves scalar double-precision floating point values. The source is either a low-order quadword of an XMM register or a 64-bit memory location. The destination is either a low-order quadword of an XMM register or a 64-bit memory location.

There are legacy and extended forms of the instruction:

MOVSD

There are three encodings.

- The source operand is an XMM register. The destination is an XMM register. Bits [127:64] of the destination are not affected.
- The source operand is a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either an XMM register or a 64-bit memory location. When the destination is a register, the 64-bit value is zero-extended to 128 bits.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVSD

The extended form of the instruction has four 128-bit encodings. Two of the encodings are functionally equivalent.

- The source operand is a 64-bit memory location. The destination is an XMM register. The 64-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is a 64-bit memory location.
- Two functionally-equivalent encodings:
There are two source XMM registers. The destination is an XMM register. Bits [127:64] of the first source register are copied to bits [127:64] of the destination; the 64-bit value in bits [63:0] of the second source register is written to bits [63:0] of the destination.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVSD is an SSE2 instruction and VMOVSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

This instruction must not be confused with the MOVSD (move string doubleword) instruction of the general-purpose instruction set. Assemblers can distinguish the instructions by the number and type of operands.

Instruction Encoding

Mnemonic	Opcode	Description
MOVSD <i>xmm1</i> , <i>xmm2</i>	F2 0F 10 /r	Moves a zero-extended 64-bit value from <i>xmm2</i> to <i>xmm1</i> .
MOVSD <i>xmm1</i> , <i>mem64</i>	F2 0F 10 /r	Moves a zero-extended 64-bit value from <i>mem64</i> to <i>xmm1</i> .
MOVSD <i>xmm2/mem64</i> , <i>xmm1</i>	F2 0F 11 /r	Moves a 64-bit value from <i>xmm1</i> to <i>xmm2</i> or <i>mem64</i> . Zero-extends for register destination.

Mnemonic	Encoding			
	VEX	RXB.map_select	W.vvvv.L.pp	Opcode
VMOVSD <i>xmm1</i> , <i>mem64</i>	C4	$\overline{\text{RXB}}$.00001	X.1111.0.11	10 /r
VMOVSD <i>mem64</i> , <i>xmm1</i>	C4	$\overline{\text{RXB}}$.00001	X.1111.0.11	11 /r
VMOVSD <i>xmm</i> , <i>xmm2</i> , <i>xmm3</i>	C4	$\overline{\text{RXB}}$.00001	X. $\overline{\text{src}}$.1.11	10 /r
VMOVSD <i>xmm</i> , <i>xmm2</i> , <i>xmm3</i>	C4	$\overline{\text{RXB}}$.00001	X. $\overline{\text{src}}$.1.11	11 /r

MOVSHDUP VMOVSHDUP

Move High and Duplicate Single-Precision

Moves and duplicates odd-indexed single-precision floating-point values.

There are legacy and extended forms of the instruction:

MOVSHDUP

Moves and duplicates two odd-indexed single-precision floating-point values.

The source operand is an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [127:96] of the source are duplicated and written to bits [127:96] and [95:64] of the destination. Bits [63:32] of the source are duplicated and written to bits [63:32] and [31:0] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVSHDUP

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves and duplicates two odd-indexed single-precision floating-point values.

The source operand is an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [127:96] of the source are duplicated and written to bits [127:96] and [95:64] of the destination. Bits [63:32] of the source are duplicated and written to bits [63:32] and [31:0] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves and duplicates four odd-indexed single-precision floating-point values.

The source operand is a YMM register or a 256-bit memory location. The destination is a YMM register. Bits [255:224] of the source are duplicated and written to bits [255:224] and [223:192] of the destination. Bits [191:160] of the source are duplicated and written to bits [191:160] and [159:128] of the destination. Bits [127:96] of the source are duplicated and written to bits [127:96] and [95:64] of the destination. Bits [63:32] of the source are duplicated and written to bits [63:32] and [31:0] of the destination.

MOVSHDUP is an SSE3 instruction and VMOVSHDUP is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MOVSHDUP <i>xmm1, xmm2/mem128</i>	F3 0F 16 /r	Moves and duplicates two odd-indexed single-precision floating-point values in <i>xmm2</i> or <i>mem128</i> . Writes to <i>xmm1</i> .

MOVSS Move

VMOVSS Scalar Single-Precision Floating-Point

Moves scalar single-precision floating point values. The source is either a low-order doubleword of an XMM register or a 32-bit memory location. The destination is either a low-order doubleword of an XMM register or a 32-bit memory location.

There are legacy and extended forms of the instruction:

MOVSS

There are three encodings.

- The source operand is an XMM register. The destination is an XMM register. Bits [127:32] of the destination are not affected.
- The source operand is a 32-bit memory location. The destination is an XMM register. The 32-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is either an XMM register or a 32-bit memory location. When the destination is a register, the 32-bit value is zero-extended to 128 bits.

Bits [255:128] of the YMM register that corresponds to the source are not affected.

VMOVSS

The extended form of the instruction has four 128-bit encodings. Two of the encodings are functionally equivalent.

- The source operand is a 32-bit memory location. The destination is an XMM register. The 32-bit value is zero-extended to 128 bits.
- The source operand is an XMM register. The destination is a 32-bit memory location.
- Two functionally-equivalent encodings:
There are two source XMM registers. The destination is an XMM register. Bits [127:64] of the first source register are copied to bits [127:64] of the destination; the 32-bit value in bits [31:0] of the second source register is written to bits [31:0] of the destination.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MOVSS is an SSE1 instruction and VMOVSS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
MOVSS <i>xmm1</i> , <i>xmm2</i>	F3 0F 10 /r	Moves a 32-bit value from <i>xmm2</i> to <i>xmm1</i> .
MOVSS <i>xmm1</i> , <i>mem32</i>	F3 0F 10 /r	Moves a zero-extended 32-bit value from <i>mem32</i> to <i>xmm1</i> .
MOVSS <i>xmm2/mem32</i> , <i>xmm1</i>	F3 0F 11 /r	Moves a 32-bit value from <i>xmm1</i> to <i>xmm2</i> or <i>mem32</i> . Zero-extended for register destination.

MOVUPD Move Unaligned

VMOVUPD Packed Double-Precision Floating-Point

Moves packed double-precision floating-point values. Values can be moved from a register or memory location to a register; or from a register to a register or memory location.

A memory operand that is not aligned does not cause a general-protection exception.

There are legacy and extended forms of the instruction:

MOVUPD

Moves two double-precision floating-point values. There are encodings for each type of move.

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMOVUPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Moves two double-precision floating-point values. There are encodings for each type of move.

- The source operand is either an XMM register or a 128-bit memory location. The destination operand is an XMM register.
- The source operand is an XMM register. The destination operand is either an XMM register or a 128-bit memory location.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Moves four double-precision floating-point values. There are encodings for each type of move.

- The source operand is either a YMM register or a 256-bit memory location. The destination operand is a YMM register.
- The source operand is a YMM register. The destination operand is either a YMM register or a 256-bit memory location.

MOVUPD is an SSE2 instruction and VMOVUPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

MPSADBW VMPSADBW

Multiple Sum of Absolute Differences

Calculates the sum of absolute differences of each member of four sequential groups of four unsigned byte integers in the first source register and each of four unsigned byte integers in a second source register, and writes the 16-bit integer sums to the destination.

Bit fields in an 8-bit immediate operand are used to calculate offsets that select sequences of bytes in the two source registers. The binary value of each bit field is multiplied by 32 to produce a 32-bit offset. Bit 2 of the immediate operand determines the offset for the first source register; 11 bytes beginning at the offset position are used. Bits [1:0] of the immediate operand determine the offset for the second source register; four bytes beginning at the offset position are used.

The selected bytes are repositioned in the source registers. Bytes [10:0] of the first source occupy bits [87:0] of the first source register; bytes [3:0] of the second source occupy bits [31:0] of the second source register.

Operation is iterative and repeats eight times. Each repetition increments the starting byte position in the first source by one and calculates the sum of differences with the four integers of the second source. Results are written to eight consecutive words in the destination, starting with the low word. In the first iteration, bytes [0:4] of the second source are subtracted from bytes [0:4] of the first source and the sum of the differences is written to bits [15:0] of the destination; in the second iteration, bytes [0:4] of the second source are subtracted from bytes [1:5] of the first source and the sum of the differences is written to bits [31:16] of the destination. The process continues until bytes [0:4] of the second source are subtracted from bytes [7:10] of the first source and the sum of the differences is written to bits [127:112] of the destination.

There are legacy and extended forms of the instruction:

MPSADBW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMPSADBW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MPSADBW is an SSE4.1 instruction and VMPSADBW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
MPSADBW <i>xmm1, xmm2/mem128, imm8</i>	66 0F 3A 42 /r ib	Sums absolute difference of groups of four 8-bit integer in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes results to <i>xmm1</i> . Starting source offsets are determined by <i>imm8</i> bit fields.

Mnemonic	Encoding

MULPD Multiply

VMULPD Packed Double-Precision Floating-Point

Multiplies each packed double-precision floating-point value of the first source operand by the corresponding packed double-precision floating-point value of the second source operand and writes the product of each multiplication into the corresponding quadword of the destination.

There are legacy and extended forms of the instruction:

MULPD

Multiplies two double-precision floating-point values in the first source XMM register by the corresponding double precision floating-point values in either a second XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMULPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Multiplies two double-precision floating-point values in the first source XMM register by the corresponding double-precision floating-point values in either a second source XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Multiplies four double-precision floating-point values in the first source YMM register by the corresponding double precision floating-point values in either a second source YMM register or a 256-bit memory location. The destination is a third YMM register.

MULPD is an SSE2 instruction and VMULPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

MULPS Multiply

VMULPS Packed Single-Precision Floating-Point

Multiplies each packed single-precision floating-point value of the first source operand by the corresponding packed single-precision floating-point value of the second source operand and writes the product of each multiplication into the corresponding elements of the destination.

There are legacy and extended forms of the instruction:

MULPS

Multiplies four single-precision floating-point values in the first source XMM register by the corresponding single-precision floating-point values of either a second source XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VMULPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Multiplies four single-precision floating-point values in the first source XMM register by the corresponding single-precision floating-point values of either a second source XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Multiplies eight single-precision floating-point values in the first source YMM register by the corresponding single-precision floating-point values of either a second source YMM register or a 256-bit memory location. Writes the results to a third YMM register.

MULPS is an SSE2 instruction and VMULPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

MULSD Multiply

VMULSD Scalar Double-Precision Floating-Point

Multiplies the double-precision floating-point value in the low-order quadword of the first source operand by the double-precision floating-point value in the low-order quadword of the second source operand and writes the product into the low-order quadword of the destination.

There are legacy and extended forms of the instruction:

MULSD

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The first source register is also the destination register. Bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are not affected.

VMULSD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The destination is a third XMM register. Bits [127:64] of the first source operand are copied to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MULSD is an SSE2 instruction and VMULSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
MULSD <i>xmm1, xmm2/mem64</i>	F2 0F 59 /r	Multiplies low-order double-precision floating-point values in <i>xmm1</i> by corresponding values in <i>xmm2</i> or <i>mem64</i> . Writes the products to <i>xmm1</i> .

MULSS Multiply Scalar Single-Precision Floating-Point VMULSS

Multiplies the single-precision floating-point value in the low-order doubleword of the first source operand by the single-precision floating-point value in the low-order doubleword of the second source operand and writes the product into the low-order doubleword of the destination.

There are legacy and extended forms of the instruction:

MULSS

The first source operand is an XMM register and the second source operand is either an XMM register or a 32-bit memory location. The first source register is also the destination. Bits [127:32] of the destination register and bits [255:128] of the corresponding YMM register are not affected.

VMULSS

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 32-bit memory location. The destination is a third XMM register. Bits [127:32] of the first source register are copied to bits [127:32] of the of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

MULSS is an SSE1 instruction and VMULSS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
MULSS <i>xmm1, xmm2/mem32</i>	F3 0F 59 /r	Multiplies a single-precision floating-point value in the low-order doubleword of <i>xmm1</i> by a corresponding value in <i>xmm2</i> or <i>mem32</i> . Writes the product to <i>xmm1</i> .

ORPD OR VORPD Packed Double-Precision Floating-Point

Performs bitwise OR of two packed double-precision floating-point values in the first source operand with the corresponding two packed double-precision floating-point values in the second source operand and writes the results into the corresponding elements of the destination.

There are legacy and extended forms of the instruction:

ORPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VORPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

ORPD is an SSE2 instruction and VORPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
ORPD <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F 56 /r	Performs bitwise OR of two packed double-precision floating-point values in <i>xmm1</i> with corresponding values in <i>xmm2</i> or <i>mem128</i> . Writes the result to <i>xmm1</i> .

PABSB VPABSB

Packed Absolute Value Signed Byte

Computes the absolute value of 16 packed 8-bit signed integers in the source operand and writes 8-bit unsigned results to the destination.

There are legacy and extended forms of the instruction:

PABSB

The source operand is an XMM register or a 128-bit memory location. The destination is another XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPABSB

The extended form of the instruction has a 128-bit encoding only.

The source operand is an XMM register or a 128-bit memory location. The destination is another XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PABSB is an SSSE3 instruction and VPABSB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
PABSB <i>xmm1, xmm2/mem128</i>	0F 38 1C /r	Computes the absolute value of each packed 8-bit signed integer value in <i>xmm2/mem128</i> and writes the 8-bit unsigned results to <i>xmm1</i> .

PACKSSDW VPACKSSDW

Pack with Signed Saturation Doubleword to Word

Converts four 32-bit signed integers from the first source operand and four 32-bit signed integers from the second source operand into eight 16-bit signed integers and packs the results into the destination.

Positive source value greater than 7FFFh are saturated to 7FFFh; negative source values less than 8000h are saturated to 8000h.

Converted values from the first source operand are packed into the low-order words of the destination; converted values from the second source operand are packed into the high-order words of the destination.

There are legacy and extended forms of the instruction:

PACKSSDW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPACKSSDW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PACKSSDW is an SSE2 instruction and VPACKSSDW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PACKSSDW <i>xmm1, xmm2/mem128</i>	66 0F 6B /r	Converts 32-bit signed integers in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> into 16-bit signed integers with saturation. Writes packed results to <i>xmm1</i> .

PACKUSDW VPACKUSDW

Pack with Unsigned Saturation Doubleword to Word

Converts four 32-bit signed integers from the first source operand and four 32-bit signed integers from the second source operand into eight 16-bit unsigned integers and packs the results into the destination.

Source values greater than FFFFh are saturated to FFFFh; source values less than 0000h are saturated to 0000h.

Packs converted values from the first source operand into the low-order words of the destination; packs converted values from the second source operand into the high-order words of the destination.

There are legacy and extended forms of the instruction:

PACKUSDW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPACKUSDW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PACKUSDW is an SSE4.1 instruction and VPACKUSDW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PACKUSDW <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F 38 2B /r	Converts 32-bit signed integers in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> into 16-bit unsigned integers with saturation. Writes packed results to <i>xmm1</i> .

PACKUSWB VPACKUSWB

Pack with Unsigned Saturation Word to Byte

Converts eight 16-bit signed integers from the first source operand and eight 16-bit signed integers from the second source operand into sixteen 8-bit unsigned integers and packs the results into the destination.

When a source value is greater than 7Fh it is saturated to FFh; when source value is less than 00h, it is saturated to 00h.

Packs converted values from the first source operand into the low-order bytes of the destination; packs converted values from the second source operand into the high-order bytes of the destination.

There are legacy and extended forms of the instruction:

PACKUSWB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPACKUSWB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PACKUSWB is an SSE2 instruction and VPACKUSWB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PACKUSWB <i>xmm1, xmm2/mem128</i>	66 0F 67 /r	Converts 16-bit signed integers in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> into 8-bit signed integers with saturation. Writes packed results to <i>xmm1</i> .

PADDB VPADDB

Packed Add Bytes

Adds 16 packed 8-bit integer values in the first source operand to corresponding values in the second source operand and writes the integer sums to the corresponding bytes of the destination.

This instruction operates on both signed and unsigned integers. When a result overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set), and only the low-order 8 bits of each result are written to the destination.

There are legacy and extended forms of the instruction:

PADDB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPADDB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PADDB is an SSE2 instruction and VPADDB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PADD VPADD

Packed Add Doublewords

Adds four packed 32-bit integer value in the first source operand to corresponding values in the second source operand and writes integer sums to the corresponding doublewords of the destination.

This instruction operates on both signed and unsigned integers. When a result overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set), and only the low-order 32 bits of each result are written to the destination.

There are legacy and extended forms of the instruction:

PADD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

<i>X — AVX and SSE exception</i> <i>A — AVX exception</i> <i>S — SSE exception</i>				

PADDW VPADDW

Packed Add Words

Adds eight packed 16-bit integer value in the first source operand to the corresponding values in the second source operand and writes the integer sums to the corresponding word of the destination.

This instruction operates on both signed and unsigned integers. When a result overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set), and only the low-order 16 bits of each result are written to the destination.

There are legacy and extended forms of the instruction:

PADDW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPADDW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PADDW is an SSE2 instruction and VPADDW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PADDW <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F FD /r	Adds packed 16-bit integer values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the sums to <i>xmm1</i> .		
Mnemonic	Encoding

PALIGNR VPALIGNR

Packed Align Right

Concatenates [source1:source2] in a temporary 256-bit location and right-shifts the concatenated value the number of bytes specified by the unsigned immediate operand. Writes the shifted result to the destination.

The binary value of the immediate operand determines the byte shift value. For byte shifts greater than 16 bytes, the upper bytes of the destination are zero-filled; when the byte shift is greater than 32 bytes, the destination is zeroed.

There are two forms of the instruction.

PALIGNR

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPALIGNR

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PALIGNR is an SSSE3 instruction and VPALIGNR is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PALIGNR <i>xmm1, xmm2/mem128, imm8</i>	66 0F 3A 0F /r ib	Right-shifts <i>xmm1:xmm2/mem128 imm8</i> bytes. Writes shifted result to <i>xmm1</i> .

PAND VPAND

Packed AND

Performs a bitwise AND of the packed values in the first and second source operands and writes the result to the destination.

There are legacy and extended forms of the instruction:

PAND

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPAND

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PAND is an SSE2 instruction and VPAND is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PAND <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F DB /r	Performs bitwise AND of values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the result to <i>xmm1</i> .

PANDN VPANDN

Packed AND NOT

Generates the ones' complement of the value in the first source operand and performs a bitwise AND of the complement and the value in the second source operand. Writes the result to the destination.

There are legacy and extended forms of the instruction:

PANDN

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPANDN

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PANDN is an SSE2 instruction and VPANDN is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
PANDN <i>xmm1, xmm2/mem128</i>	66 0F DF /r	Generates ones' complement of <i>xmm1</i> , then performs bitwise AND with value in <i>xmm2</i> or <i>mem128</i> . Writes the result to <i>xmm1</i> .

PAVGB VPAVGB

Packed Average Unsigned Bytes

Computes the rounded averages of 16 packed unsigned 8-bit integer values in the first source operand and the corresponding values of the second source operand. Writes each average to the corresponding byte of the destination.

An average is computed by adding pairs of operands, adding 1 to a 9-bit temporary sum, and right-shifting the temporary sum by one bit position.

There are legacy and extended forms of the instruction:

PAVGB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPAVGB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PAVGB is an SSE2 instruction and VPAVGB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PBLENDVB VPBLENDVB

Variable Blend Packed Bytes

Copies packed bytes from either of two sources to a destination, as specified by a mask operand.

The mask is defined by the msb of each byte of the mask operand. The position of a mask bit corresponds to the position of the most significant bit of a copied value.

- When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination.
- When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination.

There are legacy and extended forms of the instruction:

PBLENDVB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected. The mask operand is the implicit register XMM0.

VPBLENDVB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared. The mask operand is a fourth XMM register selected by bits [7:4] of an immediate byte.

PBLENDVB is an SSE4.1 instruction and VPBLENDVB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description	
PBLENDVB <i>xmm1, xmm2/mem128</i>	66 0F 38 10 /r	Selects byte values from <i>xmm1</i> or <i>xmm2/mem128</i> , depending on the value of corresponding mask bits in XMM0. Writes the selected values to <i>xmm1</i> .

PBLENDW VPBLENDW

Blend Packed Words

Copies packed words from either of two sources to a destination, as specified by an immediate 8-bit mask operand.

Each mask bit corresponds to a source word value, in ascending order. Mask bit [0] corresponds to source bits [15:0], mask bit [7] corresponds to source bits [127:112].

- When a mask bit = 0, the specified element of the first source is copied to the corresponding position in the destination.
- When a mask bit = 1, the specified element of the second source is copied to the corresponding position in the destination.

There are legacy and extended forms of the instruction:

PBLENDW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPBLENDW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PBLENDW is an SSE4.1 instruction and VPBLENDW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] respectively (see the CPUID Specification, order# 25481).

Instruction Encoding

PCLMULQDQ VPCLMULQDQ

Carry-less Multiply Quadwords

Performs a carry-less multiplication of a selected quadword element of the first source operand by a selected quadword element of the second source operand and writes the product to the destination.

Carry-less multiplication, also known as *binary polynomial multiplication*, is the mathematical operation of computing the product of two operands without generating or propagating carries. It is an essential component of cryptographic processing, and typically requires a large number of cycles.

The instruction provides an efficient means of performing the operation and is particularly useful in implementing the Galois counter mode used in the Advanced Encryption Standard (AES). See Section 1.4, “AES Instructions” for additional information.

Bits 4 and 0 of an 8-bit immediate byte operand specify which quadword of each source operand to multiply, as follows.

Mnemonic	Imm[0]	Imm[4]	Quadword Operands Selected
(V)PCLMULLQLQDQ	0	0	SRC1[63:0], SRC2[63:0]
(V)PCLMULHQLQDQ	1	0	SRC1[127:64], SRC2[63:0]
(V)PCLMULLQHQDQ	0	1	SRC1[63:0], SRC2[127:64]
(V)PCLMULHQHQDQ	1	1	SRC1[127:64], SRC2[127:64]

Alias mnemonics are provided for the various immediate byte combinations.

There are legacy and extended forms of the instruction:

PCLMULQDQ

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPCLMULQDQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PCLMULQDQ is a CLMUL instruction and VPCLMULQDQ is both a CLMUL instruction and an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[PCLMULQDQ] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PCMPEQB VPCMPEQB

Packed Compare Equal Bytes

Compares 16 packed byte values in the first source operand to corresponding values in the second source operand and writes a comparison result to the corresponding byte of the destination.

When values are equal, the result is FFh; when values are not equal, the result is 00h.

There are legacy and extended forms of the instruction:

PCMPEQB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPCMPEQB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PCMPEQB is an SSE2 instruction and VPCMPEQB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PCMPESTRI VPCMPESTRI

Packed Compare Explicit Length Strings Return Index

Compares character string data in the first and second source operands. Aggregation and comparison operations are carried out as determined by values of the fields of the immediate operand. Writes an index to the ECX register.

See Section 1.5, “String Compare Instructions” for information about immediate byte definition, compare encoding and control functions.

Each string has two associated data items: The actual characters in the two source operands, and length data in two implicit registers.

The absolute value of the data in the EAX/RAX register represents the length of the character string in the first source operand; the absolute value of the data in the EDX/RDX register represents the length of the character string in the second source operand.

The Data Size bit of the immediate operand specifies length parameters. When Data Size = 0, length values represent bytes, and saturate to 16 if greater than 16 or less than –16; when Data Size = 1, length values represent words, and saturate to 8 if greater than 8 or less than –8;

The values of the Mode and Byte fields of the immediate operand determine how the aggregation and comparison operations are carried out.

The rFLAGS are set to indicate the following conditions:

Flag	Condition
CF	Cleared if intermediate result is zero; otherwise set.
PF	cleared.
AF	cleared.
ZF	1 if the absolute value of EDX is less than 16 (8); otherwise cleared.
SF	Set if the absolute value of EAX is less than 16 (8); otherwise cleared.
OF	Equal to the value of InterimResult2[0].

There are legacy and extended forms of the instruction:

PCMPESTRI

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A result index is written to the ECX register.

VPCMPESTRI

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A result index is written to the ECX register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PCMPESTRI is an SSE4.2 instruction and VPCMPESTRI is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE42] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PCMPESTRM VPCMPESTRM

Packed Compare Explicit Length Strings Return Mask

Compares character string data in the first and second source operands. Aggregation and comparison operations are carried out as determined by values of the fields of the immediate operand. Writes a mask value to the implicit XMM0 register.

See Section 1.5, “String Compare Instructions” for information about immediate byte definition, compare encoding and control functions.

Each string has two associated data items: The actual characters in the two source operands, and length data in two implicit registers.

The absolute value of the data in the EAX/RAX register represents the length of the character string in the first source operand; the absolute value of the data in the EDX/RDX register represents the length of the character string in the second source operand.

The Data Size bit of the immediate operand specifies length parameters. When Data Size = 0, length values represent bytes, and saturate to 16 if greater than 16 or less than –16; when Data Size = 1, length values represent words, and saturate to 8 if greater than 8 or less than –8;

The rFLAGS are set to indicate the following conditions:

PCMPGTQ VPCMPGTQ

Packed Compare Greater Than Signed Quadwords

Compares two packed signed quadword values in the first source operand to corresponding values in the second source operand and writes a comparison result to the corresponding quadword of the destination.

When a value in the first operand is greater than a value in the second operand, the result is FFFFFFFFh; when a value in the first operand is less than or equal to a value in the second operand, the result is 00000000h.

There are legacy and extended forms of the instruction:

PCMPGTQ

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPCMPGTQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PCMPGTQ is an SSE4.2 instruction and VPCMPGTQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE42] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PCMPISTRI VPCMPISTRI

Packed Compare Implicit Length Strings Return Index

Compares character string data in the first and second source operands. Aggregation and comparison operations are carried out as determined by values of the fields of the immediate operand. Writes an index to the ECX register.

See Section 1.5, “String Compare Instructions” for information about immediate byte definition, compare encoding and control functions.

Each input byte or word is augmented with a valid/invalid tag. A byte or word is considered valid when it has an index lower than that of the least significant null byte/word (the least significant null byte/word is also invalid).

Aggregation and comparison operations are performed and an index is returned in ECX. If no bits are set in InterimResult2[0], ECX is set to 16 for word strings or 8 for byte strings.

The rFLAGS are set to indicate the following conditions:

Flag	Condition
CF	Cleared if intermediate result is zero; otherwise set.
PF	cleared.
AF	cleared.
ZF	1 if the absolute value of EDX is less than 16 (8); otherwise cleared.
SF	Set if the absolute value of EAX is less than 16 (8); otherwise cleared.
OF	Equal to the value of InterimResult2[0].

There are legacy and extended forms of the instruction:

PCMPISTRI

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A result index is written to the ECX register.

VPCMPISTRI

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A result index is written to the ECX register.

PCMPISTRI is an SSE4.2 instruction and VPCMPISTRI is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE42] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

PCMPISTRM VPCMPISTRM

Packed Compare Implicit Length Strings Return Mask

Compares character string data in the first and second source operands. Aggregation and comparison operations are carried out as determined by values of the fields of the immediate operand. Writes a result or mask value to the XMM0 register.

See Section 1.5, “String Compare Instructions” for information about immediate byte definition, compare encoding and control functions.

Each input byte or word is augmented with a valid/invalid tag. A byte or word is considered valid when it has an index lower than that of the least significant null byte/word (the least significant null byte/word is also invalid).

Aggregation and comparison operations are performed. Depending on the values of fields in the immediate byte, InterimResult2 is either zero-extended to 128 bits or expanded into a byte/word-mask, and then written to XMM0.

The rFLAGS are set to indicate the following conditions:

Flag	Condition
CF	Cleared if intermediate result is zero; otherwise set.
PF	cleared.
AF	cleared.
ZF	1 if the absolute value of EDX is less than 16 (8); otherwise cleared.
SF	Set if the absolute value of EAX is less than 16 (8); otherwise cleared.
OF	Equal to the value of InterimResult2[0].

There are legacy and extended forms of the instruction:

PCMPISTRM

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A mask result is written to the XMM0 register.

VPCMPISTRM

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. A mask result is written to the XMM0 register.

PCMPISTRM is an SSE4.2 instruction and VPCMPISTRM is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE42] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic		Opcode	Description

PEXTRB VPEXTRB

Extract Packed Byte

Extracts a byte from a source register and writes it to an 8-bit memory location or to the low-order byte of a general-purpose register, with zero-extension to 32 or 64 bits. Bits [3:0] of an immediate byte operand select the byte to be extracted:

Value of imm8 [3:0]	Source Bits Extracted
0000	[7:0]
0001	[15:8]
0010	[23:16]
0011	[31:24]
0100	[39:32]
0101	[47:40]
0110	[55:48]
0111	[63:56]
1000	[71:64]
1001	[79:72]
1010	[87:80]
1011	[95:88]
1100	[103:96]
1101	[111:104]
1110	[119:112]
1111	[127:120]

There are legacy and extended forms of the instruction:

PEXTRB

The source operand is an XMM register and the destination is either an 8-bit memory location or the low-order byte of a general-purpose register. When the destination is a general-purpose register, the extracted byte is zero-extended to 32 or 64 bits.

VPEXTRB

The extended form of the instruction has a 128-bit encoding only.

The source operand is an XMM register and the destination is either an 8-bit memory location or the low-order byte of a general-purpose register. When the destination is a general-purpose register, the extracted byte is zero-extended to 32 or 64 bits.

PEXTRB is an SSE4.1 instruction and VPEXTRB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
PEXTRB <i>reg/m8, xmm, imm8</i>	66 0F 3A 14 /r ib	Extracts an 8-bit value specified by <i>imm8</i> from <i>xmm</i> and writes it to <i>m8</i> or the low-order byte of a general-purpose register, with zero-extension.

PEXTRD VPEXTRD

Extract Packed Doubleword

Extracts a doubleword from a source register and writes it to a 32-bit memory location or a 32-bit general-purpose register. Bits [1:0] of an immediate byte operand select the doubleword to be extracted:

Value of imm8 [1:0]	Source Bits Extracted
00	[31:0]
01	[63:32]
10	[95:64]
11	[127:96]

There are legacy and extended forms of the instruction:

PEXTRD

The encoding is the same as PEXTRQ, with REX.W = 0.

The source operand is an XMM register and the destination is either a 32-bit memory location or a 32-bit general-purpose register.

VPEXTRD

The extended form of the instruction has a 128-bit encoding only.

The encoding is the same as VPEXTRQ, with VEX.W = 0.

The source operand is an XMM register and the destination is either a 32-bit memory location or a 32-bit general-purpose register.

PEXTRD is an SSE4.1 instruction and VPEXTRD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PEXTRQ VPEXTRQ

Extract Packed Quadword

Extracts a quadword from a source register and writes it to a 64-bit memory location or to a 64-bit general-purpose register. Bit [0] of an immediate byte operand selects the quadword to be extracted:

Value of imm8 [0]	Source Bits Extracted
0	[63:0]
1	[127:64]

There are legacy and extended forms of the instruction:

PEXTRQ

The encoding is the same as PEXTRD, with REX.W = 1.

The source operand is an XMM register and the destination is either a 64-bit memory location or a 64-bit general-purpose register.

VPEXTRQ

The extended form of the instruction has a 128-bit encoding only.

The encoding is the same as VPEXTRD, with VEX.W = 1.

The source operand is an XMM register and the destination is either a 64-bit memory location or a 64-bit general-purpose register.

PEXTRQ is an SSE4.1 instruction and VPEXTRQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PEXTRW VPEXTRW

Extract Packed Word

Extracts a word from a source register and writes it to a 16-bit memory location or to the low-order word of a general-purpose register, with zero-extension to 32 or 64 bits. Bits [3:0] of an immediate byte operand select the word to be extracted:

Value of imm8 [2:0]	Source Bits Extracted
000	[15:0]
001	[31:16]
010	[47:32]
011	[63:48]
100	[79:64]
101	[95:80]
110	[111:96]
111	[127:112]

There are legacy and extended forms of the instruction:

PEXTRW

The legacy form of the instruction has SSE2 and SSE4.1 encodings.

The source operand is an XMM register and the destination is the low-order word of a general-purpose register. The extracted word is zero-extended to 32 or 64 bits.

The source operand is an XMM register and the destination is either an 16-bit memory location or the low-order word of a general-purpose register. When the destination is a general-purpose register, the extracted word is zero-extended to 32 or 64 bits.

VPEXTRW

The extended form of the instruction has two 128-bit encodings that correspond to the two legacy encodings.

The source operand is an XMM register and the destination is the low-order word of a general-purpose register. The extracted word is zero-extended to 32 or 64 bits.

The source operand is an XMM register and the destination is either an 16-bit memory location or the low-order word of a general-purpose register. When the destination is a general-purpose register, the extracted word is zero-extended to 32 or 64 bits.

PEXTRW is either an SSE2 or an SSE4.1 instruction. VPEXTRW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2], Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PHADD VPHADD

Packed Horizontal Add Doubleword

Adds adjacent pairs of 32-bit signed integers in two source operands and packs the sums into a destination. If a sum overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set) and only the low-order 32 bits of the sum are written in the destination.

There are legacy and extended forms of the instruction:

PHADD

The first source register is also the destination register.

Adds the 32-bit signed integer values in bits [63:32] and bits [31:0] of the first source XMM register and packs the sum into bits [31:0] of the destination; adds the 32-bit signed integer values in bits [127:96] and bits [95:64] of the first source register and packs the sum into bits [63:32] of the destination. Adds the corresponding values in the second source XMM register or a 128-bit memory location and packs the sums into bits [95:64] and [127:96] of the destination. Bits [255:128] of the YMM register that corresponds to the destination not affected.

VPHADD

The extended form of the instruction has a 128-bit encoding only.

Adds the 32-bit signed integer values in bits [63:32] and bits [31:0] of the first source XMM register and packs the sum into bits [31:0] of the destination XMM register; adds the 32-bit signed integer values in bits [127:96] and bits [95:64] of the first source register and packs the sum into bits [63:32] of the destination. Adds the corresponding values in the second source XMM register or a 128-bit memory location and packs the sums into bits [95:64] and [127:96] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PHADD is an SSSE3 instruction and VPHADD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PHADDSW Packed Horizontal Add with Saturation VPHADDSW Word

Adds adjacent pairs of 16-bit signed integers in two source operands, with saturation, and packs the sums into a destination.

Positive sums greater than 7FFFh are saturated to 7FFFh; negative sums less than 8000h are saturated to 8000h.

There are legacy and extended forms of the instruction:

PHADDSW

The first source register is also the destination.

Adds four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with bits [31:16] and [15:0] and packs each saturated 16-bit sum into the low quadword of the destination sequentially, starting with bits [15:0]. Adds the corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs each saturated 16-bit sum into the high quadword of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPHADDSW

The extended form of the instruction has a 128-bit encoding only.

Adds four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with bits [31:16] and [15:0] and packs each saturated 16-bit sum into the low quadword of the destination sequentially, starting with bits [15:0]. Adds the corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs each saturated 16-bit sum into the high quadword of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PHADDSW is an SSSE3 instruction and VPHADDSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PHSUBSW Packed Horizontal Subtract with Saturation VPHSUBSW Word

Subtracts adjacent pairs of 16-bit signed integers in two source operands, with saturation, and packs the differences into a destination. The higher-order word of each pair is subtracted from the lower-order word.

Positive differences greater than 7FFFh are saturated to 7FFFh; negative differences less than 8000h are saturated to 8000h.

There are legacy and extended forms of the instruction:

PHSUBSW

The first source register is also the destination.

Subtracts four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with the value in bits [15:0] minus the value in bits [31:16], and packs four saturated 16-bit differences into bits [63:0] of the destination, starting with bits [15:0]. Subtracts the four corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs four saturated 16-bit differences into bits [127:64] of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

VPHSUBSW

The extended form of the instruction has a 128-bit encoding only.

Subtracts four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with the value in bits [15:0] minus the value in bits [31:16], and packs four saturated 16-bit differences into bits [63:0] of the destination XMM register, starting with bits [15:0]. Subtracts the four corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs four saturated 16-bit differences into bits [127:64] of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PHSUBSW is an SSSE3 instruction and VPHSUBSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PHSUBW VPHSUBW

Packed Horizontal Subtract Word

Subtracts adjacent pairs of 16-bit signed integers in two source operands and packs the differences into a destination. The higher-order word of each pair is subtracted from the lower-order word.

There are legacy and extended forms of the instruction:

PHSUBW

The first source register is also the destination register.

Subtracts four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with the value in bits [15:0] minus the value in bits [31:16], and packs four 16-bit differences into bits [63:0] of the destination, starting with bits [15:0]. Subtracts the four corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs four 16-bit differences into bits [127:64] of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

VPHSUBW

The extended form of the instruction has a 128-bit encoding only.

Subtracts four adjacent pairs of 16-bit signed integer values in the first source XMM register, starting with the value in bits [15:0] minus the value in bits [31:16], and packs four 16-bit differences into bits [63:0] of the destination XMM register, starting with bits [15:0]. Subtracts the four corresponding adjacent pairs of values in the second source XMM register or a 128-bit memory location and packs four 16-bit differences into bits [127:64] of the destination, starting with bits [79:64]. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PHSUBW is an SSSE3 instruction and VPHSUBW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PINSRB VPINSRB

Packed Insert Byte

Inserts a byte from an 8-bit memory location or the low-order byte of a 32-bit general-purpose register into a destination register. Bits [3:0] of an immediate byte operand select the location where the byte is to be inserted:

Value of imm8 [3:0]	Insertion Location
0000	[7:0]
0001	[15:8]
0010	[23:16]
0011	[31:24]
0100	[39:32]
0101	[47:40]
0110	[55:48]
0111	[63:56]
1000	[71:64]
1001	[79:72]
1010	[87:80]
1011	[95:88]
1100	[103:96]
1101	[111:104]
1110	[119:112]
1111	[127:120]

There are legacy and extended forms of the instruction:

PINSRB

The source operand is either an 8-bit memory location or the low-order byte of a 32-bit general-purpose register and the destination an XMM register. The other bytes of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPINSRB

The extended form of the instruction has a 128-bit encoding only.

There are two source operands. The first source operand is either an 8-bit memory location or the low-order byte of a 32-bit general-purpose register and the second source operand is an XMM register. The destination is a second XMM register. All the bytes of the second source other than the byte that corresponds to the location of the inserted byte are copied to the destination. Bits [255:128] of the YMM register that corresponds to destination are cleared.

PINSRB is an SSE4.1 instruction and VPINSRB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
PINSRB <i>xmm, reg32/mem8, imm8</i>	66 0F 3A 20 /r ib	Inserts an 8-bit value selected by <i>imm8</i> from the low-order byte of <i>reg32</i> or from <i>mem8</i> into <i>xmm</i> .

PINSRD VPINSRD

Packed Insert Doubleword

Inserts a doubleword from a 32-bit memory location or a 32-bit general-purpose register into a destination register. Bits [1:0] of an immediate byte operand select the location where the doubleword is to be inserted:

Value of imm8 [1:0]	Insertion Location
00	[31:0]
01	[63:32]
10	[95:64]
11	[127:96]

There are legacy and extended forms of the instruction:

PINSRD

The encoding is the same as PINSRQ, with REX.W = 0.

The source operand is either a 32-bit memory location or a 32-bit general-purpose register and the destination an XMM register. The other doublewords of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPINSRD

The extended form of the instruction has a 128-bit encoding only.

The encoding is the same as VPINSRQ, with VEX.W = 0.

There are two source operands. The first source operand is either a 32-bit memory location or a 32-bit general-purpose register and the second source operand is an XMM register. The destination is a second XMM register. All the doublewords of the second source other than the doubleword that corresponds to the location of the inserted doubleword are copied to the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PINSRD is an SSE4.1 instruction and VPINSRD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PINSRQ VPINSRQ

Packed Insert Quadword

Inserts a quadword from a 64-bit memory location or a 64-bit general-purpose register into a destination register. Bit [0] of an immediate byte operand selects the location where the doubleword is to be inserted:

Value of imm8 [0]	Insertion Location
0	[63:0]
1	[127:64]

There are legacy and extended forms of the instruction:

PINSRQ

The encoding is the same as PINSRD, with REX.W = 1.

The source operand is either a 64-bit memory location or a 64-bit general-purpose register and the destination an XMM register. The other quadwords of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPINSRQ

The extended form of the instruction has a 128-bit encoding only.

The encoding is the same as VPINSRD, with VEX.W = 1.

There are two source operands. The first source operand is either a 64-bit memory location or a 64-bit general-purpose register and the second source operand is an XMM register. The destination is a second XMM register. All the quadwords of the second source other than the quadword that corresponds to the location of the inserted quadword are copied to the destination. Bits [255:128] of the YMM register that corresponds to the destination XMM registers are cleared.

PINSRQ is an SSE4.1 instruction and VPINSRQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PMADDUBSW VPMADDUBSW

Packed Multiply and Add Unsigned Byte to Signed Word

Multiplies and adds eight sets of two packed 8-bit unsigned values from the first source register and two packed 8-bit signed values from the second source register, with signed saturation; writes eight 16-bit sums to the destination.

Source registers 1 and 2 consist of bytes [a0 a1 a2 ...] and [b0 b1 b2 ...] and the destination register consists of words [w0 w1 w2 ...]. Operation is summarized as follows.

- The product of the values in bits [7:0] of the source registers (a0b0) is added to the product of the values in bits [15:8] of the source registers (a1b1). The saturated sum $w_0 = (a_0b_0 + a_1b_1)$ is written to bits [15:0] of the destination.
- The product of the values in bits [23:16] of the source registers (a2b2) is added to the product of the values in bits [31:24] of the source registers (a3b3). The saturated sum $w_1 = (a_2b_2 + a_3b_3)$ is written to bits [31:16] of the destination.
- The product of the values in bits [39:32] of the source registers (a4b4) is added to the product of the values in bits [47:40] of the source registers (a5b5). The saturated sum $w_2 = (a_4b_4 + a_5b_5)$ is written to bits [47:32] of the destination.
- The product of the values in bits [55:48] of the source registers (a6b6) is added to the product of the values in bits [63:56] of the source registers (a7b7). The saturated sum $w_3 = (a_6b_6 + a_7b_7)$ is written to bits [63:48] of the destination.
- The product of the values in bits [71:64] of the source registers (a8b8) is added to the product of the values in bits [79:72] of the source registers (a9b9). The saturated sum $w_4 = (a_8b_8 + a_9b_9)$ is written to bits [79:64] of the destination.
- The product of the values in bits [87:80] of the source registers (a10b10) is added to the product of the values in bits [95:88] of the source registers (a11b11). The saturated sum $w_5 = (a_{10}b_{10} + a_{11}b_{11})$ is written to bits [95:80] of the destination.
- The product of the values in bits [103:96] of the source registers (a12b12) is added to the product of the values in bits [111:104] of the source registers (a13b13). The saturated sum $w_6 = (a_{12}b_{12} + a_{13}b_{13})$ is written to bits [111:96] of the destination.
- The product of the values in bits [119:112] of the source registers (a14b14) is added to the product of the values in bits [127:120] of the source registers (a15b15). The saturated sum $w_7 = (a_{14}b_{14} + a_{15}b_{15})$ is written to bits [127:112] of the destination.

There are legacy and extended forms of the instruction:

PMADDUBSW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMADDUBSW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMADDUBSW is an SSSE3 instruction and VPMADDUBSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PMADDWD VPMADDWD

Packed Multiply and Add Word to Doubleword

Multiplies and adds four sets of four packed 16-bit signed values from two source registers; writes four 32-bit sums to the destination.

Source registers 1 and 2 consist of words [a0 a1 a2 ...] and [b0 b1 b2 ...] and the destination register consists of doublewords [w0 w1 w2 ...]. Operation is summarized as follows.

- The product of the values in bits [15:0] of the source registers (a0b0) is added to the product of the values in bits [31:16] of the source registers (a1b1). The sum d0 = (a0b0 + a1b1) is written to bits [31:0] of the destination.
- The product of the values in bits [47:33] of the source registers (a2b2) is added to the product of the values in bits [63:48] of the source registers (a3b3). The sum d1 = (a2b2 + a3b3) is written to bits [63:32] of the destination.
- The product of the values in bits [79:64] of the source registers (a4b4) is added to the product of the values in bits [95:80] of the source registers (a5b5). The sum d2 = (a4b4 + a5b5) is written to bits [95:64] of the destination.
- The product of the values in bits [111:96] of the source registers (a6b6) is added to the product of the values in bits [127:112] of the source registers (a7b7). The sum d3 = (a6b6 + a7b7) is written to bits [127:96] of the destination.

When all four of the signed 16-bit source operands in a set have the value 8000h, the 32-bit overflow wraps around to 8000_0000h. There are no other overflow cases.

There are legacy and extended forms of the instruction:

PMADDWD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMADDWD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMADDWD is an SSE2 instruction and VPMADDWD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PMINSW Packed Minimum Signed Words

VPMINSW

Compares each packed 16-bit signed integer value of the first source operand to the corresponding value of the second source operand and writes the numerically lesser value into the corresponding location of the destination.

There are legacy and extended forms of the instruction:

PMINSW

Compares eight pairs of packed 16-bit signed integer values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMINSW

The extended form of the instruction has a 128-bit encoding only.

Compares eight pairs of packed 16-bit signed integer values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMINSW is an SSE2 instruction and VPMINSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PMINUB VPMINUB

Packed Minimum Unsigned Bytes

Compares each packed 8-bit unsigned integer value of the first source operand to the corresponding value of the second source operand and writes the numerically lesser value into the corresponding location of the destination.

There are legacy and extended forms of the instruction:

PMINUB

Compares 16 pairs of 8-bit unsigned integer values.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source operand is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMINUB

The extended form of the instruction has a 128-bit encoding only.

Compares 16 pairs of 8-bit unsigned integer values.

The first source operand is an XMM register and the second source operand is either another XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMINUB is an SSE2 instruction and VPMINUB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PMOVMSKB VPMOVMSKB

Packed Move Mask Byte

Copies the values of the most-significant bits of each byte element of the source operand to create a 16-bit mask value, zero-extends the value, and writes it to the destination.

There are legacy and extended forms of the instruction:

PMOVMSKB

The source operand is an XMM register. The destination is a 32-bit general purpose register. The mask is zero-extended to fill the destination register, the mask occupies bits [15:0].

VPMOVMSKB

The source operand is an XMM register. The destination is a 64-bit general purpose register. The mask is zero-extended to fill the destination register, the mask occupies bits [15:0]. VEX.W is ignored.

PMOVMSKB is an SSE2 instruction and VPMOVMSKB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PMOVMSKB <i>reg32, xmm1</i>	66 0F D7 /r	Moves a zero-extended byte mask consisting of the most-significant bit of each byte in <i>xmm1</i> to a 32-bit general-purpose register.

PMULDQ VPMULDQ

Packed Multiply Signed Doubleword to Quadword

Multiplies the packed 32-bit signed integer in bits [31:0] of the first source operand by the corresponding value of the second source operand and writes the packed 64-bit signed integer product to bits [63:0] of the destination; multiplies the packed 32-bit signed integer in bits [95:64] of the first source operand by the corresponding value of the second source operand and writes the packed 64-bit signed integer product to bits [127:64] of the destination.

When the source is a memory location, all 128 bits are fetched, but only the first and third doublewords are used in the computation.

There are legacy and extended forms of the instruction:

PMULDQ

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMULDQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMULDQ is an SSE4.1 instruction and VPMULDQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PMULHRWSW Packed Multiply High with Round and Scale VPMULHRWSW Words

Multiplies each packed 16-bit signed value in the first source operand by the corresponding value in the second source operand, truncates the 32-bit product to the 18 most significant bits by right-shifting, then rounds the truncated value by adding 1 to its least-significant bit. Writes bits [16:1] of the sum to the corresponding word of the destination.

There are legacy and extended forms of the instruction:

PMULHRWSW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPMULHRWSW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PMULHRWSW instruction is an SSSE3 instruction and VPMULHRWSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

POR VPOR

Packed OR

Performs a bitwise OR of the first and second source operands and writes the result to the destination. When one or both of a pair of corresponding bits in the first and second operands are set, the corresponding bit of the destination is set; when neither source bit is set, the destination bit is cleared.

There are legacy and extended forms of the instruction:

POR

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPOR

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

POR is an SSE2 instruction and VPOR is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSADBW VPSADBW

Packed Sum of Absolute Differences Bytes to Words

Subtracts the 16 packed 8-bit unsigned integers in the second source operand from the corresponding values in the first source operand and computes the absolute difference for each subtraction, then computes two unsigned 16-bit integer sums, one for the eight differences that correspond to the upper eight source bytes, and one for the differences that correspond to the lower eight source bytes. Writes the sums to the destination.

The unsigned 16-bit integer sum of the differences of the eight bytes in bits [127:64] of the source operands is written to bits [15:0] of the destination; bits [63:16] are cleared.

The unsigned 16-bit integer sum of the differences of the eight bytes in bits [63:0] of the source operands is written to bits [79:64] of the destination; bits [127:80] are cleared.

There are legacy and extended forms of the instruction:

PSADBW

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSADBW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSADBW is an SSE2 instruction and VPSADBW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
PSADBW <i>xmm1</i> , <i>xmm2/mem128</i>	66 0F F6 /r	Compute the sum of the absolute differences of two sets of packed 8-bit unsigned integer values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes 16-bit unsigned integer sums to <i>xmm1</i> .

Mnemonic	Encoding

PSHUFB VPSHUFB

Packed Shuffle Byte

Copies bytes from the first source operand to the destination or clears bytes in the destination, as specified by control bytes in the second source operand.

The control bytes occupy positions in the source operand that correspond to positions in the destination. Each control byte has the following fields.

Bits	Description
[7]	Set the bit to clear the corresponding byte of the destination. Clear the bit to copy the selected source byte to the corresponding byte of the destination.
[6:4]	Reserved
[3:0]	Binary value selects the source byte.

There are legacy and extended forms of the instruction:

PSHUFB

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSHUFB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSHUFB is an SSE3 instruction and VPSHUFB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSHUFD VPSHUFD

Packed Shuffle Doublewords

Copies packed doubleword values from a source to a doubleword in the destination, as specified by bit fields of an immediate byte operand. A source doubleword can be copied more than once.

Source doublewords are selected by two-bit fields in the immediate-byte operand. Each bit field corresponds to a destination doubleword, as shown:

Destination Doubleword	Immediate-Byte Bit Field	Value of Bit Field	Source Doubleword
[31:0]	[1:0]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]
[63:32]	[3:2]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]
[95:64]	[5:4]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]
[127:96]	[7:6]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]

There are legacy and extended forms of the instruction:

PSHUFD

The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSHUFD

The extended form of the instruction has a 128-bit encoding only.

The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSHUFD is an SSE2 instruction and VPSHUFD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PSHUFD <i>xmm1, xmm2/mem128, imm8</i>	66 0F 70 /r ib	Moves packed 32-bit values from <i>xmm2</i> or <i>mem128</i> to <i>xmm1</i> , as specified by <i>imm8</i> .

PSIGNB VPSIGNB

Packed Sign Byte

For each packed signed byte in the first source operand, evaluate the corresponding byte of the second source operand and perform one of the following operations.

- When a byte of the second source is negative, write the two's-complement of the corresponding byte of the first source to the destination.
- When a byte of the second source is positive, copy the corresponding byte of the first source to the destination.
- When a byte of the second source is zero, clear the corresponding byte of the destination.

There are legacy and extended forms of the instruction:

PSIGNB

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSIGNB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSIGNB is an SSSE3 instruction and VPSIGNB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSSE3] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSLLD VPSLLD

Packed Shift Left Logical Doublewords

Left-shifts each packed 32-bit value in the source operand as specified by a shift-count operand and writes the shifted values to the destination.

The shift-count operand can be an immediate byte, a source register, or a memory location. There are different encodings for immediate operands and register/memory operands. Only bits [63:0] of the source register or memory location are used to generate the shift count.

Low-order bits emptied by shifting are cleared. When the shift value is greater than 31, the destination is cleared.

There are legacy and extended forms of the instruction:

PSLLD

There are two forms of the instruction, based on the type of count operand.

The first source operand is an XMM register. The shift count is specified by either a second XMM register or a 128-bit memory location, or by an immediate 8-bit operand. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSLLD

The extended form of the instruction has two 128-bit encodings. These differ based on the type of count operand.

The first source operand is an XMM register. The shift count is specified by either a second XMM register or a 128-bit memory location, or by an immediate 8-bit operand. The destination is an XMM register. For the immediate operand encoding, the destination is specified by VEX.vvvv. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSLLD is an SSE2 instruction and VPSLLD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSRLQ VPSRLQ

Packed Shift Right Logical Quadwords

Right-shifts each packed 64-bit value in the source operand as specified by a shift-count operand and writes the shifted values to the destination.

The shift-count operand can be an immediate byte, a source register, or a memory location. There are different encodings for immediate operands and register/memory operands. Only bits [63:0] of the source register or memory location are used to generate the shift count.

Low-order bits emptied by shifting are cleared. When the shift value is greater than 31, the destination is cleared.

There are legacy and extended forms of the instruction:

PSRLQ

There are two forms of the instruction, based on the type of count operand.

The first source operand is an XMM register. The shift count is specified by either a second XMM register or a 128-bit memory location, or by an immediate 8-bit operand. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSRLQ

The extended form of the instruction has two 128-bit encodings that differ based on the type of count operand.

The first source operand is an XMM register. The shift count is specified by either a second XMM register or a 128-bit memory location, or by an immediate 8-bit operand. The destination is an XMM register. For the immediate operand encoding, the destination is specified by VEX.vvvv. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSRLQ is an SSE2 instruction and VPSRLQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSUBB VPSUBB

Packed Subtract Bytes

Subtracts 16 packed 8-bit integer values in the second source operand from the corresponding values in the first source operand and writes the integer differences to the corresponding bytes of the destination.

This instruction operates on both signed and unsigned integers. When a result overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set), and only the low-order 8 bits of each result are written to the destination.

There are legacy and extended forms of the instruction:

PSUBB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSUBB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSUBB is an SSE2 instruction and VPSUBB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSUBSB Packed Subtract Signed With Saturation Bytes

VPSUBSB

Subtracts 16 packed 8-bit signed integer value in the second source operand from the corresponding values in the first source operand and writes the signed integer differences to the corresponding byte of the destination.

For each packed value in the destination, if the value is larger than the largest signed 8-bit integer, it is saturated to 7Fh, and if the value is smaller than the smallest signed 8-bit integer, it is saturated to 80h.

There are legacy and extended forms of the instruction:

PSUBSB

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSUBSB

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSUBSB is an SSE2 instruction and VPSUBSB is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PSUBUSW Packed Subtract Unsigned With Saturation VPSUBUSW Words

Subtracts eight packed 16-bit unsigned integer value in the second source operand from the corresponding values in the first source operand and writes the unsigned integer differences to the corresponding word of the destination.

Differences greater than FFFFh are saturated to FFFFh; differences less than 0000h are saturated to 0000h.

There are legacy and extended forms of the instruction:

PSUBUSW

The first source operand is an XMM register and the second source operand is another XMM register or 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSUBUSW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSUBUSW is an SSE2 instruction and VPSUBUSW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PSUBW VPSUBW

Packed Subtract Words

Subtracts eight packed 16-bit integer values in the second source operand from the corresponding values in the first source operand and writes the integer differences to the corresponding word of the destination.

This instruction operates on both signed and unsigned integers. When a result overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set), and only the low-order 8 bits of each result are written to the destination.

There are legacy and extended forms of the instruction:

PSUBW

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPSUBW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PSUBW is an SSE2 instruction and VPSUBW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PTEST VPTEST

Packed Bit Test

First, performs a bitwise AND of the first source operand with the second source operand. Sets rFLAGS.ZF when all bit operations = 0; else, clears ZF.

Second, performs a bitwise AND of the second source operand with the logical complement (NOT) of the first source operand. Sets rFLAGS.CF when all bit operations = 0; else, clears CF.

Neither source operand is modified.

There are legacy and extended forms of the instruction:

PTEST

The first source operand is an XMM register. The second source operand is either an XMM register or a 128-bit memory location.

VPTEST

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either an XMM register or a 128-bit memory location.

YMM Encoding

The first source operand is a YMM register. The second source operand is a YMM register or 256-bit memory location.

PTEST is an SSE4.1 instruction and VPTEST is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PUNPCKHBW VPUNPCKHBW

Unpack and Interleave High Bytes

Unpacks the high-order bytes of the first and second source operands and interleaves the 16 values into the destination. The low-order bytes of the source operands are ignored.

Bytes are interleaved in ascending order from the lsb of the sources and the destination. Bits [71:64] of the first source are written to bits [7:0] of the destination; bits [71:64] of the second source are written to bits [15:8] of the destination and so on, ending with bits [127:120] of the second source in bits [127:120] of the destination

When the second source operand is all 0s, the destination effectively contains the bytes from the first source operand zero-extended to 16 bits. This operation is useful for expanding unsigned 8-bit values to unsigned 16-bit operands for subsequent processing that requires higher precision.

There are legacy and extended forms of the instruction:

PUNPCKHBW

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPUNPCKHBW

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PUNPCKHBW is an SSE2 instruction and VPUNPCKHBW is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PUNPCKHDQ VPUNPCKHDQ

Unpack and Interleave High Doublewords

Unpacks the high-order doublewords of the first and second source operands and interleaves the four values into the destination. The low-order doublewords of the source operands are ignored.

Doublewords are interleaved in ascending order from the lsb of the sources and the destination. Bits [95:64] of the first source are written to bits [31:0] of the destination; bits [95:64] of the second source are written to bits [63:32] of the destination and so on, ending with bits [127:96] of the second source in bits [127:96] of the destination

When the second source operand is all 0s, the destination effectively contains the doublewords from the first source operand zero-extended to 64 bits. This operation is useful for expanding unsigned 32-bit values to unsigned 64-bit operands for subsequent processing that requires higher precision.

There are legacy and extended forms of the instruction:

PUNPCKHDQ

The first source operand is an XMM register and the second source operand is another XMM register or 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPUNPCKHDQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PUNPCKHDQ is an SSE2 instruction and VPUNPCKHDQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

PUNPCKLDQ VPUNPCKLDQ

Unpack and Interleave Low Doublewords

Unpacks the low-order doublewords of the first and second source operands and interleaves the four values into the destination. The high-order doublewords of the source operands are ignored.

Doublewords are interleaved in ascending order from the lsb of the sources and the destination. Bits [31:0] of the first source are written to bits [31:0] of the destination; bits [31:0] of the second source are written to bits [63:32] of the destination and so on, ending with bits [63:32] of the second source in bits [127:96] of the destination

When the second source operand is all 0s, the destination effectively contains the doublewords from the first source operand zero-extended to 64 bits. This operation is useful for expanding unsigned 32-bit values to unsigned 64-bit operands for subsequent processing that requires higher precision.

There are legacy and extended forms of the instruction:

PUNPCKLDQ

The first source operand is an XMM register and the second source operand is another XMM register or 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPUNPCKLDQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PUNPCKLDQ is an SSE2 instruction and VPUNPCKLDQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PUNPCKLDQ <i>xmm1, xmm2/mem128</i>	66 0F 62 /r	Unpacks and interleaves the low-order doublewords of <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the doublewords to <i>xmm1</i> .

PUNPCKLQDQ VPUNPCKLQDQ

Unpack and Interleave Low Quadwords

Unpacks the low-order quadwords of the first and second source operands and interleaves the two values into the destination. The high-order bytes of the source operands are ignored.

Quadwords are interleaved in ascending order from the lsb of the sources and the destination. Bits [63:0] of the first source are written to bits [63:0] of the destination; bits [63:0] of the second source are written to bits [127:64] of the destination.

When the second source operand is all 0s, the destination effectively contains the quadword from the first source operand zero-extended to 128 bits. This operation is useful for expanding unsigned 64-bit values to unsigned 128-bit operands for subsequent processing that requires higher precision.

There are legacy and extended forms of the instruction:

PUNPCKLQDQ

The first source operand is an XMM register and the second source operand is another XMM register or 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPUNPCKLQDQ

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PUNPCKLQDQ is an SSE2 instruction and VPUNPCKLQDQ is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
PUNPCKLQDQ <i>xmm1, xmm2/mem128</i>	66 0F 6C /r	Unpacks and interleaves the low-order quadwords of <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the bytes to <i>xmm1</i> .

PUNPCKLWD VPUNPCKLWD

Unpack and Interleave Low Words

Unpacks the low-order words of the first and second source operands and interleaves the eight values into the destination. The high-order words of the source operands are ignored.

Words are interleaved in ascending order from the lsb of the sources and the destination. Bits [15:0] of the first source are written to bits [15:0] of the destination; bits [15:0] of the second source are written to bits [31:16] of the destination and so on, ending with bits [63:48] of the second source in bits [127:112] of the destination

When the second source operand is all 0s, the destination effectively contains the words from the first source operand zero-extended to 32 bits. This operation is useful for expanding unsigned 16-bit values to unsigned 32-bit operands for subsequent processing that requires higher precision.

There are legacy and extended forms of the instruction:

PUNPCKLWD

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source operand is also the destination register. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

PUNPCKLWD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PUNPCKLWD is an SSE2 instruction and VPUNPCKLWD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

PXOR VPXOR

Packed Exclusive OR

Performs a bitwise XOR of the first and second source operands and writes the result to the destination. When either of a pair of corresponding bits in the first and second operands are set, the corresponding bit of the destination is set; when both source bits are set or when both source bits are not set, the destination bit is cleared.

There are legacy and extended forms of the instruction:

PXOR

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source XMM register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VPXOR

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

PXOR is an SSE2 instruction and VPXOR is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

RCPPS VRCPPS

Reciprocal Packed Single-Precision Floating-Point

Computes the approximate reciprocal of each packed single-precision floating-point value in the source operand and writes the results to the corresponding doubleword of the destination.

MXCSR.RC has no effect on the result.

The maximum error is less than or equal to $1.5 * 2^{-12}$ times the true reciprocal. A source value that is \pm zero or denormal returns an infinity of the source value sign. Results that underflow are changed to signed zero. For both SNaN and QNaN source operands, a QNaN is returned.

There are legacy and extended forms of the instruction:

RCPPS

Computes four reciprocals. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VRCPPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Computes four reciprocals. The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Computes eight reciprocals. The source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

RCPPS is an SSE2 instruction and VRCPPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
RCPPS <i>xmm1</i> , <i>xmm2/mem128</i>	0F 53 /r	Computes reciprocals of packed single-precision floating-point values in <i>xmm1</i> or <i>mem128</i> . Writes result to <i>xmm1</i>

RCPSS VRCPSS

Reciprocal Scalar Single-Precision Floating-Point

Computes the approximate reciprocal of the scalar single-precision floating-point value in a source operand and writes the results to the low-order doubleword of the destination. MXCSR.RC as no effect on the result.

The maximum error is less than or equal to $1.5 * 2^{-12}$ times the true reciprocal. A source value that is \pm zero or denormal returns an infinity of the source value sign. Results that underflow are changed to signed zero. For both SNaN and QNaN source operands, a QNaN is returned.

There are legacy and extended forms of the instruction:

RCPSS

The source operand is either an XMM register or a 32-bit memory location. The destination is an XMM register. Bits [127:32] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VRCPSS

The extended form of the instruction has a 128-bit encoding only.

The first source operand and the destination are XMM registers. The second source operand is either an XMM register or a 32-bit memory location. Bits [31:0] of the destination contain the reciprocal; bits [127:32] of the destination are copied from the first source register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

RCPSS is an SSE1 instruction and VRCPSS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

ROUNDPD VROUNDPD

Round Packed Double-Precision Floating-Point

Rounds two or four double-precision floating-point values as specified by an immediate byte operand. Source values are rounded to integral values and written to the destination as double-precision floating-point values.

SNaN source values are converted to QNaN. When DAZ = 1, denormals are converted to zero before rounding.

The immediate byte operand is defined as follows.

Bits	Mnemonic	Description
[7:4]	—	Reserved
[3]	P	Precision Exception
[2]	O	Rounding Control Source
[1:0]	RC	Rounding Control

Precision exception definitions:

Value	Description
0	Normal PE exception
1	PE field is not updated. No precision exception is taken when unmasked.

Rounding control source definitions:

Value	Description
0	MXCSR:RC
1	Use RC field value.

Rounding control definition:

Value	Description
00	Nearest
01	Downward (toward negative infinity)
10	Upward (toward positive infinity)
11	Truncated

There are legacy and extended forms of the instruction:

ROUNDPD

Rounds two source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate oper-

and. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VROUNDPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Rounds two source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate operand. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Rounds four source values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. There is a third 8-bit immediate operand. The destination is a third YMM register.

ROUNDPD is an SSE4.1 instruction and VROUNDPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

ROUNDPS VROUNDPS

Round Packed Single-Precision Floating-Point

Rounds four or eight single-precision floating-point values as specified by an immediate byte operand. Source values are rounded to integral values and written to the destination as single-precision floating-point values.

SNaN source values are converted to QNaN. When DAZ = 1, denormals are converted to zero before rounding.

The immediate byte operand is defined as follows.

7	4	3	2	1	0
Reserved	P	o	RC		

Bits	Mnemonic	Description
[7:4]	—	Reserved
[3]	P	Precision Exception
[2]	O	Rounding Control Source
[1:0]	RC	Rounding Control

Precision exception definitions:

Value	Description
0	Normal PE exception
1	PE field is not updated. No precision exception is taken when unmasked.

Rounding control source definitions:

Value	Description
0	MXCSR:RC
1	Use RC field value.

Rounding control definition:

Value	Description
00	Nearest
01	Downward (toward negative infinity)
10	Upward (toward positive infinity)
11	Truncated

There are legacy and extended forms of the instruction:

ROUNDPS

Rounds four source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate oper-

and. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VROUNDPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Rounds four source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate operand. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Rounds eight source values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. There is a third 8-bit immediate operand. The destination is a third YMM register.

ROUNDPS is an SSE4.1 instruction and VROUNDPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[SSE41] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
ROUNDPS <i>xmm1, xmm2/mem128, imm8</i>	66 0F 3A 08 /r ib	Rounds single-precision floating-point values in <i>xmm2</i> or <i>mem128</i> . Writes rounded single-precision values to <i>xmm1</i> .		
Mnemonic	Encoding

RSQRTPS VRSQRTPS

Reciprocal Square Root Packed Single-Precision Floating-Point

Computes the approximate reciprocal of the square root of each packed single-precision floating-point value in the source operand and writes the results to the corresponding doublewords of the destination. MXCSR.RC has no effect on the result.

The maximum error is less than or equal to $1.5 * 2^{-12}$ times the true reciprocal square root. A source value that is \pm zero or denormal returns an infinity of the source value sign. Negative source values other than $-$ zero and $-$ denormal return a QNaN floating-point indefinite value. For both SNaN and QNaN source operands, a QNaN is returned.

There are legacy and extended forms of the instruction:

RSQRTPS

Computes four values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VRSQRTPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Computes four values. The destination is an XMM register. The source operand is either an XMM register or a 128-bit memory location. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Computes eight values. The destination is an YMM register. The source operand is either a YMM register or a 256-bit memory location.

RSQRTPS is an SSE1 instruction and VRSQRTPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
RSQRTPS <i>xmm1, xmm2/mem128</i>	0F 52 /r	Computes reciprocals of square roots of packed single-precision floating-point values in <i>xmm1</i> or <i>mem128</i> . Writes result to <i>xmm1</i>

RSQRTSS VRSQRTSS

Reciprocal Square Root Scalar Single-Precision Floating-Point

Computes the approximate reciprocal of the square root of the scalar single-precision floating-point value in a source operand and writes the result to the low-order doubleword of the destination. MXCSR.RC as no effect on the result.

The maximum error is less than or equal to $1.5 * 2^{-12}$ times the true reciprocal square root. A source value that is \pm zero or denormal returns an infinity of the source value's sign. Negative source values other than $-$ zero and $-$ denormal return a QNaN floating-point indefinite value. For both SNaN and QNaN source operands, a QNaN is returned.

There are legacy and extended forms of the instruction:

RSQRTSS

The source operand is either an XMM register or a 32-bit memory location. The destination is an XMM register. Bits [127:32] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VRSQRTSS

The extended form of the instruction has a 128-bit encoding only.

The first source operand and the destination are XMM registers. The second source operand is either an XMM register or a 32-bit memory location. Bits [31:0] of the destination contain the reciprocal square root of the single-precision floating-point value held in bits [31:0] of the second source operand; bits [127:32] of the destination are copied from the first source register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

RSQRTSS is an SSE1 instruction and VSQRTSS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

SHUFPD Shuffle

VSHUFPD Packed Double-Precision Floating-Point

Copies packed double-precision floating-point values from either of two sources to quadwords in the destination, as specified by bit fields of an immediate byte operand.

Each bit corresponds to a quadword destination. The 128-bit legacy and extended versions of the instruction use bits [1:0]; the 256-bit extended version uses bits [3:0], as shown.

Destination Quadword	Immediate-Byte Bit Field	Value of Bit Field	Source 1 Bits Copied	Source 2 Bits Copied
Used by 128-bit encoding and 256-bit encoding				
[63:0]	[0]	0	[63:0]	—
		1	[127:64]	—
[127:64]	[1]	0	—	[63:0]
		1	—	[127:64]
Used only by 256-bit encoding				
[191:128]	[2]	0	[191:128]	—
		1	[255:192]	—
[255:192]	[3]	0	—	[191:128]
		1	—	[255:192]

There are legacy and extended forms of the instruction:

SHUFPD

Shuffles four source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate operand. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VSHUFPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Shuffles four source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. There is a fourth 8-bit immediate operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Shuffles eight source values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register. There is a fourth 8-bit immediate operand.

SHUFPD is an SSE2 instruction and VSHUFPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
SHUFPD <i>xmm1, xmm2/mem128, imm8</i>	66 0F C6 /r ib	Shuffles packed double-precision floating-point values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the result to <i>xmm1</i> .

SHUFPS VSHUFPS

Shuffle Packed Single-Precision Floating-Point

Copies packed single-precision floating-point values from either of two sources to doublewords in the destination, as specified by bit fields of an immediate byte operand.

Each bit field corresponds to a doubleword destination. The 128-bit legacy and extended versions of the instruction use a single 128-bit destination; the 256-bit extended version performs duplicate operations on bits [127:0] and bits [255:128] of the source and destination.

Destination Doubleword	Immediate-Byte Bit Field	Value of Bit Field	Source 1 Bits Copied	Source 2 Bits Copied
[31:0]	[1:0]	00	[31:0]	—
		01	[63:32]	—
		10	[95:64]	—

[255:224]	[7:6]	00	—	[159:128]
		01	—	[191:160]
		10	—	[223:192]
		11	—	[255:224]

There are legacy and extended forms of the instruction:

SHUFPS

Shuffles eight source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. There is a third 8-bit immediate operand. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VSHUFPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Shuffles eight source values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. There is a fourth 8-bit immediate operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Shuffles 16 source values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register. There is a fourth 8-bit immediate operand.

SHUFPS is an SSE1 instruction and VSHUFPS is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
SHUFPS <i>xmm1, xmm2/mem128, imm8</i>	0F C6 /r ib	Shuffles packed single-precision floating-point values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> . Writes the result to <i>xmm1</i> .

SQRTPD VSQRTPD

Square Root Packed Double-Precision Floating-Point

Computes the square root of each packed double-precision floating-point value in a source operand and writes the result to the corresponding quadword of the destination.

Performing the square root of +infinity returns +infinity.

There are legacy and extended forms of the instruction:

SQRTPD

Computes two values. The destination is an XMM register. The source operand is either another XMM register or a 128-bit memory location. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VSQRTPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Computes two values. The source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Computes four values. The source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register.

SQRTPD is an SSE2 instruction and VSQRTPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

SQRTSD VSQRTSD

Square Root Scalar Double-Precision Floating-Point

Computes the square root of a double-precision floating-point value and writes the result to the low quadword of the destination. The three-operand form of the instruction also writes a copy of the upper quadword of another source operand to the upper quadword of the destination.

Performing the square root of +infinity returns +infinity.

There are legacy and extended forms of the instruction:

SQRTSD

The source operand is either an XMM register or a 64-bit memory location. When the source is an XMM register, the source value must be in the low quadword. The destination is an XMM register. Bits [127:64] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to destination XMM register are not affected.

VSQRTSD

The extended form of the instruction has a single 128-bit encoding that requires three operands:

```
VSQRTSD xmm1, xmm2, xmm3/mem64
```

The first source operand is an XMM register. The second source operand is either an XMM register or a 64-bit memory location. When the second source is an XMM register, the source value must be in the low quadword. The destination is a third XMM register. The square root of the second source operand is written to bits [63:0] of the destination register. Bits [127:64] of the destination are copied from the corresponding bits of the first source operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

SQRTSD is an SSE2 instruction and VSQRTSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX]. For more information on the CPUID instruction and defined processor feature bits, see the *CPUID Specification*, order# 25481.

SQRTSS VSQRTSS

Square Root Scalar Single-Precision Floating-Point

Computes the square root of a single-precision floating-point value and writes the result to the low doubleword of the destination. The three-operand form of the instruction also writes a copy of the three most significant doublewords of a second source operand to the upper 96 bits of the destination. Performing the square root of +infinity returns +infinity.

There are legacy and extended forms of the instruction:

SQRTSS

The source operand is either an XMM register or a 32-bit memory location. When the source is an XMM register, the source value must be in the low doubleword. The destination is an XMM register. Bits [127:32] of the destination are not affected. Bits [255:128] of the YMM register that corresponds to destination XMM register are not affected.

VSQRTSS

The extended form has a single 128-bit encoding that requires three operands:

```
VSQRTSS xmm1, xmm2, xmm3/mem64
```

The first source operand is an XMM register. The second source operand is either an XMM register or a 32-bit memory location. When the second source is an XMM register, the source value must be in the low doubleword. The destination is a third XMM register. The square root of the second source operand is written to bits [31:0] of the destination register. Bits [127:32] of the destination are copied from the corresponding bits of the first source operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

SQRTSS is an SSE1 instruction and VSQRTSS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX]. For more information on the CPUID instruction and defined processor feature bits, see the *CPUID Specification*, order# 25481.

STMXCSR VSTMXCSR

Store MXCSR

Saves the content of the MXCSR extended control/status register to a 32-bit memory location. Reserved bits are stored as zeroes. The MXCSR is described in “Registers” in Volume 1.

For both legacy STMXCSR and extended VSTMXCSR forms of the instruction, the source operand is the MXCSR and the destination is a 32-bit memory location.

There is one encoding for each instruction form.

STMXCSR is an SSE1 instruction and VSTMXCSR is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

SUBPD Subtract

VSUBPD Packed Double-Precision Floating-Point

Subtracts each packed double-precision floating-point value of the second source operand from the corresponding value of the first source operand and writes the difference to the corresponding quad-word of the destination.

There are legacy and extended forms of the instruction:

SUBPD

Subtracts two pairs of values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VSUBPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Subtracts two pairs of values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Subtracts four pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

SUBPD is an SSE2 instruction and VSUBPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
SUBPD <i>xmm1, xmm2/mem128</i>	66 0F 5C /r	Subtracts packed double-precision floating-point values in <i>xmm2</i> or <i>mem128</i> from corresponding values of <i>xmm1</i> . Writes differences to <i>xmm1</i> .

SUBPS VSUBPS

Subtract Packed Single-Precision Floating-Point

Subtracts each packed single-precision floating-point value of the second source operand from the corresponding value of the first source operand and writes the difference to the corresponding quad-word of the destination.

There are legacy and extended forms of the instruction:

SUBPS

Subtracts four pairs of values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VSUBPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Subtracts four pairs of values. The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Subtracts eight pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

SUBPS is an SSE1 instruction and VSUBPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

SUBSD Subtract VSUBSD Scalar Double-Precision Floating-Point

Subtracts the double-precision floating-point value in the low-order quadword of the second source operand from the corresponding value in the first source operand and writes the result to the low-order quadword of the destination

There are legacy and extended forms of the instruction:

SUBSD

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The first source register is also the destination register. Bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are not affected.

VSUBSD

The extended form of the instruction has a 128-bit encoding only.

The first source operand is an XMM register and the second source operand is either an XMM register or a 64-bit memory location. The destination is a third XMM register. Bits [127:64] of the first source operand are copied to bits [127:64] of the destination. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

SUBSD is an SSE2 instruction and VSUBSD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

UCOMISD VUCOMISD

Unordered Compare Scalar Double-Precision Floating-Point

Performs an unordered comparison of a double-precision floating-point value in the low-order 64 bits of an XMM register with a double-precision floating-point value in the low-order 64 bits of another XMM register or a 64-bit memory location.

The ZF, PF, and CF bits in the rFLAGS register reflect the result of the compare as follows.

Result of Compare	ZF	PF	CF
Unordered	1	1	1
Greater Than	0	0	0
Less Than	0	0	1
Equal	1	0	0

The OF, AF, and SF bits in rFLAGS are cleared. If the instruction causes an unmasked SIMD floating-point exception (#XF), the rFLAGS bits are not updated.

The result is unordered when one or both of the operand values is a NaN. UCOMISD signals a SIMD floating-point invalid operation exception (#I) only when a source operand is an SNaN.

The legacy and extended forms of the instruction operate in the same way.

UCOMISD is an SSE2 instruction and VUCOMISD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

UCOMISS VUCOMISS

Unordered Compare Scalar Single-Precision Floating-Point

Performs an unordered comparison of a single-precision floating-point value in the low-order 32 bits of an XMM register with a double-precision floating-point value in the low-order 32 bits of another XMM register or a 32-bit memory location.

The ZF, PF, and CF bits in the rFLAGS register reflect the result of the compare as follows.

Result of Compare	ZF	PF	CF
Unordered	1	1	1
Greater Than	0	0	0
Less Than	0	0	1
Equal	1	0	0

The OF, AF, and SF bits in rFLAGS are cleared. If the instruction causes an unmasked SIMD floating-point exception (#XF), the rFLAGS bits are not updated.

The result is unordered when one or both of the operand values is a NaN. UCOMISS signals a SIMD floating-point invalid operation exception (#I) only when a source operand is an SNaN.

The legacy and extended forms of the instruction operate in the same way.

UCOMISS is an SSE1 instruction and VUCOMISS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

UNPCKHPD VUNPCKHPD

Unpack High Double-Precision Floating-Point

Unpacks the high-order double-precision floating-point values of the first and second source operands and interleaves the values into the destination. Bits [63:0] of the source operands are ignored. Values are interleaved in ascending order from the lsb of the sources and the destination. Bits [127:64] of the first source are written to bits [63:0] of the destination; bits [127:64] of the second source are written to bits [127:64] of the destination. For the 256-bit encoding, the process is repeated for bits [255:192] of the sources and bits [255:128] of the destination.

There are legacy and extended forms of the instruction:

UNPCKHPD

Interleaves one pair of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VUNPCKHPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Interleaves one pair of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Interleaves two pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

UNPCKHPD is an SSE2 instruction and VUNPCKHPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
UNPCKHPD <i>xmm1, xmm2/mem128</i>	66 0F 15 /r	Unpacks the high-order double-precision floating-point values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> and interleaves them into <i>xmm1</i>

UNPCKHPS VUNPCKHPS

Unpack High Single-Precision Floating-Point

Unpacks the high-order single-precision floating-point values of the first and second source operands and interleaves the values into the destination. Bits [63:0] of the source operands are ignored.

Values are interleaved in ascending order from the lsb of the sources and the destination. Bits [95:64] of the first source are written to bits [31:0] of the destination; bits [95:64] of the second source are written to bits [63:32] of the destination and so on, ending with bits [127:96] of the second source in bits [127:96] of the destination. For the 256-bit encoding, the process continues for bits [255:192] of the sources and bits [255:128] of the destination.

There are legacy and extended forms of the instruction:

UNPCKHPS

Interleaves two pairs of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VUNPCKHPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Interleaves two pairs of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Interleaves four pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

UNPCKHPS is an SSE1 instruction and VUNPCKHPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description		
UNPCKHPS <i>xmm1, xmm2/mem128</i>	0F 15 /r	Unpacks the high-order single-precision floating-point values in <i>xmm1</i> and <i>xmm2</i> or <i>mem128</i> and interleaves them into <i>xmm1</i>

UNPCKLPD VUNPCKLPD

Unpack Low Double-Precision Floating-Point

Unpacks the low-order double-precision floating-point values of the first and second source operands and interleaves the values into the destination. Bits [127:64] of the source operands are ignored.

Values are interleaved in ascending order from the lsb of the sources and the destination. Bits [63:0] of the first source are written to bits [63:0] of the destination; bits [63:0] of the second source are written to bits [127:64] of the destination. For the 256-bit encoding, the process is repeated for bits [191:128] of the sources and bits [255:128] of the destination.

There are legacy and extended forms of the instruction:

UNPCKLPD

Interleaves one pair of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VUNPCKLPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Interleaves one pair of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Interleaves two pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

UNPCKLPD is an SSE2 instruction and VUNPCKLPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

UNPCKLPS VUNPCKLPS

Unpack Low Single-Precision Floating-Point

Unpacks the low-order single-precision floating-point values of the first and second source operands and interleaves the values into the destination. Bits [127:64] of the source operands are ignored.

Values are interleaved in ascending order from the lsb of the sources and the destination. Bits [31:0] of the first source are written to bits [31:0] of the destination; bits [31:0] of the second source are written to bits [63:32] of the destination and so on, ending with bits [63:32] of the second source in bits [127:96] of the destination. For the 256-bit encoding, the process continues for bits [191:128] of the sources and bits [255:128] of the destination.

There are legacy and extended forms of the instruction:

UNPCKLPS

Interleaves two pairs of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VUNPCKLPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Interleaves two pairs of values. The first source operand is an XMM register and the second source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

Interleaves four pairs of values. The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

UNPCKLPS is an SSE1 instruction and VUNPCKLPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

VBROADCASTSS**Load With Broadcast
From 32-Bit Memory Location**

Loads a single-precision floating-point value from a 32-bit memory location and writes it to 32-bit elements of an XMM or YMM register

This extended-form instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Broadcasts to eight 32-bit elements.

The source operand is a 32-bit memory location. The destination is an XMM register.

YMM Encoding

Broadcasts to sixteen 32-bit elements.

The source operand is a 32-bit memory location. The destination is a YMM register.

VBROADCASTSS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

A — AVX exception.

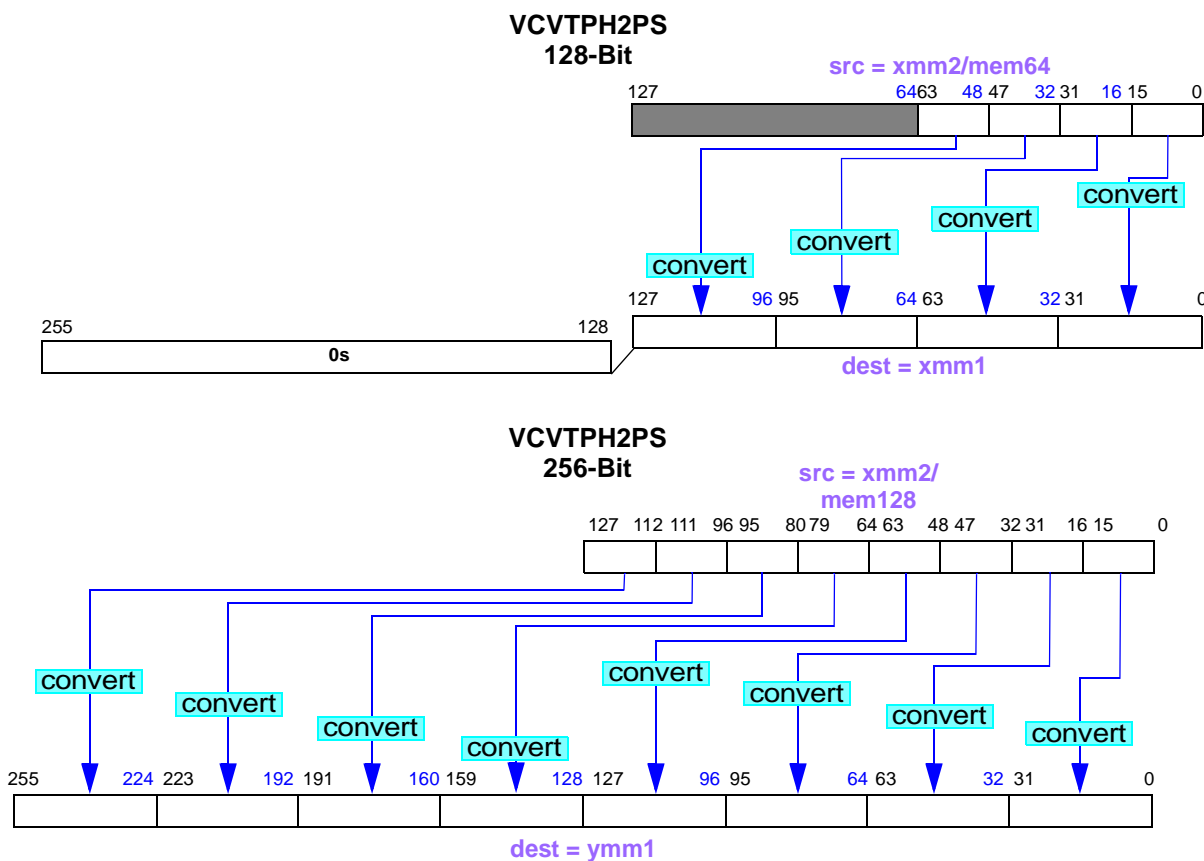

VCVTPH2PS**Convert Packed 16-Bit Floating-Point to Single-Precision Floating-Point**

Converts packed 16-bit floating point values to single-precision floating point values.

A denormal source operand is converted to a normal result in the destination register. MXCSR.DAZ is ignored and no MXCSR denormal exception is reported.

Because the full range of 16-bit floating-point encodings, including denormal encodings, can be represented exactly in single-precision format, rounding, inexact results, and denormalized results are not applicable.

The operation of this instruction is illustrated in the following diagram.

This extended-form instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts four packed 16-bit floating-point values in the low-order 64 bits of an XMM register or in a 64-bit memory location to four packed single-precision floating-point values and writes the converted values to an XMM destination register. When the result operand is written to the destination register, the upper 128 bits of the corresponding YMM register are zeroed.

YMM Encoding

Converts eight packed 16-bit floating-point values in the low-order 128 bits of a YMM register or in a 128-bit memory location to eight packed single-precision floating-point values and writes the converted values to a YMM destination register.

VCVTPH2PS is a F16C instruction. Support for this instruction is indicated by CPUID Fn0000_0001_ECX[F16C]. (See the *CPUID Specification*, order# 25481.)

Instruction Encoding

Exceptions

Exception	Mode			Cause of Exception
	Real	Virtual 8086	Protected	
Invalid opcode, #UD	X	X		F16C instructions are only recognized in protected mode.
			X	The F16C instructions are not supported, as indicated by CPUID Fn0000_0001_ECX[F16C] = 0.
			X	The operating-system XSAVE/XRSTOR support bit (OSXSAVE) of CR4 was cleared to 0, as indicated by ECX bit 27 of CPUID function 0000_0001h.
			X	The operating-system YMM and SSE support bits XFEATURE_ENABLED_MASK[2:1] were not both set to 1.
			X	VEX.W was set to 1.
			X	VEX.vvvv was not 1111b.
Device not available, #NM			X	There was an unmasked SIMD floating-point exception while CR4.OSXMMEXCPT = 0. See <i>SIMD Floating-Point Exceptions</i> , below, for details.
Stack, #SS			X	The task-switch bit (TS) of CR0 was set to 1.
General protection, #GP			X	A memory address exceeded the stack segment limit or was non-canonical.
			X	A memory address exceeded a data segment limit or was non-canonical.
Page fault, #PF			X	A null data segment was used to reference memory.
SIMD Floating-Point Exception, #XF			X	A page fault resulted from the execution of the instruction.
SIMD Floating-Point Exceptions				
Invalid-operation exception (IE)			X	There was an unmasked SIMD floating-point exception while CR4.OSXMMEXCPT was set to 1. See <i>SIMD Floating-Point Exceptions</i> , below for details.
			X	A source operand was an SNaN value.

VCVTPS2PH Convert Packed Single-Precision Floating-Point to 16-Bit Floating-Point

Converts packed single-precision floating-point values to packed 16-bit floating-point values and writes the converted values to the destination register or to memory. An 8-bit immediate operand provides dynamic control of rounding and denormalized input operand handling.

The operation of this instruction is illustrated in the following diagram.

The handling of rounding is controlled by fields in the immediate byte, as shown in the following table.

Denormal and Rounding Control with Immediate Byte Operand

Mnemonic	Rounding Source (RS)	Rounding Control (RC)		Description	Notes
		1	0		
Bit	2	1	0		
Value	0	0	0	Nearest	Ignore MXCSR.RC.
		0	1	Down	
		1	0	Up	
		1	1	Truncate	
	1	X	X	Use MXCSR.RC for rounding.	

This extended-form instruction has both 128-bit and 256-bit encodings:

XMM Encoding

Converts four packed single-precision floating-point values in an XMM register to four packed 16-bit floating-point values and writes the converted values to the low-order 64 bits of the destination XMM register or to a 64-bit memory location. When the result is written to the destination XMM register, the high-order 64 bits in the destination XMM register and the upper 128 bits of the corresponding YMM register are cleared to 0s.

YMM Encoding

Converts eight packed single-precision floating-point values in a YMM register to eight packed 16-bit floating-point values and writes the converted values to the low-order 128 bits of another YMM register or to a 128-bit memory location. When the result is written to the destination YMM register, the high-order 128 bits in the register are cleared to 0s.

VCVTPS2PH is a CVT16 instruction. Support for this instruction is indicated by CPUID Fn0000_0001_ECX[F16C]. (See the *CPUID Specification*, order# 25481.)

Exceptions

Exception	Mode			Cause of Exception
	Real	Virtual 8086	Protected	
Invalid opcode, #UD	X	X		F16C instructions are only recognized in protected mode.
			X	The F16C instructions are not supported, as indicated by CPUID Fn0000_0001_ECX[F16C] = 0.
			X	The operating-system XSAVE/XRSTOR support bit (OSXSAVE) of CR4 was cleared to 0, as indicated by ECX bit 27 of CPUID function 0000_0001h.
			X	The operating-system YMM and SSE support bits XFEATURE_ENABLED_MASK[2:1] were not both set to 1.
			X	VEX.W was set to 1.
			X	VEX.vvvv was not 1111b.
			X	There was an unmasked SIMD floating-point exception while CR4.OSXMMEXCPT = 0. See <i>SIMD Floating-Point Exceptions</i> , below, for details.
Device not available, #NM			X	The task-switch bit (TS) of CR0 was set to 1.
Stack, #SS			X	A memory address exceeded the stack segment limit or was non-canonical.
General protection, #GP			X	A memory address exceeded a data segment limit or was non-canonical.
			X	A null data segment was used to reference memory.
			X	The destination operand was in a non-writable segment.
Page fault, #PF			X	A page fault resulted from the execution of the instruction.

Exception	Mode			Cause of Exception
	Real	Virtual 8086	Protected	
SIMD Floating-Point Exception, #XF			X	There was an unmasked SIMD floating-point exception while CR4.OSXMMEXCPT was set to 1. See <i>SIMD Floating-Point Exceptions</i> , below for details.
SIMD Floating-Point Exceptions				
Invalid-operation exception (IE)			X	A source operand was an SNaN value.
Denormal operand exception (DE)			X	A source operand was a denormal value.
Overflow exception (OE)			X	A rounded result was too large to fit into the format of the destination operand.
Underflow exception (UE)			X	A rounded result was too small to fit into the format of the destination operand.
Precision exception (PE)			X	A result could not be represented exactly in the destination format.

VEXTRACTF128**Extract
Packed Values from 128-bit Memory Location**

Extracts 128-bit packed-value data from a YMM register as specified by an immediate byte operand, and writes it to either an XMM register or a 128-bit memory location.

Only bit [0] of the immediate operand is used. Operation is as follows.

- When `imm8[0] = 0`, copy bits [127:0] of the source to the destination.
- When `imm8[0] = 1`, copy bits [255:128] of the source to the destination.

This extended-form instruction has a single 256-bit encoding.

The source operand is a YMM register and the destination is either an XMM register or a 128-bit memory location. There is a third immediate byte operand.

This is an AVX instruction. Support for these instructions is indicated by CPUID `Fn0000_00001_ECX[AVX]` (see the *CPUID Specification*, order# 25481).\

<i>A — AVX exception.</i>				

VFMADDPD Multiply and Add

VFMADD132PD Packed Double-Precision Floating-Point

VFMADD213PD

VFMADD231PD

Multiplies together two double-precision floating-point vectors and adds the unrounded product to a third double-precision floating-point vector producing a precise result which is then rounded to double-precision based on the mode specified by the MXCSR[RC] field. The rounded sum is written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFMADDPD dest, src1, src2/mem, src3           // dest = (src1 * src2/mem) + src3
VFMADDPD dest, src1, src2, src3/mem          // dest = (src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFMADD132PD src1, src2, src3/mem             // src1 = (src1 * src3/mem) + src2
VFMADD213PD src1, src2, src3/mem           // src1 = (src2 * src1) + src3/mem
VFMADD231PD src1, src2, src3/mem           // src1 = (src2 * src3/mem) + src1
```

When VEX.L = 0, the vector size is 128 bits (two double-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (four double-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMADDPD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADD132PD, VFMADD213PD, and VFMADD231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

See the CPUID Specification, order# 25481, for more information on the CPUID instruction and defined feature bits.

**Multiply and Add
Packed Single-Precision Floating-Point**

Multiplies together two single-precision floating-point vectors and adds the unrounded product to a third single-precision floating-point vector producing a precise result which is then rounded to single-precision based on the mode specified by the MXCSR[RC] field. The rounded sum is written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFMADDPS dest, src1, src2/mem, src3           // dest = (src1 * src2/mem) + src3
VFMADDPS dest, src1, src2, src3/mem          // dest = (src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFMADD132PS src1, src2, src3/mem             // src1 = (src1 * src3/mem) + src2
VFMADD213PS src1, src2, src3/mem            // src1 = (src2 * src1) + src3/mem
VFMADD231PS src1, src2, src3/mem            // src1 = (src2 * src3/mem) + src1
```

When VEX.L = 0, the vector size is 128 bits (four single-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (eight single-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMADDPS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADD132PS, VFMADD213PS, and VFMADD231PS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

See the CPUID Specification, order# 25481, for more information on the CPUID instruction and defined feature bits.

VFMADDSD Multiply and Add

VFMADD132SD Scalar Double-Precision Floating-Point

VFMADD213SD

VFMADD231SD

Multiplies together two double-precision floating-point values and adds the unrounded product to a third double-precision floating-point value producing a precise result which is then rounded to double-precision based on the mode specified by the MXCSR[RC] field. The rounded sum is written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMADDSD dest, src1, src2/mem64, src3           // dest = (src1 * src2/mem64) + src3
VFMADDSD dest, src1, src2, src3/mem64         // dest = (src1 * src2) + src3/mem64
```

and three three-operand forms:

```
VFMADD132SD src1, src2, src3/mem64           // src1 = (src1 * src3/mem64) + src2
VFMADD213SD src1, src2, src3/mem64         // src1 = (src2 * src1) + src3/mem64
VFMADD231SD src1, src2, src3/mem64         // src1 = (src2 * src3/mem64) + src1
```

All 64-bit double-precision floating-point register-based operands are held in the lower quadword of XMM registers. The result is written to the lower quadword of the destination register. For those instructions that use a memory-based operand, one of the source operands is a 64-bit value read from memory.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a 64-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a 64-bit memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a 64-bit memory location.

The destination is an XMM register. When the result is written to the destination XMM register, bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are cleared.

VFMADDSD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADD132SD, VFMADD213SD, and VFMADD231SD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

See the CPUID Specification, order# 25481, for more information on the CPUID instruction and defined feature bits.

VFMADDSS Multiply and Add

VFMADD132SS Scalar Single-Precision Floating-Point

VFMADD213SS

VFMADD231SS

Multiplies together two single-precision floating-point values and adds the unrounded product to a third single-precision floating-point value producing a precise result which is then rounded to single-precision based on the mode specified by the MXCSR[RC] field. The rounded sum is written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMADDSS dest, src1, src2/mem32, src3           // dest = (src1 * src2/mem32) + src3
VFMADDSS dest, src1, src2, src3/mem32          // dest = (src1 * src2) + src3/mem32
```

and three three-operand forms:

```
VFMADD132SS src1, src2, src3/mem32             // src1 = (src1 * src3/mem32) + src2
VFMADD213SS src1, src2, src3/mem32            // src1 = (src2 * src1) + src3/mem32
VFMADD231SS src1, src2, src3/mem32            // src1 = (src2 * src3/mem32) + src1
```

All 32-bit single-precision floating-point register-based operands are held in the lower doubleword of XMM registers. The result is written to the low doubleword of the destination register. For those instructions that use a memory-based operand, one of the source operands is a 32-bit value read from memory.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a 32-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a 32-bit memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a 32-bit memory location.

The destination is an XMM register. When the result is written to the destination XMM register, bits [127:32] of the destination and bits [255:128] of the corresponding YMM register are cleared.

VFMADDSS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADD132SS, VFMADD213SS, and VFMADD231SS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMADDSUBPD Multiply with Alternating Add/Subtract

VFMADDSUB132PD Packed Double-Precision Floating-Point

VFMADDSUB213PD

VFMADDSUB231PD

Multiplies together two double-precision floating-point vectors, adds odd elements of the unrounded product to odd elements of a third double-precision floating-point vector, and subtracts even elements of the third floating point vector from even elements of unrounded product. The precise result of each addition or subtraction is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the corresponding element of the destination.

The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMADDSUBPD dest, src1, src2/mem, src3     // destodd = (src1odd * src2odd/memodd) + src3odd
VFMADDSUBPD dest, src1, src2, src3/mem     // desteven = (src1even * src2even/memeven) - src3even
VFMADDSUBPD dest, src1, src2, src3/mem     // destodd = (src1odd * src2odd) + src3odd/memodd
VFMADDSUBPD dest, src1, src2, src3/mem     // desteven = (src1even * src2even) - src3even/memeven
```

and three three-operand forms:

```
VFMADDSUB132PD scr1, src2, src3/mem       // src1odd = (src1odd * src3odd/memodd) + src2odd
VFMADDSUB132PD scr1, src2, src3/mem       // src1even = (src1even * src3even/memeven) - src2even
VFMADDSUB213PD scr1, src2, src3/mem       // src1odd = (src2odd * src1odd) + src3odd/memodd
VFMADDSUB213PD scr1, src2, src3/mem       // src1even = (src2even * src1even) - src3even/memeven
VFMADDSUB231PD scr1, src2, src3/mem       // src1odd = (src2odd * src3odd/memodd) + src1odd
VFMADDSUB231PD scr1, src2, src3/mem       // src1even = (src2even * src3even/memeven) - src1even
```

When VEX.L = 0, the vector size is 128 bits (two double-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (four double-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is a XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMADDSUBPD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADDSUB132PD, VFMADDSUB213PD, and VFMADDSUB231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMADDSUB213PS
VFMADDSUB231PS

**Multiply with Alternating Add/Subtract
Packed Single-Precision Floating-Point**

Multiplies together two single-precision floating-point vectors, adds odd elements of the unrounded product to odd elements of a third single-precision floating-point vector, and subtracts even elements of the third floating point vector from even elements of unrounded product. The precise result of each addition or subtraction is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the corresponding element of the destination.

The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMADDSUBPS dest, src1, src2/mem, src3 // destodd = (src1odd * src2odd/memodd) + src3odd
// desteven = (src1even * src2even/memeven) - src3even
VFMADDSUBPS dest, src1, src2, src3/mem // destodd = (src1odd * src2odd) + src3odd/memodd
// desteven = (src1even * src2even) - src3even/memeven
```

and three three-operand forms:

```
VFMADDSUB132PS src1, src2, src3/mem // src1odd = (src1odd * src3odd/memodd) + src2odd
// src1even = (src1even * src3even/memeven) - src2even
VFMADDSUB213PS src1, src2, src3/mem // src1odd = (src2odd * src1odd) + src3odd/memodd
// src1even = (src2even * src1even) - src3even/memeven
VFMADDSUB231PS src1, src2, src3/mem // src1odd = (src2odd * src3odd/memodd) + src1odd
// src1even = (src2even * src3even/memeven) - src1even
```

When VEX.L = 0, the vector size is 128 bits (four single-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (eight single-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMADDSUBPS is an FMA4 instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADDSUB132PS, VFMADDSUB213PS, and VFMADDSUB231PS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMSUBADDPD
VFMSUBADD132PD
VFMSUBADD213PD
VFMSUBADD231PD

**Multiply with Alternating Subtract/Add
Packed Double-Precision Floating-Point**

Multiplies together two double-precision floating-point vectors, adds even elements of the unrounded product to even elements of a third double-precision floating-point vector, and subtracts odd elements of the third floating point vector from odd elements of unrounded product. The precise result of each addition or subtraction is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the corresponding element of the destination.

The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMSUBADDPD dest, src1, src2/mem, src3 // destodd = (src1odd * src2odd/memodd) - src3odd
// desteven = (src1even * src2even/memeven) + src3even
VFMSUBADDPD dest, src1, src2, src3/mem // destodd = (src1odd * src2odd) - src3odd/memodd
// desteven = (src1even * src2even) + src3even/memeven
```

and three three-operand forms:

```
VFMSUBADD132PD scr1, src2, src3/mem // src1odd = (src1odd * src3odd/memodd) - src2odd
// src1even = (src1even * src3even/memeven) + src2even
VFMSUBADD213PD scr1, src2, src3/mem // src1odd = (src2odd * src1odd) - src3odd/memodd
// src1even = (src2even * src1even) + src3even/memeven
VFMSUBADD231PD scr1, src2, src3/mem // src1odd = (src2odd * src3odd/memodd) - src1odd
// src1even = (src2even * src3even/memeven) + src1even
```

For VEX.L = 0, vector size is 128 bits and register-based operands are held in XMM registers. For VEX.L = 1, vector size is 256 bits and register-based operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source operand is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMSUBADDPD is an FMA4 instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMSUBADD132PD, VFMSUBADD213PD, and VFMSUBADD231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMSUBADDPS VFMSUBADD132PS VFMSUBADD213PS VFMSUBADD231PS

Multiply with Alternating Subtract/Add Packed Single-Precision Floating-Point

Multiplies together two single-precision floating-point vectors, adds even elements of the unrounded product to even elements of a third single-precision floating-point vector, and subtracts odd elements of the third floating point vector from odd elements of unrounded product. The precise result of each addition or subtraction is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the corresponding element of the destination.

The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMSUBADDPS dest, src1, src2/mem, src3 // destodd = (src1odd * src2odd/memodd) - src3odd
// desteven = (src1even * src2even/memeven) + src3even
VFMSUBADDPS dest, src1, src2, src3/mem // destodd = (src1odd * src2odd) - src3odd/memodd
// desteven = (src1even * src2even) + src3even/memeven
```

and three three-operand forms:

```
VFMSUBADD132PS scr1, src2, src3/mem // src1odd = (src1odd * src3odd/memodd) - src2odd
// src1even = (src1even * src3even/memeven) + src2even
VFMSUBADD213PS scr1, src2, src3/mem // src1odd = (src2odd * src1odd) - src3odd/memodd
// src1even = (src2even * src1even) + src3even/memeven
VFMSUBADD231PS scr1, src2, src3/mem // src1odd = (src2odd * src3odd/memodd) - src1odd
// src1even = (src2even * src3even/memeven) + src1even
```

When VEX.L = 0, the vector size is 128 bits (four single-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (eight single-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMSUBADDPS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMSUBADD132PS, VFMSUBADD213PS, and VFMSUBADD231PS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMSUBPD Multiply and Subtract

VFMSUB132PD Packed Double-Precision Floating-Point

VFMSUB213PD

VFMSUB231PD

Multiplies together two double-precision floating-point vectors and subtracts a third double-precision floating-point vector from the unrounded product to produce a precise intermediate result. The intermediate result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFMSUBPD dest, src1, src2/mem, src3           // dest = (src1 * src2/mem) - src3
VFMSUBPD dest, src1, src2, src3/mem          // dest = (src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFMSUB132PD src1, src2, src3/mem             // src1 = (src1 * src3/mem) - src2
VFMSUB213PD src1, src2, src3/mem           // src1 = (src2 * src1) - src3/mem
VFMSUB231PD src1, src2, src3/mem           // src1 = (src2 * src3/mem) - src1
```

For VEX.L = 0, vector size is 128 bits and register-based operands are held in XMM registers. For VEX.L = 1, vector size is 256 bits and register-based operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFMSUBPD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMSUB132PD, VFMSUB213PD, and VFMSUB231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMSUBSD Multiply and Subtract

VFMSUB132SD Scalar Double-Precision Floating-Point

VFMSUB213SD

VFMSUB231SD

Multiplies together two double-precision floating-point values and subtracts a third double-precision floating-point value from the unrounded product to produce a precise intermediate result. The intermediate result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFMSUBSD dest, src1, src2/mem, src3           // dest = (src1 * src2/mem) - src3
VFMSUBSD dest, src1, src2, src3/mem          // dest = (src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFMSUB132SD src1, src2, src3/mem             // src1 = (src1 * src3/mem) - src2
VFMSUB213SD src1, src2, src3/mem            // src1 = (src2 * src1) - src3/mem
VFMSUB231SD src1, src2, src3/mem            // src1 = (src2 * src3/mem) - src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or 64-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is a register or 64-bit memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is an XMM register. When the result is written to the destination XMM register, bits [127:64] of the destination and bits [255:128] of the corresponding YMM register are cleared.

VFMSUBSD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMSUB132SD, VFMSUB213SD, and VFMSUB231SD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFMSUBSS
VFMSUB132SS
VFMSUB213SS
VFMSUB231SS

**Multiply and Subtract
 Scalar Single-Precision Floating-Point**

Multiplies together two single-precision floating-point values and subtracts a third single-precision floating-point value from the unrounded product to produce a precise intermediate result. The intermediate result is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFMSUBSS dest, src1, src2/mem, src3           // dest = (src1 * src2/mem) - src3
VFMSUBSS dest, src1, src2, src3/mem          // dest = (src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFMSUB132SS src1, src2, src3/mem             // src1 = (src1 * src3/mem) - src2
VFMSUB213SS src1, src2, src3/mem            // src1 = (src2 * src1) - src3/mem
VFMSUB231SS src1, src2, src3/mem            // src1 = (src2 * src3/mem) - src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or 32-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is a register or 32-bit memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is an XMM register. When the result is written to the destination XMM register, bits [127:32] of the XMM register and bits [255:128] of the corresponding YMM register are cleared.

VFMSUBSS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMSUB132SS, VFMSUB213SS, and VFMSUB231SS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMADDPD Negative Multiply and Add

VFNMADD132PD Packed Double-Precision Floating-Point

VFNMADD213PD

VFNMADD231PD

Multiplies together two double-precision floating-point vectors, negates the unrounded product, and adds it to a third double-precision floating-point vector. The precise result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFNMADDPD dest, src1, src2/mem, src3           // dest = -(src1 * src2/mem) + src3
VFNMADDPD dest, src1, src2, src3/mem          // dest = -(src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFNMADD132PD src1, src2, src3/mem             // src1 = -(src1 * src3/mem) + src2
VFNMADD213PD src1, src2, src3/mem           // src1 = -(src2 * src1) + src3/mem
VFNMADD231PD src1, src2, src3/mem           // src1 = -(src2 * src3/mem) + src1
```

When VEX.L = 0, the vector size is 128 bits (two double-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (four double-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFNMADDPD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMADD132PD, VFNMADD213PD, and VFNMADD231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMADDPS**VFNMADD132PS****VFNMADD213PS****VFNMADD231PS****Negative Multiply and Add
Packed Single-Precision Floating-Point**

Multiplies together two single-precision floating-point vectors, negates the unrounded product, and adds it to a third single-precision floating-point vector. The precise result is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFNMADDPS dest, src1, src2/mem, src3           // dest = -(src1 * src2/mem) + src3
VFNMADDPS dest, src1, src2, src3/mem          // dest = -(src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFNMADD132PS src1, src2, src3/mem             // src1 = -(src1 * src3/mem) + src2
VFNMADD213PS src1, src2, src3/mem            // src1 = -(src2 * src1) + src3/mem
VFNMADD231PS src1, src2, src3/mem            // src1 = -(src2 * src3/mem) + src1
```

When VEX.L = 0, the vector size is 128 bits (four single-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (eight single-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFNMADDPS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMADD132PS, VFNMADD213PS, and VFNMADD231PS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMADDSD Negative Multiply and Add VFNMADD132SD Scalar Double-Precision Floating-Point VFNMADD213SD VFNMADD231SD

Multiplies together two double-precision floating-point values, negates the unrounded product, and adds it to a third double-precision floating-point value. The precise result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFNMADDSD dest, src1, src2/mem, src3 // dest = -(src1 * src2/mem) + src3
VFNMADDSD dest, src1, src2, src3/mem // dest = -(src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFNMADD132SD src1, src2, src3/mem // src1 = -(src1 * src3/mem) + src2
VFNMADD213SD src1, src2, src3/mem // src1 = -(src2 * src1) + src3/mem
VFNMADD231SD src1, src2, src3/mem // src1 = -(src2 * src3/mem) + src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or 64-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is a register or 64-bit memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a 64-bit memory location.

The destination is an XMM register. When the result is written to the destination, bits [127:64] of the XMM register and bits [255:128] of the corresponding YMM register are cleared.

VFNMADDSD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMADD132SD, VFNMADD213SD, and VFNMADD231SD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

Overflow, OE			F	Rounded result too large to fit into the format of the destination operand.
Underflow, UE			F	Rounded result too small to fit into the format of the destination operand.
Precision, PE			F	A result could not be represented exactly in the destination format.
<i>F — FMA4 exception</i>				

VFMADDSS
VFMADD132SS
VFMADD213SS
VFMADD231SS

**Negative Multiply and Add
 Scalar Single-Precision Floating-Point**

Multiplies together two single-precision floating-point values, negates the unrounded product, and adds it to a third single-precision floating-point value. The precise result is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFMADDSS dest, src1, src2/mem, src3           // dest = -(src1 * src2/mem) + src3
VFMADDSS dest, src1, src2, src3/mem          // dest = -(src1 * src2) + src3/mem
```

and three three-operand forms:

```
VFMADD132SS src1, src2, src3/mem             // src1 = -(src1 * src3/mem) + src2
VFMADD213SS src1, src2, src3/mem            // src1 = -(src2 * src1) + src3/mem
VFMADD231SS src1, src2, src3/mem            // src1 = -(src2 * src3/mem) + src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or 32-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is a register or 32-bit memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a 32-bit memory location.

The destination is an XMM register. When the result is written to the destination, bits [127:32] of the XMM register and bits [255:128] of the corresponding YMM register are cleared.

VFMADDSS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFMADD132SS, VFMADD213SS, and VFMADD231SS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMSUBPD Negative Multiply and Subtract

VFNMSUB132PD Packed Double-Precision Floating-Point

VFNMSUB213PD

VFNMSUB231PD

Multiplies together two double-precision floating-point vectors, negates the unrounded product, and subtracts a third double-precision floating-point vector from it. The precise result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFNMSUBPD dest, src1, src2/mem, src3 // dest = -(src1 * src2/mem) - src3
VFNMSUBPD dest, src1, src2, src3/mem // dest = -(src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFNMSUB132PD src1, src2, src3/mem // src1 = -(src1 * src3/mem) - src2
VFNMSUB213PD src1, src2, src3/mem // src1 = -(src2 * src1) - src3/mem
VFNMSUB231PD src1, src2, src3/mem // src1 = -(src2 * src3/mem) - src1
```

When VEX.L = 0, the vector size is 128 bits (two double-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (four double-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFNMSUBPD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMSUB132PD, VFNMSUB213PD, and VFNMSUB231PD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMSUBPS Negative Multiply and Subtract

VFNMSUB132PS Packed Single-Precision Floating-Point

VFNMSUB213PS

VFNMSUB231PS

Multiplies together two single-precision floating-point vectors, negates the unrounded product, and subtracts a third single-precision floating-point vector from it. The precise result is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the vector equation in the comment on the right.

There are two four-operand forms:

```
VFNMADDPS dest, src1, src2/mem, src3 // dest = -(src1 * src2/mem) - src3
VFNMADDPS dest, src1, src2, src3/mem // dest = -(src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFNMADD132PS src1, src2, src3/mem // src1 = -(src1 * src3/mem) - src2
VFNMADD213PS src1, src2, src3/mem // src1 = -(src2 * src1) - src3/mem
VFNMADD231PS src1, src2, src3/mem // src1 = -(src2 * src3/mem) - src1
```

When VEX.L = 0, the vector size is 128 bits (four single-precision elements per vector) and register-based source operands are held in XMM registers.

When VEX.L = 1, the vector size is 256 bits (eight single-precision elements per vector) and register-based source operands are held in YMM registers.

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a memory location.

The destination is either an XMM register or a YMM register, as determined by VEX.L. When the destination is an XMM register (L = 0), bits [255:128] of the corresponding YMM register are cleared.

VFNMSUBPS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMSUB132PS, VFNMSUB213PS, and VFNMSUB231PS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

VFNMSUBSD Negative Multiply and Subtract VFNMSUB132SD Scalar Double-Precision Floating-Point VFNMSUB213SD VFNMSUB231SD

Multiplies together two double-precision floating-point values, negates the unrounded product, and subtracts a third double-precision floating-point value from it. The precise result is then rounded to double-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFNMSUBSD dest, src1, src2/mem, src3 // dest = -(src1 * src2/mem) - src3
VFNMSUBSD dest, src1, src2, src3/mem // dest = -(src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFNMSUB132SD src1, src2, src3/mem // src1 = -(src1 * src3/mem) - src2
VFNMSUB213SD src1, src2, src3/mem // src1 = -(src2 * src1) - src3/mem
VFNMSUB231SD src1, src2, src3/mem // src1 = -(src2 * src3/mem) - src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a 64-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a 64-bit memory location.

For the three-operand forms, VEX.W is 1. The first and second operands are registers and the third operand is either a register or a 64-bit memory location.

The destination is an XMM register. Bits [127:64] of the destination XMM register and bits [255:128] of the corresponding YMM register are cleared.

VFNMSUBSD is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMSUB132SD, VFNMSUB213SD, and VFNMSUB231SD are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

Underflow, UE			F	Rounded result too small to fit into the format of the destination operand.
Precision, PE			F	A result could not be represented exactly in the destination format.
<i>F — FMA4 exception</i>				

VFNMSUBSS

VFNMSUB132SS

VFNMSUB213SS

VFNMSUB231SS

Negative Multiply and Subtract Scalar Single-Precision Floating-Point

Multiplies together two single-precision floating-point values, negates the unrounded product, and subtracts a third single-precision floating-point value from it. The precise result is then rounded to single-precision based on the mode specified by the MXCSR[RC] field and written to the destination register. The role of each of the source operands specified by the assembly language prototypes given below is reflected in the equation in the comment on the right.

There are two four-operand forms:

```
VFNMSUBSS dest, src1, src2/mem, src3           // dest = -(src1 * src2/mem) - src3
VFNMSUBSS dest, src1, src2, src3/mem          // dest = -(src1 * src2) - src3/mem
```

and three three-operand forms:

```
VFNMSUB132SS src1, src2, src3/mem             // src1 = -(src1 * src3/mem) - src2
VFNMSUB213SS src1, src2, src3/mem            // src1 = -(src2 * src1) - src3/mem
VFNMSUB231SS src1, src2, src3/mem            // src1 = -(src2 * src3/mem) - src1
```

For the four-operand forms, VEX.W determines operand configuration.

- When VEX.W = 0, the second source is either a register or a 32-bit memory location and the third source is a register.
- When VEX.W = 1, the second source is a register and the third source is either a register or a 32-bit memory location.

For the three-operand forms, VEX.W is 0. The first and second operands are registers and the third operand is either a register or a 32-bit memory location.

The destination is an XMM register. Bits[127:32] of the destination XMM register and bits [255:128] of the corresponding YMM register are cleared.

VFNMSUBSS is an FMA4 instruction. Support for FMA4 instructions is indicated by CPUID Fn8000_00001_ECX[FMA4].

VFNMSUB132SS, VFNMSUB213SS, and VFNMSUB231SS are FMA instructions. Support for FMA instructions is indicated by CPUID Fn8000_00001_ECX[FMA].

For more information on the CPUID instruction and defined processor feature bits, see the CPUID Specification, order# 25481.

Precision, PE			F	A result could not be represented exactly in the destination format.
<i>F — FMA4 exception</i>				

VFRCZPD**Extract Fraction
Packed Double-Precision Floating-Point**

Extracts the fractional portion of each double-precision floating-point value of either a source register or a memory location and writes the resulting values to the corresponding elements of the destination. The fractional results are precise.

- When $XOP.L = 0$, the source is either an XMM register or a 128-bit memory location.
- When $XOP.L = 1$, the source is a YMM register or 256-bit memory location.

When the destination is an XMM register, bits [255:128] of the corresponding YMM register are cleared.

Exception conditions are the same as for other arithmetic instructions, except with respect to the sign of a zero result. A zero is returned in the following cases:

- When the operand is a zero.
- When the operand is a normal integer.
- When the operand is a denormal value and is coerced to zero by $MXCSR.DAZ$.
- When the operand is a denormal value that is not coerced to zero by $MXCSR.DAZ$.

In the first three cases, when $MXCSR.RC = 01b$ (round toward $-\infty$) the sign of the zero result is negative, and is otherwise positive.

In the fourth case, the operand is its own fractional part, which results in underflow, and the result is forced to zero by $MXCSR.FZ$; the result has the same sign as the operand.

This is an XOP instruction. Support for these instructions is indicated by CPUID $Fn8000_00001_ECX[XOP]$ (see the CPUID Specification, order# 25481).

VINSERTF128

Insert Packed Values 128-bit

Combines 128 bits of data from a YMM register with 128-bit packed-value data from an XMM register or a 128-bit memory location, as specified by an immediate byte operand, and writes the combined data to the destination.

Only bit [0] of the immediate operand is used. Operation is as follows.

- When `imm8[0] = 0`, copy bits [255:128] of the first source to bits [255:128] of the destination and copy bits [127:0] of the second source to bits [127:0] of the destination.
- When `imm8[0] = 1`, copy bits [127:0] of the first source to bits [127:0] of the destination and copy bits [127:0] of the second source to bits [255:128] of the destination.

This extended-form instruction has 256-bit encoding.

The first source operand is a YMM register. The second source operand is either an XMM register or a 128-bit memory location. The destination is a YMM register. There is a third immediate byte operand.

This is an AVX instruction. Support for these instructions is indicated by `CPUID Fn0000_00001_ECX[AVX]` (see the *CPUID Specification*, order# 25481).

A — AVX exception.

VMASKMOVPD**Masked Move
Packed Double-Precision**

Moves packed double-precision data elements from a source element to a destination element, as specified by mask bits in a source operand. There are load and store versions of the instruction.

For loads, the data elements are in a source memory location; for stores the data elements are in a source register. The mask bits are the msb of the corresponding data element of a source register.

- For loads, when a mask bit = 1, the corresponding data element is copied from the source to the same element of the destination; when a mask bit = 0, the corresponding element of the destination is cleared.
- For stores, when a mask bit = 1, the corresponding data element is copied from the source to the same element of the destination; when a mask bit = 0, the corresponding element of the destination is not affected.

XMM Encoding

There are load and store encodings.

- For loads, there are two 64-bit source data elements in a 128-bit memory location, the mask operand is an XMM register, and the destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- For stores, there are two 64-bit source data elements in an XMM register, the mask operand is another XMM register, and the destination is a 128-bit memory location.

YMM Encoding

There are load and store encodings.

- For loads, there are four 64-bit source data elements in a 256-bit memory location, the mask operand is a YMM register, and the destination is a YMM register.
- For stores, there are four 64-bit source data elements in a YMM register, the mask operand is another YMM register, and the destination is a 128-bit memory location.

This is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

VMASKMOVPS

Masked Move Packed Single-Precision

Moves packed single-precision data elements from a source element to a destination element, as specified by mask bits in a source operand. There are load and store versions of the instruction.

For loads, the data elements are in a source memory location; for stores the data elements are in a source register. The mask bits are the msb of the corresponding data element of a source register.

- For loads, when a mask bit = 1, the corresponding data element is copied from the source to the same element of the destination; when a mask bit = 0, the corresponding element of the destination is cleared.
- For stores, when a mask bit = 1, the corresponding data element is copied from the source to the same element of the destination; when a mask bit = 0, the corresponding element of the destination is not affected.

XMM Encoding

There are load and store encodings.

- For loads, there are four 32-bit source data elements in a 128-bit memory location, the mask operand is an XMM register, and the destination is an XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- For stores, there are four 32-bit source data elements in an XMM register, the mask operand is another XMM register, and the destination is a 128-bit memory location.

YMM Encoding

There are load and store encodings.

- For loads, there are eight 32-bit source data elements in a 256-bit memory location, the mask operand is a YMM register, and the destination is a YMM register.
- For stores, there are eight 32-bit source data elements in a YMM register, the mask operand is another YMM register, and the destination is a 128-bit memory location.

This is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

VPCMOV

Vector Conditional Move

Moves bits of either the first source or the second source to the corresponding positions in the destination, depending on the value of the corresponding bit of a third source.

When a bit of the third source = 1, the corresponding bit of the first source is moved to the destination; when a bit of the third source = 0, the corresponding bit of the second source is moved to the destination.

This instruction directly implements the C-language ternary “?” operation on each source bit.

Arbitrary bit-granular predicates can be constructed by any number of methods, or loaded as constants from memory. This instruction may use the results of any SSE instructions as the predicate in the selector. VPCMPEQB (VPCMPGTB), VPCMPEQW (VPCMPGTW), VPCMPEQD (VPCMPGTD) and VPCMPEQQ (VPCMPGTQ) compare bytes, words, doublewords, quadwords and integers, respectively, and set the predicate in the destination to masks of 1s and 0s accordingly. VCMPPS (VCMPPSS) and VCMPPD (VCMPPSD) compare word and doubleword floating-point source values, respectively, and provide the predicate for the floating-point instructions.

There are four operands: VPCMOV *dest*, *src1*, *src2*, *src3*.

The first source (*src1*) is an XMM or YMM register specified by XOP.vvvv.

XOP.W and bits [7:4] of an immediate byte (*imm8*) configure *src2* and *src3*:

- When XOP.W = 0, *src2* is either a register or a memory location specified by ModRM.r/m and *src3* is a register specified by *imm8*[7:4].
- When XOP.W = 1, *src2* is a register specified by *imm8*[7:4] and *src3* is either a register or a memory location specified by ModRM.r/m.

The destination (*dest*) is either an XMM or a YMM register, as determined by XOP.L. When the destination is an XMM register, bits [255:128] of the corresponding YMM register are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPCOMB

Compare Vector Signed Bytes

Compares corresponding packed signed bytes in the first and second sources and writes the result of each comparison in the corresponding byte of the destination. The result of each comparison is an 8-bit value of all 1s (TRUE) or all 0s (FALSE).

There are four operands: VPCOMB *dest, src1, src2, imm8*

The destination (*dest*) is an XMM registers specified by ModRM.reg. When the comparison results are written to the destination XMM register, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by the XOP.vvvv field and the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field.

The comparison type is specified by bits [2:0] of the immediate-byte operand (*imm8*). Each type has an alias mnemonic to facilitate coding.

<i>imm8</i> [2:0]	Comparison	Mnemonic
000	Less Than	VPCOMLTB
001	Less Than or Equal	VPCOMLEB
010	Greater Than	VPCOMGTB

VPCOMW

Compare Vector Signed Words

Compares corresponding packed signed words in the first and second sources and writes the result of each comparison in the corresponding word of the destination. The result of each comparison is a 16-bit value of all 1s (TRUE) or all 0s (FALSE).

There are four operands: VPCOMW *dest*, *src1*, *src2*, *imm8*

The destination (*dest*) is an XMM register specified by ModRM.reg. When the results are written to the destination XMM register, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by the XOP.vvvv field and the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field.

The comparison type is specified by bits [2:0] of an immediate-byte operand (*imm8*). Each type has an alias mnemonic to facilitate coding.

<i>imm8</i> [2:0]	Comparison	Mnemonic
000	Less Than	VPCOMLTW
001	Less Than or Equal	VPCOMLEW
010	Greater Than	VPCOMGTW
011	Greater Than or Equal	VPCOMGEW
100	Equal	VPCOMEQW
101	Not Equal	VPCOMNEQW
110	False	VPCOMFALSEW
111	True	VPCOMTRUEW

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

Instruction Encoding

<i>X — XOP exception</i>				

VPERM2F128**Permute Floating-Point
128-bit**

Copies 128-bit floating-point data elements from two 256-bit sources to two 128-bit elements of a 256-bit destination, as specified by an immediate byte operand.

The immediate operand is encoded as follows.

Destination	Immediate-Byte Bit Field	Value of Bit Field	Source 1 Bits Copied	Source 2 Bits Copied
[127:0]	[1:0]	00	[127:0]	—
		01	[255:128]	—
		10	—	[127:0]
		11	—	[255:128]
Setting <i>imm8</i> [3] clears bits [127:0] of the destination; <i>imm8</i> [2] is ignored.				
[255:128]	[5:4]	00	[127:0]	—
		01	[255:128]	—
		10	—	[127:0]
		11	—	[255:128]
Setting <i>imm8</i> [7] clears bits [255:128] of the destination; <i>imm8</i> [6] is ignored.				

This is a 256-bit extended-form instruction:

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

This is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

A — AVX exception.

VPERMIL2PD**Permute Two-Source
Double-Precision Floating-Point**

Copies a selected quadword from one of two source operands to a selected quadword of the destination or clears the selected quadword of the destination. Values in a third source operand and an immediate two-bit operand control the operation.

There are 128-bit and 256-bit versions of this instruction. Both versions have five operands:

VPERMIL2PD dest, src1, src2, src3, m2z.

The first four operands are either 128 bits or 256 bits wide, as determined by VEX.L. When the destination is an XMM register, bits [255:128] of the corresponding YMM register are cleared.

The third source operand is a selector that specifies how quadwords are copied or cleared in the destination. The selector contains one selector element for each quadword of the destination register.

Selector for 128-bit Instruction Form

127	S1	64 63	S0	0
-----	----	-------	----	---

The selector for the 128-bit instruction form is an octword composed of two quadword selector elements S0 and S1. S0 (the lower quadword) controls the value written to destination quadword 0 (bits [63:0]) and S1 (the upper quadword) controls the destination quadword 1 (bits [127:64]).

Selector for 256-bit Instruction Form

255	S3	192 191	S2	128
127	S1	64 63	S0	0

The selector for the 256-bit instruction form is a double octword and adds two more selector elements S2 and S3. S0 controls the value written to the destination quadword 0 (bits [63:0]), S1 controls the destination quadword 1 (bits [127:64]), S2 controls the destination quadword 2 (bits [191:128]), and S3 controls the destination quadword 3 (bits [255:192]).

The layout of each selector element is as follows:

63	Reserved, IGN	4 3 2 1 0
		M Sel

Bits	Mnemonic	Description
[63:4]	—	Reserved, IGN
[3]	M	Match
[2:1]	Sel	Select
[0]	—	Reserved, IGN

The fields are defined as follows:

- Sel — Select. Selects the source quadword to copy into the corresponding quadword of the destination:

Sel Value	Source Selected for Destination Quadwords 0 and 1 (both forms)	Source Selected for Destination Quadwords 2 and 3 (256-bit form)
00b	<i>src1</i> [63:0]	<i>src1</i> [191:128]
01b	<i>src1</i> [127:64]	<i>src1</i> [255:192]
10b	<i>src2</i> [63:0]	<i>src2</i> [191:128]
11b	<i>src2</i> [127:64]	<i>src2</i> [255:192]

- M — Match bit. The combination of the Match bit in each selector element and the value of the M2Z field determines if the Select field is overridden. This is described below.

***m2z* immediate operand**

The fifth operand is *m2z*. The assembler uses this 2-bit value to encode the M2Z field in the instruction. M2Z occupies bits [1:0] of an immediate byte. Bits [7:4] of the same byte are used to select one of 16 YMM/XMM registers. This dual use of the immediate byte is indicated in the instruction synopsis by the symbol “is5”.

The immediate byte is defined as follows.

Bits	Mnemonic	Description
[7:4]	SRS	Source Register Select
[3:2]	—	Reserved, IGN
[1:0]	M2Z	Match to Zero

Fields are defined as follows:

- SRS — Source Register Select. As with many other extended instructions, bits in the immediate byte are used to select a source operand register. This field is set by the assembler based on the operands listed in the instruction. See discussion in “*src2* and *src3* Operand Addressing” below.
- M2Z — Match to Zero. This field, combined with the M bit of the selector element, controls the function of the Sel field as follows:

M2Z Field	Selector M Bit	Value Loaded into Destination Quadword
0Xb	X	Source quadword selected by selector element Sel field.
10b	0	Source quadword selected by selector element Sel field.
10b	1	Zero
11b	0	Zero
11b	1	Source quadword selected by selector element Sel field.

src2 and src3 Operand Addressing

In 64-bit mode, VEX.W and bits [7:4] of the immediate byte specify *src2* and *src3*:

- When VEX.W = 0, *src2* is either a register or a memory location specified by ModRM.r/m and *src3* is a register specified by bits [7:4] of the immediate byte.
- When VEX.W = 1, *src2* is a register specified by bits [7:4] of the immediate byte and *src3* is either a register or a memory location specified by ModRM.r/m.

In non-64-bit mode, bit 7 is ignored.

Instruction Subset

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

VPERMIL2PS**Permute Two-Source
Single-Precision Floating-Point**

Copies a selected doubleword from one of two source operands to a selected doubleword of the destination or clears the selected doubleword of the destination. Values in a third source operand and an immediate two-bit operand control operation.

There are 128-bit and 256-bit versions of this instruction. Both versions have five operands:

VPERMIL2PS *dest, src1, src2, src3, m2z*

The first four operands are either 128 bits or 256 bits wide, as determined by VEX.L. When the destination is an XMM register, bits [255:128] of the corresponding YMM register are cleared.

The third source operand is a selector that specifies how doublewords are copied or cleared in the destination. The selector contains one selector element for each doubleword of the destination register.

Selector for 128-bit Instruction Form

127	96 95	64 63	32 31	0
S3	S2	S1	S0	

The selector for the 128-bit instruction form is an octword containing four selector elements S0–S3. S0 controls the value written to the destination doubleword 0 (bits [31:0]), S1 controls the destination doubleword 1 (bits [63:32]), S2 controls the destination doubleword 2 (bits [95:64]), and S3 controls the destination doubleword 3 (bits [127:96]).

Selector for 256-bit Instruction Form

255	224 223	192 191	160 159	128
S7	S6	S5	S4	
127	96 95	64 63	32 31	0
S3	S2	S1	S0	

The selector for the 256-bit instruction form is a double octword and adds four more selector elements S4–S7. S4 controls the value written to the destination doubleword 4 (bits [159:128]), S5 controls the destination doubleword 5 (bits [191:160]), S6 controls the destination doubleword 6 (bits [223:192]), and S7 controls the destination doubleword 7 (bits [255:224]).

The layout of each selector element is as follows.

31	4 3 2 1 0
Reserved, IGN	M Sel

Bits	Mnemonic	Description
[31:4]	—	Reserved, IGN
[3]	M	Match
[2:0]	Sel	Select

The fields are defined as follows:

- Sel — Select. Selects the source doubleword to copy into the corresponding doubleword of the destination:

Sel Value	Source Selected for Destination Doublewords 0, 1, 2 and 3 (both forms)	Source Selected for Destination Doublewords 4, 5, 6 and 7 (256-bit form)
000b	<i>src1</i> [31:0]	<i>src1</i> [159:128]
001b	<i>src1</i> [63:32]	<i>src1</i> [191:160]
010b	<i>src1</i> [95:64]	<i>src1</i> [223:192]
011b	<i>src1</i> [127:96]	<i>src1</i> [255:224]
100b	<i>src2</i> [31:0]	<i>src2</i> [159:128]
101b	<i>src2</i> [63:32]	<i>src2</i> [191:160]
110b	<i>src2</i> [95:64]	<i>src2</i> [223:192]
111b	<i>src2</i> [127:96]	<i>src2</i> [255:224]

- M — Match. The combination of the M bit in each selector element and the value of the M2Z field determines if the Sel field is overridden. This is described below.

***m2z* immediate operand**

The fifth operand is *m2z*. The assembler uses this 2-bit value to encode the M2Z field in the instruction. M2Z occupies bits [1:0] of an immediate byte. Bits [7:4] of the same byte are used to select one of 16 YMM/XMM registers. This dual use of the immediate byte is indicated in the instruction synopsis by the symbol “is5”.

The immediate byte is defined as follows.

Bits	Mnemonic	Description
[7:4]	SRS	Source Register Select
[3:2]	—	Reserved, IGN
[1:0]	M2Z	Match to Zero

Fields are defined as follows:

- SRS — Source Register Select. As with many other extended instructions, bits in the immediate byte are used to select a source operand register. This field is set by the assembler based on the operands listed in the instruction. See discussion in “*src2* and *src3* Operand Addressing” below.
- M2Z — Match to Zero. This field, combined with the M bit of the selector element, controls the function of the Sel field as follows:

M2Z Field	Selector M Bit	Value Loaded into Destination Doubleword
0Xb	X	Source doubleword selected by Sel field.
10b	0	Source doubleword selected by Sel field.

M2Z Field	Selector M Bit	Value Loaded into Destination Doubleword
10b	1	Zero
11b	0	Zero
11b	1	Source doubleword selected by Sel field.

src2 and src3 Operand Addressing

In 64-bit mode, VEX.W and bits [7:4] of the immediate byte specify *src2* and *src3*:

- When VEX.W = 0, *src2* is either a register or a memory location specified by ModRM.r/m and *src3* is a register specified by bits [7:4] of the immediate byte.
- When VEX.W = 1, *src2* is a register specified by bits [7:4] of the immediate byte and *src3* is either a register or a memory location specified by ModRM.r/m.

In non-64-bit mode, bit 7 is ignored.

Instruction Subset

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPERMILPD**Permute
Double-Precision**

Copies double-precision floating-point values from a source to a destination. Source and destination can be selected in two ways. There are different encodings for each selection method.

Selection by bits in a source register or memory location:

Each quadword of the operand is defined as follows.

A bit selects source and destination. Only bit [1] is used; bits [63:2] and bit [0] are ignored. Setting the bit selects the corresponding quadword element of the source and the destination.

Selection by bits in an immediate byte:

Each bit corresponds to a destination quadword. Only bits [3:2] and bits [1:0] are used; bits [7:4] are ignored. Selections are defined as follows.

Destination Quadword	Immediate-Byte Bit Field	Value of Bit Field	Source 1 Bits Copied
Used by 128-bit encoding and 256-bit encoding			
[63:0]	[0]	0	[63:0]
		1	[127:64]
[127:64]	[1]	0	[63:0]
		1	[127:64]
Used only by 256-bit encoding			
[191:128]	[2]	0	[191:128]
		1	[255:192]
[255:192]	[3]	0	[191:128]
		1	[255:192]

This extended-form instruction has both 128-bit and 256-bit encoding.

XMM Encoding

There are two encodings, one for each selection method:

- The first source operand is an XMM register. The second source operand is either an XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- The first source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. There is a third, immediate byte operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

There are two encodings, one for each selection method:

- The first source operand is a YMM register. The second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.
- The first source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register. There is a third, immediate byte operand.

This is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

VPERMILPS**Permute
Single-Precision**

Copies single-precision floating-point values from a source to a destination. Source and destination can be selected in two ways. There are different encodings for each selection method.

Selection by bit fields in a source register or memory location:

Each doubleword of the operand is defined as follows.

Each bit field corresponds to a destination doubleword. Bit values select a source doubleword. Only bits [1:0] of each word are used; bits [31:2] are ignored. The 128-bit encoding uses four two-bit fields; the 256-bit version uses eight two-bit fields. Field encoding is as follows.

Destination Doubleword	Immediate Operand Bit Field	Value of Bit Field	Source Bits Copied
[31:0]	[1:0]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]
[63:32]	[33:32]	00	[31:0]
		01	[63:32]

		01	[191:160]
		10	[223:192]
		11	[255:224]

Selection by bit fields in an immediate byte:

Each bit field corresponds to a destination doubleword. For the 256-bit encoding, the fields specify sources and destinations in both the upper and lower 128 bits of the register. Selections are defined as follows.

Destination Doubleword	Bit Field	Value of Bit Field	Source Bits Copied
[31:0]	[1:0]	00	[31:0]
		01	[63:32]
		10	[95:64]
		11	[127:96]

[255:224]	[7:6]	00	[159:128]
		01	[191:160]
		10	[223:192]
		11	[255:224]

This extended-form instruction has both 128-bit and 256-bit encodings:

XMM Encoding

There are two encodings, one for each selection method:

- The first source operand is an XMM register. The second source operand is either an XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.
- The first source operand is either an XMM register or a 128-bit memory location. The destination is an XMM register. There is a third, immediate byte operand. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

There are two encodings, one for each selection method:

- The first source operand is a YMM register. The second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.
- The first source operand is either a YMM register or a 256-bit memory location. The destination is a YMM register. There is a third, immediate byte operand.

This is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

General protection, #GP			A	Memory address exceeding data segment limit or non-canonical.
			A	Null data segment used to reference memory.
Page fault, #PF			A	Instruction execution caused a page fault.
Alignment check, #AC			A	4 or 8-byte unaligned memory reference with alignment checking enabled and MXCSR.MM = 1.
A — AVX exception.				

VPHADDBD**Packed Horizontal Add
Signed Byte to Signed Doubleword**

Adds four sets of four 8-bit signed integer values of the source and packs the sign-extended sums into the corresponding doubleword of the destination.

There are two operands: VPHADDBD *dest, src*

The destination is an XMM register and the source is either an XMM register or a 128-bit memory location. Bits [255:128] of the corresponding YMM register are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_0001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPHADDUWQ**Packed Horizontal Add
Unsigned Word to Quadword**

Adds two pairs of 16-bit unsigned integer values of the source and packs the sums into the corresponding quadword element of the destination.

There are two operands: VPHADDUWQ *dest, src*

The destination is an XMM register and the source is either an XMM register or a 128-bit memory location. Bits [255:128] of the corresponding YMM register are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_0001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSDDD**Packed Multiply Accumulate Signed Doubleword to Signed Doubleword**

Multiplies each packed 32-bit signed integer value of the first source by the corresponding value of the second source, adds the corresponding value of the third source to the 64-bit signed integer product, and writes four 32-bit sums to the destination.

No saturation is performed on the sum. When the result of the multiplication causes non-zero values to be set in the upper 32 bits of the 64-bit product, they are ignored. When the result of the add overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set). In both cases, only the signed low-order 32 bits of the result are written to the destination.

There are four operands: $VPMACSDDD\ dest, src1, src2, src3$ $dest = src1 * src2 + src3$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by XOP.vvvv; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When the third source designates the same XMM register as the destination, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

<i>X — XOP exception</i>				

VPMACSDQH**Packed Multiply Accumulate
Signed High Doubleword to Signed Quadword**

Multiplies the second 32-bit signed integer value of the first source by the corresponding value of the second source, then adds the low-order 64-bit signed integer value of the third source to the 64-bit signed integer product. Simultaneously, multiplies the fourth 32-bit signed integer value of the first source by the fourth 32-bit signed integer value of the second source, then adds the high-order 64-bit signed integer value of the third source to the 64-bit signed integer product. Writes two 64-bit sums to the destination.

No saturation is performed on the sum. When the result of the add overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set).

There are four operands: $VPMACSDQH\ dest, src1, src2, src3$ $dest = src1 * src2 + src3$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by the XOP.vvvv field; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When the third source designates the same XMM register as the destination, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSSDD Packed Multiply Accumulate with Saturation Signed Doubleword to Signed Doubleword

Multiplies each packed 32-bit signed integer value of the first source by the corresponding value of the second source, then adds the corresponding packed 32-bit signed integer value of the third source to each 64-bit signed integer product. Writes four saturated 32-bit sums to the destination.

Out of range results of the addition are saturated to fit into a signed 32-bit integer. For each packed value of the destination, when the value is larger than the largest signed 32-bit integer, it is saturated to 7FFF_FFFFh, and when the value is smaller than the smallest signed 32-bit integer, it is saturated to 8000_0000h.

There are four operands: VPMACSSDD *dest, src1, src2, src3* $dest = src1 * src2 + src3$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by XOP.vvvv; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSSDQH Packed Multiply Accumulate with Saturation Signed High Doubleword to Signed Quadword

Multiplies the second 32-bit signed integer value of the first source by the corresponding value of the second source, then adds the low-order 64-bit signed integer value of the third source to the 64-bit signed integer product. Simultaneously, multiplies the fourth 32-bit signed integer value of the first source by the corresponding value of the second source, then adds the high-order 64-bit signed integer value of the third source to the 64-bit signed integer product. Writes two saturated sums to the destination.

Out of range results of the addition are saturated to fit into a signed 64-bit integer. For each packed value of the destination, when the value is larger than the largest signed 64-bit integer, it is saturated to 7FFF_FFFF_FFFF_FFFFh, and when the value is smaller than the smallest signed 64-bit integer, it is saturated to 8000_0000_0000_0000h.

There are four operands: $VPMACSSDQH\ dest, src1, src2, src3$ $dest = src1 * src2 + src3$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination XMM register is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by XOP.vvvv; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSSWD Packed Multiply Accumulate with Saturation Signed Word to Signed Doubleword

Multiplies the odd-numbered packed 16-bit signed integer values of the first source by the corresponding values of the second source, then adds the corresponding packed 32-bit signed integer values of the third source to the 32-bit signed integer products. Writes four saturated sums to the destination.

Out of range results of the addition are saturated to fit into a signed 32-bit integer. For each packed value of the destination, when the value is larger than the largest signed 32-bit integer, it is saturated to 7FFF_FFFFh, and when the value is smaller than the smallest signed 32-bit integer, it is saturated to 8000_0000h.

There are four operands:

VPMACSSWD *dest, src1, src2, src3* $dest = src1 * src2 + src3$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination XMM register is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by the XOP.vvvv field; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSWD**Packed Multiply Accumulate Signed Word to Signed Doubleword**

Multiplies each odd-numbered packed 16-bit signed integer value of the first source by the corresponding value of the second source, then adds the corresponding packed 32-bit signed integer value of the third source to the 32-bit signed integer products. Writes four 32-bit results to the destination.

When the result of the add overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set). Only the low-order 32 bits of the result are written to the destination.

There are four operands: $VPMACSWD\ dest, src1, src2, src3$ $dest = src1 * src2 + src3$

The destination (*dest*) register is an XMM register specified by ModRM.reg. When the destination XMM register is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by XOP.vvvv; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMACSWW

Packed Multiply Accumulate Signed Word to Signed Word

Multiplies each packed 16-bit signed integer value of the first source by the corresponding value of the second source, then adds the corresponding packed 16-bit signed integer value of the third source to each 32-bit signed integer product. Writes eight 16-bit results to the destination.

No saturation is performed on the sum. When the result of the multiplication causes non-zero values to be set in the upper 16 bits of the 32 bit result, they are ignored. When the result of the add overflows, the carry is ignored (neither the overflow nor carry bit in rFLAGS is set). In both cases, only the signed low-order 16 bits of the result are written to the destination.

There are four operands: $VPMACSWW \text{ dest}, \text{src1}, \text{src2}, \text{src3}$ $\text{dest} = \text{src1} * \text{src2} + \text{src3}$

The destination (*dest*) is an XMM register specified by ModRM.reg. When the destination XMM register is written, bits [255:128] of the corresponding YMM register are cleared.

The first source (*src1*) is an XMM register specified by XOP.vvvv; the second source (*src2*) is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source (*src3*) is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPMADCSSWD Packed Multiply Add Accumulate with Saturation Signed Word to Signed Doubleword

Multiplies each packed 16-bit signed integer value of the first source by the corresponding value of the second source, then adds the 32-bit signed integer products of the even-odd adjacent words. Each resulting sum is then added to the corresponding packed 32-bit signed integer value of the third source. Writes four 16-bit results to the destination.

Out of range results of the addition are saturated to fit into a signed 32-bit integer. For each packed value of the destination, when the value is larger than the largest signed 32-bit integer, it is saturated to 7FFF_FFFFh, and when the value is smaller than the smallest signed 32-bit integer, it is saturated to 8000_0000h.

There are four operands: VPMADCSSWD *dest, src1, src2, src3* $dest = src1 * src2 + src3$

The destination is an XMM register specified by ModRM.reg. When the destination is written, bits [255:128] of the corresponding YMM register are cleared.

The first source is an XMM register specified by XOP.vvvv; the second source is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field; and the third source is an XMM register specified by bits [7:4] of an immediate byte operand.

When *src3* designates the same XMM register as the *dest* register, the XMM register behaves as an accumulator.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPPERM

Packed Permute
Bytes

Selects 16 of 32 packed bytes from two concatenated sources, applies a logical transformation to each selected byte, then writes the byte to a specified position in the destination.

There are four operands: VPPERM *dest*, *src1*, *src2*, *src3*

The second (*src2*) and first (*src1*) sources are concatenated to form the 32-byte source.

The *src1* operand is an XMM register specified by XOP.vvvv.

The third source (*src3*) contains 16 control bytes. Each control byte specifies the source byte and the logical operation to perform on that byte. The order of the bytes in the destination is the same as that of the control bytes in the *src3*.

For each byte of the 16-byte result, the corresponding *src3* byte is used as follows:

- Bits [7:5] select a logical operation to perform on the selected byte.

Bit Value	Selected Operation
000	Source byte (no logical operation)
001	Invert source byte
010	Bit reverse of source byte
011	Bit reverse of inverted source byte
100	00h (zero-fill)
101	FFh (ones-fill)
110	Most significant bit of source byte replicated in all bit positions.
111	Invert most significant bit of source byte and replicate in all bit positions.

- Bits [4:0] select a source byte to move from *src2:src1*.

Bit Value	Source Byte	Bit Value	Source Byte	Bit Value	Source Byte	Bit Value	Source Byte
00000	<i>src1</i> [7:0]	01000	<i>src1</i> [71:64]	10000	<i>src2</i> [7:0]	11000	<i>src2</i> [71:64]
00001	<i>src1</i> [15:8]	01001	<i>src1</i> [79:72]	10001	<i>src2</i> [15:8]	11001	<i>src2</i> [79:72]
00010	<i>src1</i> [23:16]	01010	<i>src1</i> [87:80]	10010	<i>src2</i> [23:16]	11010	<i>src2</i> [87:80]
00011	<i>src1</i> [31:24]	01011	<i>src1</i> [95:88]	10011	<i>src2</i> [31:24]	11011	<i>src2</i> [95:88]
00100	<i>src1</i> [39:32]	01100	<i>src1</i> [103:96]	10100	<i>src2</i> [39:32]	11100	<i>src2</i> [103:96]
00101	<i>src1</i> [47:40]	01101	<i>src1</i> [111:104]	10101	<i>src2</i> [47:40]	11101	<i>src2</i> [111:104]
00110	<i>src1</i> [55:48]	01110	<i>src1</i> [119:112]	10110	<i>src2</i> [55:48]	11110	<i>src2</i> [119:112]
00111	<i>src1</i> [63:56]	01111	<i>src1</i> [127:120]	10111	<i>src2</i> [63:56]	11111	<i>src2</i> [127:120]

XOP.W and an immediate byte (*imm8*) determine register configuration.

- When XOP.W = 0, *src2* is either an XMM register or a 128-bit memory location specified by ModRM.r/m and *src3* is an XMM register specified by *imm8*[7:4].

- When XOP.W = 1, *src2* is an XMM register specified by *imm8[7:4]* and *src3* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.

The destination (*dest*) is an XMM register specified by ModRM.reg. When the result is written to the *dest* XMM register, bits [255:128] of the corresponding YMM register are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPROTB

Packed Rotate Bytes

Rotates each byte of the source as specified by a count operand and writes the result to the corresponding byte of the destination.

There are two versions of the instruction, one for each source of the count byte:

- VPROTB *dest, src, fixed-count*
- VPROTB *dest, src, variable-count*

For both versions of the instruction, the destination (*dest*) operand is an XMM register specified by ModRM.reg.

The *fixed-count* version of the instruction rotates each byte of the source (*src*) the number of bits specified by the immediate *fixed-count* byte. All bytes are rotated the same amount. The source XMM register or memory location is selected by the ModRM.r/m field.

The *variable-count* version of the instruction rotates each byte of the source the amount specified in the corresponding byte element of the *variable-count*. Both *src* and *variable-count* are configured by XOP.W.

- When XOP.W = 0, *variable-count* is an XMM register specified by XOP.vvvv and *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.
- When XOP.W = 1, *variable-count* is either an XMM register or a 128-bit memory location specified by ModRM.r/m and *src* is an XMM register specified by XOP.vvvv.

When the count value is positive, bits are rotated to the left (toward the more significant bit positions). The bits rotated out left of the most significant bit are rotated back in at the right end (least-significant bit) of the byte.

When the count value is negative, bits are rotated to the right (toward the least significant bit positions). The bits rotated to the right out of the least significant bit are rotated back in at the left end (most-significant bit) of the byte.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPROTD

Packed Rotate Doublewords

Rotates each doubleword of the source as specified by a count operand and writes the result to the corresponding doubleword of the destination.

There are two versions of the instruction, one for each source of the count byte:

- VPROTD *dest, src, fixed-count*
- VPROTD *dest, src, variable-count*

For both versions of the instruction, the *dest* operand is an XMM register specified by ModRM.reg.

The fixed count version of the instruction rotates each doubleword of the source operand the number of bits specified by the immediate *fixed-count* byte operand. All doublewords are rotated the same amount. The *src* XMM register or memory location is selected by the ModRM.r/m field.

The variable count version of the instruction rotates each doubleword of the source by the amount specified in the low order byte of the corresponding doubleword of the *variable-count* operand vector.

Both *src* and *variable-count* are configured by XOP.W.

- When XOP.W = 0, *src* is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field and *variable-count* is an XMM register specified by XOP.vvvv.
- When XOP.W = 1, *src* is an XMM register specified by XOP.vvvv and *variable-count* is either an XMM register or a 128-bit memory location specified by the ModRM.r/m field.

When the count value is positive, bits are rotated to the left (toward the more significant bit positions). The bits rotated out to the left of the most significant bit of each source doubleword operand are rotated back in at the right end (least-significant bit) of the doubleword.

When the count value is negative, bits are rotated to the right (toward the least significant bit positions). The bits rotated to the right out of the least significant bit of each source doubleword operand are rotated back in at the left end (most-significant bit) of the doubleword.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPROTQ

Packed Rotate Quadwords

Rotates each quadword of the source operand as specified by a count operand and writes the result to the corresponding quadword of the destination.

There are two versions of the instruction, one for each source of the count byte:

- VPROTQ *dest, src, fixed-count*
- VPROTQ *dest, src, variable-count*

For both versions of the instruction, the *dest* operand is an XMM register specified by ModRM.reg.

The fixed count version of the instruction rotates each quadword in the source the number of bits specified by the immediate *fixed-count* byte operand. All quadword elements of the source are rotated the same amount. The *src* XMM register or memory location is selected by the ModRM.r/m field.

The variable count version of the instruction rotates each quadword of the source the amount specified by the low order byte of the corresponding quadword of the *variable-count* operand.

Both *src* and *variable-count* are configured by XOP.W.

- When XOP.W = 0, *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m and *variable-count* is an XMM register specified by XOP.vvvv.
- When XOP.W = 1, *src* is an XMM register specified by XOP.vvvv and *variable-count* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.

When the count value is positive, bits are rotated to the left (toward the more significant bit positions) of the operand element. The bits rotated out to the left of the most significant bit of the word element are rotated back in at the right end (least-significant bit).

When the count value is negative, operand element bits are rotated to the right (toward the least significant bit positions). The bits rotated to the right out of the least significant bit are rotated back in at the left end (most-significant bit) of the word element.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPROTW

Packed Rotate Words

Rotates each word of the source as specified by a count operand and writes the result to the corresponding word of the destination.

There are two versions of the instruction, one for each source of the count byte:

- VPROTW *dest, src, fixed-count*
- VPROTW *dest, src, variable-count*

For both versions of the instruction, the *dest* operand is an XMM register specified by ModRM.reg.

The fixed count version of the instruction rotates each word of the source the number of bits specified by the immediate *fixed-count* byte operand. All words of the source operand are rotated the same amount. The *src* XMM register or memory location is selected by the ModRM.r/m field.

The variable count version of this instruction rotates each word of the source operand by the amount specified in the low order byte of the corresponding word of the *variable-count* operand.

Both *src* and *variable-count* are configured by XOP.W.

- When XOP.W = 0, *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m and *variable-count* is an XMM register specified by XOP.vvvv.
- When XOP.W = 1, *src* is an XMM register specified by XOP.vvvv and *variable-count* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.

When the count value is positive, bits are rotated to the left (toward the more significant bit positions). The bits rotated out to the left of the most significant bit of an element are rotated back in at the right end (least-significant bit) of the word element.

When the count value is negative, bits are rotated to the right (toward the least significant bit positions) of the element. The bits rotated to the right out of the least significant bit of an element are rotated back in at the left end (most-significant bit) of the word element.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPSHAB

Packed Shift Arithmetic Bytes

Shifts each signed byte of the source as specified by a count byte and writes the result to the corresponding byte of the destination.

The count bytes are 8-bit signed two's-complement values in the corresponding bytes of the *count* operand.

When the count value is positive, bits are shifted to the left (toward the more significant bit positions). Zeros are shifted in at the right end (least-significant bit) of the byte.

When the count value is negative, bits are shifted to the right (toward the least significant bit positions). The most significant bit (sign bit) is replicated and shifted in at the left end (most-significant bit) of the byte.

There are three operands: VPSHAB *dest*, *src*, *count*

The destination (*dest*) is an XMM register specified by ModRM.reg.

Both *src* and *count* are configured by XOP.W.

- When XOP.W = 0, *count* is an XMM register specified by XOP.vvvv and *src* is either an XMM register or a 128-bit memory location specified by ModRM.r/m.
- When XOP.W = 1, *count* is either an XMM register or a 128-bit memory location specified by ModRM.r/m and *src* is an XMM register specified by XOP.vvvv.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPSHLB

Packed Shift Logical Bytes

Shifts each packed byte of the source as specified by a count byte and writes the result to the corresponding byte of the destination.

The count bytes are 8-bit signed two's-complement values located in the corresponding byte element of the *count* operand.

When the count value is positive, bits are shifted to the left (toward the more significant bit positions). Zeros are shifted in at the right end (least-significant bit) of the byte.

When the count value is negative, bits are shifted to the right (toward the least significant bit positions). Zeros are shifted in at the left end (most-significant bit) of the byte.

There are three operands: VPSHLB *dest, src, count*

The destination (*dest*) is an XMM register specified by ModRM.reg.

Both *src* and *count* are configured by XOP.W.

- When XOP.W = 0, *count* is an XMM register specified by XOP.vvvv and *src* is either an XMM register or a memory location specified by ModRM.r/m.
- When XOP.W = 1, *count* is either an XMM register or a memory location specified by ModRM.r/m and *src* is an XMM register specified by XOP.vvvv.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPSHLD

Packed Shift Logical Doublewords

Shifts each doubleword of the source operand as specified by a count byte and writes the result to the corresponding doubleword of the destination.

The count bytes are 8-bit signed two's-complement values located in the low-order byte of the corresponding doubleword element of the *count* operand.

When the count value is positive, bits are shifted to the left (toward the more significant bit positions). Zeros are shifted in at the right end (least-significant bit) of the doubleword.

When the count value is negative, bits are shifted to the right (toward the least significant bit positions). Zeros are shifted in at the left end (most-significant bit) of the doubleword.

The shift amount is stored in two's-complement form. The count is modulo 32.

There are three operands: *VPSHLD dest, src, count*

The destination (*dest*) is an XMM register specified by ModRM.reg.

Both *src* and *count* are configured by XOP.W.

- When XOP.W = 0, *count* is an XMM register specified by XOP.vvvv and *src* is either an XMM register or a memory location specified by ModRM.r/m.
- When XOP.W = 1, *count* is either an XMM register or a memory location specified by ModRM.r/m and *src* is an XMM register specified by XOP.vvvv.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VPSHLQ**Packed Shift Logical
Quadwords**

Shifts each quadword of the source by as specified by a count byte and writes the result in the corresponding quadword of the destination.

The count bytes are 8-bit signed two's-complement values located in the low-order byte of the corresponding quadword element of the *count* operand.

Bit 6 of the count byte is ignored.

When the count value is positive, bits are shifted to the left (toward the more significant bit positions). Zeros are shifted in at the right end (least-significant bit) of the quadword.

When the count value is negative, bits are shifted to the right (toward the least significant bit positions). Zeros are shifted in at the left end (most-significant bit) of the quadword.

There are three operands: *VPSHLQ dest, src, count*

The destination (*dest*) is an XMM register specified by ModRM.reg.

Both *src* and *count* are configured by XOP.W.

- When XOP.W = 0, *count* is an XMM register specified by XOP.vvvv and *src* is either an XMM register or a memory location specified by ModRM.r/m.
- When XOP.W = 1, *count* is either an XMM register or a memory location specified by ModRM.r/m and *src* is an XMM register specified by XOP.vvvv.

Bits [255:128] of the YMM register that corresponds to the destination are cleared.

This is an XOP instruction. Support for these instructions is indicated by CPUID Fn8000_00001_ECX[XOP] (see the CPUID Specification, order# 25481).

VTESTPD

Packed Bit Test

Tests whether selected bits in the first source operand are all zeros or all ones. The second source operand selects the bits to test.

First, performs a bitwise AND of the sign bits of each double-precision floating-point element of the first source operand with the sign bits of the corresponding elements of the second source operand. Sets rFLAGS.ZF when all bit operations = 0; else, clears ZF.

Second, performs a bitwise AND of the sign bits of each double-precision floating-point element of the first source with the complements (NOT) of the sign bits of the corresponding elements of the second source operand. Sets rFLAGS.CF when all bit operations = 0; else, clears CF.

Neither source operand is modified.

This extended-form instruction has both 128-bit and 256-bit encoding.

XMM Encoding

The first source operand is an XMM register. The second source operand is either an XMM register or a 128-bit memory location.

YMM Encoding

The first source operand is a YMM register. The second source operand is either a YMM register or a 256-bit memory location.

VTESTPD is an AVX instruction. Support for these instructions is indicated by CPUID feature identifiers (see the CPUID Specification, order# 25481).

XORPD VXORPD

XOR Packed Double-Precision Floating-Point

Performs bitwise XOR of two packed double-precision floating-point values in the first source operand with the corresponding values of the second source operand and writes the results into the corresponding elements of the destination.

There are legacy and extended forms of the instruction:

XORPD

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VXORPD

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

XORPD is an SSE2 instruction and VXORPD is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

XORPS XOR VXORPS Packed Single-Precision Floating-Point

Performs bitwise XOR of four packed single-precision floating-point values in the first source operand with the corresponding values of the second source operand and writes the results into the corresponding elements of the destination.

There are legacy and extended forms of the instruction:

XORPS

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The first source register is also the destination. Bits [255:128] of the YMM register that corresponds to the destination are not affected.

VXORPS

The extended form of the instruction has both 128-bit and 256-bit encodings:

XMM Encoding

The first source operand is an XMM register. The second source operand is either another XMM register or a 128-bit memory location. The destination is a third XMM register. Bits [255:128] of the YMM register that corresponds to the destination are cleared.

YMM Encoding

The first source operand is a YMM register and the second source operand is either a YMM register or a 256-bit memory location. The destination is a third YMM register.

XORPS is an SSE2 instruction and VXORPS is an AVX instruction. Support for these instructions is indicated by CPUID Fn0000_00001_EDX[SSE2] and Fn0000_00001_ECX[AVX] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description

XGETBV**Get Extended Control Register Value**

Copies the content of the extended control register (XCR) specified by the ECX register into the EDX:EAX register pair. The high-order 32 bits of the XCR are loaded into EDX and the low-order 32 bits are loaded into EAX. The corresponding high-order 32 bits of RAX and RDX are cleared.

This instruction and associated data structures extend the FXSAVE/FXRSTOR memory image used to manage processor states and provide additional functionality. See Listing for the instruction XSAVE – Save Extended States for more information.

Values returned to EDX:EAX in unimplemented bit locations are undefined.

Specifying a reserved or unimplemented XCR in ECX causes a general protection exception.

Currently, only XCR0 (the XFEATURE_ENABLED_MASK register) is supported. All other values of ECX are reserved.

XGETBV is an XSAVE/XRSTOR instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[XSAVE] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
XGETBV	0F 01 D0	Copies content of the XCR specified by ECX into EDX:EAX.

Related Instructions

Exceptions

Exception	Mode			Cause of Exception
	Real	Virt	Prot	
Invalid opcode, #UD	X	X	X	Instruction not supported, as indicated by CPUID feature identifier.
	X	X	X	Lock prefix (F0h) preceding opcode.
	X	X	X	CR4[OSFXSR] = 0
General protection, #GP	X	X	X	ECX specifies a reserved or unimplemented XCR address.
<i>X — exception generated</i>				

XRSTOR

Restore Extended States

Restores processor state from memory.

This instruction and associated data structures extend the FXSAVE/FXRSTOR memory image used to manage processor states and provide additional functionality. See Listing for the instruction XSAVE – Save Extended States for more information.

The XSAVE/XRSTOR save area consists of a header section and individual save areas for each processor state component. A component save area is updated when both the corresponding bits in the mask operand (EDX:EAX) and the XFEATURE_ENABLED_MASK (XCR0) register are set. A component save area is not updated when either of the corresponding bits in EDX:EAX or XCR0 is cleared. Updated state is either loaded from memory or set directly to hardware-specified initial values, depending on the corresponding `xstate_bv` bit in the save area header.

Software can set any bit in EDX:EAX, regardless of whether the bit position in XCR0 is valid for the processor. When the mask operand contains all 1's, all processor state components enabled in XCR0 are updated.

XRSTOR is an XSAVE/XRSTOR instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[XSAVE] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
XRSTOR <i>mem</i>	0F AE /5	Restores user-specified processor state from memory.

	X	X	X	CR4.OSFXSR = 0.
	X	X	X	Lock prefix (F0h) preceding opcode.
Device not available, #NM	X	X	X	CR0.TS = 1.
Stack, #SS	X	X	X	Memory address exceeding stack segment limit or non-canonical.

Exceptions

Exception	Mode			Cause of Exception
	Real	Virt	Prot	
General protection, #GP	X	X	X	Memory address exceeding data segment limit or non-canonical.
	X	X	X	Null data segment used to reference memory.
	X	X	X	Memory operand not aligned on 64-byte boundary.
	X	X	X	Any must be zero (MBZ) bits in the save area were set.
	X	X	X	Attempt to set reserved bits in MXCSR.
Page fault, #PF	X	X	X	Instruction execution caused a page fault.
<i>X — exception generated</i>				

XSAVE

Save Extended States

Saves a user-defined subset of enabled processor state data to a specified memory address.

This instruction and associated data structures extend the FXSAVE/FXRSTOR memory image used to manage processor states and provide additional functionality.

The XSAVE/XRSTOR save area consists of a header section, and individual save areas for each processor state component. A component is saved when both the corresponding bits in the mask operand (EDX:EAX) and the XFEATURE_ENABLED_MASK (XCR0) register are set. A component is not saved when either of the corresponding bits in EDX:EAX or XCR0 is cleared.

Software can set any bit in EDX:EAX, regardless of whether the bit position in XCR0 is valid for the processor. When the mask operand contains all 1's, all processor state components enabled in XCR0 are saved.

For each component saved, XSAVE sets the corresponding bit in the XSTATE_BV field of the save area header. XSAVE does not clear XSTATE_BV bits or modify individual save areas for components that are not saved. If a saved component is in the hardware-specified initialized state, XSAVE may clear the corresponding XSTATE_BV bit instead of setting it. This optimization is implementation-dependent.

XSAVE is an XSAVE/XRSTOR instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[XSAVE] (see the CPUID Specification, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
XSAVE <i>mem</i>	0F AE /4	Saves user-specified processor state to memory.

	X	X	X	Null data segment used to reference memory.
	X	X	X	Memory operand not aligned on 64-byte boundary.
	X	X	X	Attempt to write read-only memory.
Page fault, #PF	X	X	X	Instruction execution caused a page fault.
<i>X — exception generated</i>				

XSAVEOPT

Save Extended States Performance Optimized

Saves a user-defined subset of enabled processor state data to a specified memory address.

This instruction and associated data structures extend the FXSAVE/FXRSTOR memory image used to manage processor states and provide additional functionality. See Listing for the instruction XSAVE – Save Extended States for more information.

The XSAVE/XRSTOR save area consists of a header section, and individual save areas for each processor state component. A component is saved when both the corresponding bits in the mask operand (EDX:EAX) and the XFEATURE_ENABLED_MASK (XCR0) register are set. A component is not saved when either of the corresponding bits in EDX:EAX or XCR0 is cleared.

Software can set any bit in EDX:EAX, regardless of whether the bit position in XCR0 is valid for the processor. When the mask operand contains all 1's, all processor state components enabled in XCR0 are saved.

For each component saved, XSAVEOPT sets the corresponding bit in the XSTATE_BV field of the save area header. XSAVEOPT does not clear XSTATE_BV bits or modify individual save areas for components that are not saved. If a saved component is in the hardware-specified initialized state, XSAVEOPT may clear the corresponding XSTATE_BV bit instead of setting it. This optimization is implementation-dependent.

XSAVEOPT may provide other implementation-specific optimizations.

Support for XSAVEOPT is indicated by CPUID Fn0000_0000D_EAX_x1[XSAVEOPT] (see the CPUID Specification, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
XSAVEOPT <i>mem</i>	0F AE /6	Saves user-specified processor state to memory.

Related Instructions

XGETBV, XRSTOR, XSAVE, XSETBV

rFLAGS Affected

General protection, #GP	X	X	X	Memory address exceeding data segment limit or non-canonical.
	X	X	X	Null data segment used to reference memory.
	X	X	X	Memory operand not aligned on 64-byte boundary.
	X	X	X	Attempt to write read-only memory.
Page fault, #PF	X	X	X	Instruction execution caused a page fault.
<i>X — exception generated</i>				

XSETBV

Set Extended Control Register Value

Writes the content of the EDX:EAX register pair into the extended control register (XCR) specified by the ECX register. The high-order 32 bits of the XCR are loaded from EDX and the low-order 32 bits are loaded from EAX. The corresponding high-order 32 bits of RAX and RDX are ignored.

This instruction and associated data structures extend the FXSAVE/FXRSTOR memory image used to manage processor states and provide additional functionality. See Listing for the instruction XSAVE – Save Extended States for more information.

Currently, only the XFEATURE_ENABLED_MASK register (XCR0) is supported. Specifying a reserved or unimplemented XCR in ECX causes a general protection exception (#GP).

Executing XSETBV at a privilege level other than 0 causes a general-protection exception. A general protection exception also occurs when software attempts to write to reserved bits of an XCR.

The XGETBV instruction is an XSAVE/XRSTOR instruction. Support for these instructions is indicated by CPUID Fn0000_00001_ECX[XSAVE] (see the *CPUID Specification*, order# 25481).

Instruction Encoding

Mnemonic	Opcode	Description
XSETBV	0F 01 D1	Writes the content of the EDX:EAX register pair to the XCR specified by the ECX register.

Related Instructions
