The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a *contiguous output address range*. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, referring to [Figure G3-21 on page G3-3607](#), to use this hint for a block of 16 entries in the third-level translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

### ———— Note —————

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

### Field reserved for software use

The architecture reserves a 4-bit field in the Block and Page table descriptors for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in [The OS managed translation table bits on page G3-3623](#).

### Ignored fields

For stage 1 translation descriptors, the architecture defines a 4-bit Ignored field in the Block and Page table descriptors, bit[63:59], and guarantees that the PE will not alter the value of this field. For stage 2 translation descriptors, the corresponding field is reserved for use by a System MMU. In a PE that is using the Long-descriptor translator table format, this field is an ignored field and the architecture guarantees that the PE does not update the field.

## G3.8.5 EL2 control of Non-secure memory region attributes

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure PL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the [HTTBR](#) and [HTCR](#).  
These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in [VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624](#).
- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the [VTTBR](#) and [VTCR](#).

The descriptors in the virtualization translation tables define a second level of memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

[VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592](#) describes the format of the entries in these tables.

———— **Note** —————

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see [Shareability, Long-descriptor format on page G3-3624](#).
- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as [Table G3-18](#) shows:

**Table G3-18 Long-descriptor MemAttr[3:2] encoding, stage 2 translation**

MemAttr[3:2]	Memory type	Cacheability
00	Device, of type determined by MemAttr[1:0]	Not applicable
01	Normal	Outer Non-cacheable
10		Outer Write-Through Cacheable
11		Outer Write-Back Cacheable

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating a type of Device memory, [Table G3-19](#) shows the encoding of MemAttr[1:0]:

**Table G3-19 MemAttr[1:0] encoding for the types of Device memory**

MemAttr[1:0]	Meaning when MemAttr[3:2] == 0b00
00	Region is Device-nGnRnE memory
01	Region is Device-nGnRE memory
10	Region is Device-nGRE memory
11	Region is Device-GRE memory

- When MemAttr[3:2] != 0b00, indicating Normal memory, [Table G3-20](#) shows the encoding of MemAttr[1:0]:

**Table G3-20 MemAttr[1:0] encoding for Normal memory**

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
00	UNPREDICTABLE
01	Inner Non-cacheable
10	Inner Write-Through Cacheable
11	Inner Write-Back Cacheable

**Note**

The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- [Combining the memory type attribute.](#)
- [Combining the cacheability attribute on page G3-3628.](#)
- [Combining the shareability attribute on page G3-3629.](#)

**Note**

The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:

- MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
- MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

### Combining the memory type attribute

[Table G3-21](#) shows how the stage 1 and stage 2 memory type assignments are combined:

**Table G3-21 Combining the stage 1 and stage 2 memory type assignments**

Assignment in stage 1	Assignment in stage 2	Resultant type
Device-nGnRnE	Any	Device-nGnRnE
Device-nGnRE	Device-nGnRnE	Device-nGnRnE
	Not Device-nGnRnE	Device-nGnRE
Device-nGRE	Device-nGnRnE	Device-nGnRnE
	Device-nGnRE	Device-nGnRE
	Not (Device-nGnRnE or Device-nGnRE)	Device-nGRE

**Table G3-21 Combining the stage 1 and stage 2 memory type assignments (continued)**

Assignment in stage 1	Assignment in stage 2	Resultant type
Device-GRE	Device-nGnRnE	Device-nGnRnE
	Device-nGnRE	Device-nGnRE
	Device-nGRE	Device-nGRE
	Device-GRE or Normal	Device-GRE
Normal	Any type of Device	Device type assigned at stage 2
	Normal	Normal

See [Combining the shareability attribute on page G3-3629](#) for information about:

- The shareability of a region for which the resultant type is any Device type.
- The shareability requirements of a region with a resultant type of Normal for which the resultant cacheability, described in [Combining the cacheability attribute](#), is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to type of Device memory. This is likely to indicate a Guest OS error, and setting the HCR.PTW bit to 1 causes such an access to generate a Translation fault, see [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#).

### Combining the cacheability attribute

For a Normal memory region, [Table G3-22](#) shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes:

**Table G3-22 Combining the stage 1 and stage 2 cacheability assignments**

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

———— **Note** —————

Only Normal memory has a cacheability attribute.

## Combining the shareability attribute

A memory region for which the resultant memory type attribute, described in [Combining the memory type attribute on page G3-3627](#), is any type of Device memory, is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation.

For a memory region with a resultant memory type attribute of Normal, [Table G3-23](#) shows how the stage 1 and stage 2 shareability assignments are combined:

**Table G3-23 Combining the stage 1 and stage 2 shareability assignments**

Assignment in stage 1	Assignment in stage 2	Resultant shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

A memory region with a resultant memory type attribute of Normal, and a resultant cacheability attribute of Inner Non-cacheable, Outer Non-cacheable, must have a resultant shareability attribute of Outer Shareable, otherwise shareability is UNPREDICTABLE.

## G3.9 Translation Lookaside Buffers (TLBs)

*Translation Lookaside Buffers* (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.
- Any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not out of context might be allocated to an enabled TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

———— **Note** —————

An enabled TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- [Global and process-specific translation table entries](#).
- [TLB matching on page G3-3631](#).
- [TLB behavior at reset on page G3-3631](#).
- [TLB lockdown on page G3-3631](#).
- [TLB conflict aborts on page D5-1807](#).

See also [TLB maintenance requirements on page G3-3633](#).

### G3.9.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and PL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

**nG == 0**      The translation is global, meaning the region is available for all processes.

**nG == 1**      The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by the [CONTEXTIDR](#).

Each non-global region has an associated *Address Space Identifier* (ASID). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

The translation regime used for accesses made at PL2 does not support ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597](#).

### G3.9.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance operations described in [TLB maintenance requirements on page G3-3633](#) can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This is an issue regardless of whether or not the translation table entries are global. In some cases, the TLB can hold two mappings for the same address, and this might lead to UNPREDICTABLE behavior

### G3.9.3 TLB behavior at reset

The architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

The architectural requirements for TLB behavior at reset are:

- All TLBs are disabled from reset. All stages of address translation that are used from the processor state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see [Enabling stages of address translation on page G3-3572](#).
- An implementation can require the use of a specific TLB *invalidation routine*, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.  
ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance operations described in [The scope of TLB maintenance operations on page G3-3640](#).
- When TLBs that have not been invalidated by some mechanism since reset are enabled, the state of those TLBs is UNPREDICTABLE.

Similar rules apply:

- To cache behavior, see [Behavior of caches at reset on page G2-3526](#).
- To branch predictor behavior, see [Behavior of the branch predictors at reset on page G2-3534](#).

### G3.9.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- The architecture does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:

- The TLB Type Register, **TLBTR**, does not define the lockdown scheme in use.
- In AArch32 state, a region of the CP15 c10 encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  - $\langle CRm \rangle == \{c0, c1, c4, c8\}$ .
  - All values of  $\langle opc2 \rangle$  and  $\langle opc1 \rangle$ .

See also *VMSAv8-32 CP15 c10 register summary* on page G3-3720.

An implementation might use some of the CP15 c10 encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated by problems related to TLB lockdown, in a Non-secure PL1 mode, can be routed to either:

- Non-secure Abort mode, using the Non-secure Data Abort exception vector.
- Hyp mode, using the Hyp Trap exception vector.

For more information, see *Trapping accesses to lockdown, DMA, and TCM operations* on page G1-3508

### G3.9.5 TLB conflict aborts

Fault status encodings for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:

- *PL1 fault reporting with the Short-descriptor translation table format* on page G3-3663
- *PL1 fault reporting with the Long-descriptor translation table format* on page G3-3665.

An implementation can generate a TLB conflict abort if it detects that the address being looked up in the TLB hits multiple entries. This can happen if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed. If it happens, the resulting behavior is UNPREDICTABLE, but must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.

In some implementations, multiple hits in the TLB can generate a synchronous Data Abort or Prefetch Abort exception. In any case where this is possible it is IMPLEMENTATION DEFINED whether the abort is a stage 1 abort or a stage 2 abort.

———— **Note** —————

A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort.

———— **Note** —————

The TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses.

On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

## G3.10 TLB maintenance requirements

[Translation Lookaside Buffers \(TLBs\)](#) on page G3-3630 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSAv8-32 TLB maintenance operations:

- [General TLB maintenance requirements](#).
- [Maintenance requirements on changing System register values](#) on page G3-3636.
- [Atomicity of register changes on changing virtual machine](#) on page G3-3637.
- [Synchronization of changes of ASID and TTBR](#) on page G3-3637.
- [The scope of TLB maintenance operations](#) on page G3-3640.

### G3.10.1 General TLB maintenance requirements

TLB maintenance operations provide a mechanism to invalidate entries from a TLB. As stated at the start of [Translation Lookaside Buffers \(TLBs\)](#) on page G3-3630, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault might be allocated to an enabled TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

———— **Note** ————

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see [Cache maintenance requirement created by changing translation table attributes](#) on page G3-3646.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. [Maintenance requirements on changing System register values](#) on page G3-3636 gives more information about this maintenance requirement.

Each of the translation regimes defined in [Figure G3-1](#) on page G3-3563 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or PL0 modes, a change of `HCR.VM`, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of `HCR.VM` is visible to software executing in the Non-secure PL1 and PL0 modes.

Any TLB operation can affect any other TLB entries that are not locked down.

AArch32 state defines CP15 c8 functions for TLB maintenance operations, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.

———— **Note** ————

An address-based TLB maintenance operation that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the operation.

A TLB maintenance operation that specifies a virtual address that would generate any MMU fault, including a virtual address that is not in the range of virtual addresses that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance operations for use in AArch32 state at PL2, and has some implications for the effect of the other TLB maintenance operations, see [The scope of TLB maintenance operations on page G3-3640](#).

In an implementation that includes EL3, the TLB operations take account of the current Security state, as part of the address translation required for the TLB operation.

Some TLB operations are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these operations for backwards compatibility. However, more recent TLB operations do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB operations, or of Data TLB operations, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate operations, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

[The scope of TLB maintenance operations on page G3-3640](#) describes the TLB operations.

## The interaction of TLB lockdown with TLB maintenance operations

The precise interaction of TLB lockdown with the TLB maintenance operations is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance operations must comply with these rules:

- The effect on locked entries of a TLB invalidate all unlocked entries operation or a TLB invalidate by VA all ASID operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - Have no effect on entries that are locked down.
  - Generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see [Table G3-26 on page G3-3664](#) for the codes used with the Short-descriptor translation table formats, or [Table G3-27 on page G3-3665](#) for the codes used with the Long-descriptor translation table formats.  
In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see [Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508](#).
- This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.
- The effect on locked entries of a TLB invalidate by VA operation or a TLB invalidate by ASID match operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - A locked entry is invalidated in the TLB.
  - The operation has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the operation as a NOP.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see [Table G3-26 on page G3-3664](#) and [Table G3-27 on page G3-3665](#).

### ————— Note —————

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.

- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance operations on entries that can be locked down but are not actually locked down must also provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see [The interaction of cache lockdown with cache maintenance instructions on page G2-3542](#).

---

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance operation, any unlocked entry in the TLB might be invalidated.

## TLB maintenance operations and the memory order model

The following rules describe the relations between the memory order model and the TLB maintenance operations:

- A TLB invalidate operation is complete when all memory accesses using the invalidated TLB entries have been observed by all observers, to the extent that those accesses must be observed. The shareability and cacheability of the accessed memory locations determine the extent to which the accesses must be observed. In addition, once the TLB invalidate operation is complete, no new memory accesses that can be observed by those observers will be performed using the invalidated TLB entries. For a TLB invalidate operation that affects other PEs, the set of memory accesses that have been observed when the TLB maintenance operation is complete must include the memory accesses from those processes that used the invalidated TLB entries.
- A TLB maintenance operation is only guaranteed to be complete after the execution of a DSB instruction.
- An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance operations that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.
- An exception causes all completed TLB maintenance operations, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.
- All TLB maintenance operations are executed in program order relative to each other.
- The execution of a Data or Unified TLB maintenance operation is only guaranteed to be visible to a subsequent explicit load or store operation after both:
  - The execution of a DSB instruction to ensure the completion of the TLB operation.
  - Execution of a subsequent [Context synchronization operation](#).
- The execution of an Instruction or Unified TLB maintenance operation is only guaranteed to be visible to a subsequent instruction fetch after both:
  - The execution of a DSB instruction to ensure the completion of the TLB operation.
  - Execution of a subsequent [Context synchronization operation](#).

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance operations.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:

- A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a DSB and an ISB.

However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.

- A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry] ; write new entry to the translation table
DSB ; ensures visibility of the data cleaned from the D Cache
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB ; ensure completion of the Invalidate TLB operation
ISB ; ensure table changes visible to instruction fetch
```

### G3.10.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the [NMRR](#), [PRRR](#), [MAIR0](#), [MAIR1](#), [HMAIR0](#) or [HMAIR1](#) registers.
- Any change to the [SCTLR.AFE](#) bit, see [Changing the Access flag enable](#).
- Any change to any of the [SCTLR](#).{TRE, WXN, UWXN} bits.
- Changing [TTBCR.EAE](#), see [Changing the current Translation table format on page G3-3637](#).
- In an implementation that includes EL3, any change to the [SCR.SIF](#) bit.
- In an implementation that includes EL2:
  - Any change to the [HCR.VM](#) bit.
  - Any change to [HCR.PTW](#) bit, see [Changing HCR.PTW](#).
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in [TTBR0](#) or [TTBR1](#).
  - Any change to the PD0 or PD1 fields in [TTBCR](#)
- When using the Long-descriptor translation table format:
  - Any change to the  $T_n$ SZ,  $ORGN_n$ ,  $IRGN_n$ ,  $SH_n$ , or  $EPD_n$  fields in the [TTBCR](#), where  $n$  is 0 or 1.
  - Any change to the TOSZ,  $ORGN_0$ ,  $IRGN_0$ , or  $SH_0$  fields in the [HTCR](#).
  - Any change to the TOSZ,  $ORGN_0$ ,  $IRGN_0$ , or  $SH_0$  fields in the [VTCR](#).

#### Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is UNPREDICTABLE whether the TLB caches the effect of the [SCTLR.AFE](#) bit on translation tables. This means that, after changing the [SCTLR.AFE](#) bit software must invalidate the TLB before it relies on the effect of the new value of the [SCTLR.AFE](#) bit.

#### ———— Note —————

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

#### Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, [HCR.PTW](#), is 1, a stage 1 translation table access in the Non-secure PL1&O translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID

might hold entries that depend on the effect of [HCR.PTW](#). Therefore, if the value of [HCR.PTW](#) is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or PL0 mode. If this is not done, behavior is UNPREDICTABLE.

### Changing the current Translation table format

The effect of changing [TTBCR.EAE](#) when executing in the translation regime affected by [TTBCR.EAE](#) with any stage of address translation for that translation regime enabled is UNPREDICTABLE. When [TTBCR.EAE](#) is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is UNPREDICTABLE.

## G3.10.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or PL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
  - [PRRR](#) and [NMRR](#), if using the Short-descriptor translation table format.
  - [MAIR0](#) and [MAIR1](#), if using the Long-descriptor translation table format.
  - [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), and [CONTEXTIDR](#).
  - The [SCTLR](#).
- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - [VTBR](#) and [VTCR](#).
  - [HMAIR0](#) and [HMAIR1](#).
  - The [HSCTLR](#).

#### ———— Note ————

Only some bits of [SCTLR](#) affect the stage 1 translation, and only some bits of [HSCTLR](#) affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

#### ———— Note ————

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are *in context*. [Synchronization of changes of ASID and TTBR](#) describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.

## G3.10.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and Translation Table Base Registers together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.

- The use of branch prediction.

When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. [Example G3-3](#), [Example G3-4](#), and [Example G3-5 on page G3-3639](#) describe three possible approaches.

---

**Note**

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

---

---

**Example G3-3 Using a reserved ASID to synchronize ASID and TTBR changes**

---

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and Translation Table Base Register. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given virtual address is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change ASID to 0
ISB
Change Translation Table Base Register
ISB
Change ASID to new value
```

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

---

---

**Example G3-4 Using translation tables containing only global mappings when changing the ASID**

---

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change Translation Table Base Register to the global-only mappings
ISB
Change ASID to new value
ISB
Change Translation Table Base Register to new value
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in *General TLB maintenance requirements* on page G3-3633, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same shareability and cacheability attributes, as held in the `TTBR0.{ORGN, IRGN}` or `TTBR1.{ORGN, IRGN}` fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

---

### Example G3-5 Disabling non-global mappings when changing the ASID

---

In systems where only the translation tables indexed by `TTBR0` hold non-global mappings, maintenance software can use the `TTBCR.PD0` field to disable use of `TTBR0` during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the `TTBR1` register, and is marked as global:

```
Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change Translation Table Base Register to new value
ISB
Set TTBCR.PD0 = 0
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

---

When using the Long-descriptor translation table format, `TTBCR.A1` holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current Translation Table Base Register can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- `TTBR0` is the only Translation Table Base Register being used. `TTBCR.A1` must be set to 0.
- `TTBR0` points to the only translation tables that hold non-global entries, and `TTBCR.A1` is set to 0.
- `TTBR1` points to the only translation tables that hold non-global entries, and `TTBCR.A1` is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

———— **Note** —————

When using the Long-descriptor translation table format, `CONTEXTIDR.ASID` has no significance for address translation, and is only an extension of the Context ID value.

---

### G3.10.5 The scope of TLB maintenance operations

TLB maintenance operations provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.
- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the first level lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at the second or third level of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.
- In an implementation that includes EL2:
  - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
- In an implementation that includes EL2:
  - At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  - At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

Where a TLB maintenance operation is required to apply to stage 1 entries, then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Where a TLB maintenance operation is required to apply to stage 2 entries it must apply to any cached entry in the caching structures that includes any information from stage 2 translation table entries, including any entry that combines information from both stage 1 and stage 2 translation table entries.

[Table G3-24 on page G3-3641](#) summarizes the required effect of the preferred TLB operations, for execution in AArch32 state, that operate only on TLBs on the PE that executes the instruction. Additional TLB operations:

- Apply across all PEs in the same Inner Shareable domain. Each operation shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of [TLBIALL](#) is [TLBIALLIS](#). See also [EL2 upgrading of TLB maintenance operations on page G3-3643](#).
- Can apply to separate Instruction or Data TLBs, as indicated by a footnote to the table. ARM deprecates any use of these operations.

———— **Note** —————

- The architecture permits a TLB invalidation operation to affect any unlocked entry in the TLB. [Table G3-24 on page G3-3641](#) defines only the entries that each operation must invalidate.

- All TLB operations, including those that operate on an VA match, operate regardless of the value of `SCTLR.M`.

When interpreting the table:

- Related operations** Each operation description applies also to any equivalent operation that either:
- Applies to all PEs in the same Inner Shareable domain.
  - Applies only to a data TLB, or only to an instruction TLB.
- So, for example, the `TLBIALL` description applies also to `TLBIALLIS`, `ITLBIALL`, and `DTLBIALL`.
- TLB maintenance operations, functional group on page G3-3744 lists all of the TLB maintenance operations.*
- Matches the VA** Means the VA argument for the operation must match the VA value in the TLB entry.
- Matches the ASID** Means the ASID argument for the operation must match the ASID in use when the TLB entry was assigned.
- Matches the current VMID**
- Means the current VMID must match the VMID in use when the TLB entry was assigned.
- The dependency on the VMID applies even when the value of `HCR.VM` is 0, including situations where there is no use of virtualization. However, `VTTBR.VMID` resets to zero, meaning there is a valid VMID from reset.
- Execution at PL2** Descriptions of operations at PL2 apply only to implementations that include EL2.
- For the definitions of the translation regimes referred to in the table see *About VMSAv8-32 on page G3-3562*.

**Table G3-24 Effect of the TLB maintenance operations**

Operation	Executed from		Effect, must invalidate any entry that matches all stated conditions
	State	Mode	
<code>TLBIALL</code> <sup>a</sup>	Secure	PL1	All entries for the Secure PL1&0 translation regime. That is, all entries that were allocated in Secure state.
	Non-secure	PL1	All entries for stage 1 of the Non-secure PL1&0 translation regime that match the current VMID.
		Hyp	All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime that match the current VMID.
<code>TLBIMVA</code> <sup>a</sup>	Secure	PL1	Any entry for the Secure PL1&0 translation regime that both: <ul style="list-style-type: none"> <li>• Matches the VA argument.</li> <li>• Matches the ASID argument, or is global.</li> </ul>
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime for which all of the following apply. The entry: <ul style="list-style-type: none"> <li>• Matches the VA argument.</li> <li>• Matches the ASID argument, or is global.</li> <li>• Matches the current VMID.</li> </ul>
<code>TLBIASID</code> <sup>a</sup>	Secure	PL1	Any entry for the Secure PL1&0 translation regime that matches the ASID argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: <ul style="list-style-type: none"> <li>• Is not global and matches the ASID argument.</li> <li>• Matches the current VMID.</li> </ul>

**Table G3-24 Effect of the TLB maintenance operations (continued)**

Operation	Executed from		Effect, must invalidate any entry that matches all stated conditions
	State	Mode	
TLBIMVAA	Secure	PL1	Any entry for the Secure PL1&0 translation regime that matches the VA argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: <ul style="list-style-type: none"> <li>• Matches the VA argument.</li> <li>• Matches the current VMID.</li> </ul>
TLBIALLNSNH <sup>b</sup>	Secure	Monitor	All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.
	Non-secure	Hyp	
TLBIALLH <sup>b</sup>	Secure	Monitor	All entries for the Non-secure PL2 translation regime. That is, any entry that was allocated in Non-secure state from Hyp mode.
	Non-secure	Hyp	
TLBIMVAL	Secure	PL1	Any entry for stage 1 of the Secure PL1&0 translation regime that is the last level of the translation table walk and matches: <ul style="list-style-type: none"> <li>• The VA argument.</li> <li>• The ASID argument.</li> </ul>
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that is the last level of the translation table walk and matches: <ul style="list-style-type: none"> <li>• The VA argument.</li> <li>• The ASID argument.</li> <li>• The current VMID.</li> </ul>
TLBIMVAAL	Secure	PL1	Any entry for stage 1 of the Secure PL1&0 translation regime that is the last level of the translation table walk and matches the VA argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that is the last level of the translation table walk and matches: <ul style="list-style-type: none"> <li>• The VA argument.</li> <li>• The current VMID.</li> </ul>
TLBIMVAH <sup>b</sup>	Secure	Monitor	Any entry for the Non-secure PL2 translation regime that matches the VA argument.
	Non-secure	Hyp	
TLBIMVALH <sup>b</sup>	Secure	Monitor	Any entry for stage 1 of the translation regime that is the last level of the translation table walk and matches the given VA.
	Non-secure	Hyp	
TLBIIPAS2 <sup>b</sup>	Secure	Monitor	Any entry for an EL1&0 stage 2 of the translation regime holding the IPA to PA translations and the current VMID <sup>c</sup> .
	Non-secure	Hyp	Any entry for an EL1&0 stage 2 of the translation regime holding the IPA to PA translations and the current VMID <sup>d</sup> .
TLBIIPAS2L <sup>b</sup>	Secure	Monitor	Any entry for an EL1&0 stage 2 of the translation regime for the last level of translation holding the IPA to PA translations and the current VMID <sup>c</sup> .
	Non-secure	Hyp	Any entry for an EL1&0 stage 2 of the translation regime for the last level of translation holding the IPA to PA translations and the current VMID <sup>d</sup> .

a. The architecture defines variants of these operations that apply only to instruction TLBs, and only to data TLBs. ARM deprecates any use of these variants. For more information, see the referenced description of the operation.

b. Available only in an implementation that includes EL2. See also [EL2 upgrading of TLB maintenance operations on page G3-3643](#).

- c. This operation execute as NOPs when SCR.NS == 0.
- d. This operation is CONSTRAINED UNPREDICTABLE from any AArch32 Secure privileged mode.

### EL2 upgrading of TLB maintenance operations

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance operations that are not broadcast across the Inner Shareable domain are upgraded to operate across the Inner Shareable domain when performed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA operation performed in a Non-secure PL1 mode operates as a TLBIMVAIS operation,

## G3.11 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and memory translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- [Data and unified caches](#).
- [Instruction caches](#).

In addition [Cache maintenance requirement created by changing translation table attributes on page G3-3646](#) describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

- [Cache support on page G2-3524](#). This section describes the ARM cache maintenance operations.
- [Cache maintenance operations, functional group on page G3-3743](#). This section summarizes the System register encodings used for these operations when executing in AArch32 state.

### G3.11.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access that is not UNPREDICTABLE.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance operations.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

### G3.11.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- PIPT instruction caches.
- *Virtually-indexed, physically-tagged* (VIPT) instruction caches.
- ASID and VMID tagged *Virtually-indexed, virtually-tagged* (VIVT) instruction caches.

In AArch32 state, the CTR identifies the form of the instruction caches, see [CTR, Cache Type Register on page G4-3815](#).

The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

- [PIPT instruction caches.](#)
- [VIPT instruction caches.](#)
- [ASID and VMID tagged VIVT instruction caches.](#)

---

**Note**

---

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

---

### PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches that are not UNPREDICTABLE.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see [IVIPT architecture Extension on page G3-3646](#).

### VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches that are not UNPREDICTABLE, except for the effect of memory address translation on instruction cache invalidate by address operations.

---

**Note**

---

Cache invalidation is the only cache maintenance operation that can be performed on an instruction cache.

---

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see [IVIPT architecture Extension on page G3-3646](#).

### ASID and VMID tagged VIVT instruction caches

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the stage of address translation.
- Writing new mappings to the translation tables.

- In AArch32 state, any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers, unless accompanied by a change to the ContextID, or a change to the VMID.
- In AArch32 state, changes to the [VTTBR](#) or [VTCR](#) registers, unless accompanied by a change to the VMID.

———— **Note** ————

For ASID and VMID tagged VIVT instruction caches only, invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged, through the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an MMU fault.
- Changing a translation that generates a MMU fault to a valid translation.

This does not apply for VIPT or PIPT instruction caches.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

### IVIPT architecture Extension

An implementation in which the instruction cache exhibits the behaviors described in [PIPT instruction caches on page G3-3645](#), or those described in [VIPT instruction caches on page G3-3645](#), is said to implement the *IVIPT Extension* to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

### G3.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in [General TLB maintenance requirements on page G3-3633](#). If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

## G3.12 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

<b>Debug exception</b>	An exception caused by the debug configuration, see <a href="#">Chapter D2 Debug Exceptions and Exception Catch debug event on page H3-4377</a> .
<b>Alignment fault</b>	An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see <a href="#">Unaligned data access on page E2-2341</a> and <a href="#">Alignment faults on page G3-3654</a> .
<b>MMU fault</b>	A MMU fault is a fault generated by the fault checking sequence for the current translation regime.
<b>External abort</b>	Any memory system fault other than a Debug exception, an Alignment fault, or a MMU fault.

Collectively, these mechanisms are called *aborts*. [Chapter D2 Debug Exceptions](#) and [Chapter H3 Halting Debug Events](#) describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

The exception generated on a synchronous memory abort:

- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

### ———— Note ————

The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a special type of Data Abort exception.

The following sections describe the abort mechanisms:

- [Routing of aborts taken to AArch32 state](#).
- [VMSAv8-32 MMU fault terminology on page G3-3650](#).
- [The MMU fault-checking sequence on page G3-3650](#).
- [Alignment faults on page G3-3654](#).
- [MMU faults in AArch32 state on page G3-3655](#).
- [External abort on a translation table walk on page G3-3657](#).
- [Prioritization of aborts on page G3-3658](#).

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Fault Status Registers* (FSRs) to record context information. For more information about the FARs and FSRs, see [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#).

### G3.12.1 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  - Using AArch32. In this case, this chapter describes how the abort is handled.
  - Using AArch64. In this case, [Chapter D5 The AArch64 Virtual Memory System Architecture](#) describes how the abort is handled.

For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

#### Memory aborts taken to Monitor mode

If an implementation includes EL3, when the value of `SCR.EA` is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes. For more information see [Asynchronous exception routing controls on page G1-3467](#).

##### Note

- Although the referenced section mostly describes the routing of asynchronous exceptions, it includes the `SCR.EA` control that applies to both synchronous and asynchronous external aborts.
- The `SCR` is implemented only as part of EL3.

#### Memory aborts taken to Secure Abort mode

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

##### Note

The only memory aborts that can be routed to Monitor mode are External aborts.

#### Memory aborts taken to Hyp mode

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
  - When the PE is in Hyp mode.
  - When the PE is in a Non-secure PL1 or EPL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  - When the PE is in Non-secure User mode and `HCR.TGE` is set to 1. For more information see [External abort, when HCR.TGE is set to 1 on page G1-3453](#).
- When the PE is using the Non-secure PL1&0 translation regime:
  - MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  - Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#).
- When the PE is using the Non-secure PL2 translation regime, MMU faults from stage 1 translations.

##### Note

The Non-secure PL2 translation regime has only one stage of translation.

- External aborts, if `SCR.EA` is set to 0 and any of the following applies:
  - The PE was executing in Hyp mode when it took the exception.
  - The PE was executing in a Non-secure PL0 or PL1 mode when it took the exception, the abort is asynchronous, and `HCR.AMO` is set to 1. For more information see [Asynchronous exception routing controls on page G1-3467](#).
  - The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and `HCR.TGE` is set to 1. For more information see [External abort, when HCR.TGE is set to 1 on page G1-3453](#).

- The abort occurred on a stage 2 translation table walk.
- Debug exceptions, if `HDCR.TDE` is set to 1. For more information, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).

### Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

- When the PE is in a Non-secure PL1 or PL0 mode, Alignment faults taken for any of the following reasons:
  - `SCTLR.A` is set to 1.
  - An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  - The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

#### ———— Note —————

In an implementation that does not include EL2, this case results in an UNPREDICTABLE memory access, see [Cases where unaligned accesses are UNPREDICTABLE on page E2-2341](#).

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of `HCR.TGE` is 0.

- When the PE is using the Non-secure PL1&0 translation regime, a stage of address translation faults from stage 1 translations.
- External aborts, if all of the following apply:
  - The abort is not on a stage 2 translation table walk.
  - The PE is not in Hyp mode.
  - The value of `SCR.EA` is 0.
  - The abort is asynchronous, and `HCR.AMO` is set to 0.
  - The abort is synchronous, and `HCR.TGE` is set to 0.
- Virtual Aborts, see [Virtual exceptions when an implementation includes EL2 on page G1-3465](#).
- When the value of `HDCR.TDE` is 0, Debug exceptions. For more information, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).

#### ———— Note —————

If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in [Chapter D5 The AArch64 Virtual Memory System Architecture](#).

### Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the `SCTLR.A` bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

### G3.12.2 VMSAv8-32 MMU fault terminology

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. [Table G3-25](#) shows the terminology used in this manual for a MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a third-level lookup when using the Long-descriptor translation table format.

**Table G3-25 Address translation fault terminology**

Current term	Old term	Note
First level Translation fault	Section Translation fault	-
Second level Translation fault	Page Translation fault	-
Third level Translation fault	-	Long-descriptor translation table format only.
First level Access flag fault	Section Access flag fault	-
Second level Access flag fault	Page Access flag fault	-
Third level Access flag fault	-	Long-descriptor translation table format only.
First level Domain fault	Section Domain fault	Short-descriptor translation table format only, except for reporting faults on address translation operations in the 64-bit PAR, see <a href="#">Determining the PAR format on page G3-3688</a> . Cannot occur at third level.
Second level Domain fault	Page Domain fault	
First level Permission fault	Section Permission fault	-
Second level Permission fault	Page Permission fault	-
Third level Permission fault	-	Long-descriptor translation table format only.

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

- A stage 1 address translation fault, for example, a stage 1 Translation fault.
- A stage 2 address translation fault, for example, a stage 2 Translation fault.

### G3.12.3 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates a Prefetch Abort exception.
- If an data memory access faults it generates a Data Abort exception.

For more information about Prefetch Abort exceptions and Data Abort exceptions see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the translation table descriptor for the accessed VA. For more information, see [Translation tables on page G3-3573](#) and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.

---

**Note**

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address space, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

---

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

**When using the Short-descriptor format**

- There are one or two levels of lookup.
- Lookup always starts at the first level.
- The final level of lookup checks the Domain field of the descriptor and:
  - Faults if there is no access to the Domain.
  - Checks the access permissions only for Client domains.

**When using the Long-descriptor format**

- There are one, two, or three levels of lookup.
- Lookup starts at either the first level or the second level.
- Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see [About address translation for VMSAv8-32 on page G3-3565](#).

---

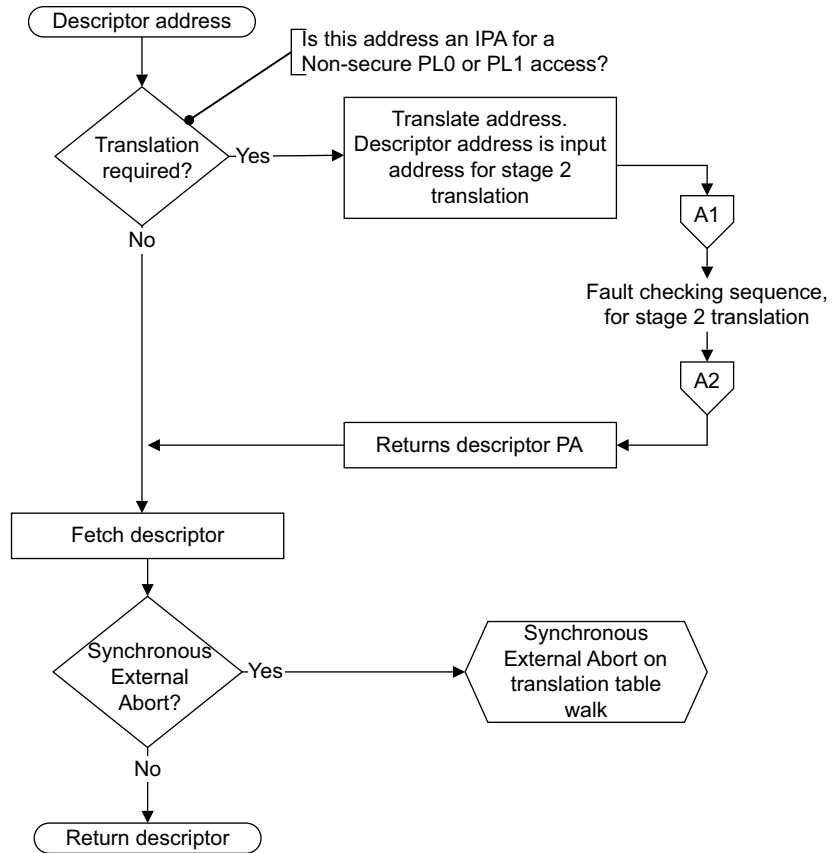

**Note**

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in [TLB conflict aborts on page G3-3632](#).

---

[MMU faults in AArch32 state on page G3-3655](#) describes the faults that a MMU fault-checking sequence can report.

[Figure G3-23 on page G3-3652](#) shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

**Figure G3-23 Fetching the descriptor in a VMSAv8-32 translation table walk**

Figure G3-24 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.

Figure G3-24 VMSAv8-32 fault checking sequence

## Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or PL0 mode, any memory access goes through two stages of translation:

- Stage 1, from VA to IPA.
- Stage 2, from IPA to PA.

---

### Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the physical address space. However, it actually specifies these addresses in its IPA space. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address space.

---

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If **SCR.EA** is set to 1, a synchronous external abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, **HSR.ISS[7]** is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see [Use of the HSR on page G3-3672](#).

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the any type of Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the **HCR.PTW** bit is 1, such an access generates a stage 2 Permission fault.

---

### Note

- On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.
- 

A TLB might hold entries that depend on the effect of **HCR.PTW**. Therefore, if **HCR.PTW** is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or PL0 mode. For more information see [Changing HCR.PTW on page G3-3636](#).

A cache maintenance operation performed from a Non-secure PL1 mode can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance operation cannot generate a Permission fault.

## G3.12.4 Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by **SCTLR.A**. In addition, some instructions do not support unaligned accesses, regardless of the value of **SCTLR.A**. [Unaligned data access on page E2-2341](#) defines when Alignment faults are generated, for both values of **SCTLR.A**.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

[Routing of aborts taken to AArch32 state on page G3-3647](#) defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see [Prioritization of aborts on page G3-3658](#).

## G3.12.5 MMU faults in AArch32 state

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page G3-3650. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When a MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The following subsections describe the MMU faults that might be detected during a fault checking sequence:

- *Translation fault.*
- *Address size fault.*
- *Access flag fault* on page G3-3656.
- *Domain fault, Short-descriptor format translation tables* only on page G3-3656.
- *Permission fault* on page G3-3657.

See also *External abort on a translation table walk* on page G3-3657.

### Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- *VMSAv8-32 Short-descriptor translation table format descriptors* on page G3-3579.
- *VMSAv8-32 Long-descriptor translation table format descriptors* on page G3-3592.

In addition, a Translation fault is generated if the input address for a translation either does not map on to an address range of a Translation Table Base Register, or the Translation Table Base Register range that it maps on to is disabled. In these cases the fault is reported as a first level Translation fault on the translation stage at which the mapping to a region described by a Translation Table Base Register failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

A data or unified cache maintenance operation by VA can generate a Translation fault. Whether an instruction cache invalidate by VA operation can generate a Translation fault is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the instruction cache invalidate by VA operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

Whether branch predictor maintenance operations can generate Translation faults is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the branch predictor maintenance operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

### Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level.

An Address size fault is generated if one of the following applies:

- The translation table entries or the **TTBR** for the stage of translation have address bits above the most significant bit of the specified PA size as non zero.

Since VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this includes any case where a translation table entry or the **TTBR** holds an address for which A[47:40] is nonzero.

- The specified output address size is larger than the implemented PA.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

### Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when `SCTLR.AFE` is set to 1.
  - The Long-descriptor format always supports an Access flag.
- A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:

- [VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3579](#)
- [VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592](#).

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

Whether any cache maintenance operations by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see [The Access flag on page G3-3615](#).

### Domain fault, Short-descriptor format translation tables only

When using the Short-descriptor translation table format, a Domain fault can be generated at the first level or second level of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

**First level** When a first-level descriptor fetch returns a valid Section first-level descriptor, the domain field of that descriptor is checked against the `DACR`. A first-level Domain fault is generated if this check fails.

**Second level** When a second-level descriptor fetch returns a valid second-level descriptor, the domain field of the first-level descriptor that required the second-level fetch is checked against the `DACR`, and a second-level Domain fault is generated if this check fails.

For more information, see [Domains, Short-descriptor format only on page G3-3614](#).

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in [TLB maintenance operations and the memory order model on page G3-3635](#).

Any change to the `DACR` must be synchronized by a context synchronization operation. For more information see [Synchronization of changes to System registers on page G3-3706](#).

## Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See [Access permissions on page G3-3609](#) for information about conditions that cause a Permission fault.

### ———— Note —————

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in [TLB maintenance operations and the memory order model on page G3-3635](#).

### ———— Note —————

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#).
- A [DCIMVAC](#) issued in Non-secure state that attempts to update a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in [Data cache maintenance instructions \(DC\\*\) on page G2-3535](#).

## G3.12.6 External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. For more information on external aborts, see [External aborts on page G2-3546](#).

An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when [CPSR.A](#) is set to 1, otherwise they are reported using the Data Abort exception.

### Behavior of external aborts on a translation table walk caused by address translation operations

The address translation operations summarized in [Address translation operations, functional group on page G3-3745](#) require translation table walks. An external abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see [Handling of faults and aborts during an address translation operation on page G3-3688](#).

### G3.12.7 Prioritization of aborts

This section describes the abort prioritization that applies to a single memory access from AArch32 state that might generate multiple aborts:

On a single memory access from AArch32 state, the following rules apply:

- If a memory access generates an Alignment fault because **SCTLR.A** is set to 1, or because it is an unaligned access by an instruction that does not support unaligned accesses, then that access cannot generate any of:
  - A MMU fault, on either the stage 1 translation or the stage 2 translation.
  - An external abort.
  - A Watchpoint debug event.An Alignment fault generated by an unaligned access to any type of Device memory is prioritized as an MMU fault. For more information see [Alignment faults caused by accessing Device memory types](#).
- If a memory access generates an MMU fault on its stage 1 translation, and also generates an abort on its stage 2 translation, the fault from the stage 1 translation has priority:
  - If a memory access made as part of a stage 1 translation table walk generates an MMU fault on its stage 2 translation, as described in [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#), the stage 1 translation table walk does not generate an MMU fault on the stage 1 translation.
  - A fault on a particular stage of translation might be a synchronous external abort on a translation table walk made at that stage of translation.
- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, then the PE cannot generate a Watchpoint debug event on that access.
- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, or generates a synchronous Watchpoint debug event, then the memory access cannot generate an external abort.
- Except as defined in this list, the architecture does not define any prioritization of asynchronous external aborts relative to any other asynchronous aborts.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

———— **Note** —————

[Debug state entry and debug event prioritization on page H2-4331](#) describes the relationship between debug events, MMU faults, and external aborts, for synchronous aborts generated by the same memory access.

#### Alignment faults caused by accessing Device memory types

Any unaligned access to any type of Device memory generates an Alignment fault. When applying the prioritization rules, this fault is prioritized at any MMU fault. The priority of this Alignment fault relative to possible MMU faults is as follows:

- The Alignment fault has lower priority than an Access flag fault.
- If the translation stage that generates the Access flag fault:
  - Can generate Domain faults, the Alignment fault has higher priority than a Domain fault.
  - Cannot generate Domain faults, the Alignment fault has higher priority than a Permission fault.

The MMU fault checking sequence in [Figure G3-24 on page G3-3653](#) shows this prioritization.

## G3.13 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

---

### Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

---

*About exception reporting* introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- *Reporting exceptions taken to PL1 modes* on page G3-3660.
- *Fault reporting in PL1 modes* on page G3-3663.
- *Summary of register updates on faults taken to PL1 modes* on page G3-3666.
- *Reporting exceptions taken to Hyp mode* on page G3-3668.
- *Use of the HSR* on page G3-3672.
- *Summary of register updates on exceptions taken to Hyp mode* on page G3-3682.

---

### Note

The registers used for exception reporting also report information about debug exceptions. For more information see:

- *Data Abort exceptions, taken to a PL1 mode* on page G3-3661.
  - *Prefetch Abort exceptions, taken to a PL1 mode* on page G3-3662.
  - *Reporting exceptions taken to Hyp mode* on page G3-3668.
- 

### G3.13.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
  - On taking an exception to Hyp mode, the *Hyp Syndrome Register*, **HSR**, returns syndrome information.
  - On taking an exception to any other mode, a *Fault Status Register* (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in *Fault Address Registers* (FARs).

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.

---

**Note**

- [PE mode for taking exceptions on page G1-3439](#) describes how the mode to which an exception is taken is determined.
  - EL2 provides:
    - Specific exception types, that can only be taken from Non-secure PL1 and PL0 modes, and are always taken to Hyp mode.
    - Routing controls that can route some exceptions from Non-secure PL1 and PL0 modes to Hyp mode.These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.
- 

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- [Reporting exceptions taken to PL1 modes.](#)
- [Memory fault reporting in Hyp mode on page G3-3670.](#)

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see [The MMU fault-checking sequence on page G3-3650](#) and [Prioritization of aborts on page G3-3658](#).

### G3.13.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- [Registers used for reporting exceptions taken to PL1 modes.](#)
- [Data Abort exceptions, taken to a PL1 mode on page G3-3661.](#)
- [Prefetch Abort exceptions, taken to a PL1 mode on page G3-3662.](#)

[Fault reporting in PL1 modes on page G3-3663](#) then describes the fault reporting in these modes, including the encodings used for reporting the faults.

---

**Note**

[Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560](#) describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

---

### Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The **DFSR** holds information about a Data Abort exception.
- The **DFAR** holds the faulting address for some synchronous Data Abort exceptions.
- The **IFSR** holds information about a Prefetch Abort exception.
- The **IFAR** holds the faulting address of a Prefetch Abort exception.

In addition, if implemented, the optional **ADFSR** and **AIFSR** can provide additional fault information, see [Auxiliary Fault Status Registers](#).

### Auxiliary Fault Status Registers

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, **ADFSR**.
- The Auxiliary Instruction Fault Status Register, **AIFSR**.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity errors.

An implementation that does not need to report additional fault information must implement these registers as UNK/SBZP. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

### Data Abort exceptions, taken to a PL1 mode

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the current translation table format. For more information about the registers used when reporting the exception, see *Data Abort on an instruction cache maintenance operation by VA*.
- If the exception is generated by a Watchpoint debug event, then its reporting depends on whether the Watchpoint debug event is synchronous or asynchronous, and on the Debug architecture version. For more information, see *Data Abort on a Watchpoint exception on page G3-3662*.

Otherwise:

- The **DFSR** is updated with details of the fault, including the appropriate fault status code.  
If the Data Abort exception is synchronous, **DFSR.WnR** is updated to indicate whether the faulted access was a read or a write. However, if the fault is on a cache maintenance operation, or on an address translation operation, **WnR** is set to 1, to indicate a write access fault, and the **CM** bit is set to 1.  
**DFSR.WnR** is UNKNOWN on an asynchronous Data Abort exception.  
See the register description for more information about the returned fault information.
- If the Data Abort exception is
  - Synchronous, the **DFAR** is updated with the VA that caused the exception.
  - Asynchronous, the **DFAR** becomes UNKNOWN.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure **DFSR** and **DFAR** are updated.

### Data Abort on an instruction cache maintenance operation by VA

If an instruction cache or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the **DFAR** is updated to hold the faulting VA. However, the reporting of the fault depends on the current translation table format:

#### Short-descriptor format

It is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The **DFSR** indicates an Instruction cache maintenance operation fault, and the **IFSR** is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The **DFSR** indicates the cause of the fault, a Translation fault or Access flag fault. The **IFSR** is UNKNOWN.

In either case:

- **DFSR.WnR** is set to 1.
- **DFSR.CM** is set to 1, to indicate a fault on a cache maintenance operation.

#### Long-descriptor format

- **DFSR.CM** is set to 1, to indicate a fault on a cache maintenance operation.
- **DFSR.STATUS** indicates the cause of the fault, a Translation or Access flag fault.
- **DFSR.WnR** is set to 1.
- The **IFSR** is UNKNOWN.

### Data Abort on a Watchpoint exception

On taking a Data Abort exception caused by a watchpoint:

- **DFSR.FS** is updated to indicate a debug event.
- **DFSR**.{WnR, Domain} are UNKNOWN.
- **DFAR** is set to the address that generated the watchpoint

---

**Note**

- **LR\_abt** indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the **DBGWFAR** is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is **RES0**.

---

A watchpointed address can be any byte-aligned address. The address reported in **DFAR** might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance operation, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

---

**Note**

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

---

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

---

**Note**

The implementation defined power-of-two size must be no larger than the block size of the AArch64 **DC ZVA** operation.

### Prefetch Abort exceptions, taken to a PL1 mode

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, debug exceptions caused by a BKPT instruction, Breakpoint, or a Vector catch debug event, generate a Prefetch Abort exception, see [Breakpoint debug events and Vector Catch exception on page H2-4333](#).

On taking a Prefetch Abort exception to a PL1 mode:

- The **IFSR** is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception.  
See the register description for more information about the returned fault information.
- For a Prefetch Abort exception generated by an instruction fetch, the **IFAR** is updated with the VA that caused the exception.
- For a Prefetch Abort exception generated by a debug exception, the **IFAR** is UNKNOWN.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure **IFSR** and **IFAR**.

### G3.13.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

- [PL1 fault reporting with the Short-descriptor translation table format.](#)
- [PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.](#)

[Reserved encodings in the IFSR and DFSR encodings tables on page G3-3666](#) gives some additional information about the encodings for both formats.

[Summary of register updates on faults taken to PL1 modes on page G3-3666](#) shows which registers are updated on each of the reported faults.

[Reporting of External aborts taken from Non-secure state to Monitor mode](#) describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

#### Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

- For a Data Abort exception, the Secure [DFSR](#) and [DFAR](#) hold information about the abort.
- For a Prefetch Abort exception, the Secure [IFSR](#) and [IFAR](#) hold information about the abort.
- The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the [DFSR](#) and [IFSR](#). However, when [SCR.EA](#) is set to 1, to route external aborts to Monitor mode, and an external abort is taken from Non-secure state, this section defines the [DFSR](#) and [IFSR](#) format.

For an External abort taken from Non-secure state to Monitor mode, the [DFSR](#) or [IFSR](#) uses the format associated with the Long-descriptor translation table format, as described in [PL1 fault reporting with the Long-descriptor translation table format on page G3-3665](#), if any of the following applies:

- The Secure [TTBCR.EAE](#) bit is set to 1.
- The External abort is synchronous and either:
  - It is taken from Hyp mode.
  - It is taken from a Non-secure PL1 mode, and the Non-secure [TTBCR.EAE](#) bit is set to 1.

Otherwise, the [DFSR](#) or [IFSR](#) uses the format associated with the Short-descriptor translation table format, as described in [PL1 fault reporting with the Short-descriptor translation table format.](#)

#### PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. [Table G3-26 on page G3-3664](#) shows the encoding of that field. [Summary of register updates on faults taken to PL1 modes on page G3-3666](#) shows:

- Whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the [IFSR](#), whether the [IFAR](#) holds a valid address.
  - For a fault reported in the [DFSR](#), whether the [DFAR](#) holds a valid address.
- For faults that update [DFSR](#), whether [DFSR.Domain](#) is valid

When reading [Table G3-26 on page G3-3664](#):

- FS values not shown in the table are reserved.

- FS values shown as **DFSR** only are reserved for the **IFSR**.

**Table G3-26 FSR encodings when using the Short-description translation table format**

FS	Source		Notes
00001	Alignment fault		<b>DFSR</b> only. Fault on first lookup
00100	Fault on instruction cache maintenance		<b>DFSR</b> only
01100 01110	Synchronous external abort on translation table walk	First level Second level	-
11100 11110	Synchronous parity error on translation table walk	First level Second level	-
00101 00111	Translation fault	First level Second level	MMU fault
00011 <sup>a</sup> 00110	Access flag fault	First level Second level	MMU fault
01001 01011	Domain fault	First level Second level	MMU fault
01101 01111	Permission fault	First level Second level	MMU fault
00010	Debug event		See <a href="#">Chapter D3 The Debug Exception Model</a>
01000	Synchronous external abort		-
10000	TLB conflict abort		See <a href="#">TLB conflict aborts on page G3-3632</a>
10100	IMPLEMENTATION DEFINED		Lockdown
11010	IMPLEMENTATION DEFINED		Coprocessor abort
11001	Synchronous parity error on memory access		-
10110	Asynchronous external abort <sup>b</sup>		<b>DFSR</b> only
11000	Asynchronous parity error on memory access <sup>c</sup>		<b>DFSR</b> only

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use

b. Including asynchronous data external abort on translation table walk or instruction fetch.

c. Including asynchronous parity error on translation table walk.

### **The Domain field in the DFSR**

The **DFSR** includes a Domain field. This is inherited from previous versions of the VMSA. The **IFSR** does not include a Domain field. [Summary of register updates on faults taken to PL1 modes on page G3-3666](#) describes when **DFSR.Domain** is valid.

ARM deprecates any use of the Domain field in the **DFSR**. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

## PL1 fault reporting with the Long-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. [Table G3-27](#) shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, [Summary of register updates on faults taken to PL1 modes on page G3-3666](#) shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the **IFSR**, whether the **IFAR** holds a valid address.
  - For a fault reported in the **DFSR**, whether the **DFAR** holds a valid address.
- For a fault taken to the Hyp mode, [Summary of register updates on exceptions taken to Hyp mode on page G3-3682](#) shows what registers are updated on the fault.

**Table G3-27 FSR encodings when using the Long-descriptor translation table format**

STATUS <sup>a</sup>	Source	Notes
0001LL	Translation fault. LL bits indicate level <sup>b</sup> .	MMU fault
0010LL	Access flag fault. LL bits indicate level <sup>b</sup> .	MMU fault
0011LL	Permission fault. LL bits indicate level <sup>b</sup> .	MMU fault
010000	Synchronous external abort.	-
011000	Synchronous parity error on memory access.	-
010001	Asynchronous external abort.	<b>DFSR</b> only
011001	Asynchronous parity error on memory access.	<b>DFSR</b> only
0101LL	Synchronous external abort on translation table walk. LL bits indicate level <sup>b</sup> .	-
0111LL	Synchronous parity error on memory access on translation table walk. LL bits indicate level <sup>b</sup> .	-
100001	Alignment fault.	Fault on first lookup
100010	Debug event.	See <a href="#">Chapter D3 The Debug Exception Model</a>
110000	TLB conflict abort.	See <a href="#">TLB conflict aborts on page G3-3632</a>
110100	IMPLEMENTATION DEFINED.	Lockdown, <b>DFSR</b> only
111010	IMPLEMENTATION DEFINED.	Coprocessor abort, <b>DFSR</b> only
1111LL	Domain fault. LL bits indicate level <sup>b</sup> .	MMU fault. 64-bit <b>PAR</b> only, First or second level only. Never used in <b>DFSR</b> , <b>IFSR</b> , or <b>HSR</b> <sup>c</sup>

a. STATUS values not shown in this table are reserved. STATUS values not supported in the **IFSR** or **DFSR** are reserved for the register or registers in which they are not supported.

b. See [The level associated with MMU faults on page G3-3666](#).

c. A Domain fault can be reported using the Long-descriptor STATUS encodings only as a result of a fault on an address translation operation. For more information see [MMU fault on an address translation operation on page G3-3689](#).

### The level associated with MMU faults

For MMU faults, [Table G3-28](#) shows how the LL bits in the xFSR.STATUS field encode the lookup level associated with the fault.

**Table G3-28 Use of LL bits to encode the lookup level at which the fault occurred**

LL bits	Meaning
00	Reserved.
01	First level.
10	Second level.
11	Third level. When xFSR.STATUS indicates a Domain fault, this value is reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

### Reserved encodings in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for each of:

- Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.
- Aborts associated with coprocessors. The details of these faults are IMPLEMENTATION DEFINED.

## G3.13.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, [Table G3-29 on page G3-3667](#) shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

For faults that update the [DFSR](#) using the Short-descriptor format FSR encodings, [Table G3-30 on page G3-3668](#) shows whether [DFSR.Domain](#) is valid.

**Table G3-29 Effect of a fault taken to a PL1 mode on the reporting registers**

Fault	IFSR	IFAR	DFSR	DFAR
Faults reported as Prefetch Abort exceptions:				
MMU fault, always synchronous.	Yes	Yes	-	-
Synchronous external abort on translation table walk.	Yes	Yes	-	-
Synchronous parity error on translation table walk.	Yes	Yes	-	-
Synchronous external abort.	Yes	Yes	-	-
Synchronous parity error on memory access.	Yes	Yes	-	-
TLB conflict abort.	Yes	Yes	-	-
Fault reported as Data Abort exception:				
Alignment fault, always synchronous.	-	-	Yes	Yes
MMU fault, always synchronous.	-	-	Yes	Yes
Fault on instruction cache maintenance, when using Long-descriptor translation table format <sup>a</sup> .	UNK	-	Yes	Yes
Fault on instruction cache maintenance, when using Short descriptor translation table format <sup>b</sup> .	<i>either</i>	Yes	-	Yes
	<i>or</i>	UNK	-	Yes
Synchronous external abort on translation table walk.	-	-	Yes	Yes
Synchronous parity error on translation table walk.	-	-	Yes	Yes
Synchronous external abort.	-	-	Yes	Yes
Synchronous parity error on memory access.	-	-	Yes	Yes
Asynchronous external abort.	-	-	Yes	UNK
Asynchronous parity error on memory access.	-	-	Yes	UNK
TLB conflict abort.	-	-	Yes	Yes
Debug exceptions:				
Breakpoint, Software Breakpoint Instruction, or Vector Catch <sup>c</sup> .	Yes	UNK	-	-
Watchpoint <sup>d</sup> .	-	-	Yes	Yes

- a. When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance operation. For more information see [Data Abort on an instruction cache maintenance operation by VA on page G3-3661](#).
- b. The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see [Data Abort on an instruction cache maintenance operation by VA on page G3-3661](#).
- c. Generates a Prefetch Abort exception.
- d. Generates a Data Abort exception.

For those faults for which [Table G3-29 on page G3-3667](#) shows that the **DFSR** is updated, if the fault is reported using the Short-descriptor FSR encodings, [Table G3-30](#) shows whether **DFSR.Domain** is valid. In this table, UNK indicates that the fault makes **DFSR.Domain** UNKNOWN.

**Table G3-30 Validity of Domain field on faults that update the **DFSR** when using the Short-descriptor encodings**

<b>DFSR.FS</b>	<b>Source</b>		<b>DFSR.Domain</b>	<b>Notes</b>
00001	Alignment fault		UNK	-
00100	Fault on instruction cache maintenance operation		UNK	-
01100	Synchronous external abort on translation table walk	First level	UNK	-
01110		Second level	Valid	
11100	Synchronous parity error on translation table walk	First level	UNK	-
11110		Second level	Valid	
00101	Translation fault	First level	UNK	MMU fault
00111		Second level	Valid	
00011 <sup>a</sup>	Access flag fault	First level	UNK	MMU fault
00110		Second level	Valid	
01001	Domain fault	First level	Valid	MMU fault
01011		Second level	Valid	
01101	Permission fault	First level	UNK	MMU fault
01111		Second level	UNK	
01000	Synchronous external abort		UNK	-
10000	TLB conflict abort		UNK	-
11001	Synchronous parity error on memory access		UNK	-
10110	Asynchronous external abort <sup>b</sup>		UNK	-
11000	Asynchronous parity error on memory access <sup>c</sup>		UNK	-
00010	Watchpoint		UNK	

- a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use
- b. Including asynchronous data external abort on translation table walk or instruction fetch.
- c. Including asynchronous parity error on translation table walk.

### G3.13.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.

———— **Note** ————

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- Asynchronous external aborts, IRQ exceptions, and FIQ exceptions, from Non-secure PL0 and PL1 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see [Asynchronous exception routing controls on page G1-3467](#).

- When [HCR.TGE](#) is set to 1, all exceptions that would be routed to Non-secure PL1 modes. For more information, see [Routing general exceptions to EL2 on page G1-3452](#).
- When [HCR.TDE](#) is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).
- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode. This includes a Prefetch Abort exception generated by a Debug exception on a BKPT instruction.

———— **Note** —————

Debug exceptions other than the exception on a BKPT instruction are not permitted in Hyp mode.

- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2. When EL2 is implemented, various operations from Non-secure PL0 and PL1 modes can be *trapped* to Hyp mode, using the Hyp Trap exception. For more information, see [AArch32 control of traps to the hypervisor on page G1-3503](#).

These exceptions include any memory system fault that occurs:

- On a memory access from Hyp mode.
- On memory access from a Non-secure PL0 or PL1 mode:
  - On a stage 2 translation, from IPA to PA.
  - On the stage 2 translation of an address accessed in performing a stage 1 translation table walk.

[Memory fault reporting in Hyp mode on page G3-3670](#) gives more information about these faults.

The following exceptions provide *syndrome* information in the [HSR](#):

- Any synchronous exception taken to Hyp mode.
- Some exceptions taken from Debug state that would be taken to Hyp mode if the PE was not in Debug state, see [Exceptions in Debug state on page H2-4355](#).

———— **Note** —————

- In Debug state, the PE does not change mode on taking an exception.
- As [Exceptions in Debug state on page H2-4355](#) describes, some other exceptions taken from Debug state make the [HSR UNKNOWN](#).

The syndrome information in the [HSR](#) includes the fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode. For more information, see [Use of the HSR on page G3-3672](#).

In addition, for a Debug exception taken to Hyp mode, [DBGDSCRint.MOE](#) or [DBGDTRRNext.MOE](#) shows what caused the Debug exception. This bit is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

[Registers used for reporting exceptions taken to Hyp mode](#) lists all of the registers used for exception reporting in Hyp mode.

## Registers used for reporting exceptions taken to Hyp mode

The following registers are used for reporting exceptions taken to Hyp mode:

- The [HSR](#) holds syndrome information for the exception.
- The [HDFAR](#) holds the VA associated with a Data Abort exception.
- The [HIFAR](#) holds the VA associated with a Prefetch Abort exception.
- The [HPFAR](#) holds bits[39:12] of the IPA associated with a Prefetch Abort exception.

In addition, if implemented, the optional [HADFSR](#) and [HAIFSR](#) can provide additional fault information, see [Hyp Auxiliary Fault Syndrome Registers](#).

### Hyp Auxiliary Fault Syndrome Registers

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, [HADFSR](#).
- The Hyp Auxiliary Instruction Fault Syndrome Register, [HAIFSR](#).

An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in [Auxiliary Fault Status Registers](#) on page G3-3660. An example use of these registers is to return more information for diagnosing parity errors.

The architectural requirements for the [HADFSR](#) and [HAIFSR](#) are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as UNK/SBZP, but the architecture does not require it to do so.

### Memory fault reporting in Hyp mode

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the [HSR](#) contains the following fault status information:

- The [HSR.EC](#) field indicates the type of abort, as [Table G3-31](#) shows.
- The [HSR.ISS](#) field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in [PL1 fault reporting with the Long-descriptor translation table format](#) on page G3-3665.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the *Syndrome description* column of [Table G3-31](#), for information about the returned fault information.

**Table G3-31 HSR.EC encodings for aborts taken to Hyp mode**

HSR.EC	Abort	Syndrome description
0x20	Prefetch Abort taken from Non-secure PL0 or PL1 mode	<i>ISS encoding for Prefetch Abort exceptions taken to Hyp mode</i> on page G3-3679
0x21	Prefetch Abort taken from Hyp mode	
0x24	Data Abort taken from Non-secure PL0 or PL1 mode	<i>ISS encoding for Data Abort exceptions taken to Hyp mode</i> on page G3-3680
0x25	Data Abort taken from Hyp mode	

For more information, see [Use of the HSR](#) on page G3-3672.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

### Register updates on exception reporting in Hyp mode

The use of the **HSR**, and of the other registers listed in *Registers used for reporting exceptions taken to Hyp mode* on page G3-3669, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the **HDFAR** holds the associated VA.
  - If the fault generates a Prefetch Abort exception, the **HIFAR** holds the associated VA.
  - In the following cases, the **HPFAR** holds the faulting IPA:
    - A Translation or Access flag fault on a stage 2 translation.
    - A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
- In all other cases, the **HPFAR** is UNKNOWN.
- On a Data Abort exception that is taken to Hyp mode, the **HIFAR** is UNKNOWN.
  - On a Prefetch Abort exception that is taken to Hyp mode, the **HDFAR** is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

#### Abort on the stage 1 translation for a memory access from Hyp mode

The **HDFAR** or **HIFAR** holds the VA that caused the fault. The **STATUS** subfield of **HSR.ISS** indicates the type of fault, Translation, Address size, Access flag, or Permission. The **HPFAR** is UNKNOWN.

#### Abort on the stage 2 translation for a memory access from a Non-secure PL1 or PL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The **HDFAR** or **HIFAR** holds the VA that caused the fault. The **STATUS** subfield of **HSR.ISS** indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the **HPFAR** holds the IPA that caused the fault. Otherwise, the **HPFAR** is UNKNOWN.

#### Abort caused by a synchronous external abort, or synchronous parity error, and taken to Hyp mode

The **HDFAR** or **HIFAR** holds the VA that caused the fault. The **HPFAR** is UNKNOWN.

#### Data Abort caused by a Watchpoint exception and routed to Hyp mode because **HDCR.TDE** is set to 1

When **HDCR.TDE** is set to 1, a Watchpoint exception generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

**HDFAR** is set to the address that generated the watchpoint.

#### ———— Note —————

**ELR\_hyp** indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in **HDFAR** might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance operation, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

#### ———— Note —————

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

---

**Note**

The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also [Watchpoint exceptions](#) on page D2-1606.

In all cases, HPFAR is UNKNOWN.

**Prefetch Abort caused by a Software Breakpoint Instruction exception and taken to Hyp mode**

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also [Breakpoint debug events and Vector Catch exception](#) on page H2-4333.

**Prefetch Abort caused by a Software Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1**

When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

---

**Note**

The difference between these two cases is:

- The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.
- Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

### G3.13.6 Use of the HSR

The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:

- Always provides details of the fault. The DFSR and IFSR are not used.
- Provides more extensive information, for a wider range of exceptions.

---

**Note**

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

The general format of the HSR is that it comprises:

- A 6-bit exception class field, EC, that indicates the cause of the exception.
- An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:  
**0** 16-bit instruction trapped.  
**1** 32-bit instruction trapped.

This field is not valid for the following cases:

- When the EC field is 0x00, indicating an exception with an unknown reason.
- Instruction Aborts.
- Data Aborts that do not have ISS information, or for which the ISS is not valid.

In these cases, the IL field is RES1.

- An instruction specific syndrome field, ISS. Architecturally, this field can be defined independently for each defined exception class.

This field is not valid, UNK/SBZP, when the EC field is 0x00, indicating an exception with an unknown reason.

Figure G3-25 shows the format of the HSR, with the subdivision of the ISS field that applies to nonzero EC values with the two most significant bits 0b00.

Figure G3-25 Format of the HSR, with subdivision of the ISS field for specified EC encodings

### HSR exception classes and associated ISS encodings

Table G3-32 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. The table divides the EC values into three groups, relating to the interpretation of the associated ISS fields. For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Table G3-32 HSR.EC field encoding

EC	Exception class	ISS description, or notes
0x00	Unknown reason	<i>Exceptions with an unknown reason on page G3-3674.</i>
Nonzero EC values with HSR[31:30] zero <sup>a</sup>		
0x01	Trapped WFI or WFE instruction	<i>ISS encoding for trapped WFI or WFE instruction on page G3-3675.</i>
0x03	Trapped MCR or MRC access to CP15	<i>ISS encoding for trapped MCR or MRC access on page G3-3675.</i>
0x04	Trapped MCRR or MRRC access to CP15	<i>ISS encoding for trapped MCRR or MRRC access on page G3-3676.</i>
0x05	Trapped MCR or MRC access to CP14	<i>ISS encoding for trapped MCR or MRC access on page G3-3675.</i>
0x06	Trapped LDC or STC access to CP14	<i>ISS encoding for trapped LDC or STC access on page G3-3677.</i>
0x07	HCPTR-trapped access to CP10 or CP11	<i>ISS encoding for HCPTR-trapped access to CP10 or CP11 on page G3-3678.</i> Includes trap on use of Advanced SIMD.
0x08	Trapped MRC or VMRS access to CP10, for ID group traps	<i>ISS encoding for trapped MCR or MRC access on page G3-3675.</i> This trap is not taken if the HCPTR settings trap the access.
0x0C	Trapped MRRC access to CP14	<i>ISS encoding for trapped MCRR or MRRC access on page G3-3676.</i>
0x0E	Illegal exception return to AArch32 state	The ISS is RES0

**Table G3-32 HSR.EC field encoding (continued)**

EC	Exception class	ISS description, or notes
EC values with HSR[31:30] nonzero		
0x11	Supervisor Call exception routed to Hyp mode	<i>ISS encoding for Hypervisor Call exception, or Supervisor Call exception routed to Hyp mode on page G3-3678.</i>
0x12	Hypervisor Call	
0x13	Trapped SMC instruction	<i>ISS encoding for trapped SMC execution on page G3-3679.</i>
0x20	Prefetch Abort routed to Hyp mode	<i>ISS encoding for Prefetch Abort exceptions taken to Hyp mode on page G3-3679.</i>
0x21	Prefetch Abort taken from Hyp mode	
0x22	PC Alignment Exception.	The ISS is RES0
0x24	Data Abort routed to Hyp mode	<i>ISS encoding for Data Abort exceptions taken to Hyp mode on page G3-3680.</i>
0x25	Data Abort taken from Hyp mode	

a. For more information see *Encoding of ISS[24:20] when HSR[31:30] is 0b00*.

All EC encodings not shown in [Table G3-31 on page G3-3670](#) are reserved by ARM.

#### **Exceptions with an unknown reason**

An HSR.EC value of 0x00 indicates an exception with an unknown reason. Any exception not covered by a nonzero EC value defined in [Table G3-32 on page G3-3673](#) returns this value. When HSR.EC returns a value of 0x00, all other fields of HSR are invalid.

*Undefined Instruction exception, when HCR.TGE is set to 1 on page G1-3452* describes the configuration settings for a trap that returns an HSR.EC value of 0x00.

#### **Encoding of ISS[24:20] when HSR[31:30] is 0b00**

For EC values that are nonzero and have the two most-significant bits 0b00, ISS[24:20] provides the condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

**CV, ISS[24]** Condition code valid. Possible values of this bit are:

<b>0</b>	The COND field is not valid.
<b>1</b>	The COND field is valid

#### **COND, ISS[23:20]**

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

If CV is set to 0, this field is UNK/SBZP.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV set to 0 and COND is set to an UNKNOWN value
- CV set to 1 and COND is set to the condition code for the condition that applied to the instruction.

When CV is set to 0, software must examine the SPSR.IT field to determine the conditionality of a T32 instruction.

Except for unconditional T32 instructions reported with CV set to 0, a trapped unconditional instruction is reported with CV set to 1 and a COND value of 0x0E, the condition code value for unconditional.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

———— **Note** ————

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its condition code check generates an Undefined Instruction exception, see [Conditional execution of undefined instructions on page G1-3478](#).

**ISS encoding for trapped WFI or WFE instruction**

This is the exception with EC value 0x01. When HSR.EC returns this value, the encoding of the ISS field is:

**ISS[24:20]** See [Encoding of ISS\[24:20\] when HSR\[31:30\] is 0b00 on page G3-3674](#).

**ISS[19:1]** Reserved, UNK/SBZP.

**ISS[0]** Indicates the trapped instruction. The possible values of this bit are:

- 0** WFI trapped.
- 1** WFE trapped.

[Trapping use of the WFI and WFE instructions on page G1-3511](#) describes the configuration settings for this trap.

**ISS encoding for trapped MCR or MRC access**

These are the exceptions with the following EC values:

- 0x03, trapped MRC or MCR access to CP15.
- 0x05, trapped MRC or MCR access to CP14.
- 0x08, trapped MRC or VMRS access to CP10.

When HSR.EC returns one of these values, the encoding of the ISS field is:

**ISS[24:20]** See [Encoding of ISS\[24:20\] when HSR\[31:30\] is 0b00 on page G3-3674](#).

**ISS[19:17]** The Opc2 value from the issued instruction.

**ISS[16:14]** The Opc1 value from the issued instruction.

**ISS[13:10]** The CRn value from the issued instruction, the coprocessor primary register value.

**ISS[9]** Reserved, UNK/SBZP.

**ISS[8:5]** The Rt value from the issued instruction, the general-purpose register used for the transfer.

**ISS[4:1]** The CRm value from the issued instruction.

**ISS[0]** Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0** Write to coprocessor. MCR instruction.
- 1** Read from coprocessor. MRC or VMRS instruction.

The following sections describe configuration settings for traps that are reported using EC value 0x03:

- [Trapping ID mechanisms on page G1-3506](#).

- [Trapping accesses to lockdown, DMA, and TCM operations](#) on page G1-3508.
- [Trapping accesses to cache maintenance operations](#) on page G1-3509.
- [Trapping accesses to TLB maintenance operations](#) on page G1-3509.
- [Trapping accesses to the Auxiliary Control Register](#) on page G1-3509.
- [Trapping accesses to the Performance Monitors Extension](#) on page G1-3510.
- [Trapping CPACR accesses](#) on page G1-3513.
- [Generic trapping of accesses to CP15 system control registers](#) on page G1-3513.

The following sections describe configuration settings for traps that are reported using EC value 0x05:

- [ID group 0, Primary device identification registers](#) on page G1-3507.
- [Trapping accesses to the T32EE configuration registers](#) on page G1-3511.
- [Trapping CP14 accesses to Debug ROM registers](#) on page G1-3514.
- [Trapping CP14 accesses to OS-related debug registers](#) on page G1-3515.
- [Trapping CP14 accesses to debug registers](#) on page G1-3514.
- [Trapping CP14 accesses to trace registers](#) on page G1-3516.

[Trapping ID mechanisms](#) on page G1-3506 describes configuration settings for traps that are reported using EC value 0x08.

**ISS encoding for trapped MCRR or MRRC access**

These are the exceptions with the following EC values:

- 0x04, trapped MRRC or MCRR access to CP15.
- 0x0C, trapped MRRC access to CP14.

When HSR.EC returns one of these values, the encoding of the ISS field is:

24	23	20	19	16	15	14	13	10	9	8	5	4	1	0
CV	COND		Opc1	(0) (0)		Rt2	(0)	Rt	CRm			Direction		

- ISS[24:20]** See [Encoding of ISS\[24:20\] when HSR\[31:30\] is 0b00](#) on page G3-3674.
- ISS[19:16]** The Opc1 value from the issued instruction.
- ISS[15:14]** Reserved, UNK/SBZP.
- ISS[13:10]** The Rt2 value from the issued instruction, one of the general-purpose registers for the transfer.
- ISS[9]** Reserved, UNK/SBZP.
- ISS[8:5]** The Rt value from the issued instruction, one of the general-purpose registers for the transfer.
- ISS[4:1]** The CRm value from the issued instruction, the coprocessor primary register value.
- ISS[0]** Indicates the direction of the trapped instruction. The possible values of this bit are:
  - 0** Write to coprocessor, MCRR instruction.
  - 1** Read from coprocessor, MRRC instruction.

The following sections describe configuration settings for traps that are reported using EC value 0x04:

- [Trapping writes to virtual memory control registers](#) on page G1-3513.
- [Generic trapping of accesses to CP15 system control registers](#) on page G1-3513.

The following sections describe configuration settings for traps that are reported using EC value 0x0C:

- [Trapping CP14 accesses to debug registers](#) on page G1-3514.
- [Trapping CP14 accesses to Debug ROM registers](#) on page G1-3514.

### ISS encoding for trapped LDC or STC access

This is the exception with EC value 0x06. When HSR.EC returns this value, the encoding of the ISS field is:

**ISS[24:20]** See [Encoding of ISS\[24:20\] when HSR\[31:30\] is 0b00](#) on page G3-3674.

**ISS[19:12]** imm8. The immediate value from the issued instruction.

**ISS[11:9]** Reserved, UNK/SBZP.

**ISS[8:5]** Encoding depends on the instruction form indicated by ISS[3]:

**ISS[3]==0** Encodes Rn, the general-purpose register that holds the base address. Applies only to immediate instruction forms.

**ISS[3]==1** UNKNOWN. Applies only to literal instruction forms, that are available only for LDC instructions

**ISS[4]** Indicates whether the offset is added or subtracted:

**0** Subtract offset.

**1** Add offset.

This bit corresponds to the U bit in the instruction encoding.

**ISS[3:1]** Addressing mode. The permitted values of this field are:

0b000 Immediate unindexed.

0b001 Immediate post-indexed.

0b010 Immediate offset.

0b011 Immediate pre-indexed.

0b100 Literal unindexed.

LDC instruction in A32 instruction set only.

For a trapped STC instruction or a trapped LDC T32 instruction, this encoding is reserved.

0b101 Reserved.

0b110 Literal offset.

LDC instruction only.

For a trapped STC instruction, this encoding is reserved.

0b111 Reserved.

ISS[3] indicates the instruction form, immediate or literal. See the description of ISS[8:5].

ISS[2:1] correspond to the bits {P, W} in the instruction encoding.

**ISS[0]** Indicates the direction of the trapped instruction. The possible values of this bit are:

**0** Write to coprocessor. STC instruction.

**1** Read from coprocessor, LDC instruction.

#### ————— Note —————

The only architected uses of these instructions to access CP14 are:

- An STC to write to [DBGDTRTXint](#).
- An LDC to read [DBGDTRTXint](#).

[Trapping general CP14 accesses to debug registers on page G1-3515](#) describes the configuration settings for the trap that is reported using EC value 0x06.

**ISS encoding for HCPTR-trapped access to CP10 or CP11**

This is the exception with EC value 0x07. When HSR.EC returns this value, the encoding of the ISS field is:

Trapped Advanced SIMD  $\lrcorner$

**ISS[24:20]** See [Encoding of ISS\[24:20\] when HSR\[31:30\] is 0b00 on page G3-3674](#).

**ISS[19:6]** Reserved, UNK/SBZP.

**ISS[5]** Indicates trapped use of the Advanced SIMD functionality. The possible values of this bit are:

- 0** Exception was not caused by trapped use of Advanced SIMD functionality.
- 1** Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

**ISS[4]** Reserved, UNK/SBZP.

**ISS[3:0]** coproc. The number of the coprocessor accessed by the trapped operation, 10 or 11.

This field is valid only when ISS[5] returns 0. Otherwise, it is UNK/SBZP.

Any use of a floating-point instruction or access to a register in the Advanced SIMD and floating-point register bank that is trapped to Hyp mode because of a trap configured in the HCPTR sets this field to 0xA.

The following sections describe the configuration settings for the traps that are reported using EC value 0x07:

- [Trapping of Advanced SIMD functionality on page G1-3512](#).
- [General trapping of coprocessor accesses on page G1-3512](#)

**ISS encoding for Hypervisor Call exception, or Supervisor Call exception routed to Hyp mode**

These are the exceptions with the following EC values:

- 0x11, Supervisor Call exception taken to Hyp mode.
- 0x12, Hypervisor Call exception.

———— **Note** —————

- A Supervisor Call exception is generated by executing an SVC instruction, see [SVC \(previously SWI\) on page F7-2926](#).
- A Hypervisor Call exception is generated by executing an HVC instruction, see [HVC on page F7-3040](#).

When HSR.EC returns one of these values, the encoding of the ISS field is:

**ISS[24:16]** Reserved, UNK/SBZP.

**ISS[15:0]** imm16. The value of the immediate field from the issued instruction.

For an SVC instruction:

- If the instruction is unconditional:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

———— **Note** —————

The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

*Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452* describes the configuration settings for the trap reported with EC value 0x11.

**ISS encoding for trapped SMC execution**

This is the exception with EC value 0x13. When HSR.EC returns this value, the ISS field does not return any syndrome information, and the encoding of the ISS field is:

**ISS[24:0]** Reserved, UNK/SBZP.

———— **Note** —————

SMC instructions cannot be trapped if they fail their condition code check. Therefore, the syndrome information for this exception does not include conditionality information.

*Trapping use of the SMC instruction on page G1-3510* describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

**ISS encoding for Prefetch Abort exceptions taken to Hyp mode**

These are the exceptions with the following EC values:

- 0x20, for a Prefetch Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0x21, for a Prefetch Abort exception taken from Hyp mode.

When HSR.EC returns one of these values, the encoding of the ISS field is:

**ISS[24:10]** Reserved, UNK/SBZP.

**ISS[9]** EA, External abort type. Can provide an IMPLEMENTATION DEFINED classification of external aborts. If the implementation does not provide any classification of external aborts, this bit is UNK/SBZP.

For any abort other than an External abort this bit returns a value of 0.

———— **Note** —————

This bit is equivalent to the IFSR.ExT bit.

**ISS[8]** Reserved, UNK/SBZP.

**ISS[7]** S1PTW. For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:  
**0** Fault not on a stage 2 translation for a stage 1 translation table walk.  
**1** Fault on the stage 2 translation of an access for a stage 1 translation table walk.  
 For a stage 1 fault, this bit is UNK/SBZP.

**ISS[6]** Reserved, UNK/SBZP.

**ISS[5:0]** IFSC, Instruction fault status code. Indicates the fault that caused the exception, using the fault codes defined for use with the Long-descriptor translation table format, see [PLI fault reporting with the Long-descriptor translation table format on page G3-3665](#).

———— **Note** —————

This field is equivalent to the **IFSR.STATUS** field, and only valid **IFSR.STATUS** values are valid for this field.

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the **HSR** with EC value 0x20:

- [External abort, when HCR.TGE is set to 1 on page G1-3453](#).
- [Routing Debug exceptions to Hyp mode on page G1-3454](#).

**ISS encoding for Data Abort exceptions taken to Hyp mode**

These are the exceptions with the following EC values:

- 0x24, for a Data Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0x25, for a Data Abort exception taken from Hyp mode.

When **HSR.EC** returns one of these values, the encoding of the ISS field is:

**ISS[24]** Instruction syndrome valid. Indicates whether ISS[24:16] provide a valid instruction syndrome, as part of the returned ISS. The possible values of this bit are:  
**0** No valid instruction syndrome. ISS[23:16] are UNK/SBZP.  
**1** ISS[24:16] hold a valid instruction syndrome.

This bit is 0 for all faults except for those generated by a stage 2 translation. For Data Abort exceptions generated by a stage 2 translation, this bit is 1 and a valid instruction syndrome is returned only if all of the following are true:

- The instruction that generated the Data Abort exception:
  - Is an LDR, LDRT, LDRSH, LDRSHT, LDRH, LDRHT, LDRSB, LDRSBT, LDRB, LDRBT, STR, STRT, STRH, STRHT, STRB, or STRBT.
  - Is not performing register writeback.
  - Is not using the PC as its destination register.

———— **Note** —————

- For ISS reporting, a stage 2 abort on a stage 1 translation table lookup is treated as a stage 1 Translation fault, and does not return a valid instruction syndrome.
- In the A32 instruction set, LDR\*T and STR\*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

- A valid instruction syndrome provides information that can help a hypervisor to emulate the instruction efficiently. Instruction syndromes are returned for instructions for which such accelerated emulation is possible.

---

**ISS[23:16], when ISS[24] is 0**

Reserved, UNK/SBZP.

**ISS[23:16], when ISS[24] is 1**

The remainder of the valid instruction syndrome, defined as follows:

**ISS[23:22] SAS**, Syndrome access size. Indicate the size of the access attempted by the faulted operation. The possible values of this field are:

0b00 Byte.  
0b01 Halfword.  
0b10 Word.  
0b11 Reserved.

**ISS[21] SSE**, Syndrome sign extend. For a byte or halfword load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

**0** Sign-extension not required.  
**1** Data item must be sign-extended.

For all other operations this bit is 0.

**ISS[20]** Reserved, UNK/SBZP.

**ISS[19:16] SRT**, Syndrome Register Transfer. The value of the Rt operand of the faulting instruction. This specifies:

- The destination register for a load operation.
- The source register for a store operation.

---

**Note**

Normally, software emulating an instruction must consider both the Rt value and the Mode value saved in the [SPSR](#), to determine the physical register to access.

---

**ISS[15:10]** Reserved, UNK/SBZP.

**ISS[9] EA**, External abort type. Can provide an IMPLEMENTATION DEFINED classification of external aborts. If the implementation does not provide any classification of external aborts, this bit is UNK/SBZP.

For any abort other than an External abort this bit returns a value of 0.

---

**Note**

This bit is equivalent to the [DFSR.ExT](#) bit.

---

**ISS[8] CM**, Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation operation. For synchronous faults, the possible values of this bit are:

**0** Fault not generated by a cache maintenance or address translation operation.  
**1** Fault generated by a cache maintenance or address translation operation.

For asynchronous faults, this bit is 0.

---

**Note**

This bit is equivalent to the [DFSR.CM](#) bit.

---

**ISS[7]** S1PTW. For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:  
**0** Fault not on a stage 2 translation for a stage 1 translation table walk.  
**1** Fault on the stage 2 translation of an access for a stage 1 translation table walk.  
For a stage 1 fault, this bit is UNK/SBZP.

**ISS[6]** WnR. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:  
**0** Abort caused by a read operation.  
**1** Abort caused by a write operation.  
For synchronous faults on cache maintenance and address translation operations, this bit always returns a value of 1.

———— **Note** —————

ISS[8] is set to 1 to identify a fault on a cache maintenance or address translation operation.

For an asynchronous Data Abort exception this bit is UNKNOWN.

———— **Note** —————

This bit is equivalent to the [DFSR.WnR](#) bit.

**ISS[5:0]** DFSC, Data fault status code. Indicates the fault that caused the exception, using the fault codes defined for use with the Long-descriptor translation table format, see [PLI fault reporting with the Long-descriptor translation table format on page G3-3665](#).

———— **Note** —————

This field is equivalent to the [DFSR.STATUS](#) field, and all valid [DFSR.STATUS](#) values are valid for this field.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the [HSR](#) with EC value 0x24:

- [MMU fault, when HCR.TGE is set to 1 on page G1-3453](#).
- [External abort, when HCR.TGE is set to 1 on page G1-3453](#).
- [Routing Debug exceptions to Hyp mode on page G1-3454](#).

### G3.13.7 Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, [Table G3-33 on page G3-3683](#) shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

**Table G3-33 Effect of an exception taken to Hyp mode on the reporting registers**

<b>Fault</b>	<b>HSR</b>	<b>HIFAR</b>	<b>HDFAR</b>	<b>HPFAR</b>
Faults reported as Prefetch Abort exceptions:				
Address translation fault <sup>a</sup> at stage 1.	Yes	Yes	UNK	UNK
Address translation or Access flag fault <sup>a</sup> at stage 2.	Yes	Yes	UNK	Yes
Address translation fault <sup>a</sup> at stage 2.	Yes	Yes	UNK	UNK
Address translation stage 2 fault <sup>a</sup> on stage 1 translation.	Yes	Yes	UNK	Yes
Synchronous external abort on translation table walk.	Yes	Yes	UNK	UNK
Synchronous parity error on translation table walk.	Yes	Yes	UNK	UNK
Synchronous external abort.	Yes	Yes	UNK	UNK
Synchronous parity error on memory access.	Yes	Yes	UNK	UNK
TLB conflict abort.	Yes	Yes	UNK	UNK
Fault reported as Data Abort exception:				
Alignment fault, always synchronous	Yes	UNK	Yes	UNK
Address translation fault <sup>a</sup> at stage 1.	Yes	UNK	Yes	UNK
Address translation Translation or Access flag fault <sup>a</sup> at stage 2.	Yes	UNK	Yes	Yes
Address translation Permission fault <sup>a</sup> at stage 2.	Yes	UNK	Yes	UNK
Address translation stage 2 fault <sup>a</sup> on stage 1 translation.	Yes	UNK	Yes	Yes
Synchronous external abort on translation table walk.	Yes	UNK	Yes	UNK
Synchronous parity error on translation table walk.	Yes	UNK	Yes	UNK
Synchronous external abort.	Yes	UNK	Yes	UNK
Synchronous parity error on memory access.	Yes	UNK	Yes	UNK
Asynchronous external abort.	Yes	UNK	UNK	UNK
Asynchronous parity error on memory access.	Yes	UNK	UNK	UNK
TLB conflict abort.	Yes	UNK	Yes	UNK
Debug exception:				
Software Breakpoint Instruction <sup>b</sup> , generates a Prefetch Abort exception.	Yes	UNK	-	UNK
Debug exception routed to Hyp mode because <b>HDCR.TDE</b> is set to 1. Generates a Hyp Trap exception.				
Breakpoint Software Breakpoint Instruction or Vector Catch	Yes	UNK	-	UNK
Watchpoint	Yes	-	Yes	UNK

a. For more information see [Classification of MMU faults taken to Hyp mode on page G3-3684](#)

b. All other debug exceptions are not permitted in Hyp mode.

---

**Note**

Unlike [Table G3-29 on page G3-3667](#), the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance operation. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance operation, see [ISS encoding for Data Abort exceptions taken to Hyp mode on page G3-3680](#).

---

### Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in [Table G3-33 on page G3-3683](#).

---

**Note**

All MMU faults are synchronous.

---

The table uses the following descriptions for MMU faults taken to Hyp mode:

#### Address translation fault at stage 1

This is an address translation fault generated on a stage 1 translation performed in the Non-secure PL2 translation regime.

#### Address translation fault at stage 2

This is an address translation fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the [HPFAR](#)
- Permission faults leave the [HPFAR](#) UNKNOWN.

#### Address translation stage 2 fault on a stage 1 translation

This is an address translation fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#).

[Figure G3-1 on page G3-3563](#) shows the different translation regimes and associated stages of translation.

## G3.14 Virtual Address to Physical Address translation operations

The system register space includes operations for *Virtual Address (VA)* to *Physical Address (PA)* translation. [Address translation operations, functional group on page G3-3745](#) summarizes these operations.

When using the Short-descriptor translation table format, all VA to PA translations take account of TEX remap when this is enabled, see [Short-descriptor format memory region attributes, with TEX remap on page G3-3620](#).

A VA to PA translation operation returns the PA in the **PAR**. This is a 64-bit register, that can hold PAs of up to 40 bits.

The following sections give more information about these operations:

- [Naming of the address translation operations, and operation summary.](#)
- [Encoding and availability of the address translation operations on page G3-3687.](#)
- [Determining the PAR format on page G3-3688.](#)
- [Handling of faults and aborts during an address translation operation on page G3-3688.](#)

### G3.14.1 Naming of the address translation operations, and operation summary

Some older documentation uses the original names for the Address translation operations that were included in the original ARMv7 documentation. [Table G3-34](#) summarizes the operations that are available in AArch32 state, and relates the old operation names to the current names.

**Table G3-34 Naming of address translation operations**

Name	Old name	Description
<a href="#">ATS1CPR</a> , <a href="#">ATS1CPW</a> , <a href="#">ATS1CUR</a> , <a href="#">ATS1CUW</a>	V2PCWPR, V2PCWPW, V2PCWUR, V2PCWUW	See <a href="#">Address translation stage 1, current security state on page G3-3686</a>
<a href="#">ATS12NSOPR</a> , <a href="#">ATS12NSOPW</a> , <a href="#">ATS12NSOUR</a> , <a href="#">ATS12NSOUW</a>	V2POWPR, V2POWPW, V2POWUR, V2POWUW	See <a href="#">Address translation stages 1 and 2, Non-secure state only on page G3-3686</a>
<a href="#">ATS1HR</a> , <a href="#">ATS1HW</a>	Not applicable <sup>a</sup>	See <a href="#">Address translation stage 1, Hyp mode on page G3-3686</a>

a. Operations are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

In the *stage 1 current state* and *stages 1 and 2 Non-secure state only* operations, the meanings of the last two letters of the names are:

<b>PR</b>	PL1 mode, read operation.
<b>PW</b>	PL1 mode, write operation.
<b>UR</b>	User mode, read operation.
<b>UW</b>	User mode, write operation.

———— **Note** —————

User mode can be described as an unprivileged mode. It is the only PL0 mode.

In the *stage 1 Hyp mode* operations, the last letter of the operation name is **R** for the read operation and **W** for the write operation.

The following sections describe the use and availability of these operations:

- [Address translation stage 1, current security state on page G3-3686.](#)
- [Address translation stages 1 and 2, Non-secure state only on page G3-3686.](#)
- [Address translation stage 1, Hyp mode on page G3-3686.](#)

[Encoding and availability of the address translation operations on page G3-3687](#) gives the encodings of the operations.

### Address translation stage 1, current security state

These are the `ATS1Cxx` operations. Any VMSAv8-32 implementation supports these operations. They can be executed by any software executing at PL1 or higher, in either Security state.

These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these operations return the IPA that is the output address of the stage 1 translation. [Figure G3-1 on page G3-3563](#) shows the different translation regimes.

#### ———— Note ————

The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

See [Determining the PAR format on page G3-3688](#) for the format used when returning the result of these operations.

### Address translation stages 1 and 2, Non-secure state only

These are the `ATS12NSOxx` operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- If the implementation includes EL3, by any software executing in Secure state at PL1.
- If the implementation includes EL2, by software executing in Non-secure state at PL2. This means by software executing in Hyp mode.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not undefined but each instruction behaves in the same way as the equivalent `ATSIC*` instruction.

ARM deprecates use of these operations from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these operations perform the translations made by the Non-secure PL1&0 translation regime.

These operations always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.

#### ———— Note ————

From Hyp mode, the `ATS1Cxx` and `ATS12NSOxx` operations both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The `ATS1Cxx` operations return the Non-secure PL1 view of these operations. That is, they return the IPA output address corresponding to the VA input address.
- The `ATS12NSOxx` operations return the EL2, or Hyp mode, view of these operations. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See [Determining the PAR format on page G3-3688](#) for the format used when returning the result of these operations.

### Address translation stage 1, Hyp mode

These are the `ATS1Hx` operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

These operations are UNPREDICTABLE if used in a Secure PL1 mode other than Monitor mode.

These operations perform the translations made by the Non-secure EL2 translation regime. The operation takes a VA input address and returns a PA output address.

These operations always return a result in a 64-bit format [PAR](#).

### G3.14.2 Encoding and availability of the address translation operations

Software executing at PL0 never has any visibility of the address translation operations, but software executing at PL1 or higher can use the unprivileged address translation operations to find the address translations used for memory accesses by software executing at PL0 and PL1.

———— **Note** ————

For information about translations when the stage of address translation is disabled see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569](#).

[Table G3-35](#) shows the encodings for the address translation operations, and their availability in different implementations in different PE modes and states.

**Table G3-35 Address translation operations in AArch32 state**

opc1	CRm	opc2	Name	Type	Description
All VMSAv8-32 implementations, in all modes, at PL1 or higher					
0	c8	0	<a href="#">ATS1CPR</a>	WO	PL1 stage 1 read translation, current state <sup>a</sup>
		1	<a href="#">ATS1CPW</a>	WO	PL1 stage 1 write translation, current state <sup>a</sup>
		2	<a href="#">ATS1CUR</a>	WO	Unprivileged stage 1 read translation, current state <sup>a</sup>
		3	<a href="#">ATS1CUW</a>	WO	Unprivileged stage 1 write translation, current state <sup>a</sup>
Implementations that include EL2, in Non-secure Hyp mode and Secure PL1 modes					
0	c8	4	<a href="#">ATS12NSOPR</a>	WO	Non-secure PL1 stage 1 and 2 read translation <sup>b</sup>
		5	<a href="#">ATS12NSOPW</a>	WO	Non-secure PL1 stage 1 and 2 write translation <sup>b</sup>
		6	<a href="#">ATS12NSOUR</a>	WO	Non-secure unprivileged stage 1 and 2 read translation <sup>b</sup>
		7	<a href="#">ATS12NSOUW</a>	WO	Non-secure unprivileged stage 1 and 2 write translation <sup>b</sup>
Implementations that include EL2, in Non-secure Hyp mode and Secure Monitor mode					
4	c8	0	<a href="#">ATS1HR</a>	WO	Hyp mode stage 1 read translation <sup>c</sup>
		1	<a href="#">ATS1HW</a>	WO	Hyp mode stage 1 write translation <sup>c</sup>

- a. For more information about these operations see [Address translation stage 1, current security state on page G3-3686](#).
- b. For more information about these operations see [Address translation stages 1 and 2, Non-secure state only on page G3-3686](#).
- c. For more information about these operations see [Address translation stage 1, Hyp mode on page G3-3686](#).

The result of an operation is always returned in the [PAR](#). The [PAR](#) is a RW register and:

- In all implementations, the 32-bit format [PAR](#) is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format [PAR](#) is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation operations that are not available in a particular implementation are reserved and UNPREDICTABLE. For example, in an implementation that does not include EL3, the encodings with `opc2` values of 4-7, and the encodings with an `opc1` value of 4, are reserved and UNPREDICTABLE.

### G3.14.3 Determining the PAR format

The `PAR` is a 64-bit register, that supports both 32-bit and 64-bit `PAR` formats. This section describes how the `PAR` format is determined, for returning a result from each of the groups of address translation operations. The returned result might be the translated address, or might indicate a fault on the translation, see *Handling of faults and aborts during an address translation operation*.

#### ATS1Cxx operations

Address translations for the current state. From modes other than Hyp mode:

- `TTBCR.EAE` determines whether the result is returned using the 32-bit or the 64-bit `PAR` format.
- If the implementation includes EL3, the translation performed is for the current security state and, depending on that state:
  - The Secure or Non-secure `TTBCR.EAE` determines the `PAR` format.
  - The result is returned to the Secure or Non-secure instance of the `PAR`

Operations from Hyp mode always return a result to the Non-secure `PAR`, using the 64-bit format.

#### ATS12NSOxx operations

Address translations for the Non-secure PL1 and PL0 modes. These operations return a result using the 64-bit `PAR` format if at least one of the following is true:

- The Non-secure `TTBCR.EAE` bit is set to 1.
- The implementation includes EL2, and the value of `HCR.VM` is 1.

Otherwise, the operation returns a result using the 32-bit `PAR` format.

Operations from a Secure PL1 mode return a result to the Secure `PAR`. Operations from Hyp mode return a result to the Non-secure `PAR`.

#### ATS1Hx operations

Address translations from Hyp mode. These operations always return a result using the 64-bit `PAR` format.

Operations from Secure Monitor mode return a result to the Secure `PAR`. Operations from Non-secure Hyp mode return a result to the Non-secure `PAR`.

### G3.14.4 Handling of faults and aborts during an address translation operation

When a stage of address translation is enabled, any corresponding address translation operation requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

*VMSAv8-32 memory aborts on page G3-3647* describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- *MMU fault on an address translation operation on page G3-3689*.
- *External abort during an address translation operation on page G3-3689*.
- *Stage 2 fault on a current state address translation operation on page G3-3690*.

## MMU fault on an address translation operation

In the following cases, an MMU fault on an address translation is reported in the [PAR](#), and no abort is taken. This applies:

- For a faulting address translation operation executed in Hyp mode, or in a Secure PL1 mode.
- For a faulting address translation operation executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the on the equivalent load or store operation.

*Using the PAR to report a fault on an address translation operation* gives more information about how these faults are reported.

### ———— Note —————

- The Domain fault encodings shown in [Table G3-27 on page G3-3665](#) are used only for reporting a fault on an address translation operation that uses the 64-bit [PAR](#) format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  - An [ATS1Cxx](#) operation from Hyp mode.
  - An [ATS12NSOxx](#) operation when [HCR.VM](#) is set to 1.These encodings are never used for fault reporting in the [DFSR](#), [IFSR](#), or [HSR](#).
- For an address translation operation executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in [Stage 2 fault on a current state address translation operation on page G3-3690](#).

### Using the PAR to report a fault on an address translation operation

For a fault on an address translation operation for which no abort is taken, the [PAR](#) is updated with the following information, to indicate the fault:

- The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  - [PL1 fault reporting with the Short-descriptor translation table format on page G3-3663](#).
  - [PL1 fault reporting with the Long-descriptor translation table format on page G3-3665](#).See also the Note at the start of [Determining the PAR format on page G3-3688](#) about the Domain fault encodings shown in [Table G3-27 on page G3-3665](#).
- A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

## External abort during an address translation operation

As stated in [External abort on a translation table walk on page G3-3657](#), an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

### Synchronous external abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The [PAR](#) is UNKNOWN.

### Asynchronous external abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The [PAR](#) is UNKNOWN.

### Stage 2 fault on a current state address translation operation

If the PE is in a Non-secure PL1 mode and performs one of the ATS1C\*\* operations, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in [Stage 2 fault on a stage 1 translation table walk on page G3-3654](#). When this fault occurs on an ATS1C\*\* address translation operation:

- A Hyp Trap exception is taken to Hyp mode.
- The **PAR** is UNKNOWN.
- The **HSR** indicates that:
  - The fault occurred on a translation table walk.
  - The operation that faulted was a cache maintenance operation.
- The **HPFAR** holds the IPA that faulted.
- The **HDFAR** holds the VA that the executing software supplied to the address translation operation.

## G3.15 About the System registers for VMSAv8-32

In AArch32 state, the System registers comprise:

- The registers accessed using the System Control Coprocessor interface, CP15.
- Registers accessed using the CP14 coprocessor interface, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

*Organization of the CP14 registers in VMSAv8-32 on page G3-3713* summarizes the CP14 registers, and indicates where the CP14 registers are described, either in this manual or in other architecture specifications.

*Organization of the CP15 registers in VMSAv8-32 on page G3-3716* summarizes the CP15 registers, and indicates where in this manual the CP15 registers are described.

This section gives general information about the control registers, the CP14 and CP15 interfaces to these registers, and the conventions used in describing these registers.

### ———— Note —————

Many implementations include other interfaces to some functional groups of CP14 and CP15 registers, for example memory-mapped interfaces to the CP14 Debug registers. These are described in the appropriate sections of this manual.

This section is organized as follows:

- *About System register accesses.*
- *General behavior of System registers on page G3-3693.*
- *Classification of System registers on page G3-3696.*
- *Synchronization of changes to System registers on page G3-3706.*
- *Meaning of fixed bit values in register diagrams on page G3-3711.*

### G3.15.1 About System register accesses

Most AArch32 System registers are 32 bits wide. *Accessing 32-bit control registers on page G3-3692* describes how these registers are accessed.

A small number of the AArch32 System registers are 64 bits wide. *Accessing 64-bit control registers on page G3-3692* describes how these registers are accessed.

When using the MCR, MRC, MCRR, and MRRC instructions to access these registers, the instruction arguments include:

- A coprocessor identifier, coproc, as a value p0-p15, corresponding to CP0-CP15.
- A coprocessor register, CRn or CRm, as a value c0-c15, to specify a coprocessor register number.
- An opcode, opc1 or opc2, as a value in the range 0-7.

### ———— Note —————

- When accessing CP15, the primary coprocessor register is the top-level indicator of the accessed functionality, and when:
  - Using an MCR or MRC instruction, CRn specifies the primary coprocessor register.
  - Using an MCRR or MRRC instruction, CRm specifies the primary coprocessor register.
- When accessing CP14 using any of these instructions, opc1 is the top-level indicator of the accessed functionality.

## Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that the data dependencies between the instructions, specified in [Synchronization of changes to System registers on page G3-3706](#), are met.

### ———— Note —————

In particular, System registers holding self-incrementing counts, for example the Performance Monitors counters or the Generic Timer counter or timers, can be read *early*. This means that, for example, if a memory communication is used to communicate a read of the Generic Timer counter, an ISB must be inserted between the read of the memory location used for this communication and the read of the Generic Timer counter if it is required that the Generic Timer counter returns a count value that is later than the memory communication.

## Accessing 32-bit control registers

Software accesses a 32-bit control register using the generic MCR and MRC coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, CP14 or CP15.
- Two coprocessor registers, CRn and CRm. CRn specifies the primary coprocessor register.
- Two coprocessor-specific opcodes, opc1 and opc2.
- A general-purpose register to hold a 32-bit value to transfer to or from the coprocessor.

CP15 and CP14 provides the control registers. A PE access to a specific 32-bit control register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRn, opc1, CRm, and opc2, to specify the required control register.
- A general-purpose register for the transferred 32-bit value.

The PE accesses a 32-bit control register using:

- An MCR instruction to write to a control register, see [MCR, MCR2 on page F7-2700](#).
- An MRC instruction to read a control register, see [MCR, MCR2 on page F7-2700](#).

## Accessing 64-bit control registers

Software accesses a 64-bit control register using the generic MCRR and MRRC coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, CP14 or CP15.
- A coprocessor register, CRm. In this case, CRm specifies the primary coprocessor register.
- A single coprocessor-specific opcode, opc1.
- Two general-purpose registers to hold two 32-bit values to transfer to or from the coprocessor.

CP15 and CP14 provide the control registers. A PE access to a specific 64-bit System register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

Therefore, PE accesses a 64-bit control register using:

- An MCRR instruction to write to a control register, see [MCRR, MCRR2 on page F7-2702](#).
- An MRRC instruction to read a control register, see [MCRR, MCRR2 on page F7-2702](#).

When using a MCRR or MRRC instruction:

- Rt contains the least-significant 32 bits of the transferred value, and Rt2 contains the most-significant 32 bits of that value.
- The access is 64-bit atomic.

Some 64-bit registers also have an MCR and MRC encoding. The MCR and MRC encodings for these registers access the least significant 32 bits of the register. For example, to access the **PAR**, software can:

- Use the following instructions to access all 64 bits of the register:  
 MRRC p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)  
 MCRR p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
- Use the following instructions to access the least-significant 32 bits of the register:  
 MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt  
 MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]

## G3.15.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in *About System register accesses on page G3-3691*, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to both CP14 and CP15 registers:

- *Read-only bits in read/write registers.*
- *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses.*
- *Read-only and write-only register encodings on page G3-3695.*
- *Reset behavior of CP14 and CP15 registers on page G3-3695.*

See also *About System register accesses on page G3-3691* and *Meaning of fixed bit values in register diagrams on page G3-3711*.

### Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the **SCTLR.NMFI** bit, **SCTLR[27]**.

### UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses

In AArch32 state the following operations are UNDEFINED:

- All CDP, LDC and STC operations to CP14 and CP15, except for the LDC access to **DBGDTRTXint** and the STC access to **DBGDTRTXint** specified in *Table G3-45 on page G3-3714*.
- All MCRR and MRRC operations to CP14 and CP15, except for those explicitly defined as accessing 64-bit CP14 and CP15 registers.
- All CDP2, MCR2, MRC2, MCRR2, MRRC2, LDC2 and STC2 operations to CP14 and CP15.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field can have an UNPREDICTABLE effect.

The following subsections give more information about UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses:

- *Accesses to unallocated CP14 and CP15 encodings.*
- *Additional rules for MCR and MRC accesses to CP14 and CP15 registers on page G3-3694.*
- *Effects of EL3 and EL2 on CP15 register accesses on page G3-3694.*

### Accesses to unallocated CP14 and CP15 encodings

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.

### **Additional rules for MCR and MRC accesses to CP14 and CP15 registers**

All MCR operations from the PC are UNPREDICTABLE for all coprocessors, including for CP14 and CP15.

All MRC operations to APSR\_nzcv are UNPREDICTABLE for CP14 and CP15, except for the CP14 MRC operation to APSR\_nzcv from [DBGDSCRint](#).

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also [Read-only and write-only register encodings on page G3-3695](#).

### **Effects of EL3 and EL2 on CP15 register accesses**

EL2 and EL3 introduce classes of System registers, described in [Classification of System registers on page G3-3696](#). Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

#### **Note**

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

#### **Restricted access System registers**

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the [NSACR](#) are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The [NSACR](#) is a special case of a Restricted access register and:

- The [NSACR](#) is:
  - Read/write accessible from Secure PL1 modes.
  - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the [NSACR](#) are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see [Restricted access System registers on page G3-3698](#).

#### **Configurable access System registers**

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the [NSACR](#) permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the [NSACR](#) control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the [NSACR](#) controls how they behave. The only architecturally-defined register of this type is the [CPACR](#).

For more information, see [Configurable access System registers on page G3-3699](#).

### EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when `SCR.NS` is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see [Banked EL2-mode CP15 read/write registers on page G3-3700](#) and [EL2-mode encodings for shared CP15 registers on page G3-3701](#).

### EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of `SCR.NS`.

Write accesses to these operations are:

- UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see [Banked EL2-mode CP15 write-only operations on page G3-3702](#).

In addition, in any implementation that includes EL3, if write access to a register is disabled by the `CP15SDISABLE` signal then any MCR access to that register is UNDEFINED.

### Read-only and write-only register encodings

Some System registers are *read-only* (RO) or *write-only* (WO). For example:

- Most identification registers are read-only.
- Most encodings that perform an operation, such as a cache maintenance operation, are write-only.

If a particular Privilege level defines a register to be:

- RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with `L == 0` is UNDEFINED.
- WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with `L == 1` is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

#### ————— Note —————

- This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.
- Although the `FPSID` is a RO register, a write using the `FPSID` encoding is a valid *serializing* operation, see [Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501](#). Such a write does not access the register.

### Reset behavior of CP14 and CP15 registers

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for CP14 debug and trace registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of CP14 and CP15 registers, see:

- [Reset and debug on page H8-4463](#), for the Debug CP14 registers.
- the appropriate Trace architecture specification, for the Trace CP14 registers.
- [Reset behavior of CP15 registers on page G3-3696](#).
- [Pseudocode details of resetting CP14 and CP15 registers on page G3-3696](#).

### Reset behavior of CP15 registers

On reset, the VMSAv8-32 architecture defines a required reset value for all or part of each of the following CP15 registers:

- The [SCTLR](#), [CPACR](#), [TTBCR](#), and [VBAR](#). If the implementation includes EL3, unless the register description says otherwise, the defined reset values apply only to the Secure instances of these registers, and the reset values of the corresponding bits are UNKNOWN in the Non-secure instances of the registers.
- In an implementation that includes EL3, when EL3 supports AArch32, the [SCR](#) and the [NSACR](#).
- In an implementation that includes EL2, when EL2 supports AArch32, the [VPIDR](#), [VMPIDR](#), [HCR](#), [HDCR](#), [HCPTR](#), [HSTR](#), and [VTTBR](#).
- In an implementation that includes the Performance Monitors Extension, the [PMCR](#), the [PMUSERENR](#), and the instance of [PMXEVTYPERR](#) that relates to the cycle counter.
- In an implementation that includes the Generic Timer Extension, the [CNTKCTL](#) and [CNTHCTL](#) registers.

#### Note

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value, and software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

For details of the reset values of these registers see the register descriptions. If the description of a register or register field does not include its reset value then the architecture does not require that register or field to reset to a defined value, and software must treat the value as UNKNOWN after a reset.

The values of all other registers at reset are architecturally UNKNOWN. An implementation can assign an IMPLEMENTATION DEFINED reset value to a register whose reset value is architecturally UNKNOWN. After a reset, software must not rely on the value of any read/write register that does not have either an architecturally-defined reset value or an IMPLEMENTATION DEFINED reset value.

### Pseudocode details of resetting CP14 and CP15 registers

The `ResetControlRegisters()` pseudocode function resets all CP14 and CP15 registers, and register fields, that have defined reset values, as described in this section.

#### Note

For CP14 debug and trace registers this function resets registers as defined for the appropriate level of reset.

## G3.15.3 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some CP15 registers.

It contains the following subsections:

- [Banked System registers on page G3-3697.](#)
- [Restricted access System registers on page G3-3698.](#)
- [Configurable access System registers on page G3-3699.](#)
- [EL2-mode System registers on page G3-3699.](#)
- [Common System registers on page G3-3702.](#)
- [The CP15SDISABLE input on page G3-3704.](#)

- [Access to registers from Monitor mode on page G3-3704.](#)

———— **Note** ————

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification. Some of these classifications can apply to some CP10 and CP11 coprocessor registers, as well as to the CP14 and CP15 System registers.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

### Banked System registers

In an implementation that includes EL3, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The [SCR.NS](#) bit selects the Secure or Non-secure instance of the register. [Table G3-36](#) shows which CP15 registers are Banked in this way, and the permitted access to each register. No CP14 registers are Banked.

**Table G3-36 Banked CP15 registers**

CRn <sup>a</sup>	Banked register	Permitted accesses <sup>b</sup>
c0	<a href="#">CSSELR</a> , Cache Size Selection Register	Read/write only at EL1 or higher
c1	<a href="#">SCTLR</a> , System Control Register <sup>c</sup>	Read/write only at EL1 or higher
	<a href="#">ACTLR</a> , Auxiliary Control Register <sup>d</sup>	Read/write only at EL1 or higher
c2	<a href="#">TTBR0</a> , Translation Table Base 0	Read/write only at EL1 or higher
	<a href="#">TTBR1</a> , Translation Table Base 1	Read/write only at EL1 or higher
	<a href="#">TTBCR</a> , Translation Table Base Control	Read/write only at EL1 or higher
c3	<a href="#">DACR</a> , Domain Access Control Register	Read/write only at EL1 or higher
c5	<a href="#">DFSR</a> , Data Fault Status Register	Read/write only at EL1 or higher
	<a href="#">IFSR</a> , Instruction Fault Status Register	Read/write only at EL1 or higher
	<a href="#">ADFSR</a> , Auxiliary Data Fault Status Register <sup>d</sup>	Read/write only at EL1 or higher
	<a href="#">AIFSR</a> , Auxiliary Instruction Fault Status Register <sup>d</sup>	Read/write only at EL1 or higher
c6	<a href="#">DFAR</a> , Data Fault Address Register	Read/write only at EL1 or higher
	<a href="#">IFAR</a> , Instruction Fault Address Register	Read/write only at EL1 or higher
c7	<a href="#">PAR</a> , Physical Address Register	Read/write only at EL1 or higher
c10	<a href="#">PRRR</a> , Primary Region Remap Register	Read/write only at EL1 or higher
	<a href="#">NMRR</a> , Normal Memory Remap Register	Read/write only at EL1 or higher
c12	<a href="#">VBAR</a> , Vector Base Address Register	Read/write only at EL1 or higher

**Table G3-36 Banked CP15 registers (continued)**

CRn <sup>a</sup>	Banked register	Permitted accesses <sup>b</sup>
c13	<a href="#">FCSEIDR</a> , FCSE PID Register <sup>e</sup>	Read/write only at EL1 or higher
	<a href="#">CONTEXTIDR</a> , Context ID Register	Read/write only at EL1 or higher
	<a href="#">TPIDRURW</a> , User Read/Write Thread ID	Read/write at all privilege levels, including EL0
	<a href="#">TPIDRURO</a> , User Read-only Thread ID	Read-only at EL0 Read/write at EL1 or higher
	<a href="#">TPIDRPRW</a> , EL1 only Thread ID	Read/write only at EL1 or higher

- a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
- b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- c. Some bits are common to the Secure and the Non-secure copies of the register, see [SCTLR, System Control Register on page G4-4005](#).
- d. Register is IMPLEMENTATION DEFINED.
- e. Banked only in an implementation that includes the FCSE. The FCSE PID Register is RAZ/WI if the FCSE is not implemented.

A Banked CP15 register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register [SCTLR](#) is an example of a register of that contains this mixture of fields.

The Secure copies of the Banked CP15 registers are sometimes referred to as the Secure Banked CP15 registers. The Non-secure copies of the Banked CP15 registers are sometimes referred to as the Non-secure Banked CP15 registers.

### Restricted access System registers

In an implementation that includes EL3, some System registers are present only in the Secure security state. These are called *Restricted access* registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the [NSACR](#), in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at PL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64d then any read of the [NSACR](#) from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value `0x00000C00`.

If EL3 is not implemented, any read of the [NSACR](#) from Non-secure EL2 using AArch32, or Secure or Non-secure EL1 using AArch32, returns the value `0x00000C00`.

- For all other Restricted access registers, Non-secure software cannot read the register.

Table G3-37 shows the Restricted access CP15 registers in an implementation that includes EL3. There are no Restricted access CP14 registers.

**Table G3-37 Restricted access CP15 registers**

CRn <sup>a</sup>	Register	Permitted accesses <sup>b</sup>
c1	SCR, Secure Configuration	Read/write in Secure PL1 modes
	SDER, Secure Debug Enable	Read/write in Secure PL1 modes
	NSACR, Non-Secure Access Control	Read/write in Secure PL1 modes Read-only in Non-secure PL1 and PL2 modes
c12	MVBAR, Monitor Vector Base Address	Read/write in Secure PL1 modes

a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.

b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

### Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.
- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a R/W field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the NSACR control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access CP14 registers.
- The only required Configurable access CP15 register is the CPACR, Coprocessor Access Control Register.
- The following registers in the CP10 and CP11 register space are Configurable access:
  - Floating-point Status and Control Register, FPSCR
  - Floating-point Exception register, FPEXC.
  - Floating-point System ID register, FPSID.
  - Media and VFP Feature Register 0, MVFR0.
  - Media and VFP Feature Register 1, MVFR1.

### EL2-mode System registers

An implementation that includes EL2, when EL2 is using AArch32 it provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of SCR.NS is 1.

The following subsections describe the EL2-mode registers:

- [Banked EL2-mode CP15 read/write registers on page G3-3700.](#)
- [EL2-mode encodings for shared CP15 registers on page G3-3701.](#)
- [Banked EL2-mode CP15 write-only operations on page G3-3702.](#)

There are no EL2-mode CP14 registers.

### Banked EL2-mode CP15 read/write registers

Architecturally, these are an extension of the Banked registers described in *Banked System registers* on page G3-3697, where:

- The implementation does not implement the Secure instance of the register.
- The Non-secure instance of the register is accessible only at PL2, that is, only from Hyp mode.

Except for accesses to **CNTVOFF** in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from Monitor mode when **SCR.NS** is set to 1, see *Access to registers from Monitor mode* on page G3-3704.
- The following accesses are UNDEFINED:
  - Accesses from Non-secure PL1 modes.
  - Accesses in Secure state when **SCR.NS** is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to **CNTVOFF** is as follows:

- Any access from Secure Monitor mode is UNPREDICTABLE, regardless of the value of **SCR.NS**.
- All other accesses are UNDEFINED.

#### ———— Note —————

Except for **CNTVOFF**, the Banked EL2-mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, **CNTVOFF** is part of any implementation that includes the Generic Timer Extension, see *Status of the CNTVOFF register* on page D7-1864. This means the behavior of **CNTVOFF** in an implementation that includes the Generic Timer Extension but does not include EL2 is not covered by the general definition of the behavior of the Banked EL2-mode CP15 read/write registers.

Table G3-38 shows the EL2-mode CP15 read/write registers:

**Table G3-38 Banked EL2-mode CP15 read/write registers**

CRn or CRm <sup>a</sup>	Register	Width	Permitted accesses <sup>b</sup>
c0	<b>VPIDR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>VMPIDR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c1	<b>HSCTLR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HACTLR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HCR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HDCR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HCPTR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HSTR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HACR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c2	<b>HTCR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>VTCR</b>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>HTTBR</b>	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<b>VTTBR</b>	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode

**Table G3-38 Banked EL2-mode CP15 read/write registers (continued)**

CRn or CRm <sup>a</sup>	Register	Width	Permitted accesses <sup>b</sup>
c5	<a href="#">HADFSR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<a href="#">HAIFSR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<a href="#">HSR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c6	<a href="#">HPFAR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c10	<a href="#">HMAIRO</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<a href="#">HMAIR1</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<a href="#">HAMAIRO</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	<a href="#">HAMAIR1</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c12	<a href="#">HVBAR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c13	<a href="#">HTPIDR</a>	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c14	<a href="#">CNTVOFF<sup>c</sup></a>	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode

- a. CRn for accesses to 32-bit registers, CRm for accesses to 64-bit registers. More correctly, this is the primary coprocessor register.  
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.  
c. Implemented only in an implementation that includes the Generic Timer Extension. See, also, the Note earlier in this section.

#### **EL2-mode encodings for shared CP15 registers**

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when [SCR.NS](#) is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when [SCR.NS](#) is set to 0.

[Table G3-39](#) lists the EL2-mode encodings for shared registers.

**Table G3-39 EL2-mode CP15 register encodings for shared registers**

CRn <sup>a</sup>	Register	Permitted accesses <sup>b</sup>	Shared register
c6	<a href="#">HDFAR</a>	Read/write. In Non-secure state, accessible only from Hyp mode <sup>c</sup>	Secure <a href="#">DFAR</a>
c6	<a href="#">HIFAR</a>	Read/write. In Non-secure state, accessible only from Hyp mode <sup>c</sup>	Secure <a href="#">IFAR</a>

- a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.  
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.  
c. Also accessible from Monitor mode when [SCR.NS](#) set to 1.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the [DFAR](#) or [IFAR](#) encoding with [SCR.NS](#) set to 0.
- Using the [HDFAR](#) or [HIFAR](#) encoding with [SCR.NS](#) set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a *Context synchronization operation* is required to ensure the ordering of the accesses.

### Banked EL2-mode CP15 write-only operations

Architecturally, these encodings are an extension of the Banked register encodings described in [Banked System registers](#) on page G3-3697, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These operations can be accessed from Monitor mode regardless of the value of SCR.NS, see [Access to registers from Monitor mode](#) on page G3-3704.
- Accesses to these operations are UNPREDICTABLE if executed in a Secure mode other than Monitor mode.

Accesses to these operations are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G3-40 shows the EL2-mode CP15 write-only operations:

**Table G3-40 Banked EL2-mode CP15 write-only operations**

CRn	Register	Width	Permitted accesses <sup>a</sup>
c8	<a href="#">ATS1HR</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">ATS1HW</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIALLHIS</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIMVAHIS</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIALLNSNHIS</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIALLH</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIMVAH</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	<a href="#">TLBIALLNSNH</a>	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode

- a. This section describes the behavior of write accesses that are not permitted. See also [Read-only and write-only register encodings](#) on page G3-3695.

For more information about these operations, see [Address translation stage 1, Hyp mode](#) on page G3-3686.

### Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the *Common access* registers, or simply as the *Common* registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The [ISR](#).
- All CP14 registers.

Table G3-41 shows the Common CP15 System registers. These registers are not affected by whether EL3 is implemented.

**Table G3-41 Common CP15 registers**

CRn <sup>a</sup>	Register	Permitted accesses <sup>b</sup>
c0	<a href="#">MIDR</a> , Main ID Register	Read-only, only at EL1 or higher
	<a href="#">CTR</a> , Cache Type Register	Read-only, only at EL1 or higher
	<a href="#">TCMTR</a> , TCM Type Register <sup>c</sup>	Read-only, only at EL1 or higher
	<a href="#">TLBTR</a> , TLB Type Register <sup>c</sup>	Read-only, only at EL1 or higher
	<a href="#">MPIDR</a> , Multiprocessor Affinity Register	Read-only, only at EL1 or higher
	<a href="#">REVIDR</a> , Revision ID	Read-only, only at EL1 or higher
c0	<a href="#">ID_PFRx</a> , Processor Feature Registers	Read-only, only at EL1 or higher
	<a href="#">ID_DFR0</a> , Debug Feature Register 0	Read-only, only at EL1 or higher
	<a href="#">ID_AFR0</a> , Auxiliary Feature Register 0	Read-only, only at EL1 or higher
	<a href="#">ID_MMFRx</a> , Memory Model Feature Registers	Read-only, only at EL1 or higher
	<a href="#">ID_ISARx</a> , Instruction Set Attribute Registers	Read-only, only at EL1 or higher
	<a href="#">CCSIDR</a> , Cache Size ID Register	Read-only, only at EL1 or higher
	<a href="#">CLIDR</a> , Cache Level ID Register	Read-only, only at EL1 or higher
	<a href="#">AIDR</a> , Auxiliary ID Register <sup>c</sup>	Read-only, only at EL1 or higher
c7	Cache maintenance operations	See <a href="#">Cache maintenance operations, functional group</a> on page G3-3743
	Address translation operations	See <a href="#">Address translation operations, functional group</a> on page G3-3745
	Data barrier operations	Write-only at all privilege levels, including EL0
c8	TLB maintenance operations	Write-only, only at EL1 or higher
c9	Performance monitors	See <a href="#">Access permissions</a> on page D6-1851
c12	<a href="#">ISR</a> , Interrupt Status Register	Read-only, only at EL1 or higher

- For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
- Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- Register or operation details are IMPLEMENTATION DEFINED.

### Secure CP15 registers

The Secure CP15 registers comprise:

- The Secure copies of the Banked CP15 registers.
- The Restricted access CP15 registers.
- The Configurable access CP15 registers that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure CP15 registers are the CP15 registers other than the Secure CP15 registers.

## The CP15SDISABLE input

EL3 provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH.

### ———— Note —————

The interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

Table G3-42 shows the registers and operations affected.

**Table G3-42 Secure registers affected by CP15SDISABLE**

CRn	Register name	Affected operation
c1	<b>SCTLR</b> , System Control Register	MCR p15, 0, <Rt>, c1, c0, 0
c2	<b>TTBR0</b> , Translation Table Base Register 0	MCR p15, 0, <Rt>, c2, c0, 0
	<b>TTBCR</b> , Translation Table Base Control Register	MCR p15, 0, <Rt>, c2, c0, 2
c3	<b>DACR</b> , Domain Access Control Register	MCR p15, 0, <Rt>, c3, c0, 0
c10	<b>PRRR</b> , Primary Region Remap Register	MCR p15, 0, <Rt>, c10, c2, 0
	<b>NMRR</b> , Normal Memory Remap Register	MCR p15, 0, <Rt>, c10, c2, 1
c12	<b>VBAR</b> , Vector Base Address Register	MCR p15, 0, <Rt>, c12, c0, 0
	<b>MVBAR</b> , Monitor Vector Base Address Register	MCR p15, 0, <Rt>, c12, c0, 1

On a reset by the external system, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in Table G3-42 results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of a Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform a Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

Use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known good state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.

## Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the **SCR.NS** bit. In Monitor mode, the **SCR.NS** bit determines whether valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked CP15 registers or the Non-secure Banked CP15 registers. That is, when:

**NS == 0** Common, Restricted access, and Secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, the registers listed in *Banked EL2-mode CP15 read/write registers on page G3-3700* and *EL2-mode encodings for shared CP15 registers on page G3-3701* are not accessible, and any attempt to access them generates an Undefined Instruction exception.

---

**Note**

The operations listed in [Banked EL2-mode CP15 write-only operations on page G3-3702](#) are accessible in Monitor mode regardless of the value of `SCR.NS`.

---

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

**NS == 1** Common, Restricted access and Non-secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, all the registers and operations listed in the subsections of [EL2-mode System registers on page G3-3699](#) are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

---

**Note**

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, `CSSELR` selects the current `CCSIDR`, and therefore `CSSELR` is used as control state. Therefore, in Monitor mode:

- `SCR.NS` determines whether the Secure or Non-secure `CSSELR` is accessible.
- Because the PE is in Secure state, the Secure `CSSELR` selects the current `CCSIDR`.

### G3.15.4 Synchronization of changes to System registers

In this section, *this PE* means the PE on which accesses are being synchronized.

———— **Note** —————

See [Definitions of direct and indirect reads and writes and their side-effects on page G3-3709](#) for definitions of the terms *direct write*, *direct read*, *indirect write*, and *indirect read*.

A *direct write* to a System register might become visible at any point after the change to the register, but without a *Context synchronization operation* there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the ARM ordering model. In this case, if permitted by the ARM ordering model, the instruction that appears in program order before the direct write can be affected by the direct write.

These rules mean that an instruction that writes to one of the address translation operations described in [Virtual Address to Physical Address translation operations on page G3-3685](#) must be explicitly synchronized to guarantee that the result of the address translation operation is visible in the **PAR**.

———— **Note** —————

In this case, the direct write to the encoding of the address translation operation causes an *indirect write* to the **PAR**. Without a *Context synchronization operation* after the direct write there is no guarantee that the indirect write to the **PAR** is visible.

Conceptually, the explicit synchronization occurs as the first step of any *Context synchronization operation*. This means that if the operation uses state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

———— **Note** —————

This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of system registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.

Except for the register reads listed in [Registers with some architectural guarantee of ordering or observability on page G3-3708](#), if no context synchronization operation is performed, direct reads of System registers can occur in any order.

[Table G3-43 on page G3-3707](#) shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, *First* and *Second* refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
- The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.
- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

———— **Note** —————

Such accesses are likely to be given the a Device memory attribute, but requiring this is outside the scope of the architecture.

- For indirect reads or writes caused by autonomous asynchronous events that count, for example events caused by the passage of time, the events are ordered so that:
  - Counts progress monotonically.
  - The events arrive at the PE in finite time and without undue delay.

**Table G3-43 Synchronization requirements for updates to System registers**

First read or write	Second read or write	Context synchronization operation required
Direct read	Direct read	No
	Direct write	No
	Indirect read	No <sup>a</sup>
	Indirect write	No <sup>a</sup> , but see text in this section for exceptions
Direct write	Direct read	No
	Direct write	No
	Indirect read	Yes <sup>a</sup>
	Indirect write	No, but see text in this section for exceptions
Indirect read	Direct read	No
	Direct write	No
	Indirect read	No
	Indirect write	No
Indirect write	Direct read	Yes, but see text in this section for exceptions
	Direct write	No, but see text in this section for exceptions
	Indirect read	Yes, but see text in this section for exceptions
	Indirect write	No, but see text in this section for exceptions

a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that *Registers with some architectural guarantee of ordering or observability* shows as having some guarantee of the visibility of an indirect writes, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

———— **Note** —————

Where a register has more than one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see [Synchronization requirements for system registers on page D8-1866](#).

To guarantee the visibility of changes to some registers, additional operations might be required before the context synchronization operation. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- *Accessing* a System register refers to a direct read or write of the register.
- *Using* a System register refers to an indirect read or write of the register.

### Registers with some architectural guarantee of ordering or observability

For the registers for which [Table G3-44](#) shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which [Table G3-44](#) shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as [Table G3-44](#) shows:

**Table G3-44 Registers with a guarantee of ordering or observability, VMSAv8-32**

Register	Ordering of direct reads	Observability of indirect writes	Notes
<a href="#">ISR</a>	Guaranteed	Guaranteed	Interrupt Status Register
<a href="#">DBGCLAIMCLR</a>	-	Guaranteed	Debug claim registers
<a href="#">DBGCLAIMSET</a>	Guaranteed	Guaranteed	

**Table G3-44 Registers with a guarantee of ordering or observability, VMSAv8-32 (continued)**

Register	Ordering of direct reads	Observability of indirect writes	Notes
DBGDTRRX	Guaranteed	Guaranteed	Debug Communication Channel registers
DBGDTRTX	Guaranteed	Guaranteed	
CNTPCT	Guaranteed	Guaranteed	Generic Timer Extension registers, if the implementation includes the extension
CNTP_TVAL	Guaranteed	Guaranteed	
CNTVCT	Guaranteed	Guaranteed	
CNTV_TVAL	Guaranteed	Guaranteed	
CNTHP_TVAL	Guaranteed	Guaranteed	
PMCCNTR	Guaranteed	Guaranteed	Performance Monitors Extension registers, if the implementation includes the extension
PMXEVNTR	Guaranteed	Guaranteed	
PMOVSSET	Guaranteed	Guaranteed	

For the specified registers, the observability requirement is more demanding than the observability requirements for other registers. However, the possibility that direct reads can occur *early*, in the absence of context synchronization, described in [Ordering of reads of System registers on page G3-3692](#), still applies to these registers.

In Debug state, additional synchronization requirements can apply to the registers shown in [Table G3-44 on page G3-3708](#). For more information, see [Synchronization of DCC and ITR accesses on page H4-4398](#).

### Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

**Direct read** Is a read of a register, using an MRC, MRC2, MRRC, MRRC2, LDC, or LDC2 instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an *indirect write*, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

———— **Note** ————

The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

**Direct write** Is a write to a register, using an MCR, MCR2, MCRR, MCRR2, STC, or STC2 instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

---

**Note**

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a [PMCNTENCLR.Px](#) bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases. For example, writing 1 to a [PMCNTENCLR.Px](#) bit that is set to 1 also changes the corresponding [PMCNTENSET.Px](#) bit from 1 to 0. This means that the direct write to the [PMCNTENCLR](#) defines indirect writes to both itself and to the [PMCNTENSET](#).

---

**Indirect read** Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether a cache is enabled.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in [Debug registers on page G4-4101](#).
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

**Indirect write** Is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of some external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see [Registers with some architectural guarantee of ordering or observability on page G3-3708](#).

---

**Note**

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#).

---

### G3.15.5 Meaning of fixed bit values in register diagrams

In register diagrams, fixed bits are indicated by one of following:

**0** In any implementation:

- The bit must read as 0.
- Writes to the bit must be ignored.
- Software:
  - Can rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

**(0)** In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. The meaning of (0) is modified for these bits. For a read/write register, this means:

**If a register bit is (0) for all uses of the register**

- The bit must read as 0.
- Writes to the bit must be ignored.
- Software:
  - Must not rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

**If a register bit is (0) only for some uses of the register, when that bit is described as (0)**

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.  
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as (0), or as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
- Software:
  - Must not rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

———— **Note** —————

This definition applies only to bits that are defined as (0), or as RES0, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as RES0, instead of having each bit marked as (0).

In a read-only register, (0) or RES0 indicates that the bit reads as 0, but software must treat the bit as UNK.

In a write-only register, (0) indicates that software must treat the bit as SBZ.

**1** In any implementation:

- The bit must read as 1.
- Writes to the bit must be ignored.
- Software:
  - Can rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

- (1) In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. The meaning of (1) is modified for these bits. For a read/write register, this means:

**If a register bit is (1) for all uses of the register**

- The bit must read as 1.
- Writes to the bit must be ignored.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

**If a register bit is (1) only for some uses of the register, when that bit is described as (1)**

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.  
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as (1), or as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

———— **Note** —————

This definition applies only to bits that are defined as (1), or as RES1, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as RES1, instead of having each bit marked as (1).

In a read-only register, (1) indicates that the bit reads as 1, but software must treat the bit as UNK.

In a write-only register, (1) indicates that software must treat the bit as SBO.

## G3.16 Organization of the CP14 registers in VMSAv8-32

The CP14 registers provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for the T32EE execution environment, if supported, and identification of the trivial Jazelle implementation.

Because these functions are so distinct, the descriptions of these registers are distributed, as follows:

- In this manual [Debug registers on page G4-4101](#) describes the Debug registers.
- The following ARM trace architecture specifications describe the Trace registers:
  - *Embedded Trace Macrocell Architecture Specification*.
  - *CoreSight Program Flow Trace Architecture Specification*.

This section summarizes the allocation of the CP14 registers between these different functions, and the CP14 register encodings that are reserved.

The CP14 register encodings are classified by the {CRn, opc1, CRm, opc2} values required to access them using an MCR or an MRC instruction. The opc1 value determines the primary allocation of these registers, as follows:

- opc1==0** Debug registers.
- opc1==1** Trace registers.
- opc1==6** T32EE registers. Support for T32EE is OPTIONAL and deprecated.
- opc1==7** Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

### Other opc1 values

Reserved.

### ———— Note —————

Primary allocation of CP14 register function by opc1 value differs from the allocation of CP15 registers, where primary allocation is by CRn value.

For the Debug registers, considering accesses using MCR or MCR instructions:

- Register encodings with CRn values 8-15 are unallocated.
- For registers with CRn values 0-7, the {CRn, opc2, CRm} values used for accessing the registers map onto a set of register numbers, as defined in [Table G3-45 on page G3-3714](#). These register numbers define the order of the registers in:
  - The memory-mapped interfaces to the registers.
  - The top-level register summary in [Debug registers on page G4-4101](#).

### ———— Note —————

Some Debug registers are not visible in some of the Debug register interfaces. For more information see [Chapter H8 About the External Debug Registers](#).

The ARM trace architectures use the same mapping of {CRn, opc2, CRm} values to register numbers for the Trace registers. The associated opc1 value determines whether a particular CP14 register number refers to the Trace register or the Debug register.

### G3.16.1 CP14 interface instruction arguments

Table G3-45 shows the instruction arguments required for accesses to each register than can be visible in the CP14 interface.

**Table G3-45 Mapping of CP14 MCR and MRC instruction arguments to registers**

CRn	op1	CRm	opc2	Name	Width	Description
c0	0	c0	0	DBGDIDR	32-bit	Debug ID, or UNALLOCATED <sup>a</sup>
c0	3	c1	0	DBGDSCRint	32-bit	Debug Communication Channel Status
c0	0	c2	0	DBGDCCINT	32-bit	Debug Communication Channel Interrupt Enable
c0	0	c5	0	DBGDTRRXint	32-bit	Full duplex, receive, 32-bit, Data Transfer
c0	0	c5	0	DBGDTRTXint	32-bit	Full duplex, transmit, 32-bit, Data Transfer
c0	0	c6	0	-	32-bit	Legacy <b>DBGWFAR</b> , RES0
c0	0	c7	0	DBGVCR	32-bit	Vector Catch
c0	0	c0	2	DBGDTRRXext	32-bit	OS Lock Data Transfer
c0	0	c2	2	DBGDSCRext	32-bit	Monitor Debug System Control
c0	0	c3	2	DBGDTRTXext	32-bit	OS Lock Data Transfer
c0	0	c6	2	DBGOSECCR	32-bit	OS Lock Exception Catch Control
c0	0	c0-15 <sup>b</sup>	4	DBGBVR<n>	32-bit	Breakpoint Value or UNALLOCATED
c0	0	c0-15 <sup>b</sup>	5	DBGBCR<n>	32-bit	Breakpoint Control or UNALLOCATED
c0	0	c0-15 <sup>b</sup>	6	DBGWVR<n>	32-bit	Watchpoint Value or UNALLOCATED
c0	0	c0-15 <sup>b</sup>	7	DBGWCR<n>	32-bit	Watchpoint Control or UNALLOCATED
c1	0	c0	0	DBGDRAR	32-bit or 64-bit	Debug ROM Address
		c1 <sup>c</sup>			32-bit	
c1	0	c0-15 <sup>b</sup>	1	DBGBXVR<n>	32-bit	Breakpoint Value
c1	0	c0	4	DBGOSLAR	32-bit	OS Lock Access
c1	0	c1	4	DBGOSLSR	32-bit	OS Lock Status
c1	0	c3	4	DBGOSDLR	32-bit	OS Double Lock
c1	0	c4	4	DBGPRCR	32-bit	Debug Power Control
c2	0	c0	0	DBGDSAR	32-bit	Debug Self Address or UNALLOCATED <sup>a</sup>
		c2				
c4	0	c0-15	0-3	-		IMPLEMENTATION DEFINED
c7	0	c8	6	DBGCLAIMSET	32-bit	Claim Tag Set
c7	0	c9	6	DBGCLAIMCLR	32-bit	Claim Tag Clear
c7	0	c14	6	DBGAUTHSTATUS	32-bit	Authentication Status

**Table G3-45 Mapping of CP14 MCR and MRC instruction arguments to registers (continued)**

CRn	op1	CRm	opc2	Name	Width	Description
c7	0	c0	7	DBGDEVID2	32-bit	Debug Device ID
c7	0	c1	7	DBGDEVID1	32-bit	
c7	0	c2	7	DBGDEVID	32-bit	
co-15	1	c0-c15	0-7	-	32-bit	Reserved for OPTIONAL Trace extension
All other encodings					32-bit	UNALLOCATED

- a. If EL1 is using AArch32 is not implemented this register is optional. See the register description for details.
- b. Not implemented breakpoint and watchpoint register access instructions are UNALLOCATED. If EL2 is not implemented or breakpoint *n* is not context-aware, [DBGBXVR<n>](#) is unallocated. CRm encodes *n*, the breakpoint or watchpoint number.
- c. MRRC instruction in AArch32 state. That is, MRRC p<14>,0,<Rt>,<Rt1>,<CRm>. There is no AArch64 state equivalent.

## G3.17 Organization of the CP15 registers in VMSAv8-32

Previous documentation has described the CP15 registers in order of their primary coprocessor register number. More precisely, the ordered set of values {CRn, opc1, CRm, opc2} determined the register order. As the number of System registers has increased this ordering has become less appropriate. Also, it applies only to 32-bit registers, since 64-bit registers are identified only by {CRm, opc1}, making it difficult to include 32-bit and 64-bit versions of a single register in a common ordering scheme.

This document now:

- Groups the CP15 registers by functional group. For more information about this grouping in VMSAv8-32, including a summary of each functional group, see [Functional grouping of VMSAv8-32 System registers on page G3-3735](#).
- Describes all of the System registers for VMSAv8-32, including the CP15 registers, in [Chapter G4 AArch32 System Register Descriptions](#).

This section gives additional information about the organization of the CP15 registers in VMSAv8-32, as follows:

### Register ordering by {CRn, opc1, CRm, opc2}

See:

- [CP15 32-bit register summary by coprocessor register number, CRn on page G3-3717](#).
- [Full list of VMSAv8-32 CP15 registers, by coprocessor register number on page G3-3722](#).

#### ———— Note —————

The ordered listing of CP15 registers by the {CRn, opc1, CRm, opc2} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

### Views of the registers, that depend on the current state of the PE

See [Views of the CP15 registers on page G3-3732](#).

#### ———— Note —————

The different register views are particularly significant in implementations that include EL2.

In addition, the indexes in [Appendix J Registers Index](#) include all of the CP15 registers.

### G3.17.1 CP15 32-bit register summary by coprocessor register number, CRn

Figure G3-26 summarizes the grouping of CP15 registers by primary coprocessor register number for a VMSAv8-32 implementation.

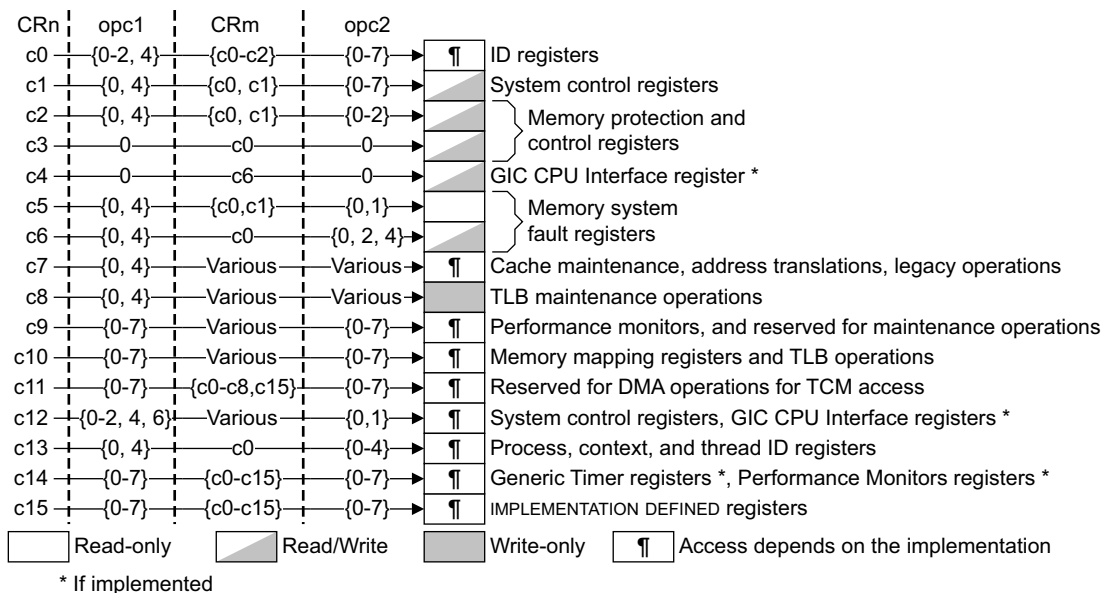

Figure G3-26 CP15 32-bit register grouping by primary coprocessor register, CRn

#### Note

- Figure G3-26 gives only an overview of the assigned encodings for 32-registers for each of the CP15 primary registers c0-c15. See the description of each primary register for the definition of the assigned and unassigned encodings for that register, including any dependencies on the implemented Exception levels.
- 64-bit registers in the CP15 encoding space use the same primary coprocessor register model, but in the 64-bit register read and write instructions, MRRR and MCRR, CRm identifies the primary coprocessor register.

The following sections give the register assignments for each of the CP15 primary registers, c0-c15:

- [VMSAv8-32 CP15 c0 register summary.](#)
- [VMSAv8-32 CP15 c1 register summary on page G3-3718.](#)
- [VMSAv8-32 CP15 c2 and c3 register summary on page G3-3718](#)
- [VMSAv8-32 CP15 c4 register summary on page G3-3718.](#)
- [VMSAv8-32 CP15 c5 and c6 register summary on page G3-3719.](#)
- [VMSAv8-32 CP15 c7 register summary on page G3-3719.](#)
- [VMSAv8-32 CP15 c8 register summary on page G3-3719.](#)
- [VMSAv8-32 CP15 c9 register summary on page G3-3719.](#)
- [VMSAv8-32 CP15 c10 register summary on page G3-3720.](#)
- [VMSAv8-32 CP15 c11 register summary on page G3-3721.](#)

- [VMSAv8-32 CP15 c15 register summary on page G3-3722.](#)

#### VMSAv8-32 CP15 c0 register summary

The CP15 c0 registers provide device and feature identification. That is, they provide the register functional group described in *Identification registers, functional group on page G3-3736*.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c0 registers. CP15 c0 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level:

- If they have an `opc1` value of zero, are `RES0`.
- Otherwise, are `UNPREDICTABLE`, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).

---

**Note**

Some of these registers were previously described as being part of the CPUID identification scheme, see [The CPUID identification scheme on page G3-3737](#).

---

### VMSAv8-32 CP15 c1 register summary

The CP15 c1 registers provide system control, including security and virtualization control. That is, they provide registers from the functional groups described in the following sections:

- [Other system control registers, functional group on page G3-3737](#).
- [Virtualization registers, functional group on page G3-3738](#).
- [Security registers, functional group on page G3-3741](#).

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c1 registers. CP15 c1 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are `UNPREDICTABLE`, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).

### VMSAv8-32 CP15 c2 and c3 register summary

The CP15 c2 and c3 registers provide memory system control. That is, they provide registers from the functional group described in the section [Virtual memory control registers, functional group on page G3-3737](#).

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c2 and c3 registers. CP15 c2 and c3 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are `UNPREDICTABLE`, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).

---

**Note**

All 64-bit CP15 register encodings not shown in [Table G3-46 on page G3-3723](#) are `UNDEFINED`.

---

### VMSAv8-32 CP15 c4 register summary

In an implementation that includes the System register interface to the Generic Interrupt Control CPU interface, the CP15 c4 registers provide a register for this interface. That is, they provide a register from the functional group described in the section [Generic Interrupt Controller CPU interface registers, functional group on page G3-3749](#).

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c4 registers. CP15 c4 32-bit register encodings not shown in the table are:

- `UNPREDICTABLE` if the implementation includes the System register interface to the Generic Interrupt Control CPU interface. See [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).
- Otherwise, `UNDEFINED`.

## VMSAv8-32 CP15 c5 and c6 register summary

The CP15 c5 and c6 registers provide exception and fault handling. That is, they provide registers from the functional group described in the section *Exception and fault handling registers, functional group* on page G3-3741.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c5 and c6 registers. CP15 c5 and c6 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

## VMSAv8-32 CP15 c7 register summary

The CP15 c7 registers provide system operations for cache maintenance, address translation, and some legacy operations. That is, they provide registers from the functional groups described in the following sections:

- *Cache maintenance operations, functional group* on page G3-3743.
- *Address translation operations, functional group* on page G3-3745.
- *Legacy feature registers, functional group* on page G3-3750.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c7 registers. CP15 c7 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

### ———— Note —————

All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

## VMSAv8-32 CP15 c8 register summary

The CP15 c8 registers provide operations for TLB maintenance. That is, they provide registers from the functional groups described in *TLB maintenance operations, functional group* on page G3-3744.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c8 registers. CP15 c8 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

## VMSAv8-32 CP15 c9 register summary

The CP15 c9 registers provide:

- Registers for the OPTIONAL Performance Monitors Extension. That is, they provide registers from the functional group described in *Performance Monitors Extension registers, functional group* on page G3-3747.
- Reserved encodings for IMPLEMENTATION DEFINED memory system functions, in particular:
  - Cache control, including lockdown.
  - TCM control, including lockdown.
  - Branch predictor control.

### ———— Note —————

The reserved encodings permit implementations that are compatible with previous versions of the ARM architecture, in particular with the ARMv6 requirements.

- Reserved encodings for additional IMPLEMENTATION DEFINED performance monitors.

Figure G3-27 shows the VMSAv8-32 allocation of CP15 c9 register encodings.

Figure G3-27 VMSAv8-32 CP15 c9 32-bit register encodings

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c9 registers. Unimplemented CP15 c9 32-bit register encodings, including encodings that are part of an unimplemented Exception level, are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

### VMSAv8-32 CP15 c10 register summary

The CP15 c10 registers provide:

- Virtual memory control registers. That is, they provide registers from the functional group described in *Virtual memory control registers, functional group* on page G3-3737.
- Reserved encodings for IMPLEMENTATION DEFINED TLB control functions, including lockdown.

Figure G3-28 shows the VMSAv8-32 allocation of CP15 c10 registers and reserved encodings.

‡ Implemented only as part of EL2

When using Short-descriptor translation table format	When using Long-descriptor translation table format
PRRR, Primary Region Remap Register	MAIR0, Memory Attribute Indirection Register 0
NMRR, Normal Memory Remap Register	MAIR1, Memory Attribute Indirection Register 1

Figure G3-28 VMSAv8-32 CP15 c10 32-bit register encodings

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c10 registers. Unimplemented CP15 c10 32-bit register encodings, including encodings that are part of an unimplemented Exception level, are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

### VMSAv8-32 CP15 c11 register summary

The CP15 c11 registers provide some reserved encodings for IMPLEMENTATION DEFINED DMA operations to and from TCM. Figure G3-29 shows these reserved encodings:

Figure G3-29 VMSAv8-32 reserved CP15 c11 encodings

CP15 c11 encodings not shown in Figure G3-29 are UNPREDICTABLE, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).

### VMSAv8-32 CP15 c12 register summary

The CP15 c12 registers provide registers from the functional groups described in the following sections:

- [Exception and fault handling registers, functional group on page G3-3741](#).
- [Virtualization registers, functional group on page G3-3738](#).
- [Security registers, functional group on page G3-3741](#).
- [Reset management registers, functional group on page G3-3742](#).
- [Generic Interrupt Controller CPU interface registers, functional group on page G3-3749](#).

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c12 registers. CP15 c12 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).

#### Note

- Some CP15 c12 registers are in more than one functional group.
- All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

### VMSAv8-32 CP15 c13 register summary

The CP15 c13 registers provide:

- An FCSE Process ID Register, that indicates that ARMv8 implementations do not include the FCSE.
- A Context ID Register.
- Software Thread ID Registers.

These registers are from the functional groups described in the following sections:

- [Virtual memory control registers, functional group on page G3-3737](#).
- [Virtualization registers, functional group on page G3-3738](#).
- [Thread and process ID registers, functional group on page G3-3743](#).
- [Legacy feature registers, functional group on page G3-3750](#).

#### Note

Some CP15 c12 registers are in more than one functional group.

Figure G3-30 shows these registers:

Figure G3-30 CP15 c13 registers in VMSAv8-32

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c13 registers. CP15 c13 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

### VMSAv8-32 CP15 c14 register summary

The CP15 c14 registers provide Performance Monitors Extension and Generic Timer Extension registers. That is, they provide registers from the functional group described in the following sections:

- *Performance Monitors Extension registers, functional group* on page G3-3747.
- *Generic Timer Extension registers, functional group* on page G3-3749

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c14 registers. CP15 c14 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

From issue C.a of this manual, CP15 c14 is reserved for the System registers of the OPTIONAL Generic Timer Extension. For more information, see *Chapter D7 The Generic Timer*. On an implementation that does not include the Generic Timer, c14 is an unallocated CP15 primary register, see *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses* on page G3-3693.

#### Note

- Some CP15 c14 registers are also in the Virtualization group, see *Virtualization registers, functional group* on page G3-3738.
- All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

### VMSAv8-32 CP15 c15 register summary

The CP15 c15 registers are reserved for IMPLEMENTATION DEFINED purposes. The architecture does not impose any restrictions on the use of these encodings. For more information, see *IMPLEMENTATION DEFINED registers, functional group* on page G3-3751.

## G3.17.2 Full list of VMSAv8-32 CP15 registers, by coprocessor register number

Table G3-46 on page G3-3723 shows the CP15 registers in VMSAv8-32, in the order of the {CRn, opc1, CRm, opc2} values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn identifies the CP15 primary register used for the access.
- For MRRR or MRRC accesses to the 64-bit registers, CRm identifies the CP15 primary register used for the access. Table G3-46 on page G3-3723 lists the 64-bit registers with the 32-bit registers accessed using the same CP15 primary register number.

**Table G3-46 Summary of VMSAv8-32 CP15 register descriptions, in coprocessor register number order**

CRn	opc1	CRm	opc2	Name	Width	Description			
c0	0	c0	0	MIDR	32-bit	Main ID Register

- a. [REVIDR](#) is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of [MIDR](#).
- b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and UNPREDICTABLE, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).
- c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#), encoding is unallocated and:
  - UNDEFINED, for the registers accessed using CRn set to c12.
  - UNPREDICTABLE, for the register accessed using CRn values other than c12.
- d. Introduced in ARMv8.
- e. Introduced in ARMv8. Implemented only if the implementation includes the System registers interface to the Generic Interrupt Controller CPU interface.
- f. This register is only accessible in Debug state.
- g. When an implementation is using the Long descriptor translation table format these encodings access the [MAIR0](#) and [MAIR1](#) registers. Otherwise, they access the [PRRR](#) and [NMRR](#).
- h. Introduced in ARMv8. Only one of [RMR \(at EL1\)](#), [HRMR](#), and [RMR \(at EL3\)](#) is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.
- i. Implemented only as part of the Generic Timers Extension. Otherwise, encoding is unallocated and UNDEFINED, see [Accesses to unallocated CP14 and CP15 encodings on page G3-3693](#).
- j. Implemented as RW only as part of the Generic Timers Extension on an implementation that includes EL2 and when EL2 is using AArch32. For more information see [Status of the CNTVOFF register on page D7-1864](#).

### G3.17.3 Views of the CP15 registers

The following sections summarize the different software views of the CP15 registers, for VMSAv8-32:

- [EL0 views of the CP15 registers.](#)
- [EL1 views of the CP15 registers on page G3-3733.](#)
- [Non-secure EL2 view of the CP15 registers on page G3-3734.](#)

#### EL0 views of the CP15 registers

Software executing at EL0, unprivileged, can access only a small subset of the CP15 registers, as [Table G3-47](#) shows. This table excludes possible EL0 access to CP15 registers that are part of the following OPTIONAL extensions to the architecture:

- The Performance Monitors Extension, see [Possible EL0 access to the Performance Monitors Extension CP15 registers.](#)
- The Generic Timer Extension, see [Possible EL0 access to the Generic Timer Extension CP15 registers on page G3-3733.](#)

**Table G3-47 CP15 registers accessible from EL0**

Name	Access	Description	Note
CP15ISB	WO	<a href="#">Memory barriers on page E2-2352</a>	ARM deprecates use of these operations
CP15DSB	WO		
CP15DMB	WO		
TPIDRURW	RW	<a href="#">TPIDRURW, Thread Pointer / ID Register, Unprivileged Read-Write on page G4-4078</a>	-
TPIDRURO	RO	<a href="#">TPIDRURO, Thread Pointer / ID Register, Unprivileged Read-Only on page G4-4077</a>	RW at EL1

#### Possible EL0 access to the Performance Monitors Extension CP15 registers

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using CP15 to access the Performance Monitors registers:

- The [PMUSERENR](#) is RO from EL0.
- When:
  - The value of [PMUSERENR.EN](#) is 1, [PMCNTENSET](#), [PMCNTENCLR](#), [PMOVSr](#), [PMSWINC](#), [PMSELR](#), [PMCEID0](#), [PMCEID1](#), [PMCCNTR](#), [PMXEVTPER](#), [PMXVCNTR](#), [PMUSERENR](#), [PMOVSSET](#), [PMEVCNTR<n>](#), [PMEVTPER<n>](#), and [PMCCFILTR](#).are accessible by reads and writes from EL0.
  - The value of [PMUSERENR.ER](#) is 1, [PMXVCNTR](#) and [PMEVCNTR<n>](#).are accessible by reads and from EL0, and [PMSELR](#) is accessible by reads and writes from EL0.
  - The value of [PMUSERENR.CR](#) is 1, [PMCCNTR](#) is accessible by reads from EL0.
  - The value of [PMUSERENR.SW](#) is 1, [PMSWINC](#) is accessible by writes from EL0.

In general, when the value of a [PMUSERENR](#).{EN, ER, CR, SW} bit is 1, the enabled registers have the same access permissions from EL0 as they do from EL1.

For more information, see:

- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1473.](#)
- [Chapter D6 The Performance Monitors Extension](#), in particular [Access permissions on page D6-1851.](#)

### Possible EL0 access to the Generic Timer Extension CP15 registers

In a VMSAv8-32 implementation that includes the Generic Timer Extension, when using CP15 to access the Generic Timer registers:

- If `CNTKCTL.PLOPCTEN` is set to 1, then if the physical counter register `CNTPCT` is accessible from EL1 it is also accessible from EL0. For more information see [Accessing the physical counter on page D7-1858](#).
- If `CNTKCTL.PLOPVTEN` is set to 1, the virtual counter register `CNTVCT` is accessible from EL0. For more information, see [Accessing the virtual counter on page D7-1859](#).
- If at least one of `CNTKCTL.{PLOPCTEN, PLOPVTEN}` is set to 1, the `CNTFRQ` register is RO from EL0.
- If:
  - `CNTKCTL.PLOPTEN` is set to 1, the physical timer registers `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` are accessible from EL0.
  - `CNTKCTL.PLOVTEN` is set to 1, the virtual timer registers `CNTV_CTL`, `CNTV_CVAL`, and `CNTV_TVAL`, are accessible from EL0.

For more information, see [Accessing the timer registers on page D7-1861](#).

### EL1 views of the CP15 registers

Software executing at EL1 can access all CP15 registers, with the following exceptions:

#### Non-secure EL1 software

EL3 restricts or prevents access to some registers by Non-secure EL1 software. In particular:

- The Restricted access CP15 registers are either not accessible to Non-secure EL1 software, or are read-only to Non-secure EL1 software, see [Restricted access System registers on page G3-3698](#)
- Configuration settings determine whether Non-secure EL1 software can access the Configurable access CP15 registers, see [Configurable access System registers on page G3-3699](#).

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure EL1 software has no visibility of the EL2-mode registers summarized in [Banked EL2-mode CP15 read/write registers on page G3-3700](#). The individual register descriptions identify these registers as EL2-mode registers.

#### Secure EL1 software

In general, Secure EL1 software has access to all CP15 registers. However:

- The `CP15SDISABLE` signal disables write access to a number of Secure registers, see [The CP15SDISABLE input on page G3-3704](#).
- To access the EL2-mode registers, Secure EL1 software must move into Monitor mode, and set `SCR.NS` to 1.  
[Banked EL2-mode CP15 read/write registers on page G3-3700](#) summarizes these registers.

The individual register descriptions identify:

- The registers affected by the `CP15SDISABLE` signal.
- The EL2-mode registers.

## Non-secure EL2 view of the CP15 registers

Non-secure software executing at EL2 can access:

- The registers that are accessible to Non-secure software executing at EL1, as defined in [EL1 views of the CP15 registers on page G3-3733](#). Access permissions for these registers are identical to those for Non-secure software executing at EL1.
- The EL2-mode registers summarized in [Banked EL2-mode CP15 read/write registers on page G3-3700](#), and described in [Virtualization registers, functional group on page G3-3738](#).

## G3.18 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

*General system control registers* on page G4-3773 describes each of these registers.

### ———— Note ————

- [Table G3-46 on page G3-3723](#) lists all of the VMSAv8-32 CP15 registers, ordered by:
  1. The CP15 primary register used when accessing the register. This is the CRn value for an access to a 32-bit register, or the CRm value for an access to a 64-bit register.
  2. The opc1 value used when accessing the register.
  3. For 32-bit registers, the {CRm, opc2} values used when accessing the register.
- The functional groups defined in this section mainly consist of the VMSAv8-32 registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information see:

- [The conceptual coprocessor interface and system control on page G1-3492](#) for general information about the System Control Coprocessor, CP15 and the register access instructions MRC and MCR
- [About the System registers for VMSAv8-32 on page G3-3691](#) for general information about the CP15 registers for VMSAv8-32, including:
  - Their organization, both by CP15 primary registers c0 to c15, and by function.
  - Their general behavior.
  - The effect of not implementing some Exception levels on the registers.
  - Different views of the registers, that depend on the state of the PE.
  - Conventions used in describing the registers.

The remainder of this chapter, and [General system control registers on page G4-3773](#), assumes you are familiar with [About the System registers for VMSAv8-32 on page G3-3691](#), and uses conventions and other information from that section without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

- [Identification registers, functional group on page G3-3736.](#)
- [Other system control registers, functional group on page G3-3737.](#)
- [Virtual memory control registers, functional group on page G3-3737.](#)
- [Virtualization registers, functional group on page G3-3738.](#)

VMPIDR	c0	4	c0	5	32-bit	RW	Virtualization Multiprocessor ID Register
VPIDR	c0	4	c0	5	32-bit	RW	Virtualization Processor ID Register

a. CPUID register, see *The CPUID identification scheme* on page G3-3737.

The other registers in this group are the [FPSID](#), [MVFR0](#), [MVFR1](#), and [MVFR2](#).

The [JIDR](#) holds legacy identification information.

## The CPUID identification scheme

The ID\_\* registers were originally called the CPUID identification scheme registers. A footnote to [Table G3-48](#) on [page G3-3736](#) identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

### G3.18.2 Other system control registers, functional group

[Table G3-49](#) shows the VMSAv8-32 CP15 registers in the Other System registers functional group.

**Table G3-49 Other System registers, VMSAv8-32**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">ACTLR</a>	c1	0	c0	1	32-bit	RW	Auxiliary Control Register, IMPLEMENTATION DEFINED
<a href="#">CPACR</a>	c1	0	c0	2	32-bit	RW	Coprocessor Access Control Register
<a href="#">HACTLR</a>	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register, IMPLEMENTATION DEFINED
<a href="#">HSCTLR</a>	c1	4	c0	0	32-bit	RW	Hyp System Control Register
<a href="#">SCTLR</a>	c1	0	c0	0	32-bit	RW	System Control Register

The following sections summarize the System registers added by the corresponding Exception levels:

- [Security registers, functional group on page G3-3741.](#)
- [Virtualization registers, functional group on page G3-3738.](#)

### G3.18.3 Virtual memory control registers, functional group

[Table G3-50](#) shows the VMSAv8-32 CP15 registers in the Virtual memory control registers functional group.

**Table G3-50 Virtual memory control registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">AMAIRO</a>	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0, IMPLEMENTATION DEFINED

<a href="#">RMR (at EL3)</a>	c12	0	c0	2	32-bit	RW	Reset Management Register
<a href="#">SCR</a>	c1	0	c1	0	32-bit	RW	Secure Configuration Register
<a href="#">SDER</a>	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

All the encodings shown in [Table G3-53](#) are unallocated and UNPREDICTABLE on an implementation that does not include EL3, see [Accesses to unallocated CP14 and CP15 encodings](#) on page G3-3693.

### G3.18.6 Exception and fault handling registers, functional group

[Table G3-54](#) shows the VMSAv8-32 CP15 registers in the Exception and fault handling registers functional group.

**Table G3-54 Exception and fault handling registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">ADFSR</a>	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register, IMPLEMENTATION DEFINED
<a href="#">AIFSR</a>	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register, IMPLEMENTATION DEFINED
<a href="#">DFAR</a>	c6	0	c0	0	32-bit	RW	Data Fault Address Register

**Table G3-54 Exception and fault handling registers (continued)**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">DFSR</a>	c5	0	c0	0	32-bit	RW	Data Fault Status Register
<a href="#">HADFSR</a>	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register, IMPLEMENTATION DEFINED
<a href="#">HAIFSR</a>	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register, IMPLEMENTATION DEFINED
<a href="#">HDFAR</a>	c6	4	c0	0	32-bit	RW	Hyp Data Fault Address Register
<a href="#">HIFAR</a>	c6	4	c0	2	32-bit	RW	Hyp Instruction Fault Address Register
<a href="#">HPFAR</a>	c6	4	c0	4	32-bit	RW	Hyp IPA Fault Address Register
<a href="#">HSR</a>	c5	4	c2	0	32-bit	RW	Hyp Syndrome Register
<a href="#">HVBAR</a>	c12	4	c0	1	32-bit	RW	Hyp Vector Base Address Register
<a href="#">IFAR</a>	c6	0	c0	2	32-bit	RW	Instruction Fault Address Register
<a href="#">IFSR</a>	c5	0	c0	1	32-bit	RW	Instruction Fault Status Register
<a href="#">ISR</a>	c12	0	c1	0	32-bit	RO	Interrupt Status Register
<a href="#">MVBAR</a>	c12	0	c0	1	32-bit	RW	Monitor Vector Base Address Register
<a href="#">RVBAR</a>	c12	0	c0	1	32-bit	RW	Reset Vector Base Address Register
<a href="#">VBAR</a>	c12	0	c0	0	32-bit	RW	Vector Base Address Register

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#).

———— **Note** —————

These registers also report information about debug exceptions. For more information see:

- [Data Abort exceptions, taken to a PL1 mode on page G3-3661](#).
- [Prefetch Abort exceptions, taken to a PL1 mode on page G3-3662](#).
- [Reporting exceptions taken to Hyp mode on page G3-3668](#).

### G3.18.7 Reset management registers, functional group

[Table G3-55](#) shows the VMSAv8-32 CP15 registers in the Reset management registers functional group.

**Table G3-55 Reset management registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">HRMR</a>	c12	4	c0	2	32-bit	RW	Hyp Reset Management Register
<a href="#">RMR (at EL1)</a>	c12	0	c0	2	32-bit	RW	Reset Management Register, EL1
<a href="#">RMR (at EL3)</a>	c12	0	c0	2	32-bit	RW	Reset Management Register, EL3
<a href="#">RVBAR</a>	c12	0	c0	1	32-bit	RW	Reset Vector Base Address Register

### G3.18.8 Thread and process ID registers, functional group

Table G3-56 shows the VMSAv8-32 Thread and process ID registers.

**Table G3-56 VMSAv8-32 Thread and process ID registers**

Name	CRn	opc1	CRm	opc2	Width	Type <sup>a</sup>	Description
<a href="#">HTPIDR</a> <sup>b</sup>	c13	4	c0	2	32-bit	RW	Hyp Software Thread ID Register
<a href="#">TPIDRPRW</a>	c13	0	c0	4	32-bit	RW	PL1 Software Thread ID Register
<a href="#">TPIDRURO</a>	c13	0	c0	3	32-bit	RW, PL0	PL0 Read-Only Software Thread ID Register
<a href="#">TPIDRURW</a>	c13	0	c0	2	32-bit	RW, PL0	PL0 Read/Write Software Thread ID Register

- PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- Implemented only as part of EL2. Otherwise, encoding is unallocated and UNPREDICTABLE, see [Accesses to unallocated CP14 and CP15 encodings](#) on page G3-3693.

### G3.18.9 Cache maintenance operations, functional group

Table G3-57 shows the VMSAv8-32 Cache and branch predictor maintenance operations functional group.

**Table G3-57 Cache and branch predictor maintenance operations**

Name	CRn	opc1	CRm	opc2	Width	Type	Description	Limits <sup>a</sup>
<a href="#">BPIALL</a> <sup>b</sup>	c7	0	c5	6	32-bit	WO	Branch predictor invalidate all	-
<a href="#">BPIALLIS</a> <sup>b</sup>	c7	0	c1	6	32-bit	WO	Branch predictor invalidate all	IS

<a href="#">TLBIMVALHIS</a>	c8	4	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable	IS
<a href="#">TLBIMVALIS</a>	c8	0	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level	IS

- a. These links are to a summary of the operation, and [The scope of TLB maintenance operations on page G3-3640](#) describes the operation.  
b. IS = Inner Shareable.  
c. Deprecated. ARM deprecates use of operations that operate only on an Instruction TLB, or only on a Data TLB.  
d. The mnemonics for the operations with CRm==c7, opc2=={0, 1, 2} were previously UTLBIALL, UTLBIMVA and UTLBIMASID.

### G3.18.11 Address translation operations, functional group

[Table G3-59](#) shows the VMSAv8-32 Address translation operations functional group.

**Table G3-59 Address translation operations**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">ATS12NSOPR</a> <sup>a, c</sup>	c7	0	c8	4	32-bit	WO	Stages 1 and 2 Non-secure only EL1 read
<a href="#">ATS12NSOPW</a> <sup>a, c</sup>	c7	0	c8	5	32-bit	WO	Stages 1 and 2 Non-secure only EL1 write
<a href="#">ATS12NSOUR</a> <sup>a, c</sup>	c7	0	c8	6	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged read
<a href="#">ATS12NSOUW</a> <sup>a, c</sup>	c7	0	c8	7	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged write
<a href="#">ATS1CPR</a> <sup>c</sup>	c7	0	c8	0	32-bit	WO	Stage 1 Current state EL1 read
<a href="#">ATS1CPW</a> <sup>c</sup>	c7	0	c8	1	32-bit	WO	Stage 1 Current state EL1 write

<a href="#">PMXEVTYPER</a>	c9	0	c13	1	32-bit	Performance Monitors Event Type Select Register

### IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional CP15c9 encodings for optional additional IMPLEMENTATION DEFINED performance monitors. [Table G3-62](#) shows the allocation of CP15 c9 encodings:

**Table G3-62 Performance Monitors register encoding allocations in CP15 c9**

CRn	opc1	CRm	opc2	Name	Width	Type	Description
c9	0-7	c12-c14	0-7	Performance Monitors Extension registers, see <a href="#">Table G3-61 on page G3-3747</a>	32-bit	RW or RO <sup>a</sup>	<i>IMPLEMENTATION DEFINED performance monitors</i>
		c15	0-7	IMPLEMENTATION DEFINED			

a. The table referenced in the *Name* entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.

b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

### G3.18.14 Generic Timer Extension registers, functional group

AArch32 state reserves CP15 primary coprocessor register c14 for access to the Generic Timer Extension registers. For more information about these registers see *About the Generic Timer registers* on page D7-1864. Table G3-63 shows the VMSAv8-32 CP15 registers in the Generic Timer registers functional group.

**Table G3-63 Generic Timer Extension registers**

Name	CRn	opc1	CRm	opc2	Width	Type <sup>a</sup>	Description
<a href="#">CNTFRQ</a>	c14	0	c0	0	32-bit	RW	Counter Frequency register
<a href="#">CNTHCTL</a>	c14	4	c1	0	32-bit	RW	Timer EL2 Control register
<a href="#">CNTHP_CTL</a>	c14	4	c2	1	32-bit	RW	EL2 Physical Timer Control register
<a href="#">CNTHP_CVAL</a>	-	6	c14	-	64-bit	RW	EL2 Physical Timer CompareValue register
<a href="#">CNTHP_TVAL</a>	c14	4	c2	0	32-bit	RW	EL2 Physical TimerValue register
<a href="#">CNTKCTL</a>	c14	0	c1	0	32-bit	RW	Timer EL1 Control register
<a href="#">CNTP_CTL</a>	c14	0	c2	1	32-bit	RW	EL1 Physical Timer Control register
<a href="#">CNTP_CVAL</a>	-	2	c14	-	64-bit	RW	EL1 Physical Timer CompareValue register
<a href="#">CNTP_TVAL</a>	c14	0	c2	0	32-bit	RW	EL1 Physical TimerValue register
<a href="#">CNTPCT</a>	-	0	c14	-	64-bit	RW	Physical Count register
<a href="#">CNTV_CTL</a>	c14	0	c3	1	32-bit	RW	Virtual Timer Control register
<a href="#">CNTV_CVAL</a>	-	3	c14	-	64-bit	RW	Virtual Timer CompareValue register
<a href="#">CNTV_TVAL</a>	c14	0	c3	0	32-bit	RW	Virtual TimerValue register
<a href="#">CNTVCT</a>	-	1	c14	-	64-bit	RO	Virtual Count register
<a href="#">CNTVOFF<sup>b</sup></a>	-	4	c14	-	64-bit	RW	Virtual Offset register

- a. See the register descriptions for more information. Accessibility can depend on configuration settings as well as on the current Exception level.
- b. Implemented as RW only as part of the Generic Timers Extension on an implementation that includes EL2 and when EL2 is using AArch32. For more information see *Status of the CNTVOFF register* on page D7-1864.

### G3.18.15 Generic Interrupt Controller CPU interface registers, functional group

Table G3-64 shows the VMSAv8-32 CP15 registers in the Generic Interrupt Controller CPU interface registers functional group.

**Table G3-64 Generic Interrupt Controller CPU interface registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">ICC_HSRE</a>	c12	4	c9	5	32-bit	RW	Interrupt Controller Hyp System Register Enable register
<a href="#">ICH_AP0R0</a>	c12	4	c8	0	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (0,0)
<a href="#">ICH_AP0R1</a>	c12	4	c8	1	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (0,1)
<a href="#">ICH_AP0R2</a>	c12	4	c8	2	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (0,2)
<a href="#">ICH_AP0R3</a>	c12	4	c8	3	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (0,3)
<a href="#">ICH_APIR0</a>	c12	4	c9	0	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (1,0)

**Table G3-64 Generic Interrupt Controller CPU interface registers (continued)**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">ICH_APIR1</a>	c12	4	c9	1	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (1,1)
<a href="#">ICH_APIR2</a>	c12	4	c9	2	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (1,2)
<a href="#">ICH_APIR3</a>	c12	4	c9	3	32-bit	RW	Interrupt Controller Hyp Active Priorities Register (1,3)
<a href="#">ICH_EISR</a>	c12	4	c11	3	32-bit	RO	Interrupt Controller End of Interrupt Status Register
<a href="#">ICH_ELSR</a>	c12	4	c11	5	32-bit	RO	Interrupt Controller Empty List Register Status Register
<a href="#">ICH_HCR</a>	c12	4	c11	0	32-bit	RW	Interrupt Controller Hyp Control Register
<a href="#">ICH_LR&lt;n&gt;, n==0-7</a>	c12	4	c12	0-7	32-bit	RW	Interrupt Controller List Registers, 0-7
<a href="#">ICH_LR&lt;n&gt;, n==8-15</a>	c12	4	c13	0-7	32-bit	RW	Interrupt Controller List Registers, 8-15
<a href="#">ICH_LRC&lt;n&gt;, n==0-7</a>	c12	4	c14	0-7	32-bit	RW	Interrupt Controller List Registers Continuation, 0-7
<a href="#">ICH_LRC&lt;n&gt;, n==8-15</a>	c12	4	c15	0-7	32-bit	RW	Interrupt Controller List Registers Continuation, 8-15
<a href="#">ICH_MISR</a>	c12	4	c11	2	32-bit	RO	Interrupt Controller Maintenance Interrupt State Register
<a href="#">ICH_VMCR</a>	c12	4	c11	7	32-bit	RW	Interrupt Controller Virtual Machine Control Register
<a href="#">ICH_VSEIR</a>	c12	4	c9	4	32-bit	RW	Interrupt Controller Virtual System Error Interrupt Register
<a href="#">ICH_VTR</a>	c12	4	c11	1	32-bit	RO	Interrupt Controller VGIC Type Register

### G3.18.16 Legacy feature registers, functional group

Table G3-65 shows the VMSAv8-32 CP15 Legacy features registers.

**Table G3-65 CP15 Legacy features registers**

Name	CRn	opc1	CRm	opc2	Width	Type <sup>a</sup>	Description
<a href="#">CP15DMB</a>	c7	0	c10	5	32-bit	WO, PL0	<a href="#">Memory barriers on page E2-2352</a>
<a href="#">CP15DSB</a>	c7	0	c10	4	32-bit	WO, PL0	
<a href="#">CP15ISB</a>	c7	0	c5	4	32-bit	WO, PL0	
<a href="#">FCSEIDR</a>	c13	0	c0	0	32-bit	<sup>b</sup>	FCSE Process ID Register

- PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- In ARMv8, the PE does not implement the [FCSEIDR](#), and therefore the register is RO. See the register description for more information.

Table G3-66 shows the VMSAv8-32 CP14 Legacy features registers.

**Table G3-66 CP14 Legacy features registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
JIDR	c0	7	c0	0	32-bit	RO	Jazelle ID Register
JMCR	c2	7	c0	0	32-bit	RW	Jazelle Main Configuration Register
JOSCR	c1	7	c0	0	32-bit	RW	Jazelle OS Control Register
TEECR <sup>a</sup>	c0	6	c0	0	32-bit	RW	T32EE Configuration Register
TEEHBR <sup>a</sup>	c1	6	c0	0	32-bit	RW	T32EE Handler Base Register

a. Implemented only if the implementation includes support for T32EE state. This support is deprecated and OPTIONAL. When T32EE state is not supported, these encodings are reserved and UNDEFINED.

### G3.18.17 IMPLEMENTATION DEFINED registers, functional group

AArch32 state reserves CP15 c15 for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of the CP15 c15 encodings. The documentation of the ARM implementation must describe fully any registers implemented in CP15 c15. Normally, for processor implementations by ARM, this information is included in the *Technical Reference Manual* for the processor.

Typically, an implementation uses CP15 c15 to provide test features, and any required configuration options that are not covered by this manual.

In addition, VMSAv8-32 defines some encodings for IMPLEMENTATION DEFINED registers. Table G3-67 shows these registers.

**Table G3-67 IMPLEMENTATION DEFINED registers with architecturally-defined encodings**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ACTLR	c1	0	c0	1	32-bit	RW	Auxiliary Control Register
ADFSR	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register
AIDR	c0	1	c0	7	32-bit	RO	Auxiliary ID Register
AIFSR	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register
AMAIRO	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0
AMAIR1	c10	0	c3	1	32-bit	RW	Auxiliary Memory Attribute Indirection Register 1
HACTLR	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register
HADFSR	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register
HAIFSR	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register
HAMAIRO	c10	4	c3	0	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 0
HAMAIR1	c10	4	c3	1	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 1

See also *IMPLEMENTATION DEFINED performance monitors* on page G3-3748.

### G3.18.18 Floating-point registers, functional group

Table G3-68 shows the VMSAv8-32 Floating-point registers. These registers are accessed using MRS and MSR instructions, see the register descriptions for more information.

**Table G3-68 Floating-point registers**

Name	Width	Type	Description
<a href="#">FPEXC</a>	32-bit	RW	Floating-Point Exception Control register
<a href="#">FPSCR</a>	32-bit	RW	Floating-Point Status and Control Register
<a href="#">FPSID</a>	32-bit	RO	Floating-Point System ID register
<a href="#">MVFR0</a>	32-bit	RO	Media and VFP Feature Register 0
<a href="#">MVFR1</a>	32-bit	RO	Media and VFP Feature Register 1
<a href="#">MVFR2</a>	32-bit	RO	Media and VFP Feature Register 2

### G3.18.19 Debug registers, functional group

In AArch32 state, most Debug registers that are accessible through the System registers interface use CP14 encodings, and are accessed with an `opc1` value of 0. Table G3-69 shows these registers.

**Table G3-69 System register CP14 encodings of Debug registers**

Name	CRn	opc2	CRm	Width	Type	Description	Number <sup>a</sup>
<a href="#">DBGAUTHSTATUS</a>	c7	6	c14	32-bit	RO	Authentication Status	1006

		4	c0	32-bit	IMP DEF		960

a. See [Debug CP14 System register numbers](#) on page G3-3754.

In AArch32 state, some Debug registers that are accessible through the System registers interface use CP15 encodings. [Table G3-70](#) shows these registers.

**Table G3-70 System register CP15 encodings of Debug registers**

Name	CRn	opc1	CRm	opc2	Width	Type	Description
<a href="#">DLR</a>	c4	3	c5	1	32-bit	RW	Debug Link Register
<a href="#">DSPSR</a>	c4	3	c5	0	32-bit	RW	Debug Saved Program Status Register
<a href="#">HDCR</a>	c1	4	c1	1	32-bit	RW	Hyp Debug Control Register
<a href="#">SDCR</a>	c1	0	c3	1	32-bit	RW	Secure Debug Configuration Register
<a href="#">SDER</a>	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

### Debug CP14 System register numbers

In AArch32 state, each debug register that is accessible using a System registers CP14 encoding can be assigned a register number, determined by the {CRn, opc2, CRm} values used to access the register. If the register is also accessible in a memory-mapped interface, then its offset in that interface is (4\*(register\_number)). [Figure G3-31](#) shows this mapping from {CRn, opc2, CRm} values to the debug register number.

**Figure G3-31 Mapping from CP14 encoding to debug register number**

———— **Note** —————

The CP14 debug register encodings only use CRn values c0-c7, meaning bit[10] of the register number is 0.

[Example G3-6](#) shows this encoding for debug register 195, [DBGOSDLR](#).

#### Example G3-6 CP14 encoding of debug register 195

## G3.19 Pseudocode details of VMSAv8-32 memory system operations

This section contains pseudocode describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- [Alignment fault](#).
- [Address translation](#).
- [Domain checking on page G3-3757](#).
- [TLB operations on page G3-3757](#).
- [Translation table walk on page G3-3757](#).
- [Reporting syndrome information on page G3-3768](#).
- [Calling the hypervisor on page G3-3769](#).
- [Memory access decode when TEX remap is enabled on page G3-3769](#).

See also the pseudocode for general memory system operations in [Pseudocode details of general memory system instructions on page G2-3549](#).

### G3.19.1 Alignment fault

The `AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception:

```
// AArch32.AlignmentFault()
// =====

FaultRecord AArch32.AlignmentFault(AccType acctype, boolean iswrite, boolean secondstage)

    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    extflag = bit UNKNOWN;
    debugmoe = bits(4) UNKNOWN;
    s2fslwalk = boolean UNKNOWN;

    return AArch32.CreateFaultRecord(Fault_Alignment, ipaddress, domain, level, acctype, iswrite,
                                     extflag, debugmoe, secondstage, s2fslwalk);
```

See also [Abort exceptions on page G2-3555](#).

### G3.19.2 Address translation

The `TranslateAddress()` pseudocode function describes a VMSAv8-32 address translation. This function calls either:

- The function described in [Address translation when the stage 1 address translation is disabled on page G3-3756](#).
- One of the functions described in [Translation table walk on page G3-3757](#).

```
// AArch32.TranslateAddress()
// =====
// Main entry point for translating an address

AddressDescriptor AArch32.TranslateAddress(bits(32) vaddress, AccType acctype, boolean iswrite,
                                           boolean wasaligned, integer size)

    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then
        return AArch64.TranslateAddress(ZeroExtend(vaddress, 64), acctype, iswrite, wasaligned,
                                         size);

    result = AArch32.FullTranslate(vaddress, acctype, iswrite, wasaligned, size);

    if !(acctype IN {AccType_PTW, AccType_IC, AccType_AT}) && !IsFault(result) then
        result.fault = AArch32.CheckDebug(vaddress, acctype, iswrite, size);

    return result;
```

[Stage 2 translation table walk on page G3-3765](#) describes the CheckPermissionS2() and CombineS1S2Desc() pseudocode functions.

### Address translation when the stage 1 address translation is disabled

The TranslateAddressS10ff() pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

```
// AArch32.TranslateAddressS10ff()
// =====
// Called for stage 1 translations when translation is disabled to supply a default translation.
// Note that there are additional constraints on instruction prefetching that are not described in
// this pseudocode.
```

```
TLBRecord AArch32.TranslateAddressS10ff(bits(32) vaddress, AccType acctype, boolean iswrite)
    assert ELUsingAArch32(TranslationRegime());
```

```
    TLBRecord result;
```

```
    if HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.DC == '1' then
        // Use default cacheable settings
        result.addrdesc.memattrs.type = MemType_Normal;
        result.addrdesc.memattrs.device = DeviceType_UNKNOWN;
        result.addrdesc.memattrs.inner.attrs = MemAttr_WB;           // Write-back
        result.addrdesc.memattrs.inner.hints = MemHint_RWA;
        result.addrdesc.memattrs.shareable = FALSE;
        result.addrdesc.memattrs.outershareable = FALSE;
        if HCR.VM != '1' then UNPREDICTABLE;
```

```
    elsif acctype != AccType_IFETCH then
        // Treat data as Device
        result.addrdesc.memattrs.type = MemType_Device;
        result.addrdesc.memattrs.device = DeviceType_nGnRnE;
        result.addrdesc.memattrs.inner = MemAttrHints_UNKNOWN;
        result.addrdesc.memattrs.shareable = TRUE;
        result.addrdesc.memattrs.outershareable = TRUE;
    else
        // Instruction cacheability controlled by SCTL/HSCTL.I
        if PSTATE.EL == EL2 then
            cacheable = HSCTL.I == '1';
        else
            cacheable = SCTL.I == '1';
        result.addrdesc.memattrs.type = MemType_Normal;
        result.addrdesc.memattrs.device = DeviceType_UNKNOWN;
        if cacheable then
            result.addrdesc.memattrs.inner.attrs = MemAttr_WT;
            result.addrdesc.memattrs.inner.hints = MemHint_RA;
        else
            result.addrdesc.memattrs.inner.attrs = MemAttr_NC;
            result.addrdesc.memattrs.inner.hints = MemHint_No;
        result.addrdesc.memattrs.shareable = TRUE;
        result.addrdesc.memattrs.outershareable = TRUE;
```

```
    result.addrdesc.memattrs.outer = result.addrdesc.memattrs.inner;
```

```
    result.perms.ap = bits(3) UNKNOWN;
    result.perms.xn = '0';
    result.perms.pxn = '0';
```

```
    result.nG = bit UNKNOWN;
    result.contiguous = boolean UNKNOWN;
    result.domain = bits(4) UNKNOWN;
    result.level = integer UNKNOWN;
    result.blocksize = integer UNKNOWN;
    result.addrdesc.paddress.physicaladdress = ZeroExtend(vaddress);
    result.addrdesc.paddress.NS = if IsSecure() then '0' else '1';
    result.addrdesc.fault = AArch32.NoFault();
```

```
return result;
```

### G3.19.3 Domain checking

The CheckDomain() pseudocode function describes domain checking:

```
// AArch32.CheckDomain()
// =====

(boolean, FaultRecord) AArch32.CheckDomain(bits(4) domain, bits(32) vaddress, integer level,
                                           AccType acctype, boolean iswrite)

    index = 2 * UInt(domain);
    attrfield = DACR<index+1:index>;

    if attrfield == '10' then           // Reserved, maps to an allocated value
        // Reserved value maps to an allocated value
        (-, attrfield) = ConstrainUnpredictableBits();

    if attrfield == '00' then
        fault = AArch32.DomainFault(domain, level, acctype, iswrite);
    else
        fault = AArch32.NoFault();

    permissioncheck = (attrfield == '01');

    return (permissioncheck, fault);
```

### G3.19.4 TLB operations

The TLBRecord() type represents the contents of a TLB entry:

```
type TLBRecord is (
    Permissions    perms,
    bit            nG,           // '0' = Global, '1' = not Global
    bits(4)        domain,      // AArch32 only
    boolean        contiguous,  // Contiguous bit from page table
    integer        level,       // In AArch32 Short-descriptor format, indicates Section/Page
    integer        blocksize,   // Describes size of memory translated in KBytes
    AddressDescriptor addrdesc
)
```

### G3.19.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- [Translation table walk using the Short-descriptor translation table format for stage 1.](#)
- [Translation table walk using the Long-descriptor translation table format for stage 1 on page G3-3761.](#)
- [Stage 2 translation table walk on page G3-3765.](#)

#### Translation table walk using the Short-descriptor translation table format for stage 1

The TranslationTableWalkSD() pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in [Stage 2 translation table walk on page G3-3765](#) if necessary:

```
// AArch32.TranslationTableWalkSD()
// =====
// Returns a result of a translation table walk using the Short-descriptor format
//
// Implementations might cache information from memory in any number of non-coherent TLB
// caching structures, and so avoid memory accesses that have been expressed in this
// pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch32.TranslationTableWalkSD(bits(32) vaddress, AccType acctype, boolean iswrite,
```

```

integer size)
assert ELUsingAArch32(TranslationRegime());

// This is only called when the MMU is enabled
TLBRecord      result;

This function calls the `ConvertAttrHints()` pseudocode function that is defined in [Translation table walk using the Short-descriptor translation table format for stage 1 on page G3-3757](#).

The `S1AttrDecode()` pseudocode function uses the `MAIR0` and `MAIR1` registers to decode the `Attr[2:0]` value from a stage 1 translation table descriptor:

```

// AArch32.S1AttrDecode()
// =====
// Converts the Stage 1 attribute fields, using the MAIR, to orthogonal
// attributes and hints.

MemoryAttributes AArch32.S1AttrDecode(bits(2) SH, bits(3) attr, AccType acctype)

MemoryAttributes memattrs;

if PSTATE.EL == EL2 then
    mair = HMAIR1:HMAIR0;
else
    mair = MAIR1:MAIR0;
index = 8 * UInt(attr);
attrfield = mair<index+7:index>;

if ((attrfield<7:4> != '0000' && attrfield<3:0> == '0000') ||
    (attrfield<7:4> == '0000' && !(attrfield<3:0> IN {'000x', '1x00'}))) then
    // Reserved, maps to an allocated value
    (-, attrfield) = ConstrainUnpredictableBits();

```

```

if attrfield<7:4> == '0000' then           // Device
    memattrs.type = MemType_Device;
    memattrs.inner = MemAttrHints UNKNOWN;
    memattrs.outer = MemAttrHints UNKNOWN;
    memattrs.shareable = TRUE;
    memattrs.outershareable = TRUE;
    case attrfield<3:0> of
        when '0000' memattrs.device = DeviceType_nGnRnE;
        when '0001' memattrs.device = DeviceType_nGnRE;
        when '1000' memattrs.device = DeviceType_nGRE;
        when '1100' memattrs.device = DeviceType_GRE;
        otherwise Unreachable();         // Reserved, handled above

elseif attrfield<3:0> != '0000' then     // Normal

    return result;
```

### G3.19.6 Reporting syndrome information

The ReportHypEntry() pseudocode function writes a syndrome value to the [HSR](#):

```
// AArch32.ReportHypEntry()
// =====
// Report syndrome information to Hyp mode registers.

AArch32.ReportHypEntry(ExceptionRecord exception)

    Exception type = exception.type;

    (ec,il) = AArch32.ExceptionClass(type);
    iss = exception.syndrome;

    // IL is not valid for Data Abort exceptions without valid instruction syndrome information
    if ec IN {0x24,0x25} && iss<24> == '0' then
        il = '1';
```

```

HSR = ec<5:0>:i1:iss;

if type IN {Exception_InstructionAbort, Exception_PCAlignmet} then
    HIFAR = exception.vaddress<31:0>;
    HDFAR = bits(32) UNKNOWN;
elseif type == Exception_DataAbort then
    HIFAR = bits(32) UNKNOWN;
    HDFAR = exception.vaddress<31:0>;

if exception.ipavalid then
    HPFAR<31:4> = exception.ipaddress<39:12>;

return;

```

### G3.19.7 Calling the hypervisor

The CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

```

// AArch32.CallHypervisor()
// =====
// Performs a HVC call

AArch32.CallHypervisor(bits(16) immediate)

if !ELUsingAArch32(EL2) then
    AArch64.CallHypervisor(immediate);

AArch32.TakeHVCException(immediate);

```

### G3.19.8 Memory access decode when TEX remap is enabled

When using the Short-descriptor translation table format, the function RemappedTEXDecode() decodes the texcb and S attributes derived from the translation tables when TEX remap is enabled. *Short-descriptor format memory region attributes, with TEX remap* on page G3-3620 shows the interpretation of the arguments.

```

// AArch32.RemappedTEXDecode()
// =====

MemoryAttributes AArch32.RemappedTEXDecode(bits(3) TEX, bit C, bit B, bit S, AccType acctype)

MemoryAttributes memattrs;

region = UInt(TEX<0>:C:B); // TEX<2:1> are ignored in this mapping scheme
if region == 6 then

# Chapter G4

## AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

- *About the AArch32 System registers* on page G4-3772.
- *General system control registers* on page G4-3773.
- *Debug registers* on page G4-4101.
- *Performance Monitors registers* on page G4-4170.
- *Generic Timer registers* on page G4-4208.
- *Generic Interrupt Controller CPU interface registers* on page G4-4230.

## G4.1 About the AArch32 System registers

The following sections describe the AArch32 system registers:

- [General system control registers](#) on page G4-3773.
- [Debug registers](#) on page G4-4101.
- [Performance Monitors registers](#) on page G4-4170.
- [Generic Timer registers](#) on page G4-4208.
- [Generic Timer registers](#) on page G4-4208.

For general information about these registers see:

- [About the System registers for VMSAv8-32](#) on page G3-3691.
- [Organization of the CP14 registers in VMSAv8-32](#) on page G3-3713.
- [Organization of the CP15 registers in VMSAv8-32](#) on page G3-3716.
- [Functional grouping of VMSAv8-32 System registers](#) on page G3-3735.

## G4.2 General system control registers

This section describe the system registers in AArch32 state that are not part of one of the other functional groups.

### G4.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

#### Purpose

Provides IMPLEMENTATION DEFINED configuration and control options.

This register is part of:

- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

#### Usage constraints

This register is accessible as shown below:

When accessed as ACTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ACTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

#### Configurations

ACTLR(NS) is architecturally mapped to AArch64 register [ACTLR\\_EL1](#).

ACTLR(S) can be mapped to AArch64 register [ACTLR\\_EL3](#), but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Some bits might define global configuration settings, and be common to the Secure and Non-secure copies of the register.

#### Attributes

ACTLR is a 32-bit register.

The ACTLR bit assignments are:

#### Accessing the ACTLR:

To access the ACTLR:

MRC p15,0,<Rt>,c1,c0,1 ; Read ACTLR into Rt

MCR p15,0,<Rt>,c1,c0,1 ; Write Rt to ACTLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0001	0000	001

## G4.2.2 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as ADFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ADFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

ADFSR(NS) is architecturally mapped to AArch64 register [AFSR0\\_EL1](#).

ADFSR(S) can be mapped to AArch64 register [AFSR0\\_EL3](#), but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

### Attributes

ADFSR is a 32-bit register.

The ADFSR bit assignments are:

### Accessing the ADFSR:

To access the ADFSR:

MRC p15,0,<Rt>,c5,c1,0 ; Read ADFSR into Rt  
MCR p15,0,<Rt>,c5,c1,0 ; Write Rt to ADFSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0101	0001	000

### G4.2.3 AIDR, Auxiliary ID Register

The AIDR characteristics are:

#### Purpose

Provides IMPLEMENTATION DEFINED identification information.

This register is part of:

- the Identification registers functional group
- the IMPLEMENTATION DEFINED functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

The value of this register must be used in conjunction with the value of [MIDR](#).

#### Configurations

AIDR is architecturally mapped to AArch64 register [AIDR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

AIDR is a 32-bit register.

The AIDR bit assignments are:

#### Accessing the AIDR:

To access the AIDR:

MRC p15,1,<Rt>,c0,c0,7 ; Read AIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	001	0000	0000	111

## G4.2.4 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as AIFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AIFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

AIFSR(NS) is architecturally mapped to AArch64 register [AFSR1\\_EL1](#).

AIFSR(S) can be mapped to AArch64 register [AFSR1\\_EL3](#), but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

### Attributes

AIFSR is a 32-bit register.

The AIFSR bit assignments are:

### Accessing the AIFSR:

To access the AIFSR:

MRC p15,0,<Rt>,c5,c1,1 ; Read AIFSR into Rt  
 MCR p15,0,<Rt>,c5,c1,1 ; Write Rt to AIFSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0101	0001	001

## G4.2.5 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

### Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as AMAIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AMAIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

### Configurations

AMAIR0(NS) is architecturally mapped to AArch64 register AMAIR\_EL1[31:0].

AMAIR0(S) can be mapped to AArch64 register AMAIR\_EL3[31:0], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Write access to the Secure copy of AMAIR0 is disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

AMAIR0 is a 32-bit register.

The AMAIR0 bit assignments are:

### Accessing the AMAIR0:

To access the AMAIR0:

MRC p15,0,<Rt>,c10,c3,0 ; Read AMAIR0 into Rt  
MCR p15,0,<Rt>,c10,c3,0 ; Write Rt to AMAIR0

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1010	0011	000

## G4.2.6 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

### Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as AMAIR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AMAIR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

### Configurations

AMAIR1(NS) is architecturally mapped to AArch64 register AMAIR\_EL1[63:32].

AMAIR1(S) can be mapped to AArch64 register AMAIR\_EL3[63:32], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Write access to the Secure copy of AMAIR1 is disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

AMAIR1 is a 32-bit register.

The AMAIR1 bit assignments are:

### Accessing the AMAIR1:

To access the AMAIR1:

MRC p15,0,<Rt>,c10,c3,1 ; Read AMAIR1 into Rt  
MCR p15,0,<Rt>,c10,c3,1 ; Write Rt to AMAIR1

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1010	0011	001

## G4.2.7 APSR, Application Program Status Register

The APSR characteristics are:

### Purpose

Hold program status and control information.

This register is part of the Process state registers functional group.

### Usage constraints

The APSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more information see [MRS on page F7-2720](#), [MSR \(immediate\) on page F7-2722](#), and [MSR \(register\) on page F7-2724](#).

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

APSR is a 32-bit register.

The APSR bit assignments are:

### N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

### Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

### C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

### V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

### Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

### Bits [26:20]

Reserved, RES0.

### GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

### Bits [15:5]

Reserved, RES0.

**Bit [4]**

Reserved, RES1.

**Bits [3:0]**

Reserved, RES0.

## G4.2.8 ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

### Purpose

Performs stage 1 and 2 address translations as defined for EL1 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

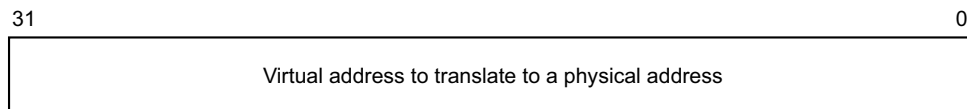

### Configurations

There are no configuration notes.

### Attributes

ATS12NSOPR is a 32-bit system operation.

The ATS12NSOPR input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS12NSOPR operation:

To perform the ATS12NSOPR operation:

MCR p15,0,<Rt>,c7,c8,4 ; ATS12NSOPR operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	100

## G4.2.9 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

### Purpose

Performs stage 1 and 2 address translations as defined for EL1 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

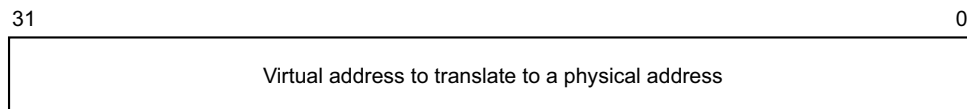

### Configurations

There are no configuration notes.

### Attributes

ATS12NSOPW is a 32-bit system operation.

The ATS12NSOPW input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS12NSOPW operation:

To perform the ATS12NSOPW operation:

MCR p15,0,<Rt>,c7,c8,5 ; ATS12NSOPW operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	101

## G4.2.10 ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

### Purpose

Performs stage 1 and 2 address translations as defined for EL0 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

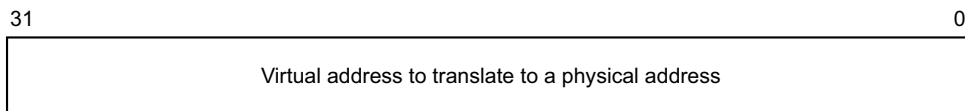

### Configurations

There are no configuration notes.

### Attributes

ATS12NSOUR is a 32-bit system operation.

The ATS12NSOUR input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS12NSOUR operation:

To perform the ATS12NSOUR operation:

MCR p15,0,<Rt>,c7,c8,6 ; ATS12NSOUR operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	110

## G4.2.11 ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

### Purpose

Performs stage 1 and 2 address translations as defined for EL0 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

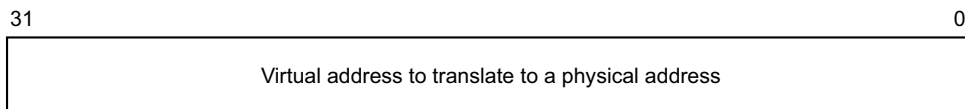

### Configurations

There are no configuration notes.

### Attributes

ATS12NSOUW is a 32-bit system operation.

The ATS12NSOUW input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS12NSOUW operation:

To perform the ATS12NSOUW operation:

MCR p15,0,<Rt>,c7,c8,7 ; ATS12NSOUW operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	111

## G4.2.12 ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

### Purpose

Performs stage 1 address translation as defined for EL1 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

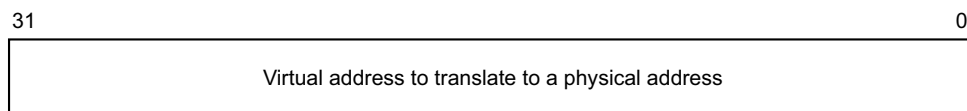

### Configurations

There are no configuration notes.

### Attributes

ATS1CPR is a 32-bit system operation.

The ATS1CPR input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS1CPR operation:

To perform the ATS1CPR operation:

MCR p15,0,<Rt>,c7,c8,0 ; ATS1CPR operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	000

### G4.2.13 ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

#### Purpose

Performs stage 1 address translation as defined for EL1 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

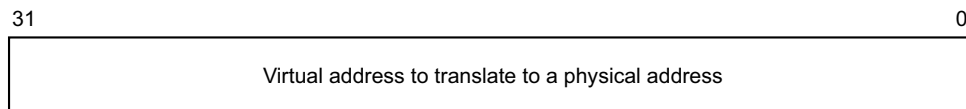

#### Configurations

There are no configuration notes.

#### Attributes

ATS1CPW is a 32-bit system operation.

The ATS1CPW input value bit assignments are:

#### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

#### Performing the ATS1CPW operation:

To perform the ATS1CPW operation:

MCR p15,0,<Rt>,c7,c8,1 ; ATS1CPW operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	001

## G4.2.14 ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

### Purpose

Performs stage 1 address translation as defined for EL0 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

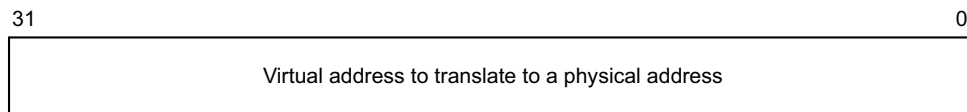

### Configurations

There are no configuration notes.

### Attributes

ATS1CUR is a 32-bit system operation.

The ATS1CUR input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS1CUR operation:

To perform the ATS1CUR operation:

MCR p15,0,<Rt>,c7,c8,2 ; ATS1CUR operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	010

## G4.2.15 ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write

The ATS1CUW characteristics are:

### Purpose

Performs stage 1 address translation as defined for EL0 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

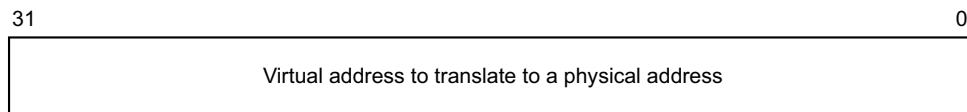

### Configurations

There are no configuration notes.

### Attributes

ATS1CUW is a 32-bit system operation.

The ATS1CUW input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS1CUW operation:

To perform the ATS1CUW operation:

MCR p15,0,<Rt>,c7,c8,3 ; ATS1CUW operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	011

### G4.2.16 ATS1HR, Address Translate Stage 1 Hyp mode Read

The ATS1HR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL2 and the current security state, with permissions as if reading from the given virtual address.

This register is part of:

- the Address translation operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

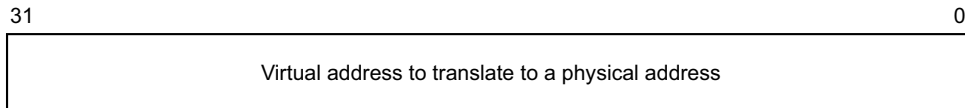

**Configurations**

There are no configuration notes.

**Attributes**

ATS1HR is a 32-bit system operation.

The ATS1HR input value bit assignments are:

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

**Performing the ATS1HR operation:**

To perform the ATS1HR operation:

```
MCR p15,4,<Rt>,c7,c8,0 ; ATS1HR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0111	1000	000

## G4.2.17 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

### Purpose

Performs stage 1 address translation as defined for EL2 and the current security state, with permissions as if writing to the given virtual address.

This register is part of:

- the Address translation operations functional group
- the Virtualization registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

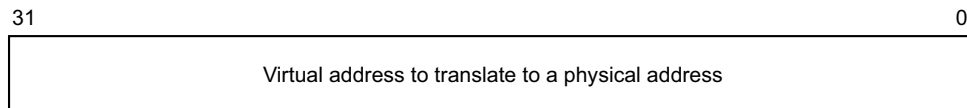

### Configurations

There are no configuration notes.

### Attributes

ATS1HW is a 32-bit system operation.

The ATS1HW input value bit assignments are:

### Bits [31:0]

Virtual address to translate to a physical address. The resulting physical address can be read from the [PAR](#).

### Performing the ATS1HW operation:

To perform the ATS1HW operation:

MCR p15,4,<Rt>,c7,c8,1 ; ATS1HW operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0111	1000	001

## G4.2.18 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

### Purpose

Invalidate all entries from branch predictors.

This register is part of the Cache maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

### Configurations

There are no configuration notes.

### Attributes

BPIALL is a 32-bit system operation.

The BPIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the BPIALL operation:

To perform the BPIALL operation:

MCR p15,0,<Rt>,c7,c5,6 ; BPIALL operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	110

## G4.2.19 BPIALLIS, Branch Predictor Invalidate All, Inner Shareable

The BPIALLIS characteristics are:

### Purpose

Invalidate all entries from branch predictors Inner Shareable.

This register is part of the Cache maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

### Configurations

There are no configuration notes.

### Attributes

BPIALLIS is a 32-bit system operation.

The BPIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the BPIALLIS operation:

To perform the BPIALLIS operation:

MCR p15,0,<Rt>,c7,c1,6 ; BPIALLIS operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0001	110

## G4.2.20 BPIMVA, Branch Predictor Invalidate VA

The BPIMVA characteristics are:

### Purpose

Invalidate virtual address from branch predictors.

This register is part of the Cache maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

### Configurations

There are no configuration notes.

### Attributes

BPIMVA is a 32-bit system operation.

The BPIMVA input value bit assignments are:

### Bits [31:0]

Virtual address to use.

### Performing the BPIMVA operation:

To perform the BPIMVA operation:

MCR p15,0,<Rt>,c7,c5,7 ; BPIMVA operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	111

## G4.2.21 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

### Purpose

Provides information about the architecture of the currently selected cache.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If [CSSELR](#) indicates a cache that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

### Configurations

CCSIDR is architecturally mapped to AArch64 register [CCSIDR\\_EL1](#).

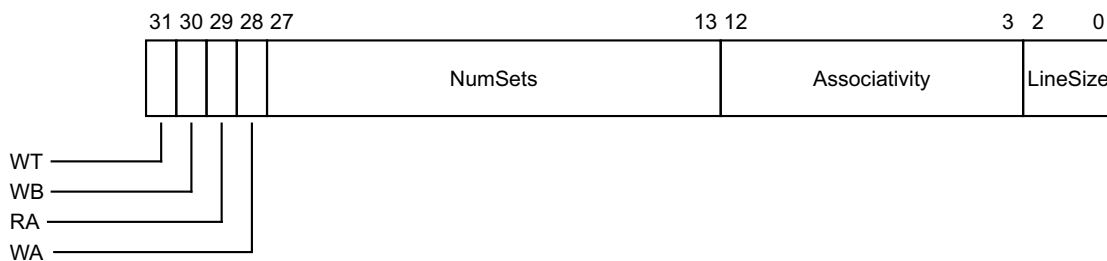

There is one instance of this register that is used in both Secure and Non-secure states.

The implementation includes one CCSIDR for each cache that it can access. [CSSELR](#) and the security state select which Cache Size ID Register is accessible.

### Attributes

CCSIDR is a 32-bit register.

The CCSIDR bit assignments are:

### WT, bit [31]

Indicates whether the selected cache level supports write-through. Permitted values are:

- 0 Write-through not supported.
- 1 Write-through supported.

### WB, bit [30]

Indicates whether the selected cache level supports write-back. Permitted values are:

- 0 Write-back not supported.
- 1 Write-back supported.

**RA, bit [29]**

Indicates whether the selected cache level supports read-allocation. Permitted values are:

- 0 Read-allocation not supported.
- 1 Read-allocation supported.

**WA, bit [28]**

Indicates whether the selected cache level supports write-allocation. Permitted values are:

- 0 Write-allocation not supported.
- 1 Write-allocation supported.

**NumSets, bits [27:13]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Associativity, bits [12:3]**

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

**LineSize, bits [2:0]**

( $\text{Log}_2(\text{Number of bytes in cache line})$ ) - 4. For example:

For a line length of 16 bytes:  $\text{Log}_2(16) = 4$ , LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes:  $\text{Log}_2(32) = 5$ , LineSize entry = 1.

**Accessing the CCSIDR:**

To access the CCSIDR:

MRC p15,1,<Rt>,c0,c0,0 ; Read CCSIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	001	0000	0000	000

## G4.2.22 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

### Purpose

Identifies the type of cache, or caches, implemented at each level, up to a maximum of seven levels. Also identifies the Level of Coherency and Level of Unification for the cache hierarchy.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

CLIDR is architecturally mapped to AArch64 register [CLIDR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

CLIDR is a 32-bit register.

The CLIDR bit assignments are:

### Bits [31:30]

Reserved, RES0.

### LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

### LoC, bits [26:24]

Level of Coherency for the cache hierarchy.

### LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

### Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache implemented at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

- 000 No cache.
- 001 Instruction cache only.
- 010 Data cache only.
- 011 Separate instruction and data caches.
- 100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 0b000, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 0b000, the values of Ctype4 to Ctype7 must be ignored.

### Accessing the CLIDR:

To access the CLIDR:

MRC p15,1,<Rt>,c0,c0,1 ; Read CLIDR into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	001	0000	0000	001

## G4.2.23 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

### Purpose

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as CONTEXTIDR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as CONTEXTIDR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

### Configurations

CONTEXTIDR(NS) is architecturally mapped to AArch64 register [CONTEXTIDR\\_EL1](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

### Attributes

CONTEXTIDR is a 32-bit register.

The CONTEXTIDR bit assignments are:

### When TTBCR.EAE==0:

#### PROCID, bits [31:8]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

#### ASID, bits [7:0]

Address Space Identifier. This field is programmed with the value of the current ASID.

**When TTBCR.EAE==1:**

**PROCID, bits [31:0]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

**Accessing the CONTEXTIDR:**

To access the CONTEXTIDR:

MRC p15,0,<Rt>,c13,c0,1 ; Read CONTEXTIDR into Rt  
MCR p15,0,<Rt>,c13,c0,1 ; Write Rt to CONTEXTIDR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1101	0000	001

## G4.2.24 CP15DMB, CP15 Data Memory Barrier operation

The CP15DMB characteristics are:

### Purpose

Performs a Data Memory Barrier.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If `SCTLR.CP15BEN` is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the DMB instruction instead.

### Configurations

There are no configuration notes.

### Attributes

CP15DMB is a 32-bit system operation.

The CP15DMB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the CP15DMB operation:

To perform the CP15DMB operation:

`MCR p15,0,<Rt>,c7,c10,5 ; CP15DMB operation, ignoring the value in Rt`

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	101

## G4.2.25 CP15DSB, CP15 Data Synchronization Barrier operation

The CP15DSB characteristics are:

### Purpose

Performs a Data Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If `SCTLR.CP15BEN` is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the DSB instruction instead.

### Configurations

There are no configuration notes.

### Attributes

CP15DSB is a 32-bit system operation.

The CP15DSB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the CP15DSB operation:

To perform the CP15DSB operation:

`MCR p15,0,<Rt>,c7,c10,4 ; CP15DSB operation, ignoring the value in Rt`

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	100

## G4.2.26 CP15ISB, CP15 Instruction Synchronization Barrier operation

The CP15ISB characteristics are:

### Purpose

Performs an Instruction Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If [SCTLR.CP15BEN](#) is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the ISB instruction instead.

### Configurations

There are no configuration notes.

### Attributes

CP15ISB is a 32-bit system operation.

The CP15ISB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the CP15ISB operation:

To perform the CP15ISB operation:

MCR p15,0,<Rt>,c7,c5,4 ; CP15ISB operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	100

## G4.2.27 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

### Purpose

Controls access to Trace, Floating-point, and Advanced SIMD functionality.  
 This register is part of the Other system control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

### Configurations

CPACR is architecturally mapped to AArch64 register [CPACR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Bits in the [NSACR](#) control Non-secure access to the CPACR fields. See the field descriptions for more information.

### Attributes

CPACR is a 32-bit register.

The CPACR bit assignments are:

### ASEDIS, bit [31]

Disable Advanced SIMD functionality:

- 0 Does not cause any instructions to be UNDEFINED.
- 1 All instruction encodings that are part of Advanced SIMD, but that are not VFPv3 or VFPv4 instructions, are UNDEFINED.

In Non-secure state, if [NSACR.NSASEDIS](#) is set to 1, this bit is RES1.

Resets to 0.

### Bits [30:29]

Reserved, RES0.

### TRCDIS, bit [28]

Disable CP14 access to trace registers:

- 0 Does not cause any instructions to be UNDEFINED.
- 1 Any MRC or MCR instruction with coproc set to 0b1110 and opc1 set to 0b001 is UNDEFINED.

In Non-secure state, if **NSACR.NSTRCDIS** is set to 1, this bit is RES1.

Reset value is architecturally UNKNOWN.

#### Bits [27:24]

Reserved, RES0.

#### cp<n>, bits [2n+1:2n], for n = 10 to 11

Defines the access rights for coprocessors 10 and 11, which control the Floating-point and Advanced SIMD features. Possible values of the fields are:

- 00 Access denied. Any attempt to access Floating-point and Advanced SIMD registers or instructions generates an Undefined Instruction exception.
- 01 Access at EL1 only. Any attempt to access Floating-point and Advanced SIMD registers or instructions from software executing at EL0 generates an Undefined Instruction exception.
- 11 Full access.

The value 0b10 is reserved.

In Non-secure state, if **NSACR.cp<n>** is set to 0, this bit is RES0.

The Floating-point and Advanced SIMD features controlled by these fields are:

- VFP floating-point instructions.
- Advanced SIMD instructions (both integer and floating-point).
- Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, **MVFR2**, **FPEXC** system registers.

If the cp11 and cp10 fields are set to different values, the behavior is **CONSTRAINED UNPREDICTABLE**, and is the same as if both fields were set to the value of cp10, in all respects other than the value read back by explicitly reading cp11.

Other coprocessors are not supported in ARMv8, so bits[27:24] and bits[19:0] are RES0.

Resets to 0.

#### Bits [19:0]

Reserved, RES0.

#### Accessing the CPACR:

To access the CPACR:

MRC p15,0,<Rt>,c1,c0,2 ; Read CPACR into Rt

MCR p15,0,<Rt>,c1,c0,2 ; Write Rt to CPACR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0000	010

## G4.2.28 CPSR, Current Program Status Register

The CPSR characteristics are:

### Purpose

Holds processor status and control information.  
 This register is part of the Process state registers functional group.

### Usage constraints

The CPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more information see [MRS on page F7-2720](#), [MSR \(immediate\) on page F7-2722](#), and [MSR \(register\) on page F7-2724](#).

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

CPSR is a 32-bit register.

The CPSR bit assignments are:

### N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

### Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

### C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

### V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

### Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

### IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

### Bits [23:20]

Reserved, RES0.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**Bit [4]**

Reserved, RES1.

**M[3:0], bits [3:0]**

Current processor mode. Possible values are:

<b>M[3:0]</b>	<b>Mode</b>
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

## G4.2.29 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

### Purpose

Selects the current Cache Size ID Register, [CCSIDR](#), by specifying the required cache level and the cache type (either instruction or data cache).

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as CSSELR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as CSSELR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If the CSSELR level field is programmed to a cache level that is not implemented, then a read of CSSELR is CONstrained UNPREDICTABLE, and returns an UNKNOWN value in CSSELR.Level.

### Configurations

CSSELR(NS) is architecturally mapped to AArch64 register [CSSELR\\_EL1](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

CSSELR is a 32-bit register.

The CSSELR bit assignments are:

### Bits [31:4]

Reserved, RES0.

### Level, bits [3:1]

Cache level of required cache. Permitted values are from 0b000, indicating Level 1 cache, to 0b110 indicating Level 7 cache.

### InD, bit [0]

Instruction not Data bit. Permitted values are:

- 0 Data or unified cache.
- 1 Instruction cache.

### Accessing the CSSELR:

To access the CSSELR:

MRC p15,2,<Rt>,c0,c0,0 ; Read CSSELR into Rt  
MCR p15,2,<Rt>,c0,c0,0 ; Write Rt to CSSELR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	010	0000	0000	000

### G4.2.30 CTR, Cache Type Register

The CTR characteristics are:

#### Purpose

Provides information about the architecture of the caches.

This register is part of the Identification registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

#### Configurations

CTR is architecturally mapped to AArch64 register [CTR\\_ELO](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

CTR is a 32-bit register.

The CTR bit assignments are:

#### Bit [31]

Reserved, RES1.

#### Bits [30:28]

Reserved, RES0.

#### CWG, bits [27:24]

Cache Writeback Granule.  $\log_2$  of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2Kbytes) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

#### ERG, bits [23:20]

Exclusives Reservation Granule.  $\log_2$  of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of `0b0000` indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2Kbytes) must be assumed.

Values greater than 0b1001 are reserved.

**DminLine, bits [19:16]**

Log<sub>2</sub> of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the processor.

**L1Ip, bits [15:14]**

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- 01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- 10 Virtual Index, Physical Tag (VIPT)
- 11 Physical Index, Physical Tag (PIPT)

Other values are reserved.

**Bits [13:4]**

Reserved, RES0.

**IminLine, bits [3:0]**

Log<sub>2</sub> of the number of words in the smallest cache line of all the instruction caches that are controlled by the processor.

**Accessing the CTR:**

To access the CTR:

MRC p15,0,<Rt>,c0,c0,1 ; Read CTR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	001

## G4.2.31 DACR, Domain Access Control Register

The DACR characteristics are:

### Purpose

Defines the access permission for each of the sixteen memory domains.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as DACR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DACR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

DACR(NS) is architecturally mapped to AArch64 register [DACR32\\_EL2](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

DACR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

In an implementation that includes the Large Physical Address Extension, this register has no function when [TTBCR.EAE](#) is set to 1, to select the Long-descriptor translation table format.

### Attributes

DACR is a 32-bit register.

The DACR bit assignments are:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0																

### D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

00 No access. Any access to the domain generates a Domain fault.

01 Client. Accesses are checked against the permission bits in the translation tables.

11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 0b10 is reserved.

### Accessing the DACR:

To access the DACR:

MRC p15,0,<Rt>,c3,c0,0 ; Read DACR into Rt

MCR p15,0,<Rt>,c3,c0,0 ; Write Rt to DACR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0011	0000	000

### G4.2.32 DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

#### Purpose

Clean and Invalidate data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

#### Configurations

DCCIMVAC performs the same function as AArch64 operation [DC CIVAC](#).

#### Attributes

DCCIMVAC is a 32-bit system operation.

The DCCIMVAC input value bit assignments are:

#### Bits [31:0]

Virtual address to use.

#### Performing the DCCIMVAC operation:

To perform the DCCIMVAC operation:

MCR p15,0,<Rt>,c7,c14,1 ; DCCIMVAC operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1110	001

### G4.2.33 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

**Configurations**

DCCISW performs the same function as AArch64 operation [DC C1SW](#).

**Attributes**

DCCISW is a 32-bit system operation.

The DCCISW input value bit assignments are:

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$$A = \text{Log}_2(\text{ASSOCIATIVITY}), L = \text{Log}_2(\text{LINELEN}), B = (L + S), S = \text{Log}_2(\text{NSETS}).$$

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Performing the DCCISW operation:**

To perform the DCCISW operation:

```
MCR p15,0,<Rt>,c7,c14,2 ; DCCISW operation
```

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0111	1110	010

### G4.2.34 DCCMVAC, Data Cache line Clean by VA to PoC

The DCCMVAC characteristics are:

#### Purpose

Clean data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

#### Configurations

DCCMVAC performs the same function as AArch64 operation [DC CVAC](#).

#### Attributes

DCCMVAC is a 32-bit system operation.

The DCCMVAC input value bit assignments are:

#### Bits [31:0]

Virtual address to use.

#### Performing the DCCMVAC operation:

To perform the DCCMVAC operation:

MCR p15,0,<Rt>,c7,c10,1 ; DCCMVAC operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	001

### G4.2.35 DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

#### Purpose

Clean data or unified cache line by virtual address to PoU.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

#### Configurations

DCCMVAU performs the same function as AArch64 operation [DC CVAU](#).

#### Attributes

DCCMVAU is a 32-bit system operation.

The DCCMVAU input value bit assignments are:

#### Bits [31:0]

Virtual address to use.

#### Performing the DCCMVAU operation:

To perform the DCCMVAU operation:

MCR p15,0,<Rt>,c7,c11,1 ; DCCMVAU operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1011	001

### G4.2.36 DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

**Purpose**

Clean data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

**Configurations**

DCCSW performs the same function as AArch64 operation [DC CSW](#).

**Attributes**

DCCSW is a 32-bit system operation.

The DCCSW input value bit assignments are:

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$$A = \text{Log}_2(\text{ASSOCIATIVITY}), L = \text{Log}_2(\text{LINELEN}), B = (L + S), S = \text{Log}_2(\text{NSETS}).$$

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Performing the DCCSW operation:**

To perform the DCCSW operation:

```
MCR p15,0,<Rt>,c7,c10,2 ; DCCSW operation
```

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0111	1010	010

### G4.2.37 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

#### Purpose

Invalidate data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

At EL1, this operation must be performed as [DCCIMVAC](#) if all of the following apply:

- EL2 is implemented.
- [HCR.VM](#) is set to 1.
- [SCR.NS](#) is set to 1 or EL3 is not implemented.

#### Configurations

DCIMVAC performs the same function as AArch64 operation [DC IVAC](#).

#### Attributes

DCIMVAC is a 32-bit system operation.

The DCIMVAC input value bit assignments are:

#### Bits [31:0]

Virtual address to use.

#### Performing the DCIMVAC operation:

To perform the DCIMVAC operation:

MCR p15,0,<Rt>,c7,c6,1 ; DCIMVAC operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0110	001

### G4.2.38 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

#### Purpose

Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

At EL1, this operation must be performed as [DCCISW](#) if all of the following apply:

- EL2 is implemented
- [HCR.VM](#) is set to 1
- [SCR.NS](#) is set to 1 or EL3 is not implemented.

#### Configurations

DCISW performs the same function as AArch64 operation [DC ISW](#).

#### Attributes

DCISW is a 32-bit system operation.

The DCISW input value bit assignments are:

#### SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$ ,  $L = \text{Log}_2(\text{LINELEN})$ ,  $B = (L + S)$ ,  $S = \text{Log}_2(\text{NSETS})$ .

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

#### Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

#### Bit [0]

Reserved, RES0.

### Performing the DCISW operation:

To perform the DCISW operation:

MCR p15,0,<Rt>,c7,c6,2 ; DCISW operation

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0111	0110	010

### G4.2.39 DFAR, Data Fault Address Register

The DFAR characteristics are:

#### Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.  
This register is part of the Exception and fault handling registers functional group.

#### Usage constraints

This register is accessible as shown below:

When accessed as DFAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DFAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

#### Configurations

DFAR(NS) is architecturally mapped to AArch64 register [FAR\\_EL1](#)[31:0].

DFAR(S) is architecturally mapped to AArch32 register [HDFAR](#) when EL2 is implemented.

DFAR(S) is architecturally mapped to AArch64 register [FAR\\_EL2](#)[31:0] when EL2 is implemented.

DFAR(S) can be mapped to AArch64 register [FAR\\_EL3](#)[31:0] when EL2 is not implemented, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

#### Attributes

DFAR is a 32-bit register.

The DFAR bit assignments are:

#### Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

#### Accessing the DFAR:

To access the DFAR:

MRC p15,0,<Rt>,c6,c0,0 ; Read DFAR into Rt

MCR p15,0,<Rt>,c6,c0,0 ; Write Rt to DFAR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0110	0000	000

## G4.2.40 DFSR, Data Fault Status Register

The DFSR characteristics are:

### Purpose

Holds status information about the last data fault.

This register is part of the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as DFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

DFSR(NS) is architecturally mapped to AArch64 register [ESR\\_EL1](#).

DFSR(S) can be mapped to AArch64 register [ESR\\_EL3](#), but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

### Attributes

DFSR is a 32-bit register.

The DFSR bit assignments are:

### When TTBCR.EAE==0:

### Bits [31:14]

Reserved, RES0.

**CM, bit [13]**

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:

- 0 Abort not caused by a cache maintenance operation.
- 1 Abort caused by a cache maintenance operation.

On an asynchronous fault, this bit is UNKNOWN.

**Ext, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

**WnR, bit [11]**

Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:

- 0 Abort caused by a read access.
- 1 Abort caused by a write access.

For faults on CP15 cache maintenance operations, including the VA to PA translation operations, this bit always returns a value of 1.

**FS[4], bit [10]**

See below for description of the FS field.

**LPAAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bit [8]**

Reserved, RES0.

**DOMAIN, bits [7:4]**

Domain of the fault address. Use of this field is deprecated.

**FS[3:0], bits [3:0]**

Fault status bits. Possible values of this field are:

- 0001 Alignment fault
- 0010 Debug event
- 0011 Access flag fault, first level
- 0100 Fault on instruction cache maintenance
- 0101 Translation fault, first level
- 0110 Access flag fault, second level
- 0111 Translation fault, second level
- 1000 Synchronous external abort
- 1001 Domain fault, first level
- 1011 Domain fault, second level
- 1100 Synchronous external abort on translation table walk, first level
- 1101 Permission fault, first level

- 1110 Synchronous external abort on translation table walk, second level
  - 1111 Permission fault, second level
  - 10000 TLB conflict abort
  - 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
  - 10101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
  - 10110 Asynchronous external abort
  - 11000 Asynchronous parity error on memory access
  - 11001 Synchronous parity error on memory access
  - 11100 Synchronous parity error on translation table walk, first level
  - 11110 Synchronous parity error on translation table walk, second level
- All other values are reserved.

**When TTBCR.EAE==1:**

**Bits [31:14]**

Reserved, RES0.

**CM, bit [13]**

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:

- 0 Abort not caused by a cache maintenance operation.
- 1 Abort caused by a cache maintenance operation.

On an asynchronous fault, this bit is UNKNOWN.

**ExT, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

**WnR, bit [11]**

Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:

- 0 Abort caused by a read access.
- 1 Abort caused by a write access.

For faults on CP15 cache maintenance operations, including the VA to PA translation operations, this bit always returns a value of 1.

**Bit [10]**

Reserved, RES0.

### LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

### Bits [8:6]

Reserved, RES0.

### STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

000000	Address size fault in <a href="#">TTBR0</a> or <a href="#">TTBR1</a>
000101	Translation fault, first level
000110	Translation fault, second level
000111	Translation fault, third level
001001	Access flag fault, first level
001010	Access flag fault, second level
001011	Access flag fault, third level
001101	Permission fault, first level
001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
010001	Asynchronous external abort
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011000	Synchronous parity error on memory access
011001	Asynchronous parity error on memory access
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.

- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

### Accessing the DFSR:

To access the DFSR:

MRC p15,0,<Rt>,c5,c0,0 ; Read DFSR into Rt  
MCR p15,0,<Rt>,c5,c0,0 ; Write Rt to DFSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0101	0000	000

### G4.2.41 DTLBIALL, Data TLB Invalidate All entries

The DTLBIALL characteristics are:

#### Purpose

Invalidate all EL1&0 regime stage 1 and 2 data TLB entries for the current VMID.  
 This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

There are no configuration notes.

#### Attributes

DTLBIALL is a 32-bit system operation.

The DTLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

#### Performing the DTLBIALL operation:

To perform the DTLBIALL operation:

MCR p15,0,<Rt>,c8,c6,0 ; DTLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	000

## G4.2.42 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

### Purpose

Invalidate EL1&0 regime stage 1 data TLB entries for the given ASID and the current VMID.  
This register is part of the TLB maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

### Configurations

There are no configuration notes.

### Attributes

DTLBIASID is a 32-bit system operation.

The DTLBIASID input value bit assignments are:

### Bits [31:8]

Reserved, RES0.

### ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

### Performing the DTLBIASID operation:

To perform the DTLBIASID operation:

MCR p15,0,<Rt>,c8,c6,2 ; DTLBIASID operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	010

### G4.2.43 DTLBIMVA, Data TLB Invalidate entry by VA

The DTLBIMVA characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 data TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

DTLBIMVA is a 32-bit system operation.

The DTLBIMVA input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the DTLBIMVA operation:**

To perform the DTLBIMVA operation:

MCR p15,0,<Rt>,c8,c6,1 ; DTLBIMVA operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	001

## G4.2.44 ELR\_hyp, Exception Link Register (Hyp mode)

The ELR\_hyp characteristics are:

### Purpose

When taking an exception to Hyp mode, holds the address to return to.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	RW

### Configurations

ELR\_hyp is architecturally mapped to AArch64 register [ELR\\_EL2](#).

### Attributes

ELR\_hyp is a 32-bit register.

The ELR\_hyp bit assignments are:

### Bits [31:0]

Return address.

### Accessing the ELR\_hyp:

To access the ELR\_hyp:

MRS <Rd>, ELR\_hyp ; Read ELR\_hyp into Rd  
MSR ELR\_hyp, <Rd> ; Write Rd to ELR\_hyp

Register access is encoded as follows:

m	m1	R
1	1110	0

### G4.2.45 FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

**Purpose**

Identifies whether the Fast Context Switch Extension (FCSE) is implemented, and if it is, also identifies the current Process ID for the FCSE.

This register is part of the Legacy feature registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as FCSEIDR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as FCSEIDR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

**Configurations**

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

FCSEIDR is a 32-bit register.

The FCSEIDR bit assignments are:

**Bits [31:0]**

Reserved, RES0.

**Accessing the FCSEIDR:**

To access the FCSEIDR:

```
MRC p15,0,<Rt>,c13,c0,0 ; Read FCSEIDR into Rt
MCR p15,0,<Rt>,c13,c0,0 ; Write Rt to FCSEIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	000

## G4.2.46 FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

### Purpose

Provides a global enable for the Advanced SIMD and Floating-point (VFP) extensions, and indicates how the state of these extensions is recorded.

This register is part of the Floating-point registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RW	RW	Config-RW	Config-RW	RW

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, and [HCPTR](#).{TCP10,TCP11}.

### Configurations

FPEXC is architecturally mapped to AArch64 register [FPEXC32\\_EL2](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

### Attributes

FPEXC is a 32-bit register.

The FPEXC bit assignments are:

### EX, bit [31]

Exception bit. A status bit that specifies how much information must be saved to record the state of the Advanced SIMD and VFP system:

- 0 The only significant state is the contents of the registers D0 - D31, [FPSCR](#), and [FPEXC](#). A context switch can be performed by saving and restoring the values of these registers.
- 1 There is additional state that must be handled by any context switch system.

In ARMv8, this bit must be RES0.

### EN, bit [30]

Enable bit. A global enable for the Advanced SIMD and VFP extensions:

- 0 The Advanced SIMD and VFP extensions are disabled.

1 The Advanced SIMD and VFP extensions are enabled and operate normally.  
This bit is made obsolete by the features in the CPACR when executing in AArch64.  
When executing in EL0 using AArch32 with EL1 using AArch64, the behavior is as if the FPEXC.EN bit is set.  
Resets to 0.

#### **DEX, bit [29]**

Defined synchronous instruction exception bit.  
When a floating-point synchronous exception has occurred, if the exception was caused by an allocated floating-point instruction that is not implemented in hardware then it is IMPLEMENTATION DEFINED whether DEX is set to 0 or 1.  
Otherwise, the meaning of this bit is:

0 A synchronous exception occurred when processing an unallocated floating-point or Advanced SIMD instruction.

1 A synchronous exception occurred on an allocated floating-point instruction that encountered an exceptional condition.

The exception-handling routine must clear DEX to 0.  
In an implementation that does not require synchronous exception handling this bit is RES0.  
Reset value is architecturally UNKNOWN.

#### **FP2V, bit [28]**

FPINST2 instruction valid bit. In ARMv8, this field is always RES0.

#### **VV, bit [27]**

VECITR valid bit. In ARMv8, this field is always RES0.

#### **TFV, bit [26]**

Trapped Fault Valid bit. Indicates whether FPEXC bits[7, 4:0] indicate trapped exceptions, or have an IMPLEMENTATION DEFINED meaning:

0 FPEXC bits[7, 4:0] have an IMPLEMENTATION DEFINED meaning

1 FPEXC bits[7, 4:0] indicate the presence of trapped exceptions that have occurred at the time of the exception. All trapped exceptions that occurred at the time of the exception have their bits set.

This bit has a fixed value and ignores writes.

#### **Bits [25:21]**

Reserved, RES0.

#### **VECITR, bits [10:8]**

Vector iteration count. In ARMv8, this field is always RES1.

#### **IDE, bit [7]**

Input Denormal trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.  
If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.  
If FPEXC.TFV is 1, this bit is the Input Denormal trapped exception bit, and indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0 Input denormal exception has not occurred.

1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.  
In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

#### **IXF, bit [4]**

Inexact trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Inexact trapped exception bit, and indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

In this case, the meaning of this bit is:

0 Inexact exception has not occurred.

1 Inexact exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

#### **UFF, bit [3]**

Underflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Underflow trapped exception bit, and indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0 Underflow exception has not occurred.

1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

#### **OFF, bit [2]**

Overflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Overflow trapped exception bit, and indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0 Overflow exception has not occurred.

1 Overflow exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

#### **DZF, bit [1]**

Divide-by-zero trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Divide-by-zero trapped exception bit, and indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:

0 Divide-by-zero exception has not occurred.

1 Divide-by-zero exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

### IOF, bit [0]

Invalid Operation trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Invalid Operation trapped exception bit, and indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0 Invalid Operation exception has not occurred.

1 Invalid Operation exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

### Accessing the FPEXC:

To access the FPEXC:

VMRS <Rt>, FPEXC ; Read FPEXC into Rt  
VMSR FPEXC, <Rt> ; Write Rt to FPEXC

Register access is encoded as follows:

---

**spec\_reg**

---

1000

---

## G4.2.47 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

### Purpose

Provides floating-point system status information and control.

This register is part of:

- the Special purpose registers functional group
- the Floating-point registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	Config-RW	RW	Config-RW	Config-RW	RW

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, [HCPTR](#).{TCP10,TCP11}, and [FPEXC](#).EN.

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 [FPCR](#) and [FPSR](#).

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

### Attributes

FPSCR is a 32-bit register.

The FPSCR bit assignments are:

### N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.

**Z, bit [30]**

Zero condition flag. This is updated by floating-point comparison operations.

**C, bit [29]**

Carry condition flag. This is updated by floating-point comparison operations.

**V, bit [28]**

Overflow condition flag. This is updated by floating-point comparison operations.

**QC, bit [27]**

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

**AHP, bit [26]**

Alternative half-precision control bit:

- 0 IEEE half-precision format selected.
- 1 Alternative half-precision format selected.

**DN, bit [25]**

Default NaN mode control bit:

- 0 NaN operands propagate through to the output of a floating-point operation.
- 1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

**FZ, bit [24]**

Flush-to-zero mode control bit:

- 0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- 1 Flush-to-zero mode enabled.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

**RMode, bits [23:22]**

Rounding Mode control field. The encoding of this field is:

- 00 Round to Nearest (RN) mode
- 01 Round towards Plus Infinity (RP) mode
- 10 Round towards Minus Infinity (RM) mode
- 11 Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

**Stride, bits [21:20]**

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

**Bit [19]**

Reserved, RES0.

### Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

### IDE, bit [15]

Input Denormal exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

### Bits [14:13]

Reserved, RES0.

### IXE, bit [12]

Inexact exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

### UFE, bit [11]

Underflow exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

### OFE, bit [10]

Overflow exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.

- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

#### DZE, bit [9]

Division by Zero exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

#### IOE, bit [8]

Invalid Operation exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

#### IDC, bit [7]

Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

#### Bits [6:5]

Reserved, RES0.

#### IXC, bit [4]

Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

#### UFC, bit [3]

Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.

Advanced SIMD instructions set this bit if the Underflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

**OFC, bit [2]**

Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

**DZC, bit [1]**

Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Division by Zero exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

**IOC, bit [0]**

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

**Accessing the FPSCR:**

To access the FPSCR:

VMRS <Rt>, FPSCR ; Read FPSCR into Rt  
VMSR FPSCR, <Rt> ; Write Rt to FPSCR

Register access is encoded as follows:

---

**spec\_reg**

---

0001

---

## G4.2.48 FPSID, Floating-Point System ID register

The FPSID characteristics are:

### Purpose

Provides top-level information about the floating-point implementation.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, and [HCPTR](#).{TCP10,TCP11}.

This register largely duplicates information held in the [MIDR](#). ARM deprecates use of it.

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

FPSID can be implemented in a system that provides only software emulation of the ARM floating-point instructions, and must be implemented if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

### Attributes

FPSID is a 32-bit register.

The FPSID bit assignments are:

### Implementer, bits [31:24]

Implementer codes are the same as those used for the [MIDR](#).

For an implementation by ARM this field is 0x41, the ASCII code for A.

### SW, bit [23]

Software bit. This bit indicates whether a system provides only software emulation of the floating-point instructions that are provided by the Floating-point extension:

- 0 The system includes hardware support for the floating-point instructions provided by the Floating-point extension.
- 1 The system provides only software emulation of the floating-point instructions provided by the Floating-point extension.

**Subarchitecture, bits [22:16]**

Subarchitecture version number. For an implementation by ARM, permitted values are:

- 0000000 VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture. Not permitted in an ARMv7 implementation.
- 0000001 VFPv2 architecture with Common VFP subarchitecture v1. Not permitted in an ARMv7 implementation.
- 0000010 VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.
- 0000011 VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers. This value can be used only by an implementation that does not support the trap enable bits in the [FPSCR](#).
- 0000100 VFPv3 architecture, or later, with Common VFP subarchitecture v3. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.

For a subarchitecture designed by ARM the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not ARM, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

**PartNum, bits [15:8]**

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

**Variant, bits [7:4]**

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

**Accessing the FPSID:**

To access the FPSID:

VMRS <Rt>, FPSID ; Read FPSID into Rt

Register access is encoded as follows:

---

**spec\_reg**

---

0000

---

## G4.2.49 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

### Purpose

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED or IMPLEMENTATION SPECIFIC aspects of Non-secure EL1 or EL0 operation.

This register is part of the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HACR is architecturally mapped to AArch64 register [HACR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HACR is a 32-bit register.

The HACR bit assignments are:

### Accessing the HACR:

To access the HACR:

MRC p15,4,<Rt>,c1,c1,7 ; Read HACR into Rt

MCR p15,4,<Rt>,c1,c1,7 ; Write Rt to HACR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	111

## G4.2.50 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

### Purpose

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HACTLR is architecturally mapped to AArch64 register [ACTLR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HACTLR is a 32-bit register.

The HACTLR bit assignments are:

### Accessing the HACTLR:

To access the HACTLR:

MRC p15,4,<Rt>,c1,c0,1 ; Read HACTLR into Rt  
MCR p15,4,<Rt>,c1,c0,1 ; Write Rt to HACTLR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0000	001

### G4.2.51 HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

**Configurations**

HADFSR is architecturally mapped to AArch64 register [AFSR0\\_EL2](#).

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HADFSR is a 32-bit register.

The HADFSR bit assignments are:

**Accessing the HADFSR:**

To access the HADFSR:

```
MRC p15,4,<Rt>,c5,c1,0 ; Read HADFSR into Rt
MCR p15,4,<Rt>,c5,c1,0 ; Write Rt to HADFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0101	0001	000

## G4.2.52 HAIFSR, Hyp Auxiliary Instruction Fault Status Register

The HAIFSR characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Prefetch Abort exceptions taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HAIFSR is architecturally mapped to AArch64 register [AFSR1\\_EL2](#).

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HAIFSR is a 32-bit register.

The HAIFSR bit assignments are:

### Accessing the HAIFSR:

To access the HAIFSR:

MRC p15,4,<Rt>,c5,c1,1 ; Read HAIFSR into Rt  
MCR p15,4,<Rt>,c5,c1,1 ; Write Rt to HAIFSR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0101	0001	001

### G4.2.53 HMAI0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HMAI0 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAI0. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAI0.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

**Configurations**

HMAI0 is architecturally mapped to AArch64 register AMAIR\_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HMAI0 is a 32-bit register.

The HMAI0 bit assignments are:

**Accessing the HMAI0:**

To access the HMAI0:

```
MRC p15,4,<Rt>,c10,c3,0 ; Read HMAI0 into Rt
MCR p15,4,<Rt>,c10,c3,0 ; Write Rt to HMAI0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0011	000

## G4.2.54 HMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

### Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by [HMAIR1](#). These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in [HMAIR1](#).

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

### Configurations

HMAIR1 is architecturally mapped to AArch64 register [AMAIR\\_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HMAIR1 is a 32-bit register.

The HMAIR1 bit assignments are:

### Accessing the HMAIR1:

To access the HMAIR1:

MRC p15,4,<Rt>,c10,c3,1 ; Read HMAIR1 into Rt  
MCR p15,4,<Rt>,c10,c3,1 ; Write Rt to HMAIR1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0011	001

### G4.2.55 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure access, at EL1 or lower, to Trace, Floating Point, and Advanced SIMD functionality. Also controls access from Hyp mode to this functionality.

This register is part of the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If a bit in the [NSACR](#) prohibits a Non-secure access, then the corresponding bit in the HCPTR behaves as RAO/WI for Non-secure accesses. See the bit descriptions for more information.

**Configurations**

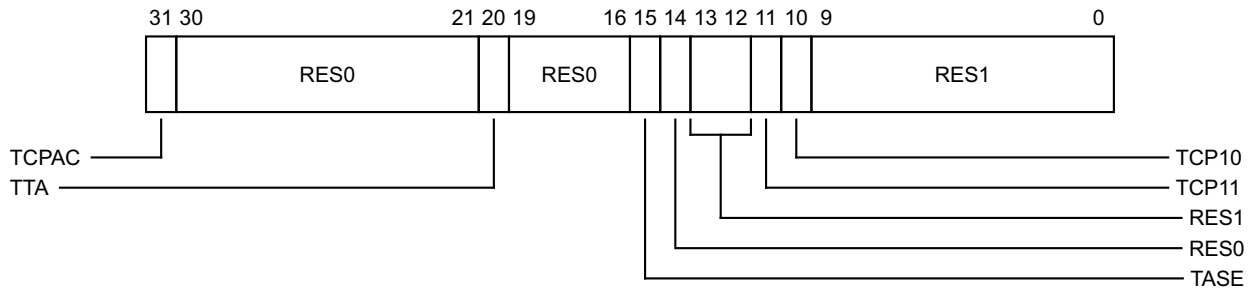

HCPTR is architecturally mapped to AArch64 register [CPTR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HCPTR is a 32-bit register.

The HCPTR bit assignments are:

**TCPAC, bit [31]**

Trap [CPACR](#) accesses. The possible values of this bit are:

- 0 Has no effect on [CPACR](#) accesses.
- 1 Trap valid Non-secure EL1 [CPACR](#) accesses to Hyp mode.

Resets to 0.

**Bits [30:21]**

Reserved, RES0.

**TTA, bit [20]**

Trap Trace Access. The possible values of this bit are:

- 0 Has no effect on accesses to CP14 Trace registers.
- 1 Trap valid Non-secure EL0 and EL1 accesses to CP14 Trace registers to Hyp mode. Valid Hyp mode accesses to CP14 Trace registers generate an Undefined Instruction exception, taken in Hyp mode.

In an implementation that does not include Trace functionality, or does not include a CP14 interface to the Trace registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RAO/WI.
- Is RAZ/WI.
- Can be written from Hyp mode, and from Secure Monitor mode when `SCR.NS` is set to 1.

Resets to 0.

#### Bits [19:16]

Reserved, RES0.

#### TASE, bit [15]

Trap Advanced SIMD Extension use. The possible values of this bit are:

- |   |  |
|---|--|
| 0 | If the <code>NSACR</code> settings permit Non-secure use of the Advanced SIMD functionality then Hyp mode can access that functionality, regardless of any settings in the CPACR. This bit value has no effect on the possible use of the Advanced SIMD functionality from Non-secure EL1 and EL0 modes. |
| 1 | Trap valid Non-secure accesses to Advanced SIMD functionality to Hyp mode. Valid Hyp mode accesses to Advanced SIMD functionality generate an Undefined Instruction exception, taken in Hyp mode.  |

Resets to 0.

#### Bit [14]

Reserved, RES0.

#### Bits [13:12]

Reserved, RES1.

#### TCP<n>, bit [n], for n = 10 to 11

Trap coprocessor n (CP<n>). The possible values of each of these bits are:

- |   |   |
|---|---|
| 0 | If <code>NSACR.cp&lt;n&gt;</code> is set to 1, then Hyp mode can access CP<n>, regardless of the value of <code>CPACR.cp&lt;n&gt;</code> . This bit value has no effect on possible use of CP<n> from Non-secure EL1 and EL0 modes. |
| 1 | Trap valid Non-secure accesses to CP<n> to Hyp mode.  |

When TCP<n> is set to 1, any otherwise-valid access to CP<n> from:

- A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
- Hyp mode generates an Undefined Instruction exception, taken in Hyp mode.

In an implementation that includes the Floating Point extension, the extension is controlled by coprocessors 10 and 11. If bits 11 and 10 are set to different values, the behavior is the same as if both bits were set to the value of bit 10, in all respects other than the value read back by explicitly reading bit 11.

Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES1.

Resets to 0.

#### Bits [9:0]

Reserved, RES1.

### Accessing the HCPTR:

To access the HCPTR:

```
MRC p15,4,<Rt>,c1,c1,2 ; Read HCPTR into Rt
MCR p15,4,<Rt>,c1,c1,2 ; Write Rt to HCPTR
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	0001	0001	010

## G4.2.56 HCR, Hyp Configuration Register

The HCR characteristics are:

### Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

This register is part of the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HCR is architecturally mapped to AArch64 register [HCR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HCR is a 32-bit register.

The HCR bit assignments are:

### Bit [31]

Reserved, RES0.

### TRVM, bit [30]

Trap Read of Virtual Memory controls. When this bit is set to 1, this causes Reads to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR/MAIR0](#), [NMRR/MAIR1](#), [AMAIR0](#), [AMAIR1](#), [CONTEXTIDR](#).

Resets to 0.

#### HCD, bit [29]

Hypervisor Call Disable, if EL3 is not implemented:

- 0 HVC instruction is enabled at EL1 or EL2.
- 1 HVC instruction is UNDEFINED at all exception levels.

If EL3 is implemented, this bit is RES0.

Resets to 0.

#### Bit [28]

Reserved, RES0.

#### TGE, bit [27]

Trap General Exceptions. If this bit is set to 1, and [SCR.NS](#) is set to 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The [SCTLR.M](#) bit is treated as being 0 regardless of its actual state other than for the purpose of reading the bit.
- The [HCR.FMO](#), [IMO](#), and [AMO](#) bits are treated as being 1 regardless of their actual state other than for the purpose of reading the bits.
- All virtual interrupts are disabled.
- Any implementation defined mechanisms for signalling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

Additionally, if [HCR.TGE](#) == 1, the [HDCR](#).{[TDRA](#),[TDOSA](#),[TDA](#)} bits are ignored and the processor behaves as if they are set to 1, other than for the value read back from [HDCR](#).

Resets to 0.

#### TVM, bit [26]

Trap Virtual Memory controls. When this bit is set to 1, this causes Writes to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR/MAIR0](#), [NMRR/MAIR1](#), [AMAIRO](#), [AMAIR1](#), [CONTEXTIDR](#).

Resets to 0.

#### TTLB, bit [25]

Trap TLB maintenance instructions. When this bit is set to 1, this causes TLB maintenance instructions executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

[TLBIALLIS](#), [TLBIMVAIS](#), [TLBIASIDIS](#), [TLBIMVAAIS](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [TLBIMVALIS](#), [TLBIMVAALIS](#), [TLBIMVAL](#), [TLBIMVAAL](#).

Resets to 0.

#### TPU, bit [24]

Trap Cache maintenance instructions to Point of Unification. When this bit is set to 1, this causes Cache maintenance instructions to the point of unification executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

[ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), [DCCMVAU](#).

Resets to 0.

**TPC, bit [23]**

Trap Data/Unified Cache maintenance operations to Point of Coherency. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by address to the point of coherency executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

[DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

Resets to 0.

**TSW, bit [22]**

Trap Data/Unified Cache maintenance operations by Set/Way. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by set/way executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

[DCISW](#), [DCCSW](#), [DCCISW](#).

Resets to 0.

**TAC, bit [21]**

Trap [ACTLR](#) accesses. When this bit is set to 1, any valid Non-secure access to the [ACTLR](#) is trapped to Hyp mode.

Resets to 0.

**TIDCP, bit [20]**

Trap Implementation Dependent functionality. When this bit is set to 1, this causes accesses to the following instruction set space executed from EL1 to be trapped to EL2.

AArch32: MCR and MRC instructions as follows:

- All CP15, CRn==9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All CP15, CRn==10, Opcode1 =={0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All CP15, CRn==11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

It is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2 when the HCR.TIDCP bit is set. If it is not trapped to EL2, it results in an Undefined exception taken to EL1.

Resets to 0.

**TSC, bit [19]**

Trap SMC instruction. When this bit is set to 1, any attempt from a Non-secure EL1 mode to execute an SMC instruction, that passes its condition check if it is conditional, is trapped to Hyp mode.

Resets to 0.

**TID3, bit [18]**

Trap ID Group 3. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

[ID\\_PFR0](#), [ID\\_PFR1](#), [ID\\_DFR0](#), [ID\\_AFR0](#), [ID\\_MMFR0](#), [ID\\_MMFR1](#), [ID\\_MMFR2](#), [ID\\_MMFR3](#), [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), [ID\\_ISAR5](#), [MVFR0](#), [MVFR1](#), [MVFR2](#). Also MRC to any of the following encodings:

- CP15, CRn == 0, Opc1 == 0, CRm == {3-7}, Opc2 == {0,1}.
- CP15, CRn == 0, Opc1 == 0, CRm == 3, Opc2 == 2.
- CP15, CRn == 0, Opc1 == 0, CRm == 5, Opc2 == {4,5}.

Resets to 0.

**TID2, bit [17]**

Trap ID Group 2. When this bit is set to 1, this causes reads (or writes to [CSSELR/CSSELR\\_EL1](#)) to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

[CTR](#), [CCSIDR](#), [CLIDR](#), [CSSELR](#).

Resets to 0.

**TID1, bit [16]**

Trap ID Group 1. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

[TCMTR](#), [TLBTR](#), [AIDR](#), [REVIDR](#).

Resets to 0.

**TID0, bit [15]**

Trap ID Group 0. When this bit is set to 1, this causes reads to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

[FPSID](#), [JIDR](#).

Resets to 0.

**TWE, bit [14]**

Trap WFE. When this bit is set to 1, this causes execution of the WFE instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if the event register is not set).

Conditional WFE instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

**TWI, bit [13]**

Trap WFI. When this bit is set to 1, this causes execution of the WFI instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if there is not a pending WFI wakeup event).

Conditional WFI instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

**DC, bit [12]**

Default cacheable. When this bit is set to 1, and the Non-secure EL1 and EL0 stage 1 MMU is disabled, the memory type and attributes determined by the stage 1 translation is Normal, Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate.

When this bit is 0 and the stage 1 MMU is disabled, the default memory attribute for Data accesses is Device-nGnRnE.

This bit is permitted to be cached in a TLB.

Resets to 0.

**BSU, bits [11:10]**

Barrier Shareability upgrade. The value in this field determines the minimum shareability domain that is applied to any barrier executed from EL1 or EL0:

00	No effect
01	Inner Shareable
10	Outer Shareable
11	Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

Resets to 0.

**FB, bit [9]**

Force broadcast. When this bit is set to 1, this causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

[BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#),  
[ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

Resets to 0.

#### **VA, bit [8]**

Virtual Asynchronous Abort exception. When the AMO bit is set to 1, setting this bit to 1 generates a virtual Asynchronous Abort exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

#### **VI, bit [7]**

Virtual IRQ exception. When the IMO bit is set to 1, setting this bit to 1 generates a virtual IRQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

#### **VF, bit [6]**

Virtual FIQ exception. When the FMO bit is set to 1, setting this bit to 1 generates a virtual FIQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

#### **AMO, bit [5]**

Asynchronous Abort Mask Override. When this bit is set to 1, it overrides the effect of CPSR.A, and enables virtual exception signalling by the VA bit.

Resets to 0.

#### **IMO, bit [4]**

IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signalling by the VI bit.

Resets to 0.

#### **FMO, bit [3]**

FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signalling by the VF bit.

Resets to 0.

#### **PTW, bit [2]**

Protected Table Walk. When this bit is set to 1, if the stage 2 translation of a translation table access made as part of a stage 1 translation table walk at EL0 or EL1 maps that translation table access to Strongly-ordered or Device memory, the access is faulted as a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

Resets to 0.

#### **SWIO, bit [1]**

Set/Way Invalidation Override. When this bit is set to 1, this causes EL1 execution of the data cache invalidate by set/way instruction to be treated as data cache clean and invalidate by set/way. That is, [DCISW](#) is executed as [DCCISW](#).

As a result of changes to the behavior of [DCISW](#), this bit is redundant in v8-A. It is permissible that an implementation makes this bit RES1.

Resets to 0.

### VM, bit [0]

Virtualization MMU enable for EL1 and EL0 stage 2 address translation. Possible values of this bit are:

- 0 EL1 and EL0 stage 2 address translation disabled.
- 1 EL1 and EL0 stage 2 address translation enabled.

This bit is permitted to be cached in a TLB.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

Resets to 0.

### Accessing the HCR:

To access the HCR:

MRC p15,4,<Rt>,c1,c1,0 ; Read HCR into Rt  
MCR p15,4,<Rt>,c1,c1,0 ; Write Rt to HCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	000

## G4.2.57 HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

### Purpose

Provides additional configuration controls for virtualization.

This register is part of the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HCR2 is architecturally mapped to AArch64 register [HCR\\_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HCR2 is a 32-bit register.

The HCR2 bit assignments are:

### Bits [31:2]

Reserved, RES0.

### ID, bit [1]

Stage 2 Instruction cache disable. When HCR.VM==1, this forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.

0 No effect on the stage 2 of the EL1&0 translation regime for instruction accesses.

1 Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

### CD, bit [0]

Stage 2 Data cache disable. When HCR.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.

0 No effect on the stage 2 of the EL1&0 translation regime for data accesses and translation table walks.

1 Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

### Accessing the HCR2:

To access the HCR2:

MRC p15,4,<Rt>,c1,c1,4 ; Read HCR2 into Rt  
MCR p15,4,<Rt>,c1,c1,4 ; Write Rt to HCR2

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	0001	0001	100

## G4.2.58 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

### Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HDFAR UNKNOWN.

### Configurations

HDFAR is architecturally mapped to AArch64 register [FAR\\_EL2](#)[31:0].

HDFAR is architecturally mapped to AArch32 register [DFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HDFAR is a 32-bit register.

The HDFAR bit assignments are:

### Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

### Accessing the HDFAR:

To access the HDFAR:

MRC p15,4,<Rt>,c6,c0,0 ; Read HDFAR into Rt

MCR p15,4,<Rt>,c6,c0,0 ; Write Rt to HDFAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	000

## G4.2.59 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

### Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HIFAR UNKNOWN.

### Configurations

HIFAR is architecturally mapped to AArch64 register [FAR\\_EL2](#)[63:32].

HIFAR is architecturally mapped to AArch32 register [IFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HIFAR is a 32-bit register.

The HIFAR bit assignments are:

### Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

### Accessing the HIFAR:

To access the HIFAR:

MRC p15,4,<Rt>,c6,c0,2 ; Read HIFAR into Rt

MCR p15,4,<Rt>,c6,c0,2 ; Write Rt to HIFAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	010

## G4.2.60 HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

### Purpose

Along with [HMAIR1](#), provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

AttrIdx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIdx[2] to 0 selects HMAIR0.

### Configurations

HMAIR0 is architecturally mapped to AArch64 register [MAIR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HMAIR0 is a 32-bit register.

The HMAIR0 bit assignments are:

### When TTBCR.EAE==1:

### Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.  
The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.  
ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.  
The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

### Accessing the HMAIRO:

To access the HMAIRO:

MRC p15,4,<Rt>,c10,c2,0 ; Read HMAIRO into Rt  
MCR p15,4,<Rt>,c10,c2,0 ; Write Rt to HMAIRO

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1010	0010	000

## G4.2.61 HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

### Purpose

Along with [HMAIR0](#), provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

AttrIdx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIdx[2] to 1 selects HMAIR1.

### Configurations

HMAIR1 is architecturally mapped to AArch64 register [MAIR\\_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HMAIR1 is a 32-bit register.

The HMAIR1 bit assignments are:

### When TTBCR.EAE==1:

### Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.  
The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

### Accessing the HMAIR1:

To access the HMAIR1:

MRC p15,4,<Rt>,c10,c2,1 ; Read HMAIR1 into Rt  
MCR p15,4,<Rt>,c10,c2,1 ; Write Rt to HMAIR1

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1010	0010	001

## G4.2.62 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

### Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

This register is part of:

- the Exception and fault handling registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

### Configurations

HPFAR is architecturally mapped to AArch64 register [HPFAR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HPFAR is a 32-bit register.

The HPFAR bit assignments are:

### FIPA[39:12], bits [31:4]

Bits [39:12] of the faulting intermediate physical address.

### Bits [3:0]

Reserved, RES0.

### Accessing the HPFAR:

To access the HPFAR:

MRC p15,4,<Rt>,c6,c0,4 ; Read HPFAR into Rt

MCR p15,4,<Rt>,c6,c0,4 ; Write Rt to HPFAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	100

### G4.2.63 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

**Purpose**

If EL2 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of:

- the Virtualization registers functional group
- the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0	EL1	EL2
-	-	RW

**Configurations**

HRMR is architecturally mapped to AArch64 register [RMR\\_EL2](#).

Only implemented if the highest exception level implemented is EL2 and supports AArch32 and AArch64.

If EL2 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

**Attributes**

HRMR is a 32-bit register when EL2 implemented, EL3 not implemented.

The HRMR bit assignments are:

**When EL2 implemented, EL3 not implemented:**

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

**AA64, bit [0]**

Determines which execution state the processor boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

### Accessing the HRMR:

To access the HRMR when EL2 implemented, EL3 not implemented:

MRC p15,4,<Rt>,c12,c0,2 ; Read HRMR into Rt  
MCR p15,4,<Rt>,c12,c0,2 ; Write Rt to HRMR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1100	0000	010

## G4.2.64 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

### Purpose

Provides top level control of the system operation in Hyp mode. This register provides Hyp mode control of features controlled by the Banked SCTL bits, and shows the values of the non-Banked SCTL bits.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

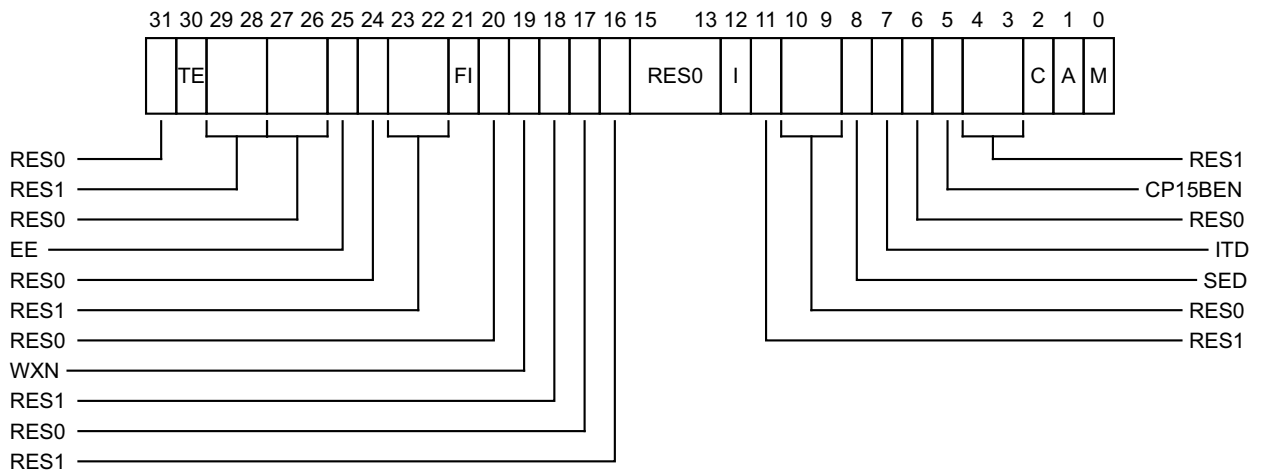

HSCTLR is architecturally mapped to AArch64 register [SCTLR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HSCTLR is a 32-bit register.

The HSCTLR bit assignments are:

### Bit [31]

Reserved, RES0.

### TE, bit [30]

Thumb Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:

- 0 Exceptions, including reset, taken in A32 state.
- 1 Exceptions, including reset, taken in T32 state.

Reset value is architecturally UNKNOWN.

**Bits [29:28]**

Reserved, RES1.

**Bits [27:26]**

Reserved, RES0.

**EE, bit [25]**

Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

**Bit [24]**

Reserved, RES0.

**Bits [23:22]**

Reserved, RES1.

**FI, bit [21]**

Fast interrupts configuration enable. This bit can be used to reduce interrupt latency in an implementation by disabling IMPLEMENTATION DEFINED performance features. The possible values of this bit are:

0 All performance features enabled.

1 Low interrupt latency configuration. Some performance features disabled.

Reset value is architecturally UNKNOWN.

**Bit [20]**

Reserved, RES0.

**WXN, bit [19]**

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

Reset value is architecturally UNKNOWN.

**Bit [18]**

Reserved, RES1.

**Bit [17]**

Reserved, RES0.

**Bit [16]**

Reserved, RES1.

**Bits [15:13]**

Reserved, RES0.

### I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL2:

- |   |   |
|---|---|
| 0 | Instruction caches disabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable. |
| 1 | Instruction caches enabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.  |

When this bit is 0, all EL2 Normal memory instruction accesses are Non-cacheable.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

### Bit [11]

Reserved, RES1.

### Bits [10:9]

Reserved, RES0.

### SED, bit [8]

SETEND Disable. The possible values of this bit are:

- |   |  |
|---|--|
| 0 | The SETEND instruction is available.   |
| 1 | The SETEND instruction is UNALLOCATED. |

If an implementation does not support mixed endian operation at EL2, this bit is RES1.

Reset value is architecturally UNKNOWN.

### ITD, bit [7]

IT Disable. The possible values of this bit are:

- |   |   |
|---|---|
| 0 | The IT instruction functionality is available.  |
| 1 | It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either: <ul style="list-style-type: none"><li>• A 16-bit instruction, which can only be followed by another 16-bit instruction.</li><li>• The first half of a 32-bit instruction.</li></ul> |

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with hw1[3:0]≠1000 are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):

11xxxxxxxxxxxx

All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

1x11xxxxxxxxxxxx

Miscellaneous 16-bit instructions

1x100xxxxxxxxxxxx

ADD Rd, PC, #imm

01001xxxxxxxxxxxx

LDR Rd, [PC, #imm]

0100x1xxx1111xxx

ADD(4),CMP(3), MOV, BX pc, BLX pc

010001xx1xxxx111

ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)

Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

Reset value is architecturally UNKNOWN.

**Bit [6]**

Reserved, RES0.

**CP15BEN, bit [5]**

CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL2:

0 CP15 barrier operations disabled at EL2. Their encodings are UNDEFINED.

1 CP15 barrier operations enabled at EL2.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

Reset value is architecturally UNKNOWN.

**Bits [4:3]**

Reserved, RES1.

**C, bit [2]**

Cache enable. This is an enable bit for data and unified caches at EL2:

0 Data and unified caches disabled at EL2.

1 Data and unified caches enabled at EL2.

When this bit is 0, all EL2 Normal memory data accesses and all accesses to the EL2 translation tables are Non-cacheable.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

**M, bit [0]**

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0 EL2 stage 1 address translation disabled.

1 EL2 stage 1 address translation enabled.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

### Accessing the HSCTLR:

To access the HSCTLR:

MRC p15,4,<Rt>,c1,c0,0 ; Read HSCTLR into Rt  
MCR p15,4,<Rt>,c1,c0,0 ; Write Rt to HSCTLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	0001	0000	000

## G4.2.65 HSR, Hyp Syndrome Register

The HSR characteristics are:

### Purpose

Holds syndrome information for an exception taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

### Configurations

HSR is architecturally mapped to AArch64 register [ESR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HSR is a 32-bit register.

The HSR bit assignments are:

### EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

Possible values of this field are:

- |        |   |
|--------|---|
| 000000 | Unknown reason.   |
| 000001 | Trapped WFI or WFE instruction.<br>Conditional WFE and WFI instructions that fail their condition code check do not cause an exception. |
| 000011 | Trapped MCR or MRC access to CP15.  |
| 000100 | Trapped MCRR or MRRC access to CP15.  |
| 000101 | Trapped MCR or MRC access to CP14.  |
| 000110 | Trapped LDC or STC access to CP14.  |
| 000111 | HCPTR-trapped access to CP10 or CP11.   |
| 001000 | Trapped MRC or VMRS access to CP10, for ID group traps.   |
| 001100 | Trapped MRRC or MCRR access to CP14.  |

001111	Illegal exception return to AArch32 state.
010001	SVC taken to Hyp mode.
010010	HVC executed.
010011	Trapped SMC instruction.
100000	Prefetch Abort routed to Hyp mode.
100001	Prefetch Abort taken from Hyp mode.
100010	PC Alignment Exception.
100100	Data Abort routed to Hyp mode.
100101	Data Abort taken from Hyp mode.

Other values are reserved.

#### IL, bit [25]

Instruction Length. Indicates the size of the instruction that has been trapped to this exception level. Possible values of this bit are:

0	16-bit instruction trapped.				
1	32-bit instruction trapped. This value also applies to the following exceptions: <ul style="list-style-type: none"><li>• An SError interrupt.</li><li>• An Instruction Abort exception.</li><li>• A Misaligned PC exception.</li><li>• A Misaligned Stack Pointer exception.</li><li>• A Data Abort for which the value of the ISV bit is 0.</li><li>• An Illegal Execution State exception.</li><li>• Any debug exception except for Software Breakpoint Instruction exceptions. For Software Breakpoint Instruction exceptions, this bit has its standard meaning:<table><tr><td>0</td><td>16-bit T32 BKPT instruction.</td></tr><tr><td>1</td><td>32-bit A32 BKPT instruction.</td></tr></table></li><li>• An exception reported using EC value 0b000000.</li></ul>	0	16-bit T32 BKPT instruction.	1	32-bit A32 BKPT instruction.
0	16-bit T32 BKPT instruction.				
1	32-bit A32 BKPT instruction.				

#### ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number, even if the reported exception was taken from AArch32 state. If the register number is AArch32 register R15, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

**Exceptions with an unknown reason:**

**Bits [24:0]**

Reserved, RES0.

**Exception from a WFI or WFE instruction:**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

**Bits [19:1]**

Reserved, RES0.

**TI, bit [0]**

Trapped instruction. Possible values of this bit are:

- 0 WFI trapped.
- 1 WFE trapped.

**Exception from an MCR or MRC access:**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

**Opc2, bits [19:17]**

The Opc2 value from the issued instruction.

**Opc1, bits [16:14]**

The Opc1 value from the issued instruction.

**CRn, bits [13:10]**

The CRn value from the issued instruction, the coprocessor primary register value.

**Bit [9]**

Reserved, RES0.

**Rt, bits [8:5]**

The Rt value from the issued instruction, the general purpose register used for the transfer.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to coprocessor. MCR instruction.
- 1 Read from coprocessor. MRC or VMRS instruction.

**Exception from an MCRR or MRRC access:**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.

**Bits [15:14]**

Reserved, RES0.

**Rt2, bits [13:10]**

The Rt2 value from the issued instruction, the second general purpose register used for the transfer.

**Bit [9]**

Reserved, RES0.

**Rt, bits [8:5]**

The Rt value from the issued instruction, the general purpose register used for the transfer.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to coprocessor. MCRR instruction.
- 1 Read from coprocessor. MRRC instruction.

**Exception from an LDC or STC access to CP14:**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

**imm8, bits [19:12]**

The immediate value from the issued instruction.

**Bits [11:9]**

Reserved, RES0.

**Rn, bits [8:5]**

The Rn value from the issued instruction. Valid only when the Direction field is 0, indicating a trapped STC instruction.

When the Direction field is 1, indicating a trapped LDC instruction, this field is RES0.

**Offset, bit [4]**

Indicates whether the offset is added or subtracted:

- 0 Subtract offset.
- 1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

**AM, bits [3:1]**

Addressing mode. The permitted values of this field are:

- 000 Immediate unindexed.
- 001 Immediate post-indexed.
- 010 Immediate offset.
- 011 Immediate pre-indexed.
- 100 Literal unindexed.  
A32 instruction set only.  
For a trapped LDC or STC T32 instruction, this encoding is reserved.
- 110 Literal offset.  
For the STC instruction, valid only in the A32 instruction set.  
For a trapped STC T32 instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to coprocessor. STC instruction.
- 1 Read from coprocessor. LDC instruction.

**Exception from an access to SIMD or floating-point registers:**

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

**Bits [19:6]**

Reserved, RES0.

**TA, bit [5]**

Indicates trapped use of the Advanced SIMD extension. The possible values of this bit are:

- 0 Exception was not caused by trapped use of the Advanced SIMD extension.
- 1 Exception was caused by trapped use of the Advanced SIMD extension.

Any use of an Advanced SIMD instruction that is trapped to Hyp mode because of a trap configured in the **HCPTR** sets this bit to 1.

**Bit [4]**

Reserved, RES0.

**coproc, bits [3:0]**

The number of the coprocessor accessed by the trapped operation, 0-13.

**Exception from HVC or SVC instruction execution:**

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

- If the instruction is unconditional, then:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

**Exception from SMC instruction execution in AArch32 state:**

**Bits [24:0]**

Reserved, RES0.

**Exception from an Instruction abort:**

**Bits [24:10]**

Reserved, RES0.

**EA, bit [9]**

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

**Bit [8]**

Reserved, RES0.

**S1PTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

0 Fault not on a stage 2 translation for a stage 1 translation table walk.

1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

**Bit [6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code. Possible values of this field are:

000000	Address size fault, zeroth level of translation or translation table base register
000001	Address size fault, first level
000010	Address size fault, second level
000011	Address size fault, third level
000100	Translation fault, zeroth level
000101	Translation fault, first level
000110	Translation fault, second level
000111	Translation fault, third level
001001	Access flag fault, first level
001010	Access flag fault, second level
001011	Access flag fault, third level
001101	Permission fault, first level
001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
011000	Synchronous parity error on memory access

010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

**Exception from an Instruction set state, PC alignment, or SP alignment fault:**

**Bits [24:0]**

Reserved, RES0.

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

- 0 No valid instruction syndrome. ISS[23:16] are RES0.
- 1 ISS[24:16] hold a valid instruction syndrome.

This bit is 0 for all faults except those generated by a stage 2 translation. For Data Abort exceptions generated by a stage 2 translation, this bit is 1 and a valid instruction syndrome is returned, only if all of the following are true:

- The instruction that generated the Data Abort exception:
  - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using the PC as its source or destination register.

For ISS reporting, a stage 2 abort on a stage 1 translation table lookup is treated as a stage 1 Translation fault, and does not return a valid instruction syndrome.

It is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous external abort on stage 2 translation table walks.

In the A32 instruction set, LDR\*T and STR\*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

**SAS, bits [23:22]**

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

- 00 Byte
- 01 Halfword
- 10 Word
- 11 Doubleword

**SSE, bit [21]**

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

- 0 Sign-extension not required.
- 1 Data item must be sign-extended.

For all other operations this bit is 0.

**Bit [20]**

Reserved, RES0.

**SRT, bits [19:16]**

Syndrome Register transfer. The register number of the Rt operand of the faulting instruction.

**Bit [15]**

Reserved, RES0.

**AR, bit [14]**

Acquire/Release. Possible values of this bit are:

- 0 Instruction did not have acquire/release semantics.
- 1 Instruction did have acquire/release semantics.

**Bits [13:10]**

Reserved, RES0.

**EA, bit [9]**

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

**CM, bit [8]**

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation operation. For synchronous faults, the possible values of this bit are:

- 0 Fault not generated by a cache maintenance or address translation operation.
- 1 Fault generated by a cache maintenance or address translation operation.

For asynchronous faults, this bit is 0.

**S1PTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

**WnR, bit [6]**

Write not Read. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:

- 0 Abort caused by a read operation.
- 1 Abort caused by a write operation.

For faults on cache maintenance and address translation operations, this bit always returns a value of 1.

**DFSC, bits [5:0]**

Data Fault Status Code. Possible values of this field are:

- 000000 Address size fault, zeroth level of translation or translation table base register
- 000001 Address size fault, first level
- 000010 Address size fault, second level
- 000011 Address size fault, third level
- 000100 Translation fault, zeroth level
- 000101 Translation fault, first level
- 000110 Translation fault, second level

000111	Translation fault, third level
001001	Access flag fault, first level
001010	Access flag fault, second level
001011	Access flag fault, third level
001101	Permission fault, first level
001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
011000	Synchronous parity error on memory access
010001	Asynchronous external abort
011001	Asynchronous parity error on memory access
010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
111101	Section Domain Fault, used only for faults reported in the <a href="#">PAR_EL1</a>
111110	Page Domain Fault, used only for faults reported in the <a href="#">PAR_EL1</a>

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.

- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

### Accessing the HSR:

To access the HSR:

MRC p15,4,<Rt>,c5,c2,0 ; Read HSR into Rt  
MCR p15,4,<Rt>,c5,c2,0 ; Write Rt to HSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	0101	0010	000

## G4.2.66 HSTR, Hyp System Trap Register

The HSTR characteristics are:

### Purpose

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, of use of T32EE or the CP15 primary coprocessor registers, {c0-c3,c5-c13,c15}.

This register is part of the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HSTR is architecturally mapped to AArch64 register [HSTR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HSTR is a 32-bit register.

The HSTR bit assignments are:

### Bits [31:17]

Reserved, RES0.

### TTEE, bit [16]

Trap T32EE. The possible values of this bit are:

- 0 Has no effect on accesses to the T32EE configuration registers.
- 1 Trap valid Non-secure accesses to T32EE configuration registers to Hyp mode.

When this bit is set to 1, any valid Non-secure access to the T32EE configuration registers is trapped to Hyp mode.

If T32EE is not implemented, then this bit is RES0.

Resets to 0.

### T<n>, bit [n], for n = 0 to 15

Trap coprocessor primary register. For each field T<n>, the possible values of this bit are:

- 0 Has no effect on Non-secure accesses to CP15 coprocessor registers.
- 1 Trap valid Non-secure accesses to coprocessor primary register c<n> to Hyp mode.

When T<n> is set to 1, any valid Non-secure access to CP15 primary coprocessor register c<n> is trapped to Hyp mode. For example, when T7 is set to 1:

- Any valid Non-secure 32-bit CP15 accesses, using MRC or MCR instructions with CRn==c7, are trapped to Hyp mode.
- Any valid Non-secure 64-bit CP15 accesses, using MRRC or MCRR instructions with CRm==c7, are trapped to Hyp mode.

Fields T14 and T4 are RES0.

Resets to 0.

### Accessing the HSTR:

To access the HSTR:

MRC p15,4,<Rt>,c1,c1,3 ; Read HSTR into Rt  
MCR p15,4,<Rt>,c1,c1,3 ; Write Rt to HSTR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	011

## G4.2.67 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

### Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with [HTTBR](#), that defines the translation table base address for the translations.

### Configurations

HTCR is architecturally mapped to AArch64 register [TCR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HTCR is a 32-bit register.

The HTCR bit assignments are:

#### Bit [31]

Reserved, RES1.

#### Bits [29:24]

Reserved, RES0.

#### Bit [23]

Reserved, RES1.

#### Bits [22:14]

Reserved, RES0.

#### SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [TTBR0](#).

- 00 Non-shareable
- 10 Outer Shareable

11 Inner Shareable

Other values are reserved.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using [TTBR0](#).

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using [TTBR0](#).

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

**Bits [7:3]**

Reserved, RES0.

**T0SZ, bits [2:0]**

The size offset of the memory region addressed by [TTBR0](#). The region size is  $2^{32-T0SZ}$  bytes.

**Accessing the HTCR:**

To access the HTCR:

MRC p15,4,<Rt>,c2,c0,2 ; Read HTCR into Rt

MCR p15,4,<Rt>,c2,c0,2 ; Write Rt to HTCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0010	0000	010

## G4.2.68 HTPIDR, Hyp Thread Pointer / ID Register

The HTPIDR characteristics are:

### Purpose

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

This register is part of:

- the Virtualization registers functional group
- the Thread and process ID registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Processor hardware never updates this register.

### Configurations

HTPIDR is architecturally mapped to AArch64 register [TPIDR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HTPIDR is a 32-bit register.

The HTPIDR bit assignments are:

### Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

### Accessing the HTPIDR:

To access the HTPIDR:

MRC p15,4,<Rt>,c13,c0,2 ; Read HTPIDR into Rt  
 MCR p15,4,<Rt>,c13,c0,2 ; Write Rt to HTPIDR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1101	0000	010

## G4.2.69 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

### Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with the [HTCR](#).

### Configurations

HTTBR is architecturally mapped to AArch64 register [TTBR0\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HTTBR is a 64-bit register.

The HTTBR bit assignments are:

### Bits [63:48]

Reserved, RES0.

### BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of [HTCR.TOSZ](#), and is calculated as follows:

- If [HTCR.TOSZ](#) is 0 or 1,  $x = 5 - \text{HTCR.TOSZ}$ .
- If [HTCR.TOSZ](#) is greater than 1,  $x = 14 - \text{HTCR.TOSZ}$ .

The value of x determines the required alignment of the translation table, which must be aligned to  $2^x$  bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONstrained UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

### Accessing the HTTBR:

To access the HTTBR:

MRRC p15,4,<Rt>,<Rt2>,c2 ; Read 64-bit HTTBR into Rt (low word) and Rt2 (high word)  
MCRR p15,4,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit HTTBR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0100	0010

## G4.2.70 HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

### Purpose

Holds the exception base address for any exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

HVBAR is architecturally mapped to AArch64 register [VBAR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

HVBAR is a 32-bit register.

The HVBAR bit assignments are:

### Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

### Bits [4:0]

Reserved, RES0.

### Accessing the HVBAR:

To access the HVBAR:

MRC p15,4,<Rt>,c12,c0,0 ; Read HVBAR into Rt

MCR p15,4,<Rt>,c12,c0,0 ; Write Rt to HVBAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	0000	000

## G4.2.71 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

### Purpose

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

This register is part of the Cache maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

### Configurations

ICIALLU performs the same function as AArch64 operation [IC IALLU](#).

### Attributes

ICIALLU is a 32-bit system operation.

The ICIALLU operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the ICIALLU operation:

To perform the ICIALLU operation:

MCR p15,0,<Rt>,c7,c5,0 ; ICIALLU operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	000

## G4.2.72 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

### Purpose

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

This register is part of the Cache maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

### Configurations

ICIALLUIS performs the same function as AArch64 operation [IC IALLUIS](#).

### Attributes

ICIALLUIS is a 32-bit system operation.

The ICIALLUIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the ICIALLUIS operation:

To perform the ICIALLUIS operation:

MCR p15,0,<Rt>,c7,c1,0 ; ICIALLUIS operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0001	000

### G4.2.73 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

#### Purpose

Invalidate instruction cache line by virtual address to PoU.

This register is part of the Cache maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

#### Configurations

ICIMVAU performs the same function as AArch64 operation [IC IVAU](#).

#### Attributes

ICIMVAU is a 32-bit system operation.

The ICIMVAU input value bit assignments are:

#### Bits [31:0]

Virtual address to use.

#### Performing the ICIMVAU operation:

To perform the ICIMVAU operation:

MCR p15,0,<Rt>,c7,c5,1 ; ICIMVAU operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	001

## G4.2.74 ID\_AFR0, Auxiliary Feature Register 0

The ID\_AFR0 characteristics are:

### Purpose

Provides information about the IMPLEMENTATION DEFINED features of the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with the Main ID Register, [MIDR](#).

### Configurations

ID\_AFR0 is architecturally mapped to AArch64 register [ID\\_AFR0\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_AFR0 is a 32-bit register.

The ID\_AFR0 bit assignments are:

### Bits [31:16]

Reserved, RES0.

### Accessing the ID\_AFR0:

To access the ID\_AFR0:

MRC p15,0,<Rt>,c0,c1,3 ; Read ID\_AFR0 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	011

### G4.2.75 ID\_DFR0, Debug Feature Register 0

The ID\_DFR0 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32.  
 This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with the Main ID Register, [MIDR](#).

**Configurations**

ID\_DFR0 is architecturally mapped to AArch64 register [ID\\_DFR0\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID\_DFR0 is a 32-bit register.

The ID\_DFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
RES0	PerfMon	MProfDbg	MMapTrc	CopTrc	MMapDbg	CopSDBG	CopDbg	

**Bits [31:28]**

Reserved, RES0.

**PerfMon, bits [27:24]**

Performance Monitors. Support for coprocessor-based ARM Performance Monitors Extension, for A and R profile processors. Possible values are:

- 0000 Performance Monitors Extension system registers not implemented.
- 0001 Support for Performance Monitors Extension version 1 (PMUv1) system registers. Not permitted in v8-A.
- 0010 Support for Performance Monitors Extension version 2 (PMUv2) system registers. Not permitted in v8-A.
- 0011 Support for Performance Monitors Extension version 3 (PMUv3) system registers.
- 1111 IMPLEMENTATION DEFINED form of Performance Monitors system registers supported. PMUv3 not supported.

All other values are reserved.

In v7, the value 0b0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in a v8-A implementation.

**MProfDbg, bits [23:20]**

M Profile Debug. Support for memory-mapped debug model for M profile processors. Permitted values are:

- 0000 Not supported.

0001 Support for M profile Debug architecture, with memory-mapped access.  
All other values are reserved. For v8-A, this field is 0b0000.

#### **MMapTrc, bits [19:16]**

Memory Mapped Trace. Support for memory-mapped trace model. Permitted values are:

0000 Not supported.  
0001 Support for ARM trace architecture, with memory-mapped access.  
All other values are reserved.

In the Trace registers, the ETMIDR gives more information about the implementation.

#### **CopTrc, bits [15:12]**

Coprocessor Trace. Support for coprocessor-based trace model. Permitted values are:

0000 Not supported.  
0001 Support for ARM trace architecture, with CP14 access.  
All other values are reserved.

In the Trace registers, the ETMIDR gives more information about the implementation.

#### **MMapDbg, bits [11:8]**

Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.

In v8-A this field is RES0. The optional memory map defined by v8-A is not compatible with v7-A.

#### **CopSDBG, bits [7:4]**

Coprocessor Secure Debug. Support for coprocessor-based Secure debug model, for an A profile processor that includes the Security Extensions.

If EL3 is not implemented and the processor is Non-secure, this field is RES0. Otherwise, this field reads the same as bits [3:0].

#### **CopDbg, bits [3:0]**

Coprocessor Debug. Support for coprocessor based debug model, for A and R profile processors. Permitted values are:

0000 Not supported.  
0010 Support for v6 Debug architecture, with CP14 access.  
0011 Support for v6.1 Debug architecture, with CP14 access.  
0100 Support for v7 Debug architecture, with CP14 access.  
0101 Support for v7.1 Debug architecture, with CP14 access.  
0110 Support for v8-A debug architecture, with CP14 access. This is the value that this field has in v8-A.

All other values are reserved.

### **Accessing the ID\_DFR0:**

To access the ID\_DFR0:

MRC p15,0,<Rt>,c0,c1,2 ; Read ID\_DFR0 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0001	010

## G4.2.76 ID\_ISAR0, Instruction Set Attribute Register 0

The ID\_ISAR0 characteristics are:

### Purpose

Provides information about the instruction sets implemented by the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), and [ID\\_ISAR5](#).

### Configurations

ID\_ISAR0 is architecturally mapped to AArch64 register [ID\\_ISAR0\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_ISAR0 is a 32-bit register.

The ID\_ISAR0 bit assignments are:

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
RES0	Divide		Debug		Coproc		CmpBranch		BitField		BitCount		Swap		

### Bits [31:28]

Reserved, RES0.

### Divide, bits [27:24]

Indicates the implemented Divide instructions. Permitted values are:

- 0000 None implemented.
  - 0001 Adds SDIV and UDIV in the T32 instruction set.
  - 0010 As for 0b0001, and adds SDIV and UDIV in the A32 instruction set.
- All other values are reserved.

### Debug, bits [23:20]

Indicates the implemented Debug instructions. Permitted values are:

- 0000 None implemented.
  - 0001 Adds BKPT.
- All other values are reserved.

### Coproc, bits [19:16]

Indicates the implemented Coprocessor instructions. Permitted values are:

- 0000 None implemented, except for instructions separately attributed by the architecture, including CP15, CP14, and Advanced SIMD and VFP.
- 0001 Adds generic CDP, LDC, MCR, MRC, and STC.
- 0010 As for 0b0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.

0011 As for 0b0010, and adds generic MCRR and MRRC.  
 0100 As for 0b0011, and adds generic MCRR2 and MRRC2.  
 All other values are reserved.

**CmpBranch, bits [15:12]**

Indicates the implemented combined Compare and Branch instructions in the T32 instruction set.  
 Permitted values are:  
 0000 None implemented.  
 0001 Adds CBNZ and CBZ.  
 All other values are reserved.

**BitField, bits [11:8]**

Indicates the implemented BitField instructions. Permitted values are:  
 0000 None implemented.  
 0001 Adds BFC, BFI, SBFX, and UBFX.  
 All other values are reserved.

**BitCount, bits [7:4]**

Indicates the implemented Bit Counting instructions. Permitted values are:  
 0000 None implemented.  
 0001 Adds CLZ.  
 All other values are reserved.

**Swap, bits [3:0]**

Indicates the implemented Swap instructions in the A32 instruction set. Permitted values are:  
 0000 None implemented.  
 0001 Adds SWP and SWPB.  
 All other values are reserved.  
 In v8-A this field is 0b0000. The SWP and SWPB instructions are not supported in v8-A.

**Accessing the ID\_ISAR0:**

To access the ID\_ISAR0:

MRC p15,0,<Rt>,c0,c2,0 ; Read ID\_ISAR0 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	000

## G4.2.77 ID\_ISAR1, Instruction Set Attribute Register 1

The ID\_ISAR1 characteristics are:

### Purpose

Provides information about the instruction sets implemented by the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_ISAR0](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), and [ID\\_ISAR5](#).

### Configurations

ID\_ISAR1 is architecturally mapped to AArch64 register [ID\\_ISAR1\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_ISAR1 is a 32-bit register.

The ID\_ISAR1 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Jazelle	Interwork	Immediate	IfThen	Extend	Except_AR	Except	Endian	

### Jazelle, bits [31:28]

Indicates the implemented Jazelle extension instructions. Permitted values are:

- 0000 No support for Jazelle.
- 0001 Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

### Interwork, bits [27:24]

Indicates the implemented Interworking instructions. Permitted values are:

- 0000 None implemented.
- 0001 Adds the BX instruction, and the T bit in the PSR.
- 0010 As for 0b0001, and adds the BLX instruction. PC loads have BX-like behavior.
- 0011 As for 0b0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

### Immediate, bits [23:20]

Indicates the implemented data-processing instructions with long immediates. Permitted values are:

- 0000 None implemented.
- 0001 Adds:
  - The MOVT instruction.

- The MOV instruction encodings with zero-extended 16-bit immediates.
- The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

#### **IfThen, bits [19:16]**

Indicates the implemented If-Then instructions in the T32 instruction set. Permitted values are:

- 0000 None implemented.  
0001 Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

#### **Extend, bits [15:12]**

Indicates the implemented Extend instructions. Permitted values are:

- 0000 No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.  
0001 Adds the SXTB, SXTH, UXTB, and UXTH instructions.  
0010 As for 0b0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.

#### **Except\_AR, bits [11:8]**

Indicates the implemented A and R profile exception-handling instructions. Permitted values are:

- 0000 None implemented.  
0001 Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

#### **Except, bits [7:4]**

Indicates the implemented exception-handling instructions in the ARM instruction set. Permitted values are:

- 0000 Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.  
0001 Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.

#### **Endian, bits [3:0]**

Indicates the implemented Endian instructions. Permitted values are:

- 0000 None implemented.  
0001 Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

### **Accessing the ID\_ISAR1:**

To access the ID\_ISAR1:

MRC p15,0,<Rt>,c0,c2,1 ; Read ID\_ISAR1 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0010	001

## G4.2.78 ID\_ISAR2, Instruction Set Attribute Register 2

The ID\_ISAR2 characteristics are:

### Purpose

Provides information about the instruction sets implemented by the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), and [ID\\_ISAR5](#).

### Configurations

ID\_ISAR2 is architecturally mapped to AArch64 register [ID\\_ISAR2\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_ISAR2 is a 32-bit register.

The ID\_ISAR2 bit assignments are:

### Reversal, bits [31:28]

Indicates the implemented Reversal instructions. Permitted values are:

- 0000 None implemented.
- 0001 Adds the REV, REV16, and REVSH instructions.
- 0010 As for 0b0001, and adds the RBIT instruction.

All other values are reserved.

### PSR\_AR, bits [27:24]

Indicates the implemented A and R profile instructions to manipulate the PSR. Permitted values are:

- 0000 None implemented.
- 0001 Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

**MultU, bits [23:20]**

Indicates the implemented advanced unsigned Multiply instructions. Permitted values are:

- 0000 None implemented.
  - 0001 Adds the UMULL and UMLAL instructions.
  - 0010 As for 0b0001, and adds the UMAAL instruction.
- All other values are reserved.

**MultS, bits [19:16]**

Indicates the implemented advanced signed Multiply instructions. Permitted values are:

- 0000 None implemented.
  - 0001 Adds the SMULL and SMLAL instructions.
  - 0010 As for 0b0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
  - 0011 As for 0b0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLS D, SMLS DX, SMLS LD, SMLS LD X, SMMLA, SMMLAR, SMMLS, SMMLSR, SMMUL, SMMULR, SMUAD, SMUADX, SMUSD, and SMUSD X instructions.
- All other values are reserved.

**Mult, bits [15:12]**

Indicates the implemented additional Multiply instructions. Permitted values are:

- 0000 No additional instructions implemented. This means only MUL is implemented.
  - 0001 Adds the MLA instruction.
  - 0010 As for 0b0001, and adds the MLS instruction.
- All other values are reserved.

**MultiAccessInt, bits [11:8]**

Indicates the support for interruptible multi-access instructions. Permitted values are:

- 0000 No support. This means the LDM and STM instructions are not interruptible.
  - 0001 LDM and STM instructions are restartable.
  - 0010 LDM and STM instructions are continuable.
- All other values are reserved.

**MemHint, bits [7:4]**

Indicates the implemented Memory Hint instructions. Permitted values are:

- 0000 None implemented.
  - 0001 Adds the PLD instruction.
  - 0010 Adds the PLD instruction. (0b0001 and 0b0010 have identical effects.)
  - 0011 As for 0b0001 (or 0b0010), and adds the PLI instruction.
  - 0100 As for 0b0011, and adds the PLDW instruction.
- All other values are reserved.

**LoadStore, bits [3:0]**

Indicates the implemented additional load/store instructions. Permitted values are:

- 0000 No additional load/store instructions implemented.
- 0001 Adds the LDRD and STRD instructions.

0010 As for 0b0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

### Accessing the ID\_ISAR2:

To access the ID\_ISAR2:

MRC p15,0,<Rt>,c0,c2,2 ; Read ID\_ISAR2 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0010	010

### G4.2.79 ID\_ISAR3, Instruction Set Attribute Register 3

The ID\_ISAR3 characteristics are:

#### Purpose

Provides information about the instruction sets implemented by the processor in AArch32.  
 This register is part of the Identification registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR4](#), and [ID\\_ISAR5](#).

#### Configurations

ID\_ISAR3 is architecturally mapped to AArch64 register [ID\\_ISAR3\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ID\_ISAR3 is a 32-bit register.

The ID\_ISAR3 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
T32EE	TrueNOP	ThumbCopy	TabBranch	SynchPrim	SVC	SIMD	Saturate	

#### T32EE, bits [31:28]

Indicates the implemented TT32EE instructions. Permitted values are:

- 0000 None implemented.
- 0001 Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

This field can only have a value other than 0b0000 when the ID\_PFR0.State3 field has a value of 0b0001.

#### TrueNOP, bits [27:24]

Indicates the implemented True NOP instructions. Permitted values are:

- 0000 None implemented. This means there are no NOP instructions that do not have any register dependencies.
- 0001 Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

#### ThumbCopy, bits [23:20]

Indicates the support for T32 non flag-setting MOV instructions. Permitted values are:

- 0000 Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.

0001 Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

#### TabBranch, bits [19:16]

Indicates the implemented Table Branch instructions in the T32 instruction set. Permitted values are:

0000 None implemented.

0001 Adds the TBB and TBH instructions.

All other values are reserved.

#### SynchPrim, bits [15:12]

Used in conjunction with ID\_ISAR4.SynchPrim\_frac to indicate the implemented Synchronization Primitive instructions. Permitted values are:

0000 If SynchPrim\_frac == 0b0000, no Synchronization Primitives implemented.

0001 If SynchPrim\_frac == 0b0000, adds the LDREX and STREX instructions.

If SynchPrim\_frac == 0b0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.

0010 If SynchPrim\_frac == 0b0000, as for [0b0001, 0b0011] and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim\_frac are reserved.

#### SVC, bits [11:8]

Indicates the implemented SVC instructions. Permitted values are:

0000 Not implemented.

0001 Adds the SVC instruction.

All other values are reserved.

#### SIMD, bits [7:4]

Indicates the implemented SIMD instructions. Permitted values are:

0000 None implemented.

0001 Adds the SSAT and USAT instructions, and the Q bit in the PSRs.

0011 As for 0b0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. **MVFR0** and **MVFR1** give information about the SIMD instructions implemented by the optional Advanced SIMD Extension.

#### Saturate, bits [3:0]

Indicates the implemented Saturate instructions. Permitted values are:

0000 None implemented. This means no non-Advanced SIMD saturate instructions are implemented.

0001 Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.

All other values are reserved.

### Accessing the ID\_ISAR3:

To access the ID\_ISAR3:

MRC p15,0,<Rt>,c0,c2,3 ; Read ID\_ISAR3 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0010	011

## G4.2.80 ID\_ISAR4, Instruction Set Attribute Register 4

The ID\_ISAR4 characteristics are:

### Purpose

Provides information about the instruction sets implemented by the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), and [ID\\_ISAR5](#).

### Configurations

ID\_ISAR4 is architecturally mapped to AArch64 register [ID\\_ISAR4\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_ISAR4 is a 32-bit register.

The ID\_ISAR4 bit assignments are:

### SWP\_frac, bits [31:28]

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Permitted values are:

0000 SWP or SWPB instructions not implemented.

0001 SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the [ID\\_ISAR0.Swap\\_instrs](#) field is 0b0000.

In v8-A this field is 0b0000. The SWP and SWPB instructions are not supported in v8-A.

### PSR\_M, bits [27:24]

Indicates the implemented M profile instructions to modify the PSRs. Permitted values are:

0000 None implemented.

0001 Adds the M profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved.

#### SynchPrim\_frac, bits [23:20]

Used in conjunction with ID\_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- 0000 If SynchPrim == 0b0000, no Synchronization Primitives implemented. If SynchPrim == 0b0001, adds the LDREX and STREX instructions. If SynchPrim == 0b0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.
- 0011 If SynchPrim == 0b0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim\_frac are reserved.

#### Barrier, bits [19:16]

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Permitted values are:

- 0000 None implemented. Barrier operations are provided only as CP15 operations.
- 0001 Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

#### SMC, bits [15:12]

Indicates the implemented SMC instructions. Permitted values are:

- 0000 None implemented.
- 0001 Adds the SMC instruction.

All other values are reserved.

#### Writeback, bits [11:8]

Indicates the support for Writeback addressing modes. Permitted values are:

- 0000 Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- 0001 Adds support for all of the writeback addressing modes defined in ARMv7.

All other values are reserved.

#### WithShifts, bits [7:4]

Indicates the support for instructions with shifts. Permitted values are:

- 0000 Nonzero shifts supported only in MOV and shift instructions.
- 0001 Adds support for shifts of loads and stores over the range LSL 0-3.
- 0011 As for 0b0001, and adds support for other constant shift options, both on load/store and other instructions.
- 0100 As for 0b0011, and adds support for register-controlled shift options.

All other values are reserved.

#### Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Permitted values are:

- 0000 None implemented. No T variant instructions are implemented.
- 0001 Adds the LDRBT, LDRT, STRBT, and STRT instructions.
- 0010 As for 0b0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

#### Accessing the ID\_ISAR4:

To access the ID\_ISAR4:

MRC p15,0,<Rt>,c0,c2,4 ; Read ID\_ISAR4 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0010	100

### G4.2.81 ID\_ISAR5, Instruction Set Attribute Register 5

The ID\_ISAR5 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the processor in AArch32.  
 This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID\_ISAR0, ID\_ISAR1, ID\_ISAR2, ID\_ISAR3, and ID\_ISAR4.

**Configurations**

ID\_ISAR5 is architecturally mapped to AArch64 register ID\_ISAR5\_EL1.  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID\_ISAR5 is a 32-bit register.

The ID\_ISAR5 bit assignments are:

**Bits [31:20]**

Reserved, RES0.

**CRC32, bits [19:16]**

Indicates whether CRC32 instructions are implemented in AArch32.

0000 No CRC32 instructions implemented.

0001 CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

This field must have the same value as ID\_AA64ISAR0\_EL1.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

**SHA2, bits [15:12]**

Indicates whether SHA2 instructions are implemented in AArch32.

0000 No SHA2 instructions implemented.

0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

**SHA1, bits [11:8]**

Indicates whether SHA1 instructions are implemented in AArch32.

0000 No SHA1 instructions implemented.

0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

**AES, bits [7:4]**

Indicates whether AES instructions are implemented in AArch32.

- 0000 No AES instructions implemented.
  - 0001 AESE, AESD, AESMC, and AESIMC implemented.
  - 0010 As for 0b0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.
- All other values are reserved.

**SEVL, bits [3:0]**

Indicates whether the SEVL instruction is implemented in AArch32.

- 0000 SEVL is implemented as a NOP.
- 0001 SEVL is implemented as Send Event Local.

**Accessing the ID\_ISAR5:**

To access the ID\_ISAR5:

MRC p15,0,<Rt>,c0,c2,5 ; Read ID\_ISAR5 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0010	101

## G4.2.82 ID\_MMFR0, Memory Model Feature Register 0

The ID\_MMFR0 characteristics are:

### Purpose

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_MMFR1](#), [ID\\_MMFR2](#), and [ID\\_MMFR3](#).

### Configurations

ID\_MMFR0 is architecturally mapped to AArch64 register [ID\\_MMFR0\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_MMFR0 is a 32-bit register.

The ID\_MMFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
InnerShr	FCSE	AuxReg	TCM	ShareLvl	OuterShr	PMSA	VMSA	

### InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Permitted values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

This field is valid only if the implementation distinguishes between Inner Shareable and Outer Shareable, by implementing two levels of shareability, as indicated by the value of the Shareability levels field, bits[15:12].

When the Shareability level field is zero, this field is UNK.

### FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Permitted values are:

- 0000 Not supported.
- 0001 Support for FCSE.

All other values are reserved.

The value of 0b0001 is only permitted when the VMSA field has a value greater than 0b0010.

#### AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Permitted values are:

- 0000 None supported.
- 0001 Support for Auxiliary Control Register only.
- 0010 Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.

All other values are reserved.

#### TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Permitted values are:

- 0000 Not supported.
- 0001 Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.
- 0010 Support for TCM only, ARMv6 implementation.
- 0011 Support for TCM and DMA, ARMv6 implementation.

All other values are reserved.

An ARMv7 implementation might include an ARMv6 model for TCM support. However, in ARMv7 this is an IMPLEMENTATION DEFINED option, and therefore it must be represented by the 0b0001 encoding in this field.

#### ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Permitted values are:

- 0000 One level of shareability implemented.
- 0001 Two levels of shareability implemented.

All other values are reserved.

#### OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Permitted values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

#### PMSA, bits [7:4]

Indicates support for a PMSA. Permitted values are:

- 0000 Not supported.
- 0001 Support for IMPLEMENTATION DEFINED PMSA.
- 0010 Support for PMSAv6, with a Cache Type Register implemented.
- 0011 Support for PMSAv7, with support for memory subsections. ARMv7-R profile.

All other values are reserved.

When the PMSA field is set to a value other than 0b0000 the VMSA field must be set to 0b0000.

#### VMSA, bits [3:0]

Indicates support for a VMSA. Permitted values are:

- 0000 Not supported.
- 0001 Support for IMPLEMENTATION DEFINED VMSA.
- 0010 Support for VMSAv6, with Cache and TLB Type Registers implemented.
- 0011 Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.

0100 As for 0b0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.

0101 As for 0b0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

When the VMVA field is set to a value other than 0b0000 the PMSA field must be set to 0b0000.

### Accessing the ID\_MMFR0:

To access the ID\_MMFR0:

MRC p15,0,<Rt>,c0,c1,4 ; Read ID\_MMFR0 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	100

## G4.2.83 ID\_MMFR1, Memory Model Feature Register 1

The ID\_MMFR1 characteristics are:

### Purpose

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_MMFR0](#), [ID\\_MMFR2](#), and [ID\\_MMFR3](#).

### Configurations

ID\_MMFR1 is architecturally mapped to AArch64 register [ID\\_MMFR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_MMFR1 is a 32-bit register.

The ID\_MMFR1 bit assignments are:

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
BPred			L1TstCln		L1Uni		L1Hvd		L1UniSW		L1HvdSW		L1UniVA		L1HvdVA

### BPred, bits [31:28]

Branch Predictor. Indicates branch predictor management requirements. Permitted values are:

0000 No branch predictor, or no MMU present. Implies a fixed MPU configuration.

0001 Branch predictor requires flushing on:

- Enabling or disabling the MMU.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers.
- Changes of FCSE ProcessID or ContextID.

0010 Branch predictor requires flushing on:

- Enabling or disabling the MMU.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers without a corresponding change to the FCSE ProcessID or ContextID.

0011 Branch predictor requires flushing only on writing new data to instruction locations.

0100 For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

The branch predictor is described in some documentation as the Branch Target Buffer.

#### L1TstCln, bits [27:24]

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7.
- 0001 Supported Level 1 data cache test and clean operations are:
  - Test and clean data cache.
- 0010 As for 0b0001, and adds:
  - Test, clean, and invalidate data cache.

All other values are reserved.

#### L1Uni, bits [23:20]

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations, for a unified cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported entire Level 1 cache operations are:
  - Invalidate cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- 0010 As for 0b0001, and adds:
  - Clean cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 Harvard cache field, bits[19:16], must be set to 0b0000.

#### L1Hvd, bits [19:16]

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations, for a Harvard cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported entire Level 1 cache operations are:
  - Invalidate instruction cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- 0010 As for 0b0001, and adds:
  - Invalidate data cache.
  - Invalidate data cache and instruction cache, including branch predictor if appropriate.
- 0011 As for 0b0010, and adds:
  - Clean data cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 unified cache field, bits[23:20], must be set to 0b0000.

#### L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported Level 1 unified cache line maintenance operations by set/way are:
  - Clean cache line by set/way.
- 0010 As for 0b0001, and adds:
  - Clean and invalidate cache line by set/way.
- 0011 As for 0b0010, and adds:
  - Invalidate cache line by set/way.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 Harvard cache s/w field, bits[11:8], must be set to 0b0000.

#### L1HvdSW, bits [11:8]

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported Level 1 Harvard cache line maintenance operations by set/way are:
  - Clean data cache line by set/way.
  - Clean and invalidate data cache line by set/way.
- 0010 As for 0b0001, and adds:
  - Invalidate data cache line by set/way.
- 0011 As for 0b0010, and adds:
  - Invalidate instruction cache line by set/way.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 unified cache s/w field, bits[15:12], must be set to 0b0000.

#### L1UniVA, bits [7:4]

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported Level 1 unified cache line maintenance operations by VA are:
  - Clean cache line by VA.
  - Invalidate cache line by VA.
  - Clean and invalidate cache line by VA.
- 0010 As for 0b0001, and adds:
  - Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 Harvard cache VA field, bits[3:0], must be set to 0b0000.

### L1HvdVA, bits [3:0]

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Permitted values are:

- 0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
- 0001 Supported Level 1 Harvard cache line maintenance operations by VA are:
  - Clean data cache line by VA.
  - Invalidate data cache line by VA.
  - Clean and invalidate data cache line by VA.
  - Clean instruction cache line by VA.
- 0010 As for 0b0001, and adds:
  - Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 unified cache VA field, bits[7:4], must be set to 0b0000.

### Accessing the ID\_MMFR1:

To access the ID\_MMFR1:

MRC p15,0,<Rt>,c0,c1,5 ; Read ID\_MMFR1 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	101

## G4.2.84 ID\_MMFR2, Memory Model Feature Register 2

The ID\_MMFR2 characteristics are:

### Purpose

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_MMFR0](#), [ID\\_MMFR1](#), and [ID\\_MMFR3](#).

### Configurations

ID\_MMFR2 is architecturally mapped to AArch64 register [ID\\_MMFR2\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_MMFR2 is a 32-bit register.

The ID\_MMFR2 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
HWAccFlg	WFIStall	MemBarr	UniTLB	HvdTLB	L1HvdRng	L1HvdBG	L1HvdFG	

### HWAccFlg, bits [31:28]

Hardware Access Flag. Indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Permitted values are:

0000 Not supported.

0001 Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

On an ARMv7-R implementation this field must be 0b0000.

### WFIStall, bits [27:24]

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Permitted values are:

0000 Not supported.

0001 Support for WFI stalling.

All other values are reserved.

### MemBarr, bits [23:20]

Memory Barrier. Indicates the supported CP15 memory barrier operations:

0000 None supported.

0001 Supported CP15 Memory barrier operations are:

- Data Synchronization Barrier (DSB), which in previous versions of the ARM architecture was named Data Write Barrier (DWB).

- 0010 As for 0b0001, and adds:
- Instruction Synchronization Barrier (ISB), which in previous versions of the ARM architecture was called Prefetch Flush.
  - Data Memory Barrier (DMB).

All other values are reserved.

From ARMv7, ARM deprecates the use of these operations. ID\_ISAR4.Barrier\_instrs indicates the level of support for the preferred barrier instructions.

#### UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Permitted values are:

- 0000 Not supported.
- 0001 Supported unified TLB maintenance operations are:
- Invalidate all entries in the TLB.
  - Invalidate TLB entry by VA.
- 0010 As for 0b0001, and adds:
- Invalidate TLB entries by ASID match.
- 0011 As for 0b0010, and adds:
- Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.
- 0100 As for 0b0011, and adds:
- Invalidate Hyp mode unified TLB entry by VA.
  - Invalidate entire Non-secure EL1&0 unified TLB.
  - Invalidate entire Hyp mode unified TLB.
- 0101 As for 0b0100, and adds the following operations: [TLBIMVALIS](#), [TLBIMVAALIS](#), [TLBIMVALHIS](#), [TLBIMVAL](#), [TLBIMVAAL](#), [TLBIMVALH](#).
- 0110 As for 0b0101, and adds the following operations: [TLBIIPAS2IS](#), [TLBIIPAS2LIS](#), [TLBIIPAS2](#), [TLBIIPAS2L](#).

All other values are reserved.

If this field is set to a value other than 0b0000 then the Harvard TLB field, bits[15:12], must be set to 0b0000.

#### HvdTLB, bits [15:12]

Harvard TLB. Indicates the supported TLB maintenance operations, for a Harvard TLB implementation. Permitted values are:

- 0000 Not supported.
- 0001 Supported Harvard TLB maintenance operations are:
- Invalidate all entries in the ITLB and the DTLB. This is a shared unified TLB operation.
  - Invalidate all ITLB entries.
  - Invalidate all DTLB entries.
  - Invalidate ITLB entry by VA.
  - Invalidate DTLB entry by VA.
- 0010 As for 0b0001, and adds:
- Invalidate ITLB and DTLB entries by ASID match. This is a shared unified TLB operation.
  - Invalidate ITLB entries by ASID match.
  - Invalidate DTLB entries by ASID match.

All other values are reserved.

If this field is set to a value other than 0b0000 then the Unified TLB field, bits[19:16], must be set to 0b0000.

#### L1HvdRng, bits [11:8]

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache maintenance range operations are:

- Invalidate data cache range by VA.
- Invalidate instruction cache range by VA.
- Clean data cache range by VA.
- Clean and invalidate data cache range by VA.

All other values are reserved.

#### L1HvdBG, bits [7:4]

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache background fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

#### L1HvdFG, bits [3:0]

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache foreground fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

### Accessing the ID\_MMFR2:

To access the ID\_MMFR2:

MRC p15,0,<Rt>,c0,c1,6 ; Read ID\_MMFR2 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	110

### G4.2.85 ID\_MMFR3, Memory Model Feature Register 3

The ID\_MMFR3 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID\_MMFR0, ID\_MMFR1, and ID\_MMFR2.

**Configurations**

ID\_MMFR3 is architecturally mapped to AArch64 register ID\_MMFR3\_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID\_MMFR3 is a 32-bit register.

The ID\_MMFR3 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Supersec	CMemSz	CohWalk	RES0	MaintBcst	BPMaint	CMaintSW	CMaintVA	

**Supersec, bits [31:28]**

Supersections. On a VMSA implementation, indicates whether Supersections are supported. Permitted values are:

- 0000 Supersections supported.
- 1111 Supersections not supported.

All other values are reserved.

The sense of this identification is reversed from the normal usage in the CPUID mechanism, with the value of zero indicating that the feature is supported.

**CMemSz, bits [27:24]**

Cached Memory Size. Indicates the physical memory size supported by the processor caches. Permitted values are:

- 0000 4GBbyte, corresponding to a 32-bit physical address range.
- 0001 64GBbyte, corresponding to a 36-bit physical address range.
- 0010 1TBbyte or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

#### CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Permitted values are:

- 0000 Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks.
- 0001 Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

#### Bits [19:16]

Reserved, RES0.

#### MaintBcst, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Permitted values are:

- 0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

#### BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Permitted values are:

- 0000 None supported.
- 0001 Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- 0010 As for 0b0001, and adds:
  - Invalidate branch predictors by VA.

All other values are reserved.

#### CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Permitted values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance operations by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.

All other values are reserved.

In a unified cache implementation, the data cache operations apply to the unified caches.

#### CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Permitted values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance operations by VA are:
  - Invalidate data cache by VA.
  - Clean data cache by VA.

- Clean and invalidate data cache by VA.
- Invalidate instruction cache by VA.
- Invalidate all instruction cache entries.

All other values are reserved.

In a unified cache implementation, the data cache operations apply to the unified caches, and the instruction cache operations are not implemented.

### Accessing the ID\_MMFR3:

To access the ID\_MMFR3:

MRC p15,0,<Rt>,c0,c1,7 ; Read ID\_MMFR3 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	111

## G4.2.86 ID\_PFR0, Processor Feature Register 0

The ID\_PFR0 characteristics are:

### Purpose

Gives top-level information about the instruction sets supported by the processor in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_PFR1](#).

### Configurations

ID\_PFR0 is architecturally mapped to AArch64 register [ID\\_PFR0\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_PFR0 is a 32-bit register.

The ID\_PFR0 bit assignments are:

### Bits [31:16]

Reserved, RES0.

### State3, bits [15:12]

T32EE instruction set support. Permitted values are:

0000 Not implemented.  
0001 T32EE instruction set implemented.

All other values are reserved.

The value of 0b0001 is only permitted when State1 == 0b0011.

### State2, bits [11:8]

Jazelle extension support. Permitted values are:

0000 Not implemented.  
0001 Jazelle extension implemented, without clearing of [JOSCR.CV](#) on exception entry.  
0010 Jazelle extension implemented, with clearing of [JOSCR.CV](#) on exception entry.

All other values are reserved.

### State1, bits [7:4]

T32 instruction set support. Permitted values are:

0000 T32 instruction set not implemented.

- 0001 T32 encodings before the introduction of Thumb-2 technology implemented:
- All instructions are 16-bit.
  - A BL or BLX is a pair of 16-bit instructions.
  - 32-bit instructions other than BL and BLX cannot be encoded.
- 0011 T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.
- All other values are reserved.

**State0, bits [3:0]**

- A32 instruction set support. Permitted values are:
- 0000 A32 instruction set not implemented.
- 0001 A32 instruction set implemented.
- All other values are reserved.

**Accessing the ID\_PFR0:**

To access the ID\_PFR0:

MRC p15,0,<Rt>,c0,c1,0 ; Read ID\_PFR0 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0001	000

## G4.2.87 ID\_PFR1, Processor Feature Register 1

The ID\_PFR1 characteristics are:

### Purpose

Gives information about the programmers' model and extensions support in AArch32.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with [ID\\_PFR0](#).

### Configurations

ID\_PFR1 is architecturally mapped to AArch64 register [ID\\_PFR1\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ID\_PFR1 is a 32-bit register.

The ID\_PFR1 bit assignments are:

### GIC, bits [31:28]

GIC CP15 interface. Permitted values are:

- 0000 No GIC CP15 registers are supported.
- 0001 GICv3 CP15 registers are supported.

All other values are reserved.

### Virt\_frac, bits [27:24]

Virtualization fractional field. When the Virtualization field is 0b0000, determines the support for features from the ARMv7 Virtualization Extensions. Permitted values are:

- 0000 No features from the ARMv7 Virtualization Extensions are implemented.
- 0001 The [SCR.SIF](#) bit is implemented. The modifications to the [SCR.AW](#) and [SCR.FW](#) bits are part of the control of whether the [CPSR.A](#) and [CPSR.F](#) bits mask the corresponding aborts. The [MSR](#) (Banked register) and [MRS](#) (Banked register) instructions are implemented.

This value is permitted only when ID\_PFR1.Security is not 0b0000.

All other values are reserved.

This field is only valid when ID\_PFR1[15:12] == 0, otherwise it holds the value 0b0000.

#### Sec\_frac, bits [23:20]

Security fractional field. When the Security field is 0b0000, determines the support for features from the ARMv7 Security Extensions. Permitted values are:

- 0000 No features from the ARMv7 Security Extensions are implemented.
- 0001 The implementation includes the VBAR, and the TCR.PD0 and TCR.PD1 bits.
- 0010 As for 0b0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

This field is only valid when ID\_PFR1[7:4] == 0, otherwise it holds the value 0b0000.

#### GenTimer, bits [19:16]

Generic Timer Extension support. Permitted values are:

- 0000 Not implemented.
- 0001 Generic Timer Extension implemented.

All other values are reserved.

#### Virtualization, bits [15:12]

Virtualization support. Permitted values are:

- 0000 EL2 not implemented.
- 0001 EL2 implemented.

All other values are reserved.

A value of 0b0001 implies implementation of the HVC, ERET, MRS (banked register), and MSR (banked register) instructions. The ID\_ISARs do not identify whether these instructions are implemented.

#### MProgMod, bits [11:8]

M profile programmers' model support. Permitted values are:

- 0000 Not supported.
- 0010 Support for two-stack programmers' model.

All other values are reserved.

#### Security, bits [7:4]

Security support. Permitted values are:

- 0000 EL3 not implemented.
- 0001 EL3 implemented.  
This includes support for Monitor mode and the SMC instruction.
- 0010 As for 0b0001, and adds the ability to set the NSACR.RFR bit. Not permitted in v8-A as the NSACR.RFR bit is RES0.

All other values are reserved.

#### ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Permitted values are:

- 0000 Not supported.
- 0001 Supported.

All other values are reserved.

### Accessing the ID\_PFR1:

To access the ID\_PFR1:

MRC p15,0,<Rt>,c0,c1,1 ; Read ID\_PFR1 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0001	001

## G4.2.88 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

### Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

This register is part of the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as IFAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as IFAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

IFAR(NS) is architecturally mapped to AArch64 register [FAR\\_EL1](#)[63:32].

IFAR(S) is architecturally mapped to AArch32 register [HIFAR](#) when EL2 is implemented.

IFAR(S) is architecturally mapped to AArch64 register [FAR\\_EL2](#)[63:32] when EL2 is implemented.

IFAR(S) can be mapped to AArch64 register [FAR\\_EL3](#)[63:32] when EL2 is not implemented, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

IFAR is a 32-bit register.

The IFAR bit assignments are:

### Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

### Accessing the IFAR:

To access the IFAR:

MRC p15,0,<Rt>,c6,c0,2 ; Read IFAR into Rt  
 MCR p15,0,<Rt>,c6,c0,2 ; Write Rt to IFAR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0110	0000	010

## G4.2.89 IFSR, Instruction Fault Status Register

The IFSR characteristics are:

### Purpose

Holds status information about the last instruction fault.

This register is part of the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as IFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as IFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

IFSR(NS) is architecturally mapped to AArch64 register [IFSR32\\_EL2](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

### Attributes

IFSR is a 32-bit register.

The IFSR bit assignments are:

### When TTBCR.EAE==0:

### Bits [31:13]

Reserved, RES0.

### ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

**Bit [11]**

Reserved, RES0.

**FS[4], bit [10]**

See below for description of the FS field.

**LPAAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bits [8:4]**

Reserved, RES0.

**FS[3:0], bits [3:0]**

Fault status bits. Possible values of this field are:

- 0010 Debug event
- 0011 Access flag fault, first level
- 0101 Translation fault, first level
- 0110 Access flag fault, second level
- 0111 Translation fault, second level
- 1000 Synchronous external abort
- 1001 Domain fault, first level
- 1011 Domain fault, second level
- 1100 Synchronous external abort on translation table walk, first level
- 1101 Permission fault, first level
- 1110 Synchronous external abort on translation table walk, second level
- 1111 Permission fault, second level
- 10000 TLB conflict abort
- 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 11001 Synchronous parity error on memory access
- 11100 Synchronous parity error on translation table walk, first level
- 11110 Synchronous parity error on translation table walk, second level

All other values are reserved.

**When TTBCR.EAE==1:**

**Bits [31:13]**

Reserved, RES0.

**ExT, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

**Bits [11:10]**

Reserved, RES0.

**LPAAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bits [8:6]**

Reserved, RES0.

**STATUS, bits [5:0]**

Fault status bits. Possible values of this field are:

000000 Address size fault in [TTBR0](#) or [TTBR1](#)

000101 Translation fault, first level

000110 Translation fault, second level

000111 Translation fault, third level

001001 Access flag fault, first level

001010 Access flag fault, second level

001011 Access flag fault, third level

001101 Permission fault, first level

001110 Permission fault, second level

001111 Permission fault, third level

010000 Synchronous external abort

010101 Synchronous external abort on translation table walk, first level

010110 Synchronous external abort on translation table walk, second level

010111 Synchronous external abort on translation table walk, third level

011000 Synchronous parity error on memory access

011101 Synchronous parity error on memory access on translation table walk, first level

011110 Synchronous parity error on memory access on translation table walk, second level

011111 Synchronous parity error on memory access on translation table walk, third level

100001 Alignment fault

100010 Debug event

110000 TLB conflict abort

110100 IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

### Accessing the IFSR:

To access the IFSR:

MRC p15,0,<Rt>,c5,c0,1 ; Read IFSR into Rt  
 MCR p15,0,<Rt>,c5,c0,1 ; Write Rt to IFSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0101	0000	001

## G4.2.90 ISR, Interrupt Status Register

The ISR characteristics are:

### Purpose

Shows whether an IRQ, FIQ, or external abort is pending. If EL2 is implemented, an indicated pending abort might be a physical abort or a virtual abort.

This register is part of the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

ISR is architecturally mapped to AArch64 register [ISR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ISR is a 32-bit register.

The ISR bit assignments are:

### Bits [31:9]

Reserved, RES0.

### A, bit [8]

External abort pending bit:

0 No pending external abort.

1 An external abort is pending.

### I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0 No pending IRQ.

1 An IRQ interrupt is pending.

### F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0 No pending FIQ.

1 An FIQ interrupt is pending.

### Bits [5:0]

Reserved, RES0.

### Accessing the ISR:

To access the ISR:

MRC p15,0,<Rt>,c12,c1,0 ; Read ISR into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	0001	000

### G4.2.91 ITLBIALL, Instruction TLB Invalidate All entries

The ITLBIALL characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 and 2 instruction TLB entries for the current VMID.  
 This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIALL is a 32-bit system operation.

The ITLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the ITLBIALL operation:**

To perform the ITLBIALL operation:

MCR p15,0,<Rt>,c8,c5,0 ; ITLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	000

## G4.2.92 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

### Purpose

Invalidate EL1&0 regime stage 1 instruction TLB entries for the given ASID and the current VMID.  
This register is part of the TLB maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

### Configurations

There are no configuration notes.

### Attributes

ITLBIASID is a 32-bit system operation.

The ITLBIASID input value bit assignments are:

### Bits [31:8]

Reserved, RES0.

### ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

### Performing the ITLBIASID operation:

To perform the ITLBIASID operation:

MCR p15,0,<Rt>,c8,c5,2 ; ITLBIASID operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	010

### G4.2.93 ITLBIMVA, Instruction TLB Invalidate entry by VA

The ITLBIMVA characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 1 and 2 instruction TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

There are no configuration notes.

#### Attributes

ITLBIMVA is a 32-bit system operation.

The ITLBIMVA input value bit assignments are:

#### VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

#### Bits [11:8]

Reserved, RES0.

#### ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

#### Performing the ITLBIMVA operation:

To perform the ITLBIMVA operation:

MCR p15,0,<Rt>,c8,c5,1 ; ITLBIMVA operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	001

## G4.2.94 JIDR, Jazelle ID Register

The JIDR characteristics are:

### Purpose

A Jazelle register, which identifies the Jazelle architecture and subarchitecture version.  
This register is part of the Legacy feature registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RO	RO	RO	RO	RO

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.  
Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

### Attributes

JIDR is a 32-bit register.

The JIDR bit assignments are:

### Bits [31:0]

Reserved, RES0.

### Accessing the JIDR:

To access the JIDR:

MRC p14,7,<Rt>,c0,c0,0 ; Read JIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0000	0000	000

## G4.2.95 JMCR, Jazelle Main Configuration Register

The JMCR characteristics are:

### Purpose

A Jazelle register, which provides control of the Jazelle extension.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

### Attributes

JMCR is a 32-bit register.

The JMCR bit assignments are:

### Bits [31:0]

Reserved, RES0.

### Accessing the JMCR:

To access the JMCR:

MRC p14,7,<Rt>,c2,c0,0 ; Read JMCR into Rt

MCR p14,7,<Rt>,c2,c0,0 ; Write Rt to JMCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0010	0000	000

## G4.2.96 JOSCR, Jazelle OS Control Register

The JOSCR characteristics are:

### Purpose

A Jazelle register, which provides operating system control of the use of the Jazelle extension by processes and threads.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

### Attributes

JOSCR is a 32-bit register.

The JOSCR bit assignments are:

### Bits [31:0]

Reserved, RES0.

### Accessing the JOSCR:

To access the JOSCR:

MRC p14,7,<Rt>,c1,c0,0 ; Read JOSCR into Rt

MCR p14,7,<Rt>,c1,c0,0 ; Write Rt to JOSCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0001	0000	000

## G4.2.97 MAIRO, Memory Attribute Indirection Register 0

The MAIRO characteristics are:

### Purpose

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as MAIRO(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as MAIRO(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Long-descriptor translation table format.

AttrIdx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIdx[2] to 0 selects MAIRO.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

### Configurations

MAIRO(NS) is architecturally mapped to AArch64 register MAIR\_EL1[31:0] when TTBCR.EAE==1.

MAIRO(S) can be mapped to AArch64 register MAIR\_EL3[31:0] when TTBCR.EAE==1, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIRO has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

MAIRO is a 32-bit register when TTBCR.EAE==1.

The MAIRO bit assignments are:

### When TTBCR.EAE==1:

**Attr<n>, bits [8n+7:8n], for n = 0 to 3**

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

### Accessing the MAIR0:

To access the MAIR0 when TTBCR.EAE==1:

MRC p15,0,<Rt>,c10,c2,0 ; Read MAIR0 into Rt  
MCR p15,0,<Rt>,c10,c2,0 ; Write Rt to MAIR0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	000

## G4.2.98 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

### Purpose

Along with [MAIR0](#), provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as MAIR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as MAIR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Long-descriptor translation table format.

AttrIndx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIndx[2] to 1 selects MAIR1.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

### Configurations

MAIR1(NS) is architecturally mapped to AArch64 register [MAIR\\_EL1](#)[63:32] when TTBCR.EAE==1.

MAIR1(S) can be mapped to AArch64 register [MAIR\\_EL3](#)[63:32] when TTBCR.EAE==1, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIR1 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

MAIR1 is a 32-bit register when TTBCR.EAE==1.

The MAIR1 bit assignments are:

### When TTBCR.EAE==1:

31	24 23	16 15	8 7	0
Attr7	Attr6	Attr5	Attr4	

**Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7**

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

### Accessing the MAIR1:

To access the MAIR1 when TTBCR.EAE==1:

MRC p15,0,<Rt>,c10,c2,1 ; Read MAIR1 into Rt  
MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to MAIR1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	001

## G4.2.99 MIDR, Main ID Register

The MIDR characteristics are:

### Purpose

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

MIDR is architecturally mapped to AArch64 register [MIDR\\_EL1](#).

MIDR is architecturally mapped to external register [MIDR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Some fields of the MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

### Attributes

MIDR is a 32-bit register.

The MIDR bit assignments are:

### Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation

Hex representation	ASCII representation	Implementer
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

#### Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

#### Architecture, bits [19:16]

The permitted values of this field are:

0001	ARMv4
0010	ARMv4T
0011	ARMv5 (obsolete)
0100	ARMv5T
0101	ARMv5TE
0110	ARMv5TEJ
0111	ARMv6
1111	Defined by CPUID scheme

All other values are reserved.

#### PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

#### Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

#### Accessing the MIDR:

To access the MIDR:

MRC p15,0,<Rt>,c0,c0,0 ; Read MIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	000

### G4.2.100 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

**Purpose**

In a multiprocessor system, provides an additional processor identification mechanism for scheduling purposes, and indicates whether the implementation includes the Multiprocessing Extensions.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

**Configurations**

MPIDR is architecturally mapped to AArch64 register [MPIDR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

In a uniprocessor system ARM recommends that this register returns a value of 0.

**Attributes**

MPIDR is a 32-bit register.

The MPIDR bit assignments are:

**M, bit [31]**

Indicates whether this implementation includes the Multiprocessing Extensions. The possible values of this bit are:

- 0 This implementation does not include the Multiprocessing Extensions.
- 1 This implementation includes the Multiprocessing Extensions.

In v8-A this bit is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from processor 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical processors that are implemented using a multi-threading type approach. The possible values of this bit are:

- 0 Performance of processors at the lowest affinity level is largely independent.
- 1 Performance of processors at the lowest affinity level is very interdependent.

**Aff2, bits [23:16]**

Affinity level 2. The least significant affinity level field, for this processor in the system.

**Aff1, bits [15:8]**

Affinity level 1. The intermediate affinity level field, for this processor in the system.

**Aff0, bits [7:0]**

Affinity level 0. The most significant affinity level field, for this processor in the system.

**Accessing the MPIDR:**

To access the MPIDR:

MRC p15,0,<Rt>,c0,c0,5 ; Read MPIDR into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0000	0000	101

## G4.2.101 MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

### Purpose

Holds the exception base address for any exception that is taken to Monitor mode.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

Secure software must program the MVBAR with the required initial value as part of the processor boot sequence.

If EL3 is implemented and is using AArch64, any read or write to MVBAR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The reset value of MVBAR, when resetting into EL3 using AArch32, is an IMPLEMENTATION DEFINED choice between the following:

- Either:
  - MVBAR[31:5] is an IMPLEMENTATION DEFINED value, which might be UNKNOWN.
  - MVBAR[4:1] is RES0.
  - MVBAR[0] is 0.
- Or:
  - MVBAR[31:1] is an IMPLEMENTATION DEFINED value being the AArch32 reset address, bits[31:1].
  - MVBAR[0] is 1.

The reset value of MVBAR[0] can be used to distinguish between these two approaches.

### Attributes

MVBAR is a 32-bit register.

The MVBAR bit assignments are:

### Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

### Bits [4:0]

Reserved, RES0.

### Accessing the MVBAR:

To access the MVBAR:

MRC p15,0,<Rt>,c12,c0,1 ; Read MVBAR into Rt  
MCR p15,0,<Rt>,c12,c0,1 ; Write Rt to MVBAR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	0000	001

### G4.2.102 MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**

Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, and [HCPTR](#).{TCP10,TCP11}.

Must be interpreted with [MVFR1](#) and [MVFR2](#).

**Configurations**

MVFR0 is architecturally mapped to AArch64 register [MVFR0\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

MVFR0 is a 32-bit register.

The MVFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
FPRound	FPSHVec	FPSqrt	FPDivide	FPTrap	FPDP	FPSP	SIMDReg	

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates the rounding modes supported by the VFP floating-point hardware. Permitted values are:

0000 Only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the [FPSCR](#) setting.

0001 All rounding modes supported.

All other values are reserved.

**FPSHVec, bits [27:24]**

Short Vectors. Indicates the hardware support for VFP short vectors. Permitted values are:

0000 Not supported.

0001 Short vector operation supported.

All other values are reserved.

#### **FPSqrt, bits [23:20]**

Square Root. Indicates the hardware support for VFP square root operations. Permitted values are:

0000 Not supported in hardware.

0001 Supported.

All other values are reserved.

The VSQRT.F32 instruction also requires the single-precision VFP attribute, and the VSQRT.F64 instruction also requires the double-precision VFP attribute.

#### **FPDivide, bits [19:16]**

Indicates the hardware support for VFP divide operations. Permitted values are:

0000 Not supported in hardware.

0001 Supported.

All other values are reserved.

The VDIV.F32 instruction also requires the single-precision VFP attribute, and the VDIV.F64 instruction also requires the double-precision VFP attribute.

#### **FPTrap, bits [15:12]**

Floating Point Exception Trapping. Indicates whether the VFP hardware implementation supports exception trapping. Permitted values are:

0000 Not supported. This is the value for VFPv3 and VFPv4.

0001 Supported by the hardware. This is the value for VFPv3U, VFP4U, and for VFPv2. When exception trapping is supported, support code is needed to handle the trapped exceptions.

All other values are reserved.

A value of 0b0001 does not indicate that trapped exception handling is available. Because trapped exception handling requires support code, only the support code can provide this information.

#### **FPDP, bits [11:8]**

Double Precision. Indicates the hardware support for VFP double-precision operations. Permitted values are:

0000 Not supported in hardware.

0001 Supported, VFPv2.

0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.

A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is 0b0001.
- VDIV.F64 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

#### **FPSP, bits [7:4]**

Single Precision. Indicates the hardware support for VFP single-precision operations. Permitted values are:

0000 Not supported in hardware.

0001 Supported, VFPv2.

0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0b0001.
- VDIV.F32 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

#### SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates support for the Advanced SIMD register bank. Permitted values are:

0000 Not supported.  
0001 Supported, 16 x 64-bit registers.  
0010 Supported, 32 x 64-bit registers.

All other values are reserved.

If this field is nonzero:

- All VFP LDC, STC, MCR, and MRC instructions are supported.
- If the CPUID registers show that the MCRR and MRRC instructions are supported then the corresponding VFP instructions are supported.

#### Accessing the MVFR0:

To access the MVFR0:

VMRS <Rt>, MVFR0 ; Read MVFR0 into Rt

Register access is encoded as follows:

---

**spec\_reg**

---

0111

---

## G4.2.103 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

### Purpose

Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, and [HCPTR](#).{TCP10,TCP11}.

Must be interpreted with [MVFR0](#) and [MVFR2](#).

### Configurations

MVFR1 is architecturally mapped to AArch64 register [MVFR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

### Attributes

MVFR1 is a 32-bit register.

The MVFR1 bit assignments are:

### SIMDFMAC, bits [31:28]

Advanced SIMD Fused Multiply-Accumulate. Indicates whether any implemented VFP or Advanced SIMD extension implements the fused multiply accumulate instructions. Permitted values are:

0000 Not implemented.

0001 Implemented.

All other values are reserved.

If an implementation includes both the VFP extension and the Advanced SIMD extension, both extensions must provide the same level of support for these instructions.

### FPHP, bits [27:24]

Floating Point Half Precision. Indicates whether the VFP extension implements half-precision floating-point conversion instructions. Permitted values are:

0000 Not implemented.

- 0001 Instructions to convert between half-precision and single-precision implemented.
- 0010 As for 0b0001, and also instructions to convert between half-precision and double-precision implemented.

All other values are reserved.

**SIMDHP, bits [23:20]**

Advanced SIMD Half Precision. Indicates whether the Advanced SIMD extension implements half-precision floating-point conversion instructions. Permitted values are:

- 0000 Not implemented.
- 0001 Implemented. This value is permitted only if the AdvSIMD SPFP field is 0b0001.

All other values are reserved.

**SIMDSP, bits [19:16]**

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD extension implements single-precision floating-point instructions. Permitted values are:

- 0000 Not implemented.
- 0001 Implemented. This value is permitted only if the AdvSIMD integer field is 0b0001.

All other values are reserved.

**SIMDInt, bits [15:12]**

Advanced SIMD Integer. Indicates whether the Advanced SIMD extension implements integer instructions. Permitted values are:

- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

**SIMDLS, bits [11:8]**

Advanced SIMD Load/Store. Indicates whether the Advanced SIMD extension implements load/store instructions. Permitted values are:

- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

**FPDNaN, bits [7:4]**

Default NaN mode. Indicates whether the VFP hardware implementation supports only the Default NaN mode. Permitted values are:

- 0000 Hardware supports only the Default NaN mode. If a VFP subarchitecture is implemented its support code might include support for propagation of NaN values.
- 0001 Hardware supports propagation of NaN values.

All other values are reserved.

**FPFtZ, bits [3:0]**

Flush to Zero mode. Indicates whether the VFP hardware implementation supports only the Flush-to-Zero mode of operation. Permitted values are:

- 0000 Hardware supports only the Flush-to-Zero mode of operation. If a VFP subarchitecture is implemented its support code might include support for full denormalized number arithmetic.
- 0001 Hardware supports full denormalized number arithmetic.

All other values are reserved.

### Accessing the MVFR1:

To access the MVFR1:

VMRS <Rt>, MVFR1 ; Read MVFR1 into Rt

Register access is encoded as follows:

---

**spec\_reg**

---

0110

---

### G4.2.104 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

**Purpose**

Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of [CPACR](#).{cp10,cp11}, [NSACR](#).{cp10,cp11}, and [HCPTR](#).{TCP10,TCP11}.

Must be interpreted with [MVFR0](#) and [MVFR1](#).

**Configurations**

MVFR2 is architecturally mapped to AArch64 register [MVFR2\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

MVFR2 is a 32-bit register.

The MVFR2 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**FPMisc, bits [7:4]**

Indicates support for miscellaneous VFP features.

0000 No support for miscellaneous features.

0001 Support for Floating-point selection.

0010 As 0b0001, and Floating-point Conversion to Integer with Directed Rounding modes.

0011 As 0b0010, and Floating-point Round to Integral Floating-point.

0100 As 0b0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

**SIMDMisc, bits [3:0]**

Indicates support for miscellaneous Advanced SIMD features.

0000 No support for miscellaneous features.

- 0001 Floating-point Conversion to Integer with Directed Rounding modes.
  - 0010 As 0b0001, and Floating-point Round to Integral Floating-point.
  - 0011 As 0b0010, and Floating-point MaxNum and MinNum.
- All other values are reserved.

### Accessing the MVFR2:

To access the MVFR2:

VMRS <Rt>, MVFR2 ; Read MVFR2 into Rt

Register access is encoded as follows:

---

<b>spec_reg</b>
0101

---

### G4.2.105 NMRR, Normal Memory Remap Register

The NMRR characteristics are:

#### Purpose

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the [PRRR](#).

This register is part of the Virtual memory control registers functional group.

#### Usage constraints

This register is accessible as shown below:

When accessed as NMRR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as NMRR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the [PRRR](#).

Only accessible when using the Short-descriptor translation table format.

#### Configurations

NMRR(NS) is architecturally mapped to AArch64 register [MAIR\\_EL1](#)[63:32] when TTBCR.EAE==0.

NMRR(S) can be mapped to AArch64 register [MAIR\\_EL3](#)[63:32] when TTBCR.EAE==0, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

NMRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

#### Attributes

NMRR is a 32-bit register when TTBCR.EAE==0.

The NMRR bit assignments are:

#### When TTBCR.EAE==0:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
OR7	OR6	OR5	OR4	OR3	OR2	OR1	OR0	IR7	IR6	IR5	IR4	IR3	IR2	IR1	IR0																	

#### OR<n>, bits [2n+17:2n+16], for n = 0 to 7

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

- 00 Region is Non-cacheable.
- 01 Region is Write-Back, Write-Allocate.

10 Region is Write-Through, no Write-Allocate.

11 Region is Write-Back, no Write-Allocate.

The meaning of the field with  $n = 6$  is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

**IR<n>, bits [2n+1:2n], for n = 0 to 7**

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Region is Non-cacheable.

01 Region is Write-Back, Write-Allocate.

10 Region is Write-Through, no Write-Allocate.

11 Region is Write-Back, no Write-Allocate.

The meaning of the field with  $n = 6$  is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

**Accessing the NMRR:**

To access the NMRR when TTBCR.EAE==0:

MRC p15,0,<Rt>,c10,c2,1 ; Read NMRR into Rt

MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to NMRR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	001

## G4.2.106 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

### Purpose

Defines the Non-secure access permissions to coprocessors CP0 to CP13, and can include additional IMPLEMENTATION DEFINED bits that define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

This register is part of the Security registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RW	RO	RW	RW

If EL3 is implemented and is using AArch64, any read or write to NSACR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

When EL3 is using AArch64, then any reads of the NSACR from Non-secure EL2 using AArch32 or Non-secure EL1 using AArch32 will return a fixed value of 0x00000C00.

If EL3 is not implemented, then any reads of the NSACR from Non-secure EL2 using AArch32 or Secure or Non-secure EL1 using AArch32 will return a fixed value of 0x00000C00.

In AArch64, the NSACR functionality is replaced by the behavior in [CPTR\\_EL3](#).

### Attributes

NSACR is a 32-bit register.

The NSACR bit assignments are:

### Bits [31:21]

Reserved, RES0.

### NSTRCDIS, bit [20]

Disable Non-secure access to CP14 trace registers. The implementation of this bit must correspond to the implementation of the [CPACR.TRCDIS](#) bit:

If [CPACR.TRCDIS](#) is RES0 then this bit is RES0.

If [CPACR.TRCDIS](#) is RW then this bit is RW and its possible values are:

- 0 This bit has no effect on the ability to write to [CPACR.TRCDIS](#).
- 1 When executing in Non-secure state, [CPACR.TRCDIS](#) is RES1.

**Bit [19]**

Reserved, RES0.

**NSASEDIS, bit [15]**

Disable Non-secure Advanced SIMD functionality. The implementation of this bit must correspond to the implementation of the CPACR.ASEDIS bit.

If CPACR.ASEDIS is not RW then this bit is RES0.

If CPACR.ASEDIS is RW then this bit is RW and its possible values are:

- 0 This bit has no effect on the ability to write to CPACR.ASEDIS.
- 1 When executing in Non-secure state, CPACR.ASEDIS is RES1.

**Bits [14:12]**

Reserved, RES0.

**cp<n>, bit [n], for n = 10 to 11**

Enable Non-secure access to coprocessors 10 and 11, which control the Floating-point and Advanced SIMD features. Possible values of the fields are:

- 0 Coprocessor <n> can be accessed only from Secure state. Any attempt to access coprocessor <n> in Non-secure state results in an Undefined Instruction exception. If the processor is in Non-secure state, the corresponding bits in the CPACR ignore writes and read as 0b00, access denied.
- 1 Coprocessor <n> can be accessed from any security state.

If Non-secure access to a coprocessor is enabled, the CPACR must be checked to determine the level of access that is permitted.

The Floating-point and Advanced SIMD features controlled by these fields are:

- VFP floating-point instructions.
- Advanced SIMD instructions (both integer and floating-point).
- Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- FPSCR, FPSID, MVFR0, MVFR1, MVFR2, FPEXC system registers.

If the cp11 and cp10 fields are set to different values, the behavior is CONSTRAINED UNPREDICTABLE, and is the same as if both fields were set to the value of cp10, in all respects other than the value read back by explicitly reading cp11.

Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES0.

**Bits [9:0]**

Reserved, RES0.

**Accessing the NSACR:**

To access the NSACR:

MRC p15,0,<Rt>,c1,c1,2 ; Read NSACR into Rt  
MCR p15,0,<Rt>,c1,c1,2 ; Write Rt to NSACR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	010

## G4.2.107 PAR, Physical Address Register

The PAR characteristics are:

### Purpose

Receives the PA from any address translation operation.

This register is part of the Address translation operations functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as PAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as PAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

An implementation that does not support a cacheability attribute can report its corresponding behavior instead of the actual value in the translation table entry.

### Configurations

PAR(NS) is architecturally mapped to AArch64 register [PAR\\_EL1](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If the implementation includes the Large Physical Address Extension, the PAR is extended to be a 64-bit register and:

- The 64-bit PAR is used:
  - When using the Long-descriptor translation table format.
  - In an implementation that includes EL2, for the result of an ATSI Cxx operation performed from Hyp mode.
- The 32-bit PAR is used when using the Short-descriptor translation table format. In this case, PAR[63:32] is RES0.

Otherwise, the PAR is a 32-bit register.

### Attributes

PAR is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The PAR bit assignments are:

For all register layouts:

### F, bit [0]

Indicates whether the conversion completed successfully.

0 VA to PA conversion completed successfully.

1 VA to PA conversion aborted.

**When TTBCR.EAE==0, PAR.F==0:**

**PA, bits [31:12]**

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[31:12].

**LPAE, bit [11]**

When updating the PAR with the result of a translation operation, this bit is set as follows:

- 0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- 1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**NOS, bit [10]**

Not Outer Shareable attribute for the region. Indicates whether Shareable physical memory is Outer Shareable:

- 0 Memory is Outer Shareable.
- 1 Memory is not Outer Shareable.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry read from Secure state. This bit is UNKNOWN for a translation table entry read from Non-secure state.

**SH, bit [7]**

Shareable attribute for the region. Indicates whether the physical memory is Shareable:

- 0 Memory is Non-shareable.
- 1 Memory is Shareable.

**Inner[2:0], bits [6:4]**

Inner memory attributes for the region. Permitted values are:

- 000 Non-cacheable.
- 001 Strongly-ordered.
- 011 Device.
- 101 Write-Back, Write-Allocate.
- 110 Write-Through.
- 111 Write-Back, no Write-Allocate.

The values 0b010 and 0b100 are reserved.

An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

**Outer[1:0], bits [3:2]**

Outer memory attributes for the region. Permitted values are:

- 00 Non-cacheable.
- 01 Write-Back, Write-Allocate.
- 10 Write-Through, no Write-Allocate.
- 11 Write-Back, no Write-Allocate.

An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

**SS, bit [1]**

Supersection. Used to indicate if the result is a Supersection:

- 0 Page is not a Supersection. That is, PAR[31:12] contains PA[31:12], regardless of the page size.
- 1 Page is part of a Supersection:
  - PAR[31:24] contains PA[31:24].
  - PAR[23:16] contains PA[39:32].
  - PAR[15:12] contains 0b0000.

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.

**F, bit [0]**

Indicates whether the conversion completed successfully.

- 0 VA to PA conversion completed successfully.

**When TTBCR.EAE==0, PAR.F==1:**

**Bits [31:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of a translation operation, this bit is set as follows:

- 0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- 1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bits [10:7]**

Reserved, RES0.

**FS, bits [6:1]**

Fault status bits. Bits [12,10,3:0] from the **DFSR**, indicating the source of the abort.

**F, bit [0]**

Indicates whether the conversion completed successfully.

1 VA to PA conversion aborted.

**When TTBCR.EAE==1, PAR.F==0:**

**ATTR, bits [63:56]**

Memory attributes for the returned PA, as indicated by the translation table entry. This field uses the same encoding as the Attr<7:0> fields in **MAIRO** and **MAIR1**.

**Bits [55:40]**

Reserved, RES0.

**PA, bits [39:12]**

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[39:12].

**LPAE, bit [11]**

When updating the PAR with the result of a translation operation, this bit is set as follows:

- 0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- 1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry read from Secure state.

This bit is UNKNOWN for a translation table entry read from Non-secure state.

**SHA, bits [8:7]**

Shareability attribute, from the translation table entry for the returned PA. Permitted values are:

- 00 Non-shareable.
- 10 Outer Shareable.
- 11 Inner Shareable.

The value 0b01 is reserved.

Note: this takes the value 0b10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

**Bits [6:1]**

Reserved, RES0.

**F, bit [0]**

Indicates whether the conversion completed successfully.  
 0 VA to PA conversion completed successfully.

**When TTBCR.EAE==1, PAR.F==1:**

**Bits [63:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of a translation operation, this bit is set as follows:

- 0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- 1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bit [10]**

Reserved, RES0.

**FSTAGE, bit [9]**

Indicates the translation stage at which the translation aborted:

- 0 Translation aborted because of a fault in the stage 1 translation.
- 1 Translation aborted because of a fault in the stage 2 translation.

**S2WLK, bit [8]**

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

**Bit [7]**

Reserved, RES0.

**FST, bits [6:1]**

Fault status field. Values are as in the [DFSR.STATUS](#) and [IFSR.STATUS](#) fields (when using the Long-descriptor translation table format).

**F, bit [0]**

Indicates whether the conversion completed successfully.  
 1 VA to PA conversion aborted.

### Accessing the PAR:

To access the PAR when TTBCR.EAE==0:

MRC p15,0,<Rt>,c7,c4,0 ; Read PAR into Rt  
MCR p15,0,<Rt>,c7,c4,0 ; Write Rt to PAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0100	000

To access the PAR when TTBCR.EAE==1:

MRRC p15,0,<Rt>,<Rt2>,c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)  
MCRR p15,0,<Rt>,<Rt2>,c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	0111

## G4.2.108 PRRR, Primary Region Remap Register

The PRRR characteristics are:

### Purpose

Controls the top level mapping of the TEX[0], C, and B memory region attributes.  
This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as PRRR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as PRRR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Short-descriptor translation table format.

### Configurations

PRRR(NS) is architecturally mapped to AArch64 register [MAIR\\_EL1](#)[31:0] when TTBCR.EAE==0.

PRRR(S) can be mapped to AArch64 register [MAIR\\_EL3](#)[31:0] when TTBCR.EAE==0, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

PRRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

PRRR is a 32-bit register when TTBCR.EAE==0.

The PRRR bit assignments are:

**When TTBCR.EAE==0:**

**NOS<n>, bit [n+24], for n = 0 to 7**

NOS<n> is the Outer Shareable property mapping for memory attributes n, if the region is mapped as Normal or Device memory that is Shareable. n is the value of the TEX[0], C, and B bits concatenated. The possible values of each NOS<n> bit are:

- 0 Memory region is Outer Shareable.
- 1 Memory region is Inner Shareable.

The value of this bit is ignored if the region is Normal or Device memory that is not Shareable.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

If the implementation does not distinguish between Inner Shareable and Outer Shareable then these bits are reserved and are RES0.

**Bits [23:20]**

Reserved, RES0.

**NS1, bit [19]**

Mapping of S = 1 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 1.

The possible values of this bit are:

- 0 Region is not Shareable.
- 1 Region is Shareable.

**NS0, bit [18]**

Mapping of S = 0 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 0.

The possible values of this bit are:

- 0 Region is not Shareable.

1 Region is Shareable.

**DS1, bit [17]**

Mapping of S = 1 attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 1.

The possible values of this bit are:

0 Region is not Shareable.  
 1 Region is Shareable.

**DS0, bit [16]**

Mapping of S = 0 attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 0.

The possible values of this bit are:

0 Region is not Shareable.  
 1 Region is Shareable.

**TR<n>, bits [2n+1:2n], for n = 0 to 7**

TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Device-nGnRnE memory  
 01 Device-nGnRE memory  
 10 Normal memory

The value 0b11 is reserved.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

**Accessing the PRRR:**

To access the PRRR when TTBCR.EAE==0:

MRC p15,0,<Rt>,c10,c2,0 ; Read PRRR into Rt  
 MCR p15,0,<Rt>,c10,c2,0 ; Write Rt to PRRR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	000

## G4.2.109 REVIDR, Revision ID Register

The REVIDR characteristics are:

### Purpose

Provides implementation-specific minor revision information that can only be interpreted in conjunction with the Main ID Register.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

REVIDR is architecturally mapped to AArch64 register [REVIDR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

An optional register. When REVIDR is not implemented, its encoding is an alias of the [MIDR](#).

### Attributes

REVIDR is a 32-bit register.

The REVIDR bit assignments are:

### Accessing the REVIDR:

To access the REVIDR:

MRC p15,0,<Rt>,c0,c0,6 ; Read REVIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	110

### G4.2.110 RMR (at EL1), Reset Management Register

The RMR (at EL1) characteristics are:

**Purpose**

If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0	EL1
-	RW

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SSDISABLE, which prevents writing to this register when the CP15SSDISABLE signal is asserted.

**Configurations**

RMR (at EL1) is architecturally mapped to AArch64 register [RMR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Only implemented if this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

**Attributes**

RMR (at EL1) is a 32-bit register when EL2 and EL3 not implemented.

The RMR (at EL1) bit assignments are:

**When EL2 and EL3 not implemented:**

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

**AA64, bit [0]**

Determines which execution state the processor boots into after a Warm reset:

0        AArch32.

1        AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

### Accessing the RMR (at EL1):

To access the RMR (at EL1) when EL2 and EL3 not implemented:

MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt  
 MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	0000	010

### G4.2.111 RMR (at EL3), Reset Management Register

The RMR (at EL3) characteristics are:

**Purpose**

If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SSDISABLE, which prevents writing to this register when the CP15SSDISABLE signal is asserted.

**Configurations**

RMR (at EL3) is architecturally mapped to AArch64 register [RMR\\_EL3](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Only implemented if this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

**Attributes**

RMR (at EL3) is a 32-bit register when EL3 implemented.

The RMR (at EL3) bit assignments are:

**When EL3 implemented:**

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

**AA64, bit [0]**

Determines which execution state the processor boots into after a Warm reset:

0 AArch32.

1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

### Accessing the RMR (at EL3):

To access the RMR (at EL3) when EL3 implemented:

MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt  
MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	0000	010

### G4.2.112 RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

**Purpose**

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

This register is part of the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0	EL1	EL2
-	Config-RO	Config-RO

This register can only be read at the highest exception level implemented. It is UNDEFINED at all other exception levels.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is only implemented if the highest exception level implemented is not EL3 and can use AArch32. In such an implementation, whether this register is implemented is implementation defined. If RVBAR is not implemented its encoding is UNDEFINED.

**Attributes**

RVBAR is a 32-bit register.

The RVBAR bit assignments are:

**RVec, bits [31:1]**

Bits [31:1] of the IMPLEMENTATION DEFINED AArch32 reset address.

**Bit [0]**

Reserved, RES1.

**Accessing the RVBAR:**

To access the RVBAR:

MRC p15,0,<Rt>,c12,c0,1 ; Read RVBAR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	001

## G4.2.113 SCR, Secure Configuration Register

The SCR characteristics are:

### Purpose

Defines the configuration of the current security state. It specifies:

- The security state, either Secure or Non-secure.
- What mode the processor branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

This register is part of the Security registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

If EL3 is implemented and is using AArch64, any read or write to SCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

### Configurations

SCR can be mapped to AArch64 register [SCR\\_EL3](#), but this is not architecturally mandated.

This register is only accessible in Secure state.

### Attributes

SCR is a 32-bit register.

The SCR bit assignments are:

### Bits [31:14]

Reserved, RES0.

### TWE, bit [13]

Trap WFE. The possible values of this bit are:

- 0 WFE instructions are not trapped.

- 1 WFE instructions executed in any mode other than Monitor mode are trapped to Monitor mode as UNDEFINED if the instruction would otherwise cause suspension of execution, i.e. if the event register is not set, there is not a pending WFE wakeup event, and the instruction does not cause another exception.

Conditional WFE instructions that fail their condition do not cause an exception by this mechanism.  
Resets to 0.

**TWI, bit [12]**

Trap WFI. The possible values of this bit are:

- 0 WFI instructions are not trapped.
- 1 WFI instructions executed in any mode other than Monitor mode are trapped to Monitor mode as UNDEFINED if the instruction would otherwise cause suspension of execution.

Conditional WFI instructions that fail their condition do not cause an exception by this mechanism.  
Resets to 0.

**Bits [11:10]**

Reserved, RES0.

**SIF, bit [9]**

Secure instruction fetch. When the processor is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

- 0 Secure state instruction fetches from Non-secure memory are permitted.
- 1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.  
Resets to 0.

**HCE, bit [8]**

Hypervisor Call enable. This bit enables use of the HVC instruction from Non-secure EL1 modes. The possible values of this bit are:

- 0 HVC instruction is UNDEFINED in Non-secure EL1 modes, and either UNDEFINED or a NOP in Hyp mode, depending on the implementation.
  - 1 HVC instruction is enabled in Non-secure EL1 modes, and performs a Hypervisor Call.
- If EL3 is implemented but EL2 is not implemented, this bit is RES0.

Resets to 0.

**SCD, bit [7]**

Secure Monitor Call disable. Makes the SMC instruction UNDEFINED in Non-secure state. The possible values of this bit are:

- 0 SMC executes normally in Non-secure state, performing a Secure Monitor Call.
- 1 SMC instruction is either UNDEFINED or a NOP in Non-secure state, depending on the implementation.

A trap of the SMC instruction to Hyp mode takes priority over the value of this bit.  
Resets to 0.

**nET, bit [6]**

Not Early Termination. This bit disables early termination. The possible values of this bit are:

- 0 Early termination permitted. Execution time of data operations can depend on the data values.
- 1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

Resets to 0.

#### AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

- 0 External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.  
External aborts taken from Secure state are masked by CPSR.A.
- 1 External aborts taken from either security state are masked by CPSR.A. When CPSR.A is 0, the abort is taken to EL3.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

Resets to 0.

#### FW, bit [4]

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

- 0 An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.  
An FIQ taken from Secure state is masked by CPSR.F.
- 1 An FIQ taken from either security state is masked by CPSR.F. When CPSR.F is 0, the FIQ is taken to EL3.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

Resets to 0.

#### EA, bit [3]

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

- 0 External aborts taken in Abort mode.
- 1 External aborts taken in Monitor mode.

Resets to 0.

#### FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

- 0 FIQs taken in FIQ mode.
- 1 FIQs taken in Monitor mode.

Resets to 0.

#### IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

- 0 IRQs taken in IRQ mode.
- 1 IRQs taken in Monitor mode.

Resets to 0.

#### NS, bit [0]

Non-secure bit. Except when the processor is in Monitor mode, this bit determines the security state of the processor:

- 0 Processor is in Secure state.
- 1 Processor is in Non-secure state.

If the [HCR.TGE](#) bit is set, an attempt to change from a Secure Kernel mode to a Non-secure Kernel mode by changing the SCR.NS bit from 0 to 1 will result in the SCR.NS bit remaining as 0.  
Resets to 0.

### Accessing the SCR:

To access the SCR:

MRC p15,0,<Rt>,c1,c1,0 ; Read SCR into Rt  
MCR p15,0,<Rt>,c1,c1,0 ; Write Rt to SCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	000

## G4.2.114 SCTLR, System Control Register

The SCTLR characteristics are:

### Purpose

Provides the top level control of the system, including its memory system.  
This register is part of the Other system control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as SCTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as SCTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

### Configurations

SCTLR(NS) is architecturally mapped to AArch64 register [SCTLR\\_EL1](#).

SCTLR(S) can be mapped to AArch64 register [SCTLR\\_EL3](#), but this is not architecturally mandated.

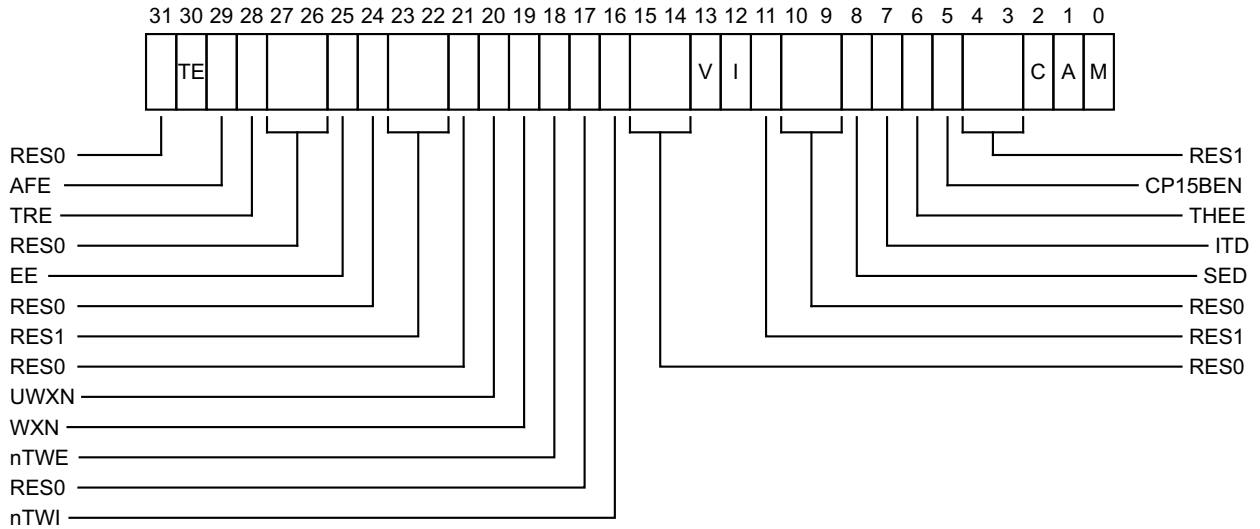

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

SCTLR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

SCTLR is a 32-bit register.

The SCTLR bit assignments are:

**Bit [31]**

Reserved, RES0.

**TE, bit [30]**

Thumb Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:

- 0 Exceptions, including reset, taken in A32 state.
- 1 Exceptions, including reset, taken in T32 state.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**AFE, bit [29]**

Access Flag Enable. When using the Short-descriptor translation table format, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

- 0 In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.
- 1 In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**TRE, bit [28]**

TEX remap enable. This bit enables remapping of the TEX[2:1] bits for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

- 0 TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.

1 TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

The TRE bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bits [27:26]**

Reserved, RES0.

**EE, bit [25]**

Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bit [24]**

Reserved, RES0.

**Bits [23:22]**

Reserved, RES1.

**Bit [21]**

Reserved, RES0.

**UWXN, bit [20]**

Unprivileged write permission implies EL1 XN (Execute Never). This bit can be used to require all memory regions with unprivileged write permissions to be treated as XN for accesses from software executing at EL1. The possible values of this bit are:

0 Regions with unprivileged write permission are not forced to XN.

1 Regions with unprivileged write permission are forced to XN for accesses from software executing at EL1.

The UWXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 0.

**WXN, bit [19]**

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 0.

**nTWE, bit [18]**

Not trap WFE. Possible values of this bit are:

- 0 If a WFE instruction executed at EL0 would cause execution to be suspended, such as if the event register is not set and there is not a pending WFE wakeup event, it is treated as UNDEFINED.
- 1 WFE instructions are executed as normal.

Conditional WFE instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field resets to 1.

**Bit [17]**

Reserved, RES0.

**nTWI, bit [16]**

Not trap WFI. Possible values of this bit are:

- 0 If a WFI instruction executed at EL0 would cause execution to be suspended, such as if there is not a pending WFI wakeup event, it is treated as UNDEFINED.
- 1 WFI instructions are executed as normal.

Conditional WFI instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field resets to 1.

**Bits [15:14]**

Reserved, RES0.

**V, bit [13]**

Vectors bit. This bit selects the base address of the exception vectors:

- 0 Normal exception vectors, base address 0x00000000. In an implementation that includes EL3, this base address can be re-mapped.
- 1 High exception vectors (Hivecs), base address 0xFFFF0000. This base address is never remapped.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**I, bit [12]**

Instruction cache enable. This is a global enable bit for instruction caches:

- 0 Instruction caches disabled. If SCTL.R.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- 1 Instruction caches enabled. If SCTL.R.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all Normal memory instruction accesses are Non-cacheable.

If the HCR.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of this bit.

For the Secure copy of this register, the field if this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bit [11]**

Reserved, RES1.

**Bits [10:9]**

Reserved, RES0.

**SED, bit [8]**

SETEND Disable. The possible values of this bit are:

- 0 The SETEND instruction is available.
- 1 The SETEND instruction is UNALLOCATED.

If an implementation does not support mixed endian operation, this bit is RES1.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 1.

**ITD, bit [7]**

IT Disable. The possible values of this bit are:

- 0 The IT instruction functionality is available.
- 1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:
  - A 16-bit instruction, which can only be followed by another 16-bit instruction.
  - The first half of a 32-bit instruction.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with hw1[3:0]!=1000 are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):

11xxxxxxxxxxxx

All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

1x11xxxxxxxxxxxx

Miscellaneous 16-bit instructions

1x100xxxxxxxxxxx

ADD Rd, PC, #imm

01001xxxxxxxxxxx

LDR Rd, [PC, #imm]

0100x1xxx1111xxx

ADD(4),CMP(3), MOV, BX pc, BLX pc

010001xx1xxx111

ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)

Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 0.

**THEE, bit [6]**

T32EE enable. The possible values of this bit are:

- 0 T32EE is disabled.
- 1 T32EE is enabled.

If T32EE is not implemented, this bit is RES0.

For the Secure copy of this register, the field resets to 1 if T32EE is implemented. Otherwise, its reset value is UNKNOWN.

For the Non-secure copy of this register, the field resets to 1 if T32EE is implemented. Otherwise, its reset value is UNKNOWN.

#### **CP15BEN, bit [5]**

CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL0 and EL1:

0 CP15 barrier operations disabled at EL0 and EL1. Their encodings are UNDEFINED.

1 CP15 barrier operations enabled at EL0 and EL1.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field resets to 1.

#### **Bits [4:3]**

Reserved, RES1.

#### **C, bit [2]**

Cache enable. This is a global enable bit for data and unified caches:

0 Data and unified caches disabled.

1 Data and unified caches enabled.

When this bit is 0, all Normal memory data accesses and all accesses to the EL1&0 stage 1 translation tables are Non-cacheable.

If the HCR.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of the SCTLR.C bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

#### **A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

#### **M, bit [0]**

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0 EL1 and EL0 stage 1 address translation disabled.

1 EL1 and EL0 stage 1 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with SCTLR.M being 0, regardless of the actual value of SCTLR.M, other than the value returned by an explicit read of SCTLR.M.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

### Accessing the SCTLR:

To access the SCTLR:

MRC p15,0,<Rt>,c1,c0,0 ; Read SCTLR into Rt

MCR p15,0,<Rt>,c1,c0,0 ; Write Rt to SCTLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0001	0000	000

## G4.2.115 SPSR, Saved Program Status Register

The SPSR characteristics are:

### Purpose

Holds the saved processor state for the current mode.

### Usage constraints

The SPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more information see [MRS on page F7-2720](#), [MSR \(immediate\) on page F7-2722](#), and [MSR \(register\) on page F7-2724](#).

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR is a 32-bit register.

The SPSR bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to the current mode, and copied to [CPSR.N](#) on executing an exception return operation in the current mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to the current mode, and copied to [CPSR.Z](#) on executing an exception return operation in the current mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to the current mode, and copied to [CPSR.C](#) on executing an exception return operation in the current mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to the current mode, and copied to [CPSR.V](#) on executing an exception return operation in the current mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to the current mode, and copied to [CPSR.Q](#) on executing an exception return operation in the current mode.

### IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

### J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

### T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

### M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

### M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

## G4.2.116 SPSR\_abt, Saved Program Status Register (Abort mode)

The SPSR\_abt characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to Abort mode.

This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !ABT)	EL1 (S, !ABT)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.

### Configurations

SPSR\_abt is architecturally mapped to AArch64 register [SPSR\\_abt](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_abt is a 32-bit register.

The SPSR\_abt bit assignments are:

#### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Abort mode, and copied to [CPSR.N](#) on executing an exception return operation in Abort mode.

#### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Abort mode, and copied to [CPSR.Z](#) on executing an exception return operation in Abort mode.

#### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Abort mode, and copied to [CPSR.C](#) on executing an exception return operation in Abort mode.

#### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Abort mode, and copied to [CPSR.V](#) on executing an exception return operation in Abort mode.

#### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Abort mode, and copied to [CPSR.Q](#) on executing an exception return operation in Abort mode.

**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_abt:**

To access the SPSR\_abt:

MRS <Rd>, SPSR\_abt ; Read SPSR\_abt into Rd  
MSR SPSR\_abt, <Rd> ; Write Rd to SPSR\_abt

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	0100	1

## G4.2.117 SPSR\_fiq, Saved Program Status Register (FIQ mode)

The SPSR\_fiq characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to FIQ mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !FIQ)	EL1 (S, !FIQ)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.

### Configurations

SPSR\_fiq is architecturally mapped to AArch64 register [SPSR\\_fiq](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_fiq is a 32-bit register.

The SPSR\_fiq bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to FIQ mode, and copied to [CPSR.N](#) on executing an exception return operation in FIQ mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to FIQ mode, and copied to [CPSR.Z](#) on executing an exception return operation in FIQ mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to FIQ mode, and copied to [CPSR.C](#) on executing an exception return operation in FIQ mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to FIQ mode, and copied to [CPSR.V](#) on executing an exception return operation in FIQ mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to FIQ mode, and copied to [CPSR.Q](#) on executing an exception return operation in FIQ mode.

**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- |   |   |
|---|---|
| 0 | Processor in A32 state if T is 0, or T32 state if T is 1.                                       |
| 1 | Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1. |

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- |   |                         |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation.   |

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- |   |                       |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked.     |

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_fiq:**

To access the SPSR\_fiq:

MRS <Rd>, SPSR\_fiq ; Read SPSR\_fiq into Rd  
MSR SPSR\_fiq, <Rd> ; Write Rd to SPSR\_fiq

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
0	1110	1

## G4.2.118 SPSR\_hyp, Saved Program Status Register (Hyp mode)

The SPSR\_hyp characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to Hyp mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

### Configurations

SPSR\_hyp is architecturally mapped to AArch64 register [SPSR\\_EL2](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_hyp is a 32-bit register.

The SPSR\_hyp bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Hyp mode, and copied to [CPSR.N](#) on executing an exception return operation in Hyp mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Hyp mode, and copied to [CPSR.Z](#) on executing an exception return operation in Hyp mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Hyp mode, and copied to [CPSR.C](#) on executing an exception return operation in Hyp mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Hyp mode, and copied to [CPSR.V](#) on executing an exception return operation in Hyp mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Hyp mode, and copied to [CPSR.Q](#) on executing an exception return operation in Hyp mode.

### IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

### J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

### Bits [23:21]

Reserved, RES0.

### IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

### GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

### IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

### E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

### A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<b>M[3:0]</b>	<b>Mode</b>
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_hyp:**

To access the SPSR\_hyp:

MRS <Rd>, SPSR\_hyp ; Read SPSR\_hyp into Rd  
MSR SPSR\_hyp, <Rd> ; Write Rd to SPSR\_hyp

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	1110	1

## G4.2.119 SPSR\_irq, Saved Program Status Register (IRQ mode)

The SPSR\_irq characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to IRQ mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !IRQ)	EL1 (S, !IRQ)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.

### Configurations

SPSR\_irq is architecturally mapped to AArch64 register [SPSR\\_irq](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_irq is a 32-bit register.

The SPSR\_irq bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to IRQ mode, and copied to [CPSR.N](#) on executing an exception return operation in IRQ mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to IRQ mode, and copied to [CPSR.Z](#) on executing an exception return operation in IRQ mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to IRQ mode, and copied to [CPSR.C](#) on executing an exception return operation in IRQ mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to IRQ mode, and copied to [CPSR.V](#) on executing an exception return operation in IRQ mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to IRQ mode, and copied to [CPSR.Q](#) on executing an exception return operation in IRQ mode.

**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- |   |   |
|---|---|
| 0 | Processor in A32 state if T is 0, or T32 state if T is 1.                                       |
| 1 | Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1. |

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- |   |                         |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation.   |

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- |   |                       |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked.     |

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<b>M[3:0]</b>	<b>Mode</b>
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_irq:**

To access the SPSR\_irq:

MRS <Rd>, SPSR\_irq ; Read SPSR\_irq into Rd  
MSR SPSR\_irq, <Rd> ; Write Rd to SPSR\_irq

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	0000	1

## G4.2.120 SPSR\_mon, Saved Program Status Register (Monitor mode)

The SPSR\_mon characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to Monitor mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	-

### Configurations

SPSR\_mon can be mapped to AArch64 register [SPSR\\_EL3](#), but this is not architecturally mandated.

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_mon is a 32-bit register.

The SPSR\_mon bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Monitor mode, and copied to [CPSR.N](#) on executing an exception return operation in Monitor mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Monitor mode, and copied to [CPSR.Z](#) on executing an exception return operation in Monitor mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Monitor mode, and copied to [CPSR.C](#) on executing an exception return operation in Monitor mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Monitor mode, and copied to [CPSR.V](#) on executing an exception return operation in Monitor mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Monitor mode, and copied to [CPSR.Q](#) on executing an exception return operation in Monitor mode.

### IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

### J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

### Bits [23:21]

Reserved, RES0.

### IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

### GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

### IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

### E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

### A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_mon:**

To access the SPSR\_mon:

MRS <Rd>, SPSR\_mon ; Read SPSR\_mon into Rd  
MSR SPSR\_mon, <Rd> ; Write Rd to SPSR\_mon

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	1100	1

## G4.2.121 SPSR\_svc, Saved Program Status Register (Sup. Call mode)

The SPSR\_svc characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to Supervisor mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, ISVC)	EL1 (S, ISVC)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.

### Configurations

SPSR\_svc is architecturally mapped to AArch64 register [SPSR\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_svc is a 32-bit register.

The SPSR\_svc bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Supervisor mode, and copied to [CPSR.N](#) on executing an exception return operation in Supervisor mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Supervisor mode, and copied to [CPSR.Z](#) on executing an exception return operation in Supervisor mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Supervisor mode, and copied to [CPSR.C](#) on executing an exception return operation in Supervisor mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Supervisor mode, and copied to [CPSR.V](#) on executing an exception return operation in Supervisor mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Supervisor mode, and copied to [CPSR.Q](#) on executing an exception return operation in Supervisor mode.

**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- |   |   |
|---|---|
| 0 | Processor in A32 state if T is 0, or T32 state if T is 1.                                       |
| 1 | Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1. |

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- |   |                         |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation.   |

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- |   |                       |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked.     |

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_svc:**

To access the SPSR\_svc:

MRS <Rd>, SPSR\_svc ; Read SPSR\_svc into Rd  
MSR SPSR\_svc, <Rd> ; Write Rd to SPSR\_svc

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	0010	1

## G4.2.122 SPSR\_und, Saved Program Status Register (Undefined mode)

The SPSR\_und characteristics are:

### Purpose

Holds the saved processor state when an exception is taken to Undefined mode.  
This register is part of the Special purpose registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !UND)	EL1 (S, !UND)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.

### Configurations

SPSR\_und is architecturally mapped to AArch64 register [SPSR\\_und](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

SPSR\_und is a 32-bit register.

The SPSR\_und bit assignments are:

### N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Undefined mode, and copied to [CPSR.N](#) on executing an exception return operation in Undefined mode.

### Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Undefined mode, and copied to [CPSR.Z](#) on executing an exception return operation in Undefined mode.

### C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Undefined mode, and copied to [CPSR.C](#) on executing an exception return operation in Undefined mode.

### V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Undefined mode, and copied to [CPSR.V](#) on executing an exception return operation in Undefined mode.

### Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Undefined mode, and copied to [CPSR.Q](#) on executing an exception return operation in Undefined mode.

**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the SPSR\_und:**

To access the SPSR\_und:

MRS <Rd>, SPSR\_und ; Read SPSR\_und into Rd  
MSR SPSR\_und, <Rd> ; Write Rd to SPSR\_und

Register access is encoded as follows:

<b>m</b>	<b>m1</b>	<b>R</b>
1	0110	1

## G4.2.123 TCMTR, TCM Type Register

The TCMTR characteristics are:

### Purpose

Provides information about the implementation of the TCM.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

TCMTR is a 32-bit register.

The TCMTR bit assignments are:

For all register layouts:

### Format, bits [31:29]

Indicates the implemented TCMTR format. The possible values of this are:

000 ARMv6 format, or no TCMs implemented.

100 ARMv7 format.

Other values are reserved.

### When TCMTR.Format==0b000:

31	29 28	19 18	16 15	3 2	0
Format	UNKNOWN	RES0	UNKNOWN	RES0	RES0

### Format, bits [31:29]

Indicates the implemented TCMTR format. The possible values of this are:

000 ARMv6 format, or no TCMs implemented.

Other values are reserved.

### Bits [18:16]

Reserved, RES0.

### Bits [2:0]

Reserved, RES0.

**When TCMTR.Format==0b100:**

**Format, bits [31:29]**

Indicates the implemented TCMTR format. The possible values of this are:

100          ARMv7 format.

Other values are reserved.

**Accessing the TCMTR:**

To access the TCMTR:

MRC p15,0,<Rt>,c0,c0,2 ; Read TCMTR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	010

## G4.2.124 TEECR, T32EE Configuration Register

The TEECR characteristics are:

### Purpose

A T32EE register. Controls unprivileged access to the [TEEHBR](#).

This register is part of the Legacy feature registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

### Configurations

TEECR is architecturally mapped to AArch64 register [TEECR32\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is implemented in any system that implements T32EE.

It is optional in ARMv8, and is UNDEFINED when T32EE is not implemented, or when SCTLR.THEE is 0.

### Attributes

TEECR is a 32-bit register.

The TEECR bit assignments are:

### Bits [31:1]

Reserved, RES0.

### XED, bit [0]

Execution Environment Disable bit. Control unprivileged access to [TEEHBR](#):

0 Unprivileged access permitted.

1 Unprivileged access disabled.

The effects of a write to this register on T32EE configuration are only guaranteed to be visible to subsequent instructions after the execution of a context synchronization operation. However, a read of this register always returns the value most recently written to the register.

Resets to 0.

### Accessing the TEECR:

To access the TEECR:

```
MRC p14,6,<Rt>,c0,c0,0 ; Read TEECR into Rt
MCR p14,6,<Rt>,c0,c0,0 ; Write Rt to TEECR
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	110	0000	0000	000

## G4.2.125 TEEHBR, T32EE Handler Base Register

The TEEHBR characteristics are:

### Purpose

A T32EE register. Holds the base address for T32EE handlers.

This register is part of the Legacy feature registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

### Configurations

TEEHBR is architecturally mapped to AArch64 register [TEEHBR32\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented in any system that implements T32EE.

This register is optional in ARMv8, and is UNDEFINED when not implemented, or when disabled by [SCTLR.THEE](#).

### Attributes

TEEHBR is a 32-bit register.

The TEEHBR bit assignments are:

### HandlerBase, bits [31:2]

The address of the T32EE Handler\_00 implementation. This is the address of the first of the T32EE handlers.

### Bits [1:0]

Reserved, RES0.

### Accessing the TEEHBR:

To access the TEEHBR:

MRC p14,6,<Rt>,c1,c0,0 ; Read TEEHBR into Rt  
MCR p14,6,<Rt>,c1,c0,0 ; Write Rt to TEEHBR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	110	0001	0000	000

## G4.2.126 TLBIALL, TLB Invalidate All entries

The TLBIALL characteristics are:

### Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID.  
 This register is part of the TLB maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

### Configurations

There are no configuration notes.

### Attributes

TLBIALL is a 32-bit system operation.

The TLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the TLBIALL operation:

To perform the TLBIALL operation:

MCR p15,0,<Rt>,c8,c7,0 ; TLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	000

## G4.2.127 TLBIALLH, TLB Invalidate All entries, Hyp mode

The TLBIALLH characteristics are:

### Purpose

Invalidate all EL2 regime stage 1 TLB entries.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is **CONSTRAINED UNPREDICTABLE** and may be one of the following:

- The operation is **UNDEFINED**.
- The operation is treated as a **NOP**.
- The operation is executed as if it had been executed in Monitor mode.

### Configurations

There are no configuration notes.

### Attributes

TLBIALLH is a 32-bit system operation.

The TLBIALLH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the TLBIALLH operation:

To perform the TLBIALLH operation:

MCR p15,4,<Rt>,c8,c7,0 ; TLBIALLH operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	000

## G4.2.128 TLBIALLHIS, TLB Invalidate All entries, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

### Purpose

Invalidate all EL2 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

### Configurations

There are no configuration notes.

### Attributes

TLBIALLHIS is a 32-bit system operation.

The TLBIALLHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the TLBIALLHIS operation:

To perform the TLBIALLHIS operation:

MCR p15,4,<Rt>,c8,c3,0 ; TLBIALLHIS operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	000

## G4.2.129 TLBIALLIS, TLB Invalidate All entries, Inner Shareable

The TLBIALLIS characteristics are:

### Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

### Configurations

There are no configuration notes.

### Attributes

TLBIALLIS is a 32-bit system operation.

The TLBIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

### Performing the TLBIALLIS operation:

To perform the TLBIALLIS operation:

MCR p15,0,<Rt>,c8,c3,0 ; TLBIALLIS operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	000

### G4.2.130 TLBIALLNSNH, TLB Invalidate All entries, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

**Purpose**

Invalidate all Non-secure EL1&0 regime stage 1 and 2 TLB entries.  
 This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLNSNH is a 32-bit system operation.

The TLBIALLNSNH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLNSNH operation:**

To perform the TLBIALLNSNH operation:

MCR p15,4,<Rt>,c8,c7,4 ; TLBIALLNSNH operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	100

### G4.2.131 TLBIALLNSNHIS, TLB Invalidate All entries, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

#### Purpose

Invalidate all Non-secure EL1&0 regime stage 1 and 2 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIALLNSNHIS is a 32-bit system operation.

The TLBIALLNSNHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

#### Performing the TLBIALLNSNHIS operation:

To perform the TLBIALLNSNHIS operation:

MCR p15,4,<Rt>,c8,c3,4 ; TLBIALLNSNHIS operation, ignoring the value in Rt

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	100

### G4.2.132 TLBIASID, TLB Invalidate entry by ASID match

The TLBIASID characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID.  
This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIASID is a 32-bit system operation.

The TLBIASID input value bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

#### Performing the TLBIASID operation:

To perform the TLBIASID operation:

MCR p15,0,<Rt>,c8,c7,2 ; TLBIASID operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	010

### G4.2.133 TLBIASIDIS, TLB Invalidate entry by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIASIDIS is a 32-bit system operation.

The TLBIASIDIS input value bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

#### Performing the TLBIASIDIS operation:

To perform the TLBIASIDIS operation:

MCR p15,0,<Rt>,c8,c3,2 ; TLBIASIDIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	010

### G4.2.134 TLBIIPAS2, TLB Invalidate entry by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

#### Configurations

This operation is not implemented in architecture versions before ARMv8.

#### Attributes

TLBIIPAS2 is a 32-bit system operation.

The TLBIIPAS2 input value bit assignments are:

#### Bits [31:28]

Reserved, RES0.

#### IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

#### Performing the TLBIIPAS2 operation:

To perform the TLBIIPAS2 operation:

MCR p15,4,<Rt>,c8,c4,1 ; TLBIIPAS2 operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0100	001

## G4.2.135 TLBIIPAS2IS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

### Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

### Configurations

This operation is not implemented in architecture versions before ARMv8.

### Attributes

TLBIIPAS2IS is a 32-bit system operation.

The TLBIIPAS2IS input value bit assignments are:

### Bits [31:28]

Reserved, RES0.

### IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

### Performing the TLBIIPAS2IS operation:

To perform the TLBIIPAS2IS operation:

MCR p15,4,<Rt>,c8,c0,1 ; TLBIIPAS2IS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0000	001

### G4.2.136 TLBIIPAS2L, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level

The TLBIIPAS2L characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2L is a 32-bit system operation.

The TLBIIPAS2L input value bit assignments are:

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Performing the TLBIIPAS2L operation:**

To perform the TLBIIPAS2L operation:

MCR p15,4,<Rt>,c8,c4,5 ; TLBIIPAS2L operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0100	101

### G4.2.137 TLBIIPAS2LIS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

#### Configurations

This operation is not implemented in architecture versions before ARMv8.

#### Attributes

TLBIIPAS2LIS is a 32-bit system operation.

The TLBIIPAS2LIS input value bit assignments are:

#### Bits [31:28]

Reserved, RES0.

#### IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

#### Performing the TLBIIPAS2LIS operation:

To perform the TLBIIPAS2LIS operation:

MCR p15,4,<Rt>,c8,c0,5 ; TLBIIPAS2LIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0000	101

### G4.2.138 TLBIMVA, TLB Invalidate entry by VA

The TLBIMVA characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVA is a 32-bit system operation.

The TLBIMVA input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVA operation:**

To perform the TLBIMVA operation:

MCR p15,0,<Rt>,c8,c7,1 ; TLBIMVA operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	001

### G4.2.139 TLBIMVAA, TLB Invalidate entry by VA, All ASID

The TLBIMVAA characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID.  
This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIMVAA is a 32-bit system operation.

The TLBIMVAA input value bit assignments are:

#### VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

#### Bits [11:0]

Reserved, RES0.

#### Performing the TLBIMVAA operation:

To perform the TLBIMVAA operation:

MCR p15,0,<Rt>,c8,c7,3 ; TLBIMVAA operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	011

### G4.2.140 TLBIMVAAIS, TLB Invalidate entry by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAAIS is a 32-bit system operation.

The TLBIMVAAIS input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVAAIS operation:**

To perform the TLBIMVAAIS operation:

MCR p15,0,<Rt>,c8,c3,3 ; TLBIMVAAIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	011

### G4.2.141 TLBIMVAAL, TLB Invalidate entry by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

#### Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID.

This register is part of the TLB maintenance operations functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

#### Configurations

This operation is not implemented in architecture versions before ARMv8.

#### Attributes

TLBIMVAAL is a 32-bit system operation.

The TLBIMVAAL input value bit assignments are:

#### VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

#### Bits [11:0]

Reserved, RES0.

#### Performing the TLBIMVAAL operation:

To perform the TLBIMVAAL operation:

MCR p15,0,<Rt>,c8,c7,7 ; TLBIMVAAL operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	111

### G4.2.142 TLBIMVAALIS, TLB Invalidate entry by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVAALIS is a 32-bit system operation.

The TLBIMVAALIS input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVAALIS operation:**

To perform the TLBIMVAALIS operation:

MCR p15,0,<Rt>,c8,c3,7 ; TLBIMVAALIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	111

### G4.2.143 TLBIMVAH, TLB Invalidate entry by VA, Hyp mode

The TLBIMVAH characteristics are:

#### Purpose

Invalidate EL2 regime stage 1 TLB entries for the given VA.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIMVAH is a 32-bit system operation.

The TLBIMVAH input value bit assignments are:

#### VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

#### Bits [11:0]

Reserved, RES0.

#### Performing the TLBIMVAH operation:

To perform the TLBIMVAH operation:

MCR p15,4,<Rt>,c8,c7,1 ; TLBIMVAH operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	001

### G4.2.144 TLBIMVAHIS, TLB Invalidate entry by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

#### Purpose

Invalidate EL2 regime stage 1 TLB entries for the given VA on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIMVAHIS is a 32-bit system operation.

The TLBIMVAHIS input value bit assignments are:

#### VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

#### Bits [11:0]

Reserved, RES0.

#### Performing the TLBIMVAHIS operation:

To perform the TLBIMVAHIS operation:

MCR p15,4,<Rt>,c8,c3,1 ; TLBIMVAHIS operation

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1000	0011	001

### G4.2.145 TLBIMVAIS, TLB Invalidate entry by VA, Inner Shareable

The TLBIMVAIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAIS is a 32-bit system operation.

The TLBIMVAIS input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVAIS operation:**

To perform the TLBIMVAIS operation:

MCR p15,0,<Rt>,c8,c3,1 ; TLBIMVAIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	001

## G4.2.146 TLBIMVAL, TLB Invalidate entry by VA, Last level

The TLBIMVAL characteristics are:

### Purpose

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID.

This register is part of the TLB maintenance operations functional group.

### Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

### Configurations

This operation is not implemented in architecture versions before ARMv8.

### Attributes

TLBIMVAL is a 32-bit system operation.

The TLBIMVAL input value bit assignments are:

### VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

### Bits [11:8]

Reserved, RES0.

### ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

### Performing the TLBIMVAL operation:

To perform the TLBIMVAL operation:

MCR p15,0,<Rt>,c8,c7,5 ; TLBIMVAL operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	101

### G4.2.147 TLBINVALH, TLB Invalidate entry by VA, Last level, Hyp mode

The TLBINVALH characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBINVALH is a 32-bit system operation.

The TLBINVALH input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBINVALH operation:**

To perform the TLBINVALH operation:

MCR p15,4,<Rt>,c8,c7,5 ; TLBINVALH operation

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1000	0111	101

### G4.2.148 TLBIMVALHIS, TLB Invalidate entry by VA, Last level, Hyp mode, Inner Shareable

The TLBIMVALHIS characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONstrained UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALHIS is a 32-bit system operation.

The TLBIMVALHIS input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVALHIS operation:**

To perform the TLBIMVALHIS operation:

MCR p15,4,<Rt>,c8,c3,5 ; TLBIMVALHIS operation

The operation is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1000	0011	101

### G4.2.149 TLBIMVALIS, TLB Invalidate entry by VA, Last level, Inner Shareable

The TLBIMVALIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALIS is a 32-bit system operation.

The TLBIMVALIS input value bit assignments are:

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVALIS operation:**

To perform the TLBIMVALIS operation:

MCR p15,0,<Rt>,c8,c3,5 ; TLBIMVALIS operation

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	101

## G4.2.150 TLBTR, TLB Type Register

The TLBTR characteristics are:

### Purpose

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

TLBTR is a 32-bit register.

The TLBTR bit assignments are:

### nU, bit [0]

Not Unified TLB. Indicates whether the implementation has a unified TLB:

- 0 Unified TLB.
- 1 Separate Instruction and Data TLBs.

### Accessing the TLBTR:

To access the TLBTR:

MRC p15,0,<Rt>,c0,c0,3 ; Read TLBTR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	011

### G4.2.151 TPIDRPRW, Thread Pointer / ID Register, Privileged Read-Write

The TPIDRPRW characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TPIDRPRW(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TPIDRPRW(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Processor hardware never updates this register.

**Configurations**

TPIDRPRW(NS) is architecturally mapped to AArch64 register [TPIDR\\_EL1](#)[31:0].

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

TPIDRPRW is a 32-bit register.

The TPIDRPRW bit assignments are:

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this exception level.

**Accessing the TPIDRPRW:**

To access the TPIDRPRW:

```
MRC p15,0,<Rt>,c13,c0,4 ; Read TPIDRPRW into Rt
MCR p15,0,<Rt>,c13,c0,4 ; Write Rt to TPIDRPRW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	100

## G4.2.152 TPIDRURO, Thread Pointer / ID Register, Unprivileged Read-Only

The TPIDRURO characteristics are:

### Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as TPIDRURO(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	-	RW	-	-	RW

When accessed as TPIDRURO(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	-	RW	-	RW	RW	-

Processor hardware never updates this register.

### Configurations

TPIDRURO(NS) is architecturally mapped to AArch64 register [TPIDRRO\\_EL0](#)[31:0].

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

TPIDRURO is a 32-bit register.

The TPIDRURO bit assignments are:

### Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

### Accessing the TPIDRURO:

To access the TPIDRURO:

MRC p15,0,<Rt>,c13,c0,3 ; Read TPIDRURO into Rt  
MCR p15,0,<Rt>,c13,c0,3 ; Write Rt to TPIDRURO

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	011

### G4.2.153 TPIDRURW, Thread Pointer / ID Register, Unprivileged Read-Write

The TPIDRURW characteristics are:

**Purpose**

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TPIDRURW(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	RW	-	-	RW

When accessed as TPIDRURW(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	-	RW	RW	-

Processor hardware never updates this register.

**Configurations**

TPIDRURW(NS) is architecturally mapped to AArch64 register [TPIDR\\_EL0](#)[31:0].

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

TPIDRURW is a 32-bit register.

The TPIDRURW bit assignments are:

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this exception level.

**Accessing the TPIDRURW:**

To access the TPIDRURW:

```
MRC p15,0,<Rt>,c13,c0,2 ; Read TPIDRURW into Rt
MCR p15,0,<Rt>,c13,c0,2 ; Write Rt to TPIDRURW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	010

## G4.2.154 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

### Purpose

Determines which of the Translation Table Base Registers defined the base address for a translation table walk required for the stage 1 translation of a memory access from any mode other than Hyp mode. Also controls the translation table format and, when using the Long-descriptor translation table format, holds cacheability and shareability information.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as TTBCR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBCR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

### Configurations

TTBCR(NS) is architecturally mapped to AArch64 register [TCR\\_EL1](#)[31:0].

TTBCR(S) can be mapped to AArch64 register [TCR\\_EL3](#)[31:0], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

TTBCR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

TTBCR is a 32-bit register.

The TTBCR bit assignments are:

For all register layouts:

#### EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

- 0 Use the 32-bit translation system, with the Short-descriptor translation table format.
- 1 Use the 40-bit translation system, with the Long-descriptor translation table format.

**When TTBCR.EAE==0:**

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

0 Use the 32-bit translation system, with the Short-descriptor translation table format.

Resets to 0.

**Bits [30:6]**

Reserved, RES0.

**PD1, bit [5]**

Translation table walk disable for translations using [TTBR1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR1](#). The encoding of this bit is:

0 Perform translation table walks using [TTBR1](#).

1 A TLB miss on an address that is translated using [TTBR1](#) generates a Translation fault. No translation table walk is performed.

Resets to 0.

**PD0, bit [4]**

Translation table walk disable for translations using [TTBR0](#). This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using [TTBR0](#). The encoding of this bit is:

0 Perform translation table walks using [TTBR0](#).

1 A TLB miss on an address that is translated using [TTBR0](#) generates a Translation fault. No translation table walk is performed.

Resets to 0.

**Bit [3]**

Reserved, RES0.

**N, bits [2:0]**

Indicate the width of the base address held in [TTBR0](#). In [TTBR0](#), the base address field is bits[31:14-N]. The value of N also determines:

- Whether [TTBR0](#) or [TTBR1](#) is used as the base address for translation table walks.
- The size of the translation table pointed to by [TTBR0](#).

N can take any value from 0 to 7, that is, from 0b000 to 0b111.

When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6.

Resets to 0.

**When TTBCR.EAE==1:**

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

- 1 Use the 40-bit translation system, with the Long-descriptor translation table format.

Resets to 0.

**SH1, bits [29:28]**

Shareability attribute for memory associated with translation table walks using [TTBR1](#).

- 00 Non-shareable
- 10 Outer Shareable
- 11 Inner Shareable

Other values are reserved.

Resets to 0.

**ORGN1, bits [27:26]**

Outer cacheability attribute for memory associated with translation table walks using [TTBR1](#).

- 00 Normal memory, Outer Non-cacheable
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable
- 10 Normal memory, Outer Write-Through Cacheable
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

Resets to 0.

**IRGN1, bits [25:24]**

Inner cacheability attribute for memory associated with translation table walks using [TTBR1](#).

- 00 Normal memory, Inner Non-cacheable
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable
- 10 Normal memory, Inner Write-Through Cacheable
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Resets to 0.

**EPD1, bit [23]**

Translation table walk disable for translations using [TTBR1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR1](#). The encoding of this bit is:

- 0 Perform translation table walks using [TTBR1](#).
- 1 A TLB miss on an address that is translated using [TTBR1](#) generates a Translation fault. No translation table walk is performed.

Resets to 0.

**A1, bit [22]**

Selects whether [TTBR0](#) or [TTBR1](#) defines the ASID. The encoding of this bit is:

0 [TTBR0](#).ASID defines the ASID.

1 [TTBR1](#).ASID defines the ASID.

Resets to 0.

**Bits [21:19]**

Reserved, RES0.

**T1SZ, bits [18:16]**

The size offset of the memory region addressed by [TTBR1](#). The region size is  $2^{32-T1SZ}$  bytes.

Resets to 0.

**Bits [15:14]**

Reserved, RES0.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using [TTBR0](#).

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

Resets to 0.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using [TTBR0](#).

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

Resets to 0.

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using [TTBR0](#).

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Resets to 0.

**EPD0, bit [7]**

Translation table walk disable for translations using [TTBR0](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR0](#). The encoding of this bit is:

0 Perform translation table walks using [TTBR0](#).

1 A TLB miss on an address that is translated using [TTBR0](#) generates a Translation fault. No translation table walk is performed.

Resets to 0.

**Bits [6:3]**

Reserved, RES0.

**T0SZ, bits [2:0]**

The size offset of the memory region addressed by [TTBR0](#). The region size is  $2^{32-T0SZ}$  bytes.

Resets to 0.

**Accessing the TTBCR:**

To access the TTBCR:

MRC p15,0,<Rt>,c2,c0,2 ; Read TTBCR into Rt

MCR p15,0,<Rt>,c2,c0,2 ; Write Rt to TTBCR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0010	0000	010

## G4.2.155 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

### Purpose

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as TTBR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the [TTBCR](#). When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the [TTBCR](#), not in TTBR0.

### Configurations

TTBR0(NS) is architecturally mapped to AArch64 register [TTBR0\\_EL1](#).

TTBR0(S) can be mapped to AArch64 register [TTBR0\\_EL3](#), but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension extends TTBR0 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR0 format is used:

EAE==0 32-bit format is used. TTBR0[63:32] are ignored.

EAE==1 64-bit format is used.

TTBR0 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

TTBR0 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The TTBR0 bit assignments are:

**When TTBCR.EAE==0:**

**TTB0, bits [31:7]**

Translation table base 0 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0.

The value of x determines the required alignment of the translation table, which must be aligned to  $2^x$  bytes.

If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

**IRGN[0], bit [6]**

See IRGN[1] below for description of the IRGN field.

**NOS, bit [5]**

Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a translation table walk that has the Shareable attribute, indicated by `TTBR0.S == 1`:

- 0 Outer Shareable
- 1 Inner Shareable.

This bit is ignored when `TTBR0.S == 0`.

**RGN, bits [4:3]**

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- 00 Normal memory, Outer Non-cacheable.
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Outer Write-Through Cacheable.
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

**IMP, bit [2]**

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

**S, bit [1]**

Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table walks:

- 0 Non-shareable
- 1 Shareable.

**IRGN[1], bit [0]**

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- 00 Normal memory, Inner Non-cacheable.
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Inner Write-Through Cacheable.
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.

**When TTBCR.EAE==1:**

**Bits [63:56]**

Reserved, RES0.

**ASID, bits [55:48]**

An ASID for the translation table base address. The [TTBCR.A1](#) field selects either TTBR0.ASID or TTBR1.ASID.

**BADDR[47:x], bits [47:0]**

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of [TTBCR.TOSZ](#), and is calculated as follows:

- If [TTBCR.TOSZ](#) is 0 or 1,  $x = 5 - \text{TTBCR.TOSZ}$ .
- If [TTBCR.TOSZ](#) is greater than 1,  $x = 14 - \text{TTBCR.TOSZ}$ .

The value of x determines the required alignment of the translation table, which must be aligned to  $2^x$  bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

**Accessing the TTBR0:**

To access the TTBR0 when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c2,c0,0 ; Read TTBR0 into Rt
MCR p15,0,<Rt>,c2,c0,0 ; Write Rt to TTBR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	000

To access the TTBR0 when TTBCR.EAE==1:

MRRC p15,0,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR0 into Rt (low word) and Rt2 (high word)  
MCRR p15,0,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR0

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0000	0010

### G4.2.156 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

**Purpose**

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TTBR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the [TTBCR](#). When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the [TTBCR](#), not in TTBR1.

**Configurations**

TTBR1(NS) is architecturally mapped to AArch64 register [TTBR1\\_EL1](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension extends TTBR1 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR1 format is used:

- EAE==0 32-bit format is used. TTBR1[63:32] are ignored.
- EAE==1 64-bit format is used.

**Attributes**

TTBR1 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The TTBR1 bit assignments are:

**When TTBCR.EAE==0:**

### TTB1, bits [31:7]

Translation table base 1 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0.

The translation table must be aligned on a 16KByte boundary.

If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONstrained UNPREDICTABLE, and can be one of the following:

- Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

### IRGN[0], bit [6]

See IRGN[1] below for description of the IRGN field.

### NOS, bit [5]

Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a translation table walk that has the Shareable attribute, indicated by `TTBR0.S == 1`:

0	Outer Shareable
1	Inner Shareable.

This bit is ignored when `TTBR0.S == 0`.

### RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

00	Normal memory, Outer Non-cacheable.
01	Normal memory, Outer Write-Back Write-Allocate Cacheable.
10	Normal memory, Outer Write-Through Cacheable.
11	Normal memory, Outer Write-Back no Write-Allocate Cacheable.

### IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

### S, bit [1]

Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table walks:

0	Non-shareable
1	Shareable.

### IRGN[1], bit [0]

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

00	Normal memory, Inner Non-cacheable.
01	Normal memory, Inner Write-Back Write-Allocate Cacheable.
10	Normal memory, Inner Write-Through Cacheable.
11	Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.

**When TTBCR.EAE==1:**

**Bits [63:56]**

Reserved, RES0.

**ASID, bits [55:48]**

An ASID for the translation table base address. The [TTBCR.A1](#) field selects either TTBR0.ASID or TTBR1.ASID.

**BADDR[47:x], bits [47:0]**

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of [TTBCR.T1SZ](#), and is calculated as follows:

- If [TTBCR.T1SZ](#) is 0 or 1,  $x = 5 - \text{TTBCR.T1SZ}$ .
- If [TTBCR.T1SZ](#) is greater than 1,  $x = 14 - \text{TTBCR.T1SZ}$ .

The value of x determines the required alignment of the translation table, which must be aligned to  $2^x$  bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

**Accessing the TTBR1:**

To access the TTBR1 when [TTBCR.EAE](#)==0:

MRC p15,0,<Rt>,c2,c0,1 ; Read TTBR1 into Rt  
 MCR p15,0,<Rt>,c2,c0,1 ; Write Rt to TTBR1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	001

To access the TTBR1 when [TTBCR.EAE](#)==1:

MRRC p15,1,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR1 into Rt (low word) and Rt2 (high word)  
 MCRR p15,1,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR1

Register access is encoded as follows:

coproc	opc1	CRm
1111	0001	0010

## G4.2.157 VBAR, Vector Base Address Register

The VBAR characteristics are:

### Purpose

When high exception vectors are not selected, holds the exception base address for exceptions that are not taken to Monitor mode or to Hyp mode.

This register is part of the Exception and fault handling registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as VBAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as VBAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Software must program the Non-secure copy of the register with the required initial value as part of the processor boot sequence.

### Configurations

VBAR(NS) is architecturally mapped to AArch64 register [VBAR\\_EL1](#)[31:0].

VBAR(S) can be mapped to AArch64 register [VBAR\\_EL3](#)[31:0], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

VBAR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

### Attributes

VBAR is a 32-bit register.

The VBAR bit assignments are:

### Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

### Bits [4:0]

Reserved, RES0.

### Accessing the VBAR:

To access the VBAR:

MRC p15,0,<Rt>,c12,c0,0 ; Read VBAR into Rt  
MCR p15,0,<Rt>,c12,c0,0 ; Write Rt to VBAR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	0000	000

## G4.2.158 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

### Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of [MPIDR](#).

This register is part of:

- the Identification registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

VMPIDR is architecturally mapped to AArch64 register [VMPIDR\\_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

VMPIDR is a 32-bit register.

The VMPIDR bit assignments are:

### M, bit [31]

Indicates whether this implementation includes the Multiprocessing Extensions. The possible values of this bit are:

- 0 This implementation does not include the Multiprocessing Extensions.
- 1 This implementation includes the Multiprocessing Extensions.

In v8-A this bit is RES1.

### U, bit [30]

Indicates a Uniprocessor system, as distinct from processor 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

Resets to an IMPLEMENTATION DEFINED value.

### Bits [29:25]

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical processors that are implemented using a multi-threading type approach. The possible values of this bit are:

- 0 Performance of processors at the lowest affinity level is largely independent.
- 1 Performance of processors at the lowest affinity level is very interdependent.

Resets to an IMPLEMENTATION DEFINED value.

**Aff2, bits [23:16]**

Affinity level 2. The least significant affinity level field, for this processor in the system.

Resets to an IMPLEMENTATION DEFINED value.

**Aff1, bits [15:8]**

Affinity level 1. The intermediate affinity level field, for this processor in the system.

Resets to an IMPLEMENTATION DEFINED value.

**Aff0, bits [7:0]**

Affinity level 0. The most significant affinity level field, for this processor in the system.

Resets to an IMPLEMENTATION DEFINED value.

**Accessing the VMPIDR:**

To access the VMPIDR:

MRC p15,4,<Rt>,c0,c0,5 ; Read VMPIDR into Rt  
MCR p15,4,<Rt>,c0,c0,5 ; Write Rt to VMPIDR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	0000	0000	101

## G4.2.159 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

### Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of [MIDR](#).

This register is part of:

- the Virtualization registers functional group
- the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

VPIDR is architecturally mapped to AArch64 register [VPIDR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

VPIDR is a 32-bit register.

The VPIDR bit assignments are:

### Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation

Hex representation	ASCII representation	Implementer
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Resets to the value of the equivalent field in MIDR.

#### Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Resets to the value of the equivalent field in MIDR.

#### Architecture, bits [19:16]

The permitted values of this field are:

0001	ARMv4
0010	ARMv4T
0011	ARMv5 (obsolete)
0100	ARMv5T
0101	ARMv5TE
0110	ARMv5TEJ
0111	ARMv6
1111	Defined by CPUID scheme

All other values are reserved.

Resets to the value of the equivalent field in MIDR.

#### PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Resets to the value of the equivalent field in MIDR.

#### Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Resets to the value of the equivalent field in MIDR.

#### Accessing the VPIDR:

To access the VPIDR:

MRC p15,4,<Rt>,c0,c0,0 ; Read VPIDR into Rt  
 MCR p15,4,<Rt>,c0,c0,0 ; Write Rt to VPIDR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0000	0000	000

## G4.2.160 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

### Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with [VTTBR](#), that defines the translation table base address for the translations.

### Configurations

VTCR is architecturally mapped to AArch64 register [VTCR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

VTCR is a 32-bit register.

The VTCR bit assignments are:

### Bit [31]

Reserved, RES1.

### Bits [30:14]

Reserved, RES0.

### SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [TTBR0](#).

- 00 Non-shareable
- 10 Outer Shareable
- 11 Inner Shareable

Other values are reserved.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using [TTBR0](#).

- 00 Normal memory, Outer Non-cacheable
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable
- 10 Normal memory, Outer Write-Through Cacheable
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using [TTBR0](#).

- 00 Normal memory, Inner Non-cacheable
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable
- 10 Normal memory, Inner Write-Through Cacheable
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

**SL0, bits [7:6]**

Starting level for translation table walks using [VTTBR](#).

- 00 Start at second level
- 01 Start at first level

Other values are reserved.

If the stage 2 input address size, as programmed in [VTCR.T0SZ](#), is out of range with respect to the starting level at the time of a translation walk that uses the stage 2 translation, then a second stage level 1 translation fault is generated.

**Bit [5]**

Reserved, RES0.

**S, bit [4]**

Sign extension bit. This bit must be programmed to the value of [T0SZ\[3\]](#). If it is not, then the stage 2 [T0SZ](#) value is treated as an UNKNOWN value within the legal range that can be programmed.

**T0SZ, bits [3:0]**

The size offset of the memory region addressed by [TTBR0](#). The region size is  $2^{32-T0SZ}$  bytes.

**Accessing the VTCR:**

To access the VTCR:

MRC p15,4,<Rt>,c2,c1,2 ; Read VTCR into Rt  
 MCR p15,4,<Rt>,c2,c1,2 ; Write Rt to VTCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0010	0001	010

## G4.2.161 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

### Purpose

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with the [VTCR](#).

### Configurations

VTTBR is architecturally mapped to AArch64 register [VTTBR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

VTTBR is a 64-bit register.

The VTTBR bit assignments are:

### Bits [63:56]

Reserved, RES0.

### VMID, bits [55:48]

The VMID for the translation table.

Resets to 0.

### BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of [VTCR.T0SZ](#), and is calculated as follows:

- If [VTCR.T0SZ](#) is 0 or 1,  $x = 5 - \text{VTCR.T0SZ}$ .
- If [VTCR.T0SZ](#) is greater than 1,  $x = 14 - \text{VTCR.T0SZ}$ .

The value of x determines the required alignment of the translation table, which must be aligned to  $2^x$  bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.

- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Reset value is architecturally UNKNOWN.

### Accessing the VTTBR:

To access the VTTBR:

MRRC p15,6,<Rt>,<Rt2>,c2 ; Read 64-bit VTTBR into Rt (low word) and Rt2 (high word)

MCRR p15,6,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit VTTBR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0110	0010

## G4.3 Debug registers

This section describes the Debug registers in AArch32 state.

### G4.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

#### Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

#### Configurations

DBGAUTHSTATUS is architecturally mapped to AArch64 register [DBGAUTHSTATUS\\_EL1](#).

DBGAUTHSTATUS is architecturally mapped to external register [DBGAUTHSTATUS\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

#### Attributes

DBGAUTHSTATUS is a 32-bit register.

The DBGAUTHSTATUS bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Non-secure.
- 10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

**SID, bits [5:4]**

Secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Non-secure.
  - 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
  - 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.
- Other values are reserved.

**NSNID, bits [3:2]**

Non-secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Secure.
  - 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
  - 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.
- Other values are reserved.

**NSID, bits [1:0]**

Non-secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Secure.
  - 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
  - 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.
- Other values are reserved.

**Accessing the DBGAUTHSTATUS:**

To access the DBGAUTHSTATUS:

MRC p14,0,<Rt>,c7,c14,6 ; Read DBGAUTHSTATUS into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1110	110

### G4.3.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

#### Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register [DBGBVR<n>](#), where n is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, [DBGBVR<n>](#) can be associated with a Breakpoint Extended Value Register [DBGBXVR<n>](#) for VMID matching.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

#### Configurations

DBGBCR<n> is architecturally mapped to AArch64 register [DBGBCR<n>\\_EL1](#).

DBGBCR<n> is architecturally mapped to external register [DBGBCR<n>\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGBCR<n> is a 32-bit register.

The DBGBCR<n> bit assignments are:

#### Bits [31:24]

Reserved, RES0.

#### BT, bits [23:20]

Breakpoint Type. Possible values are:

- 0000 Unlinked instruction address match.
- 0001 Linked instruction address match.
- 0010 Unlinked context ID match.
- 0011 Linked context ID match
- 0100 Unlinked instruction address mismatch.
- 0101 Linked instruction address mismatch.
- 1000 Unlinked VMID match.
- 1001 Linked VMID match.
- 1010 Unlinked VMID and context ID match.

1011 Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.
  - 000 Match address. `DBGBVR<n>` is the address of an instruction.
  - 010 Mismatch address. Behaves as type 0b000 if in an AArch64 translation, or if Halting debug-mode is enabled and halting is allowed. Otherwise, `DBGBVR<n>` is the address of an instruction to be stepped.
  - 001 Match context ID. `DBGBVR<n>` is a context ID.
  - 100 Match VMID. `DBGXVR<n>`[7:0] is a VMID.
  - 101 Match VMID and context ID. `DBGBVR<n>` is a context ID, and `DBGXVR<n>`[7:0] is a VMID.
- BT[0]: Enable linking.

If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### **LBN, bits [19:16]**

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### **SSC, bits [15:14]**

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### **HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### **Bits [12:9]**

Reserved, RES0.

#### **BAS, bits [8:5]**

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0b0011 and 0b1100 are only supported if AArch32 is supported at any exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints:

BAS	Match instruction at	Constraint for debuggers
0b0011	DBGBVR<n>	Use for T32 and T32EE instructions.
0b1100	DBGBVR<n>+2	Use for T32 and T32EE instructions.
0b1111	DBGBVR<n>	Use for A32 instructions.

0b0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

BAS	Step instruction at	Constraint for debuggers
0b0000	-	Use for a match anywhere breakpoint.
0b0011	DBGBVR<n>	Use for stepping T32 and T32EE instructions.
0b1100	DBGBVR<n>+2	Use for stepping T32 and T32EE instructions.
0b1111	DBGBVR<n>	Use for stepping A32 instructions.

For Context matching breakpoints, this field is RES1 and ignored.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Bits [4:3]

Reserved, RES0.

#### PMC, bits [2:1]

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### E, bit [0]

Enable breakpoint DBGBVR<n>. Possible values are:

- 0 Breakpoint disabled.
- 1 Breakpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Accessing the DBGBCR<n>:

To access the DBGBCR<n>:

MRC p14,0,<Rt>,c0,<CRm>,5 ; Read DBGBCR<n> into Rt, where n is in the range 0 to 15  
MCR p14,0,<Rt>,c0,<CRm>,5 ; Write Rt to DBGBCR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	101

### G4.3.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

#### Purpose

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register [DBGBCR<n>](#), where n is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register [DBGBXVR<n>](#) for VMID matching.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Some breakpoints might not support Context ID comparison. For more information, see the description of the [DBGDIDR.CTX\\_CMPs](#) field.

#### Configurations

DBGBVR<n> is architecturally mapped to AArch64 register [DBGBVR<n>\\_EL1](#)[31:0].

DBGBVR<n> is architecturally mapped to external register [DBGBVR<n>\\_EL1](#)[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGBVR<n> is a 32-bit register.

The DBGBVR<n> bit assignments are:

#### When [DBGBCR<n>.BT==0b0x0x](#):

#### VA[31:2], bits [31:2]

Bits[31:2] of the address value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Bits [1:0]

Reserved, RES0.

#### When [DBGBCR<n>.BT==0b1x0x](#):

**Bits [31:0]**

Reserved, RES0.

**When DBGBCR<n>.BT==0xxx1x:**

**ContextID, bits [31:0]**

Context ID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGBVR<n>:**

To access the DBGBVR<n>:

MRC p14,0,<Rt>,c0,<CRm>,4 ; Read DBGBVR<n> into Rt, where n is in the range 0 to 15

MCR p14,0,<Rt>,c0,<CRm>,4 ; Write Rt to DBGBVR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	100

### G4.3.4 DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15

The DBGBXVR<n> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register **DBGBCR<n>** and a value register **DBGBVR<n>**, where n is 0 to 15. Used if EL2 is implemented and breakpoint n supports Context matching.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

**Configurations**

DBGBXVR<n> is architecturally mapped to AArch64 register **DBGBVR<n>\_EL1**[63:32].

DBGBXVR<n> is architecturally mapped to external register **DBGBVR<n>\_EL1**[63:32].

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGBXVR<n> is a 32-bit register.

The DBGBXVR<n> bit assignments are:

**When DBGBCR<n>.BT==0b0xxx:**

**Bits [31:0]**

Reserved, RES0.

**When DBGBCR<n>.BT==0b1xxx and EL2 implemented:**

**Bits [31:8]**

Reserved, RES0.

**VMID, bits [7:0]**

VMID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

### Accessing the DBGXVR<n>:

To access the DBGXVR<n>:

MRC p14,0,<Rt>,c1,<CRm>,1 ; Read DBGXVR<n> into Rt, where n is in the range 0 to 15  
MCR p14,0,<Rt>,c1,<CRm>,1 ; Write Rt to DBGXVR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0001	n<3:0>	001

### G4.3.5 DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

#### Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The architecture does not define any functionality for the CLAIM bits.  
Used in conjunction with the [DBGCLAIMSET](#) register.

#### Configurations

DBGCLAIMCLR is architecturally mapped to AArch64 register [DBGCLAIMCLR\\_EL1](#).  
DBGCLAIMCLR is architecturally mapped to external register [DBGCLAIMCLR\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.  
This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

#### Attributes

DBGCLAIMCLR is a 32-bit register.

The DBGCLAIMCLR bit assignments are:

#### Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

#### CLAIM, bits [7:0]

Claim clear bits. Reading this field returns the current value of the CLAIM bits.  
Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.  
A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.  
On Cold reset, the field resets to 0.

#### Accessing the DBGCLAIMCLR:

To access the DBGCLAIMCLR:

MRC p14,0,<Rt>,c7,c9,6 ; Read DBGCLAIMCLR into Rt  
MCR p14,0,<Rt>,c7,c9,6 ; Write Rt to DBGCLAIMCLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0111	1001	110

### G4.3.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

**Purpose**

Used by software to set CLAIM bits to 1.  
 This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The architecture does not define any functionality for the CLAIM bits.  
 Used in conjunction with the [DBGCLAIMCLR](#) register.

**Configurations**

DBGCLAIMSET is architecturally mapped to AArch64 register [DBGCLAIMSET\\_EL1](#).  
 DBGCLAIMSET is architecturally mapped to external register [DBGCLAIMSET\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.  
 This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

**Attributes**

DBGCLAIMSET is a 32-bit register.

The DBGCLAIMSET bit assignments are:

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Claim set bits. RAO.  
 Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.  
 A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

**Accessing the DBGCLAIMSET:**

To access the DBGCLAIMSET:

```
MRC p14,0,<Rt>,c7,c8,6 ; Read DBGCLAIMSET into Rt
MCR p14,0,<Rt>,c7,c8,6 ; Write Rt to DBGCLAIMSET
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0111	1000	110

### G4.3.7 DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

**Purpose**

Enables interrupt requests to be signaled based on the DCC status flags.  
 This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

**Configurations**

DBGDCCINT is architecturally mapped to AArch64 register [MDCCINT\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGDCCINT is a 32-bit register.

The DBGDCCINT bit assignments are:

**Bit [31]**

Reserved, RES0.

**RX, bit [30]**

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0 No interrupt request generated by DTRRX.
- 1 Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

**TX, bit [29]**

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0 No interrupt request generated by DTRTX.
- 1 Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

**Bits [28:0]**

Reserved, RES0.

**Accessing the DBGDCCINT:**

To access the DBGDCCINT:

MRC p14,0,<Rt>,c0,c2,0 ; Read DBGDCCINT into Rt  
MCR p14,0,<Rt>,c0,c2,0 ; Write Rt to DBGDCCINT

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0010	000

### G4.3.8 DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

**Purpose**

Adds to the information given by the [DBGDIDR](#) by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDEVID is a 32-bit register.

The DBGDEVID bit assignments are:

**CIDMask, bits [31:28]**

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

0000 Context ID masking is not implemented.

0001 Context ID masking is implemented.

All other values are reserved. The value of this for v8-A is 0b0000.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

0000 None supported.

0001 Support for External Debug Auxiliary Control Register, [EDACR](#).

All other values are reserved.

**DoubleLock, bits [23:20]**

Indicates the presence of the [DBGOSDLR](#), OS Double Lock Register. Permitted values of this field are:

0000 The [DBGOSDLR](#) is not present.

0001 The [DBGOSDLR](#) is present.

All other values are reserved. The value of this for v8-A is 0b0001.

#### VirtExtns, bits [19:16]

Indicates whether EL2 is implemented. Permitted values of this field are:

- 0000 EL2 is not implemented.
  - 0001 EL2 is implemented.
- All other values are reserved.

#### VectorCatch, bits [15:12]

Defines the form of Vector catch debug event implemented. Permitted values of this field are:

- 0000 Address matching vector catch debug event implemented.
  - 0001 Exception matching vector catch debug event implemented.
- All other values are reserved.

#### BPAddrMask, bits [11:8]

Indicates the level of support for the IVA matching breakpoint masking capability. Permitted values of this field are:

- 0000 Breakpoint address matching may be implemented. If not implemented, [DBGBCR<n>](#)[28:24] is RAZ/WI.
  - 0001 Breakpoint address matching is implemented.
  - 1111 Breakpoint address matching is not implemented. [DBGBCR<n>](#)[28:24] is RES0.
- All other values are reserved. The value of this for v8-A is 0b1111.

#### WPAddrMask, bits [7:4]

Indicates the level of support for the data VA matching watchpoint masking capability. Permitted values of this field are:

- 0000 Watchpoint address matching may be implemented. If not implemented, [DBGWCR<n>.MASK](#) (Address mask) is RAZ/WI.
- 0001 Watchpoint address matching is implemented.
- 1111 Watchpoint address matching is not implemented. [DBGWCR<n>.MASK](#) (Address mask) is RES0.

All other values are reserved. The value of this for v8-A is 0b0001.

#### PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in v8-A are:

- 0000 Architecture-defined form of Sample-based profiling not implemented.
- 0010 [EDPCSR](#) and [EDCIDSR](#) are implemented (only permitted if EL3 and EL2 are not implemented).
- 0011 [EDPCSR](#), [EDCIDSR](#), and [EDVIDSR](#) are implemented.

All other values are reserved.

### Accessing the DBGDEVID:

To access the DBGDEVID:

MRC p14,0,<Rt>,c7,c2,7 ; Read DBGDEVID into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0010	111

### G4.3.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

**Purpose**

Adds to the information given by the [DBGDIDR](#) by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDEVID1 is a 32-bit register.

The DBGDEVID1 bit assignments are:

**Bits [31:4]**

Reserved, RES0.

**PCSROffset, bits [3:0]**

This field indicates the offset applied to PC samples returned by reads of [EDPCSR](#). Permitted values of this field in v8-A are:

0000 [EDPCSR](#) not implemented.

In v7-A, this field being 0b0000 can also mean that [EDPCSR](#) is implemented and that values returned by reads have an offset applied and indicate the instruction set state. This is not a permitted implementation for v8-A.

0010 [EDPCSR](#) implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

**Accessing the DBGDEVID1:**

To access the DBGDEVID1:

MRC p14,0,<Rt>,c7,c1,7 ; Read DBGDEVID1 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0001	111

### G4.3.10 DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

#### Purpose

Reserved for future descriptions of features of the debug implementation.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

#### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGDEVID2 is a 32-bit register.

The DBGDEVID2 bit assignments are:

#### Bits [31:0]

Reserved, RES0.

#### Accessing the DBGDEVID2:

To access the DBGDEVID2:

MRC p14,0,<Rt>,c7,c0,7 ; Read DBGDEVID2 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0000	111

### G4.3.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

**Purpose**

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if [DBGDSCRext.UDCCdis](#) is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

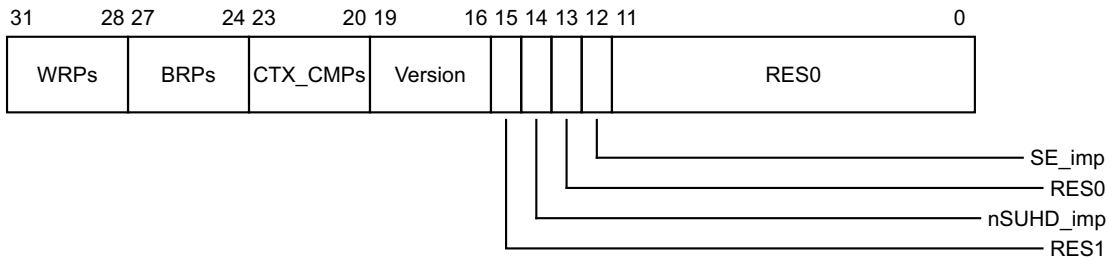

This register is required in all implementations.

If external debug over powerdown is implemented, this register can be implemented in either or both power domains.

**Attributes**

DBGDIDR is a 32-bit register.

The DBGDIDR bit assignments are:

**WRPs, bits [31:28]**

The number of watchpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented watchpoints, to 0b1111 for 16 implemented watchpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as [ID\\_AA64DFR0\\_EL1.WRPs](#).

**BRPs, bits [27:24]**

The number of breakpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented breakpoint, to 0b1111 for 16 implemented breakpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as [ID\\_AA64DFR0\\_EL1.BRPs](#).

**CTX\_CMPs, bits [23:20]**

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from 0b0000 for 1 Context matching breakpoint, to 0b1111 for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as [ID\\_AA64DFR0\\_EL1.CTX\\_CMPs](#).

**Version, bits [19:16]**

The Debug architecture version. The permitted values of this field are:

- 0001 ARMv6, v6 Debug architecture
- 0010 ARMv6, v6.1 Debug architecture
- 0011 ARMv7, v7 Debug architecture, with baseline CP14 registers implemented
- 0100 ARMv7, v7 Debug architecture, with all CP14 registers implemented
- 0101 ARMv7, v7.1 Debug architecture.
- 0110 ARMv8, v8 Debug architecture.

All other values are reserved.

**Bit [15]**

Reserved, RES1.

**nSUHD\_imp, bit [14]**

In v7-A, was Secure User Halting Debug not implemented.

The value of this bit must match the value of the SE\_imp bit.

**Bit [13]**

Reserved, RES0.

**SE\_imp, bit [12]**

EL3 implemented. The meanings of the values of this bit are:

- 0 EL3 not implemented.
- 1 EL3 implemented.

The value of this bit must match the value of the nSUHD\_imp bit.

**Bits [11:0]**

Reserved, RES0.

**Accessing the DBGDIDR:**

To access the DBGDIDR:

MRC p14,0,<Rt>,c0,c0,0 ; Read DBGDIDR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0000	000

### G4.3.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

#### Purpose

Defines the base physical address of a memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. However, if this processor is the only memory-mapped debug component in the system, or the only memory mapped-debug component visible to this processor, this register defines the base physical address of this processor's debug registers.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if `DBGDSCRext.UDCCdis` is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

#### Configurations

DBGDRAR is architecturally mapped to AArch64 register `MDRAR_EL1`.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

If no memory-mapped debug components are implemented, `DBGDRAR.Valid` is `RES0`.

DBGDRAR is accessible either as a 64-bit register (using `MRRC`) or a 32-bit register (using `MRC`).

#### Attributes

DBGDRAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

The DBGDRAR bit assignments are:

#### When accessing the 32-bit version:

#### ROMADDR[31:12], bits [31:12]

Bits[31:12] of the ROM table physical address. Bits [11:0] of the address are zero.

#### Bits [11:2]

Reserved, `RES0`.

#### Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

- 00 ROM Table address is not valid
- 11 ROM Table address is valid.

Other values are reserved.

**When accessing the 64-bit version:**

**Bits [63:48]**

Reserved, RES0.

**ROMADDR[P-1:12], bits [47:12]**

Bits[P-1:12] of the ROM table physical address, where P is the physical address size in bits (up to 48 bits) as stored in [ID\\_AA64MMFR0\\_EL1](#). If P is less than 48, bits[47:P] of this register are RES0.

Bits [11:0] of the ROM table physical address are zero.

If EL3 is implemented, ROMADDR is an address in Non-secure memory. Whether the ROM table is also accessible in Secure memory is IMPLEMENTATION DEFINED.

ARM recommends that bits [P-1:32] are zero in systems that support AArch32 at the highest exception level.

**Bits [11:2]**

Reserved, RES0.

**Valid, bits [1:0]**

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00 ROM Table address is not valid

11 ROM Table address is valid.

Other values are reserved.

**Accessing the DBGDRAR:**

To access the DBGDRAR when accessing the 32-bit version:

MRC p14,0,<Rt>,c1,c0,0 ; Read DBGDRAR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	000

To access the DBGDRAR when accessing the 64-bit version:

MRRC p14,0,<Rt>,<Rt2>,c1 ; Read 64-bit DBGDRAR into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

coproc	opc1	CRm
1110	0000	0001

### G4.3.13 DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

**Purpose**

Previously defined the offset from the base address defined in [DBGDRAR](#) of the physical base address of the debug registers for the processor. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if [DBGDSCRExt.UDCCdis](#) is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGDSAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

The DBGDSAR bit assignments are:

**When accessing the 32-bit version:**

**Bits [31:0]**

Reserved, RES0.

**When accessing the 64-bit version:**

**Bits [63:0]**

Reserved, RES0.

**Accessing the DBGDSAR:**

To access the DBGDSAR when accessing the 32-bit version:

```
MRC p14,0,<Rt>,c2,c0,0 ; Read DBGDSAR into Rt
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0010	0000	000

To access the DBGDSAR when accessing the 64-bit version:

MRRC p14,0,<Rt>,<Rt2>,c2 ; Read 64-bit DBGDSAR into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1110	0000	0010

### G4.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

**Purpose**

Main control register for the debug implementation.  
 This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

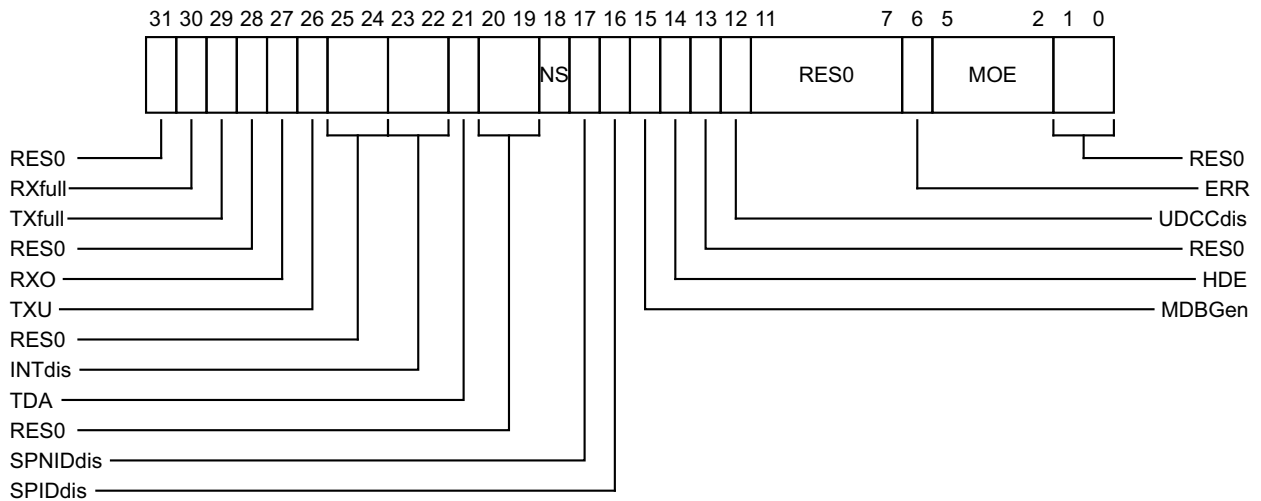

**Configurations**

DBGDSCRext is architecturally mapped to AArch64 register [MDSCR\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.  
 This register is required in all implementations.

**Attributes**

DBGDSCRext is a 32-bit register.

The DBGDSCRext bit assignments are:

**Bit [31]**

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. Used for save/restore of [EDSCR.RXfull](#).  
 When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO.  
 When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.  
 ARM deprecates use of this bit other than for save/restore. Use [DBGDSCRint](#) to access the DTRRX full status.

**TXfull, bit [29]**

DTRTX full. Used for save/restore of [EDSCR.TXfull](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

ARM deprecates use of this bit other than for save/restore. Use [DBGDSCRint](#) to access the DTRTX full status.

**Bit [28]**

Reserved, RES0.

**RXO, bit [27]**

Used for save/restore of [EDSCR.RXO](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

**TXU, bit [26]**

Used for save/restore of [EDSCR.TXU](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

**Bits [25:24]**

Reserved, RES0.

**INTdis, bits [23:22]**

Used for save/restore of [EDSCR.INTdis](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this field is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this field is RW.

**TDA, bit [21]**

Used for save/restore of [EDSCR.TDA](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

**Bits [20:19]**

Reserved, RES0.

**NS, bit [18]**

Non-secure status. Returns the inverse of `IsSecure()`. This bit is RO.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

**SPNIDdis, bit [17]**

Secure privileged profiling disabled status bit. This bit is RO and reflects the value of `ProfilingProhibited(TRUE,EL1)`. Permitted values are:

0 Profiling allowed in Secure privileged modes.

1 Profiling prohibited in Secure privileged modes.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### SPIDdis, bit [16]

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and returns the inverse of DebugSPD32(). Permitted values are:

- 0 Self-hosted debug enabled in Secure privileged AArch32 modes.
- 1 Self-hosted debug disabled in Secure privileged AArch32 modes.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### MDBGGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

- 0 Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.
- 1 Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.

On Warm reset, the field resets to 0.

#### HDE, bit [14]

Used for save/restore of [EDSCR.HDE](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### Bit [13]

Reserved, RES0.

#### UDCCdis, bit [12]

User mode access to Debug Communications Channel disable. When set, then any EL0 access to [DBGDIDR](#), [DBGDRAR](#), [DBGDSAR](#), [DBGDSCRint](#), [DBGDTRTXint](#), or [DBGDTRRXint](#) is trapped to EL1.

On Warm reset, the field resets to 0.

#### Bits [11:7]

Reserved, RES0.

#### ERR, bit [6]

Used for save/restore of [EDSCR.ERR](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0001 Breakpoint
- 0011 Software breakpoint (BKPT) instruction
- 0101 Vector catch
- 1010 Watchpoint

On Warm reset, the field reset value is architecturally UNKNOWN.

#### Bits [1:0]

Reserved, RES0.

### Accessing the DBGDSCRExt:

To access the DBGDSCRExt:

MRC p14,0,<Rt>,c0,c2,2 ; Read DBGDSCRExt into Rt  
MCR p14,0,<Rt>,c0,c2,2 ; Write Rt to DBGDSCRExt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0010	010

### G4.3.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

**Purpose**

Main control register for the debug implementation. This is an internal, read-only view.  
 This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when `DBGDSCRext.UDCCdis` is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

**Configurations**

DBGDSCRint is architecturally mapped to AArch64 register `MDCCSR_EL0`.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

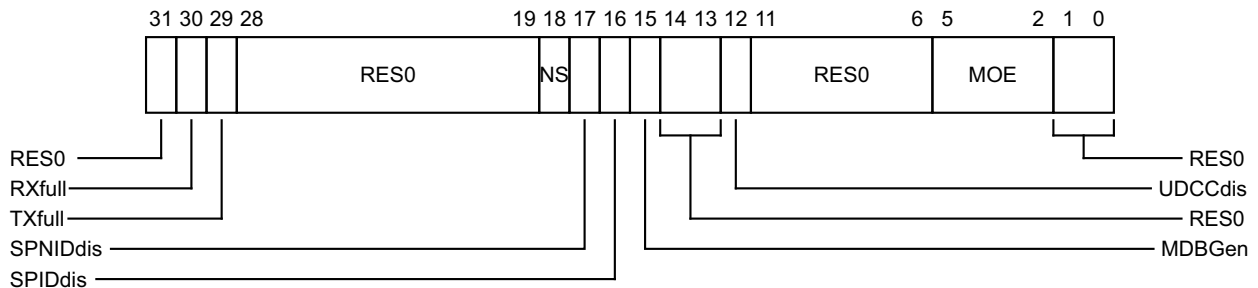

`DBGDSCRint.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE}` are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of `DBGDSCRext.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE}` for these fields at EL0.

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

**Attributes**

DBGDSCRint is a 32-bit register.

The DBGDSCRint bit assignments are:

**Bit [31]**

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. Read-only view of the equivalent bit in the `EDSCR`.

**TXfull, bit [29]**

DTRTX full. Read-only view of the equivalent bit in the `EDSCR`.

**Bits [28:19]**

Reserved, RES0.

**NS, bit [18]**

Non-secure status.

Read-only view of the equivalent bit in the [DBGDSCRExt](#). ARM deprecates use of this field.

**SPNIDdis, bit [17]**

Secure privileged non-invasive debug disable.

Read-only view of the equivalent bit in the [DBGDSCRExt](#). ARM deprecates use of this field.

**SPIDdis, bit [16]**

Secure privileged invasive debug disable.

Read-only view of the equivalent bit in the [DBGDSCRExt](#). ARM deprecates use of this field.

**MDBGGen, bit [15]**

Monitor debug events enable.

Read-only view of the equivalent bit in the [DBGDSCRExt](#).

**Bits [14:13]**

Reserved, RES0.

**UDCCdis, bit [12]**

User mode access to Debug Communications Channel disable.

Read-only view of the equivalent bit in the [DBGDSCRExt](#). ARM deprecates use of this field.

**Bits [11:6]**

Reserved, RES0.

**MOE, bits [5:2]**

Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0001 Breakpoint
- 0011 Software breakpoint (BKPT) instruction
- 0101 Vector catch
- 1010 Watchpoint

Read-only view of the equivalent bit in the [DBGDSCRExt](#).

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGDSCRint:**

To access the DBGDSCRint:

MRC p14,0,<Rt>,c0,c1,0 ; Read DBGDSCRint into Rt, where Rt can be R0-R14 or APSR\_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the RT field of the encoding to 0b1111.

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0001	000

### G4.3.16 DBGDTRRXext, Debug Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

**Purpose**

Used for save/restore of [DBGDTRRXint](#). It is a component of the Debug Communications Channel. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

ARM deprecates reads and writes of DBGDTRRXext through the CP14 interface when the OS lock is unlocked.

If [EDSCR.ITE](#) == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRRXext is architecturally mapped to AArch64 register [OSDTRRX\\_EL1](#).

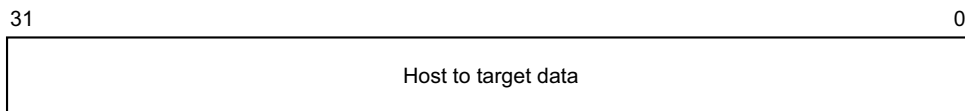

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDTRRXext is a 32-bit register.

The DBGDTRRXext bit assignments are:

**Bits [31:0]**

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRRXext:**

To access the DBGDTRRXext:

```
MRC p14,0,<Rt>,c0,c0,2 ; Read DBGDTRRXext into Rt
MCR p14,0,<Rt>,c0,c0,2 ; Write Rt to DBGDTRRXext
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0000	010

### G4.3.17 DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View

The DBGDTRRXint characteristics are:

**Purpose**

Transfers data from an external host to the ARM processor. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when [DBGDSCRint.UDCCdis](#) is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If [EDSCR.ITE](#) == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONstrained UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRRXint is architecturally mapped to AArch64 register [DBGDTRRX\\_EL0](#).

DBGDTRRXint is architecturally mapped to external register [DBGDTRRX\\_EL0](#).

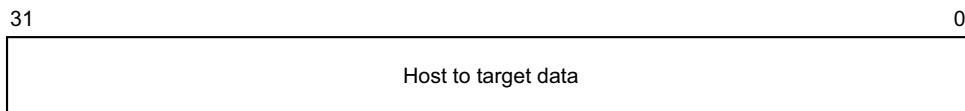

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDTRRXint is a 32-bit register.

The DBGDTRRXint bit assignments are:

**Bits [31:0]**

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRRXint:**

To access the DBGDTRRXint:

MRC p14,0,<Rt>,c0,c5,0 ; Read DBGDTRRXint into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0101	000

### G4.3.18 DBGDTRTXext, Debug Data Transfer Register, Transmit, External View

The DBGDTRTXext characteristics are:

**Purpose**

Used for save/restore of [DBGDTRTXint](#). It is a component of the Debug Communication Channel. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

ARM deprecates reads and writes of DBGDTRTXext through the CP14 interface when the OS Lock is unlocked.

If [EDSCR.ITE](#) == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONstrained UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

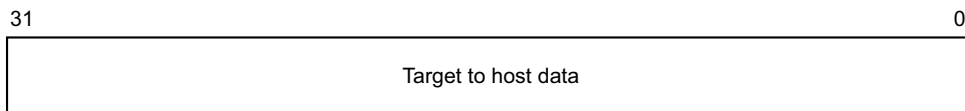

DBGDTRTXext is architecturally mapped to AArch64 register [OSDTRTX\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states. This register is required in all implementations.

**Attributes**

DBGDTRTXext is a 32-bit register.

The DBGDTRTXext bit assignments are:

**Bits [31:0]**

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRTXext:**

To access the DBGDTRTXext:

```
MRC p14,0,<Rt>,c0,c3,2 ; Read DBGDTRTXext into Rt
MCR p14,0,<Rt>,c0,c3,2 ; Write Rt to DBGDTRTXext
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0011	010

### G4.3.19 DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View

The DBGDTRTXint characteristics are:

**Purpose**

Transfers data from the ARM processor to an external host. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO	WO

This register can be written at EL0 when [DBGDSCRint.UDCCdis](#) is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If [EDSCR.ITE](#) == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONstrained UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRTXint is architecturally mapped to AArch64 register [DBGDTRTX\\_EL0](#).

DBGDTRTXint is architecturally mapped to external register [DBGDTRTX\\_EL0](#).

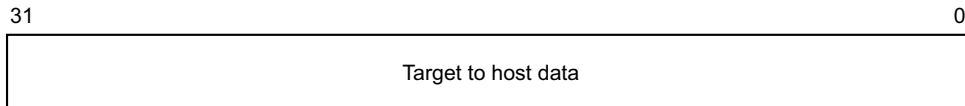

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDTRTXint is a 32-bit register.

The DBGDTRTXint bit assignments are:

**Bits [31:0]**

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRTXint:**

To access the DBGDTRTXint:

```
MCR p14,0,<Rt>,c0,c5,0 ; Write Rt to DBGDTRTXint
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0000	0101	000

### G4.3.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

#### Purpose

Locks out the external debug interface.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

DBGOSDLR is architecturally mapped to AArch64 register [OSDLR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGOSDLR is a 32-bit register.

The DBGOSDLR bit assignments are:

#### Bits [31:1]

Reserved, RES0.

#### DLK, bit [0]

OS Double Lock control bit. Possible values are:

0 OS Double Lock unlocked.

1 OS Double Lock locked, if [DBGPRCR.CORENPDRQ](#) (Core no power-down request) bit is set to 0 and the processor is in Non-debug state.

On Warm reset, the field resets to 0.

#### Accessing the DBGOSDLR:

To access the DBGOSDLR:

MRC p14,0,<Rt>,c1,c3,4 ; Read DBGOSDLR into Rt

MCR p14,0,<Rt>,c1,c3,4 ; Write Rt to DBGOSDLR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0011	100

### G4.3.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

#### Purpose

Provides a mechanism for an operating system to access the contents of [EDECCR](#) that are otherwise invisible to software, so it can save/restore the contents of [EDECCR](#) over powerdown on behalf of the external debugger.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

DBGOSECCR is architecturally mapped to AArch64 register [OSECCR\\_EL1](#).

DBGOSECCR is architecturally mapped to external register [EDECCR](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGOSECCR is a 32-bit register.

The DBGOSECCR bit assignments are:

#### When `OSLSR.OSLK==1`:

#### EDECCR, bits [31:0]

Used for save/restore to [EDECCR](#) over powerdown.

#### Accessing the DBGOSECCR:

To access the DBGOSECCR:

MRC p14,0,<Rt>,c0,c6,2 ; Read DBGOSECCR into Rt

MCR p14,0,<Rt>,c0,c6,2 ; Write Rt to DBGOSECCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0110	010

### G4.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

**Purpose**

Provides a lock for the debug registers. The OS lock also disables some Software debug events.  
 This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

**Configurations**

DBGOSLAR is architecturally mapped to AArch64 register [OSLAR\\_EL1](#).  
 DBGOSLAR is architecturally mapped to external register [OSLAR\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGOSLAR is a 32-bit register.

The DBGOSLAR bit assignments are:

**Bits [31:0]**

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.  
 Use [DBGOSLSR.OSLK](#) to check the current status of the lock.

**Accessing the DBGOSLAR:**

To access the DBGOSLAR:

```
MCR p14,0,<Rt>,c1,c0,4 ; Write Rt to DBGOSLAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	100

### G4.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

#### Purpose

Provides status information for the OS lock.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

#### Configurations

DBGOSLSR is architecturally mapped to AArch64 register [OSLSR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

The OS lock status is also visible in the external debug interface through EDPRSR.

#### Attributes

DBGOSLSR is a 32-bit register.

The DBGOSLSR bit assignments are:

#### Bits [31:4]

Reserved, RES0.

#### OSLM[1], bit [3]

See below for description of the OSLM field.

#### nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

#### OSLK, bit [1]

OS Lock Status. The possible values are:

0 OS lock unlocked.

1 OS lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On Cold reset, the field resets to 1.

**OSLM[0], bit [0]**

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.  
In v8-A these bits are as follows:  
10 OS lock implemented. DBGOSSRR not implemented.  
All other values are reserved.

**Accessing the DBGOSLSR:**

To access the DBGOSLSR:

MRC p14,0,<Rt>,c1,c1,4 ; Read DBGOSLSR into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0001	0001	100

### G4.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

#### Purpose

Controls behavior of processor on power-down request.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

DBGPRCR is architecturally mapped to AArch64 register [DBGPRCR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

Bit [0] of this register is mapped to [EDPRCR.CORENPDRQ](#), bit [0] of the external view of this register. The other bits in these registers are not mapped to each other.

#### Attributes

DBGPRCR is a 32-bit register.

The DBGPRCR bit assignments are:

#### Bits [31:1]

Reserved, RES0.

#### CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

0 On a powerdown request, the system powers down the Core power domain.

1 On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field resets to the value of [EDPRCR.COREPURQ](#).

#### Accessing the DBGPRCR:

To access the DBGPRCR:

MRC p14,0,<Rt>,c1,c4,4 ; Read DBGPRCR into Rt

MCR p14,0,<Rt>,c1,c4,4 ; Write Rt to DBGPRCR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1110	000	0001	0100	100

### G4.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

#### Purpose

Controls Vector catch debug events.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

DBGVCR is architecturally mapped to AArch64 register [DBGVCR32\\_EL2](#).

There is one instance of this register that is used in both Secure and Non-secure states.

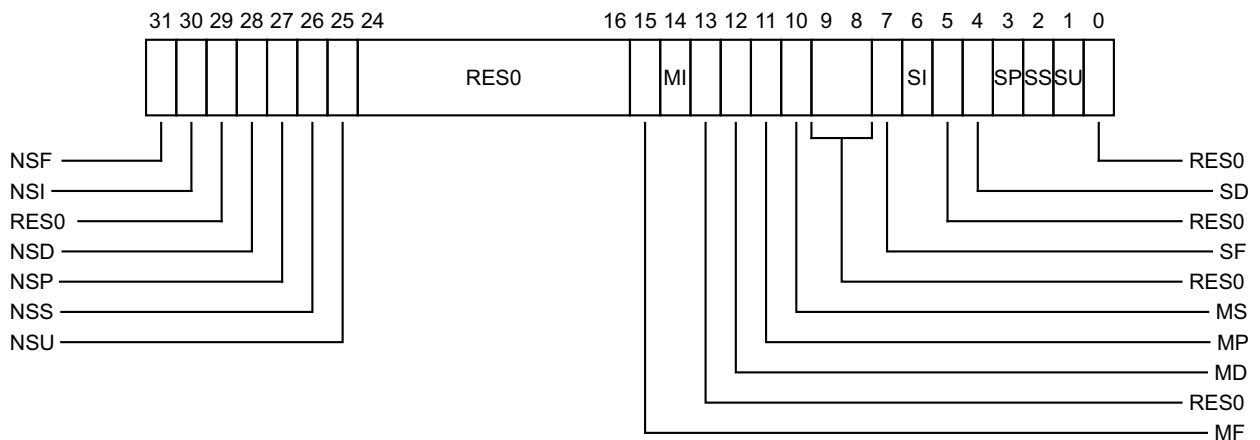

This register is required in all implementations.

#### Attributes

DBGVCR is a 32-bit register.

The DBGVCR bit assignments are:

#### When EL3 implemented and using AArch32:

#### NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is  $0x1C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

#### NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is  $0x18$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [29]**

Reserved, RES0.

**NSD, bit [28]**

Data Abort vector catch enable in Non-secure state.

The exception vector offset is  $0x10$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSP, bit [27]**

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is  $0x0C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSS, bit [26]**

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is  $0x08$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSU, bit [25]**

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is  $0x04$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [24:16]**

Reserved, RES0.

**MF, bit [15]**

FIQ vector catch enable in Monitor mode.

The exception vector offset is  $0x1C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**MI, bit [14]**

IRQ vector catch enable in Monitor mode.

The exception vector offset is  $0x18$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [13]**

Reserved, RES0.

**MD, bit [12]**

Data Abort vector catch enable in Monitor mode.

The exception vector offset is  $0x10$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**MP, bit [11]**

Prefetch Abort vector catch enable in Monitor mode.

The exception vector offset is  $0x0C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**MS, bit [10]**

Secure Monitor Call (SMC) vector catch enable in Monitor mode.

The exception vector offset is  $0x08$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [9:8]**

Reserved, RES0.

**SF, bit [7]**

FIQ vector catch enable in Secure state.

The exception vector offset is  $0x1C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**SI, bit [6]**

IRQ vector catch enable in Secure state.

The exception vector offset is  $0x18$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [5]**

Reserved, RES0.

**SD, bit [4]**

Data Abort vector catch enable in Secure state.

The exception vector offset is  $0x10$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**SP, bit [3]**

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is  $0x0C$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**SS, bit [2]**

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is  $0x08$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**SU, bit [1]**

Undefined Instruction vector catch enable in Secure state.

The exception vector offset is  $0x04$ .

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [0]**

Reserved, RES0.

**When EL3 implemented and using AArch64:**

**NSF, bit [31]**

FIQ vector catch enable in Non-secure state.  
 The exception vector offset is 0x1C.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**NSI, bit [30]**

IRQ vector catch enable in Non-secure state.  
 The exception vector offset is 0x18.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [29]**

Reserved, RES0.

**NSD, bit [28]**

Data Abort vector catch enable in Non-secure state.  
 The exception vector offset is 0x10.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**NSP, bit [27]**

Prefetch Abort vector catch enable in Non-secure state.  
 The exception vector offset is 0x0C.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**NSS, bit [26]**

Supervisor Call (SVC) vector catch enable in Non-secure state.  
 The exception vector offset is 0x08.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**NSU, bit [25]**

Undefined Instruction vector catch enable in Non-secure state.  
 The exception vector offset is 0x04.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [24:8]**

Reserved, RES0.

**SF, bit [7]**

FIQ vector catch enable in Secure state.  
The exception vector offset is 0x1C.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**SI, bit [6]**

IRQ vector catch enable in Secure state.  
The exception vector offset is 0x18.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [5]**

Reserved, RES0.

**SD, bit [4]**

Data Abort vector catch enable in Secure state.  
The exception vector offset is 0x10.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**SP, bit [3]**

Prefetch Abort vector catch enable in Secure state.  
The exception vector offset is 0x0C.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**SS, bit [2]**

Supervisor Call (SVC) vector catch enable in Secure state.  
The exception vector offset is 0x08.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**SU, bit [1]**

Undefined Instruction vector catch enable in Secure state.  
The exception vector offset is 0x04.  
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [0]**

Reserved, RES0.

**When EL3 not implemented:**

**Bits [31:8]**

Reserved, RES0.

**F, bit [7]**

FIQ vector catch enable.

The exception vector offset is 0x1C.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**I, bit [6]**

IRQ vector catch enable.  
 The exception vector offset is 0x18.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [5]**

Reserved, RES0.

**D, bit [4]**

Data Abort vector catch enable.  
 The exception vector offset is 0x10.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**P, bit [3]**

Prefetch Abort vector catch enable.  
 The exception vector offset 0x0C.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**S, bit [2]**

Supervisor Call (SVC) vector catch enable.  
 The exception vector offset is 0x08.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**U, bit [1]**

Undefined Instruction vector catch enable.  
 The exception vector offset is 0x04.  
 On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [0]**

Reserved, RES0.

**Accessing the DBGVCR:**

To access the DBGVCR:

MRC p14,0,<Rt>,c0,c7,0 ; Read DBGVCR into Rt  
 MCR p14,0,<Rt>,c0,c7,0 ; Write Rt to DBGVCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0111	000

### G4.3.26 DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

#### Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register [DBGWVR<n>](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

#### Configurations

DBGWCR<n> is architecturally mapped to AArch64 register [DBGWCR<n>\\_EL1](#).

DBGWCR<n> is architecturally mapped to external register [DBGWCR<n>\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGWCR<n> is a 32-bit register.

The DBGWCR<n> bit assignments are:

#### Bits [31:29]

Reserved, RES0.

#### MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

00000 No mask.

00001 Reserved.

00010 Reserved.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Bits [23:21]

Reserved, RES0.

#### WT, bit [20]

Watchpoint type. Possible values are:

0 Unlinked data address match.

1 Linked data address match.  
On Cold reset, the field reset value is architecturally UNKNOWN.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.  
On Cold reset, the field reset value is architecturally UNKNOWN.

**SSC, bits [15:14]**

Security state control. Determines the security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.  
On Cold reset, the field reset value is architecturally UNKNOWN.

**HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.  
On Cold reset, the field reset value is architecturally UNKNOWN.

**BAS, bits [12:5]**

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by [DBGWVR<n>](#) is being watched.

BAS	Description
xxxxxxx1	Match byte at <a href="#">DBGWVR&lt;n&gt;</a>
xxxxxx1x	Match byte at <a href="#">DBGWVR&lt;n&gt;+1</a>
xxxxx1xx	Match byte at <a href="#">DBGWVR&lt;n&gt;+2</a>
xxxx1xxx	Match byte at <a href="#">DBGWVR&lt;n&gt;+3</a>

In cases where [DBGWVR<n>](#) addresses a double-word:

BAS	Description, if <a href="#">DBGWVR&lt;n&gt;</a> [2] == 0
xxx1xxxx	Match byte at <a href="#">DBGWVR&lt;n&gt;+4</a>
xx1xxxxx	Match byte at <a href="#">DBGWVR&lt;n&gt;+5</a>
x1xxxxxx	Match byte at <a href="#">DBGWVR&lt;n&gt;+6</a>
1xxxxxxx	Match byte at <a href="#">DBGWVR&lt;n&gt;+7</a>

If [DBGWVR<n>](#)[2] == 1, only BAS[3:0] is used. ARM deprecates setting [DBGWVR<n>](#) == 1.  
The valid values for BAS are 0b000000, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

### LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

### PAC, bits [2:1]

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

### E, bit [0]

Enable watchpoint n. Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

### Accessing the DBGWCR<n>:

To access the DBGWCR<n>:

MRC p14,0,<Rt>,c0,<CRm>,7 ; Read DBGWCR<n> into Rt, where n is in the range 0 to 15  
MCR p14,0,<Rt>,c0,<CRm>,7 ; Write Rt to DBGWCR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	111

### G4.3.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

#### Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGWFAR is a 32-bit register.

The DBGWFAR bit assignments are:

#### Bits [31:0]

Reserved, RES0.

#### Accessing the DBGWFAR:

To access the DBGWFAR:

MRC p14,0,<Rt>,c0,c6,0 ; Read DBGWFAR into Rt  
MCR p14,0,<Rt>,c0,c6,0 ; Write Rt to DBGWFAR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0110	000

### G4.3.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

#### Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

#### Configurations

DBGWVR<n> is architecturally mapped to AArch64 register [DBGWVR<n>\\_EL1](#)[31:0].

DBGWVR<n> is architecturally mapped to external register [DBGWVR<n>\\_EL1](#)[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGWVR<n> is a 32-bit register.

The DBGWVR<n> bit assignments are:

#### VA, bits [31:2]

Bits[31:2] of the address value for comparison.

ARM deprecates setting [DBGWVR<n>](#)[2] == 1.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Bits [1:0]

Reserved, RES0.

#### Accessing the DBGWVR<n>:

To access the DBGWVR<n>:

MRC p14,0,<Rt>,c0,<CRm>,6 ; Read DBGWVR<n> into Rt, where n is in the range 0 to 15

MCR p14,0,<Rt>,c0,<CRm>,6 ; Write Rt to DBGWVR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	110

### G4.3.29 DLR, Debug Link Register

The DLR characteristics are:

#### Purpose

In Debug state, holds the address to restart from.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

#### Configurations

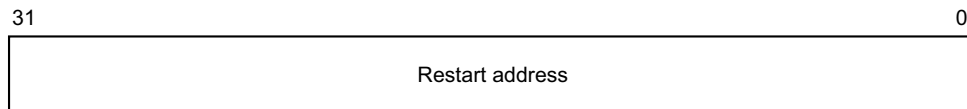

DLR is architecturally mapped to AArch64 register [DLR\\_EL0](#)[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DLR is a 32-bit register.

The DLR bit assignments are:

#### Bits [31:0]

Restart address.

#### Accessing the DLR:

To access the DLR:

MRC p15,3,<Rt>,c4,c5,1 ; Read DLR into Rt

MCR p15,3,<Rt>,c4,c5,1 ; Write Rt to DLR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	011	0100	0101	001

### G4.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

#### Purpose

Holds the saved processor state on entry to Debug state.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

#### Configurations

DSPSR is architecturally mapped to AArch64 register [DSPSR\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DSPSR is a 32-bit register.

The DSPSR bit assignments are:

#### N, bit [31]

Set to the value of [CPSR.N](#) on entering Debug state, and copied to [CPSR.N](#) on exiting Debug state.

#### Z, bit [30]

Set to the value of [CPSR.Z](#) on entering Debug state, and copied to [CPSR.Z](#) on exiting Debug state.

#### C, bit [29]

Set to the value of [CPSR.C](#) on entering Debug state, and copied to [CPSR.C](#) on exiting Debug state.

#### V, bit [28]

Set to the value of [CPSR.V](#) on entering Debug state, and copied to [CPSR.V](#) on exiting Debug state.

#### Q, bit [27]

Set to the value of [CPSR.Q](#) on entering Debug state, and copied to [CPSR.Q](#) on exiting Debug state.

#### IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

### J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

- 0 Processor in A32 state if T is 0, or T32 state if T is 1.
- 1 Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to exit Debug state with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

### Bits [23:22]

Reserved, RES0.

### SS, bit [21]

Software step. Indicates whether software step was enabled when Debug state was entered.

### IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

### GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

### IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

### E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

### A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

- 0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
- 1 Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to exit Debug state with those values is an illegal exception return.

If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<b>M[3:0]</b>	<b>Mode</b>
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

**Accessing the DSPSR:**

To access the DSPSR:

MRC p15,3,<Rt>,c4,c5,0 ; Read DSPSR into Rt

MCR p15,3,<Rt>,c4,c5,0 ; Write Rt to DSPSR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	011	0100	0101	000

### G4.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

#### Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors extension.

This register is part of:

- the Debug registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

#### Configurations

HDCR is architecturally mapped to AArch64 register [MDCR\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

#### Attributes

HDCR is a 32-bit register.

The HDCR bit assignments are:

#### Bits [31:12]

Reserved, RES0.

#### TDRA, bit [11]

Trap debug ROM address register access. The possible values of this bit are:

- 0 Has no effect on accesses to debug ROM address registers from EL1 and EL0.
- 1 Trap valid Non-secure EL1 and EL0 access to debug ROM address registers to Hyp mode.

When this bit is set to 1, any valid Non-secure access to the [DBGDRAR](#) or [DBGDSAR](#) is trapped to Hyp mode.

If [HCR.TGE](#) == 1 or [HDCR.TDE](#) == 1, the behavior is CONstrained UNPREDICTABLE, and this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

#### TDOSA, bit [10]

Trap debug OS-related register access. The possible values of this bit are:

- 0 Has no effect on accesses to CP14 debug registers.
- 1 Trap valid Non-secure accesses to CP14 OS-related debug registers to Hyp mode.

When this bit is set to 1, any valid Non-secure CP14 access to [DBGOSLAR](#), [DBGOSLSR](#), [DBGOSDLR](#), or [DBGPRCR](#) is trapped to Hyp mode.

If [HCR.TGE](#) == 1 or [HDCR.TDE](#) == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from [HDCR](#).

On Warm reset, the field resets to 0.

#### TDA, bit [9]

Trap debug access. The possible values of this bit are:

- 0 Has no effect on accesses to CP14 Debug registers.
- 1 Trap valid Non-secure accesses to CP14 Debug registers to Hyp mode.

When this bit is set to 1, any valid access to the CP14 Debug registers, other than the registers trapped by the [TDRA](#) and [TDOSA](#) bits, is trapped to Hyp mode.

If [HCR.TGE](#) == 1 or [HDCR.TDE](#) == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from [HDCR](#).

On Warm reset, the field resets to 0.

#### TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

- 0 Has no effect on Debug exceptions.
- 1 Route Non-secure Debug exceptions to Hyp mode.

When this bit is set to 1, any Debug exception taken in Non-secure state is routed to Hyp mode.

If [HCR.TGE](#) == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from [HDCR](#).

On Warm reset, the field resets to 0.

#### HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

- 0 Hyp mode Performance Monitors disabled.
- 1 Hyp mode Performance Monitors enabled.

When this bit is set to 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the [HPMN](#) field.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### TPM, bit [6]

Trap Performance Monitors accesses. The possible values of this bit are:

- 0 Has no effect on Performance Monitors accesses.
- 1 Trap valid Non-secure Performance Monitors accesses to Hyp mode.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field resets to 0.

#### TPMCR, bit [5]

Trap [PMCR](#) accesses. The possible values of this bit are:

- 0 Has no effect on [PMCR](#) accesses.
- 1 Trap valid Non-secure [PMCR](#) accesses to Hyp mode.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field resets to 0.

#### HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If the Performance Monitors extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter  $n$  then, in Non-secure state:

- If  $n$  is in the range  $0 \leq n < \text{HPMN}$ , the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. **PMCR.E** enables the operation of counters in this range.
- If  $n$  is in the range  $\text{HPMN} \leq n < \text{PMCR.N}$ , the counter is accessible only from EL2. **HDCR.HPME** enables the operation of counters in this range.

If this field is set to 0, or to a value larger than **PMCR.N**, then the behavior in Non-secure EL0 and EL1 is CONstrained UNPREDICTABLE, and one of the following must happen:

- The number of counters accessible is an UNKNOWN non-zero value less than **PMCR.N**.
- There is no access to any counters.

For reads of **HDCR.HPMN** by EL2 or higher, if this field is set to 0 or to a value larger than **PMCR.N**, the processor must return a CONstrained UNPREDICTABLE value being one of:

- **PMCR.N**.
- The value that was written to **HDCR.HPMN**.
- (The value that was written to **HDCR.HPMN**) modulo  $2^h$ , where  $h$  is the smallest number of bits required for a value in the range 0 to **PMCR.N**.

On Warm reset, the field resets to an IMPLEMENTATION DEFINED value.

#### Accessing the HDCR:

To access the HDCR:

MRC p15,4,<Rt>,c1,c1,1 ; Read HDCR into Rt  
MCR p15,4,<Rt>,c1,c1,1 ; Write Rt to HDCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	001

### G4.3.32 SDCR, Secure Debug Configuration Register

The SDCR characteristics are:

**Purpose**

Controls debug and performance monitors functionality in Secure state.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

If EL3 is implemented and is using AArch64, any read or write to SDCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

SDCR can be mapped to AArch64 register [MDCR\\_EL3](#), but this is not architecturally mandated.

This register is only accessible in Secure state.

**Attributes**

SDCR is a 32-bit register.

The SDCR bit assignments are:

**Bits [31:22]**

Reserved, RES0.

**EPMAD, bit [21]**

External debugger access to Performance Monitors registers disabled. This disables access to these registers by an external debugger:

- 0 Access to Performance Monitors registers from external debugger is permitted.
- 1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

**EDAD, bit [20]**

External debugger access to breakpoint and watchpoint registers disabled. This disables access to these registers by an external debugger:

- 0 Access to breakpoint and watchpoint registers from external debugger is permitted.
- 1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

**Bits [19:18]**

Reserved, RES0.

**SPME, bit [17]**

Secure performance monitors enable. This allows event counting in Secure state:

- 0 Event counting prohibited in Secure state, unless overridden by the authentication interface.
- 1 Event counting allowed in Secure state.

On Warm reset, the field resets to 0.

**Bit [16]**

Reserved, RES0.

**SPD, bits [15:14]**

AArch32 secure privileged debug. Enables or disables debug exceptions from Secure state, other than Software breakpoint instructions. Valid values for this field are:

- 00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.
- 10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
- 11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if `SDER32_EL3.SUIDEN == 1`.

Ignored in Non-secure state. Debug exceptions from Software breakpoint instruction debug events are always enabled.

On Warm reset, the field resets to 0.

**Bits [13:0]**

Reserved, RES0.

**Accessing the SDCR:**

To access the SDCR:

MRC p15,0,<Rt>,c1,c3,1 ; Read SDCR into Rt

MCR p15,0,<Rt>,c1,c3,1 ; Write Rt to SDCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0011	001

### G4.3.33 SDER, Secure Debug Enable Register

The SDER characteristics are:

#### Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

#### Configurations

SDER is architecturally mapped to AArch64 register [SDER32\\_EL3](#).

This register is only accessible in Secure state.

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the processor is Secure.

#### Attributes

SDER is a 32-bit register.

The SDER bit assignments are:

#### Bits [31:2]

Reserved, RES0.

#### SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

- 0 Non-invasive debug not permitted in Secure EL0 mode.
- 1 Non-invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.

#### SUIDEN, bit [0]

Secure User Invasive Debug Enable:

- 0 Invasive debug not permitted in Secure EL0 mode.
- 1 Invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.

### Accessing the SDER:

To access the SDER:

MRC p15,0,<Rt>,c1,c1,1 ; Read SDER into Rt  
MCR p15,0,<Rt>,c1,c1,1 ; Write Rt to SDER

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	0001	0001	001

## G4.4 Performance Monitors registers

This section describes the Performance Monitors registers in AArch32 state.

### G4.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

#### Purpose

Determines the modes in which the Cycle Counter, [PMCCNTR](#), increments.  
 This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

PMCCFILTR can also be accessed by using [PMXEVTYPER](#) with [PMSELR.SEL](#) set to 0b11111.

#### Configurations

PMCCFILTR is architecturally mapped to AArch64 register [PMCCFILTR\\_EL0](#).

PMCCFILTR is architecturally mapped to external register [PMCCFILTR\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

PMCCFILTR is a 32-bit register.

The PMCCFILTR bit assignments are:

#### P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.
- 1 Do not count cycles in EL1.

On Warm reset, the field resets to 0.

**U, bit [30]**

ELO filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count cycles in EL0.
- 1 Do not count cycles in EL0.

On Warm reset, the field resets to 0.

**NSK, bit [29]**

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On Warm reset, the field resets to 0.

**NSU, bit [28]**

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

On Warm reset, the field resets to 0.

**NSH, bit [27]**

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

- 0 Do not count cycles in EL2.
- 1 Count cycles in EL2.

On Warm reset, the field resets to 0.

**Bits [26:0]**

Reserved, RES0.

**Accessing the PMCCFILTR:**

To access the PMCCFILTR:

MRC p15,0,<Rt>,c14,c15,7 ; Read PMCCFILTR into Rt  
MCR p15,0,<Rt>,c14,c15,7 ; Write Rt to PMCCFILTR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	1111	111

## G4.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

### Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) or [PMUSERENR.CR](#) is set to 1.

The [PMCR.{LC, D}](#) bits configure whether PMCCNTR increments every clock cycle, or once every 64 clock cycles.

[PMCCFILTR](#) determines the modes and states in which the PMCCNTR can increment.

### Configurations

PMCCNTR is architecturally mapped to AArch64 register [PMCCNTR\\_ELO](#) when accessing as a 64-bit register.

PMCCNTR is architecturally mapped to external register [PMCCNTR\\_ELO](#).

PMCCNTR is architecturally mapped to AArch64 register [PMCCNTR\\_ELO\[31:0\]](#).

There is one instance of this register that is used in both Secure and Non-secure states.

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is **CONSTRAINED UNPREDICTABLE** whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

### Attributes

PMCCNTR is a 32-bit register when accessing as a 32-bit register and a 64-bit register when accessing as a 64-bit register.

The PMCCNTR bit assignments are:

### When accessing as a 32-bit register:

### CCNT, bits [31:0]

Cycle count. Depending on the values of [PMCR.{LC,D}](#), this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to [PMCR.C](#).

On Warm reset, the field reset value is architecturally UNKNOWN.

**When accessing as a 64-bit register:**

**CCNT, bits [63:0]**

Cycle count. Depending on the values of **PMCR**.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to **PMCR.C**.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMCCNTR:**

To access the PMCCNTR when accessing as a 32-bit register:

MRC p15,0,<Rt>,c9,c13,0 ; Read PMCCNTR into Rt  
MCR p15,0,<Rt>,c9,c13,0 ; Write Rt to PMCCNTR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	000

To access the PMCCNTR when accessing as a 64-bit register:

MRRC p15,0,<Rt>,<Rt2>,c9 ; Read 64-bit PMCCNTR into Rt (low word) and Rt2 (high word)  
MCRR p15,0,<Rt>,<Rt2>,c9 ; Write Rt (low word) and Rt2 (high word) to 64-bit PMCCNTR

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1001

### G4.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

#### Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

#### Configurations

PMCEID0 is architecturally mapped to AArch64 register [PMCEID0\\_EL0](#).

PMCEID0 is architecturally mapped to external register [PMCEID0\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

PMCEID0 is a 32-bit register.

The PMCEID0 bit assignments are:

#### CE[31:0], bits [31:0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For each bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
31	0x01F	L1D_CACHE_ALLOCATE
30	0x01E	CHAIN
29	0x01D	BUS_CYCLES
28	0x01C	TTBR_WRITE_RETIRED
27	0x01B	INST_SPEC
26	0x01A	MEMORY_ERROR
25	0x019	BUS_ACCESS
24	0x018	L2D_CACHE_WB

Bit	Event number	Event mnemonic
23	0x017	L2D_CACHE_REFILL
22	0x016	L2D_CACHE
21	0x015	L1D_CACHE_WB
20	0x014	L1I_CACHE
19	0x013	MEM_ACCESS
18	0x012	BR_PRED
17	0x011	CPU_CYCLES
16	0x010	BR_MIS_PRED
15	0x00F	UNALIGNED_LDST_RETIRED
14	0x00E	BR_RETURN_RETIRED
13	0x00D	BR_IMMED_RETIRED
12	0x00C	PC_WRITE_RETIRED
11	0x00B	CID_WRITE_RETIRED
10	0x00A	EXC_RETURN
9	0x009	EXC_TAKEN
8	0x008	INST_RETIRED
7	0x007	ST_RETIRED
6	0x006	LD_RETIRED
5	0x005	L1D_TLB_REFILL
4	0x004	L1D_CACHE
3	0x003	L1D_CACHE_REFILL
2	0x002	L1I_TLB_REFILL
1	0x001	L1I_CACHE_REFILL
0	0x000	SW_INCR

### Accessing the PMCEID0:

To access the PMCEID0:

MRC p15,0,<Rt>,c9,c12,6 ; Read PMCEID0 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	110

### G4.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

**Purpose**

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

**Configurations**

PMCEID1 is architecturally mapped to AArch64 register [PMCEID1\\_EL0](#).

PMCEID1 is architecturally mapped to external register [PMCEID1\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCEID1 is a 32-bit register.

The PMCEID1 bit assignments are:

**Bits [31:1]**

Reserved, RES0.

**CE[32], bit [0]**

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
0	0x020	L2D_CACHE_ALLOCATE

**Accessing the PMCEID1:**

To access the PMCEID1:

MRC p15,0,<Rt>,c9,c12,7 ; Read PMCEID1 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1100	111

## G4.4.5 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

### Purpose

Disables the Cycle Count Register, [PMCCNTR](#), and any implemented event counters [PMEVCNTR<x>](#). Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMCNTENCLR. See the description of the Px bit.

PMCNTENCLR is used in conjunction with the [PMCNTENSET](#) register.

### Configurations

PMCNTENCLR is architecturally mapped to AArch64 register [PMCNTENCLR\\_EL0](#).

PMCNTENCLR is architecturally mapped to external register [PMCNTENCLR\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

PMCNTENCLR is a 32-bit register.

The PMCNTENCLR bit assignments are:

### C, bit [31]

[PMCCNTR](#) disable bit. Disables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter disable bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) is enabled. When written, disables [PMEVCNTR<x>](#).

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMNTENCLR:

To access the PMNTENCLR:

MRC p15,0,<Rt>,c9,c12,2 ; Read PMNTENCLR into Rt

MCR p15,0,<Rt>,c9,c12,2 ; Write Rt to PMNTENCLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1100	010

### G4.4.6 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

**Purpose**

Enables the Cycle Count Register, [PMCCNTR](#), and any implemented event counters [PMEVCNTR<x>](#). Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMCNTENSET. See the description of the Px bit.

PMCNTENSET is used in conjunction with the [PMCNTENCLR](#) register.

**Configurations**

PMCNTENSET is architecturally mapped to AArch64 register [PMCNTENSET\\_ELO](#).

PMCNTENSET is architecturally mapped to external register [PMCNTENSET\\_ELO](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCNTENSET is a 32-bit register.

The PMCNTENSET bit assignments are:

**C, bit [31]**

[PMCCNTR](#) enable bit. Enables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

**P<x>, bit [x] for x = 0 to (N - 1)**

Event counter enable bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) event counter is enabled. When written, enables [PMEVCNTR<x>](#).

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMCNTENSET:

To access the PMCNTENSET:

MRC p15,0,<Rt>,c9,c12,1 ; Read PMCNTENSET into Rt

MCR p15,0,<Rt>,c9,c12,1 ; Write Rt to PMCNTENSET

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1100	001

### G4.4.7 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

**Purpose**

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

**Configurations**

PMCR is architecturally mapped to AArch64 register [PMCR\\_EL0](#).

PMCR is architecturally mapped to external register [PMCR\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCR is a 32-bit register.

The PMCR bit assignments are:

**IMP, bits [31:24]**

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the [MIDR](#).

**IDCODE, bits [23:16]**

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

**N, bits [15:11]**

Number of event counters. This field is RO with an IMPLEMENTATION DEFINED value that indicates the number of counters implemented.

The value of this field is the number of counters implemented, from 0b000000 for no counters to 0b11111 for 31 counters.

An implementation can implement only the Cycle Count Register, [PMCCNTR](#). This is indicated by a value of 0b000000 for the N field.

**Bits [10:7]**

Reserved, RES0.

### LC, bit [6]

Long cycle counter enable. Determines which **PMCCNTR** bit generates an overflow recorded by **PMOVSr**[31].

- 0 Cycle counter overflow on increment that changes **PMCCNTR**[31] from 1 to 0.
- 1 Cycle counter overflow on increment that changes **PMCCNTR**[63] from 1 to 0.

ARM deprecates use of **PMCR.LC** = 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

### DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0 **PMCCNTR**, if enabled, counts when event counting is prohibited.
- 1 **PMCCNTR** does not count when event counting is prohibited.

Event counting is prohibited when `ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE`.

This bit is RW.

On Warm reset, the field resets to 0.

### X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0 Do not export events.
- 1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

On Warm reset, the field resets to 0.

### D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, **PMCCNTR** counts every clock cycle.
- 1 When enabled, **PMCCNTR** counts once every 64 clock cycles.

This bit is RW.

If **PMCR.LC** == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of **PMCR.D** = 1.

On Warm reset, the field resets to 0.

### C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset **PMCCNTR** to zero.

This bit is always RAZ.

Resetting **PMCCNTR** does not clear the **PMCCNTR** overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

### P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset all event counters accessible in the current EL, not including [PMCCNTR](#), to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that [HDCR.HPMN](#) reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

### E, bit [0]

Enable. The possible values of this bit are:

- 0 All counters, including [PMCCNTR](#), are disabled.
- 1 All counters are enabled by [PMCNTENSET](#).

This bit is RW.

In Non-secure EL0 and EL1, if EL2 is implemented, this bit does not affect the operation of event counters that [HDCR.HPMN](#) reserves for EL2 use.

On Warm reset, the field resets to 0.

### Accessing the PMCR:

To access the PMCR:

MRC p15,0,<Rt>,c9,c12,0 ; Read PMCR into Rt  
MCR p15,0,<Rt>,c9,c12,0 ; Write Rt to PMCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	000

## G4.4.8 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

### Purpose

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when [PMUSERENR.EN](#) or [PMUSERENR.ER](#) is set to 1, and can be written at EL0 when [PMUSERENR.ER](#) is set to 1.

PMEVCNTR<n> can also be accessed by using [PMXVCNTR](#) with [PMSELR.SEL](#) set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> are CONstrained UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.

### Configurations

PMEVCNTR<n> is architecturally mapped to AArch64 register [PMEVCNTR<n>\\_EL0](#).

PMEVCNTR<n> is architecturally mapped to external register [PMEVCNTR<n>\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

PMEVCNTR<n> is a 32-bit register.

The PMEVCNTR<n> bit assignments are:

### Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMEVCNTR<n>:

To access the PMEVCNTR<n>:

MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVCNTR<n> into Rt, where n is in the range 0 to 30  
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVCNTR<n>, where n is in the range 0 to 30

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1110	10:n<4:3>	n<2:0>

## G4.4.9 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

### Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

PMEVTYPER<n> can also be accessed by using [PMXEVTYPER](#) with [PMSELR.SEL](#) set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVTYPER<n> are CONstrained UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.

### Configurations

PMEVTYPER<n> is architecturally mapped to AArch64 register [PMEVTYPER<n>\\_EL0](#).

PMEVTYPER<n> is architecturally mapped to external register [PMEVTYPER<n>\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

PMEVTYPER<n> is a 32-bit register.

The PMEVTYPER<n> bit assignments are:

### P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

**U, bit [30]**

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSK, bit [29]**

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSU, bit [28]**

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

**NSH, bit [27]**

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

- 0 Do not count events in EL2.
- 1 Count events in EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [26]**

Reserved, RES0.

**Bits [25:10]**

Reserved, RES0.

**evtCount, bits [9:0]**

Event to count. The event number of the event that is counted by event counter `PMEVCNTR<n>`. Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMEVTYPER<n>:

To access the PMEVTYPER<n>:

MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVTYPER<n> into Rt, where n is in the range 0 to 30  
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVTYPER<n>, where n is in the range 0 to 30

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1110	11:n<4:3>	n<2:0>

### G4.4.10 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

#### Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR](#), and the event counters [PMEVCNTR<n>](#). Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMINTENCLR. See the description of the P<x> bit.

PMINTENCLR is used in conjunction with the [PMINTENSET](#) register.

#### Configurations

PMINTENCLR is architecturally mapped to AArch64 register [PMINTENCLR\\_EL1](#).

PMINTENCLR is architecturally mapped to external register [PMINTENCLR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

PMINTENCLR is a 32-bit register.

The PMINTENCLR bit assignments are:

#### C, bit [31]

[PMCCNTR](#) overflow interrupt request disable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow interrupt request disable bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#).

Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<x>](#) event counter interrupt request is disabled. When written, has no effect.

- 1            When read, means that the PMEVCNTR<x> event counter interrupt request is enabled.  
              When written, disables the PMEVCNTR<x> interrupt request.
- On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMINTENCLR:

To access the PMINTENCLR:

MRC p15,0,<Rt>,c9,c14,2 ; Read PMINTENCLR into Rt  
MCR p15,0,<Rt>,c9,c14,2 ; Write Rt to PMINTENCLR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	010

### G4.4.11 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

#### Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR](#), and the event counters [PMEVCNTR<n>](#). Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMINTENSET. See the description of the P<x> bit.

PMINTENSET is used in conjunction with the [PMINTENCLR](#) register.

#### Configurations

PMINTENSET is architecturally mapped to AArch64 register [PMINTENSET\\_EL1](#).

PMINTENSET is architecturally mapped to external register [PMINTENSET\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

PMINTENSET is a 32-bit register.

The PMINTENSET bit assignments are:

#### C, bit [31]

[PMCCNTR](#) overflow interrupt request enable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow interrupt request enable bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#).

Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<x>](#) event counter interrupt request is disabled. When written, has no effect.

- 1            When read, means that the PMEVCNTR<x> event counter interrupt request is enabled.  
              When written, enables the PMEVCNTR<x> interrupt request.
- On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMINTENSET:

To access the PMINTENSET:

MRC p15,0,<Rt>,c9,c14,1 ; Read PMINTENSET into Rt  
MCR p15,0,<Rt>,c9,c14,1 ; Write Rt to PMINTENSET

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1110	001

### G4.4.12 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR](#), and each of the implemented event counters [PMEVCNTR<x>](#). Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMOVSR. See the description of the Px bit.

**Configurations**

PMOVSR is architecturally mapped to AArch64 register [PMOVSLR\\_EL0](#).

PMOVSR is architecturally mapped to external register [PMOVSLR\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMOVSR is a 32-bit register.

The PMOVSR bit assignments are:

**C, bit [31]**

[PMCCNTR](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

[PMCR.LC](#) is used to control from which bit of [PMCCNTR](#) (bit 31 or bit 63) an overflow is detected. On Warm reset, the field reset value is architecturally UNKNOWN.

**P<x>, bit [x] for x = 0 to (N - 1)**

Event counter overflow clear bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) has not overflowed. When written, has no effect.

- 1 When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMOVSr:

To access the PMOVSr:

MRC p15,0,<Rt>,c9,c12,3 ; Read PMOVSr into Rt  
MCR p15,0,<Rt>,c9,c12,3 ; Write Rt to PMOVSr

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	011

### G4.4.13 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

#### Purpose

Sets the state of the overflow bit for the Cycle Count Register, [PMCCNTR](#), and each of the implemented event counters [PMEVCNTR<x>](#).

This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMOVSSET. See the description of the Px bit.

#### Configurations

PMOVSSET is architecturally mapped to AArch64 register [PMOVSSET\\_EL0](#).

PMOVSSET is architecturally mapped to external register [PMOVSSET\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

PMOVSSET is a 32-bit register.

The PMOVSSET bit assignments are:

#### C, bit [31]

[PMCCNTR](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

#### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow set bit for [PMEVCNTR<x>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#).

Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that [PMEVCNTR<x>](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) has overflowed. When written, sets the [PMEVCNTR<x>](#) overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMOVSSET:

To access the PMOVSSET:

MRC p15,0,<Rt>,c9,c14,3 ; Read PMOVSSET into Rt  
MCR p15,0,<Rt>,c9,c14,3 ; Write Rt to PMOVSSET

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1110	011

### G4.4.14 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

**Purpose**

Selects the current event counter `PMEVCNTR<x>` or the cycle counter, `CCNT`.  
 This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when `PMUSERENR.EN` or `PMUSERENR.ER` is set to 1.

PMSELR is used in conjunction with `PMXEVTYPER` to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with `PMXEVCNTR`, to determine the value of a selected event counter.

**Configurations**

PMSELR is architecturally mapped to AArch64 register `PMSELR_ELO`.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMSELR is a 32-bit register.

The PMSELR bit assignments are:

**Bits [31:5]**

Reserved, RES0.

**SEL, bits [4:0]**

Selects event counter, `PMEVCNTR<x>`, where `x` is the value held in this field. This value identifies which event counter is accessed when a subsequent access to `PMXEVTYPER` or `PMXEVCNTR` occurs.

This field can take any value from 0 (`0b00000`) to `(PMCR.N)-1`, or 31 (`0b11111`).

When `PMSELR.SEL` is `0b11111` it selects the cycle counter and:

- A read of the `PMXEVTYPER` returns the value of `PMCCFILTR`.
- A write of the `PMXEVTYPER` writes to `PMCCFILTR`.
- A read or write of `PMXEVCNTR` has CONstrained UNPREDICTABLE effects, that can be one of the following:
  - Access to `PMXEVCNTR` is UNDEFINED.
  - Access to `PMXEVCNTR` behaves as a NOP.
  - Access to `PMXEVCNTR` behaves as if the register is RAZ/WI.

— Access to **PMXEVNTR** behaves as if the **PMSELR.SEL** field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to **PMXEVTYPER** or **PMXEVNTR** are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to **PMXEVTYPER** or **PMXEVNTR** is UNDEFINED.
- Access to **PMXEVTYPER** or **PMXEVNTR** behaves as a NOP.
- Access to **PMXEVTYPER** or **PMXEVNTR** behaves as if the register is RAZ/WI.
- Access to **PMXEVTYPER** or **PMXEVNTR** behaves as if the **PMSELR.SEL** field contains an UNKNOWN value.
- Access to **PMXEVTYPER** or **PMXEVNTR** behaves as if the **PMSELR.SEL** field contains 0b11111.

On Warm reset, the field reset value is architecturally UNKNOWN.

### Accessing the PMSELR:

To access the PMSELR:

MRC p15,0,<Rt>,c9,c12,5 ; Read PMSELR into Rt  
 MCR p15,0,<Rt>,c9,c12,5 ; Write Rt to PMSELR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	101

### G4.4.15 PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00.  
 This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO	WO

This register is accessible at EL0 when [PMUSERENR.EN](#) or [PMUSERENR.SW](#) is set to 1.  
 If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to PMSWINC. See the description of the Px bit.

**Configurations**

PMSWINC is architecturally mapped to AArch64 register [PMSWINC\\_EL0](#).  
 PMSWINC is architecturally mapped to external register [PMSWINC\\_EL0](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMSWINC is a 32-bit register.

The PMSWINC bit assignments are:

**Bit [31]**

Reserved, RES0.

**P<x>, bit [x] for x = 0 to (N - 1)**

Event counter software increment bit for [PMEVCNTR<x>](#).  
 When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#).  
 Otherwise, N is the value in [PMCR.N](#).  
 Bits [30:N] are RAZ/WI.  
 The effects of writing to this bit are:

- 0 No action. The write to this bit is ignored.
- 1 If [PMEVCNTR<x>](#) is enabled and configured to count the software increment event, increments [PMEVCNTR<x>](#) by 1. If [PMEVCNTR<x>](#) is disabled, or not configured to count the software increment event, the write to this bit is ignored.

**Accessing the PMSWINC:**

To access the PMSWINC:

MCR p15,0,<Rt>,c9,c12,4 ; Write Rt to PMSWINC

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1100	100

### G4.4.16 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

**Purpose**

Enables or disables User mode access to the Performance Monitors.  
 This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RW	RW	RW	RW	RW

**Configurations**

PMUSERENR is architecturally mapped to AArch64 register [PMUSERENR\\_EL0](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMUSERENR is a 32-bit register.

The PMUSERENR bit assignments are:

**Bits [31:4]**

Reserved, RES0.

**ER, bit [3]**

Event counter read enable. The possible values of this bit are:

- 0 EL0 read access to [PMXVCNTR](#) / [PMEVCNTR<n>](#) and read/write access to [PMSELR](#) disabled if PMUSERENR.EN is also 0.
- 1 EL0 read access to [PMXVCNTR](#) / [PMEVCNTR<n>](#) and read/write access to [PMSELR](#) enabled.

On Warm reset, the field resets to 0.

**CR, bit [2]**

Cycle counter read enable. The possible values of this bit are:

- 0 EL0 read access to [PMCCNTR](#) disabled if PMUSERENR.EN is also 0.
- 1 EL0 read access to [PMCCNTR](#) enabled.

On Warm reset, the field resets to 0.

**SW, bit [1]**

Software Increment write enable. The possible values of this bit are:

- 0 ELO write access to [PMSWINC](#) disabled if PMUSERENR.EN is also 0.
- 1 ELO write access to [PMSWINC](#) enabled.

On Warm reset, the field resets to 0.

**EN, bit [0]**

ELO access enable bit. The possible values of this bit are:

- 0 ELO access to the Performance Monitors disabled.
- 1 ELO access to the Performance Monitors enabled. Can access all PMU registers at ELO, except for writes to PMUSERENR and reads/writes of [PMINTENSET](#) and [PMINTENCLR](#).

On Warm reset, the field resets to 0.

**Accessing the PMUSERENR:**

To access the PMUSERENR:

MRC p15,0,<Rt>,c9,c14,0 ; Read PMUSERENR into Rt  
 MCR p15,0,<Rt>,c9,c14,0 ; Write Rt to PMUSERENR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	000

### G4.4.17 PMXEVNTR, Performance Monitors Selected Event Count Register

The PMXEVNTR characteristics are:

**Purpose**

Reads or writes the value of the selected event counter, PMXEVNTR<x>. PMSELR.SEL determines which event counter is selected.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

If PMSELR.SEL selects a counter that is not accessible then reads and writes of PMXEVNTR are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.
- As if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current exception level and security state.
- As if PMSELR.SEL is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If PMSELR.SEL is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if PMSELR.SEL >= HDCR.HPMN.

**Configurations**

PMXEVNTR is architecturally mapped to AArch64 register PMXEVNTR\_ELO.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMXEVNTR is a 32-bit register.

The PMXEVNTR bit assignments are:

**PMXEVNTR<x>, bits [31:0]**

Value of the selected event counter, PMXEVNTR<x>, where x is the value stored in PMSELR.SEL.

**Accessing the PMXEVNTR:**

To access the PMXEVNTR:

MRC p15,0,<Rt>,c9,c13,2 ; Read PMXEVNTR into Rt  
MCR p15,0,<Rt>,c9,c13,2 ; Write Rt to PMXEVNTR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1101	010

### G4.4.18 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

**Purpose**

When [PMSELR.SEL](#) selects an event counter, this accesses a [PMEVTYPER<n>](#) register. When [PMSELR.SEL](#) selects the cycle counter, this accesses [PMCCFILTR](#).

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

If [PMSELR.SEL](#) selects a counter that is not accessible then reads and writes of PMXEVTYPER are CONstrained UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.
- As if [PMSELR.SEL](#) has an UNKNOWN value less than the number of counters accessible at the current exception level and security state.
- As if [PMSELR.SEL](#) is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If [PMSELR.SEL](#) is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if [PMSELR.SEL](#) >= [HDCR.HPMN](#).

**Configurations**

PMXEVTYPER is architecturally mapped to AArch64 register [PMXEVTYPER\\_EL0](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMXEVTYPER is a 32-bit register.

The PMXEVTYPER bit assignments are:

**Bits [31:0]**

Event type register or [PMCCFILTR](#).

When [PMSELR.SEL](#) == 31, this register accesses [PMCCFILTR](#).

Otherwise, this register accesses [PMEVTYPER<n>](#) where n is the value in [PMSELR.SEL](#).

### Accessing the PMXEVTYPYPER:

To access the PMXEVTYPYPER:

MRC p15,0,<Rt>,c9,c13,1 ; Read PMXEVTYPYPER into Rt  
MCR p15,0,<Rt>,c9,c13,1 ; Write Rt to PMXEVTYPYPER

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1001	1101	001

## G4.5 Generic Timer registers

This section describes the Generic Timer registers in AArch32 state.

### G4.5.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

#### Purpose

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RW

Can only be written at the highest exception level implemented. For example, if EL3 is the highest implemented exception level, CNTFRQ can only be written at EL3.

If EL3 is using AArch64, write access to CNTFRQ in AArch32 at Secure EL1 is UNDEFINED.

This register is accessible and read-only at EL0 when [CNTKCTL.EL0PCTEN](#) or [CNTKCTL.EL0VCTEN](#) is set to 1.

#### Configurations

CNTFRQ is architecturally mapped to AArch64 register [CNTFRQ\\_EL0](#).

CNTFRQ is architecturally mapped to external register [CNTFRQ](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

CNTFRQ is a 32-bit register.

The CNTFRQ bit assignments are:

#### Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

#### Accessing the CNTFRQ:

To access the CNTFRQ:

MRC p15,0,<Rt>,c14,c0,0 ; Read CNTFRQ into Rt

MCR p15,0,<Rt>,c14,c0,0 ; Write Rt to CNTFRQ

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0000	000

## G4.5.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

### Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

CNTHCTL is architecturally mapped to AArch64 register [CNTHCTL\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

CNTHCTL is a 32-bit register.

The CNTHCTL bit assignments are:

### Bits [31:8]

Reserved, RES0.

### EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register ([CNTPTCT](#) or [CNTVCT](#)) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

### EVNTDIR, bit [3]

Controls which transition of the counter register ([CNTPTCT](#) or [CNTVCT](#)) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0 A 0 to 1 transition of the trigger bit triggers an event.
- 1 A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

**EVNTEN, bit [2]**

Enables the generation of an event stream from the corresponding counter:

- 0 Disables the event stream.
- 1 Enables the event stream.

Resets to 0.

**EL1PCEN, bit [1]**

Controls whether the Non-secure copies of the physical timer registers are accessible from Non-secure EL1 and EL0 modes:

- 0 The Non-secure [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#) registers are not accessible from Non-secure EL1 and EL0 modes.
- 1 The Non-secure [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#) registers are accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

**EL1PCTEN, bit [0]**

Controls whether the physical counter, [CNTPCT](#), is accessible from Non-secure EL1 and EL0 modes:

- 0 The [CNTPCT](#) register is not accessible from Non-secure EL1 and EL0 modes.
- 1 The [CNTPCT](#) register is accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

**Accessing the CNTHCTL:**

To access the CNTHCTL:

MRC p15,4,<Rt>,c14,c1,0 ; Read CNTHCTL into Rt  
MCR p15,4,<Rt>,c14,c1,0 ; Write Rt to CNTHCTL

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0001	000

### G4.5.3 CNTHP\_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP\_CTL characteristics are:

#### Purpose

Control register for the Hyp mode physical timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

#### Configurations

CNTHP\_CTL is architecturally mapped to AArch64 register [CNTHP\\_CTL\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

#### Attributes

CNTHP\_CTL is a 32-bit register.

The CNTHP\_CTL bit assignments are:

#### Bits [31:3]

Reserved, RES0.

#### ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

- 0 Interrupt not asserted.
- 1 Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked.
- 1 Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

#### ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.

1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

### Accessing the CNTHP\_CTL:

To access the CNTHP\_CTL:

MRC p15,4,<Rt>,c14,c2,1 ; Read CNTHP\_CTL into Rt

MCR p15,4,<Rt>,c14,c2,1 ; Write Rt to CNTHP\_CTL

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	100	1110	0010	001

## G4.5.4 CNTHP\_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP\_CVAL characteristics are:

### Purpose

Holds the compare value for the Hyp mode physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

CNTHP\_CVAL is architecturally mapped to AArch64 register [CNTHP\\_CVAL\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

CNTHP\_CVAL is a 64-bit register.

The CNTHP\_CVAL bit assignments are:

### Bits [63:0]

EL2 physical timer compare value.

### Accessing the CNTHP\_CVAL:

To access the CNTHP\_CVAL:

MRRC p15,6,<Rt>,<Rt2>,c14 ; Read 64-bit CNTHP\_CVAL into Rt (low word) and Rt2 (high word)

MCRW p15,6,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTHP\_CVAL

Register access is encoded as follows:

coproc	opc1	CRm
1111	0110	1110

### G4.5.5 CNTHP\_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP\_TVAL characteristics are:

**Purpose**

Holds the timer value for the Hyp mode physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

**Configurations**

CNTHP\_TVAL is architecturally mapped to AArch64 register [CNTHP\\_TVAL\\_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP\_TVAL is a 32-bit register.

The CNTHP\_TVAL bit assignments are:

**Bits [31:0]**

EL2 physical timer value.

**Accessing the CNTHP\_TVAL:**

To access the CNTHP\_TVAL:

MRC p15,4,<Rt>,c14,c2,0 ; Read CNTHP\_TVAL into Rt

MCR p15,4,<Rt>,c14,c2,0 ; Write Rt to CNTHP\_TVAL

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0010	000

## G4.5.6 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

### Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

### Configurations

CNTKCTL is architecturally mapped to AArch64 register [CNTKCTL\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

CNTKCTL is a 32-bit register.

The CNTKCTL bit assignments are:

### Bits [31:10]

Reserved, RES0.

### EL0PTEN, bit [9]

Controls whether the physical timer registers are accessible from EL0 modes:

0 The [CNTP\\_CVAL](#), [CNTP\\_CTL](#), and [CNTP\\_TVAL](#) registers are not accessible from EL0.

1 The [CNTP\\_CVAL](#), [CNTP\\_CTL](#), and [CNTP\\_TVAL](#) registers are accessible from EL0.

Resets to 0.

### EL0VTEN, bit [8]

Controls whether the virtual timer registers are accessible from EL0 modes:

0 The [CNTV\\_CVAL](#), [CNTV\\_CTL](#), and [CNTV\\_TVAL](#) registers are not accessible from EL0.

1 The [CNTV\\_CVAL](#), [CNTV\\_CTL](#), and [CNTV\\_TVAL](#) registers are accessible from EL0.

Resets to 0.

#### EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register ([CNTPCT](#) or [CNTVCT](#)) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

#### EVNTDIR, bit [3]

Controls which transition of the counter register ([CNTPCT](#) or [CNTVCT](#)) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0 A 0 to 1 transition of the trigger bit triggers an event.

1 A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

#### EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

Resets to 0.

#### EL0VCTEN, bit [1]

Controls whether the virtual counter, [CNTVCT](#), and the frequency register [CNTFRQ](#), are accessible from EL0 modes:

0 [CNTVCT](#) is not accessible from EL0. If [EL0PCTEN](#) is set to 0, [CNTFRQ](#) is not accessible from EL0.

1 [CNTVCT](#) and [CNTFRQ](#) are accessible from EL0.

Resets to 0.

#### EL0PCTEN, bit [0]

Controls whether the physical counter, [CNTPCT](#), and the frequency register [CNTFRQ](#), are accessible from EL0 modes:

0 [CNTPCT](#) is not accessible from EL0 modes. If [EL0VCTEN](#) is set to 0, [CNTFRQ](#) is not accessible from EL0.

1 [CNTPCT](#) and [CNTFRQ](#) are accessible from EL0.

Resets to 0.

### Accessing the CNTKCTL:

To access the CNTKCTL:

MRC p15,0,<Rt>,c14,c1,0 ; Read CNTKCTL into Rt

MCR p15,0,<Rt>,c14,c1,0 ; Write Rt to CNTKCTL

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0001	000

## G4.5.7 CNTP\_CTL, Counter-timer Physical Timer Control register

The CNTP\_CTL characteristics are:

### Purpose

Control register for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as CNTP\_CTL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP\_CTL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when [CNTKCTL.ELOPTEN](#) is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when [CNTHCTL.ELIPCEN](#) is set to 1.

### Configurations

CNTP\_CTL(NS) is architecturally mapped to AArch64 register [CNTP\\_CTL\\_EL0](#).

CNTP\_CTL is architecturally mapped to external register [CNTP\\_CTL](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

CNTP\_CTL is a 32-bit register.

The CNTP\_CTL bit assignments are:

### Bits [31:3]

Reserved, RES0.

### ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

- 0 Interrupt not asserted.
- 1 Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0           Timer interrupt is not masked.

1           Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

#### ENABLE, bit [0]

Enables the timer. Permitted values are:

0           Timer disabled.

1           Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

#### Accessing the CNTP\_CTL:

To access the CNTP\_CTL:

MRC p15,0,<Rt>,c14,c2,1 ; Read CNTP\_CTL into Rt

MCR p15,0,<Rt>,c14,c2,1 ; Write Rt to CNTP\_CTL

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0010	001

## G4.5.8 CNTP\_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP\_CVAL characteristics are:

### Purpose

Holds the compare value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as CNTP\_CVAL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP\_CVAL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when [CNTKCTL.EL0PTEN](#) is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when [CNTHCTL.EL1PCEN](#) is set to 1.

### Configurations

CNTP\_CVAL(NS) is architecturally mapped to AArch64 register [CNTP\\_CVAL\\_EL0](#).

CNTP\_CVAL is architecturally mapped to external register [CNTP\\_CVAL](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

CNTP\_CVAL is a 64-bit register.

The CNTP\_CVAL bit assignments are:

### Bits [63:0]

EL1 physical timer compare value.

### Accessing the CNTP\_CVAL:

To access the CNTP\_CVAL:

MRRC p15,2,<Rt>,<Rt2>,c14 ; Read 64-bit CNTP\_CVAL into Rt (low word) and Rt2 (high word)  
MCRR p15,2,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTP\_CVAL

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0010	1110

## G4.5.9 CNTP\_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP\_TVAL characteristics are:

### Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.  
This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as CNTP\_TVAL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP\_TVAL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when [CNTKCTL.ELOPTEN](#) is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when [CNTHCTL.ELIPCEN](#) is set to 1.

### Configurations

CNTP\_TVAL(NS) is architecturally mapped to AArch64 register [CNTP\\_TVAL\\_ELO](#).

CNTP\_TVAL is architecturally mapped to external register [CNTP\\_TVAL](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

### Attributes

CNTP\_TVAL is a 32-bit register.

The CNTP\_TVAL bit assignments are:

### Bits [31:0]

EL1 physical timer value.

### Accessing the CNTP\_TVAL:

To access the CNTP\_TVAL:

MRC p15,0,<Rt>,c14,c2,0 ; Read CNTP\_TVAL into Rt  
MCR p15,0,<Rt>,c14,c2,0 ; Write Rt to CNTP\_TVAL

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1110	0010	000

## G4.5.10 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

### Purpose

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	Config-RO	RO	RO	RO	RO

This register is accessible at EL0 when [CNTKCTL.EL0PCTEN](#) is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when [CNTHCTL.EL1PCTEN](#) is set to 1.

### Configurations

CNTPCT is architecturally mapped to AArch64 register [CNTPCT\\_EL0](#).

CNTPCT is architecturally mapped to external register [CNTPCT](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

CNTPCT is a 64-bit register.

The CNTPCT bit assignments are:

### Bits [63:0]

Physical count value.

### Accessing the CNTPCT:

To access the CNTPCT:

MRRC p15,0,<Rt>,<Rt2>,c14 ; Read 64-bit CNTPCT into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1110

### G4.5.11 CNTV\_CTL, Counter-timer Virtual Timer Control register

The CNTV\_CTL characteristics are:

**Purpose**

Control register for the virtual timer.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [CNTKCTL.EL0VTEN](#) is set to 1.

**Configurations**

CNTV\_CTL is architecturally mapped to AArch64 register [CNTV\\_CTL\\_EL0](#).

CNTV\_CTL is architecturally mapped to external register [CNTV\\_CTL](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTV\_CTL is a 32-bit register.

The CNTV\_CTL bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer interrupt. This bit is read-only. Permitted values are:

- 0 Interrupt not asserted.
- 1 Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked.
- 1 Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0           Timer disabled.

1           Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

**Accessing the CNTV\_CTL:**

To access the CNTV\_CTL:

MRC p15,0,<Rt>,c14,c3,1 ; Read CNTV\_CTL into Rt

MCR p15,0,<Rt>,c14,c3,1 ; Write Rt to CNTV\_CTL

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1110	0011	001

### G4.5.12 CNTV\_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV\_CVAL characteristics are:

**Purpose**

Holds the compare value for the virtual timer.  
 This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

**Configurations**

CNTV\_CVAL is architecturally mapped to AArch64 register CNTV\_CVAL\_EL0.  
 CNTV\_CVAL is architecturally mapped to external register CNTV\_CVAL.  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTV\_CVAL is a 64-bit register.

The CNTV\_CVAL bit assignments are:

**Bits [63:0]**

Virtual timer compare value.

**Accessing the CNTV\_CVAL:**

To access the CNTV\_CVAL:

MRRR p15,3,<Rt>,<Rt2>,c14 ; Read 64-bit CNTV\_CVAL into Rt (low word) and Rt2 (high word)  
 MCRR p15,3,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTV\_CVAL

Register access is encoded as follows:

coproc	opc1	CRm
1111	0011	1110

### G4.5.13 CNTV\_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV\_TVAL characteristics are:

#### Purpose

Holds the timer value for the virtual timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when [CNTKCTL.EL0VTEN](#) is set to 1.

#### Configurations

CNTV\_TVAL is architecturally mapped to AArch64 register [CNTV\\_TVAL\\_EL0](#).

CNTV\_TVAL is architecturally mapped to external register [CNTV\\_TVAL](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

CNTV\_TVAL is a 32-bit register.

The CNTV\_TVAL bit assignments are:

#### Bits [31:0]

Virtual timer value.

#### Accessing the CNTV\_TVAL:

To access the CNTV\_TVAL:

MRC p15,0,<Rt>,c14,c3,0 ; Read CNTV\_TVAL into Rt

MCR p15,0,<Rt>,c14,c3,0 ; Write Rt to CNTV\_TVAL

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0011	000

### G4.5.14 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

**Purpose**

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when CNTKCTL.EL0VCTEN is set to 1.

**Configurations**

CNTVCT is architecturally mapped to AArch64 register CNTVCT\_EL0.

CNTVCT is architecturally mapped to external register CNTVCT.

There is one instance of this register that is used in both Secure and Non-secure states.

The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

When EL2 is not implemented, CNTVOFF is RES0, and the value of this register is the same as the value of CNTPCT.

**Attributes**

CNTVCT is a 64-bit register.

The CNTVCT bit assignments are:

**Bits [63:0]**

Virtual count value.

**Accessing the CNTVCT:**

To access the CNTVCT:

MRRC p15,1,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVCT into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

coproc	opc1	CRm
1111	0001	1110

## G4.5.15 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

### Purpose

Holds the 64-bit virtual offset.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

### Configurations

CNTVOFF is architecturally mapped to AArch64 register [CNTVOFF\\_EL2](#).

CNTVOFF is architecturally mapped to external register [CNTVOFF](#).

CNTVOFF is architecturally mapped to external register [CNTVOFF<n>](#).

If EL2 is not implemented, this register is RES0 from EL3.

### Attributes

CNTVOFF is a 64-bit register.

The CNTVOFF bit assignments are:

### Bits [63:0]

Virtual offset.

### Accessing the CNTVOFF:

To access the CNTVOFF:

MRRC p15,4,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVOFF into Rt (low word) and Rt2 (high word)

MCRW p15,4,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTVOFF

Register access is encoded as follows:

coproc	opc1	CRm
1111	0100	1110

## G4.6 Generic Interrupt Controller CPU interface registers

This section describes the GIC CPU interface registers in AArch32 state.

### G4.6.1 ICC\_AP0R0, Interrupt Controller Active Priorities Register (0,0)

The ICC\_AP0R0 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICC\_AP0R0 is architecturally mapped to AArch64 register [ICC\\_AP0R0\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP0R0 is a 32-bit register.

The ICC\_AP0R0 bit assignments are:

**P<n>, bit [n], for n = 0 to 31**

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by  $2^U$ ) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICC\_AP0R0:**

To access the ICC\_AP0R0:

MRC p15,0,<Rt>,c12,c8,4 ; Read ICC\_AP0R0 into Rt  
MCR p15,0,<Rt>,c12,c8,4 ; Write Rt to ICC\_AP0R0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	100

## G4.6.2 ICC\_AP0R1, Interrupt Controller Active Priorities Register (0,1)

The ICC\_AP0R1 characteristics are:

### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

### Configurations

ICC\_AP0R1 is architecturally mapped to AArch64 register [ICC\\_AP0R1\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ICC\_AP0R1 is a 32-bit register.

The ICC\_AP0R1 bit assignments are:

### P<n>, bit [(n-32)], for n = 32 to 63

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP0R1:

To access the ICC\_AP0R1:

MRC p15,0,<Rt>,c12,c8,5 ; Read ICC\_AP0R1 into Rt  
MCR p15,0,<Rt>,c12,c8,5 ; Write Rt to ICC\_AP0R1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	101

### G4.6.3 ICC\_AP0R2, Interrupt Controller Active Priorities Register (0,2)

The ICC\_AP0R2 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICC\_AP0R2 is architecturally mapped to AArch64 register [ICC\\_AP0R2\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP0R2 is a 32-bit register.

The ICC\_AP0R2 bit assignments are:

#### P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP0R2:

To access the ICC\_AP0R2:

MRC p15,0,<Rt>,c12,c8,6 ; Read ICC\_AP0R2 into Rt  
MCR p15,0,<Rt>,c12,c8,6 ; Write Rt to ICC\_AP0R2

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	110

### G4.6.4 ICC\_AP0R3, Interrupt Controller Active Priorities Register (0,3)

The ICC\_AP0R3 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICC\_AP0R3 is architecturally mapped to AArch64 register [ICC\\_AP0R3\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP0R3 is a 32-bit register.

The ICC\_AP0R3 bit assignments are:

#### P<n>, bit [(n-96)], for n = 96 to 127

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP0R3:

To access the ICC\_AP0R3:

MRC p15,0,<Rt>,c12,c8,7 ; Read ICC\_AP0R3 into Rt  
MCR p15,0,<Rt>,c12,c8,7 ; Write Rt to ICC\_AP0R3

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	111

### G4.6.5 ICC\_AP1R0, Interrupt Controller Active Priorities Register (1,0)

The ICC\_AP1R0 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

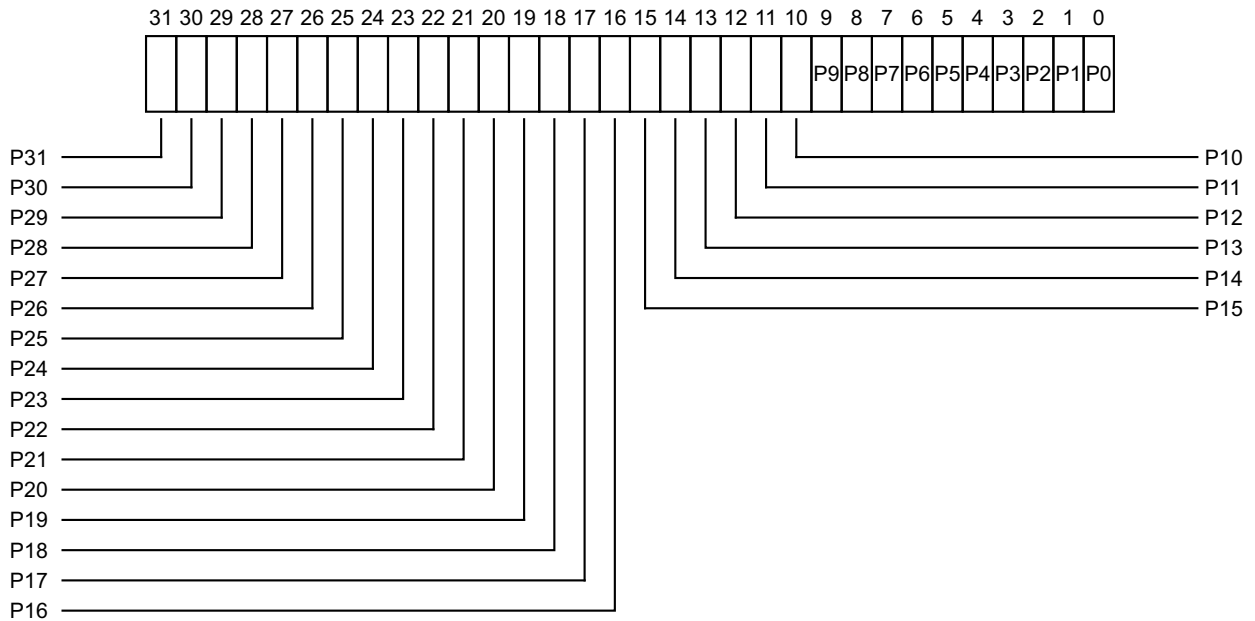

#### Configurations

ICC\_AP1R0 is architecturally mapped to AArch64 register [ICC\\_AP1R0\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP1R0 is a 32-bit register.

The ICC\_AP1R0 bit assignments are:

#### P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIBits).

For example, in a system with ICC\_CTLR\_EL1.PRIBits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP1R0:

To access the ICC\_AP1R0:

MRC p15,0,<Rt>,c12,c9,0 ; Read ICC\_AP1R0 into Rt  
MCR p15,0,<Rt>,c12,c9,0 ; Write Rt to ICC\_AP1R0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	000

### G4.6.6 ICC\_AP1R1, Interrupt Controller Active Priorities Register (1,1)

The ICC\_AP1R1 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC\_AP1R1 is architecturally mapped to AArch64 register [ICC\\_AP1R1\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_AP1R1 is a 32-bit register.

The ICC\_AP1R1 bit assignments are:

**P<n>, bit [(n-32)], for n = 32 to 63**

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP1R1:

To access the ICC\_AP1R1:

MRC p15,0,<Rt>,c12,c9,1 ; Read ICC\_AP1R1 into Rt  
MCR p15,0,<Rt>,c12,c9,1 ; Write Rt to ICC\_AP1R1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	001

### G4.6.7 ICC\_AP1R2, Interrupt Controller Active Priorities Register (1,2)

The ICC\_AP1R2 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICC\_AP1R2 is architecturally mapped to AArch64 register [ICC\\_AP1R2\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP1R2 is a 32-bit register.

The ICC\_AP1R2 bit assignments are:

#### P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP1R2:

To access the ICC\_AP1R2:

MRC p15,0,<Rt>,c12,c9,2 ; Read ICC\_AP1R2 into Rt  
MCR p15,0,<Rt>,c12,c9,2 ; Write Rt to ICC\_AP1R2

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	010

### G4.6.8 ICC\_AP1R3, Interrupt Controller Active Priorities Register (1,3)

The ICC\_AP1R3 characteristics are:

#### Purpose

Provides information about the active priorities for the current interrupt regime.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICC\_AP1R3 is architecturally mapped to AArch64 register [ICC\\_AP1R3\\_EL1](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_AP1R3 is a 32-bit register.

The ICC\_AP1R3 bit assignments are:

#### P<n>, bit [(n-96)], for n = 96 to 127

Provides information about priority M, according to the following relationship:  
 Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.

- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC\_AP1R3:

To access the ICC\_AP1R3:

MRC p15,0,<Rt>,c12,c9,3 ; Read ICC\_AP1R3 into Rt  
MCR p15,0,<Rt>,c12,c9,3 ; Write Rt to ICC\_AP1R3

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	011

### G4.6.9 ICC\_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register

The ICC\_ASGI1R characteristics are:

#### Purpose

Provides software the ability to generate group 1 SGIs for the other security state.  
 This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:  
 When accessed as ICC\_ASGI1R(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC\_ASGI1R(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

#### Configurations

ICC\_ASGI1R(S) is architecturally mapped to AArch64 register [ICC\\_ASGI1R\\_EL1 \(S\)](#).  
 ICC\_ASGI1R(NS) is architecturally mapped to AArch64 register [ICC\\_ASGI1R\\_EL1 \(NS\)](#).  
 If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

#### Attributes

ICC\_ASGI1R is a 64-bit register.

The ICC\_ASGI1R bit assignments are:

#### Bits [63:56]

Reserved, RES0.

#### Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

#### Bits [47:41]

Reserved, RES0.

#### IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

- 0 Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

1 Interrupts routed to all processors in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [31:28]**

Reserved, RES0.

**SGIID, bits [27:24]**

SGI Interrupt ID.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

**TargetList, bits [15:0]**

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SGI.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

**Accessing the ICC\_ASGI1R:**

To access the ICC\_ASGI1R:

MCRR p15,1,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC\_ASGI1R

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0001	1100

### G4.6.10 ICC\_BPR0, Interrupt Controller Binary Point Register 0

The ICC\_BPR0 characteristics are:

#### Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine interrupt preemption.

This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

When accessed as ICC\_BPR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC\_BPR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

In Secure state, this register is the binary point register for Group 0 interrupts. In Non-secure state, this is the BPR for Group 1 interrupts.

The minimum binary point value is IMPLEMENTATION DEFINED in the range:

- 0-3 if the implementation supports one security state, and for the Secure copy of the register if the implementation supports two security states.
- 1-4 for the Non-secure copy of the register.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

#### Configurations

ICC\_BPR0(S) is architecturally mapped to AArch64 register [ICC\\_BPR0\\_EL1 \(S\)](#).

ICC\_BPR0(NS) is architecturally mapped to AArch64 register [ICC\\_BPR0\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

#### Attributes

ICC\_BPR0 is a 32-bit register.

The ICC\_BPR0 bit assignments are:

#### Bits [31:3]

Reserved, RES0.

**BinaryPoint, bits [2:0]**

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	ggggg.ss
2	[7:3]	[2:0]	ggggg.sss
3	[7:4]	[3:0]	gggg.ssss
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

**Accessing the ICC\_BPR0:**

To access the ICC\_BPR0:

MRC p15,0,<Rt>,c12,c8,3 ; Read ICC\_BPR0 into Rt  
MCR p15,0,<Rt>,c12,c8,3 ; Write Rt to ICC\_BPR0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	011

### G4.6.11 ICC\_BPR1, Interrupt Controller Binary Point Register 1

The ICC\_BPR1 characteristics are:

**Purpose**

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine Group 1 interrupt preemption.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is an alias of the Non-secure view of [ICC\\_BPR0](#), and a Secure access to this register is identical to a Non-secure access to [ICC\\_BPR0](#).

The minimum binary point value is IMPLEMENTATION DEFINED in the range 1-4.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

**Configurations**

ICC\_BPR1 is architecturally mapped to AArch64 register [ICC\\_BPR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_BPR1 is a 32-bit register.

The ICC\_BPR1 bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**BinaryPoint, bits [2:0]**

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	gggggg.ss
2	[7:3]	[2:0]	ggggg.sss
3	[7:4]	[3:0]	gggg.ssss

Binary point value	Group priority field	Subpriority field	Field with binary point
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

### Accessing the ICC\_BPR1:

To access the ICC\_BPR1:

MRC p15,0,<Rt>,c12,c12,3 ; Read ICC\_BPR1 into Rt  
MCR p15,0,<Rt>,c12,c12,3 ; Write Rt to ICC\_BPR1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	011

### G4.6.12 ICC\_CTLR, Interrupt Controller Control Register

The ICC\_CTLR characteristics are:

**Purpose**

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ICC\_CTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC\_CTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

**Configurations**

ICC\_CTLR(S) is architecturally mapped to AArch64 register [ICC\\_CTLR\\_EL1 \(S\)](#).

ICC\_CTLR(NS) is architecturally mapped to AArch64 register [ICC\\_CTLR\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC\_CTLR is a 32-bit register.

The ICC\_CTLR bit assignments are:

**Bits [31:16]**

Reserved, RES0.

**A3V, bit [15]**

Affinity 3 Valid. Read-only. Possible values are:

- 0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
- 1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH\_VTR.A3V.

#### SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports local generation of SEIs:

- 0 The CPU interface logic does not support local generation of SEIs by the CPU interface.
- 1 The CPU interface logic supports local generation of SEIs by the CPU interface.

Virtual accesses return the value from ICH\_VTR.SEIS.

#### IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

- 000 16 bits.
- 001 24 bits.

All other values are reserved.

Virtual accesses return the value from ICH\_VTR.IDbits.

Reset value is architecturally UNKNOWN.

#### PRBits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

Virtual accesses return the value from ICH\_VTR.PRBits.

#### Bits [7:3]

Reserved, RES0.

#### PMHE, bit [2]

Priority Mask Hint Enable.

If EL3 is present and GICD\_CTLR.DS == 0, this bit is a read-only alias of ICC\_MCTLR.PMHE.

If EL3 is present and GICD\_CTLR.DS == 1, this bit is writeable at EL1 and EL2.

Resets to 0.

#### EOImode, bit [1]

Alias of ICC\_MCTLR.EOImode\_EL1{S,NS} as appropriate to the current security state.

Virtual accesses modify ICH\_VMCR.VEOIM.

Reset value is architecturally UNKNOWN.

#### CBPR, bit [0]

Common Binary Point Register.

If EL3 is present and GICD\_CTLR.DS == 0, this bit is a read-only alias of ICC\_MCTLR.CBPR\_EL1{S,NS} as appropriate.

If EL3 is not present, this field resets to zero.

If EL3 is present and GICD\_CTLR.DS == 1, this bit is writeable at EL1 and EL2.

Virtual accesses modify ICH\_VMCR.VCBPR. An access is virtual when accessed at non-secure EL1 and either of FIQ or IRQ has been virtualized. That is, when (SCR.NS == '1' && (HCR.FMO == '1' || HCR.IMO == '1')).

### Accessing the ICC\_CTLR:

To access the ICC\_CTLR:

MRC p15,0,<Rt>,c12,c12,4 ; Read ICC\_CTLR into Rt  
MCR p15,0,<Rt>,c12,c12,4 ; Write Rt to ICC\_CTLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1100	100

### G4.6.13 ICC\_DIR, Interrupt Controller Deactivate Interrupt Register

The ICC\_DIR characteristics are:

#### Purpose

When interrupt priority drop is separated from interrupt deactivation, a write to this register deactivates the specified interrupt.

This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

#### Configurations

ICC\_DIR is architecturally mapped to AArch64 register [ICC\\_DIR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_DIR is a 32-bit register.

The ICC\_DIR bit assignments are:

#### Bits [31:24]

Reserved, RES0.

#### InterruptID, bits [23:0]

The interrupt ID.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

#### Accessing the ICC\_DIR:

To access the ICC\_DIR:

MCR p15,0,<Rt>,c12,c11,1 ; Write Rt to ICC\_DIR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1011	001

### G4.6.14 ICC\_EOIR0, Interrupt Controller End Of Interrupt Register 0

The ICC\_EOIR0 characteristics are:

**Purpose**

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ICC\_EOIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC\_EOIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

**Configurations**

ICC\_EOIR0(S) is architecturally mapped to AArch64 register [ICC\\_EOIR0\\_EL1 \(S\)](#).

ICC\_EOIR0(NS) is architecturally mapped to AArch64 register [ICC\\_EOIR0\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

In Secure state, this register is the end of interrupt register for Group 0 interrupts. In Non-secure state, this is the EOIR for Group 1 interrupts.

**Attributes**

ICC\_EOIR0 is a 32-bit register.

The ICC\_EOIR0 bit assignments are:

**Bits [31:24]**

Reserved, RES0.

**EOIINTID, bits [23:0]**

The InterruptID value from the corresponding GICC\_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

### Accessing the ICC\_EOIR0:

To access the ICC\_EOIR0:

MCR p15,0,<Rt>,c12,c8,1 ; Write Rt to ICC\_EOIR0

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1000	001

### G4.6.15 ICC\_EOIR1, Interrupt Controller End Of Interrupt Register 1

The ICC\_EOIR1 characteristics are:

**Purpose**

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified Group 1 interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

**Configurations**

ICC\_EOIR1 is architecturally mapped to AArch64 register [ICC\\_EOIR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of [ICC\\_EOIRO](#), and a Secure access to this register is identical to a Non-secure access to [ICC\\_EOIRO](#).

**Attributes**

ICC\_EOIR1 is a 32-bit register.

The ICC\_EOIR1 bit assignments are:

**Bits [31:24]**

Reserved, RES0.

**EOINTID, bits [23:0]**

The InterruptID value from the corresponding GICC\_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC\_EOIR1:**

To access the ICC\_EOIR1:

MCR p15,0,<Rt>,c12,c12,1 ; Write Rt to ICC\_EOIR1

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1100	001

## G4.6.16 ICC\_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0

The ICC\_HPPIR0 characteristics are:

### Purpose

Indicates the Interrupt ID, and processor ID if appropriate, of the highest priority pending interrupt on the CPU interface.

This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as ICC\_HPPIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	-	-	RO

When accessed as ICC\_HPPIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	-	RO	RO	-

### Configurations

ICC\_HPPIR0(S) is architecturally mapped to AArch64 register [ICC\\_HPPIR0\\_EL1 \(S\)](#).

ICC\_HPPIR0(NS) is architecturally mapped to AArch64 register [ICC\\_HPPIR0\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

In Secure state, this register is the highest priority pending interrupt register for Group 0 interrupts.

In Non-secure state, this is the HPPIR for Group 1 interrupts.

### Attributes

ICC\_HPPIR0 is a 32-bit register.

The ICC\_HPPIR0 bit assignments are:

### Bits [31:24]

Reserved, RES0.

### PENDINTID, bits [23:0]

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

### Accessing the ICC\_HPPIR0:

To access the ICC\_HPPIR0:

MRC p15,0,<Rt>,c12,c8,2 ; Read ICC\_HPPIR0 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1000	010

### G4.6.17 ICC\_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1

The ICC\_HPPIR1 characteristics are:

**Purpose**

If the highest priority pending interrupt on the CPU interface is a Group 1 interrupt, returns the interrupt ID of that interrupt. Otherwise, returns a spurious interrupt ID of 1023.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

**Configurations**

ICC\_HPPIR1 is architecturally mapped to AArch64 register [ICC\\_HPPIR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of [ICC\\_HPPIR0](#), and a Secure access to this register is identical to a Non-secure access to [ICC\\_HPPIR0](#).

**Attributes**

ICC\_HPPIR1 is a 32-bit register.

The ICC\_HPPIR1 bit assignments are:

**Bits [31:24]**

Reserved, RES0.

**PENDINTID, bits [23:0]**

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC\_HPPIR1:**

To access the ICC\_HPPIR1:

MRC p15,0,<Rt>,c12,c12,2 ; Read ICC\_HPPIR1 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	010

## G4.6.18 ICC\_HSRE, Interrupt Controller Hyp System Register Enable register

The ICC\_HSRE characteristics are:

### Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	RW

If EL3 is present and ICC\_MSRE.Enable is 0, EL2 accesses to this register will trap to EL3.

### Configurations

ICC\_HSRE is architecturally mapped to AArch64 register [ICC\\_SRE\\_EL2](#).

### Attributes

ICC\_HSRE is a 32-bit register.

The ICC\_HSRE bit assignments are:

### Bits [31:4]

Reserved, RES0.

### Enable, bit [3]

Enable. Enables lower exception level access to ICC\_SRE\_EL1.

- 0 Non-secure EL1 accesses to ICC\_SRE\_EL1 trap to EL2.
- 1 Non-secure EL1 accesses to ICC\_SRE\_EL1 are permitted if EL3 is not present or ICC\_SRE\_EL3.Enable is 1, otherwise Non-secure EL1 accesses to ICC\_SRE\_EL1 trap to EL3.

Resets to 0.

### DIB, bit [2]

Disable IRQ bypass.

If EL3 is present and GICD\_CTLR.DS is 0, this field is a read-only alias of ICC\_MSRE.DIB.

Resets to 0.

**DFB, bit [1]**

Disable FIQ bypass.

If EL3 is present and GICD\_CTLR.DS is 0, this field is a read-only alias of ICC\_MSRE.DFB.

Resets to 0.

**SRE, bit [0]**

System Register Enable.

0 The memory mapped interface must be used. Access at EL2 to any ICH\_\* system register, or any EL1 or EL2 ICC\_\* register other than ICC\_SRE or ICC\_HSRE, results in an Undefined exception.

1 The system register interface to the ICH\_\* registers and the EL1 and EL2 ICC\_\* registers is enabled for EL2.

0 The memory mapped interface must be used. Access at EL2 to any ICH\_\* system register, or any EL1 or EL2 ICC\_\* register other than ICC\_SRE\_EL1 or ICC\_SRE\_EL2, results in an Undefined exception.

1 The system register interface to the ICH\_\* registers and the EL1 and EL2 ICC\_\* registers is enabled for EL2.

System Register Enable.

Resets to 0.

**Accessing the ICC\_HSRE:**

To access the ICC\_HSRE:

MRC p15,4,<Rt>,c12,c9,5 ; Read ICC\_HSRE into Rt

MCR p15,4,<Rt>,c12,c9,5 ; Write Rt to ICC\_HSRE

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	101

## G4.6.19 ICC\_IAR0, Interrupt Controller Interrupt Acknowledge Register 0

The ICC\_IAR0 characteristics are:

### Purpose

The processor reads this register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

When accessed as ICC\_IAR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	-	-	RO

When accessed as ICC\_IAR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	-	RO	RO	-

### Configurations

ICC\_IAR0(S) is architecturally mapped to AArch64 register [ICC\\_IAR0\\_EL1 \(S\)](#).

ICC\_IAR0(NS) is architecturally mapped to AArch64 register [ICC\\_IAR0\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

In Secure state, this register is the interrupt acknowledge register for Group 0 interrupts. In Non-secure state, this is the IAR for Group 1 interrupts.

### Attributes

ICC\_IAR0 is a 32-bit register.

The ICC\_IAR0 bit assignments are:

### Bits [31:24]

Reserved, RES0.

### InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

### Accessing the ICC\_IAR0:

To access the ICC\_IAR0:

MRC p15,0,<Rt>,c12,c8,0 ; Read ICC\_IAR0 into Rt

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1000	000

## G4.6.20 ICC\_IAR1, Interrupt Controller Interrupt Acknowledge Register 1

The ICC\_IAR1 characteristics are:

### Purpose

The processor reads this register to obtain the interrupt ID of the signaled Group 1 interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

### Configurations

ICC\_IAR1 is architecturally mapped to AArch64 register [ICC\\_IAR1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of [ICC\\_IAR0](#), and a Secure access to this register is identical to a Non-secure access to [ICC\\_IAR0](#).

### Attributes

ICC\_IAR1 is a 32-bit register.

The ICC\_IAR1 bit assignments are:

### Bits [31:24]

Reserved, RES0.

### InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in [ICC\\_CTLR\\_EL1.IDbits](#) and [ICC\\_CTLR\\_EL3.IDbits](#). If only 16 bits are implemented, bits [23:16] of this register are RES0.

### Accessing the ICC\_IAR1:

To access the ICC\_IAR1:

MRC p15,0,<Rt>,c12,c12,0 ; Read ICC\_IAR1 into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	000

### G4.6.21 ICC\_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register

The ICC\_IGRPEN0 characteristics are:

**Purpose**

Controls whether Group 0 interrupts are enabled or not.  
 This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:  
 When accessed as ICC\_IGRPEN0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC\_IGRPEN0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**

ICC\_IGRPEN0(S) is architecturally mapped to AArch64 register [ICC\\_IGRPEN0\\_EL1 \(S\)](#).  
 ICC\_IGRPEN0(NS) is architecturally mapped to AArch64 register [ICC\\_IGRPEN0\\_EL1 \(NS\)](#).  
 If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC\_IGRPEN0 is a 32-bit register.

The ICC\_IGRPEN0 bit assignments are:

**Bits [31:1]**

Reserved, RES0.

**Accessing the ICC\_IGRPEN0:**

To access the ICC\_IGRPEN0:

```
MRC p15,0,<Rt>,c12,c12,6 ; Read ICC_IGRPEN0 into Rt
MCR p15,0,<Rt>,c12,c12,6 ; Write Rt to ICC_IGRPEN0
```

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	000	1100	1100	110

### G4.6.22 ICC\_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register

The ICC\_IGRPEN1 characteristics are:

**Purpose**

Controls whether Group 1 interrupts are enabled for the current security state.  
 This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**

ICC\_IGRPEN1 is architecturally mapped to AArch64 register [ICC\\_IGRPEN1\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_IGRPEN1 is a 32-bit register.

The ICC\_IGRPEN1 bit assignments are:

**Bits [31:1]**

Reserved, RES0.

**Accessing the ICC\_IGRPEN1:**

To access the ICC\_IGRPEN1:

```
MRC p15,0,<Rt>,c12,c12,7 ; Read ICC_IGRPEN1 into Rt
MCR p15,0,<Rt>,c12,c12,7 ; Write Rt to ICC_IGRPEN1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	111

## G4.6.23 ICC\_MCTLR, Interrupt Controller Monitor Control Register

The ICC\_MCTLR characteristics are:

### Purpose

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

### Configurations

ICC\_MCTLR is architecturally mapped to AArch64 register [ICC\\_CTLR\\_EL3](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ICC\_MCTLR is a 32-bit register.

The ICC\_MCTLR bit assignments are:

### Bits [31:16]

Reserved, RES0.

### A3V, bit [15]

Affinity 3 Valid. Read-only. Possible values are:

- 0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
- 1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH\_VTR.A3V.

#### SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports generation of SEIs:

- |   |  |
|---|--|
| 0 | The CPU interface logic does not support generation of SEIs. |
| 1 | The CPU interface logic supports generation of SEIs.         |

Virtual accesses return the value from ICH\_VTR.SEIS.

#### IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

- |     |          |
|-----|----------|
| 000 | 16 bits. |
| 001 | 24 bits. |

All other values are reserved.

Reset value is architecturally UNKNOWN.

#### PRBits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

#### Bit [7]

Reserved, RES0.

#### PMHE, bit [6]

Priority Mask Hint Enable.

When set, enables use of the PMR as a hint for interrupt distribution.

Resets to 0.

#### RM, bit [5]

Routing Modifier. This bit is used to modify the behaviour of [ICC\\_IAR0](#) and [ICC\\_IAR1](#) such that systems with legacy secure software may be supported correctly.

- |   |   |
|---|---|
| 0 | Reading <a href="#">ICC_IAR0</a> and <a href="#">ICC_IAR1</a> at EL3 acknowledges interrupts normally.  |
| 1 | Reading <a href="#">ICC_IAR0</a> and <a href="#">ICC_IAR1</a> at EL3 returns special values: <ul style="list-style-type: none"><li>Reading <a href="#">ICC_IAR0</a> at EL3 returns ID 1020, indicating the interrupt should be handled at Secure EL1.</li><li>Reading <a href="#">ICC_IAR1</a> at EL3 returns ID 1021, indicating the interrupt should be handled at Non-secure EL1 or EL2.</li></ul> |

Reset value is architecturally UNKNOWN.

#### EOImode\_EL1NS, bit [4]

EOI mode for interrupts handled at non-secure EL1 and EL2.

Reset value is architecturally UNKNOWN.

#### EOImode\_EL1S, bit [3]

EOI mode for interrupts handled at secure EL1.

Reset value is architecturally UNKNOWN.

#### EOImode\_EL3, bit [2]

EOI mode for interrupts handled at EL3.

Reset value is architecturally UNKNOWN.

#### CBPR\_EL1NS, bit [1]

When set, non-secure accesses to [GICC\\_BPR](#) and [ICC\\_BPR1](#) access the state of [ICC\\_BPR0](#). [ICC\\_BPR0](#) is used to determine the preemption group for Non-secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

### CBPR\_EL1S, bit [0]

When set, secure EL1 accesses to [ICC\\_BPR1](#) access the state of [ICC\\_BPR0](#). [ICC\\_BPR0](#) is used to determine the preemption group for Secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

### Accessing the ICC\_MCTLR:

To access the ICC\_MCTLR:

MRC p15,6,<Rt>,c12,c12,4 ; Read ICC\_MCTLR into Rt

MCR p15,6,<Rt>,c12,c12,4 ; Write Rt to ICC\_MCTLR

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	110	1100	1100	100

### G4.6.24 ICC\_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register

The ICC\_MGRPEN1 characteristics are:

**Purpose**

Controls whether Group 1 interrupts are enabled or not.  
 This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

If an interrupt is pending within the CPU interface when an Enable bit becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**

ICC\_MGRPEN1 is architecturally mapped to AArch64 register [ICC\\_IGRPEN1\\_EL3](#).  
 There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_MGRPEN1 is a 32-bit register.

The ICC\_MGRPEN1 bit assignments are:

**Bits [31:2]**

Reserved, RES0.

**EnableGrp1S, bit [1]**

Enables Group 1 interrupts for the Secure state.  
 0 Group 1 interrupts are disabled for the Secure state.  
 1 Group 1 interrupts are enabled for the Secure state.  
 Resets to 0.

**EnableGrp1NS, bit [0]**

Enables Group 1 interrupts for the Non-secure state.  
 0 Group 1 interrupts are disabled for the Non-secure state.  
 1 Group 1 interrupts are enabled for the Non-secure state.  
 Resets to 0.

**Accessing the ICC\_MGRPEN1:**

To access the ICC\_MGRPEN1:

MRC p15,6,<Rt>,c12,c12,7 ; Read ICC\_MGRPEN1 into Rt  
MCR p15,6,<Rt>,c12,c12,7 ; Write Rt to ICC\_MGRPEN1

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	110	1100	1100	111

### G4.6.25 ICC\_MSRE, Interrupt Controller Monitor System Register Enable register

The ICC\_MSRE characteristics are:

#### Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

#### Configurations

ICC\_MSRE is architecturally mapped to AArch64 register [ICC\\_SRE\\_EL3](#).

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

ICC\_MSRE is a 32-bit register.

The ICC\_MSRE bit assignments are:

#### Bits [31:4]

Reserved, RES0.

#### Enable, bit [3]

Enable. Enables lower exception level access to ICC\_SRE\_EL1 and ICC\_SRE\_EL2.

0 EL1 and EL2 accesses to ICC\_SRE\_EL1 or ICC\_SRE\_EL2 trap to EL3.

1 EL2 accesses to ICC\_SRE\_EL2 are permitted. If the Enable bit of ICC\_SRE\_EL2 is 1, then EL1 accesses to ICC\_SRE\_EL1 are also permitted.

Resets to 0.

#### DIB, bit [2]

Disable IRQ bypass.

Resets to 0.

#### DFB, bit [1]

Disable FIQ bypass.

Resets to 0.

**SRE, bit [0]**

System Register Enable.

- 0 The memory mapped interface must be used. Access at EL3 to any ICH\_\* system register, or any EL1, EL2, or EL3 ICC\_\* register other than ICC\_SRE, ICC\_HSRE, or ICC\_MSRE, results in an Undefined exception.
- 1 The system register interface to the ICH\_\* registers and the EL1, EL2, and EL3 ICC\_\* registers is enabled for EL3.

Resets to 0.

**Accessing the ICC\_MSRE:**

To access the ICC\_MSRE:

MRC p15,6,<Rt>,c12,c12,5 ; Read ICC\_MSRE into Rt  
MCR p15,6,<Rt>,c12,c12,5 ; Write Rt to ICC\_MSRE

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRn</b>	<b>CRm</b>	<b>opc2</b>
1111	110	1100	1100	101

### G4.6.26 ICC\_PMR, Interrupt Controller Interrupt Priority Mask Register

The ICC\_PMR characteristics are:

**Purpose**

Provides an interrupt priority filter. Only interrupts with higher priority than the value in this register are signaled to the processor.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

**Configurations**

ICC\_PMR is architecturally mapped to AArch64 register [ICC\\_PMR\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_PMR is a 32-bit register.

The ICC\_PMR bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**Priority, bits [7:0]**

The priority mask level for the CPU interface. If the priority of an interrupt is higher than the value indicated by this field, the interface signals the interrupt to the processor.

If the GIC supports fewer than 256 priority levels then some bits are RAZ/WI, as follows:

128 supported levels Bit [0] = 0.

64 supported levels Bits [1:0] = 0b00.

32 supported levels Bits [2:0] = 0b000.

16 supported levels Bits [3:0] = 0b0000.

The possible priority field values are as follows:

Implemented priority bits	Possible priority field values	Number of priority levels
[7:0]	0x00-0xFF (0-255), all values	256
[7:1]	0x00-0xFE (0-254), even values only	128

Implemented priority bits	Possible priority field values	Number of priority levels
[7:2]	0x00-0xFC (0-252), in steps of 4	64
[7:3]	0x00-0xF8 (0-248), in steps of 8	32
[7:4]	0x00-0xF0 (0-240), in steps of 16	16

### Accessing the ICC\_PMR:

To access the ICC\_PMR:

MRC p15,0,<Rt>,c4,c6,0 ; Read ICC\_PMR into Rt  
MCR p15,0,<Rt>,c4,c6,0 ; Write Rt to ICC\_PMR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0100	0110	000

## G4.6.27 ICC\_RPR, Interrupt Controller Running Priority Register

The ICC\_RPR characteristics are:

### Purpose

Indicates the Running priority of the CPU interface.  
This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If there is no active interrupt on the CPU interface, the value returned is the Idle priority.  
Software cannot determine the number of implemented priority bits from a read of this register.

### Configurations

ICC\_RPR is architecturally mapped to AArch64 register [ICC\\_RPR\\_EL1](#).  
There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ICC\_RPR is a 32-bit register.

The ICC\_RPR bit assignments are:

### Bits [31:8]

Reserved, RES0.

### Priority, bits [7:0]

The current running priority on the CPU interface. This is the priority of the current active interrupt.

### Accessing the ICC\_RPR:

To access the ICC\_RPR:

MRC p15,0,<Rt>,c12,c11,3 ; Read ICC\_RPR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1011	011

## G4.6.28 ICC\_SEIEN, Interrupt Controller System Error Interrupt Enable register

The ICC\_SEIEN characteristics are:

### Purpose

Controls whether System Error Interrupts generated by bus message are enabled.  
This register is part of the GIC registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The lowest exception level at which this register may be accessed is governed by the exception level to which SError is routed. This routing depends on SCR.EA, SCR.NS and HCR.AMO.

Internally generated SEIs and pin-generated SEIs might still be generated.

### Configurations

ICC\_SEIEN is architecturally mapped to AArch64 register [ICC\\_SEIEN\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

### Attributes

ICC\_SEIEN is a 32-bit register.

The ICC\_SEIEN bit assignments are:

### Accessing the ICC\_SEIEN:

To access the ICC\_SEIEN:

MRC p15,0,<Rt>,c12,c13,0 ; Read ICC\_SEIEN into Rt  
MCR p15,0,<Rt>,c12,c13,0 ; Write Rt to ICC\_SEIEN

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1101	000

### G4.6.29 ICC\_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register

The ICC\_SGI0R characteristics are:

**Purpose**

Provides software the ability to generate secure group 0 SGIs, including from the Non-secure state when permitted by GICR\_NSACR.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

**Configurations**

ICC\_SGI0R is architecturally mapped to AArch64 register [ICC\\_SGI0R\\_EL1](#).

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC\_SGI0R is a 64-bit register.

The ICC\_SGI0R bit assignments are:

**Bits [63:56]**

Reserved, RES0.

**Aff3, bits [55:48]**

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [47:41]**

Reserved, RES0.

**IRM, bit [40]**

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

- 0 Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.
- 1 Interrupts routed to all processors in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [31:28]**

Reserved, RES0.

**SGIID, bits [27:24]**

SIGI Interrupt ID.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SIGI interrupts will be generated.

**TargetList, bits [15:0]**

Target List. The set of processors for which SIGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SIGI.

This restricts distribution of SIGIs to the first 16 processors of an affinity 1 cluster.

**Accessing the ICC\_SGI0R:**

To access the ICC\_SGI0R:

MCRR p15,2,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC\_SGI0R

Register access is encoded as follows:

<b>coproc</b>	<b>opc1</b>	<b>CRm</b>
1111	0010	1100

### G4.6.30 ICC\_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register

The ICC\_SGI1R characteristics are:

**Purpose**

Provides software the ability to generate group 1 SGIs for the current security state.  
 This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:  
 When accessed as ICC\_SGI1R(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC\_SGI1R(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

**Configurations**

ICC\_SGI1R(S) is architecturally mapped to AArch64 register [ICC\\_SGI1R\\_EL1 \(S\)](#).  
 ICC\_SGI1R(NS) is architecturally mapped to AArch64 register [ICC\\_SGI1R\\_EL1 \(NS\)](#).  
 If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC\_SGI1R is a 64-bit register.

The ICC\_SGI1R bit assignments are:

**Bits [63:56]**

Reserved, RES0.

**Aff3, bits [55:48]**

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [47:41]**

Reserved, RES0.

**IRM, bit [40]**

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

- 0 Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.
- 1 Interrupts routed to all processors in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [31:28]**

Reserved, RES0.

**SGIID, bits [27:24]**

SGI Interrupt ID.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

**TargetList, bits [15:0]**

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SGI.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

**Accessing the ICC\_SGI1R:**

To access the ICC\_SGI1R:

MCRR p15,0,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC\_SGI1R

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1100

### G4.6.31 ICC\_SRE, Interrupt Controller System Register Enable register

The ICC\_SRE characteristics are:

**Purpose**

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL0 and EL1.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ICC\_SRE(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC\_SRE(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

**Configurations**

ICC\_SRE(S) is architecturally mapped to AArch64 register [ICC\\_SRE\\_EL1 \(S\)](#).

ICC\_SRE(NS) is architecturally mapped to AArch64 register [ICC\\_SRE\\_EL1 \(NS\)](#).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC\_SRE is a 32-bit register.

The ICC\_SRE bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**DIB, bit [2]**

Disable IRQ bypass.

If EL3 is present, this field is a read-only alias of ICC\_MSRE.DIB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC\_HSRE.DIB.

Resets to 0.

**DFB, bit [1]**

Disable FIQ bypass.

If EL3 is present, this field is a read-only alias of ICC\_MSRE.DFB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC\_HSRE.DFB.

Resets to 0.

#### SRE, bit [0]

System Register Enable.

0 The memory mapped interface must be used. Access at EL1 to any ICC\_\* system register other than ICC\_SRE results in an Undefined exception.

1 The system register interface for the current security state is enabled.

Virtual accesses modify ICH\_VMCR.VSRE.

Resets to 0.

#### Accessing the ICC\_SRE:

To access the ICC\_SRE:

MRC p15,0,<Rt>,c12,c12,5 ; Read ICC\_SRE into Rt

MCR p15,0,<Rt>,c12,c12,5 ; Write Rt to ICC\_SRE

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	101

### G4.6.32 ICH\_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0)

The ICH\_AP0R0 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP0R0 is architecturally mapped to AArch64 register [ICH\\_AP0R0\\_EL2](#).

#### Attributes

ICH\_AP0R0 is a 32-bit register.

The ICH\_AP0R0 bit assignments are:

#### P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority  $(M \text{ divided by } 2^U) \text{ minus } 1$ , where U is the number of unimplemented bits of priority and is equal to  $(7 - \text{ICC\_CTLR\_EL1.PRIbits})$ .

For example, in a system with `ICC_CTLR_EL1.PRIbits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP0R0:

To access the ICH\_AP0R0:

MRC p15,4,<Rt>,c12,c8,0 ; Read ICH\_AP0R0 into Rt  
MCR p15,4,<Rt>,c12,c8,0 ; Write Rt to ICH\_AP0R0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	000

### G4.6.33 ICH\_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1)

The ICH\_AP0R1 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP0R1 is architecturally mapped to AArch64 register [ICH\\_AP0R1\\_EL2](#).

#### Attributes

ICH\_AP0R1 is a 32-bit register.

The ICH\_AP0R1 bit assignments are:

#### P<n>, bit [(n-32)], for n = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with `ICC_CTLR_EL1.PRIbits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP0R1:

To access the ICH\_AP0R1:

MRC p15,4,<Rt>,c12,c8,1 ; Read ICH\_AP0R1 into Rt  
MCR p15,4,<Rt>,c12,c8,1 ; Write Rt to ICH\_AP0R1

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	001

### G4.6.34 ICH\_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2)

The ICH\_AP0R2 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP0R2 is architecturally mapped to AArch64 register [ICH\\_AP0R2\\_EL2](#).

#### Attributes

ICH\_AP0R2 is a 32-bit register.

The ICH\_AP0R2 bit assignments are:

#### P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with `ICC_CTLR_EL1.PRIbits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP0R2:

To access the ICH\_AP0R2:

MRC p15,4,<Rt>,c12,c8,2 ; Read ICH\_AP0R2 into Rt  
MCR p15,4,<Rt>,c12,c8,2 ; Write Rt to ICH\_AP0R2

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	010

### G4.6.35 ICH\_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3)

The ICH\_AP0R3 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP0R3 is architecturally mapped to AArch64 register [ICH\\_AP0R3\\_EL2](#).

#### Attributes

ICH\_AP0R3 is a 32-bit register.

The ICH\_AP0R3 bit assignments are:

#### P<n>, bit [(n-96)], for n = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with `ICC_CTLR_EL1.PRIbits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP0R3:

To access the ICH\_AP0R3:

MRC p15,4,<Rt>,c12,c8,3 ; Read ICH\_AP0R3 into Rt  
MCR p15,4,<Rt>,c12,c8,3 ; Write Rt to ICH\_AP0R3

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	011

### G4.6.36 ICH\_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0)

The ICH\_AP1R0 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP1R0 is architecturally mapped to AArch64 register [ICH\\_AP1R0\\_EL2](#).

#### Attributes

ICH\_AP1R0 is a 32-bit register.

The ICH\_AP1R0 bit assignments are:

#### P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP1R0:

To access the ICH\_AP1R0:

MRC p15,4,<Rt>,c12,c9,0 ; Read ICH\_AP1R0 into Rt  
MCR p15,4,<Rt>,c12,c9,0 ; Write Rt to ICH\_AP1R0

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	000

### G4.6.37 ICH\_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1)

The ICH\_AP1R1 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP1R1 is architecturally mapped to AArch64 register [ICH\\_AP1R1\\_EL2](#).

#### Attributes

ICH\_AP1R1 is a 32-bit register.

The ICH\_AP1R1 bit assignments are:

#### P<n>, bit [(n-32)], for n = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with `ICC_CTLR_EL1.PRIBits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When <code>SCR_EL3.NS</code> is 0, accesses Group 1 Secure active priorities. When <code>SCR_EL3.NS</code> is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	<code>ICH_AP1Rn_EL2</code>
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the `ICH_AP1R1`:

To access the `ICH_AP1R1`:

MRC `p15,4,<Rt>,c12,c9,1` ; Read `ICH_AP1R1` into `Rt`  
MCR `p15,4,<Rt>,c12,c9,1` ; Write `Rt` to `ICH_AP1R1`

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	001

### G4.6.38 ICH\_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2)

The ICH\_AP1R2 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP1R2 is architecturally mapped to AArch64 register [ICH\\_AP1R2\\_EL2](#).

#### Attributes

ICH\_AP1R2 is a 32-bit register.

The ICH\_AP1R2 bit assignments are:

#### P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with `ICC_CTLR_EL1.PRIbits == 0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When <code>SCR_EL3.NS</code> is 0, accesses Group 1 Secure active priorities. When <code>SCR_EL3.NS</code> is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	<code>ICH_AP1Rn_EL2</code>
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the `ICH_AP1R2`:

To access the `ICH_AP1R2`:

MRC `p15,4,<Rt>,c12,c9,2` ; Read `ICH_AP1R2` into `Rt`  
MCR `p15,4,<Rt>,c12,c9,2` ; Write `Rt` to `ICH_AP1R2`

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	010

### G4.6.39 ICH\_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3)

The ICH\_AP1R3 characteristics are:

#### Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

#### Configurations

ICH\_AP1R3 is architecturally mapped to AArch64 register [ICH\\_AP1R3\\_EL2](#).

#### Attributes

ICH\_AP1R3 is a 32-bit register.

The ICH\_AP1R3 bit assignments are:

#### P<n>, bit [(n-96)], for n = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2<sup>U</sup>) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC\_CTLR\_EL1.PRIbits).

For example, in a system with ICC\_CTLR\_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by  $2^3$  gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICH\_AP1R3:

To access the ICH\_AP1R3:

MRC p15,4,<Rt>,c12,c9,3 ; Read ICH\_AP1R3 into Rt  
MCR p15,4,<Rt>,c12,c9,3 ; Write Rt to ICH\_AP1R3

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	011

### G4.6.40 ICH\_EISR, Interrupt Controller End of Interrupt Status Register

The ICH\_EISR characteristics are:

**Purpose**

When a maintenance interrupt is received, this register helps determine which List registers have outstanding EOI interrupts that require servicing.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

**Configurations**

ICH\_EISR is architecturally mapped to AArch64 register [ICH\\_EISR\\_EL2](#).

**Attributes**

ICH\_EISR is a 32-bit register.

The ICH\_EISR bit assignments are:

**Bits [31:16]**

Reserved, RES0.

**Status<n>, bit [n], for n = 0 to 15**

EOI status bit for List register <n>:

- 0 List register <n>, ICH\_LR<n>\_EL2, does not have an EOI.
- 1 List register <n>, ICH\_LR<n>\_EL2, has an EOI.

For any ICH\_LR<n>\_EL2, the corresponding status bit is set to 1 if ICH\_LR<n>\_EL2.State is 0b00 and ICH\_LR<n>\_EL2.HW is 0 and ICH\_LR<n>\_EL2.EOI is 1.

### Accessing the ICH\_EISR:

To access the ICH\_EISR:

MRC p15,4,<Rt>,c12,c11,3 ; Read ICH\_EISR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	011

### G4.6.41 ICH\_ELSR, Interrupt Controller Empty List Register Status Register

The ICH\_ELSR characteristics are:

#### Purpose

This register can be used to locate a usable List register when the hypervisor is delivering an interrupt to a Guest OS.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

#### Configurations

ICH\_ELSR is architecturally mapped to AArch64 register [ICH\\_ELSR\\_EL2](#).

#### Attributes

ICH\_ELSR is a 32-bit register.

The ICH\_ELSR bit assignments are:

#### Bits [31:16]

Reserved, RES0.

#### Status<n>, bit [n], for n = 0 to 15

Status bit for List register <n>, ICH\_LR<n>\_EL2:

- 0 List register ICH\_LR<n>\_EL2, if implemented, contains a valid interrupt. Using this List register can result in overwriting a valid interrupt.

- 1 List register ICH\_LR<n>\_EL2 does not contain a valid interrupt. The List register is empty and can be used without overwriting a valid interrupt or losing an EOI maintenance interrupt.

For any ICH\_LR<n>\_EL2, the corresponding status bit is set to 1 if ICH\_LR<n>\_EL2.State is 0b00 and either ICH\_LR<n>\_EL2.HW is 1 or ICH\_LR<n>\_EL2.EOI is 0.

### Accessing the ICH\_ELSR:

To access the ICH\_ELSR:

MRC p15,4,<Rt>,c12,c11,5 ; Read ICH\_ELSR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	101

### G4.6.42 ICH\_HCR, Interrupt Controller Hyp Control Register

The ICH\_HCR characteristics are:

**Purpose**

Controls the environment for guest operating systems.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

**Configurations**

ICH\_HCR is architecturally mapped to AArch64 register [ICH\\_HCR\\_EL2](#).

**Attributes**

ICH\_HCR is a 32-bit register.

The ICH\_HCR bit assignments are:

**EOIcount, bits [31:27]**

Counts the number of EOIs received that do not have a corresponding entry in the List registers. The virtual CPU interface increments this field automatically when a matching EOI is received.

EOIs that do not clear a bit in one of the Active Priorities registers ICH\_ApMn do not cause an increment.

Although not possible under correct operation, if an EOI occurs when the value of this field is 31, this field wraps to 0.

The maintenance interrupt is asserted whenever this field is non-zero and the LRENPIE bit is set to 1.

**Bits [26:13]**

Reserved, RES0.

**TALL1, bit [12]**

Trap all Non-secure EL1 accesses to ICC\_\* system registers for group 1 interrupts to EL2.

- 0 Non-Secure EL1 accesses to ICC\_\* registers for group 1 interrupts proceed as normal.
- 1 Any Non-secure EL1 accesses to ICC\_\* registers for group 1 interrupts trap to EL2.

**TALL0, bit [11]**

Trap all Non-secure EL1 accesses to ICC\_\* system registers for group 0 interrupts to EL2.

- 0 Non-Secure EL1 accesses to ICC\_\* registers for group 0 interrupts proceed as normal.
- 1 Any Non-secure EL1 accesses to ICC\_\* registers for group 0 interrupts trap to EL2.

**TC, bit [10]**

Trap all Non-secure EL1 accesses to system registers that are common to group 0 and group 1 to EL2.

- 0 Non-secure EL1 accesses to common registers proceed as normal.
- 1 Any Non-secure EL1 accesses to common registers trap to EL2.

This affects [ICC\\_DIR](#), [ICC\\_PMR](#), and [ICC\\_RPR](#).

**VARE, bit [9]**

Virtual ARE.

- 0 The guest operating system does not use affinity routing and expects a Source CPU ID for SGIs.
- 1 The guest operating system uses affinity routing.

When VARE is 0, the guest operating system does not support LPIs and software must ensure that no LPIs are presented to the guest either using the List registers or from the Distributor.

**VSEIE, bit [8]**

Virtual SEI Enable. Enables the signaling of a maintenance interrupt when performing a virtual access to a system register and a condition that would result in an (optional) SEI for a physical access is detected.

- 0 VSEIE maintenance interrupt is disabled.
- 1 VSEIE maintenance interrupt is enabled.

**VGrp1DIE, bit [7]**

VM Disable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled while GICV\_CTLR.EnableGrp1 is set to 0.

**VGrp1EIE, bit [6]**

VM Enable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled while GICV\_CTLR.EnableGrp1 is set to 1.

**VGrp0DIE, bit [5]**

VM Disable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled while GICV\_CTLR.EnableGrp0 is set to 0.

**VGrp0EIE, bit [4]**

VM Enable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled while GICV\_CTLR.EnableGrp0 is set to 1.

**NPIE, bit [3]**

No Pending Interrupt Enable. Enables the signaling of a maintenance interrupt while no pending interrupts are present in the List registers:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled while the List registers contain no interrupts in the pending state.

**LRENPIE, bit [2]**

List Register Entry Not Present Interrupt Enable. Enables the signaling of a maintenance interrupt while the virtual CPU interface does not have a corresponding valid List register entry for an EOI request:

- 0 Maintenance interrupt disabled.
- 1 A maintenance interrupt is asserted while the EOICount field is not 0.

**UIE, bit [1]**

Underflow Interrupt Enable. Enables the signaling of a maintenance interrupt when the List registers are empty, or hold only one valid entry:

- 0 Maintenance interrupt disabled.
- 1 A maintenance interrupt is asserted if none, or only one, of the List register entries is marked as a valid interrupt.

**En, bit [0]**

Enable. Global enable bit for the virtual CPU interface:

- 0 Virtual CPU interface operation disabled.
- 1 Virtual CPU interface operation enabled.

When this field is set to 0:

- The virtual CPU interface does not signal any maintenance interrupts.
- The virtual CPU interface does not signal any virtual interrupts.
- A read of GICV\_IAR or GICV\_AIAR returns a spurious interrupt ID.

**Accessing the ICH\_HCR:**

To access the ICH\_HCR:

```
MRC p15,4,<Rt>,c12,c11,0 ; Read ICH_HCR into Rt
MCR p15,4,<Rt>,c12,c11,0 ; Write Rt to ICH_HCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	000

### G4.6.43 ICH\_LRC<n>, Interrupt Controller List Registers, n = 0 - 15

The ICH\_LRC<n> characteristics are:

#### Purpose

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

ICH\_LR<n> and ICH\_LRC<n> may be updated independently.

#### Configurations

ICH\_LRC<n> is architecturally mapped to AArch64 register ICH\_LR<n>\_EL2[63:32].

#### Attributes

ICH\_LRC<n> is a 32-bit register.

The ICH\_LRC<n> bit assignments are:

#### State, bits [31:30]

The state of the interrupt:

- 00 Invalid
- 01 Pending
- 10 Active
- 11 Pending and active.

The GIC updates these state bits as virtual interrupts proceed through the interrupt life cycle. Entries in the invalid state are ignored, except for the purpose of generating virtual maintenance interrupts.

For hardware interrupts, the pending and active state is held in the physical Distributor rather than the virtual CPU interface. A hypervisor must only use the pending and active state for software originated interrupts, which are typically associated with virtual devices, or SGIs.

#### HW, bit [29]

Indicates whether this virtual interrupt is a hardware interrupt, meaning that it corresponds to a physical interrupt. Deactivation of the virtual interrupt also causes the deactivation of the physical interrupt with the ID that the PhysicalID field indicates.

- 0 The interrupt is triggered entirely in software. No notification is sent to the Distributor when the virtual interrupt is deactivated.

- 1 The interrupt is a hardware interrupt. A deactivate interrupt request is sent to the Distributor when the virtual interrupt is deactivated, using the PhysicalID field from this register to indicate the physical interrupt ID.  
 If GICV\_CTLR.EOI mode is 0, this request corresponds to a write to the GICV\_EOIR or GICV\_AEOIR, otherwise it corresponds to a write to the GICV\_DIR.

**Bits [27:24]**

Reserved, RES0.

**Priority, bits [23:16]**

The priority of this interrupt.

It is IMPLEMENTATION DEFINED how many bits of priority are implemented, though at least five bits must be implemented. Unimplemented bits are RES0 and start from bit [48] up to bit [50]. The number of implemented bits can be discovered from ICH\_VTR\_EL2.PRIBits, and determines how many GICH\_APR<n> registers exist.

**Bits [15:10]**

Reserved, RES0.

**PhysicalID, bits [9:0]**

Physical ID, for hardware interrupts.

When HW is 0 (i.e. there is no corresponding physical interrupt), some of these bits have a special meaning:

Bit [39] EOI. When this bit is 1, a maintenance interrupt is asserted to signal EOI when the interrupt state is invalid, which typically occurs when the interrupt is deactivated.

Bits [38:32]Reserved, RES0.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH\_VTR\_EL2.IDbits.

**Accessing the ICH\_LRC<n>:**

To access the ICH\_LRC<n>:

MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH\_LRC<n> into Rt, where n is in the range 0 to 15

MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH\_LRC<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	111:n<3:3>	n<2:0>

#### G4.6.44 ICH\_LR<n>, Interrupt Controller List Registers, n = 0 - 15

The ICH\_LR<n> characteristics are:

##### Purpose

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

##### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

ICH\_LR<n> and ICH\_LRC<n> may be updated independently.

##### Configurations

ICH\_LR<n> is architecturally mapped to AArch64 register ICH\_LR<n>\_EL2[31:0].

##### Attributes

ICH\_LR<n> is a 32-bit register.

The ICH\_LR<n> bit assignments are:

##### VirtualID, bits [31:0]

Virtual ID of the interrupt.

When VARE is zero, software must ensure the correct Source CPU ID is provided in bits [12:10].

Software must ensure there is only a single valid entry for a given VirtualID.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH\_VTR\_EL2.IDbits.

##### Accessing the ICH\_LR<n>:

To access the ICH\_LR<n>:

MRC p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH\_LR<n> into Rt, where n is in the range 0 to 15  
MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH\_LR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	110:n<3:3>	n<2:0>

### G4.6.45 ICH\_MISR, Interrupt Controller Maintenance Interrupt State Register

The ICH\_MISR characteristics are:

**Purpose**

Indicates which maintenance interrupts are asserted.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

**Configurations**

ICH\_MISR is architecturally mapped to AArch64 register [ICH\\_MISR\\_EL2](#).

**Attributes**

ICH\_MISR is a 32-bit register.

The ICH\_MISR bit assignments are:

**Bits [31:9]**

Reserved, RES0.

**VSEI, bit [8]**

Virtual SEI. Set to 1 when a condition that would result in generation of an SEI is detected during a virtual access to an ICC\_\* system register.

**VGrp1D, bit [7]**

Disabled Group 1 maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.VGrp1DIE is 1 and ICH\_VMCR\_EL2.VMGrp1En is 0.

**VGrp1E, bit [6]**

Enabled Group 1 maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.VGrp1EIE is 1 and ICH\_VMCR\_EL2.VMGrp1En is 1.

**VGrp0D, bit [5]**

Disabled Group 0 maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.VGrp0DIE is 1 and ICH\_VMCR\_EL2.VMGrp0En is 0.

**VGrp0E, bit [4]**

Enabled Group 0 maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.VGrp0EIE is 1 and ICH\_VMCR\_EL2.VMGrp0En is 1.

**NP, bit [3]**

No Pending maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.NPIE is 1 and no List register is in pending state.

**LRENP, bit [2]**

List Register Entry Not Present maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.LRENPIE is 1 and ICH\_HCR\_EL2.EOIcount is non-zero.

**U, bit [1]**

Underflow maintenance interrupt.

Asserted whenever ICH\_HCR\_EL2.UIE is 1 and if none, or only one, of the List register entries are marked as a valid interrupt, that is, if the corresponding ICH\_LR<n>\_EL2.State bits do not equal 0x0.

**EOI, bit [0]**

EOI maintenance interrupt.

Asserted whenever at least one List register is asserting an EOI interrupt. That is, when at least one bit in ICH\_EISR0\_EL1 or ICH\_EISR1\_EL1 is 1.

**Accessing the ICH\_MISR:**

To access the ICH\_MISR:

MRC p15,4,<Rt>,c12,c11,2 ; Read ICH\_MISR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	010

### G4.6.46 ICH\_VMCR, Interrupt Controller Virtual Machine Control Register

The ICH\_VMCR characteristics are:

**Purpose**

Enables the hypervisor to save and restore the virtual machine view of the GIC state.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

When EL2 is using system register access, EL1 using either system register or memory-mapped access must be supported.

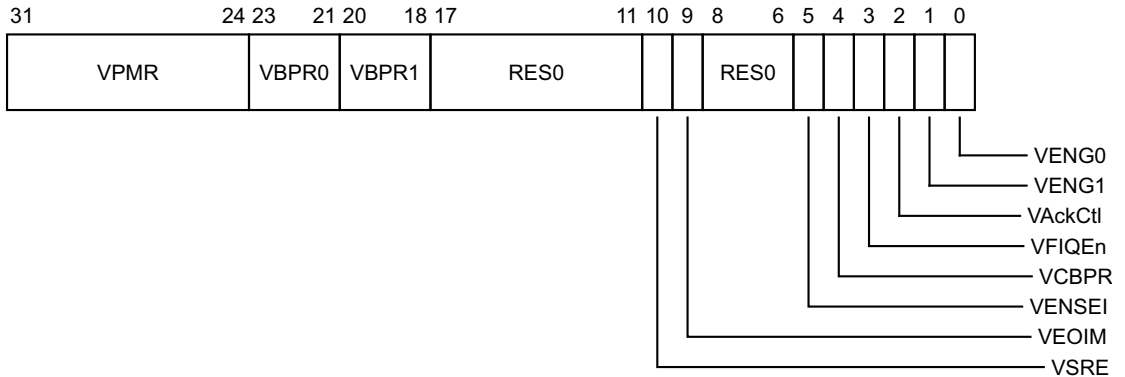

**Configurations**

ICH\_VMCR is architecturally mapped to AArch64 register [ICH\\_VMCR\\_EL2](#).

**Attributes**

ICH\_VMCR is a 32-bit register.

The ICH\_VMCR bit assignments are:

**VPMR, bits [31:24]**

Virtual Priority Mask.

Visible to the guest OS as ICC\_PMR\_EL1 / GICV\_PMR.

**VBPR0, bits [23:21]**

Virtual BPR0.

Visible to the guest OS as ICC\_BPR0\_EL1 / GICV\_BPR.

**VBPR1, bits [20:18]**

Virtual BPR1.

Visible to the guest OS as ICC\_BPR1\_EL1 / GICV\_ABPR.

**Bits [17:11]**

Reserved, RES0.

**VSRE, bit [10]**

Virtual SRE.

Visible to the guest OS as ICC\_SRE\_EL1.SRE.

If EL2 is not configured to use system registers, this bit is treated as if it is 0.

**VEOIM, bit [9]**

Virtual EOImode.

Visible to the guest OS as ICC\_CTLR\_EL1.EOImode / GICV\_CTLR.EOImode.

**Bits [8:6]**

Reserved, RES0.

**VENSEL, bit [5]**

This bit is IMPLEMENTATION DEFINED.

If an implementation does not have functionality associated with this bit, ARM recommends that the bit is RES0.

**VCBPR, bit [4]**

Virtual CBPR.

Visible to the guest OS as ICC\_CTLR\_EL1.CBPR / GICV\_CTLR.CBPR.

**VFIQEn, bit [3]**

Virtual FIQ enable.

Visible to the guest OS as GICV\_CTLR.FIQEn.

**VAckCtl, bit [2]**

Virtual AckCtl.

Visible to the guest OS as GICV\_CTLR.AckCtl.

**VENG1, bit [1]**

Virtual group 1 interrupt enable.

Visible to the guest OS as ICC\_IGRPEN1\_EL1.Enable / GICV\_CTLR.EnableGrp1.

**VENG0, bit [0]**

Virtual group 0 interrupt enable.

Visible to the guest OS as ICC\_IGRPEN0\_EL1.Enable / GICV\_CTLR.EnableGrp0.

**Accessing the ICH\_VMCR:**

To access the ICH\_VMCR:

MRC p15,4,<Rt>,c12,c11,7 ; Read ICH\_VMCR into Rt

MCR p15,4,<Rt>,c12,c11,7 ; Write Rt to ICH\_VMCR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	111

### G4.6.47 ICH\_VSEIR, Interrupt Controller Virtual System Error Interrupt Register

The ICH\_VSEIR characteristics are:

**Purpose**

Allows the hypervisor to inject a virtual SEI.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

**Configurations**

ICH\_VSEIR is architecturally mapped to AArch64 register [ICH\\_VSEIR\\_EL2](#).

**Attributes**

ICH\_VSEIR is a 32-bit register.

The ICH\_VSEIR bit assignments are:

**Accessing the ICH\_VSEIR:**

To access the ICH\_VSEIR:

MRC p15,4,<Rt>,c12,c9,4 ; Read ICH\_VSEIR into Rt

MCR p15,4,<Rt>,c12,c9,4 ; Write Rt to ICH\_VSEIR

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	100

## G4.6.48 ICH\_VTR, Interrupt Controller VGIC Type Register

The ICH\_VTR characteristics are:

### Purpose

Describes the number of implemented virtual priority bits and List registers.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

### Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

### Configurations

ICH\_VTR is architecturally mapped to AArch64 register [ICH\\_VTR\\_EL2](#).

### Attributes

ICH\_VTR is a 32-bit register.

The ICH\_VTR bit assignments are:

### PRBits, bits [31:29]

The number of virtual priority bits implemented, minus one.

### PREbits, bits [28:26]

The number of virtual preemption bits implemented, minus one.

### IDbits, bits [25:23]

The number of virtual interrupt identifier bits supported:

000 16 bits.

001 24 bits.

All other values are reserved.

### SEIS, bit [22]

SEI Support. Indicates whether the virtual CPU interface supports generation of SEIs:

0 The virtual CPU interface logic does not support generation of SEIs.

1 The virtual CPU interface logic supports generation of SEIs.

Virtual system errors may still be generated by writing to ICH\_VSEIR\_EL2 regardless of the value of this field.

**A3V, bit [21]**

Affinity 3 Valid. Possible values are:

- 0 The virtual CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
- 1 The virtual CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

**Bits [20:5]**

Reserved, RES0.

**ListRegs, bits [4:0]**

The number of implemented List registers, minus one. For example, a value of 0b01111 indicates that the maximum of 16 List registers are implemented.

**Accessing the ICH\_VTR:**

To access the ICH\_VTR:

MRC p15,4,<Rt>,c12,c11,1 ; Read ICH\_VTR into Rt

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	001

# Part H

## External Debug

# Chapter H1

## Introduction to External Debug

This chapter introduces the external debug components of ARMv8. It contains the following sections:

- [Introduction to external debug](#) on page H1-4324.
- [External debug](#) on page H1-4325.

———— **Note** —————

For information about self-hosted debug, see [Chapter D2 Debug Exceptions](#) and [Chapter D3 The Debug Exception Model](#).

---

## H1.1 Introduction to external debug

ARMv8 supports both:

### Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

### External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called *external debug features*.

---

### Note

---

When the description of external debug in this part of the manual describes a debugger as controlling external debug this might be a second on-chip PE or a processor in an off-chip device such as a JTAG debugger.

---

## H1.2 External debug

The following halting debug events are available in ARMv8:

- [Halting Step debug event on page H3-4366](#):
  - The debugger can use this resource to make the PE step through code one line at a time.
- [Halt Instruction debug event on page H3-4376](#):
  - This might occur when software executes the Halting software breakpoint instruction, HLT.
- [Exception Catch debug event on page H3-4377](#):
  - This can be programmed to occur on all entries to a given Exception level.
- [External Debug Request debug event on page H3-4380](#):
  - An embedded cross-trigger can signal this debug event.
- [OS Unlock Catch debug event on page H3-4381](#):
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- [Reset Catch debug event on page H3-4382](#):
  - This might occur when the PE exits reset state.
- [Software Access debug event on page H3-4383](#):
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Halting debug events allow an external debugger to halt the PE. Breakpoints and watchpoints can also halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

[Chapter H2 Debug State](#) describes Debug state in more detail.

# Chapter H2

## Debug State

This chapter describes Debug state. It contains the following sections:

- [About Debug state on page H2-4328.](#)
- [Halting the PE on debug events on page H2-4329.](#)
- [Entering Debug state on page H2-4337.](#)
- [Behavior in Debug state on page H2-4341.](#)
- [Exiting Debug state on page H2-4361.](#)

———— **Note** ————

[Table J-1 on page AppxJ-5088](#) disambiguates the general register references used in this chapter.

---

## H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

## H2.2 Halting the PE on debug events

For details of debug events see [Introduction to Halting debug events on page H3-4364](#) and [Breakpoint and Watchpoint debug events on page H2-4330](#).

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See [Halting allowed and halting prohibited](#).
- The type of debug event and the programming of the debug control registers.
  - See [Halting debug events](#) for all Halting debug events.
  - See [Breakpoint and Watchpoint debug events on page H2-4330](#) for Breakpoint and Watchpoint debug events.

See also [Other debug exceptions on page H2-4331](#).

This means that behavior can be UNPREDICTABLE if the conditions change. See [Synchronization and Halting debug events on page H3-4384](#).

[Summary of debug events and possible outcomes on page H3-4364](#) summarizes the possible outcomes of each type of debug event.

### H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus() == TRUE`.
  - This means that OS Double Lock is locked, that is `EDPRSR.DLK == 1`.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  - The PE is in Non-secure state and `ExternalInvasiveDebugEnabled() == FALSE`.
  - The PE is in Secure state and `ExternalSecureInvasiveDebugEnabled() == FALSE`.

———— **Note** ————

See [Appendix B Recommended External Debug Interface](#) for more information on these functions.

- Otherwise, halting is allowed.

See [Pseudocode details of Halting on debug events on page H2-4335](#).

### H2.2.2 Halting debug events

When a Halting debug event is generated, it causes entry to Debug state if both:

- Halting is allowed. See [Halting allowed and halting prohibited](#).
- The Halting debug event is either:
  - A Halt Instruction debug event and Halting debug-mode is enabled. This means that `EDSCR.HDE == 1`.
  - Not a Halt Instruction debug event.

———— **Note** —————

- An Halt Instruction debug event is the only Halting debug event that relies on `EDSCR.HDE == 1`. This is to prevent malicious code from causing an entry Debug state. `EDSCR.HDE == 0` on a Cold reset.
- Halting on Breakpoint and Watchpoint Software debug events is also controlled by `EDSCR.HDE`. See [Breakpoint and Watchpoint debug events](#).
- `EDSCR.HDE` can be written by software when the OS Lock is locked. Privileged code can use `SDCR.TDOSA` and `HDCR.TDOSA` to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, it generates an Undefined Instruction exception.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.
- In all other cases the Halting debug event is pended, meaning that:
  - The pending Halting debug event is recorded in `EDESR`.
  - The pending Halting debug event is taken when halting is allowed. See [Pending Halting debug events on page H3-4384](#).

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to `EDESR`. [Summary of actions from debug events on page H2-4334](#) summarizes the possible outcome for each type of Debug event.

———— **Note** —————

Halting debug events never generate Debug exceptions.

### H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug-mode is enabled, that is `EDSCR.HDE == 1`.
- Halting is allowed. See [Halting allowed and halting prohibited on page H2-4329](#).
- The OS Lock is unlocked, that is `OSLSR.OSLK == 0`.

The Address Mismatch breakpoint type is reserved when all of these conditions are met. See [Legacy debug exceptions on page D2-1564](#).

`MDSCR_EL1.MDE` or `DBGDSCRext.MDBGen` is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

———— **Note** —————

`EDSCR.HDE` is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting-debug mode in Non-secure state does not affect the Exception model in Secure state.

See [Chapter D2 Debug Exceptions](#) and the Note in [Other debug exceptions on page H2-4331](#).

## H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Software Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions. See also [Legacy debug exceptions on page D2-1564](#).

The behavior of these events is unchanged when Halting debug mode is enabled, that is when `EDSCR.HDE == 1`. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see [Chapter D2 Debug Exceptions](#).

## H2.2.5 Debug state entry and debug event prioritization

The architecture does not define when asynchronous Halting debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED.

Synchronous Halting debug events do have a priority order.

The following are synchronous Halting debug events:

- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous Halting debug events is treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, the synchronous Halting debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

### ———— Note —————

Reset Catch and Exception Catch debug events can also be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.

The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events, these are taken first.

OS Unlock Catch debug events are always pended and taken asynchronously.

Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously at a later time.

The following list shows how the events are prioritized, with -2.0 being the highest priority.

### ———— Note —————

The priority numbering is the same as the numbering for synchronous exception priorities listed in [Synchronous exception types, routing and priorities on page D1-1450](#). The Debug events in this section with a negative priority are a higher priority than any synchronous exception. The debug events with fractional priorities have a priority between two or more exceptions.

The priority for synchronous debug events is as follows:

- 2           Reset Catch debug event. See [Reset Catch debug event on page H3-4382](#).  
              This debug event has a higher priority than the synchronous exceptions listed in [Synchronous exception types, routing and priorities on page D1-1450](#).

- 1 Exception Catch debug event. See [Exception Catch debug event on page H3-4377](#).  
This debug event can be assigned one of two priorities. When it has a priority of -1, it has a higher priority than the synchronous exceptions listed in the Exception model. See [Exception Catch debug event on page H3-4377](#).
- 0 Halting Step debug event. See [Halting Step debug event on page H3-4366](#).  
This debug event has a higher priority than the synchronous exceptions listed in the Exception model.
- 1 Software Step debug event. See [Software Step exceptions on page D2-1634](#).
- 1.5 Exception Catch debug event. See [Exception Catch debug event on page H3-4377](#).  
This debug event can be assigned one of two priorities, -1 or 1.5. See [Exception Catch debug event on page H3-4377](#).
- 2 - 3 These events are not debug events.
- 4 Breakpoint exception or debug event or Address Matching Vector Catch exception. See [Breakpoint exceptions on page D2-1569](#) and [Vector Catch exceptions on page D2-1627](#).  
These two debug events have the same priority.
- 5 - 13 These events are not debug events.
- 14 Halt Instruction debug event. See [Halt Instruction debug event on page H3-4376](#).
- 15 - 19 These events are not debug events.
- 19.5 Software Access debug event. See [Software Access debug event on page H3-4383](#).
- 20 - 21 These events are not debug events.
- 22 Watchpoint exception or debug event. See [Watchpoint exceptions on page D2-1606](#).

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pending.

The prioritization of asynchronous Halting debug events, including pending Halting debug events taken asynchronously, is IMPLEMENTATION DEFINED. See [Taking Halting debug events asynchronously on page H3-4385](#).

For more information on the prioritization of exceptions see [Synchronous exception types, routing and priorities on page D1-1450](#).

## Debug state entry and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with `DSPSR.SS` set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with `DSPSR.SS` set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with `DSPSR.SS` set to 0. This is because `PSTATE.SS` is set to 0 by taking the exception.

- If the PE is reset, `PSTATE.SS` is reset to 0. If the following debug events are enabled, the PE enters Debug state with `DSPSR.SS` set to 0:
  - Reset Catch debug events at the reset Exception level.
  - Exception Catch debug events at the reset Exception level.
  - Halting Step debug events.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and `DSPSR.SS` is set to 0.

### Breakpoint debug events and Vector Catch exception

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See [Synchronous exception prioritization on page D1-1451](#).

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONstrained UNpredictable choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug-mode is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

## H2.2.6 Forcing entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to `EDRCR.CBRRQ` to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled() == FALSE`.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled() == FALSE`, and either:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented.

[Example H2-1](#) shows how entry to Debug state can be forced.

### Example H2-1 Forcing entry to Debug state

---

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to `EDRCR.CBRRQ`. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

---

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

## H2.2.7 Summary of actions from debug events

Table H2-2 on page H2-4347 shows the Software and Halting debug events. In Table H2-2 on page H2-4347 the columns have the following meaning:

### Debug event type

This means the type of debug event where:

**Other software** means one of:

- [Software Step exceptions on page D2-1634](#).
- [Software Breakpoint Instruction exceptions on page D2-1566](#).
- [Vector Catch exceptions on page D2-1627](#).

**Other Halting** means one of the following:

- [Halting Step debug event on page H3-4366](#).
- [External Debug Request debug event on page H3-4380](#).
- [Reset Catch debug event on page H3-4382](#).
- [OS Unlock Catch debug event on page H3-4381](#).

Other debug events are referred to explicitly.

### Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

**In Secure state**

ExternalSecureInvasiveDebugEnabled().

**In Non-secure state**

ExternalInvasiveDebugEnabled().

**DLK** This is the value EDPRSR.DLK. It indicates whether the OS Double Lock is locked, DoubleLockStatus() == TRUE.

**OSLK** This is the value of EDSCR.OSLK. It indicates whether the OS Lock is locked.

**HDE** This is the value of EDSCR.HDE. It indicates whether Halting debug-mode is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

**Table H2-1 Debug authentication for external debug**

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model

Table H2-1 Debug authentication for external debug (continued)

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Breakpoint or Watchpoint debug event	X	1	X	X	Handled by the Exception model (ignored)
	X	0	1	X	Handled by the Exception model (ignored)
	FALSE	0	0	X	Handled by the Exception model
	TRUE	0	0	0	Handled by the Exception model
	TRUE	0	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNALLOCATED
	TRUE	1	X	X	UNALLOCATED
	TRUE	0	X	0	UNALLOCATED
	TRUE	0	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Ignored
	TRUE	0	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Ignored
	TRUE	0	1	X	Ignored
	TRUE	0	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Debug event is pended
	TRUE	0	X	X	Entry to Debug state

## H2.2.8 Pseudocode details of Halting on debug events

The following pseudocode outlines the Halting(), Restarting(), HaltOnBreakpointOrWatchpoint(), and HaltingAllowed() functions.

```
// Halting()
// =====

boolean HaltingAllowed()
    return !(EDSCR.STATUS IN {'000001', '000010'});           // Halting

// Restarting()
// =====

boolean Restarting()
    return EDSCR.STATUS == '000001';                          // Restarting
```

```
// HaltOnBreakpointOrWatchpoint()
// =====
// Returns TRUE if the Breakpoint and Watchpoint debug events should be considered for Debug
// state entry, FALSE if they should be considered for a debug exception.

boolean HaltOnBreakpointOrWatchpoint()
    return HaltingAllowed() && EDSCR.HDE == '1' && OSLSR_EL1.OSLK == '0';

// HaltingAllowed()
// =====
// Returns TRUE if halting is currently allowed, FALSE if halting is prohibited.

boolean HaltingAllowed()
    if Halted() || DoubleLockStatus() then
        return FALSE;
    elsif IsSecure() then
        return ExternalSecureInvasiveDebugEnabled();
    else
        return ExternalInvasiveDebugEnabled();
```

## H2.3 Entering Debug state

On entry to Debug state the preferred restart address and **PSTATE** are saved in **DLR** and **DSPSR**. The PE remains in the mode and security state from which it entered Debug state.

If **EDRCR.CBRRQ** has a value of 0, entry to Debug state is precise. If **EDRCR.CBRRQ** has a value of 1 imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in **EDWAR**.

Other than the effect on **PSTATE** and **EDSCR**, entry to Debug state is not a *Context synchronization operation*. The effects of entry to Debug state on **PSTATE** and **EDSCR** are synchronized.

### H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the values of **PSTATE**.{J,T} before entering Debug state.

To allow the debugger to determine the state of the PE, the current execution state for all four Exception levels can be read from **EDSCR.RW**.

The current endianness state, **PSTATE.E**, is unchanged on entry to Debug state.

———— **Note** —————

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by **SCTLR.EE**.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by **HSCTLR.EE**.
- On entry to Debug state from AArch32 state, **PSTATE.SS** is copied to **DSPSR.SS**, even though the PE remains in AArch32 state.

See also *Effect of entering Debug state on PSTATE* on page H2-4338.

### H2.3.2 Effect of entering Debug state on DLR and DSPSR

**DLR** is set to the preferred restart address for the debug event, and depends on the event type. The value of **PSTATE** is saved in **DSPSR**. For entry to Debug state from AArch32 state, the values saved in **DSPSR.IT**, bits[7:0], are always correct for the preferred return address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception. See *Preferred return addresses* on page D3-1667.
- For Halt Instruction debug events **DLR** is set to the address of the HLT instruction and **DSPSR.IT** is correct for the HLT instruction.
- For Software Access debug events, **DLR** is set to the address of the accessing instruction and **DSPSR.IT** is correct for this instruction.
- For Halting Step debug events taken synchronously, **DLR** and **DSPSR** are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and **PSTATE** for, the instruction after the one that was stepped.

- For Exception Catch debug events, **DLR** is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. **DSPSR** records the value of **PSTATE** after taking the exception. The exception catch occurs after **ELR\_ELx** and **SPSR\_ELx** are set, and the debugger can use these registers to determine where in the application program the exception occurred.
- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
- For pending Halting debug events and External Debug Request debug events, **DLR** is set to the address of the first instruction that must be executed on exit from Debug state and **DSPSR.IT** is correct for this instruction. See *Pending Halting debug events on page H3-4384*.

Normally **DLR** is aligned according to the instruction set state indicated in **DSPSR**. However, a debug event might be taken at a point where the PC is not aligned.

### H2.3.3 Effect of entering Debug state on system registers, the Event register, and exclusive monitors

Entering Debug state has no effect on system registers other than **DLR** and **DSPSR**. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. **SCR** is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and exclusive monitors.

#### ———— Note ————

Entry to Debug state might set the Event Register or clear the exclusive monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the system registers, Event register, and exclusive monitors.

### H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on **PSTATE** is described in *Entering Debug state on page H2-4337* and *Entering Debug state from AArch32 state on page H2-4337*.

**PSTATE**.{E, M, nRW, EL, SP} are unchanged on entry to Debug state.

**PSTATE**.IL is cleared to 0 on entry to Debug state, after being saved in **DSPSR\_ELO**.

The other **PSTATE** fields are ignored and not observable in Debug state:

- **PSTATE**.{N, Z, C, V, Q, GE} are unchanged.
- **PSTATE**.{IT, J, T, SS, D, A, I, F} are set to UNKNOWN values, after being saved in **DSPSR\_ELO**.

For more information see *Process state (PSTATE) in Debug state on page H2-4341*.

### H2.3.5 Pseudocode details for entering Debug state

The following pseudocode shows the definition of the DebugHalt() function.

```
constant bits(6) DebugHalt_Breakpoint      = '000111';
constant bits(6) DebugHalt_EDBGRQ         = '010011';
constant bits(6) DebugHalt_Step_Normal    = '011011';
constant bits(6) DebugHalt_Step_Exclusive = '011111';
constant bits(6) DebugHalt_OSUnlockCatch  = '100011';
constant bits(6) DebugHalt_ResetCatch     = '100111';
constant bits(6) DebugHalt_Watchpoint     = '101011';
constant bits(6) DebugHalt_HaltInstruction = '101111';
```

```
constant bits(6) DebugHalt_SoftwareAccess = '110011';
constant bits(6) DebugHalt_ExceptionCatch = '110111';
constant bits(6) DebugHalt_Step_NoSyndrome = '111011';
```

The pseudocode for the UpdateEDSCRFIELDS() function is as follows:

```
// UpdateEDSCRFIELDS()
// =====
// Update EDSCR processor state fields

UpdateEDSCRFIELDS()

    // This might be invoked at any time, but updates are explicitly visible only following a
    // context synchronization operation and after entry to Debug state.
    // This function illustrates how EDSCR.RW is constructed.

    if !Halted() then
        EDSCR.EL = '00';
        EDSCR.NS = bit UNKNOWN;
        EDSCR.RW = '1111';
    else
        EDSCR.EL = PSTATE.EL;
        EDSCR.NS = if IsSecure() then '0' else '1';
        EDSCR.RW<3> = (if HighestELUsingAArch32() then '0' else '1');
        EDSCR.RW<2> = EDSCR.RW<3> AND (if !HaveEL(EL3) then '1' else SCR_GEN[].RW);
        EDSCR.RW<1> = EDSCR.RW<2> AND (if !CurrentStateHasEL2() then '1' else HCR_EL2.RW);
        EDSCR.RW<0> = EDSCR.RW<1> AND (if PSTATE.EL != EL0 || !UsingAArch32() then '1' else '0');

    return;
```

The pseudocode for the Halt() function is as follows:

```
// Halt()
// =====

Halt(bits(6) reason)

    CTI_SignalEvent(CrossTriggerIn_CrossHalt); // Trigger other cores to halt

    // Save debug entry state in DLR_EL0 and DSPSR_EL0 (see text). Note: no offset on DLR_EL0.
    // Preferred return address is always the address of instruction that generated the debug event.
    // For a Halting Step debug event this is the address of the next instruction.
    // For an Exception Catch debug event this is the target address inside the target EL.
    DLR_EL0 = ThisInstrAddr();
    DSPSR_EL0 = GetSPSRFromPSTATE();

    DSPSR_EL0.SS = PSTATE.SS; // Always save PSTATE.SS

    // Set up EDSCR bits
    EDSCR.ITE = '1'; EDSCR.ITO = '0';
    if IsSecure() then
        EDSCR.SDD = '0'; // If entered in Secure state, allow debug
    elseif HaveEL(EL3) then
        EDSCR.SDD = (if ExternalSecureInvasiveDebugEnabled() then '0' else '1');
    else
        assert EDSCR.SDD == '1'; // Otherwise EDSCR.SDD is RES1
    EDSCR.MA = '0';

    // ERR is not explicitly cleared. An RX0 or TXU error may be pending.
    // PSTATE.{IT,J,T,SS,D,A,I,F} are not observable and ignored in Debug state, so it does not
    // matter what they are set to on entry to Debug state. The processor treats them as if they
    // have specific fixed values. This code sets them to UNKNOWN values to illustrate this.
```

```
if UsingAArch32() then // entering from AArch32 state
    PSTATE.<IT,J,T,SS,A,I,F> = bits(14) UNKNOWN;
else
    PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;

// However, a possible implementation is to explicitly set them to values consistent with the
// behavior in Debug state, but this is not required. Such an implementation is shown in the
// following comments. See Effect of entering Debug state on PSTATE.
// if UsingAArch32() then // entering from AArch32 state
//     PSTATE.<J,T> = '01'; // Force execution of T32 instructions
//     PSTATE.IT = Zeros(8); // Force IT bits ignored
//     PSTATE.<A,I,F> = '111'; // Mask asynchronous exceptions
// else
//     PSTATE.<D,A,I,F> = '1111'; // Mask asynchronous exceptions
//     PSTATE.SS = '0';

// PSTATE.IL is cleared on entry to Debug state.
PSTATE.IL = '0';

// PSTATE.{E,M,nRW,EL,SP} and PSTATE.{N,Z,C,V,Q,GE} are unchanged.

StopInstructionPrefetchAndEnableITR();
EDSCR.STATUS = reason; // Signal entered Debug state
UpdateEDSCRFields(); // Update EDSCR processor state flags.

return;
```

## H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, [EDITR](#). The execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See [Debug state instructions on page H2-4344](#). In Non-debug state these instructions are UNALLOCATED.

### H2.4.1 Process state (PSTATE) in Debug state

[PSTATE](#).{N, Z, C, V, Q, GE, IT, J, T, SS, D, A, I, F} are all ignored in Debug state:

- There are no conditional instruction in Debug state.
- In AArch32 state, the PE only executes T32 instructions and [PSTATE.IT](#) is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

---

**Note**

[Halt\(\)](#) and [DRPSInstruction\(\)](#) set these fields to UNKNOWN, but the pseudocode provides comments that show how an implementation can set them to fixed values on entry to Debug state and on changing Exception level within Debug state. See [Pseudocode details for entering Debug state on page H2-4338](#).

Instructions executed in Debug state indirectly read [PSTATE](#).{IL, E, M, nRW, EL, SP} as they would in Non-debug state.

### H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current execution state.

In Debug state, an instruction does one of the following:

- It is UNALLOCATED.
- It behaves as defined in [Debug state instructions on page H2-4344](#).
- It behaves as defined for Non-debug state.

The only A64 and T32 instructions with modified behavior in Debug state are:

- The hint instructions WFE and WFI, which do not cause a suspension of execution.
- The T32 ERET instruction, which is decoded as DRPS.

---

**Note**

- This chapter is not the instruction set specification. In case of any encoding discrepancies, [Chapter C3 A64 Instruction Set Encoding](#), [Chapter F3 T32 Base Instruction Set Encoding](#), and [Chapter D1 The AArch64 System Level Programmers' Model](#), are authoritative.
- If [EDSCR.SDD](#) == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See [Security in Debug state on page H2-4349](#).

---

All T32 instructions are treated as unconditional, regardless of [PSTATE.IT](#). See [Process state \(PSTATE\) in Debug state](#).

## Instructions that are UNALLOCATED in Debug state

The instruction classes in this section are UNALLOCATED in Debug state. The behavior of UNALLOCATED instructions in Debug state is described in *Exceptions in Debug state* on page H2-4355.

The A64 instruction classes that are UNALLOCATED are listed here.

Data Processing Immediate:

- All [PC-rel. addressing](#) instructions.
- The following [Add/subtract \(immediate\)](#) instructions:
  - [Flag-setting only](#).
- All [Logical \(immediate\)](#) instructions.
- All [Bitfield](#) instructions.
- All [Extract](#) instructions.

Branches, Exception Generating and System:

- All [Unconditional branch \(immediate\)](#) instructions.
- All [Compare & branch \(immediate\)](#) instructions.
- All [Test & branch \(immediate\)](#) instructions.
- All [Conditional branch \(immediate\)](#) instructions.
- All [Exception generation](#) instructions, except:
  - [DCPS](#), see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4351.
- The following [System](#) instructions:
  - [MSR \(set PSTATE field, immediate\)](#).
  - [MSR | MRS SPSEL, register](#).
  - [MSR | MRS DAIF, register](#).
  - [MSR | MRS NZCV, register](#).
  - [MRS CurrentEL, register](#)
- All [Unconditional branch \(register\)](#) instructions, except:
  - [DRPS](#).

Loads and Stores:

- All [Load register \(literal\)](#) instructions.
- All [Load/store no-allocate pair \(offset\)](#) instructions.
- All [Load/store register pair \(post-indexed\)](#) instructions.
- All [Load/store register pair \(offset\)](#) instructions.
- All [Load/store register pair \(pre-indexed\)](#) instructions.
- The following [Load/store register \(unscaled immediate\)](#) instructions:
  - [SIMD and FP only](#).
- The following [Load/store register \(immediate post-indexed\)](#) instructions:
  - [SIMD and FP only](#).
- The following [Load/store register \(immediate pre-indexed\)](#) instructions:
  - [SIMD and FP only](#).
- All [Load/store register \(register offset\)](#) instructions.
- All [Load/store register \(unsigned immediate\)](#) instructions.
- All [AdvSIMD load/store multiple structures](#) instructions.
- All [AdvSIMD load/store multiple structures \(post-indexed\)](#) instructions.
- All [AdvSIMD load/store single structure](#) instructions.
- All [AdvSIMD load/store single structure \(post-indexed\)](#) instructions.

Data Processing Register:

- All [Logical \(shifted register\)](#) instructions.
- All [Add/subtract \(shifted register\)](#) instructions.
- All [Add/subtract \(extended register\)](#) instructions.

- All [Add/subtract \(with carry\)](#) instructions.
- All [Conditional compare \(register\)](#) instructions.
- All [Conditional compare \(immediate\)](#) instructions.
- All [Conditional select](#) instructions.
- All [Data-processing \(3 source\)](#) instructions.
- All [Data-processing \(2 source\)](#) instructions.
- All [Data-processing \(1 source\)](#) instructions.

SIMD Data Processing:

- All [AdvSIMD three same](#) instructions.
- All [AdvSIMD three different](#) instructions.
- All [AdvSIMD two-reg misc](#) instructions.
- All [AdvSIMD across lanes](#) instructions.
- All [AdvSIMD vector x indexed element](#) instructions.
- All [AdvSIMD shift by immediate](#) instructions.
- All [AdvSIMD modified immediate](#) instructions.
- All [AdvSIMD TBL/TBX](#) instructions.
- All [AdvSIMD ZIP/UZP/TRN](#) instructions.
- All [AdvSIMD EXT](#) instructions.
- All [Crypto AES](#) instructions.
- All [Floating-point<->fixed-point conversions](#) instructions.
- All [Floating-point conditional compare](#) instructions.
- All [Floating-point conditional select](#) instructions.
- All [Floating-point immediate](#) instructions.
- All [Floating-point compare](#) instructions.
- All [Floating-point data-processing \(1 source\)](#) instructions.
- All [Floating-point data-processing \(2 source\)](#) instructions.
- All [Floating-point data-processing \(3 source\)](#) instructions.
- All [AdvSIMD scalar three same](#) instructions.
- All [AdvSIMD scalar three different](#) instructions.
- All [AdvSIMD scalar two-reg misc](#) instructions.
- All [AdvSIMD scalar pairwise](#) instructions.
- All [AdvSIMD scalar copy](#) instructions.
- All [AdvSIMD scalar x indexed element](#) instructions.
- All [AdvSIMD scalar shift by immediate](#) instructions.
- All [Crypto three-reg SHA](#) instructions.
- All [Crypto two-reg SHA](#) instructions.

The UNALLOCATED T32 instruction classes are:

- All [16-bit Thumb instruction encodings](#).
- All [Data-processing \(modified immediate\)](#) instructions.
- All [Data-processing \(plain binary immediate\)](#) instructions except:
  - [Move Wide \(16-bit\)](#).
  - [Move Top \(16-bit\)](#).
- The following [Branches and miscellaneous control](#) instructions:
  - [Conditional branch](#).
  - [Move to Special register, Application level](#).
  - [Move to Special register, System level, except MSR SPSR \(register\)](#).
  - [CPS from Change Processor State, and hints](#).
  - [ENTERX from Miscellaneous control](#).
  - [LEAVEX from Miscellaneous control](#).
  - [Branch and Exchange Jazelle](#).

- Exception Return. This excludes ERET, which is decoded as DRPS.
- Move from Special register, Application level.
- Move from Special register, System level, except MRS SPSR (register).
- Hypervisor Call.
- Secure Monitor Call.
- Branch.
- Permanently UNDEFINED.
- Branch with Link and Exchange.
- Branch with Link.
- All [Load/store multiple](#) instructions.
- The following [Load/store dual](#), [load/store exclusive](#), [table branch](#) instructions:
  - All load/store with  $Rn(hw1[3:0]) == 0b1111$ .
  - Table Branch Byte.
  - Table Branch Halfword.
- The following [Load word](#), [Load halfword](#), [memory hints](#), and [Load byte](#), [memory hints](#) instructions:
  - Preload data.
  - Preload data with intent to Write.
  - Preload instruction.
  - All Load single data items with either  $Rt(hw2[15:12]) == 0b1111$  or  $Rn(hw1[3:0]) == 0b1111$ .
- All [Data-processing \(shifted register\)](#) instructions.
- All [Data-processing \(register\)](#) instructions.
- All [Parallel addition and subtraction, signed](#) instructions.
- All [Parallel addition and subtraction, unsigned](#) instructions.
- All [Miscellaneous operations](#) instructions.
- All [Multiply, multiply accumulate, and absolute difference](#) instructions.
- All [Long multiply, long multiply accumulate, and divide](#) instructions.
- The following [Coprocessor](#), [Advanced SIMD](#), and [Floating-point](#) instructions:
  - Load Coprocessor (immediate).
  - Load Coprocessor (literal).
  - Store Coprocessor.
  - Coprocessor data operations.
- All [Advanced SIMD data-processing](#) instructions.
- All [Floating-point data-processing](#) instructions.
- All [Extension register load/store](#) instructions.
- All [Advanced SIMD element or structure load/store](#) instructions.

———— **Note** —————

The Move to Special Register and Move From Special Register classes in this list refer only to those MSR and MRS instructions listed under [Branches and miscellaneous control](#) instructions. For MRS and MSR instructions in the Move To Banked Register, Move From Banked Register, Move To Special Register and Move From Special Register classes see [Instructions that are unchanged in Debug state on page H2-4345](#).

## Debug state instructions

The A64 and T32 instructions that are defined in [Debug state instructions](#), [DCPS](#), [DRPS](#), [MRS](#), [MSR](#) on [page H2-4351](#) are allowed in Debug state but are UNALLOCATED in Non-debug state:

- DCPS. See [DCPS on page H2-4351](#).

———— **Note** —————

DCPS can be UNALLOCATED in certain conditions in Debug state. See [DCPS on page H2-4351](#).

- DRPS. See [DRPS on page H2-4353](#).

- System instructions for accessing [DLR](#) and [DSPSR](#).

### Instructions with modified behavior in Debug state

In Debug state the hint instructions are allowed, but:

- NOP, YIELD, WFI, and WFE must execute as NOPs. This means that WFE and WFI never cause a suspension of execution in Debug state and are never trapped.
- ERET is decoded as DRPS.

### Instructions that are unchanged in Debug state

The remaining instruction classes are allowed in Debug state if they are allowed at the current Exception level and security state in Non-debug state.

The A64 instruction classes that are allowed in Debug state are listed here.

Data Processing Immediate:

- The following [Add/subtract \(immediate\)](#) instructions:
  - All non flag-setting instructions.
- All [Move wide \(immediate\)](#) instructions.

Branches, Exception Generating and System:

- All [System](#) instructions, except:
  - MSR, set PSTATE field, immediate.
  - MSR | MRS SPSe1, register.
  - MSR | MRS DAI, register.
  - MSR | MRS NZCV, register.
  - MRS CurrentEL, register.
  - Hints, see [Instructions with modified behavior in Debug state](#).

Loads and Stores:

- All [Load/store exclusive](#) instructions.
- All [Load/store register \(unscaled immediate\)](#) instructions except:
  - SIMD and FP instructions.
- All [Load/store register \(immediate post-indexed\)](#) instructions except:
  - SIMD and FP instructions.
- All [Load/store register \(unprivileged\)](#) instructions.
- All [Load/store register \(immediate pre-indexed\)](#) instructions, except:
  - SIMD and FP instructions.

SIMD Data Processing:

- [AdvSIMD copy](#), all.
- [Floating-point<->integer conversions](#), all.

In T32 the allowed instruction classes in Debug state are:

- The following [Data-processing \(plain binary immediate\)](#) instructions:
  - Move Wide (16-bit).
  - Move Top (16-bit).
- The following [Branches and miscellaneous control](#) instructions
  - Move to Banked or Special register.
  - MSR SPSR (register) from Move to Special Register, System level.
  - All hint instructions in [Change Processor State, and hints](#).

———— **Note** ————

See [Instructions with modified behavior in Debug state on page H2-4345](#) for further details.

- All miscellaneous control instructions except ENTERX and LEAVEX.
- ERET from Exception return. This is decoded as DRPS.
- Move from Banked or Special register.
- MRS SPSR register from Move from Special register, System level.
- The following [Load/store dual](#), [load/store exclusive](#), [table branch](#) instructions:
  - All Load/Store with Rn(hw1[3:0]) != 0b1111.
- The following [Load word](#), [Load halfword](#), [memory hints](#), [Load byte](#), [memory hints](#) instructions:
  - All load single data item with both Rt(hw2[15:12]) != 0b1111 and Rn(hw1[3:0]) != 0b1111.
- All [Store single data item](#) instructions.
- The following [Coprocessor](#), [Advanced SIMD](#), and [Floating-point instructions](#):
  - Move to Coprocessor from two general-purpose registers.
  - Move to two general-purpose registers from Coprocessor.
  - Move to Coprocessor from general-purpose register.
  - Move to general-purpose register from Coprocessor.
- All [8, 16, and 32-bit transfer between ARM core and extension registers](#).
- All [64-bit transfers between ARM core and extension registers](#).

### UNPREDICTABLE instructions in Debug state

The list of [Instructions that are unchanged in Debug state on page H2-4345](#) includes instructions that are UNPREDICTABLE in both Debug state and Non-debug state. This includes some T32 instructions that specify R15 as a destination register or a source register, such as:

```
MOV.W R15, #<uimm16>  
LDREX R15, [Rn]
```

[Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#) describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state, these CONSTRAINED UNPREDICTABLE choices are further restricted:

- Instructions that specify R15 as a destination register are not permitted to branch. There is no concept of a branch operation in Debug state:
  - Instructions that specify R15 as a destination register are permitted to set [DLR](#) to an UNKNOWN value.
- Instructions that specify R15 as a source operand cannot use the PC + offset. There is no architecturally-defined PC in Debug state.

All other options, for example treating the instruction as a NOP, are permitted in Debug state.

### H2.4.3 Debug state UNALLOCATED decode tables

Table H2-2 shows how the System Register instructions are modified in Debug state when using AArch64. All other System Register instructions are unchanged.

**Table H2-2 System Register instructions decode in Debug state in AArch64 state**

op0	CRn	CRm	op2	op1	Description	Instruction in Debug state	
0	c2	-	-	3	Architectural Hint Instruction	Allowed, but see <i>Instructions with modified behavior in Debug state on page H2-4345</i>	
				5	0	MSR SPSe1, #imm	UNALLOCATED
				6	3	MSR DAIFSet, #imm	UNALLOCATED
				7	3	MSR DAIFClr, #imm	UNALLOCATED
3	c4	c2	0	0	MSR MRS SPSe1	UNALLOCATED	
				0	3	MSR MRS NZCV	UNALLOCATED
				1	3	MSR MRS DAIF	UNALLOCATED
				2	0	MRS CurrentEL	UNALLOCATED
		c5	0	3	0	MSR MRS DSPSR_EL0	Allowed <sup>a</sup>
					1	3	MSR MRS DLR_EL0

a. These instructions are UNALLOCATED in Non-debug state.

Table H2-3 shows how the System Register instructions are modified in Debug state when using AArch32. All other System Register instructions are unchanged.

**Table H2-3 System Register instructions decode in Debug state in AArch32 state**

coproc	CRn	CRm	opc2	opc1	Description	Instruction in Debug state
15	-	c5	0	3	The MCR and MRC instructions that access DSPSR	Allowed <sup>a</sup>
			1	3	The MCR and MRC instructions that access DLR	Allowed <sup>a</sup>

a. These instructions are UNALLOCATED in Non-debug state.

## H2.4.4 Instructions that debuggers might use in Debug state

[Executing instructions in Debug state on page H2-4341](#) lists the instructions that implementations must provide in Debug state. However, ARM strongly recommends that debuggers use only the instructions shown in [Table H2-4](#).

**Table H2-4 Instructions that debug tools must use in Debug state**

A64 Instruction Set	T32 Instruction Set
Instructions that move the data in system registers to or from a general-purpose register, including DBGDTRRX, DBGDTRTX, DBGDTR, DLR, and DSPSR <sup>a</sup>	
MRS <system_reg> <sup>b</sup>	MRC <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{,<opc2>}
MSR <system_reg> <sup>b</sup>	MCR <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{,<opc2>}
-	VMRS <vfp_system_reg>
-	VMSR <vfp_system_reg>
MRS <special_reg> <sup>b</sup>	MRS <banked_reg>_<mode>
MSR <special_reg> <sup>b</sup>	MSR <banked_reg>_<mode>
Debug state instructions	
DCPS1, DCPS2, DCPS3	DCPS
DRPS	ERET (decoded as DRPS)
[Instructions that move floating-point data between a SIMD and floating-point register and a general-purpose register	
FMOV (general-purpose register to or from a single-precision SIMD and floating-point register)	VMOV (between general-purpose register and a single-precision register)
FMOV (general-purpose register to or from a double-precision SIMD and floating-point register)	VMOV (between two general-purpose registers and a doubleword extension register)
FMOV (general-purpose register to or from a SIMD element)	-
Instructions that move SIMD data between a SIMD and floating-point register and a general-purpose register	
INS (from a general-purpose register to a SIMD element)	VMOV (general-purpose register to scalar)
UMOV (from a SIMD element to general-purpose register)	VMOV (scalar to general-purpose register)
-	VMOV (between two general-purpose registers and a doubleword extension register)
Barrier instructions	
ISB	ISB
DSB	DSB
DMB	DMB
Memory access instructions at various access sizes <sup>c</sup>	
LDR, LDRB, LDRH (immediate, not literal)	LDRB, LDRH (immediate, not literal)
STR, STRB, STRH (immediate)	STRB, STRH (immediate)
-	LDRD (immediate, not literal)
-	STRD (immediate)

**Table H2-4 Instructions that debug tools must use in Debug state (continued)**

<b>A64 Instruction Set</b>	<b>T32 Instruction Set</b>
Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release operations with the same addressing modes as memory access <sup>d</sup>	
LDXR, LDXRB, LDXRH	LDREX, LDREXB, LDREXH
LDAR, LDARB, LDARH	LDA, LDAB, LDAH
LDAXR, LDAXRB, LDAXRH	LDAEX, LDAEXB, LDAEXH
STXR, STXRB, STXRH	STREX, STREXB, STREXH
STLR, STLRB, STLRH	STL, STLB, STLH
STLXR, STLXRB, STLXRH	STLEX, STLEXB, STLEXH
LDXP	LDREXD
LDAXP	LDAEXD
STXP	STREXD
STLXP	STLEXD
CLREX	CLREX
Move to register	
MOVZ (immediate)	MOVW (immediate)
MOVN (immediate)	MOVT (immediate)
MOVK (immediate)	-
MOV (between general-purpose register and SP)	-
Cache and TLB maintenance and address translation operations	
SEV, SEVL	SEV.W
IC	ICIALLU, ICIALLUIS, ICIMVAU
DC	DCCIMVAC, DCCISW, DCCMVAC, DCCMVAU, DCCSW, DCIMVAC, DCISW
TLBI	TLBIALL, TLBIALLIS, TLBIASID, TLBIASIDIS, TLBIMVAA, TLBIMVAAIS, TLBIMVA, TLBIMVAIS
AT	ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW, ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW, ATS1HR, ATS1HW

- These instructions cannot access banked registers in the current mode.
- Other than NZCV, DAIF, SPSEL, and CurrentEL.
- This includes write-back addressing modes [`<Rn>, #imm`] ! or [`<Rn>`], #imm, immediate offsets only, and general-purpose register only. It includes both 32-bit and 64-bit general-purpose registers in AArch64.
- This includes both 32-bit and 64-bit general-purpose registers in AArch64.

### H2.4.5 Security in Debug state

If EL3 is implemented or the PE is Secure, security in Debug state is governed by the Secure debug disabled flag, [EDSCR.SDD](#).

#### On entry to Debug state

If entering in Secure state, `EDSCR.SDD` is set to 0. Otherwise `EDSCR.SDD` is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled() == TRUE`, `EDSCR.SDD` is set to 0.
- If `ExternalSecureInvasiveDebugEnabled() == FALSE`, `EDSCR.SDD` is set to 1.

———— **Note** ————

Normally, if `ExternalSecureInvasiveDebugEnabled() == FALSE` then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a *Context synchronization operation* to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

### In Debug state

The value of `EDSCR.SDD` does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

———— **Note** ————

- `DBGAUTHSTATUS_EL1`.{SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If `EDSCR.SDD` set to 1 in Debug state, then there is no means no enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

### In Non-debug state

`EDSCR.SDD` returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a *Context synchronization operation* is required to guarantee their effect.

———— **Note** ————

- In Non-debug state, `EDSCR.SDD` is unaffected by the Security state of the PE.
- A *Context synchronization operation* is also required to guarantee that changes in the authentication signals are visible in `DBGAUTHSTATUS_EL1`.{SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the PE is Non-secure, `EDSCR.SDD` is RES1.

## H2.4.6 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4351.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

In Non-debug state, the Debug state instructions are UNALLOCATED, except for the T32 DRPS instruction. The T32 DRPS instruction uses the encoding of the Non-debug T32 ERET instruction.

In Debug state, the Debug state instructions can be executed at any Exception level. However, there are some cases where the instructions are UNALLOCATED. For more information, see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4351. These instructions generate an Undefined Instruction exception when they are UNALLOCATED. If this Undefined Instruction exception is taken to an Exception level using AArch64, it is reported using `ESR_ELx.EC`, with the code 0x00, and if taken to AArch32 Hyp mode, reported using `HSR.EC` of 0x00.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNALLOCATED or trapped in Non-debug state. These instruction are MRS and MSR:

- The MRS and MSR instructions that access `DBGDTR_EL0`, `DBGDTRTX_EL0`, and `DBGDTRRX_EL0` in AArch64 state.
- The MRC and MCR instructions that access `DBGDTRTXint` and `DBGDTRRXint` in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all special and system registers accesses, memory accesses, and UNALLOCATED instructions, and includes generating exceptions when the system registers trap or disable an instruction.

## H2.4.7 Debug state instructions, DCPS, DRPS, MRS, MSR

ARMv8 defines instructions to change between Exception levels in Debug state. These instructions can also change the mode at the current Exception level.

### DCPS

DCPS allows the debugger to move the PE to a higher Exception level or to a specific mode at the current Exception level.

If the DCPS instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See [Execution state on page D1-1411](#).

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64, the current endianness is set according to [SCTLR\\_ELx.EE](#) for the target Exception level.
- In AArch32, the current endianness is set according to [SCTLR.EE](#) or [HSCTLR.EE](#) for the target Exception level.

The assembler syntax for the DCPS instructions is:

```
DCPS1    {#<uimm16>}
DCPS2    {#<uimm16>}
DCPS3    {#<uimm16>}
```

<uimm16> is only available in the A64 encoding and is ignored by hardware.

The decode can be found in the instruction descriptions for [DCPS1](#), [DCPS2](#), and [DCPS3](#) for A64, and [DCPS1](#), [DCPS2](#), [DCPS3](#) for T32.

DCPS is UNALLOCATED in Non-debug state.

[Table H2-5 on page H2-4352](#) shows the target of the instruction. In [Table H2-5 on page H2-4352](#) the column entries have the following meaning:

<b>EL1h/Svc</b>	This means that the target mode is EL1 handler mode, if EL1 is using AArch64. Otherwise this is Svc mode.
<b>EL2h/Hyp</b>	This means that the target mode is EL2 handler mode, if EL2 is using AArch64. Otherwise this is Hyp mode.

**EL3h/Monitor** This means that the target mode is EL3 handler mode, if EL3 is using AArch64. Otherwise this is Monitor mode.

**Table H2-5 Target for DCPS instructions in Debug state**

Instruction	Target modes when taken from Exception level				
	EL0	EL1	EL2	EL3 (AArch64)	EL3 (AArch32)
DCPS1	EL1h/Svc	EL1h/Svc	EL2h/Hyp	EL3h	Svc, clears NS to 0
DCPS2	EL2h/Hyp	EL2h/Hyp	EL2h/Hyp	EL3h	UNDEFINED
DCPS3	EL3h/Monitor	EL3h/Monitor	EL3h/Monitor	EL3h	Monitor, clears NS to 0

**Note**

- In AArch32 Monitor mode, [DCPS1](#) and [DCPS3](#) clear [SCR.NS](#) to 0.
- In AArch64, at EL3, DCPS does not change [SCR\\_EL3.NS](#).

However:

- [DCPS1](#) is UNALLOCATED at EL0 in Non-secure state if both:
  - EL2 is implemented.
  - [HCR\\_EL2.TGE](#) == 1.
- [DCPS2](#) is UNALLOCATED at all Exception levels if EL2 is not implemented.
- [DCPS2](#) is UNALLOCATED at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state.
  - At EL3 if EL3 is using AArch32.
- [DCPS3](#) is UNALLOCATED at all Exception levels if either:
  - [EDSCR.SDD](#) == 1.
  - EL3 is not implemented.

DCPS is also defined in T32, see [DCPS1](#), [DCPS2](#), [DCPS3](#) on page F7-2597. There is no A32 encoding.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - [ELR\\_ELx](#) of the target Exception level becomes UNKNOWN.
  - [SPSR\\_ELx](#) of the target Exception level becomes UNKNOWN.
  - [ESR\\_ELx](#) of the target Exception level becomes UNKNOWN.
  - [DLR\\_EL0](#) and [DSPSR\\_EL0](#) become UNKNOWN.
- If the target Exception level is using AArch32 [DLR](#) and [DSPSR](#) become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then [ELR\\_hyp](#), [SPSR\\_hyp](#), and [HSR](#) become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

The pseudocode for DCPSInstruction() is as follows:

```
// DCPSInstruction()
// =====
// Operation of the DCPS instruction in Debug state

DCPSInstruction(bits(2) target_el)

SynchronizeContext();
```

```

case target_el of
  when EL1
    if PSTATE.EL == EL2 || (PSTATE.EL == EL3 && !UsingAArch32()) then handle_e1 = PSTATE.EL;
    elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then UndefinedFault();
    else handle_e1 = EL1;

  when EL2
    if !HaveEL(EL2) then UndefinedFault();
    elsif PSTATE.EL == EL3 && !UsingAArch32() then handle_e1 = EL3;
    elsif IsSecure() then UndefinedFault();
    else handle_e1 = EL2;

  when EL3
    if EDSCR.SDD == '1' || !HaveEL(EL3) then UndefinedFault();
    handle_e1 = EL3;

if ELUsingAArch32(handle_e1) then
  if PSTATE.M == M32_Monitor then SCR.NS = '0';
  assert UsingAArch32(); // Cannot move from AArch64 to AArch32
  case handle_e1 of
    when EL1 AArch32.WriteMode(M32_Svc);
    when EL2 AArch32.WriteMode(M32_Hyp);
    when EL3 AArch32.WriteMode(M32_Monitor);
  if handle_e1 == EL2 then
    ELR_hyp = bits(32) UNKNOWN; HSR = bits(32) UNKNOWN;
  else
    LR = bits(32) UNKNOWN;
    SPSR[] = bits(32) UNKNOWN;
    PSTATE.E = SCTLRL[.EE];
else // Targetting AArch64
  if UsingAArch32() then MaybeZeroRegisterUppers(handle_e1);
  ELR[] = bits(64) UNKNOWN; SPSR[] = bits(32) UNKNOWN; ESR[] = bits(32) UNKNOWN;
  PSTATE.nRW = '0'; PSTATE.SP = '1'; PSTATE.EL = handle_e1;

DLR_EL0 = bits(64) UNKNOWN; DSPSR_EL0 = bits(32) UNKNOWN;
UpdateEDSCRFields(); // Update EDSCR processor state flags.

return;

```

## DRPS

**DRPS** allows the debugger to move the PE to a lower Exception level or to another mode at the current Exception level by copying the current SPSR to **PSTATE**.

If **DRPS** is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See *Execution state on page D1-1411*.

Otherwise the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to **SCTLRL\_ELx.EE**, or **SCTLRL\_EL1.EOE** for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The assembler syntax for the DRPS instruction is:

```
DRPS
```

The decode can be found in the instruction description for [DRPS](#).

If the SPSR specifies an illegal exception return, then `PSTATE.{M, nRW, EL, SP}` are unchanged and `PSTATE.IL` is set to 1. For further information on illegal exception returns, see [Illegal return events on page D1-1441](#).

`PSTATE.{N, Z, C, V, Q, GE, IT, J, T, SS, D, A, I, F}` are ignored in Debug state. This means that the effect of [DRPS](#) on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see [Process state \(PSTATE\) in Debug state on page H2-4341](#).

All other `PSTATE` fields are copied from SPSR.

[DRPS](#) is UNALLOCATED at EL0 and in Non-debug state. In Debug state, the T32 encoding for [ERET](#) is decoded as [DRPS](#). There is no A32 encoding for [DRPS](#).

———— **Note** ————

Unlike an exception return, [DRPS](#) has no architecturally-defined effect on the Event Register and exclusive monitors. [DRPS](#) might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a [DRPS](#) instruction:

- If the target Exception level is using AArch64:
  - [DLR\\_EL0](#) and [DSPSR\\_EL0](#) become UNKNOWN.
- If the target Exception level is using AArch32:
  - [DLR](#) and [DSPSR](#) become UNKNOWN.

The pseudocode for `DRPSInstruction()` is as follows:

```
// DRPSInstruction()
// =====
// Operation of the A64 DRPS and T32 ERET instructions in Debug state

DRPSInstruction()

    SynchronizeContext();

    bits(32) spsr = SPSR[];
    // This actions are the same as for an exception return. In particular, see [v8Exception] for
    // details of illegal exception return handling.
    // PSTATE.{NZCV,Q,GE,IT,J,T,SS,DAIF} are ignored and not onservable in Debug state, so it
    // does not matter what they are set to by DRPS. The processor treats some of these fields as if
    // they have specific fixed values in Debug state. This code sets them to UNKNOWN values to
    // illustrate this.
    if spsr<4> == '1' then // returning to AArch32 state
        spsr<31:24,21,19:10,8:5> = bits(23) UNKNOWN; // SPSR[].[NZCV,Q,GE,IT,J,SS,AIF,T}
    else
        spsr<31:28,21,9:6> = bits(9) UNKNOWN; // SPSR[].[NZCV,SS,DAIF}

    // However, a possible implementation is to explicitly set them to values consistent with the
    // behavior in Debug state, or unchanged (meaning they are copied to PSTATE) but this is not
    // required. Such an implementation is shown in the following comments.
    // if spsr<4> == '1' then // returning to AArch32 state
    //     spsr<26:25,15:10> = Zeros(8); // SPSR[].[IT
    //     spsr<24,5> = '01'; // SPSR[].[J,T}
    // else
    //     spsr<9> = '1'; // SPSR[].[D
    //     spsr<21> = '0'; // SPSR[].[SS
    //     spsr<8:6> = '111'; // SPSR[].[A,I,F}

    SetPSTATEFromSPSR(spsr);
    DLR_EL0 = bits(64) UNKNOWN; DSPSR_EL0 = bits(32) UNKNOWN;
    UpdateEDSCRFields(); // Update EDSCR processor state flags.

    return;
```

## MRS and MSR instructions to access DLR\_EL0 and DSPSR\_EL0

The other Debug state instructions are [MRS](#) and [MSR \(register\)](#) instructions to read or write [DLR\\_EL0](#) and [DSPSR\\_EL0](#), and the equivalent MRC and MCR operations in AArch32 state.

```
MRS <Xt>, DLR_EL0      ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0   ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt>     ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt>  ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNALLOCATED in Non-debug state.

### H2.4.8 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- [Generating exceptions in Debug state.](#)
- [Taking exceptions in Debug state on page H2-4356.](#)
- [Reset in Debug state on page H2-4357.](#)

#### Generating exceptions in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in [ISR](#).
- Debug exceptions are ignored.
- [SCR.EA](#) is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- All instruction bit patterns that are an allocated instruction at the current Exception level, but listed in [Executing instructions in Debug state on page H2-4341](#) as UNALLOCATED in Debug state, generate Undefined Instruction exceptions, which are taken to the current Exception level, or to EL1 if executing at EL0. This includes SVC, HVC, SMC, BRK, and HLT. The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.
- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  - Generate the appropriate trap exception taken to EL3 if [EDSCR.SDD](#) == 0.
  - Generate an Undefined Instruction exception taken to the current Exception level, or to EL1 if executing at EL0, if [EDSCR.SDD](#) == 1. If the exception is taken to an Exception level using AArch64 or AArch32 Hyp mode, this is reported with an exception class of 0x00.

Otherwise configurable traps, enables, and disables, for instructions are unaffected by Debug state, and executing the affected instructions generates the appropriate exceptions.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

#### ———— Note ————

If [EDSCR.SDD](#) == 1 then an exception from Non-secure state is never taken to Secure state. See [Security in Debug state on page H2-4349](#).

## Taking exceptions in Debug state

Once generated, exceptions, all of which are synchronous, are taken in Debug state. This means that:

- The target Exception level and mode are as defined for the exception in Non-debug state. That is:
  - For exceptions taken to an Exception level using AArch64, the mode is the handler mode for that Exception level.
  - For exceptions taken to an Exception level using AArch32, the mode is the exception mode appropriate for the exception.
- The exception is reported as defined for the exception in Non-debug state, using the syndrome register or registers for the target Exception level. In AArch64, these are [ESR\\_ELx](#), and [FAR\\_ELx](#). In AArch32, these are [DFSR](#), [DFAR](#), [HSR](#), [HDFAR](#), and [HPFAR](#). For example:
  - If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the [DFSR](#) reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken in Abort mode, [DFSR](#) is not updated.
  - If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

- The PE remains in Debug state and changes to the target mode.
- If EL3 is using AArch32 and the exception is taken from Monitor mode, [SCR.NS](#) is cleared to 0.
- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the system control register for the target Exception level.
- The endianness switches to that indicated by the EE bit of the system control register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, [ELR\\_ELx](#) for the target Exception level becomes UNKNOWN.
- If the target Exception level is EL2 using AArch32, [ELR\\_hyp](#) becomes UNKNOWN.
- If the target Exception level is EL1 or EL3 using AArch32, [LR\\_<mode>](#) for the target mode becomes UNKNOWN.
- [DLR](#) and [DSPSR](#) become UNKNOWN.
- The cumulative error flag, [EDSCR.ERR](#), is set to 1. See [Cumulative error flag on page H4-4397](#).
- [PSTATE.IL](#) is cleared to 0.
- [PSTATE.{IT, J, T, SS, D, A, I, F}](#) are set to UNKNOWN values, and [PSTATE.{N, Z, C, V, Q, GE}](#) are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see [Process state \(PSTATE\) in Debug state on page H2-4341](#).

The pseudocode for `TakeExceptionInDebugState()` is as follows:

```
// TakeExceptionInDebugState()
// =====
```

```
TakeExceptionInDebugState(bits(2) target_exception_level, bits(5) target_mode)
```

```
if ELUsingAArch32(target_exception_level) then
    assert target_mode<4> == '1';
    if PSTATE.M == M32_Monitor then SCR_EL3.NS = '0';
    PSTATE.M = target_mode;
    // PSTATE.{IT, J, T, SS, D, A, I, F} are not observable and ignored in Debug state, so it does not
    // matter what they are set to on taking an exception in Debug state. The processor treats
    // them as if they have specific fixed values. This code sets them to UNKNOWN values to
```

```

// illustrate this.
PSTATE.<IT,J,T,SS,A,I,F> = bits(14) UNKNOWN;
// However, a possible implementation is to explicitly set them to values consistent with
// the behavior in Debug state, but this is not required. Such an implementation is shown in
// the following comments.
// PSTATE.<J,T> = '01';           // Force execution of T32 instructions
// PSTATE.IT = Zeros(8);         // Force IT bits ignored
// PSTATE.<A,I,F> = '111';       // Mask asynchronous exceptions
// PSTATE.SS = '0';             // Disable step
if PSTATE.EL == EL2 then ELR_hyp = bits(32) UNKNOWN;
else R[14] = bits(32) UNKNOWN;
PSTATE.E = SCTLR[].EE;
else
  PSTATE.EL = target_exception_level; PSTATE.nRW = '0'; PSTATE.SP = '1';
  ELR[] = bits(64) UNKNOWN;
  // See comments above.
  PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;
  // PSTATE.<D,A,I,F> = '1111';   // Mask asynchronous exceptions
  // PSTATE.SS = '0';           // Disable step

_PC           = bits(64) UNKNOWN;           // PC is invisible in Debug state
SPSR[]       = bits(32) UNKNOWN;
PSTATE.IL    = '0';
DLR_EL0     = bits(64) UNKNOWN;
DPSR_EL0    = bits(32) UNKNOWN;
EDSCR.ERR   = '1';

UpdateEDSCRFields();                       // Update EDSCR processor state flags.

return;

```

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

### Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, `EDSCR.STATUS == 0b000010` and writes to `EDITR` are ignored.

#### ————— Note —————

If `EDECR.RCE == 1`, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See [Reset Catch debug event on page H3-4382](#). All PE registers have taken their reset values, which might be UNKNOWN.

## H2.4.9 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

### General-purpose register access, other than SP access in AArch64 state

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write `DBGDTR_EL0` in AArch64 state, or an MCR instruction through the ITR to write `DBGDTRXint` in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

[Figure H2-1 on page H2-4358](#) shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

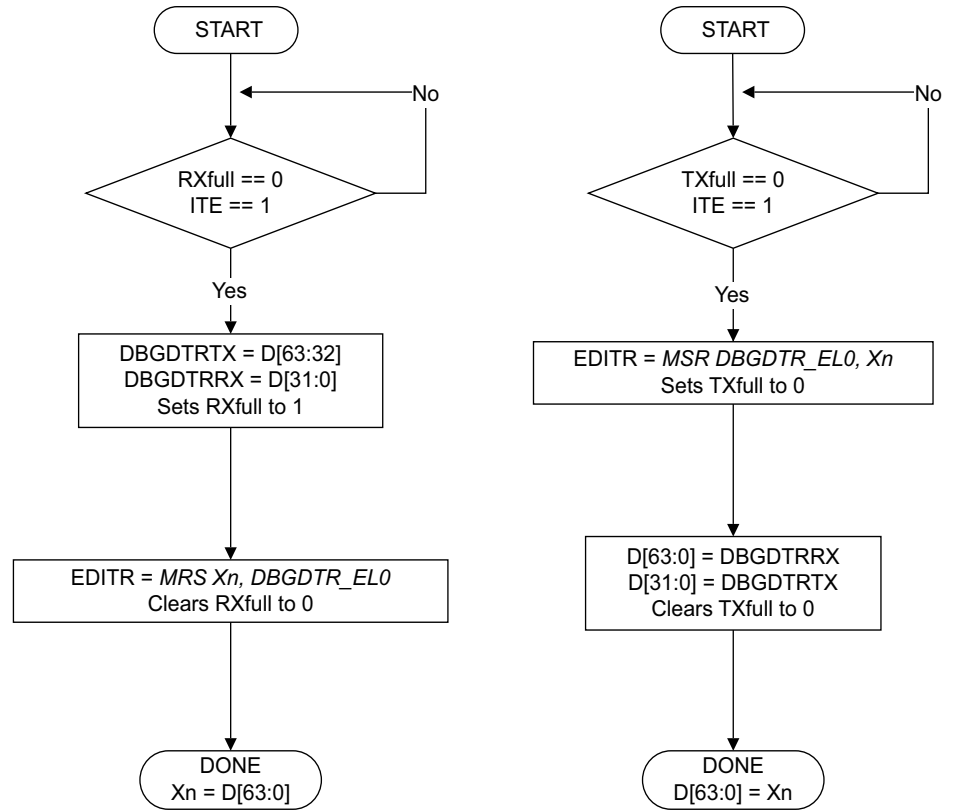

Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

Figure H2-2 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

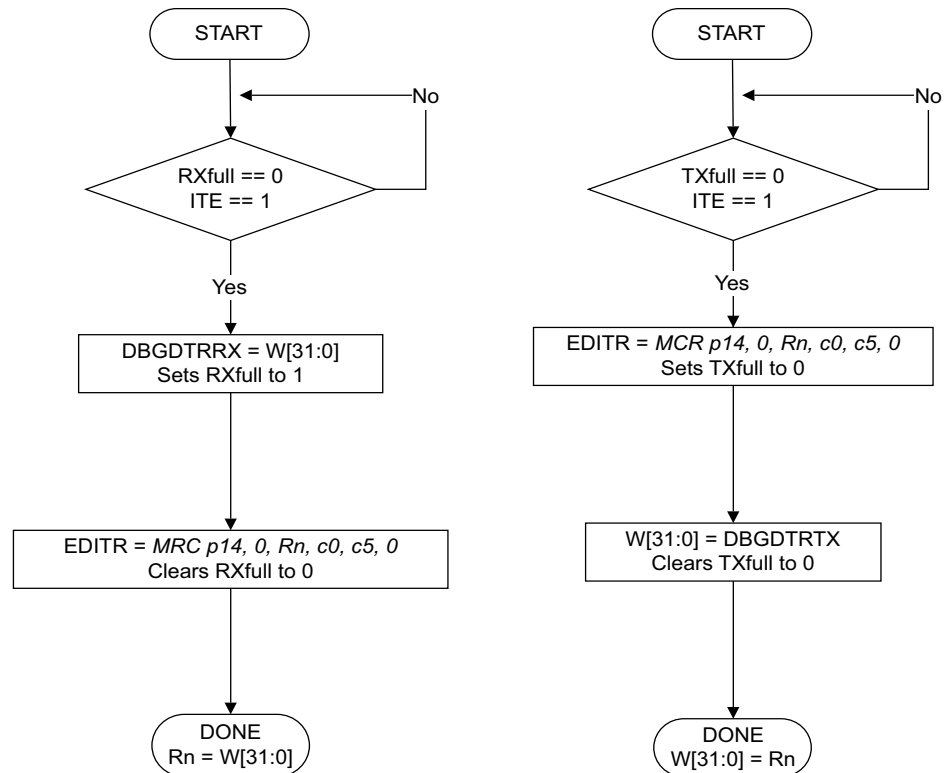

Figure H2-2 Reading and writing general-purpose registers in Debug state in AArch32 state

### SIMD and floating-point, and system register accesses, and SP access in AArch64 state

To read a SIMD and floating-point register or a system register, the debugger must first copy the value into a general-purpose register using:

- An FMOV instruction in AArch64 or a VMOV instruction in AArch32 for floating-point transfers to SIMD and FP registers.
- A UMOV instruction in AArch64 or a VMOV instruction in AArch32 for SIMD transfers to SIMD and FP registers.
- An MRS instruction in AArch64 or an MRC instruction in AArch32 for system registers.
- A MOV Xd, SP instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

### PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR\_EL0 and DSPSR\_EL0 system registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNALLOCATED in Debug state.
- On taking an exception, ELR\_ELx and SPSR\_ELx at the target exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.{IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- [Process state \(PSTATE\) in Debug state on page H2-4341.](#)
- [Executing instructions in Debug state on page H2-4341.](#)
- [Exceptions in Debug state on page H2-4355.](#)

## H2.4.10 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

### Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. [Executing instructions in Debug state on page H2-4341](#) lists the memory access instructions that are supported in Debug state.

### Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See [DCC and ITR access modes on page H4-4391](#).

## H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If `EDSCR.ITE == 0` the behavior of any instruction issued through the ITR in normal mode or an operation issued by a DTR access in memory access mode that has not completed execution is `CONSTRAINED UNPREDICTABLE`, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an `UNKNOWN` state.

---

### Note

- Implementations can set `EDSCR.ITE` to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and `EDSCR.ITE == 1`, then the PE must complete these instructions in Debug state before executing the restart sequence. `EDSCR.ITE == 0` indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through `EDITR` that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the `EDSCR.{TXfull, RXfull}` flags.

On exiting Debug state, the PE sets the program counter to the address in `DLR`, where:

- If exiting to AArch32 state:
  - Bits[63:32] of `DLR` are ignored.
  - Bits[31:1] of the PC are set to the value of bits[31:1] of `DLR`.
  - Bit[0] of the PC is set to a `CONSTRAINED UNPREDICTABLE` choice of 0 or the value of bit[0] in `DLR`.
- If exiting to AArch64 state:
  - Bits[63:56] of `DLR` might be ignored as part of tagged address handling. See *Address tagging in AArch64 state on page D5-1708*.
  - Otherwise the PC is set from `DLR`.

Exit from Debug state can give rise to a misaligned PC exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see *PC alignment checking on page D1-1423*.

`PSTATE` is set from `DSPSR_EL0` in the same way that an exception return sets `PSTATE` from `SPSR_ELx`:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on `PSTATE` and the PC is the same as for any other illegal exception return. See *Exception return on page D1-1439*.
- The checks on the `PSTATE.IT` bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See *Appendix A Architectural Constraints on UNPREDICTABLE behaviors*.
- `PSTATE.SS` is copied from `DSPSR.SS` if all of the following hold:
  - `MDSCR_EL1.SS == 1`.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.
 See *Entering the active-not-pending state on page D2-1637*.

---

### Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, `PSTATE.{D, A, I, F}` is updated regardless of the value of `SCTLR_EL1.UMA`.

- Exit from Debug state has no architecturally-defined effect on the Event Register and exclusive monitors. An exit from Debug state might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The pseudocode for ExitDebugState() is as follows.

```
// ExitDebugState()
// =====

ExitDebugState()
  assert Halted();
  SynchronizeContext();

  // Although EDSCR.STATUS signals that the processor is restarting, debuggers must use EDPRSR.SDR
  // to detect that the processor has restarted.
  EDSCR.STATUS = '000001'; // Signal restarting
  // Return to saved processing state
  EDESRR2:0 = '000'; // Clear any pending Halting debug events

  from_32 = (PSTATE.nRW == '1');

  new_pc = DLR_EL0;
  spsr = DSPSR;

  SetPSTATEFromSPSR(spsr); // Can update privileged bits, even at EL0.

  if spsr<4> == '1' then
    // Requesting exit to AArch32 state. If coming from AArch64 and PSTATE.IL==1 then the state
    // did not change, but the PC alignment might have occurred
    // Align PC[1:0] according to the target instruction set state
    if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
      if spsr<5> == '1' then // T32 or T32EE state
        new_pc<0> = '0';
      else // A32 state
        new_pc<1:0> = '00';

    // Zero the 32 most significant bits of the target PC
    if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
      new_pc<63:32> = Zeros();

  if PSTATE.nRW == '1' then
    BranchTo(new_pc<31:0>, BranchType_UNKNOWN); // AArch32 branch
  else
    BranchTo(new_pc, BranchType_DBGEXIT); // A type of branch that is never predicted

  (EDSCR.STATUS, EDPRSR.SDR) = ('000010', '1'); // Atomically signal restarted
  UpdateEDSCRFields(); // Stop signalling processor state.
  DisableITRAndResumeInstructionPrefetch();

  return;
```

# Chapter H3

## Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- *Introduction to Halting debug events* on page H3-4364.
- *Halting Step debug event* on page H3-4366.
- *Halt Instruction debug event* on page H3-4376.
- *Exception Catch debug event* on page H3-4377.
- *External Debug Request debug event* on page H3-4380.
- *OS Unlock Catch debug event* on page H3-4381.
- *Reset Catch debug event* on page H3-4382.
- *Software Access debug event* on page H3-4383.
- *Synchronization and Halting debug events* on page H3-4384.

---

**Note**

Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.

---

## H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- [Halting Step debug event on page H3-4366](#).
- [Halt Instruction debug event on page H3-4376](#).
- [Exception Catch debug event on page H3-4377](#).
- [External Debug Request debug event on page H3-4380](#).
- [OS Unlock Catch debug event on page H3-4381](#).
- [Reset Catch debug event on page H3-4382](#).
- [Software Access debug event on page H3-4383](#).

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See [Breakpoint and Watchpoint debug events on page H2-4330](#). Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see [Chapter H2 Debug State](#). For a definition of halting allowed, see [Halting allowed and halting prohibited on page H2-4329](#).

[Debug state entry and debug event prioritization on page H2-4331](#) describes the behavior when multiple debug events are generated by an instruction.

See also [Synchronization and Halting debug events on page H3-4384](#).

[Table H3-1](#) shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

**Table H3-1 Summary of debug events and possible outcomes**

Debug event type	Outcome	
	Halting allowed	Halting prohibited
<a href="#">Breakpoint and Watchpoint debug events on page H2-4330</a>	Address mismatch breakpoint	Not possible <sup>a</sup>
	Other breakpoint	Halt
	Watchpoint	Halt
<a href="#">Halt Instruction debug event on page H3-4376</a>	Halt	UNALLOCATED
<a href="#">Software Access debug event on page H3-4383</a>	Halt	Ignored

## H3.2 Halting Step debug event

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- [Overview of a Halting Step debug event.](#)
- [The Halting Step state machine.](#)
- [Using Halting Step on page H3-4369.](#)
- [Detailed Halting Step state machine behavior on page H3-4369.](#)
- [Synchronization and the Halting Step state machine on page H3-4372.](#)
- [Stepping T32 IT instructions on page H3-4373.](#)
- [Disabling interrupts while stepping on page H3-4374.](#)
- [Syndrome information on Halting Step on page H3-4374.](#)
- [Pseudocode details for Halting Step debug events on page H3-4375.](#)

The architecture describes the behavior as a simple Halting Step state machine. See [The Halting Step state machine.](#)

### H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in [Figure H3-1 on page H3-4368](#). A Halting Step debug event executes a single instruction and then return control to the debugger. When debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, [EDECR.SS](#) and [EDES.R.SS](#).

#### ———— **Note** —————

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

### H3.2.2 The Halting Step state machine

The state machine states are:

**Inactive** Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, [EDECR.SS](#) is set to 0 and [EDES.R.SS](#) is set to 0.
- Halting is prohibited. See [Halting the PE on debug events on page H2-4329](#).

In [Figure H3-1 on page H3-4368](#) this state is shown in red.

#### **Active-not-pending**

Halting Step is enabled and active. This is the state in which the PE steps an instruction. [EDECR.SS](#) == 1 and [EDES.R.SS](#) == 0. A debugger must only set [EDECR.SS](#) to 1 when the PE is in Debug state.

In [Figure H3-1 on page H3-4368](#) this state is shown in green.

#### **Active-pending**

Halting Step is enabled and active. The step has completed, and the PE enters Debug state.  
`EDESR.SS == 1`.

In [Figure H3-1 on page H3-4368](#) this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on `EDESR.SS`. [Halting Step state machine states on page H3-4369](#) shows this.

In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:

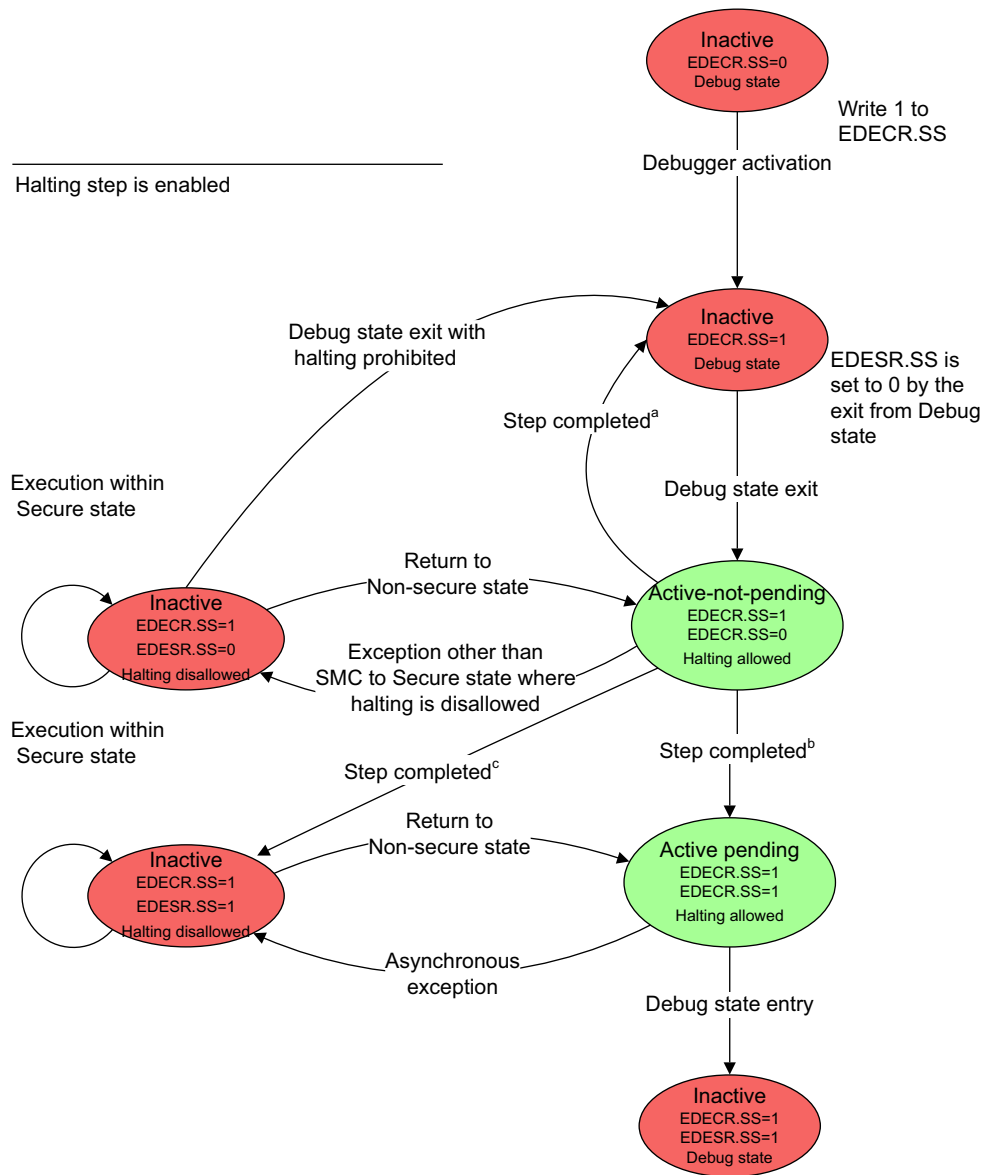

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

[Figure H3-1 on page H3-4368](#) shows a Halting Step state machine.

Halting step is disabled

Halting step is enabled

- a. Step completed occurs when:
- A debug event, other than a Halting Step debug event, causes entry into Debug state.
- b. Step completed occurs when:
- An instruction is executed without taking an exception.
  - An exception is taken to a state where halting is allowed.
  - A reset.
- c. Step completed occurs when:
- An SMC exception is taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine

———— **Note** ————

Figure H3-1 on page H3-4368 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as [EDEC.R](#) and [OSDLR](#) and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE behavior. See *Synchronization and the Halting Step state machine* on page H3-4372.

The following bits control the state machine, as shown in [Table H3-3](#):

- [EDEC.R.SS](#). This is the Halting Step enable bit.

———— **Note** ————

- The [EDEC.R](#) value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.
- A debugger must only set [EDEC.R.SS](#) to 1 when the PE is in Debug state.

- [EDES.R.SS](#).

[Table H3-3](#) shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

**Table H3-3 Halting Step state machine states**

Halting	<a href="#">EDEC.R.SS</a>	<a href="#">EDES.R.SS</a>	Halting Step state
Prohibited	X	X	Inactive
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

### H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets [EDEC.R.SS](#) to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with [DLR](#) set to the address of the instruction being stepped. The PE clears [EDES.R.SS](#) to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.  
If an exception is taken to a state where halting is prohibited, then [EDES.R.SS](#) is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

### H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- *Entering the active-not-pending state* on page H3-4370.
- *PE behavior in the active-not-pending state* on page H3-4370.
- *Entering the active-pending state* on page H3-4371.
- *PE behavior in the inactive state when in Non-debug state* on page H3-4372.
- *PE behavior in Debug state* on page H3-4372.

## Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state with `EDECR.SS == 1`.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with `EDECR.SS == 1` and `EDESR.SS == 0`.
- As described in *Synchronization and the Halting Step state machine* on page H3-4372.

## PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

### ***If no exception or debug event is generated***

If no exception or debug event is generated the PE sets `EDESR.SS` to 1. This means that the Halting Step state machine advances to the active-pending state.

### ***If an exception or debug event is generated***

The PE sets `EDESR.SS` according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of `ExternalSecureInvasiveDebugEnabled()`.

If an exception or debug event is generated, the PE sets `EDESR.SS` to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is not an SMC exception and `ExternalSecureInvasiveDebugEnabled() == TRUE`.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and `ExternalSecureInvasiveDebugEnabled() == TRUE`.
- A PE reset occurs.

Otherwise `EDESR.SS` is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and `ExternalSecureInvasiveDebugEnabled() == FALSE`.
  - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and `ExternalSecureInvasiveDebugEnabled() == FALSE`.
  - Generates a synchronous debug event and causes entry to Debug state.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

———— **Note** ————

The underlying criteria for the value of `EDESR.SS` on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

**Table H3-4 Summary of active-not-pending state behavior**

Event	Target EL	ExternalSecureInvasiveDebugEnabled()	Value written to EDESR.SS
No exception or debug event	Not applicable	X	1
SMC exception	EL3	X	1
Reset	Highest	X	1
Exception, other than SMC exception	EL1	X	1
	EL2	X	1
	EL3	TRUE	1
		FALSE	0
Debug event	Debug state	X	0

### Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when `EDESR.SS == 1`.

———— **Note** ————

That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled() == FALSE` to Non-secure state with `ExternalInvasiveDebugEnabled() == TRUE`.

- A reset when the value of `EDECR.SS == 1`, regardless of the state the PE was in before the reset occurred.
- Following the description in *Synchronization and the Halting Step state machine on page H3-4372*.

When the PE is in the active-pending state, it enters Debug state before executing an instruction. However, if `ExternalSecureInvasiveDebugEnabled() == FALSE`, the architecture does not define the prioritization of this Debug state entry with respect to any pending asynchronous exception that is taken from Non-secure state to EL3.

If an exception is prioritized over the halt, then `EDESR.SS` is unchanged. On return from the exception the Halting Step state machine re-enters the active-pending state.

The entry into Debug state has higher priority than all other types of exception, including all other asynchronous exceptions.

———— **Note** —————

This means that it is possible to step a reentrant exception in the exception vector table.

### PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a *Context synchronization operation*.

See also *Synchronization and the Halting Step state machine*.

### PE behavior in Debug state

Entry to Debug state, the execution of an instruction in Debug state, or the taking of an exception when in Debug state, does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. This forces the Halting Step state machine to active-not-pending if EDECR.SS == 1.

———— **Note** —————

Using Halting Step to step over an A32 instruction that generates a misaligned PC value does not suppress the resulting misaligned PC exception. On exiting Debug state, the misaligned PC value is written from DLR and a misaligned PC exception is generated.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then the PE immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

## H3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See *State and mode changes without explicit context synchronization operations* on page D2-1647.
  - The external authentication interface changes.
  - The OS Double Lock status, DoubleLockStatus(), changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.
- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a *Context synchronization operation*.

The PE must perform the required behavior of the new state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next *Context synchronization operation*. This is illustrated in *Example H3-1* on page H3-4373 and *Example H3-2* on page H3-4373.

### Example H3-1 Synchronization requirements 1

---

**EDECR.SS** is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled() == FALSE`, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. **EDESR.SS** remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

---

### Example H3-2 Synchronization requirements 2

---

**EDECR.SS** is set to 1 in Debug state. On exit from Debug the PE executes an MSR instruction that sets **OSDLR\_EL1.DLK** to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a *Context synchronization operation* to guarantee its effect, meaning it is CONstrained UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in **EDESR.SS** depends on whether halting was allowed or prohibited when the write to **OSDLR\_EL1.DLK** completed, and so it might be 0 or 1. If a second MSR instruction clears **OSDLR\_EL1.DLK** to 0, the PE must perform the required behavior of the state indicated by **EDESR.SS** before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

---

See also *Synchronization and Halting debug events* on page H3-4384.

## H3.2.6 Stepping T32 IT instructions

The ARMv8 architecture permits a combination of one T32 IT instruction and another 16-bit T32 instruction to be treated as one 32-bit instruction when the value of **SCTLR.ITD**, **SCTLR\_EL1.ITD** or **HSCTLR.ITD** as applicable, is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions to be one instruction, regardless of the state of **SCTLR.ITD**, **SCTLR\_EL1.ITD**, or **HSCTLR.ITD**.
- The debug logic might consider such a pair of instructions to be two instructions, regardless of the state of **SCTLR.ITD**, **SCTLR\_EL1.ITD**, or **HSCTLR.ITD**.
- The debug logic might consider such a pair of instructions to be one instruction when **SCTLR.ITD**, **SCTLR\_EL1.ITD**, or **HSCTLR.ITD** is set to 1, and two instructions when the ITD bit is set to 0.

### H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting `EDSCR.INTdis`, to allow the code being debugged to make forward progress.

### H3.2.8 Syndrome information on Halting Step

Three `EDSCR.STATUS` encodings record different scenarios for entering Debug state on a Halting Step debug event:

#### Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

#### Halting Step, exclusive

A Load-Exclusive instruction was stepped.

#### Halting Step, no syndrome

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, `EDSCR.STATUS` is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test, `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, `EDSCR.STATUS` is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- A pending asynchronous exception is taken before the instruction is executed.
- The active-pending state is entered for other reasons. See [Synchronization and the Halting Step state machine on page H3-4372](#)

In these cases the debugger cannot determine whether the instruction that was stepped was a Load-Exclusive instruction.

In addition, `EDSCR.STATUS` is set to one of a CONSTRAINED UNPREDICTABLE choice if:

- The instruction being stepped generated a synchronous exception, meaning that it was not completed. In this case `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of:
  - Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
  - Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an exception return instruction or an ISB. As these instructions are not in the Load-Exclusive instructions, `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if `EDSCR.STATUS` is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting `EDSCR.STATUS` to Halting Step, normal or Halting Step, exclusive.

———— **Note** —————

An implementation that always sets `EDSCR.STATUS` to Halting Step, no syndrome is not compliant.

### H3.2.9 Pseudocode details for Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if `EDECR.RCE == 1`. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingDebugStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

```
// RunHaltingStep()
// =====

RunHaltingStep(boolean exception_generated, bits(2) exception_target, boolean syscall,
               boolean reset)
    // "exception_generated" is TRUE if the previous instruction generated a synchronous exception
    // or was cancelled by an asynchronous exception.
    // if "exception_generated" == TRUE then "exception_target" is the target of the exception, and
    // "syscall" is TRUE if the exception is a synchronous exception where the preferred return
    // address is the instruction following that which generated the exception.
    // "reset" = TRUE if exiting reset state into the highest EL.
    if reset then assert !Halted();           // Cannot come out of reset halted

    active = EDECR.SS == '1' && !Halted();

    if active && reset then                    // Coming out of reset with EDECR.SS set.
        EDESR.SS = '1';
    elseif active && HaltingAllowed() then
        if exception_generated && exception_target == EL3 then
            advance = syscall || ExternalSecureInvasiveDebugEnabled();
        else
            advance = TRUE;
        if advance then EDESR.SS = '1';

    return;

// CheckHaltingStep()
// =====
// Check whether EDESR.SS has been set by Halting Step

CheckHaltingStep()
    if HaltingAllowed() && EDESR.SS == '1' then
        // The STATUS code depends on how we arrived at the state where EDESR.SS == 1.
        if HaltingStep_DidNotStep() then
            Halt(DebugHalt_Step_NoSyndrome);
        elseif HaltingStep_SteppedEX() then
            Halt(DebugHalt_Step_Exclusive);
        else
            Halt(DebugHalt_Step_Normal);
```

## H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when `EDSCR.HDE == 1`, halting is allowed, and software executes the Halting software breakpoint instruction, HLT.

The pseudocode for Halt Instruction Debug events is described in [HLT on page C5-484](#) for A64 and [HLT on page F7-2608](#) for A32 and T32.

HLT never generates a debug exception. It is UNALLOCATED if `EDSCR.HDE == 0`, or if halting is prohibited.

---

———— **Note** —————

A debugger can replace a program instruction with a Halt instruction to generate a Halting Software Breakpoint. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See [Concurrent modification and execution of instructions on page B2-91](#).

---

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is UNALLOCATED. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the condition code field is not `0b1110`, with the set of behaviors the same as for BKPT. See [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

---

———— **Note** —————

The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 CP15 register `ID_ISAR0.Debug` does not indicate the presence of the HLT instruction.

---

### H3.3.1 HLT instructions as the first instruction in a T32 IT block

The ARMv8 architecture defines combinations of IT and a single 16-bit T32 instruction that can be treated as a 32-bit instruction when `SCTLR.ITD`, `SCTLR_EL1.ITD` or `HSCTLR.ITD`, as applicable, is set to 1.

The T32 HLT instruction is not such an instruction. If the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of `SCTLR.ITD`, `SCTLR_EL1.ITD` or `HSCTLR.ITD`, as applicable:

- If the ITD bit is set to 1, then the combination is UNALLOCATED and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the ITD bit is set to 0, then the HLT instruction either:
  - Is UNALLOCATED and generates an Undefined Instruction exception.
  - Generates an HLT Instruction debug event.

To set an HLT Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

---

———— **Note** —————

An HLT instruction is always unconditional, even within an IT block.

---

## H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, [EDECCR](#), is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
  - Entry to the Exception level due to reset. This is an overlap with a Reset Catch debug event. See [Reset Catch debug event on page H3-4382](#).
  - Exit from Debug state to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the execution state of the target Exception level.
- Are ignored if halting is prohibited.

The [EDECCR](#) contains two fields:

- One field for Non-secure state.
- One field for Secure state.

Each field contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. See [EDECCR, External Debug Exception Catch Control Register on page H9-4501](#).

### ———— Note —————

- [EDECCR](#) does not replace [DBGVCR](#):
  - [DBGVCR](#) is retained in AArch32 state for backwards compatibility.
  - [DBGVCR](#) is ignored in AArch64 state and never generates entries to Debug state.
  - [DBGVCR](#) cannot be accessed by the external debug interface.
- [EDECCR](#) is only visible as [OSECCR\\_EL1](#) by System Register instructions in AArch64 state, and as [DBGOSECCR](#) by CP14 register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if the translation regime MMU at the target Exception level is disabled.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - [DLR](#) contains the exception vector address.

### H3.4.1 Prioritization of Exception Catch debug events

Exception Catch debug events have a higher priority than all synchronous exceptions other than [Software Step exceptions on page D2-1634](#) and a lower priority than [Reset Catch debug event on page H3-4382](#). It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than both:

- [Software Step exceptions on page D2-1634](#).
- [Halting Step debug event on page H3-4366](#).

---

**Note**

---

As described in [Synchronous exception prioritization on page D1-1451](#), an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See [Vector Catch exceptions on page D2-1627](#).

---

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also [Debug state entry and debug event prioritization on page H2-4331](#).

### H3.4.2 UNPREDICTABLE generation of Exception Catch debug events

When the PE is executing code at a given Exception level and the corresponding **EDECCR** bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

---

**Note**

---

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in [Detailed Halting Step state machine behavior on page H3-4369](#).

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an ISB operation executed at the Exception level.

---

Examples of this are:

- If the debugger writes to **EDECCR** so that the current Exception level is trapped.
- If the OS restore code writes to **OSECCR** so that the current Exception level is trapped.
- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See [State and mode changes without explicit context synchronization operations on page D2-1647](#).

### H3.4.3 Examples of Exception Catch debug events

If **EDECCR** == 0x20, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- **ELR\_EL1** and **SPSR\_EL1** are written with the preferred return address and PE state for a return to EL0.
- **ESR\_EL1** and **FAR\_EL1** are written with the syndrome information for the exception.
- **DLR\_EL0** is set to **VBAR\_EL1** + 0x400, the synchronous exception vector.
- **DSPSR\_EL0** is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to EL2 or EL3.
- An exception return from EL2 to Non-secure EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

### H3.4.4 Pseudocode details for Exception Catch debug events

The pseudocode for the CheckExceptionCatch() function is as follows:

```
// CheckExceptionCatch()
// =====
// Check whether an Exception Catch debug event is set on the current Exception level

CheckExceptionCatch()
// Called after taking an exception, that is, such that IsSecure() and PSTATE.EL are correct
// for the exception target.
base = if IsSecure() then 0 else 4;
if HaltingAllowed() && EDECCR<UInt(PSTATE.EL) + base> == '1' then
    Halt(DebugHalt_ExceptionCatch);
```

## H3.5 External Debug Request debug event

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See [Chapter H5 The Embedded Cross Trigger Interface](#).

———— **Note** —————

ARMv8-A requires the implementation of an embedded cross-trigger.

External Debug Request debug events are asynchronous debug events.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

### H3.5.1 Pseudocode details for External Debug Request debug events

The pseudocode details for the ExternalDebugRequest() function is as follows:

```
// ExternalDebugRequest()
// =====

ExternalDebugRequest()
    if HaltingAllowed() then
        Halt(DebugHalt_EDBGRQ);
    // Otherwise the CTI continues to assert the debug request until it is taken.
```

## H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when `EDECR.OSUCE == 1` and the state of the OS Lock changes from locked to unlocked.

When the OS Unlock Catch debug event is generated, it is recorded by setting `EDESR.OSUC` to 1, meaning it immediately becomes pending and is not guaranteed to be taken immediately. Clearing the OS Lock is not a self-synchronizing operation. See *Synchronization and Halting debug events* on page H3-4384.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- *Debug behavior when the OS Lock is unlocked* on page H6-4432.
- *EDECR, External Debug Execution Control Register* on page H9-4503.
- *EDESR, External Debug Event Status Register* on page H9-4505.

`EDESR.OSUC` is cleared to 0 on a Warm reset and on exiting Debug state.

### H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered-up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in *Debug OS Save and Restore sequences* on page H6-4430, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

### H3.6.2 Pseudocode details for OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

```
// CheckOSUnlockCatch()
// =====
// Called on unlocking the OS Lock to pend an OS Unlock Catch debug event
```

```
CheckOSUnlockCatch()
    if EDECR.OSUCE == '1' && !Halted() then EDESR.OSUC = '1';
```

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

```
// CheckPendingOSUnlockCatch()
// =====
// Check whether EDESR.OSUC has been set by an OS Unlock Catch debug event
```

```
CheckPendingOSUnlockCatch()
    if HaltingAllowed() && EDESR.OSUC == '1' then
        Halt(DebugHalt_OSUnlockCatch);
```

## H3.7 Reset Catch debug event

A Reset Catch debug event is generated when `EDECR.RCE == 1` and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting `EDESR.RC` to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, `DLR` has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:

- [Synchronization and Halting debug events](#) on page H3-4384.
- [EDECR, External Debug Execution Control Register](#) on page H9-4503.
- [EDESR, External Debug Event Status Register](#) on page H9-4505.

This means that `EDESR.RC` is set to the value of `EDECR.RCE` on a Warm reset. `EDESR.RC` is cleared to 0 on exiting Debug state.

### H3.7.1 Pseudocode details for Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

```
// CheckResetCatch()
// =====
// Called after reset
```

```
CheckResetCatch()
    if EDECR.RCE == '1' then
        EDESR.RC = '1';
        // If halting is allowed then halt immediately
        if HaltingAllowed() then Halt(DebugHalt_ResetCatch);
```

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

```
// CheckPendingResetCatch()
// =====
// Check whether EDESR.RC has been set by a Reset Catch debug event
```

```
CheckPendingResetCatch()
    if HaltingAllowed() && EDESR.RC == '1' then
        Halt(DebugHalt_ResetCatch);
```

## H3.8 Software Access debug event

When the value of `EDSCR.TDA == 1`, software access to the following debug registers cause a trap to Debug state:

- The Breakpoint Value Registers, [DBGBVR](#).
- The Breakpoint Control Registers, [DBGBCR](#).
- The Watchpoint Value Registers, [DBGWVR](#).
- The Watchpoint Control Registers, [DBGWCR](#).

However, `EDSCR.TDA` is ignored if either:

- The value of `OSLSR.OSLK == 1`, meaning that the OS Lock is locked.
- Halting is prohibited. See [Halting allowed and halting prohibited on page H2-4329](#).

---

**Note**

- The accesses are only trapped into Debug state if they do not generate an exception. For more information see the relevant register description in [Chapter D8 AArch64 System Register Descriptions](#), [Chapter G4 AArch32 System Register Descriptions](#), or [Chapter I1 Memory-Mapped System Register Descriptions](#).
  - `DBGPRCR.CORENPDRQ` (Core No-powerdown Request), DCC registers, and CLAIM tag bits are also shared, but are deliberately excluded from this list.
- 

### H3.8.1 Pseudocode details for Software Access debug event

The pseudocode details for `CheckSoftwareAccessToDebugRegisters()` are as follows:

```
// CheckSoftwareAccessToDebugRegisters()
// =====
// Check for access to Breakpoint and Watchpoint registers.

CheckSoftwareAccessToDebugRegisters()
    if HaltingAllowed() && EDSCR.TDA == '1' && OSLSR_EL1.OSLK == '0' then
        Halt(DebugHalt_SoftwareAccess);
```

## H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special purpose registers.
- The state of the external authentication interface.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a *Context synchronization operation* before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Software debug events. See *Synchronization and debug exceptions on page D2-1647*.
- The generation of all Halting debug events.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - *Pending Halting debug events*.
  - *Taking Halting debug events asynchronously on page H3-4385*.
- The behavior of the Halting Step state machine. See *Synchronization and the Halting Step state machine on page H3-4372*.

If there is an instruction between the write and the *Context synchronization operation*, it is CONstrained UNPREDICTABLE whether the PE uses the old state or the new state.

Some register updates are self-synchronizing, but others require an explicit *Context synchronization operation*. For more information on the synchronization of register updates see:

- *Synchronization requirements for system registers on page D8-1866*.
- *Synchronization of changes to the external debug registers on page H8-4445*.
- *State and mode changes without explicit context synchronization operations on page D2-1647*.

A change on the external authentication interface is typically asynchronous to software and can happen without a *Context synchronization operation*.

External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

**Example H3-3** shows an example of the synchronization requirements.

### Example H3-3 Synchronization requirements

---

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

---

### H3.9.1 Pending Halting debug events

A pending Halting debug event is taken when halting becomes allowed. This can happen without a *Context synchronization operation* if:

- The PE enters Non-secure state with `ExternalInvasiveDebugEnabled() == TRUE`, and this is not the result of an exception return. See *State and mode changes without explicit context synchronization operations on page D2-1647*.
- A change on the external authentication interface means halting becomes allowed in the current state.
- The OS Double Lock status, `DoubleLockStatus()` becomes FALSE. For example, this can happen when software clears `OSDLR.DLK` to 0 or sets `DBGPRCR.CORENPDRQ` to 1.

- The debug event is an OS Unlock Catch debug event. OS Unlock Catch debug events are generated in a pending state, rather than taken synchronously.

In these cases a pending Halting debug event is taken asynchronously.

### H3.9.2 Taking Halting debug events asynchronously

The ARM architecture does not define when Halting debug events that are taken asynchronously are taken.

Any Halting debug event that is observed as pending in the [EDES](#)R before a *Context synchronization operation*, or an External Debug Request debug event that is asserted before a *Context synchronization operation*, is taken and the PE enters Debug state before the first instruction following the *Context synchronization operation* completes its execution. This is only possible if halting is allowed after completion of the *Context synchronization operation*.

If the first instruction after the *Context synchronization operation* generates a synchronous exception, or an asynchronous exception is also pending, then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. `EDES`R.SS == 1.
- The *Context synchronization operation* is an exception return from a state where halting is prohibited to a state where halting is allowed.

———— **Note** —————

This applies to an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

In this case the order in which the debug events are handled is specified to avoid a double-step. See [Entering the active-pending state on page H3-4371](#).

———— **Note** —————

These rules are based on the rules that apply to taking asynchronous exceptions. See [Asynchronous exception types, routing, masking and priorities on page D1-1456](#).

# Chapter H4

## The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- [Introduction on page H4-4388.](#)
- [DCC and ITR registers on page H4-4389.](#)
- [DCC and ITR access modes on page H4-4391.](#)
- [Flow-control of the DCC and ITR registers on page H4-4395.](#)
- [Synchronization of DCC and ITR accesses on page H4-4398.](#)
- [Interrupt-driven use of the DCC on page H4-4402.](#)
- [Pseudocode details for the operation of the DCC and ITR registers on page H4-4403.](#)

---

**Note**

Where necessary [Table J-1 on page AppxJ-5088](#) disambiguates the general register references used in this chapter.

---

## H4.1 Introduction

The *Debug Communications Channel*, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

## H4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, [EDITR](#), and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only [DBGDTRTX\\_EL0](#) register to transmit data.
  - The read-only [DBGDTRRX\\_EL0](#) register to receive data.
- A single 64-bit read/write register, [DBGDTR\\_EL0](#), for 64-bit half-duplex operation.
- The read/write [OSDTRTX\\_EL1](#) and [OSDTRRX\\_EL1](#) registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
  - The write-only [DBGDTRTXint](#) register to transmit data.
  - The read-only [DBGDTRRXint](#) register to receive data.
- The read/write [DBGDTRTXext](#) and [DBGDTRRXext](#) registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, [DBGDTRRX\\_EL0](#) and [DBGDTRTX\\_EL0](#). Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are [EDSCR](#).{RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the debug system registers in [DCCSR](#).
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in [DSCR](#).
- The flow-control flags are accessible from the external debug interface in [EDSCR](#).

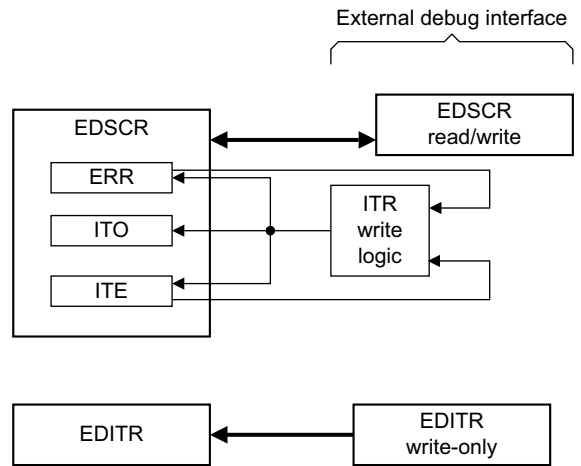

[Figure H4-1 on page H4-4390](#) shows the system register and external debug interface views of the [EDSCR](#) and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

**Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode**

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

**Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode**

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

## H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

- *Normal access mode*, when `EDSCR.MA == 0` or the PE is in Non-debug state.
- *Memory access mode* on page H4-4392, when `EDSCR.MA == 1` and the PE is in Debug state.

### H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

#### For accesses by software:

- Direct writes to `DBGDTRTX` update the value in `DTRTX` and indirectly write 1 to `TXfull`.
- Direct reads from `DBGDTRRX` return the value in `DTRRX` and indirectly write 0 to `RXfull`.
- In AArch64 state, direct writes to `DBGDTR_EL0` update both `DTRTX` and `DTRRX`, indirectly write 1 to `TXfull`, and do not change `RXfull`:
  - `DTRTX` is set from bits[31:0] of the transfer register.
  - `DTRRX` is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from `DBGDTR_EL0` return the concatenation of `DTRRX` and `DTRTX`, indirectly write 0 to `RXfull`, and do not change `TXfull`:
  - Bits[31:0] of the transfer register are set from `DTRRX`.
  - Bits[63:32] of the transfer register are set from `DTRTX`.

#### Note

For `DBGDTR_EL0`, the word order is reversed for reads with respect to writes.

Software reads `TXfull` and `RXfull` using `DCCSR`.

#### For accesses by the external debug interface:

- Writes to `EDITR` trigger the instruction to be executed if the PE is in Debug state:
  - If the PE is in AArch64 state, this is an A64 instruction.
  - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of `DBGDTRTX_EL0` return the value in `DTRTX` and indirectly write 0 to `TXfull`.
- Writes to `DBGDTRTX_EL0` update the value in `DTRTX` and do not change `TXfull`.
- Reads of `DBGDTRRX_EL0` return the value in `DTRRX` and do not change `RXfull`.
- Writes to `DBGDTRRX_EL0` update the value in `DTRRX` and indirectly write 1 to `RXfull`.

`TXfull` and `RXfull` are visible to the external debug interface in `EDSCR`.

The PE detects overrun and underrun by the external debug interface, and records errors in `EDSCR.{TXU, RXO, ITO, ERR}`. See *Flow-control of the DCC and ITR registers* on page H4-4395.

See also *Synchronization of DCC and ITR accesses* on page H4-4398.

## H4.3.2 Memory access mode

When the PE is in Debug state, a special Memory access mode can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from [DBGDTRTX\\_ELO](#) cause:
  1. The existing value in DTRTX to be returned. This clears [EDSCR.TXfull](#) to 0.
  2. The equivalent of `LDR W1, [X0], #4`, if in AArch64 state, or `LDR R1, [R0], #4`, if in AArch32 state, to be executed.
  3. The equivalent of the MSR `DBGDTRTX_ELO, X1` instruction, if in AArch64 state, or the MCR `p14, 0, R1, c0, c5, 0` instruction, if in AArch32 state, to be executed.
  4. [EDSCR.{TXfull, ITE}](#) to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to [DBGDTRRX\\_ELO](#) cause:
  1. The value in DTRRX to be updated. This sets [EDSCR.RXfull](#) to 1.
  2. The equivalent of the instruction `MRS X1, DBGDTRRX_ELO`, if in AArch64 state, or `MRC p14, 0, R1, c0, c5, 0` if in AArch32 state, to be executed.
  3. The equivalent of the instruction `STR W1, [X0], #4`, if in AArch64 state, or `STR R1, [R0], #4`, if in AArch32 state, to be executed.
  4. [EDSCR.{RXfull, ITE}](#) to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from [DBGDTRRX\\_ELO](#) return the last value written to DTRRX.
- External writes to [EDITR](#) generate an overrun error.

During these accesses, [EDSCR.{TXfull, RXfull, ITE}](#) are used for flow control.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to [DBGDTRRX\\_ELO](#), in AArch64 state, [RXfull](#) might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing [External reads from DBGDTRTX\\_ELO](#):
  - The MSR equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the MSR equivalent operation at the previous iteration of step 3.
- In the list describing [External writes to DBGDTRRX\\_ELO](#):
  - The MRS equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The STR equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun

See [Flow-control of the DCC and ITR registers on page H4-4395](#) for more information on overrun and underrun.

### Ordering, access sizes and effect on exclusive monitors

For the purposes of memory ordering, access sizes, and effect on the exclusive monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

### Data aborts

If the memory access generates a Data Abort, then:

- The Data Abort exception is taken. See [Exceptions in Debug state on page H2-4355](#). In particular, `EDSCR.ERR` is set to 1. See [Cumulative error flag on page H4-4397](#).
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- `EDSCR.TXfull`, for a load, or `EDSCR.RXfull`, for a store, is set to an UNKNOWN value.
- `DTRTX`, for a load, or `DTRRX`, for a store, is set to an UNKNOWN value.
- `EDSCR.ITE` is set to 1.

### Illegal State exception

If `PSTATE.IL` is set to 1 when `EDSCR.MA == 1`, then on an external write access to `DBGDTRRX_ELO` or an external read from `DBGDTRTX_ELO`, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Does all of the following without performing any operations:
  - The PE takes an Illegal State exception. See [Exceptions in Debug state on page H2-4355](#). In particular, `EDSCR.ERR` is set to 1, see [Cumulative error flag on page H4-4397](#).
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.
  - `EDSCR.TXfull` or `EDSCR.RXfull`, as applicable, is set to an UNKNOWN value.
  - `DTRTX` or `DTRRX`, as applicable, is set an UNKNOWN value.
  - `EDSCR.ITE` is set to 1.
- Ignores `PSTATE.IL`.

#### ———— Note —————

The typical usage model for Memory access mode involves executing instructions in Normal mode to set up X0 before setting `EDSCR.MA` to 1. These instructions generate an Illegal State exception if `PSTATE.IL` is set to 1.

### Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to `Align(X[0], 4)` in AArch64 state, or `Align(R[0], 4)` in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.

- For external writes to [DBGDTRRX\\_ELO](#), if the PE writes to memory, an UNKNOWN value is written.
- For external reads of [DBGDTRTX\\_ELO](#) an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a [DBGDTRTX\\_ELO](#) read can trigger a TX underrun, and a [DBGDTRTX\\_ELO](#) write can trigger an RX overrun.

### H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in [EDSCR](#) by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses](#) on page H8-4449.

## H4.4 Flow-control of the DCC and ITR registers

This sub-section describes the flow-control of the DCC and ITR registers:

- [Ready flags](#).
- [Overflow and underflow flags](#).
- [Cumulative error flag on page H4-4397](#).

### H4.4.1 Ready flags

In Normal mode:

- For the DTR registers there are two ready flags:
  - [EDSCR.RXfull](#) == 1 indicates that [DBGDTRRX\\_ELO](#) contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - [EDSCR.TXfull](#) == 1 indicates that [DBGDTRTX\\_ELO](#) contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
  - [EDSCR.ITE](#) == 1 indicates that the PE is ready to accept an instruction to the ITR.

———— **Note** —————

The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if [EDSCR.ERR](#) is set, either by an underflow or overflow or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- [EDSCR.{RXfull, ITE}](#) == {0,1} indicates that [DBGDTRRX\\_ELO](#) is empty and the PE is ready to accept a word external write to [DBGDTRRX\\_ELO](#).
- [EDSCR.{TXfull, ITE}](#) == {1,1} indicates that [DBGDTRTX\\_ELO](#) is full and the PE is ready to accept a word external read from [DBGDTRTX\\_ELO](#).

All other values indicate that the PE is not ready, and result in a DTR overflow or underflow error, an ITR overflow error, or both, as defined in [Overflow and underflow flags](#).

### H4.4.2 Overflow and underflow flags

Each of the ready flags has a corresponding overflow or a corresponding underflow flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to [EDRCR.CSE](#).

———— **Note** —————

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

**Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags**

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write <a href="#">DBGDTRRX_ELO</a>	$\text{EDSCR.RXfull} == '1' \mid\mid (\text{Halted}() \ \&\& \ \text{EDSCR.MA} == '1' \ \&\& \ \text{EDSCR.ITE} == '0')$	RXO
Read <a href="#">DBGDTRTX_ELO</a>	$\text{EDSCR.TXfull} == '0' \mid\mid (\text{Halted}() \ \&\& \ \text{EDSCR.MA} == '1' \ \&\& \ \text{EDSCR.ITE} == '0')$	TXU
Write <a href="#">EDITR</a>	$\text{Halted}() \ \&\& \ (\text{EDSCR.ITE} == '0' \mid\mid \text{EDSCR.MA} == '1')$	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, [EDSCR.ERR](#), described in *Cumulative error flag* on page H4-4397, is also set to 1. This has the effect that all subsequent external debug interface accesses to the [EDITR](#) or [DTR](#) registers are ignored.

In the event of an external write to [DBGDTRRX\\_ELO](#) or [EDITR](#) generating an overrun, or an external read from [DBGDTRTX\\_ELO](#) generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- [EDSCR.TXfull](#), [EDSCR.RXfull](#) or [EDSCR.ITE](#), as applicable, are not updated.

There is no overrun or underrun detection on external reads of [DBGDTRRX\\_ELO](#) or external writes of [DBGDTRTX\\_ELO](#).

There is no overrun or underrun detection of direct reads and direct writes of the [DTR](#) system registers by software:

- If  $\text{RXfull} == 0$ , a direct read of [DBGDTRRX](#) or [DBGDTR\\_ELO](#) returns UNKNOWN.
- If  $\text{TXfull} == 1$ , a direct write of:
  - [DBGDTRTX](#) sets [DTRTX](#) to UNKNOWN.
  - [DBGDTR\\_ELO](#) sets [DTRRX](#) and [DTRTX](#) to UNKNOWN.

See *DCC accesses in Non-debug state* on page H4-4399 for more information.

### Accessing 64-bit data

In AArch64 state, a software access to the [DBGDTR\\_ELO](#) register and an external debugger access to both [DBGDTRRX\\_ELO](#) and [DBGDTRTX\\_ELO](#) can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to [DBGDTR\\_ELO](#), only  $\text{TXfull}$  is set to 1, meaning:
  - A subsequent external write to [DBGDTRRX\\_ELO](#) would not be detected as an overrun.
  - If the external debugger reads [DBGDTRTX\\_ELO](#) first, software might observe [MDCCSR\\_ELO.TXfull](#) == 0 and send a second value before the external debugger reads [DBGDTRRX\\_ELO](#), leading to an undetected overrun.
- On external writes to both [DBGDTRRX\\_ELO](#) and [DBGDTRTX\\_ELO](#) only  $\text{RXfull}$  is set to 1, meaning:
  - A subsequent direct write of [DBGDTRTX\\_ELO](#) would not be detected as an overrun.
  - If the external debugger writes to [DBGDTRRX\\_ELO](#) first, software might observe [MDCCSR\\_ELO.RXfull](#) == 1 and read a full 64-bit value, before the external debugger writes to [DBGDTRTX\\_ELO](#), leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check `EDSCR.{RXfull, TXfull}` before each transfer.
- To receive a 64-bit value from the target, the external debugger must read `DBGDTRRX_ELO` before reading `DBGDTRTX_ELO`.
- To send a 64-bit value to the target, the external debugger must write to `DBGDTRTX_ELO` before writing `DBGDTRRX_ELO`.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

### H4.4.3 Cumulative error flag

The cumulative error flag, `EDSCR.ERR`, is set to 1 on taking exceptions taken in Debug state and on any signaled overrun or underrun in the DCC or ITR.

When `EDSCR.ERR == 1`:

- External reads of `DBGDTRTX_ELO` do not have any side-effects.
- External writes to `DBGDTRRX_ELO` are ignored.
- External writes to `EDITR` are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to `EDITR` that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check `EDSCR.{RXfull, TXfull, ITE}` before each access.
- Check `EDSCR.{ITO, RXO, TXU}` following each access, for overrun or underrun.
- Check `PSTATE` or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared by writing 1 to `EDRCR.CSE`. See *EDRCR, External Debug Reserve Control Register* on page H9-4529.

For overruns and underruns, `EDSCR.{ITO, RXO, TXU}` record the error type.

#### Pseudocode details for clearing the error flag

The pseudocode details for the `ClearStickyError()` function is as follows:

```
// ClearStickyErrors()
// =====

ClearStickyErrors()
    EDSCR.TXU = '0';           // Clear TX underrun flag
    EDSCR.RXO = '0';           // Clear RX overrun flag
    if Halted() then          // in Debug state
        EDSCR.ITO = '0';      // Clear ITR overrun flag
    EDSCR.ERR = '0';          // Clear cumulative error flag
    return;
```

## H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- [Summary of system register accesses to the DCC.](#)
- [DCC accesses in Non-debug state on page H4-4399.](#)

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to system registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

———— **Note** —————

In [Synchronization requirements for system registers on page D8-1866](#) external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to [DBGDTRRX\\_EL0](#) and [DBGDTRTX\\_EL0](#) are asynchronous to direct reads of, and direct writes to, [DBGDTRRX](#), [DBGDTRTX](#), and in AArch64 state [DBGDTR\\_EL0](#), made by software using system register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

### H4.5.1 Summary of system register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in [Table H4-2](#). Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, [DBGDTRRX](#) and [DBGDTRTX](#) are the same encoding, but use different registers. The ARMv8 architecture governs the order of these instructions, as described in [Synchronization requirements for system registers on page D8-1866](#). For more details, see the description of the individual register in the relevant chapter, [Chapter D8 AArch64 System Register Descriptions](#) or [Chapter G4 AArch32 System Register Descriptions](#).

[Table H4-2](#) shows a summary of system register accesses to the DCC.

**Table H4-2 Summary of system register accesses to the DCC**

Operation	OS Lock	AArch64 (MRS/MSR)	AArch32 (MRC/MCR)	Description
Read	-	<a href="#">DBGDTRRX_EL0</a>	<a href="#">DBGDTRRXint</a>	Direct read of DTRRX
Write	-	<a href="#">DBGDTRTX_EL0</a>	<a href="#">DBGDTRTXint</a>	Direct read of DTRTX
Read/write	-	<a href="#">DBGDTR_EL0</a>	-	Direct read/write of both DTRRX and DTRTX
All of the above				Indirect write to the DCC flags
Read	-	<a href="#">MDCCSR_EL0</a>	<a href="#">DBGDSCRint</a>	Direct read of the DCC flags
Read/write	-	<a href="#">OSDTRRX_EL1</a>	<a href="#">DBGDTRRXext</a>	Direct read/write of DTRRX
Read/write	-	<a href="#">OSDTRTX_EL1</a>	<a href="#">DBGDTRTXext</a>	Direct read/write of DTRTX
Read	Unlocked	<a href="#">MDSCR_EL1</a>	<a href="#">DBGDSCRext</a>	Direct read of DCC flags
Read/write	Locked	<a href="#">MDSCR_EL1</a>	<a href="#">DBGDSCRext</a>	Direct read/write of DCC flags

## H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in *Normal access mode* on page H4-4391:

- If a direct read of `DCCSR` returns `RXfull == 1`, then a following direct read of `DBGDTRRX` or in AArch64 state of `DBGDTR_EL0`, returns valid data and indirectly writes 0 to `DCCSR.RXfull` as a side-effect.
- If a direct read of `DCCSR` returns `TXfull == 0`, then a following direct write to `DBGDTRTX`, or in AArch64 state to `DBGDTR_EL0`, writes the intended value, and indirectly writes 1 to `DCCSR.TXfull` as a side-effect.

No context synchronization operation is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of `DBGDTRRX` is an indirect write to `DCCSR.RXfull`, it must occur in program order with respect to the direct read of `DCCSR`, meaning it must not return a speculative value for `DTTRX` that predates the `RXfull` flag returned by the read of `DCCSR`. The direct write to `DBGDTRTX` must not be executed speculatively.

Direct reads of `DBGDTRRX`, or in AArch64 state `DBGDTR_EL0`, and `DCCSR`, must occur in program order with respect to other direct reads of the same register using the same encoding.

All observers must observe the same order for accesses.

### ———— Note ————

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.
- In the simple sequential execution model, for an external read of `DBGDTRTX_EL0` or an external write of `DBGDTRRX_EL0`:
  - The check of the DCC flags for overrun or underrun occurs immediately before the access.
  - If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

This means that:

- Following a direct read of `DBGDTRRX`, or in AArch64 state `DBGDTR_EL0`, made when the value of `RXfull` is 1, if an external write to `DBGDTRRX_EL0` checks the `RXfull` flag for overrun and observes that the value of `RXfull` is 0, the value returned by the previous direct read must not be affected by the external write.
- Following a direct write to `DBGDTRTX`, or in AArch64 state `DBGDTR_EL0`, made when the value of `TXfull` is 0, if an external read of `DBGDTRTX_EL0` checks the `TXfull` flag for underrun and observes that the value of `TXfull` is 1, the value returned by the external read must be the value written by the previous direct write.
- Following an external read of `DBGDTRTX_EL0` that does not underrun, if a direct read of `DCCSR` returns a `TXfull` value of 0, then the value returned by the external read must not be affected by a following direct write to `DBGDTRTX`, or in AArch64 state `DBGDTR_EL0`.
- Following an external write to `DBGDTRRX_EL0` that does not overrun, if a direct read of `DCCSR` returns the `RXfull` value of 1, then the value returned by a following direct read of `DBGDTRRX` must be the value written by the previous external write.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to `DBGDTRRX_EL0` must be observable to direct reads of `DBGDTRRX` in finite time.

- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To direct reads of **DCCSR** in finite time.
  - To subsequent external reads of **EDSCR**.
  - To subsequent external reads of **DBGDTRRX\_EL0** and external writes to **DBGDTRTX\_EL0** when checking for overrun and underrun.

However, explicit synchronization is required to guarantee that a direct read of **DCCSR** returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that **DCCSR** must be read, an ISB is required to ensure that the read of **DCCSR** occurs after the signal has been received. This also synchronizes the value in **DBGDTRRX**, if applicable. However, if that signal is an interrupt exception triggered by **COMMIRQ**, **COMMTX**, or **COMMRX**, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals*.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to **DBGDTRTX** is observable to external reads of **DBGDTRTX\_EL0**.
- To ensure that a value directly written to **DBGDTR\_EL0** is observable to external reads of **DBGDTRTX\_EL0** and **DBGDTRRX\_EL0**.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of **EDSCR**.
  - Observable to external reads of **DBGDTRRX\_EL0**.
  - Observable to external writes of **DBGDTRTX\_EL0** when checking for overrun and underrun
  - Returned by a following direct read of **DCCSR**.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-4394 and *Synchronization of changes to the external debug registers* on page H8-4445.

———— **Note** —————

These ordering rules mean that software:

- Must not read **DBGDTRRX** without first checking **DCCSR.RXfull** or if the previously-read value of **DCCSR.RXfull** is 0.  
It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.
- Must not write **DBGDTRTX** without first checking **DCCSR.TXfull** or if the previously-read value of **DCCSR.TXfull** is 1.  
The write to **DBGDTRTX** overwrites the value in **DTRTX**, and the external debugger might or might not have read this value.
- Must ensure there is an explicit context synchronization operation following a DTR access, even if not immediately returning to read **DCCSR** again. This synchronization operation can be an exception return.

### H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of **DCCSR** or **DBGDTRRX**, or a direct write of **DBGDTRTX** executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of **DBGDTRTX** executed after taking an interrupt exception generated by the interrupt request.

Following a direct read of [DBGDTRRX](#) or a direct write to [DBGDTRRX](#), software must execute a context synchronization operation to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

#### H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to [EDITR](#) must be observable to an external write or an external read in finite time:

- A direct read of [DBGDTRRX](#) must be observable to an external write of [DBGDTRRX\\_ELO](#).

- A direct write of [DBGDTRTX](#) must be observable to an external read of [DBGDTRTX\\_ELO](#).

This includes the indirect write to the DCC flags that occurs atomically with the access as described in [DCC accesses in Non-debug state on page H4-4399](#).

The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old DCC flag values indicate an overrun or underrun condition, as would normally be the case.

This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in [EDSCR](#), because it can rely on overrun and underrun tests.

- External reads of [DBGDTRTX\\_ELO](#) that do not underrun and external writes to [DBGDTRRX\\_ELO](#) that do not overrun must be observable to an instruction subsequently written to [EDITR](#) on completion of the first external access. This includes the indirect write to the DCC flags.

This means that without explicit synchronization and without the need to first check the DCC flags in [DCCSR](#):

- If the instruction is a direct read of [DBGDTRRX](#), it observes the external write.

- If the instruction is a direct write of [DBGDTRTX](#), it observes the external read.

- Writes to [EDITR](#) that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in [Memory access mode on page H4-4392](#).

## H4.6 Interrupt-driven use of the DCC

ARM recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

———— **Note** —————

In addition to connection to the interrupt controller ARM also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.

The **DCCINT** register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also [Synchronization of DCC interrupt request signals on page H4-4400](#).

## H4.7 Pseudocode details for the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when `OSLSR.OSLK == 1`, meaning that the OS lock is locked.

The definition of the DTR Registers is:

```
bits(32) DTRRX;
```

```
bits(32) DTRTX;
```

The pseudocode for the `DBGDTR_EL0()` function is as follows:

```
// DBGDTR_EL0[] (write)
// =====
// System register writes to DBGDTR_EL0, DBGDTRTX_EL0 (AArch64) and DBGDTRTXint (AArch32)

DBGDTR_EL0[] = bits(N) value
  // For MSR DBGDTRTX_EL0,<Rt> N=32, value=X[t]<31:0>, X[t]<63:32> is ignored
  // For MSR DBGDTR_EL0,<Xt> N=64, value=X[t]<63:0>
  assert(N == 32 || N == 64);
  if EDSCR.TXfull == '1' then
    value = bits(N) UNKNOWN;
  // On a 64-bit write, implement a half-duplex channel
  if N == 64 then DTRRX = value<63:32>;
  DTRTX = value<31:0>; // 32-bit or 64-bit write
  EDSCR.TXfull = '1';
  return;

// DBGDTR_EL0[] (read)
// =====
// System register reads of DBGDTR_EL0, DBGDTRRX_EL0 (AArch64) and DBGDTRRXint (AArch32)

bits(N) DBGDTR_EL0[]
  // For MRS <Rt>,DBGDTRTX_EL0 N=32, X[t]=Zeros(32):result
  // For MRS <Xt>,DBGDTR_EL0 N=64, X[t]=result
  assert(N == 32 || N == 64);
  bits(N) result;
  if EDSCR.RXfull == '0' then
    result = bits(N) UNKNOWN;
  else
    // On a 64-bit read, implement a half-duplex channel
    // NOTE: the word order is reversed on reads with regards to writes
    if N == 64 then result<63:32> = DTRTX;
    result<31:0> = DTRRX;
  EDSCR.RXfull = '0';
  return result;
```

The pseudocode for the `DBGDTRRX_EL0()` function is as follows:

```
// DBGDTRRX_EL0[] (external write)
// =====
// Called on writes to debug register 0x08C.

DBGDTRRX_EL0[boolean memory_mapped] = bits(32) value

  if EDPRSR<6:5,0> != '001' then // Check DLK, OSLK and PU bits
    IMPLEMENTATION_DEFINED "signal slave-generated error";
    return;

  if EDSCR.ERR == '1' then return; // Error flag set: ignore write

  // The Software lock is OPTIONAL.
  if memory_mapped && EDLSR.SLK == '1' then return; // Software lock locked: ignore write

  if EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
```

```

EDSCR.RXO = '1'; EDSCR.ERR = '1';           // Overrun condition: ignore write
return;

EDSCR.RXfull = '1';
DTRRX = value;

if Halted() && EDSCR.MA == '1' then
    EDSCR.ITE = '0';                         // See comments in EDITR[] (external write)

    if !UsingAArch32() then
        ExecuteA64(0xD5330501<31:0>);      // A64 "MRS X1,DBGDTRRX_EL0"
        ExecuteA64(0xB8004401<31:0>);      // A64 "STR W1,[X0],#4"
        X[1] = bits(64) UNKNOWN;
    else
        ExecuteT32(0xEE10<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/); // T32 "MRS R1,DBGDTRRXint"
        ExecuteT32(0xF840<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/); // T32 "STR R1,[R0],#4"
        R[1] = bits(32) UNKNOWN;

    // If the store aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
    if EDSCR.ERR == '1' then
        EDSCR.RXfull = bit UNKNOWN;
        DBGDTRRX_EL0 = bits(32) UNKNOWN;
    else
        // "MRS X1,DBGDTRRX_EL0" calls DBGDTR_EL0[] (read) which clears RXfull.
        assert EDSCR.RXfull == '0';

    EDSCR.ITE = '1';                         // See comments in EDITR[] (external write)
return;

// DBGDTRRX_EL0[] (external read)
// =====
bits(32) DBGDTRRX_EL0[boolean memory_mapped]
return DTRRX;

```

The pseudocode for the DBGDTRTX\_EL0() function is as follows:

```

// DBGDTRTX_EL0[] (external read)
// =====
// Called on reads of debug register 0x080.

bits(32) DBGDTRTX_EL0[boolean memory_mapped]

if EDPRSR<6:5,0> != '001' then              // Check DLK, OSLK and PU bits
    IMPLEMENTATION_DEFINED "signal slave-generated error";
    return bits(32) UNKNOWN;

if EDSCR.ERR == '1' then return DTRTX;      // Error flag set: no side-effects

// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then   // Software lock locked: no side-effects
    return DTRTX;

if EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
    EDSCR.TXU = '1'; EDSCR.ERR = '1';      // Underrun condition: block side-effects
    return bits(32) UNKNOWN;               // Return UNKNOWN

EDSCR.TXfull = '0';
value = DTRTX;                             // Return previous value of DTRTX

if Halted() && EDSCR.MA == '1' then
    EDSCR.ITE = '0';                       // See comments in EDITR[] (external write)

    if !UsingAArch32() then
        ExecuteA64(0xB8404401<31:0>);      // A64 "LDR W1,[X0],#4"
    else
        ExecuteT32(0xF850<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/); // T32 "LDR R1,[R0],#4"

```

```

// If the load aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
if EDSCR.ERR == '1' then
    EDSCR.TXfull = bit UNKNOWN;
    DBGDTRTX_EL0 = bits(32) UNKNOWN;
else
    if !UsingAArch32() then
        ExecuteA64(0xD5130501<31:0>); // A64 "MSR DBGDTRTX_EL0,X1"
    else
        ExecuteT32(0xEE00<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/); // T32 "MSR DBGDTRTXint,R1"
        // "MSR DBGDTRTX_EL0,X1" calls DBGDTR_EL0[] (write) which sets TXfull.
        assert EDSCR.TXfull == '1';

    if !UsingAArch32() then
        X[1] = bits(64) UNKNOWN;
    else
        R[1] = bits(32) UNKNOWN;

    EDSCR.ITE = '1'; // See comments in EDITR[] (external write)

return value;

// DBGDTRTX_EL0[] (external write)
// =====

DBGDTRTX_EL0[boolean memory_mapped] = bits(32) value
// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then return; // Software lock locked: ignore write
DTRTX = value;
return;

```

The pseudocode for the EDITR() function is as follows:

```

// EDITR[] (external write)
// =====
// Called on writes to debug register 0x088.

EDITR[boolean memory_mapped] = bits(32) value
if EDPRSR<6:5,0> != '001' then // Check DLK, OSLK and PU bits
    IMPLEMENTATION_DEFINED "signal slave-generated error";
    return;

if EDSCR.ERR == '1' then return; // Error flag set: ignore write

// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then return; // Software lock locked: ignore write

if !Halted() then return; // Non-debug state: ignore write

if EDSCR.ITE == '0' || EDSCR.MA == '1' then
    EDSCR.ITO = '1'; EDSCR.ERR = '1'; // Overrun condition: block write
    return;

// ITE indicates whether the processor is ready to accept another instruction; the processor
// may support multiple outstanding instructions. Unlike the "InstrComp1" flag in [v7A] there
// is no indication that the pipeline is empty (all instructions have completed). In this
// pseudocode, the assumption is that only one instruction can be executed at a time,
// meaning ITE acts like "InstrComp1".
EDSCR.ITE = '0';

if !UsingAArch32() then
    ExecuteA64(value);
else
    ExecuteT32(value<15:0> /*hw1*/, value<31:16> /*hw2*/);

EDSCR.ITE = '1';

```

```
return;
```

The pseudocode for the CheckForDCCInterrupts() function is as follows:

```
// CheckForDCCInterrupts()
// =====

CheckForDCCInterrupts()
    commrx = (EDSCR.RXfull == '1');
    commtx = (EDSCR.TXfull == '0');

    // COMMRX and COMMTX support is optional and not recommended for new designs.
    // SetInterruptRequestLevel(InterruptID_COMMRX, if commrx then HIGH else LOW);
    // SetInterruptRequestLevel(InterruptID_COMMTX, if commtx then HIGH else LOW);

    // The value to be driven onto the common COMMIRQ signal.
    commirq = ((commrx && MDCCINT_EL1.RX == '1') ||
               (commtx && MDCCINT_EL1.TX == '1'));
    SetInterruptRequestLevel(InterruptID_COMMIRQ, if commirq then HIGH else LOW);

return;
```

# Chapter H5

## The Embedded Cross Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

- *About the Embedded Cross Trigger (ECT) on page H5-4408.*
- *Basic operation on the ECT on page H5-4410.*
- *Cross-triggers on a PE in an ARMv8 implementation on page H5-4414.*
- *Description and allocation of CTI triggers on page H5-4415.*
- *CTI registers programmers' model on page H5-4418.*
- *Examples on page H5-4419.*

## H5.1 About the Embedded Cross Trigger (ECT)

The *Embedded Cross Trigger*, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs when a trigger event occurs on another PE. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

**Figure H5-1 Structure of an embedded cross trigger**

The ECT can deliver many types of trigger events, which are described in the following sections:

- [Debug request trigger event on page H5-4415.](#)
- [Restart request trigger event on page H5-4416.](#)
- [Cross-halt trigger event on page H5-4416.](#)
- [Performance Monitors overflow trigger event on page H5-4416.](#)
- [Generic trace external input trigger events on page H5-4417.](#)
- [Generic trace external output trigger events on page H5-4417.](#)
- [Generic CTI interrupt trigger event on page H5-4417.](#)

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

See [Cross-triggers on a PE in an ARMv8 implementation on page H5-4414.](#)

In addition, ARM recommends that the cross-trigger includes:

- The ability to route trigger events between Trace extensions:
  - These typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

### ———— **Note** ————

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

## H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an ARMv8-A implementation, see [Appendix B Recommended External Debug Interface](#). See also *CoreSight™ SoC Technical Reference Manual*.

## H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

[Figure H5-2 on page H5-4411](#) shows the logical internal structure of a CTI.

The input channel gate function was not implemented in previous versions of this architecture.

**Figure H5-2 Structure of a cross-trigger interface**

**Note**

- The number of triggers is IMPLEMENTATION DEFINED. [Figure H5-2](#) shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. [Figure H5-2](#) shows four channels.
- In [Figure H5-2](#) the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, [CTIINEN<n>](#).

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *cross-trigger matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

———— **Note** ————

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel* → *output trigger mapping registers*, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See *Multicycle events*.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

———— **Note** ————

ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

## H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

———— **Note** ————

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

## An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

### ———— **Note** —————

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can set a channel active for multiple cycles. [CTIAPPULSE](#) generates a single channel event. [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) can report whether a channel is active.

## An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

### ———— **Note** —————

A single event is typically a single cycle, but there is no guarantee that this is always the case.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can only generate a single channel event. [CTIAPPULSE](#) generates a single channel event. If the ECT does not support multicycle channel events, use of [CTIAPPSET](#) and [CTIAPPCLEAR](#) is deprecated, and the debugger must only use [CTIAPPULSE](#). [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) must be treated as UNKNOWN.

## H5.3 Cross-triggers on a PE in an ARMv8 implementation

An ARMv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the ARMv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

———— **Note** ————

In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

Any CTI connected to a PE that is not an ARMv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight™ SoC Technical Reference Manual*. ARMv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.

## H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

**Table H5-1 Allocation of CTI output trigger events**

Number	Source	Destination	Event description
0	CTI	PE	<i>Debug request trigger event</i>
1	CTI	PE	<i>Restart request trigger event on page H5-4416</i>
2	CTI	IRQ controller	<i>Generic CTI interrupt trigger event on page H5-4417</i>
3	-	-	Reserved
4 - 7	CTI	Trace extension	OPTIONAL <i>Generic trace external input trigger events on page H5-4417</i>

———— **Note** —————

Output triggers from the CTI are inputs to other blocks.

Table H5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

**Table H5-2 Allocation of CTI input trigger events**

Number	Source	Destination	Event description
0	PE	CTI	<i>Cross-halt trigger event on page H5-4416</i>
1	PE	CTI	<i>Performance Monitors overflow trigger event on page H5-4416</i>
2 - 3	-	-	Reserved
4 - 7	Trace extension	CTI	OPTIONAL <i>Generic trace external output trigger events on page H5-4417</i>

———— **Note** —————

Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL Trace extension is implemented. If the OPTIONAL Trace extension is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An ARMv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

### H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the assert by writing 1 to `CTIINTACK[0]`.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also [External Debug Request debug event on page H3-4380](#).

#### H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is not in Debug state, the request is ignored and dropped by the CTI.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONstrained UNPREDICTABLE whether:

- The restart is ignored. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event.

Debuggers can use `EDPRSR.{SDR, HALTED}` to determine the execution state of the PE.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. See also [Exiting Debug state on page H2-4361](#).

#### H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

———— **Note** —————

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the `EDSCR.STATUS` field. This applies to Debug request trigger events that are acting as inputs to the PE.

#### H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts a new Performance Monitors counter overflow interrupt request. See [Chapter D6 The Performance Monitors Extension](#).

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared by a write to `PMOVSCLR_ELO`. Otherwise, the trigger event is not asserted again until the overflow is cleared by a write to `PMOVSCLR_ELO`.

———— **Note** —————

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled() == FALSE`, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled() == FALSE`. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

#### H5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL Trace extension, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

#### H5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL Trace extension, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external output trigger events.

#### H5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, Trace extension, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

———— **Note** —————

ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to [CTIINTACK\[2\]](#). This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

## H5.5 CTI registers programmers' model

The CTI registers programmers' model is described in [Chapter H8 About the External Debug Registers](#). The following sections contain information specific to the CTI:

- [External debug register resets](#) on page H8-4465.
- [External debug interface register access permissions](#) on page H8-4451.
- [Cross-trigger interface registers](#) on page H8-4461.
- The individual register descriptions in [Cross-Trigger Interface registers](#) on page H9-4554.

See also [Memory-mapped accesses to the external debug interface](#) on page H8-4449.

### H5.5.1 CTI reset

An External Debug reset resets the CTI. See [External debug register resets](#) on page H8-4465 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

### H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- [CTITRIGINSTATUS](#) shows the status of the input triggers and [CTICHINSTATUS](#) shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

———— **Note** —————

The PE does not generate the Cross-halt trigger event and the Trace extension does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled() == FALSE`. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

———— **Note** —————

The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled() == FALSE`. The Trace extension ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled() == FALSE`. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled() == FALSE`.

## H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

———— **Note** —————

This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the Trace extension. They can do this:
  - To pass trace events between Trace extensions.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the Trace extension.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- [Halting a single PE.](#)
- [Halting all PEs in a group when any one PE halts on page H5-4420.](#)
- [Synchronously restarting a group of PEs on page H5-4420.](#)
- [Halting a single PE on Performance Monitors overflow on page H5-4420.](#)

### Example H5-1 Halting a single PE

---

To halt a single PE, set:

1. `CTIGATE[0] = 0`, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. `CTIOUTEN<n>[0] = 1`, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

———— **Note** —————

In this example, *n* is 0.

3. `CTIAPPULSE[0] = 1`, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to `CTIINTACK[0]`, before restarting the PE.

---

---

### Example H5-2 Halting all PEs in a group when any one PE halts

---

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. **CTIGATE**[2] = 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. **CTIINEN**<n>[2] = 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.

———— **Note** —————

In this example, *n* is 0.

---

3. **CTIOUTEN**<n>[2] = 1, so that each CTI generates a Debug request trigger event in response to an channel event on channel 2.

———— **Note** —————

In this example, *n* is 0.

---

When a PE has halted, clear the Debug request trigger event by writing a value of 1 to **CTIINTACK**[0], before restarting the PE.

---

---

### Example H5-3 Synchronously restarting a group of PEs

---

To restart a group of PEs, for each PE in the group set:

1. **CTIGATE**[1] = 1, so that each CTI passes channel events on internal channel 1 to the CTM.
2. **CTIOUTEN**<n>[1] = 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

———— **Note** —————

In this example, *n* is 1.

---

3. **CTIAPPULSE**[1] = 1 on any one PE in the group, to generate a channel event on channel 1.
- 

---

### Example H5-4 Halting a single PE on Performance Monitors overflow

---

To halt a single PE on a Performance Monitors overflow set:

1. **CTIGATE**[3] = 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. **CTIINEN**<n>[3] = 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

———— **Note** —————

In this example, *n* is 1.

---

3. `CTIOUTEN<n>[3] = 1`, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

———— **Note** ————

In this example, *n* is 0.

---

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to `CTINTACK[0]`, before restarting the PE. Clear the overflow status by writing to `PMOVSCLR_ELO`.

---

# Chapter H6

## Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-4424.
- *Power domains and debug* on page H6-4425.
- *Core power domain power states* on page H6-4426.
- *Emulating low-power states* on page H6-4428.
- *Debug OS Save and Restore sequences* on page H6-4430.

———— **Note** —————

Where necessary, [Table J-1 on page AppxJ-5088](#) disambiguates the general register references used in this chapter.

## H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the *Core power domain* and the *Debug power domain*. See:

- [Power domains and debug on page H6-4425.](#)
- [Core power domain power states on page H6-4426.](#)

## H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.
- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

———— **Note** ————

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals **DBGPWRUPREQ**, **DBGNOPWRDWN**, and **DBGPWRDUP** shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See [Appendix B Recommended External Debug Interface](#).

**Figure H6-1 Recommended power domain split between core and debug power domains**

## H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

- Normal** The core power domain is fully powered on and the debug registers are accessible.
- Standby** The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a WFI or WFE instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby. The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE. Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the debug architecture requires only the following:
- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a WFE or a WFI instruction to enter standby, then it retires that instruction,
  - If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a WFI or WFE instruction to enter standby, then it does not retire that instruction.
- Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.
- Retention** The OS takes some measures, including IMPLEMENTATION DEFINED measures, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off. Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.
- **Note** —————
- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.
- Powerdown** The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. Changing from powerdown to normal operation must include:
- A Cold reset of the PE after the power level has been restored.
  - The OS restoring the saved PE state.
- External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

- Off** The debug power domain is turned off.  
**On** The debug power domain is turned on.

The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

———— **Note** —————

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.

---

## H6.4 Emulating low-power states

The control registers [DBGPRCR.CORENPDRQ](#) and [EDPRCR.COREPURQ](#) provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

[EDPRSR.{SPD, PU}](#) indicates the core power domain power state. For more information see:

- [DBGPRCR\\_ELI, Debug Power Control Register on page D8-2093](#) and [DBGPRCR, Debug Power Control Register on page G4-4145](#).
- [EDPRCR, External Debug Power/Reset Control Register on page H9-4520](#).
- [EDPRSR, External Debug Processor Status Register on page H9-4523](#).
- [Appendix B Recommended External Debug Interface](#).

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug registers in both the debug power domain and the core power domain as if the core power domain were on. That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence. To stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, `DoubleLockStatus() == FALSE` when [DBGPRCR.CORENPDRQ == 1](#).

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

[Example H6-1](#) and [Example H6-2](#) are examples of two approaches to emulating powerdown.

### Example H6-1 An example of emulating powerdown

---

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

---

### Example H6-2 Another example of emulating powerdown

---

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

---

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset.

#### Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, [RMR\\_ELx](#) is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.

- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.
-

## H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- The *OS Lock Access Register*, [OSLAR](#), locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, [OSLSR](#), shows the status of the OS Lock.
- The *External Debug Execution Control Register*, [EDECR](#), can be configured to generate a debug event when the OS Lock is unlocked.
- The *OS Double Lock Register*, [OSDLR](#), locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- [Reset and debug on page H8-4463](#)
- [Appendix D Example OS Save and Restore sequences](#)

### H6.5.1 Debug registers to save over powerdown

[Table H6-1](#) shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when [OSLSR.OSLK](#) is locked. These registers include [OSECCR](#), [OSDTRRX](#), and [OSDTRTX](#).
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. [DBGVCR32\\_EL2](#) and [SDER32\\_EL3](#) are only required to support AArch32.

[Table H6-1](#) does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

**Table H6-1 Debug registers to save over powerdown**

**Table H6-1 Debug registers to save over powerdown (continued)**

Register in AArch64	Register in AArch32	Self-hosted	External
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	DBGCLAIMSET, DBGCLAIMCLR	-	Yes <sup>c</sup>
OSECCR_EL1	DBGOSECCR	-	Yes <sup>ab</sup>
OSDTRRX_EL1 OSDTRTX_EL1	DBGDTRRXext DBGDTRTXext	-	Yes

- a. The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, **DSCR** is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of **EDSCR** that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.
- b. This register is new in ARMv8-A. Sequences written for ARMv7 do not preserve the register over powerdown.
- c. Read **DBGCLAIMCLR** to save, write **DBGCLAIMSET** to restore.

### H6.5.2 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
  - Writing the key value 0xC5ACCE55 to the **DBGOSLAR** in AArch32 state.
  - Writing 1 to **OSLAR\_EL1.OSLK** in AArch64 state.
2. Execute an ISB instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown on page H6-4430* and save the values to the nonvolatile storage.

Before removing power from the core power domain, software must:

1. Lock the OS Double Lock by writing 1 to **OSDLR\_EL1.DLK**.
2. Execute a context synchronization operation.

### H6.5.3 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in *Debug registers to save over powerdown on page H6-4430*. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an ISB instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown on page H6-4430*, and restore the values from the nonvolatile storage.
4. Execute an ISB instruction.
5. Unlock the OS Lock by:
  - Writing any non-key value to **DBGOSLAR** in AArch32 state.
  - Writing 0 to **OSLAR\_EL1.OSLK** in AArch64 state.
6. Execute a context synchronization operation.

———— **Note** ————

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

---

#### H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the system register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in [DSCR](#) and [OSECCR](#) that are normally read-only become read/write.This allows the state to be saved or restored. For more information, see the relevant register description in [Chapter H9 External Debug Register Descriptions](#).
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see [External debug interface register access permissions summary on page H8-4453](#).
- Debug exceptions, other than Software Breakpoint Instruction exceptions are not generated.

The OS Lock has no effect on Software Breakpoint Instruction debug events and Halting debug events.

#### H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, an OS Unlock Catch debug event is generated if [EDEC.R.OUCE](#) is set to 1. See [OS Unlock Catch debug event on page H3-4381](#).

#### H6.5.6 Debug behavior when the OS Double Lock is locked

The OS Double Lock is locked immediately before a powerdown sequence. The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus() == TRUE`:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See [External debug interface register access permissions summary on page H8-4453](#).
- Debug exceptions, other than Software Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See [Halting allowed and halting prohibited on page H2-4329](#).

———— **Note** ————

Pending Halting debug events might be lost when core power is removed.

---

- No asynchronous debug events are WFI or WFE wake-up events.

Software must synchronize the update to [OSDLR](#) before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the [OSDLR](#) update before issuing the WFI instruction.

[OSDLR.DLK](#) is ignored and `DoubleLockStatus() == FALSE` if either:

- The PE is in Debug state.
- [DBGPRCR.CORENPDRQ](#) is set to 1.

———— **Note** ————

It is possible to enter Debug state with `OSDLR.DLK` set to 1. This is because a context synchronization operation is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the `OSDLR` update is synchronized.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, it is important to avoid race conditions that defeat this purpose. ARM recommends that:

- Once the write to `OSDLR.DLK` has been synchronized by a *Context synchronization operation* and `DoubleLockStatus() == TRUE`, a PE must:
  - Not allow a debug event generated before the *Context synchronization operation* to cause an entry to Debug state or act as a wake-up event for a WFI or WFE instruction after the context synchronization operation has completed.
  - Complete any external debug access started before the *Context synchronization operation* by the time the context synchronization operation completes.

———— **Note** ————

A debug register access might be in progress when software sets `OSDLR.DLK` to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets `OSDLR.DLK` to 1 must complete or return an error in finite time.

- If a write to `DBGPRCR` or `EDPRCR` made when `OSDLR.DLK == 1` changes `DBGPRCR.CORENPDRQ` or `EDPRCR.CORENPDRQ` from 1 to 0, meaning `DoubleLockStatus()` changes from `FALSE` to `TRUE`, then before signaling to the system that the `CORENPDRQ` field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus() == TRUE` listed in this section are met.

In the standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to `CORENPDRQ` are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus() == FALSE`, an external debugger can clear the OS Lock at any time, and then write to `EDPRCR`.

The pseudocode for the `DoubleLockStatus()` function is as follows:

```
// DoubleLockStatus()
// =====

boolean DoubleLockStatus()
// Returns the value of EDPRSR.DLK:
// FALSE if OSDLR_EL1.DLK == 0 or DBGPRCR_EL1.CORENPDRQ == 1 or the processor is in Debug state.
// TRUE if OSDLR_EL1.DLK == 1 and DBGPRCR_EL1.CORENPDRQ == 0 and the processor is in Non-debug
// state.
return OSDLR_EL1.DLK == '1' && DBGPRCR_EL1.CORENPDRQ == '0' && !Halted();
```

# Chapter H7

## The Sample-based Profiling Extension

This chapter describes the Sample-based Profiling extension, that is an OPTIONAL extension to the ARMv8 architecture. The extension provides a non-invasive external debug component.

———— **Note** ————

This form of the Sample-based Profiling extension is OPTIONAL. ARM recommends that if extension [EDPCSR](#) is not implemented that an alternative IMPLEMENTATION DEFINED form of Sample-based Profiling is implemented.

It contains the following section:

- [Sample-based profiling on page H7-4436.](#)

## H7.1 Sample-based profiling

Sample-based profiling is an OPTIONAL extension to the architecture. It provides a mechanism for coarse-grained profiling of software executing on the PE by an external debugger, without changing the behavior of that software. The following sections describe this extension:

- [The implemented Sample-based profiling registers](#)
- [Reads of the External Debug Program Counter Sampling Registers](#)
- [Reads of the External Debug Virtual Context Sample Register on page H7-4437](#)
- [Accuracy of sampling on page H7-4437](#)
- [Sample-based Profiling and security on page H7-4438](#)
- [Pseudocode details of Sample-based Profiling on page H7-4438](#)

### H7.1.1 The implemented Sample-based profiling registers

An implementation that includes the Sample-based profiling extension implements the following external debug registers:

- **EDPCSR** is a 64-bit read-only register that contains a sampled program counter value. As external debug register accesses are atomic only at word granularity, **EDPCSR** is split into two registers: **EDPCSRhi** and **EDPCSRlo**. See [Reads of the External Debug Program Counter Sampling Registers](#).
- **EDCIDS** is a read-only register that contains the sampled value of **CONTEXTIDR\_EL1** captured on reading **EDPCSRlo**.

———— **Note** —————

If EL3 is implemented and using AArch32 then **CONTEXTIDR** is a Banked register and **EDCIDS** samples the current Banked copy of **CONTEXTIDR**.

- **EDVIDSR** is a read-only register that contains sampled values captured on reading **EDPSRlo**. If neither EL3 nor EL2 are implemented, **EDVIDSR** is not implemented.

### H7.1.2 Reads of the External Debug Program Counter Sampling Registers

A read of the **EDPCSRlo** normally has the side-effect of indirectly writing to **EDCIDS**, **EDVIDSR**, and **EDPCSRhi**. When **EDPCSRlo** is read, the bottom 32 bits of a program counter sample are returned. The top 32 bits are captured in **EDPCSRhi** and can be read later. However:

- If the PE is in Debug state, or Sample-based Profiling is prohibited, **EDPCSRlo** reads as 0xFFFFFFFF and **EDCIDS**, **EDVIDSR** and **EDPCSRhi** become UNKNOWN. See [Sample-based Profiling and security on page H7-4438](#).
- If the PE is in Reset state, the sampled value is UNKNOWN and **EDCIDS**, **EDVIDSR** and **EDPCSRhi** become UNKNOWN.
- If no instruction has been retired since the PE left Reset state, Debug state, or a state where Sample-based Profiling is prohibited, the sampled value is UNKNOWN and **EDCIDS**, **EDVIDSR** and **EDPCSRhi** become UNKNOWN.
- The indirect writes to **EDCIDS**, **EDVIDSR**, and **EDPCSRhi** might not occur for a memory-mapped access to the external debug interface. For more information, see [Memory-mapped accesses to the external debug interface on page H8-4449](#).

———— **Note** —————

In ARMv7 the Sample-based Profiling extension an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the ARMv8 Sample-based Profiling extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

### H7.1.3 Reads of the External Debug Virtual Context Sample Register

A read of the [EDVIDSR](#) contains sampled values captured on reading [EDPSRlo](#), where:

- [EDVIDSR.NS](#) indicates the security state associated with the most recent [EDPCSR](#) sample.
- [EDVIDSR.E2](#) indicates whether the most recent [EDPCSR](#) sample was associated with EL2. If [EDVIDSR.NS](#) == 0, this bit is 0.
- [EDVIDSR.E3](#) indicates whether the most recent [EDPCSR](#) sample was associated with EL3 using AArch64. If [EDVIDSR.NS](#) == 1 or the PE was in AArch32 state when [EDPSRlo](#) was read, this bit is 0.
- [EDVIDSR.HV](#) indicates whether [EDPCSRhi](#) is valid, that is, bits [63:32] of the most recent program counter sample are non-zero.

———— **Note** —————

- [EDVIDSR.HV](#) == 1 does not mean that [EDPCSRhi](#) != 0. [EDVIDSR.HV](#) == 0 is a hint that [EDPCSRhi](#) does not need to be read.
- Tools must take care to avoid skewing sampled data by over-sampling code for which [EDVIDSR.HV](#) == 0.

- [EDVIDSR.VMID](#) indicates the value of the [VTTBR\\_EL2.VMID](#) register associated with the most recent [EDPSRlo](#) sample. If [EDVIDSR.NS](#) == 0 or [EDVIDSR.E2](#) == 1, this field is RAZ.

If EL2 is not implemented, [EDVIDSR.E2](#) and [EDVIDSR.VMID](#) are RES0.

If EL3 is not implemented, [EDVIDSR.E3](#) is RES0, and [EDVIDSR.NS](#) has a fixed read-only value.

### H7.1.4 Accuracy of sampling

Sample-based Profiling is provided as a mechanism for tools to populate a statistical model of the performance of software executing on the PE. The statistical data returned by random sampling of [EDPCSR](#), [EDCIDSR](#), and [EDVIDSR](#) must allow such statistical modeling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the whole sample, [EDPCSR](#), [EDCIDSR](#), and [EDVIDSR](#), must reference an instruction, including its context.
- In exceptional circumstances, such as a change in security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under very unusual non-repeating pathological cases the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.

See also *Non-invasive behavior* on page D6-1824.

## H7.1.5 Sample-based Profiling and security

Sample-based Profiling is a non-invasive external debug component, controlled by an IMPLEMENTATION DEFINED authentication interface. Sample-based Profiling is prohibited unless both:

- Allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`
- Any one of:
  - Executing in Non-secure state.
  - EL3 is not implemented.
  - EL3 is implemented, executing in Secure state, and allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.
  - EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0 in Secure state, and `SDER32_EL3.SUNIDEN == 1`.

The state of IMPLEMENTATION DEFINED authentication interface is visible through `DBGAUTHSTATUS_EL1`.

See also [Appendix B Recommended External Debug Interface](#).

## H7.1.6 Pseudocode details of Sample-based Profiling

`PCSample()` records a PC sample for the EDPCSR and associated registers.

```
type PCSample is (
    boolean valid,
    bits(64) pc,
    bits(2) el,
    bit rw,
    bit ns,
    bits(32) contextidr,
    bits(8) vmid
)

PCSample pc_sample;
// CreatePCSample()
// =====

CreatePCSample()
// In a simple sequential execution of the program, CreatePCSample is executed each time the PE
// executes an instruction that can be sampled. An implementation is not constrained such that
// reads of EDPCSRlo return the current values of PC, etc.
enabled = (if IsSecure() then ExternalSecureNoninvasiveDebugEnabled()
           else ExternalNoninvasiveDebugEnabled());

pc_sample.valid = enabled && !Halted();
pc_sample.pc = ThisInstrAddr();
pc_sample.el = PSTATE.EL;
pc_sample.rw = if UsingAArch32() then '0' else '1';
pc_sample.ns = if IsSecure() then '0' else '1';
pc_sample.contextidr = CONTEXTIDR_GEN[];
pc_sample.vmid = VTTBR_EL2.VMID;

return;

// EDPCSRlo[] (read)
// =====

bits(32) EDPCSRlo[]

if pc_sample.valid then
    sample = pc_sample.pc<31:0>;
    EDPCSRhi = (if pc_sample.rw == '0' then Zeros(32) else pc_sample.pc<63:32>);
    EDCIDSR = pc_sample.contextidr;
    EDVIDSR.VMID = (if HaveEL(EL2) && pc_sample.ns == '1' && pc_sample.el IN {EL1,EL0}
                   then pc_sample.vmid else Zeros(8));
```

```
EDVIDSR.NS = pc_sample.ns;
EDVIDSR.E2 = (if pc_sample.el == EL2 then '1' else '0');
EDVIDSR.E3 = (if pc_sample.el == EL3 then '1' else '0') AND pc_sample.rw;
// The conditions for setting HV are not specified if PCSRhi is zero.
// An example implementation may be "pc_sample.rw".
EDVIDSR.HV = (if !IsZero(EDPCSRhi) then '1' else bit IMPLEMENTATION_DEFINED "0 or 1");
else
    sample = Ones(32);
    EDPCSRhi = bits(32) UNKNOWN;
    EDCIDSR = bits(32) UNKNOWN;
    EDVIDSR = (bits(4) UNKNOWN):Zeros(20):(bits(8) UNKNOWN);

return sample;
```

# Chapter H8

## About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- *Relationship between external debug and System registers* on page H8-4442.
- *Supported access sizes* on page H8-4444.
- *Synchronization of changes to the external debug registers* on page H8-4445.
- *Memory-mapped accesses to the external debug interface* on page H8-4449.
- *External debug interface register access permissions* on page H8-4451.
- *External debug interface registers* on page H8-4456.
- *Cross-trigger interface registers* on page H8-4461.
- *Reset and debug* on page H8-4463.
- *External debug register resets* on page H8-4465.

———— **Note** —————

Where necessary [Table J-1 on page AppxJ-5088](#) disambiguates the general register references used in this chapter.

## H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and system registers. Where no relationship exists, the registers are not listed.

**Table H8-1 Equivalence between external debug and System registers**

External debug register	System register		Notes

a. This is a word of a 64-bit register.

In addition:

- [EDSCR](#).{TXfull, RXfull} are read-only aliases for [DCCSR](#).{TXfull, RXfull}.
- [EDPRCR](#).CORENPDRQ is a read/write alias for [DBGPRCR](#).CORENPDRQ.
- [EDPRSR](#).OSLK is a read-only alias for [OSLSR](#).OSLK.

- [EDPRSR.DLK](#) is a read-only function of [OSLSR.DLK](#).

## H8.2 Supported access sizes

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitor registers, and CTI registers, implementations must support:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations.

———— **Note** ————

This means that a system implementing the debug registers using a 32-bit bus, such as an AMBA™ APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte.
- Halfword.
- Unaligned word. These accesses are not word single-copy atomic.
- Unaligned doubleword. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusive accesses.

For each of these access types, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN data.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIV5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

See [Access sizes for memory-mapped accesses on page H8-4450](#).

## H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- [Synchronization and debug exceptions on page D2-1647.](#)
- [Synchronization and Halting debug events on page H3-4384.](#)
- [Synchronization of DCC and ITR accesses on page H4-4398.](#)

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to system registers as direct reads, direct writes, indirect reads, and indirect writes.

### ———— **Note** —————

[Synchronization requirements for system registers on page D8-1866](#) defines direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of `DBGBCR<n>_EL1`, `DBGBVR<n>_EL1`, `DBGWCR<n>_EL1`, and `DBGWVR<n>_EL1`, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

[Synchronization of DCC and ITR accesses on page H4-4398](#) describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See [Synchronization and the authentication interface on page H8-4446](#).

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible only in the external debug interface.

Some registers are guaranteed to be observable to all observers in finite time, without explicit synchronization. For more information, see [Synchronization requirements for system registers on page D8-1866](#). Otherwise, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a context synchronization operation.
- The context synchronization operation was executed after the write completed.

The order and synchronization of direct reads and direct writes of system registers is defined by [Synchronization requirements for system registers on page D8-1866](#).

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

### ———— **Note** —————

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, a write is guaranteed to complete before the APB-AP allows a second APB transaction to complete.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the context synchronization operation, and relying on the memory ordering rules provided by the memory model.

External reads and external writes complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order by:

- Marking the memory as Device-nGnRnE or Device-nGnRE.
- Using the appropriate memory barriers.
- Some guaranteed property of the connection between the PE and the external agent.

———— **Note** —————

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an ISB instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an ISB instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to [EDITR](#).

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, [DBGBCR<n>\\_EL1](#) and [DBGBVR<n>\\_EL1](#).
- The watchpoint registers, [DBGWCR<n>\\_EL1](#) and [DBGWVR<n>\\_EL1](#).

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example [EDSCR](#), or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

———— **Note** —————

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in [Examples of the synchronization of changes to the external debug registers](#) on page H8-4447.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and system register access include [DBGCLAIMSET\\_EL1](#), [DBGCLAIMCLR\\_EL1](#), [PMCR\\_ELO](#).{C,P}, [PMOVSET\\_ELO](#), [PMOVCLR\\_ELO](#), [PMCNTENSET\\_ELO](#), [PMCNTENCLR\\_ELO](#), [PMINTENSET\\_EL1](#), [PMINTENCLR\\_EL1](#), and [PMSWINC\\_ELO](#). This last register is OPTIONAL and deprecated in the external debug interface.

### H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the Authentication Status registers by the master of the authentication interface. For each of these Authentication Status registers, it is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external debug interface read of the register only after a context synchronization operation or in finite time.

For [DBGAUTHSTATUS\\_EL1](#), a change on the authentication interface is guaranteed to be observable to a system register read of [DBGAUTHSTATUS\\_EL1](#) only after a context synchronization operation.

## H8.3.2 Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2, and Example H8-3 show the synchronization of changes to the external debug registers.

### Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

---

Initially `DBGBVR<n>_EL1` is `0x8000` and `DBGBCR<n>_EL1` is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to `DBGBCR<n>_EL1`, disabling the breakpoint.
2. `0x9000` is written to `DBGBVR<n>_EL1[31:0]`.
3. `0x0061` is written to `DBGBCR<n>_EL1`, enabling a breakpoint on the halfword at address `0x9000`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8000` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
  - If any of the `DBGBCR<n>_EL1` or `DBGWCR<n>_EL1` fields are modified at the same time as updating the address.
- 

### Example H8-2 Simultaneous accesses to DTR registers

---

Initially `EDSCR.{TXfull, TXU, ERR}` are 0. Then:

- `0x0DCCDA7A` is directly written to `DBGDTRTX_EL0` by an MSR instruction.
- `DBGDTRTX_EL0` is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to `DBGDTRTX_EL0` is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` clears `EDSCR.TXfull` to 0.
- `EDSCR.{TXU, ERR}` are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of `DBGDTRTX_EL0` by the external debug interface is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` causes an underrun and as a result `EDSCR.{TXU, ERR}` are both set to 1.
  - The external debug interface returns an UNKNOWN value.
  - Writing `0x0DCCDA7A` to `DBGDTRTX_EL0` sets `DTRTX` to `0x0DCCDA7A` and `EDSCR.TXfull` to 1.
- 

### Example H8-3 Simultaneous writes to CLAIM registers

---

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to `DBGCLAIMSET_EL1` by a direct write, followed by an explicit context synchronization operation.
- `0x02` is written to `DBGCLAIMSET_EL1` by an external write.

These events might happen at the same time and in either order.

After this:

- `DBGCLAIMCLR_EL1` is read by a direct read.

- [DBGCLAIMCLR\\_EL1](#) is read by an external read.

In this case, a direct read can return either 0x01 or 0x03, and the external read can return either 0x02 or 0x03.

The only permitted final result for the CLAIM tags is the value 0x03, because this would be the result regardless of whether 0x01 or 0x02 is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See [Synchronization requirements for system registers on page D8-1866](#).

It is not possible for a direct read to return 0x01 and the external read to return 0x02, because the writes to [DBGCLAIMCLR\\_EL1](#) are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value 0x03, and then, at the same time, two writes occur:

- 0x04 is written to [DBGCLAIMSET\\_EL1](#) by a direct write, followed by an explicit context synchronization operation.
- 0x01 is written to [DBGCLAIMCLR\\_EL1](#) by an external write.

In this case only permitted final result for the CLAIM tags is the value 0x06.

---

## H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component. The Software Locks are controlled by [EDLSR](#) and [EDLAR](#), [PMLSR](#) and [PMLAR](#), and [CTILSR](#) and [CTILAR](#). See *Management registers and CoreSight compliance on page AppxB-4782*.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

### ———— Note —————

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when [OSLSR.OSLK == 1](#), meaning that the OS Lock is locked.

### H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If memory-mapped accesses are made through an ADiv5 interface, the Debug Access Port can block the access using [DBGSWENABLE](#). This is outside the scope of the ARMv8-A architecture. See *ARM® Debug Interface Architecture Specification ADiv5.0 to ADiv5.2*.

#### Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and [EDLSR.SLK](#), [PMLSR.SLK](#), or [CTILSR.SLK](#) is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only (RO).
  - Write-only (WO) registers become write-ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
- Writes to [EDLAR](#), [PMLAR](#), and [CTILAR](#) are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if [EDLSR.SLK](#) is set to 1:

- [EDSCR](#).{TXfull, TXU, ERR} are unchanged by a memory-mapped read from [DBGDTRTX\\_ELO](#).
- [EDSCR](#).{RXfull, RXO, ERR} are unchanged by a memory-mapped write to [DBGDTRRX\\_ELO](#) that is ignored.
- [EDSCR](#).{ITE, ITO, ERR} are unchanged by a memory-mapped write to [EDITR](#) that is ignored.
- [OSLSR.OSLK](#) is unchanged by a memory-mapped write to [OSLAR\\_EL1](#) that is ignored.
- [EDPCSR](#)[63:32], [EDCIDS](#)R, and [EDVIDSR](#) are unchanged by a memory-mapped read from [EDPCSR](#)[31:0].

- [EDPRSR](#).{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from [EDPRSR](#).
- [EDPRSR](#).SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to [DBGCLAIMSET\\_EL1](#) and [DBGCLAIMCLR\\_EL1](#) which are ignored.

Similarly, if [PMLSR](#).SLK is set to 1, then [EDPRSR](#).SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

### Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:

- A synchronous external Data Abort.
- A System Error interrupt.

## H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in [Synchronization of changes to the external debug registers on page H8-4445](#).

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

## H8.4.3 Access sizes for memory-mapped accesses

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory accessed, determine the size of the access made by an instruction. [Example H8-4](#) shows this.

### Example H8-4 Access sizes for memory-mapped accesses

---

Two Load Doubleword instructions made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

---

ARMv8 does not require the size of each element accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Any memory-mapped access to a debug register is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory-type and use only single register load and store instructions to create memory accesses that are supported by the peripheral. For more information, see [Memory types and attributes on page B2-89](#).

## H8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered-down or is in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`. The OS Lock is locked.
- `DoubleLockStatus() == TRUE`. The OS Double Lock is locked, that is, `EDPRSR.DLK == 1`.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see [External debug interface register access permissions summary](#) on page H8-4453.

———— **Note** —————

`OSLSR.OSLK` is visible through `EDPRSR`.

### H8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.

———— **Note** —————

In this case `OSLAR_EL1` can be accessed, meaning an external debugger can override this lock.

- `DoubleLockStatus() == TRUE`. This means that the OS Double Lock is locked and `EDPRSR.DLK == 1`. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

See also [Debug registers to save over powerdown](#) on page H6-4430.

The following pseudocode outlines the `AllowExternalAccess()` function.

```
// AllowExternalAccess()
// =====

boolean AllowExternalAccess()
    return !DoubleLockStatus() && OSLSR_EL1.OSLK == '0' && EDPRSR.PU == '1';
```

### H8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then `SDCR` provides additional external access disable controls for those registers if Secure external invasive debugging is disabled.

The disable applies to:

- [DBGBVR<n>\\_EL1, Debug Breakpoint Value Registers, n = 0 - 15](#) on page H9-4474.
- [DBGBCR<n>\\_EL1, Debug Breakpoint Control Registers, n = 0 - 15](#) on page H9-4471.
- [DBGWVR<n>\\_EL1, Debug Watchpoint Value Registers, n = 0 - 15](#) on page H9-4484.
- [DBGWCR<n>\\_EL1, Debug Watchpoint Control Registers, n = 0 - 15](#) on page H9-4481.

The external debug interface cannot access these registers if either:

- External debugging is not enabled. `ExternalInvasiveDebugEnabled() == FALSE`.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled() == FALSE`, and any of the following:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and `SDCR.EDAD == 1`.

The following pseudocode outlines the `AllowExternalDebugAccess()` function.

```
// AllowExternalDebugAccess()
// =====
// Returns the status of EDPRSR.EDAD.

boolean AllowExternalDebugAccess()
// The access may also be subject to OS lock, power-down, etc.
if AllowExternalAccess() && ExternalInvasiveDebugEnabled() then
    if ExternalSecureInvasiveDebugEnabled() then
        return TRUE;
    elseif HaveEL(EL3) then
        return (if ELUsingAArch32(EL3) then SDCR.EDAD else MDCR_EL3.EDAD) == '0';
    else
        return !IsSecure();
else
    return FALSE;
```

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and `SDCR` provide similar external access disable controls for those registers.

The external debug interface cannot access the Performance Monitor registers if either:

- External non-invasive debug is not enabled. `ExternalNoninvasiveDebugEnabled() == FALSE`.
- Secure external non-invasive debugging is not enabled, `ExternalSecureNoninvasiveDebugEnabled() == FALSE`, and any of:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and `SDCR.EPMAD == 1`.

The following pseudocode outlines the `AllowExternalPMUAccess()` function.

```
// AllowExternalPMUAccess()
// =====
// Returns the status of EDPRSR.EPMAD.

boolean AllowExternalPMUAccess()
// The access may also be subject to OS lock, power-down, etc.
if AllowExternalAccess() && ExternalNoninvasiveDebugEnabled() then
    if ExternalSecureNoninvasiveDebugEnabled() then
        return TRUE;
    elseif HaveEL(EL3) then
        return (if ELUsingAArch32(EL3) then SDCR.EPMAD else MDCR_EL3.EPMAD) == '0';
    else
        return !IsSecure();
else
    return FALSE;
```

———— **Note** —————

- ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- ARMv8-A does not provide the equivalent control over access to Trace extension registers.

### H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIV5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in [EDPRSR](#) is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess() == FALSE`, [EDPRSR.SDAD](#) is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccess() == FALSE`, [EDPRSR.SPMAD](#) is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses on page H8-4449](#).

If no error is returned, or the error is returned because of a higher priority error condition, the flag in [EDPRSR](#) is unchanged.

See also [Behavior of a not permitted memory-mapped access on page H8-4450](#).

For more information, see *ARM® Debug Interface Architecture Specification*.

### H8.5.4 Trapping software access to debug registers

When [EDSCR.TDA](#) == 1, software access to the breakpoint and watchpoint registers generate a Halting debug event and entry to Debug state. For more information see [Software Access debug event on page H3-4383](#).

### H8.5.5 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see [implementation defined registers](#).
- OPTIONAL registers for CoreSight compliance, see [optional CoreSight management registers](#).
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see [Reserved and unallocated registers on page H8-4454](#).

For all other external debug interface, CTI, and Performance Monitor registers, [Table H8-3 on page H8-4459](#), [Table H8-4 on page H8-4461](#) and [Table I3-2 on page I3-4696](#), show the response of the PE to accesses by the external debug interface.

### H8.5.6 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see [Register access permissions for memory-mapped accesses on page H8-4449](#).

### H8.5.7 OPTIONAL CoreSight management registers

Compliance with CoreSight architecture requires additional registers in the range 0xF00 - 0xFFC that are always accessible. See [Management registers and CoreSight compliance on page AppxB-4782](#).

## H8.5.8 Reserved and unallocated registers

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
  - OPTIONAL features that are not implemented.
  - Breakpoints and watchpoints that are not implemented.
  - Performance Monitors counters that are not implemented.
  - CTI triggers that are not implemented.

These accesses are reserved.

- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RES0. That is, they must return zero on reads and ignore writes.

### ———— Note ————

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range 0xF00 - 0xFFC. See [Management register access permissions on page AppxB-4783](#).
- All unallocated Processor ID Registers. That is, unallocated debug registers in the range 0xD00 - 0xDFC.
- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:
  - Off** The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.
  - DLK** DoubleLockStatus() == TRUE. The OS Double Lock is locked, that is, [EDPRSR.DLK](#) == 1.
  - OSLK** [OSLSR.OSLK](#) == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges 0x400 - 0x4FC and 0x800 - 0x8FC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
  - EDAD** AllowExternalDebugAccess() == FALSE. External debug is disabled.

### ———— Note ————

See also [Behavior of a not permitted access on page H8-4453](#).

4. In addition, for reserved Performance Monitors registers in the address ranges 0x000 - 0x0FC and 0x400 - 0x47C, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
  - EPMAD** AllowExternalPMUAccess() == FALSE. External Performance Monitor access is disabled.

———— **Note** —————

See also *Behavior of a not permitted access* on page H8-4453.

---

## H8.6 External debug interface registers

The external debug interface register map is described by:

- [Performance Monitors memory-mapped register views](#) on page I3-4694.
- [Cross-trigger interface registers](#) on page H8-4461.
- [Table H8-2](#).

**Table H8-2 External debug interface register map**

a. Only if the OPTIONAL Sample-based Profiling extension is implemented.

- b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See [Supported access sizes on page H8-4444](#). Software must ensure a breakpoint or watchpoint is disabled before altering the value register.
- c. Implemented breakpoints and watchpoints only. *n* is the breakpoint or the watchpoint number.

———— **Note** ————

All other locations are reserved.

[Table H8-3 on page H8-4459](#) shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

**Domain** This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

**Conditions** This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

**Off** [EDPRSR.PU == 0](#). The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

———— **Note** ————

If debug power is off, then all external debug interface accesses return an error.

**DLK** [DoubleLockStatus\(\) == TRUE](#). The OS Double Lock is locked, that is, [EDPRSR.DLK == 1](#).

**OSLK** [OSLSR.OSLK == 1](#). The OS Lock is locked.

**EDAD** [AllowExternalDebugAccess\(\) == FALSE](#). External debug access is disabled. See also [Behavior of a not permitted access on page H8-4453](#).

**EPMAD** [AllowExternalPMUAccess\(\) == FALSE](#). Access to the external Performance Monitors is disabled. See also [Behavior of a not permitted access on page H8-4453](#).

**Default** This provides the default access permissions, if there are no conditions that prevent access to the register.

**SLK** This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See [Register access permissions for memory-mapped accesses on page H8-4449](#). For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

**RO** This means that the register or field is read-only.

**RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

**RC** This means that the bit clears to 0 after a read.

**(SE)** This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

**WO** This means that the register or field is write-only.

**WI** This means that the register or field ignores writes.

**IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-4449](#).

**Table H8-3 Access permissions for the external debug interface registers**

- a. Only if the Sample-based profiling extension is implemented.
- b. Some control bits are in the Core power domain. These bits ignore writes when Core power domain registers cannot be accessed as shown.
- c. Some status bits are fetched from the Core power domain. These bits read UNKNOWN when Core power domain registers cannot be accessed as shown.
- d. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.

For the reset values for the external debug interface registers, see [Table H8-6 on page H8-4465](#).

## H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block per PE or cluster of virtual PEs.

If the CTI of a PE does not implement the [CTIDEVAFF0](#) or [CTIDEVAFF1](#) registers it must be located 64KB above the debug registers in the external debug interface.

[Table H8-4](#) shows the CTI register map.

**Table H8-4 Cross-trigger interface map**

0xFC8	<a href="#">CTIDEVID</a>	Debug	-	-	-	-	RO	RO

a. Implemented triggers only (including triggers that are not connected). *n* is the trigger number.

For the reset values of the CTI registers, see [Table H8-7 on page H8-4466](#).

## H8.8 Reset and debug

All registers in the Core power domain are reset either by a Warm reset or a Cold reset, as described in [Reset on page D1-1426](#), including external debug logic registers.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H8-1 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

**Figure H8-1 Power and reset domains**

For more information about power domains and power states, see [Power domains and debug on page H6-4425](#).

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

———— **Note** ————

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

**CPUPORESET** is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also [Emulating low-power states on page H6-4428](#) and [EDPRSR, External Debug Processor Status Register on page H9-4523](#).

### H8.8.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is **CONSTRAINED UNPREDICTABLE** whether the register or register field takes the reset value or the value written. The reset value might be **UNKNOWN**.
  - Otherwise the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned is **UNKNOWN**.

- Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

## H8.9 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

Table H8-6 and Table H8-7 on page H8-4466 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see *Management register resets on page AppxB-4787* and *Power domains and Performance Monitors registers reset on page I3-4697*.

### ———— Note —————

By reference to Figure H8-1 on page H8-4463 the power domain can be deduced from the reset domain. Table B-7 on page AppxB-4787 also shows reset power domains.

Table H8-6 and Table H8-7 on page H8-4466 do not include:

- Read-only identification registers, such as Processor ID Registers and **PMCFGR**, that have a fixed value from reset.
- Read-only status registers, such as **EDSCR.RW**, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as **EDRCR**, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and **EDPRCR.CORENPDRQ**, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

**Table H8-6 Summary of external debug register resets, debug registers**

Register	Reset domain	Field	Value	Description
EDESR	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDECR	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields

**Table H8-6 Summary of external debug register resets, debug registers (continued)**

Register	Reset domain	Field	Value	Description
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
EDECCR	Cold	NSE[2:1]	0b00	Coarse-grained Non-secure exception catch
		SE[3,1]	0b00	Coarse-grained Secure exception catch
EDPCSR	Cold	-	-	All fields
EDCDSR	Cold	-	-	All fields
EDVIDSR	Cold	-	-	All fields
EDPRCR	External debug	COREPURQ	0	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

Table H8-7 shows the reset values for the CTI registers

**Table H8-7 Summary of external debug register resets, CTI registers**

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields

# Chapter H9

## External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following items:

- [Introduction on page H9-4468](#)
- [Debug registers on page H9-4469](#)
- [Cross-Trigger Interface registers on page H9-4554](#)

## H9.1 Introduction

The following sections describe the registers that are accessible through the external debug interface:

- [Debug registers on page H9-4469.](#)
- [Cross-Trigger Interface registers on page H9-4554.](#)

#### SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Non-secure.
- 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

#### NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Secure.
- 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

#### NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the processor is Secure.
- 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

### Accessing the DBGAUTHSTATUS\_EL1:

DBGAUTHSTATUS\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFB8

## H9.2.2 DBGBCR<n>\_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>\_EL1 characteristics are:

### Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register [DBGBVR<n>\\_EL1](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

### Configurations

DBGBCR<n>\_EL1 is architecturally mapped to AArch64 register [DBGBCR<n>\\_EL1](#).

DBGBCR<n>\_EL1 is architecturally mapped to AArch32 register [DBGBCR<n>](#).

DBGBCR<n>\_EL1 is in the Core power domain.

### Attributes

DBGBCR<n>\_EL1 is a 32-bit register.

The DBGBCR<n>\_EL1 bit assignments are:

### Bits [31:24]

Reserved, RES0.

### BT, bits [23:20]

Breakpoint Type. Possible values are:

0000	Unlinked instruction address match.
0001	Linked instruction address match.
0010	Unlinked context ID match.
0011	Linked context ID match
0100	Unlinked instruction address mismatch.
0101	Linked instruction address mismatch.
1000	Unlinked VMID match.
1001	Linked VMID match.
1010	Unlinked VMID and context ID match.
1011	Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.
  - 000 Match address. `DBGVVR<n>_EL1` is the address of an instruction.
  - 010 Mismatch address. Behaves as type 0b000 if in an AArch64 translation, or if halting debug-mode is enabled and halting is allowed. Otherwise, `DBGVVR<n>_EL1` is the address of an instruction to be stepped.
  - 001 Match context ID. `DBGVVR<n>_EL1`[31:0] is a context ID.
  - 100 Match VMID. `DBGVVR<n>_EL1`[39:32] is a VMID.
  - 101 Match VMID and context ID. `DBGVVR<n>_EL1`[31:0] is a context ID, and `DBGVVR<n>_EL1`[39:32] is a VMID.
- BT[0]: Enable linking.

If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

#### LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

#### SSC, bits [15:14]

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

#### HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

#### Bits [12:9]

Reserved, RES0.

#### BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0b0011 and 0b1100 are only supported if AArch32 is supported at any exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state:

BAS	Match instruction at	Constraint for debuggers
0b0011	<code>DBGVVR&lt;n&gt;_EL1</code>	Use for T32 and T32EE instructions.
0b1100	<code>DBGVVR&lt;n&gt;_EL1+2</code>	Use for T32 and T32EE instructions.
0b1111	<code>DBGVVR&lt;n&gt;_EL1</code>	Use for A64 and A32 instructions.

0b0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

BAS	Step instruction at	Constraint for debuggers
0b0000	-	Use for a match anywhere breakpoint.
0b0011	DBGBVR<n>_EL1	Use for stepping T32 and T32EE instructions.
0b1100	DBGBVR<n>_EL1+2	Use for stepping T32 and T32EE instructions.
0b1111	DBGBVR<n>_EL1	Use for stepping A64 and A32 instructions.

For Context matching breakpoints, this field is RES1 and ignored.

#### Bits [4:3]

Reserved, RES0.

#### PMC, bits [2:1]

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

#### E, bit [0]

Enable breakpoint [DBGBVR<n>\\_EL1](#). Possible values are:

- 0 Breakpoint disabled.
- 1 Breakpoint enabled.

#### Accessing the [DBGBCR<n>\\_EL1](#):

[DBGBCR<n>\\_EL1](#) can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x408 + 16n

### H9.2.3 DBGBVR<n>\_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>\_EL1 characteristics are:

#### Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register [DBGBCR<n>\\_EL1](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

DBGBVR<n>\_EL1 is architecturally mapped to AArch64 register [DBGBVR<n>\\_EL1](#).

DBGBVR<n>\_EL1[31:0] is architecturally mapped to AArch32 register [DBGBVR<n>](#).

DBGBVR<n>\_EL1[63:32] is architecturally mapped to AArch32 register [DBGBXVR<n>](#).

DBGBVR<n>\_EL1 is in the Core power domain.

#### Attributes

DBGBVR<n>\_EL1 is a 64-bit register.

The DBGBVR<n>\_EL1 bit assignments are:

#### When [DBGBCR<n>\\_EL1.BT==0b0x0x](#):

#### RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

#### VA, bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime, this field contains bits[48:2] of the address for comparison.

If the address is being matched in an AArch32 stage 1 translation regime, the first 16 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

#### Bits [1:0]

Reserved, RES0.

**When  $DBGBCR\langle n \rangle\_EL1.BT == 0b0x1x$ :**

**Bits [63:32]**

Reserved, RES0.

**ContextID, bits [31:0]**

Context ID value for comparison.

**When  $DBGBCR\langle n \rangle\_EL1.BT == 0b1x0x$  and EL2 implemented:**

**Bits [63:40]**

Reserved, RES0.

**VMID, bits [39:32]**

VMID value for comparison.

**Bits [31:0]**

Reserved, RES0.

**When  $DBGBCR\langle n \rangle\_EL1.BT == 0x1x1x$  and EL2 implemented:**

**Bits [63:40]**

Reserved, RES0.

**VMID, bits [39:32]**

VMID value for comparison.

**ContextID, bits [31:0]**

Context ID value for comparison.

### Accessing the DBGBVR<n>\_EL1:

DBGBVR<n>\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
Debug	0x400 + 16n

---

DBGBVR<n>\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
Debug	0x404 + 16n

---

## H9.2.4 DBGCLAIMCLR\_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR\_EL1 characteristics are:

### Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

### Configurations

DBGCLAIMCLR\_EL1 is architecturally mapped to AArch64 register [DBGCLAIMCLR\\_EL1](#).  
DBGCLAIMCLR\_EL1 is architecturally mapped to AArch32 register [DBGCLAIMCLR](#).  
DBGCLAIMCLR\_EL1 is in the Core power domain.

### Attributes

DBGCLAIMCLR\_EL1 is a 32-bit register.

The DBGCLAIMCLR\_EL1 bit assignments are:

### Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

### CLAIM, bits [7:0]

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

### Accessing the DBGCLAIMCLR\_EL1:

DBGCLAIMCLR\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA4

## H9.2.5 DBGCLAIMSET\_EL1, Debug Claim Tag Set register

The DBGCLAIMSET\_EL1 characteristics are:

### Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

### Configurations

DBGCLAIMSET\_EL1 is architecturally mapped to AArch64 register [DBGCLAIMSET\\_EL1](#).

DBGCLAIMSET\_EL1 is architecturally mapped to AArch32 register [DBGCLAIMSET](#).

DBGCLAIMSET\_EL1 is in the Core power domain.

### Attributes

DBGCLAIMSET\_EL1 is a 32-bit register.

The DBGCLAIMSET\_EL1 bit assignments are:

### Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

### CLAIM, bits [7:0]

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

### Accessing the DBGCLAIMSET\_EL1:

DBGCLAIMSET\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA0

## H9.2.6 DBGDTRRX\_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX\_EL0 characteristics are:

### Purpose

Transfers 32 bits of data from an external host to the processor.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

### Configurations

DBGDTRRX\_EL0 is architecturally mapped to AArch64 register [DBGDTRRX\\_EL0](#).  
DBGDTRRX\_EL0 is architecturally mapped to AArch32 register [DBGDTRRXint](#).  
DBGDTRRX\_EL0 is in the Core power domain.

### Attributes

DBGDTRRX\_EL0 is a 32-bit register.

The DBGDTRRX\_EL0 bit assignments are:

### Bits [31:0]

Update DTRRX. Writes to this register update the value in DTRRX and set RXfull to 1.  
Reads of this register return the last value written to DTRRX and do not change RXfull.

### Accessing the DBGDTRRX\_EL0:

DBGDTRRX\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x080

## H9.2.7 DBGDTRTX\_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX\_EL0 characteristics are:

### Purpose

Transfers 32 bits of data from the processor to an external host.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

### Configurations

DBGDTRTX\_EL0 is architecturally mapped to AArch64 register [DBGDTRTX\\_EL0](#).  
DBGDTRTX\_EL0 is architecturally mapped to AArch32 register [DBGDTRTXint](#).  
DBGDTRTX\_EL0 is in the Core power domain.

### Attributes

DBGDTRTX\_EL0 is a 32-bit register.

The DBGDTRTX\_EL0 bit assignments are:

### Bits [31:0]

Return DTRTX. Reads of this register return the value in DTRTX and clear TXfull to 0.  
Writes of this register update the value in DTRTX and do not change TXfull.

### Accessing the DBGDTRTX\_EL0:

DBGDTRTX\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x08C

## H9.2.8 DBGWCR<n>\_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>\_EL1 characteristics are:

### Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register [DBGWVR<n>\\_EL1](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

### Configurations

DBGWCR<n>\_EL1 is architecturally mapped to AArch64 register [DBGWCR<n>\\_EL1](#).

DBGWCR<n>\_EL1 is architecturally mapped to AArch32 register [DBGWCR<n>](#).

DBGWCR<n>\_EL1 is in the Core power domain.

### Attributes

DBGWCR<n>\_EL1 is a 32-bit register.

The DBGWCR<n>\_EL1 bit assignments are:

### Bits [31:29]

Reserved, RES0.

### MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

00000 No mask.

00001 Reserved.

00010 Reserved.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0xFFFFFFFF mask for address).

### Bits [23:21]

Reserved, RES0.

### WT, bit [20]

Watchpoint type. Possible values are:

0 Unlinked data address match.

1 Linked data address match.

#### LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

#### SSC, bits [15:14]

Security state control. Determines the security states under which a watchpoint debug event for watchpoint *n* is generated. This field must be interpreted along with the HMC and PAC fields.

#### HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint *n* is generated. This field must be interpreted along with the SSC and PAC fields.

#### BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by `DBGWVR<n>_EL1` is being watched.

BAS	Description
xxxxxxx1	Match byte at <code>DBGWVR&lt;n&gt;_EL1</code>
xxxxxx1x	Match byte at <code>DBGWVR&lt;n&gt;_EL1+1</code>
xxxxx1xx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+2</code>
xxxx1xxx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+3</code>

In cases where `DBGWVR<n>_EL1` addresses a double-word:

BAS	Description, if <code>DBGWVR&lt;n&gt;_EL1[2] == 0</code>
xxx1xxxx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+4</code>
xx1xxxxx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+5</code>
x1xxxxxx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+6</code>
1xxxxxxx	Match byte at <code>DBGWVR&lt;n&gt;_EL1+7</code>

If `DBGWVR<n>_EL1[2] == 1`, only `BAS[3:0]` is used. ARM deprecates setting `DBGWVR<n>_EL1 == 1`.

The valid values for BAS are `0b0000000`, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

#### LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

**PAC, bits [2:1]**

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

**E, bit [0]**

Enable watchpoint n. Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

**Accessing the DBGWCR<n>\_EL1:**

DBGWCR<n>\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x808 + 16n

## H9.2.9 DBGWVR<n>\_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>\_EL1 characteristics are:

### Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>\\_EL1](#), where n is 0 to 15.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

DBGWVR<n>\_EL1 is architecturally mapped to AArch64 register [DBGWVR<n>\\_EL1](#).

DBGWVR<n>\_EL1[31:0] is architecturally mapped to AArch32 register [DBGWVR<n>](#).

DBGWVR<n>\_EL1 is in the Core power domain.

### Attributes

DBGWVR<n>\_EL1 is a 64-bit register.

The DBGWVR<n>\_EL1 bit assignments are:

### RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

### VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting [DBGWVR<n>\\_EL1\[2\] == 1](#).

### Bits [1:0]

Reserved, RES0.

### Accessing the DBGWVR<n>\_EL1:

DBGWVR<n>\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x800 + 16n

DBGWVR<n>\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x804 + 16n

## H9.2.10 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

### Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
IMP DEF	IMP DEF	IMP DEF	RO	RW

### Configurations

It is IMPLEMENTATION DEFINED whether EDACR is in the Core power domain or in the Debug power domain.

### Attributes

EDACR is a 32-bit register.

The EDACR bit assignments are:

### Accessing the EDACR:

EDACR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x094

## H9.2.11 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

RO

---

### Configurations

EDCIDR0 is in the Debug power domain.  
EDCIDR0 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

EDCIDR0 is a 32-bit register.

The EDCIDR0 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### PRMBL\_0, bits [7:0]

Preamble. Must read as 0x00.

### Accessing the EDCIDR0:

EDCIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

Debug	0xFF0
-------	-------

---

## H9.2.12 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

EDCIDR1 is in the Debug power domain.  
EDCIDR1 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

EDCIDR1 is a 32-bit register.

The EDCIDR1 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

### PRMBL\_1, bits [3:0]

Preamble. RAZ.

### Accessing the EDCIDR1:

EDCIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xFF4
-------	-------

---

### H9.2.13 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

#### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RO

#### Configurations

EDCIDR2 is in the Debug power domain.  
EDCIDR2 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

#### Attributes

EDCIDR2 is a 32-bit register.

The EDCIDR2 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_2, bits [7:0]

Preamble. Must read as 0x05.

#### Accessing the EDCIDR2:

EDCIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFF8

## H9.2.14 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

EDCIDR3 is in the Debug power domain.  
EDCIDR3 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

EDCIDR3 is a 32-bit register.

The EDCIDR3 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### PRMBL\_3, bits [7:0]

Preamble. Must read as 0xB1.

### Accessing the EDCIDR3:

EDCIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFFC

## H9.2.15 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

### Purpose

Contains the sampled value of [CONTEXTIDR\\_EL1](#), captured on reading the low half of [EDPCSR](#).  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

### Configurations

EDCIDSR is in the Core power domain.

### Attributes

EDCIDSR is a 32-bit register.

The EDCIDSR bit assignments are:

### CONTEXTIDR, bits [31:0]

The sampled value of [CONTEXTIDR\\_EL1](#), captured on reading the low half of [EDPCSR](#).

If EL3 is implemented and using AArch32 then [CONTEXTIDR](#) is a Banked register, and EDCIDSR samples the current Banked copy of [CONTEXTIDR](#).

On Cold reset, the field reset value is architecturally UNKNOWN.

### Accessing the EDCIDSR:

EDCIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A4

## H9.2.16 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

### Purpose

Copy of the low half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

Default
---------

---

RO
----

---

### Configurations

EDDEVAFF0 is in the Debug power domain.

EDDEVAFF0 is optional to implement in the external register interface.

### Attributes

EDDEVAFF0 is a 32-bit register.

The EDDEVAFF0 bit assignments are:

### Bits [31:0]

[MPIDR\\_EL1](#) low half. Read-only copy of the low half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

### Accessing the EDDEVAFF0:

EDDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xFA8
-------	-------

---

## H9.2.17 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

### Purpose

Copy of the high half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Default
RO

### Configurations

EDDEVAFF1 is in the Debug power domain.

EDDEVAFF1 is optional to implement in the external register interface.

### Attributes

EDDEVAFF1 is a 32-bit register.

The EDDEVAFF1 bit assignments are:

### Bits [31:0]

[MPIDR\\_EL1](#) high half. Read-only copy of the high half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

### Accessing the EDDEVAFF1:

EDDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFAC

## H9.2.18 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

### Purpose

Identifies the programmers' model architecture of the external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

EDDEVARCH is in the Debug power domain.  
EDDEVARCH is optional to implement in the external register interface.

### Attributes

EDDEVARCH is a 32-bit register.

The EDDEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Defines the architecture of the component. For debug, this is ARM Limited.  
Bits [31:28] are the JEP 106 continuation code, 0x4.  
Bits [27:21] are the JEP 106 ID code, 0x3B.

### PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.  
This field is 1 in v8-A.

### REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.  
For debug, the revision defined by v8-A is 0x0.  
All other values are reserved.

### ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For debug:

- Bits [15:12] are the architecture version, 0x6.
- Bits [11:0] are the architecture part number, 0xA15.

This corresponds to debug architecture version v8-A.

**Accessing the EDDEVARCH:**

EDDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

---

<b>Component</b>	<b>Offset</b>
Debug	0xFBC

---

## H9.2.19 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

### Purpose

Provides extra information for external debuggers about features of the debug implementation.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

EDDEVID is in the Debug power domain.

### Attributes

EDDEVID is a 32-bit register.

The EDDEVID bit assignments are:

31	28 27	24 23	4 3	0
RES0	AuxRegs	RES0	PCSample	

### Bits [31:28]

Reserved, RES0.

### AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

0000 None supported.

0001 Support for External Debug Auxiliary Control Register, [EDACR](#).

All other values are reserved.

### Bits [23:4]

Reserved, RES0.

### PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43.  
Permitted values of this field in v8-A are:

0000 Architecture-defined form of Sample-based profiling not implemented.

0010 [EDPCSR](#) and [EDCIDS](#) are implemented (only permitted if EL3 and EL2 are not implemented).

0011 [EDPCSR](#), [EDCIDS](#), and [EDVIDSR](#) are implemented.

All other values are reserved.

### Accessing the EDDEVID:

EDDEVID can be accessed through the internal memory-mapped interface and the external debug interface:

---

<b>Component</b>	<b>Offset</b>
Debug	0xFC8

---

## H9.2.20 EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

### Purpose

Provides extra information for external debuggers about features of the debug implementation.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

EDDEVID1 is in the Debug power domain.

### Attributes

EDDEVID1 is a 32-bit register.

The EDDEVID1 bit assignments are:

### Bits [31:4]

Reserved, RES0.

### PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of [EDPCSR](#). Permitted values of this field in v8-A are:

0000 [EDPCSR](#) not implemented.

0010 [EDPCSR](#) implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

### Accessing the EDDEVID1:

EDDEVID1 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xFC4
-------	-------

---

## H9.2.21 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

### Purpose

Reserved for future descriptions of features of the debug implementation.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Default
RO

### Configurations

EDDEVID2 is in the Debug power domain.

### Attributes

EDDEVID2 is a 32-bit register.

The EDDEVID2 bit assignments are:

### Bits [31:0]

Reserved, RES0.

### Accessing the EDDEVID2:

EDDEVID2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFC0

## H9.2.22 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

### Purpose

Indicates to a debugger that this component is part of a processor's debug logic.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Default
RO

### Configurations

EDDEVTYPE is in the Debug power domain.  
EDDEVTYPE is optional to implement in the external register interface.

### Attributes

EDDEVTYPE is a 32-bit register.

The EDDEVTYPE bit assignments are:

### Bits [31:8]

Reserved, RES0.

### SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a processor component.

### MAJOR, bits [3:0]

Major type. Must read as 0x5 to indicate this is a debug logic component.

### Accessing the EDDEVTYPE:

EDDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFCC

## H9.2.23 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

### Purpose

Controls exception catch debug events.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

### Configurations

EDECCR is architecturally mapped to AArch64 register [OSECCR\\_EL1](#).

EDECCR is architecturally mapped to AArch32 register [DBGOSECCR](#).

EDECCR is in the Core power domain.

### Attributes

EDECCR is a 32-bit register.

The EDECCR bit assignments are:

### Bits [31:8]

Reserved, RES0.

### NSE, bits [7:4]

Coarse-grained Non-secure exception catch. Possible values of this field are:

0000 Exception catch debug event disabled for Non-secure exception levels.

0010 Exception catch debug event enabled for Non-secure EL1.

0100 Exception catch debug event enabled for Non-secure EL2.

0110 Exception catch debug event enabled for Non-secure EL1 and EL2.

All other values are reserved. Bits [7,4] are reserved, RES0.

On Cold reset, the field resets to 0.

### SE, bits [3:0]

Coarse-grained Secure exception catch. Possible values of this field are:

0000 Exception catch debug event disabled for Secure exception levels.

0010 Exception catch debug event enabled for Secure EL1.

1000 Exception catch debug event enabled for Secure EL3.

1010 Exception catch debug event enabled for Secure EL1 and EL3.

All other values are reserved. Bits [2,0] are reserved. RES0. Ignored if ExternalSecureInvasiveDebugEnabled() == FALSE.

On Cold reset, the field resets to 0.

### Accessing the EDECCR:

EDECCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x098

## H9.2.24 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

### Purpose

Controls Halting debug events.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

### Configurations

EDECR is in the Debug power domain.

### Attributes

EDECR is a 32-bit register.

The EDECR bit assignments are:

### Bits [31:3]

Reserved, RES0.

### SS, bit [2]

Halting step enable. Possible values of this field are:

0 Halting step debug event disabled.

1 Halting step debug event enabled.

If the value of EDECR.SS is changed when the processor is in Non-debug state, the resulting value of EDECR.SS is UNKNOWN.

On External debug reset, the field resets to 0.

### RCE, bit [1]

Reset catch enable. Possible values of this field are:

0 Reset catch debug event disabled.

1 Reset catch debug event enabled.

On External debug reset, the field resets to 0.

### OSUCE, bit [0]

OS unlock catch enabled. Possible values of this field are:

0 OS unlock catch debug event disabled.

1 OS unlock catch debug event enabled.

On External debug reset, the field resets to 0.

### Accessing the EDECR:

EDECR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x024

## H9.2.25 EDESR, External Debug Event Status Register

The EDESR characteristics are:

### Purpose

Indicates the status of internally pending Halting debug events.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	SLK	Default
Error	Error	RO	RW

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONstrained UNPREDICTABLE whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it may become pending again when the Core is powered back on and Cold reset.

### Configurations

EDESR is in the Core power domain.

### Attributes

EDESR is a 32-bit register.

The EDESR bit assignments are:

### Bits [31:3]

Reserved, RES0.

### SS, bit [2]

Halting step debug event pending. Possible values of this field are:

- 0 Reading this means that a Halting step debug event is not pending. Writing this means no action.
- 1 Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

On Warm reset, the field resets to 0.

### RC, bit [1]

Reset catch debug event pending. Possible values of this field are:

- 0 Reading this means that a Reset catch debug event is not pending. Writing this means no action.
- 1 Reading this means that a Reset catch debug event is pending. Writing this clears the pending Reset catch debug event.

On Warm reset, the field resets to 0.

**OSUC, bit [0]**

OS unlock debug event pending. Possible values of this field are:

- 0 Reading this means that an OS unlock catch debug event is not pending. Writing this means no action.
- 1 Reading this means that an OS unlock catch debug event is pending. Writing this clears the pending OS unlock catch debug event.

On Warm reset, the field resets to 0.

**Accessing the EDESR:**

EDESR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x020

## H9.2.26 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

### Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

### Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is in the Core power domain or in the Debug power domain.

EDITCTRL is optional to implement in the external register interface.

### Attributes

EDITCTRL is a 32-bit register.

The EDITCTRL bit assignments are:

### Bits [31:1]

Reserved, RES0.

### IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

### Accessing the EDITCTRL:

EDITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xF00

## H9.2.27 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

### Purpose

Used in Debug state for passing instructions to the processor for execution.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

If `EDSCR.ITE == 0` when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in normal mode that has not completed execution is **CONSTRAINED UNPREDICTABLE**, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

### Configurations

EDITR is in the Core power domain.

### Attributes

EDITR is a 32-bit register.

The EDITR bit assignments are:

### When in AArch32 state:

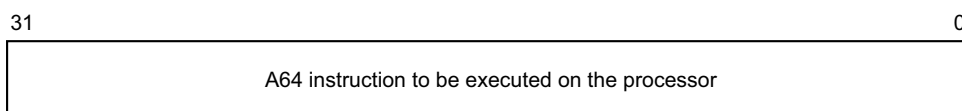

### T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the processor.

### T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the processor.

### When in AArch64 state:

**Bits [31:0]**

A64 instruction to be executed on the processor.

**Accessing the EDITR:**

EDITR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x084

## H9.2.28 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

### Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Default
WO

### Configurations

EDLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses EDLAR to set or clear the lock, and [EDLSR](#) to check the current status of the lock.

### Attributes

EDLAR is a 32-bit register.

The EDLAR bit assignments are:

### KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

### Accessing the EDLAR:

EDLAR can be accessed through the internal memory-mapped interface:

Component	Offset
Debug	0xFB0

## H9.2.29 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

### Purpose

Indicates the current status of the software lock for external debug registers.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

EDLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses [EDLAR](#) to set or clear the lock, and EDLSR to check the current status of the lock.

### Attributes

EDLSR is a 32-bit register.

The EDLSR bit assignments are:

### Bits [31:3]

Reserved, RES0.

### nTT, bit [2]

Not thirty-two bit access required. RAZ.

### SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

**SLI, bit [0]**

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

- 0 Software lock not implemented or not memory-mapped access.
- 1 Software lock implemented and memory-mapped access.

**Accessing the EDLSR:**

EDLSR can be accessed through the internal memory-mapped interface:

Component	Offset
Debug	0xFB4

### H9.2.30 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

#### Purpose

Holds a sampled instruction address value.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

#### Configurations

EDPCSR is in the Core power domain.

EDPCSR is optional to implement in the external register interface.

#### Attributes

EDPCSR is a 64-bit register.

The EDPCSR bit assignments are:

#### Bits [63:32]

PC Sample high word, EDPCSRhi. If `EDVIDSR.HV == 0` then this field is RAZ, otherwise bits [63:32] of the sampled PC.

On Cold reset, the field reset value is architecturally UNKNOWN.

#### Bits [31:0]

PC Sample low word, EDPCSRlo. Bits [31:0] of the sampled instruction address value. Reading EDPCSRlo has the side-effect of updating `EDCIDSR`, `EDVIDSR`, and `EDPCSRhi`. However:

- If the processor is in Debug state, or Sample-based profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF and `EDCIDSR`, `EDVIDSR`, and `EDPCSRhi` become UNKNOWN.
- If the processor is in Reset state, the sampled value is unknown and `EDCIDSR`, `EDVIDSR` and `EDPCSRhi` become UNKNOWN.
- If no instruction has been retired since the processor left Reset state, Debug state, or a state where Non-invasive debug is not permitted, the sampled value is UNKNOWN and `EDCIDSR`, `EDVIDSR`, and `EDPCSRhi` become UNKNOWN.
- For a read of EDPCSRlo from the memory-mapped interface, if `EDLSR.SLK == 1`, meaning the Software Lock is locked, then the access has no side-effects. That is, `EDCIDSR`, `EDVIDSR`, and `EDPCSRhi` are unchanged.

On Cold reset, the field reset value is architecturally UNKNOWN.

### Accessing the EDPCSR:

EDPCSR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A0

EDPCSR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0AC

### H9.2.31 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

#### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

RO

---

#### Configurations

EDPIDR0 is in the Debug power domain.  
EDPIDR0 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

#### Attributes

EDPIDR0 is a 32-bit register.

The EDPIDR0 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PART\_0, bits [7:0]

Part number, least significant byte.

#### Accessing the EDPIDR0:

EDPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

Debug	0xFE0
-------	-------

---

## H9.2.32 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

RO

---

### Configurations

EDPIDR1 is in the Debug power domain.  
EDPIDR1 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

EDPIDR1 is a 32-bit register.

The EDPIDR1 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### DES\_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

### PART\_1, bits [3:0]

Part number, most significant nibble.

### Accessing the EDPIDR1:

EDPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xFE4
-------	-------

---

### H9.2.33 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

#### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

#### Configurations

EDPIDR2 is in the Debug power domain.  
EDPIDR2 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

#### Attributes

EDPIDR2 is a 32-bit register.

The EDPIDR2 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

#### JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

#### DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

#### Accessing the EDPIDR2:

EDPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
Debug	0xFE8

---

### H9.2.34 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

#### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

#### Configurations

EDPIDR3 is in the Debug power domain.  
EDPIDR3 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

#### Attributes

EDPIDR3 is a 32-bit register.

The EDPIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVAND, bits [7:4]

Part minor revision. Parts using [EDPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

#### CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

#### Accessing the EDPIDR3:

EDPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFEC

## H9.2.35 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

### Purpose

Provides information to identify an external debug component.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

RO

---

### Configurations

EDPIDR4 is in the Debug power domain.  
EDPIDR4 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

EDPIDR4 is a 32-bit register.

The EDPIDR4 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### SIZE, bits [7:4]

Size of the component. RAZ.  $\log_2$  of the number of 4KB pages from the start of the component to the end of the component ID registers.

### DES\_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

### Accessing the EDPIDR4:

EDPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

Debug	0xFD0
-------	-------

---

## H9.2.36 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

### Purpose

Controls processor functionality related to powerup, reset, and powerdown.  
This register is part of the Debug registers functional group.

### Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

### Configurations

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Bit [0] of this register is mapped to [DBGPRCR.CORENPDRQ](#), bit [0] of the AArch32 view of this register.

Bit [0] of this register is mapped to [DBGPRCR\\_EL1.CORENPDRQ](#), bit [0] of the AArch64 view of this register.

The other bits in these registers are not mapped to each other.

### Attributes

EDPRCR is a 32-bit register.

The EDPRCR bit assignments are:

### Bits [31:4]

Reserved, RES0.

### COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain. The actions on writing to this bit are:

- 0 No effect.
- 1 Request the power controller to powerup the core.

In an implementation that includes the recommended external debug interface, this bit drives the [DBGPWRUPREQ](#) signal.

This bit can be read and written when the Core power domain is powered off.

The power controller must not allow the Core power domain to switch off while this bit is one.

On External debug reset, the field resets to 0.

This field is accessible as shown below:

SLK	Default
RO	RW

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### Bit [2]

Reserved, RES0.

#### CWRR, bit [1]

Warm reset request. Write only bit that reads as zero. The actions on writing to this bit are:

- 0 No action.
- 1 Request Warm reset.

The processor ignores writes to this bit if any of the following are the case:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the processor is Non-secure.
- ExternalSecureInvasiveDebugEnabled() == FALSE and one of the following is true:
  - EL3 is implemented.
  - The processor is Secure.
- The Core power domain is either completely off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OLSR.OSLK == 1 (OS lock is locked).

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On Warm reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	WI	WO

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

- 0 On a powerdown request, the system powers down the Core power domain.
- 1 On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	RO	RW

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

### Accessing the EDPRCR:

EDPRCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x310

## H9.2.37 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

### Purpose

Holds information about the reset and powerdown state of the processor.

This register is part of the Debug registers functional group.

### Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

If the Core power domain is on (EDPRSR.PU == 1), then following a read of EDPRSR:

- If EDPRSR.DLK == 0, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the processor is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

### Configurations

EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

### Attributes

EDPRSR is a 32-bit register.

The EDPRSR bit assignments are:

### Bits [31:12]

Reserved, RES0.

### SDR, bit [11]

Sticky debug restart. Set to 1 when the processor exits Debug state and cleared to 0 following reads of EDPRSR.

0 The processor has not restarted since EDPRSR was last read.

1 The processor has restarted since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### SPMAD, bit [10]

Sticky EPMAD error. Set to 1 if an access returns an error because AllowExternalPMUAccess() == FALSE.

0 No accesses to the external performance monitors registers have failed since EDPRSR was last read.

1 At least one access to the external performance monitors registers has failed since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### EPMAD, bit [9]

External performance monitors access disable status.

0 External performance monitors access enabled.

1 External performance monitors access disabled.

If external performance monitors access is not implemented, EPMAD is RAO. This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### SDAD, bit [8]

Sticky EDAD error. Set to 1 if an access returns an error because AllowExternalDebugAccess() == FALSE.

0 No accesses to the external debug registers have failed since EDPRSR was last read.

1 At least one access to the external debug registers has failed since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### EDAD, bit [7]

External debug access disable status.

0 External debug access enabled.

1 External debug access disabled.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	EDAD	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### DLK, bit [6]

OS Double Lock status bit.

0 [OSDLR\\_EL1.DLK](#) == 0 or [EDPRCR.CORENPDRQ](#) == 1 or the processor is in Debug state.

1 [OSDLR\\_EL1.DLK](#) == 1 and [EDPRCR.CORENPDRQ](#) == 0 and the processor is in Non-debug state.

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### OSLK, bit [5]

OS lock status bit. A read of this bit returns the value of [OSLSR\\_EL1.OSLK](#).

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1 or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	OSLK	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### HALTED, bit [4]

Halted status bit. Possible values are:

0 [EDSCR.STATUS](#) is 0b000010 (processor in Non-debug state).

1 [EDSCR.STATUS](#) is not 0b000010.

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAZ	RO

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### SR, bit [3]

Sticky core reset status bit. Possible values are:

0 The non-debug logic of the processor is not in reset state and has not been reset since the last time EDPRSR was read.

1 The non-debug logic of the processor is in reset state or has been reset since the last time EDPRSR was read.

This bit is UNKNOWN on reads if EDPRSR.DLK is 1 or EDPRSR.PU is 0.

This bit clears to 0 following a read of EDPRSR if the non-debug logic of the processor is not in reset state.

On Warm reset, the field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### R, bit [2]

Core reset status bit. Possible values are:

0 The non-debug logic of the processor is not in reset state.

1 The non-debug logic of the processor is in reset state.  
This bit is UNKNOWN on reads if either EDPRSR.DLK is 1 or EDPRSR.PU is 0.  
On Warm reset, the field reset value is architecturally UNKNOWN.  
This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

### SPD, bit [1]

Sticky core power-down status bit.

This bit is set to 1 on Cold reset to indicate the state of the debug registers has been lost. Since a Cold reset is required on powering up the processor, this usually indicates the Core power domain has been completely powered off.

Possible values are:

0 If the Core power domain is off (EDPRSR.PU is 0), it is not known whether the state of the debug registers in the Core power domain is lost. Otherwise, the Core power domain is on, and the state of the debug registers in the Core power domain has not been lost.

1 The state of the debug registers in the Core power domain is lost.

This bit is UNKNOWN on reads if both EDPRSR.DLK and EDPRSR.PU are 1.

This bit clears to 0 following a read of EDPRSR if the processor is not in the powered down state.

There are two logical power off states for the Core power domain:

**Retention** The states of the debug registers, including EDPRSR.SPD, in the Core power domain is preserved, and restored on leaving retention state.

**Power-down** The states of the debug registers in the Core power domain is lost, and a Cold reset is asserted on leaving power-down state.

In these states, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time EDPRSR was read when the Core power domain was on.
- EDPRSR.SPD reads-as-zero.

EDPRSR.SPD is not cleared following a read of EDPRSR in these states.

This means it is IMPLEMENTATION DEFINED whether a processor implements EDPRSR.SPD as:

- Fixed RAZ when in one or both of the retention and power-down states.
- Retaining its previous value when in the retention state.
- Fixed RAO in the power-down state.

Note that this definition does not allow EDPRSR.SPD to be fixed RAO in the low-power retention state, as the state of the debug registers in the Core power domain is not lost by entering this state. However, the bit can be read as 1 in this state if the state of the registers was lost before entering this state (i.e. EDPRSR has not been read since the last Cold reset).

ARM recommends that an implementation make EDPRSR.SPD fixed RAO when in the power-down state, particularly if it does not support a low-power retention state.

On Cold reset, the field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
RO	UNK	RO	RC

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### PU, bit [0]

Core power-up status bit. Indicates whether the Core power domain debug registers can be accessed:

0 Core is in a low-power or power-down state where the debug registers cannot be accessed.

1 Core is in a power-up state where the debug registers can be accessed.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	Default
RAZ	RAO

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

#### Accessing the EDPRSR:

EDPRSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x314

## H9.2.38 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

### Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in [EDSCR](#).  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

### Configurations

EDRCR is in the Core power domain.

### Attributes

EDRCR is a 32-bit register.

The EDRCR bit assignments are:

### Bits [31:5]

Reserved, RES0.

### CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

- 0 No action.
- 1 Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

### CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the [EDSCR.PipeAdv](#) bit to 0. The actions on writing to this bit are:

- 0 No action.
- 1 Clear the [EDSCR.PipeAdv](#) bit to 0.

### CSE, bit [2]

Clear Sticky Error. Used to clear the [EDSCR](#) cumulative error bits to 0. The actions on writing to this bit are:

- 0 No action.

- 1 Clear the [EDSCR](#).{TXU, RXO, ERR} bits, and, if the processor is in Debug state, the [EDSCR](#).ITO bit, to 0.

**Bits [1:0]**

Reserved, RES0.

**Accessing the EDRCR:**

EDRCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x090

### H9.2.39 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

#### Purpose

Main control register for the debug implementation.  
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

#### Configurations

EDSCR is in the Core power domain.

#### Attributes

EDSCR is a 32-bit register.

The EDSCR bit assignments are:

#### Bit [31]

Reserved, RES0.

#### RXfull, bit [30]

DTRRX full. This bit is RO.  
On Cold reset, the field resets to 0.

#### TXfull, bit [29]

DTRTX full. This bit is RO.  
On Cold reset, the field resets to 0.

**ITO, bit [28]**

EDITR overrun. This bit is RO.

If the processor is not in Debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

**RXO, bit [27]**

DTRRX overrun. This bit is RO.

On Cold reset, the field resets to 0.

**TXU, bit [26]**

DTRTX underrun. This bit is RO.

On Cold reset, the field resets to 0.

**PipeAdv, bit [25]**

Pipeline advance. Read-only. Set to 1 every time the processor pipeline retires one or more instructions. Cleared to 0 by a write to [EDRCR.CSPA](#).

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

**ITE, bit [24]**

ITR empty. This bit is RO.

If the processor is not in Debug state, this bit is UNKNOWN. It is always valid in Debug state.

**INTdis, bits [23:22]**

Interrupt disable. Disables taking interrupts (including virtual interrupts and System Error interrupts) in Non-Debug state.

If external invasive debug is disabled, the value of this field is ignored.

If external invasive debug is enabled, the possible values of this field are:

- |    |  |
|----|--|
| 00 | Do not disable interrupts  |
| 01 | Disable interrupts targeting Non-secure EL1.   |
| 10 | Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable interrupts targeting Secure EL1. |
| 11 | Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable all other interrupts.            |

The value of INTdis does not affect whether an interrupt is a WFI wake-up event, but can mask an interrupt as a WFE wake-up event.

If EL3 and EL2 are not implemented, INTdis[0] is RO and reads the same value as INTdis[1], meaning only the values 0b00 and 0b11 can be selected.

On Cold reset, the field resets to 0.

**TDA, bit [21]**

Trap debug registers accesses.

On Cold reset, the field resets to 0.

**MA, bit [20]**

Memory access mode. Controls use of memory-access mode for accessing [EDITR](#) and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

- |   |                     |
|---|---------------------|
| 0 | Normal access mode  |
| 1 | Memory access mode. |

On Cold reset, the field resets to 0.

**Bit [19]**

Reserved, RES0.

**NS, bit [18]**

Non-secure status. Read-only. When in Debug state, gives the current security state:

- 0 Secure state, `IsSecure() == TRUE`
- 1 Non-secure state, `IsSecure() == FALSE`.

In Non-debug state, this bit is UNKNOWN.

**Bit [17]**

Reserved, RES0.

**SDD, bit [16]**

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.
- If entering in Non-secure state, SDD is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`.

In Debug state, the value of the SDD bit does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

In Non-debug state:

- SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a context synchronization operation is required to guarantee their effect.
- This bit is unaffected by the Security state of the processor.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

**Bit [15]**

Reserved, RES0.

**HDE, bit [14]**

Halting debug mode enable. Possible values of this bit are:

- 0 Halting debug mode disabled.
- 1 Halting debug mode enabled.

On Cold reset, the field resets to 0.

**RW, bits [13:10]**

Exception level register-width status. Read-only. In Debug state, each bit gives the current register width status of each EL:

- 1111 All exception levels are AArch64 state.
- 1110 EL0 is AArch32 state. All other exception levels are AArch64 state.
- 1100 EL0 and EL1 are AArch32 state. All other exception levels are AArch64 state. Never seen if EL2 is not implemented in the current security state.
- 1000 EL0, EL1, and, if implemented in the current security state, EL2 are AArch32 state. All other exception levels are AArch64 state.
- 0000 All exception levels are set to AArch32 state (32-bit configuration).

However:

- If not at EL0: `RW[0] == RW[1]`.
- If EL2 is not implemented in the current security state: `RW[2] == RW[1]`.
- If EL3 is not implemented: `RW[3] == RW[2]`.

In Non-debug state, this field is RAO.

**EL, bits [9:8]**

Exception level. Read-only. In Debug state, this gives the current EL of the processor.

In Non-debug state, this field is RAZ.

**A, bit [7]**

System Error interrupt pending. Read-only. In Debug state, indicates whether a SError interrupt is pending:

- If `HCR_EL2.{AMO, TGE} = {1, 0}` and in Non-secure EL0 or EL1, a virtual SError interrupt.
- Otherwise, a physical SError interrupt.

0 No SError interrupt pending.

1 SError interrupt pending.

A debugger can read EDSCR to check whether a SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

UNKNOWN in Non-debug state.

**ERR, bit [6]**

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

On Cold reset, the field resets to 0.

**STATUS, bits [5:0]**

Debug status flags. This field is RO.

The possible values of this field are:

- 000010 Processor is in Non-debug state.
- 000001 Processor is restarting (exiting Debug state).
- 000111 Breakpoint.
- 010011 External debug request.
- 011011 Halting step, normal.
- 011111 Halting step, exclusive.
- 100011 OS unlock catch.
- 100111 Reset catch.
- 101011 Watchpoint.
- 101111 HLT instruction.
- 110011 Software access to debug register.
- 110111 Exception catch.
- 111011 Halting step, no syndrome.

All other values of STATUS are reserved.

**Accessing the EDSCR:**

EDSCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x088

## H9.2.40 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

### Purpose

Contains sampled values captured on reading [EDPCSR](#).

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

### Configurations

EDVIDSR is in the Core power domain.

### Attributes

EDVIDSR is a 32-bit register.

The EDVIDSR bit assignments are:

### NS, bit [31]

Non-secure state sample. Indicates the security state associated with the most recent [EDPCSR](#) sample.

On Cold reset, the field reset value is architecturally UNKNOWN.

### E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent [EDPCSR](#) sample was associated with EL2. If  $EDVIDSR.NS == 0$ , this bit is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

### E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent [EDPCSR](#) sample was associated with AArch64 EL3. If  $EDVIDSR.NS == 1$  or the processor was in AArch32 state when [EDPCSR](#) was read, this bit is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

### HV, bit [28]

[EDPCSR](#) high half valid. Indicates whether bits [63:32] of the most recent [EDPCSR](#) sample are valid. If  $EDVIDSR.HV == 0$ , the value of [EDPCSR](#)[63:32] is RAZ.

On Cold reset, the field reset value is architecturally UNKNOWN.

### Bits [27:8]

Reserved, RES0.

**VMID, bits [7:0]**

VMID sample. The value of [VTTBR\\_EL2.VMID](#) associated with the most recent [EDPCSR](#) sample. If [EDVIDSR.NS](#) == 0 or [EDVIDSR.E2](#) == 1, this field is RAZ.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the EDVIDSR:**

EDVIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A8

## H9.2.41 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

### Purpose

Contains the virtual data address being accessed when a watchpoint debug event was triggered.  
This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

### Configurations

EDWAR is in the Core power domain.

### Attributes

EDWAR is a 64-bit register.

The EDWAR bit assignments are:

### Bits [63:0]

Watchpoint address. The virtual data address being accessed when a watchpoint debug event was triggered and caused entry to Debug state.

UNKNOWN if the processor is not in Debug state, or if Debug state was entered other than for a watchpoint debug event.

The address must be within a naturally-aligned block of memory of power-of-two size no larger than the [DC ZVA](#) block size.

### Accessing the EDWAR:

EDWAR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x030

EDWAR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x034

## H9.2.42 ID\_AA64DFR0\_EL1, Debug Feature Register 0

The ID\_AA64DFR0\_EL1 characteristics are:

### Purpose

Provides top level information about the debug system in AArch64.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

ID\_AA64DFR0\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64DFR0\\_EL1](#).  
ID\_AA64DFR0\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64DFR0\_EL1 is a 64-bit register.

The ID\_AA64DFR0\_EL1 bit assignments are:

### Bits [63:32]

Reserved, RES0.

### CTX\_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

### Bits [27:24]

Reserved, RES0.

### WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of 0b0000 is reserved.

### Bits [19:16]

Reserved, RES0.

### BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of 0b0000 is reserved.

### PMUVer, bits [11:8]

Performance Monitors extension version. Indicates whether system register interface to Performance Monitors extension is implemented. Permitted values are:

0000	Performance Monitors extension system registers not implemented.
0001	Performance Monitors extension system registers implemented, PMUv3.
1111	IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

**TraceVer, bits [7:4]**

Trace extension. Indicates whether system register interface to Trace extension is implemented.

Permitted values are:

0000 Trace extension system registers not implemented.

0001 Trace extension system registers implemented.

All other values are reserved.

A value of 0b0000 only indicates that no system register interface to the trace extension is implemented. A trace extension may nevertheless be implemented without a system register interface.

**DebugVer, bits [3:0]**

Debug architecture version. Indicates presence of v8-A debug architecture.

0110 v8-A debug architecture.

All other values are reserved.

**Accessing the ID\_AA64DFR0\_EL1:**

ID\_AA64DFR0\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD28

ID\_AA64DFR0\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD2C

### H9.2.43 ID\_AA64DFR1\_EL1, Debug Feature Register 1

The ID\_AA64DFR1\_EL1 characteristics are:

#### Purpose

Reserved for future expansion of top level information about the debug system in AArch64.  
This register is part of the Identification registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RO

#### Configurations

ID\_AA64DFR1\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64DFR1\\_EL1](#).  
ID\_AA64DFR1\_EL1 is in the Debug power domain.

#### Attributes

ID\_AA64DFR1\_EL1 is a 64-bit register.

The ID\_AA64DFR1\_EL1 bit assignments are:

#### Bits [63:0]

Reserved, RES0.

#### Accessing the ID\_AA64DFR1\_EL1:

ID\_AA64DFR1\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD48

ID\_AA64DFR1\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD4C

## H9.2.44 ID\_AA64ISAR0\_EL1, Instruction Set Attribute Register 0

The ID\_AA64ISAR0\_EL1 characteristics are:

### Purpose

Provides information about the instructions implemented by the processor in AArch64.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

ID\_AA64ISAR0\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64ISAR0\\_EL1](#).  
ID\_AA64ISAR0\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64ISAR0\_EL1 is a 64-bit register.

The ID\_AA64ISAR0\_EL1 bit assignments are:

### Bits [63:20]

Reserved, RES0.

### CRC32, bits [19:16]

CRC32 instructions in AArch64. Possible values of this field are:

- 0000 No CRC32 instructions implemented.
- 0001 CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX instructions implemented.

All other values are reserved.

This field must have the same value as [ID\\_ISAR5.CRC32](#). The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

### SHA2, bits [15:12]

SHA2 instructions in AArch64. Possible values of this field are:

- 0000 No SHA2 instructions implemented.
- 0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

### SHA1, bits [11:8]

SHA1 instructions in AArch64. Possible values of this field are:

- 0000 No SHA1 instructions implemented.
- 0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.

**AES, bits [7:4]**

AES instructions in AArch64. Possible values of this field are:

- 0000 No AES instructions implemented.
- 0001 AESE, AESD, AESMC, and AESIMC instructions implemented.
- 0010 As for 0b0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

**Bits [3:0]**

Reserved, RES0.

**Accessing the ID\_AA64ISAR0\_EL1:**

ID\_AA64ISAR0\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD30

ID\_AA64ISAR0\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD34

## H9.2.45 ID\_AA64ISAR1\_EL1, Instruction Set Attribute Register 1

The ID\_AA64ISAR1\_EL1 characteristics are:

### Purpose

Reserved for future expansion of the information about the instruction sets implemented by the processor in AArch64.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

ID\_AA64ISAR1\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64ISAR1\\_EL1](#).

ID\_AA64ISAR1\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64ISAR1\_EL1 is a 64-bit register.

The ID\_AA64ISAR1\_EL1 bit assignments are:

### Bits [63:0]

Reserved, RES0.

### Accessing the ID\_AA64ISAR1\_EL1:

ID\_AA64ISAR1\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xD50
-------	-------

---

ID\_AA64ISAR1\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

---

Component	Offset
-----------	--------

---

Debug	0xD54
-------	-------

---

## H9.2.46 ID\_AA64MMFR0\_EL1, Memory Model Feature Register 0

The ID\_AA64MMFR0\_EL1 characteristics are:

### Purpose

Provides information about the implemented memory model and memory management support in AArch64.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

ID\_AA64MMFR0\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64MMFR0\\_EL1](#).

ID\_AA64MMFR0\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64MMFR0\_EL1 is a 64-bit register.

The ID\_AA64MMFR0\_EL1 bit assignments are:

### Bits [63:32]

Reserved, RES0.

### TGran4, bits [31:28]

Support for 4 Kbyte memory translation granule size. Permitted values are:

0000 4 KB granule supported.

1111 4 KB granule not supported.

All other values are reserved.

### TGran64, bits [27:24]

Support for 64 Kbyte memory translation granule size. Permitted values are:

0000 64 KB granule supported.

1111 64 KB granule not supported.

All other values are reserved.

### TGran16, bits [23:20]

Support for 16 Kbyte memory translation granule size. Permitted values are:

0000 16 KB granule not supported.

0001 16 KB granule supported.

All other values are reserved.

**BigEndEL0, bits [19:16]**

Mixed-endian support at EL0 only. Permitted values are:

0000 No mixed-endian support at EL0. The `SCTLR_EL1.E0E` bit has a fixed value.

0001 Mixed-endian support at EL0. The `SCTLR_EL1.E0E` bit can be configured.

All other values are reserved.

This field is invalid and is RES0 if the `BigEnd` field, bits [11:8], is not 0b0000.

**SNSMem, bits [15:12]**

Secure versus Non-secure Memory distinction. Permitted values are:

0000 Does not support a distinction between Secure and Non-secure Memory.

0001 Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

**BigEnd, bits [11:8]**

Mixed-endian configuration support. Permitted values are:

0000 No mixed-endian support. The `SCTLR_ELx.EE` bits have a fixed value. See the `BigEndEL0` field, bits [19:16], for whether EL0 supports mixed-endian.

0001 Mixed-endian support. The `SCTLR_ELx.EE` and `SCTLR_EL1.E0E` bits can be configured.

All other values are reserved.

**ASIDBits, bits [7:4]**

Number of ASID bits. Permitted values are:

0000 8 bits.

0010 16 bits.

All other values are reserved.

**PARange, bits [3:0]**

Physical Address range supported. Permitted values are:

0000 32 bits, 4 GB.

0001 36 bits, 64 GB.

0010 40 bits, 1 TB.

0011 42 bits, 4 TB.

0100 44 bits, 16 TB.

0101 48 bits, 256 TB.

All other values are reserved.

**Accessing the ID\_AA64MMFR0\_EL1:**

ID\_AA64MMFR0\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD38

ID\_AA64MMFR0\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD3C

## H9.2.47 ID\_AA64MMFR1\_EL1, Memory Model Feature Register 1

The ID\_AA64MMFR1\_EL1 characteristics are:

### Purpose

Reserved for future expansion of the information about the implemented memory model and memory management support in AArch64.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

ID\_AA64MMFR1\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64MMFR1\\_EL1](#).

ID\_AA64MMFR1\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64MMFR1\_EL1 is a 64-bit register.

The ID\_AA64MMFR1\_EL1 bit assignments are:

### Bits [63:0]

Reserved, RES0.

### Accessing the ID\_AA64MMFR1\_EL1:

ID\_AA64MMFR1\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD58

ID\_AA64MMFR1\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD5C

## H9.2.48 ID\_AA64PFR0\_EL1, Processor Feature Register 0

The ID\_AA64PFR0\_EL1 characteristics are:

### Purpose

Provides additional information about implemented processor features in AArch64.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

ID\_AA64PFR0\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64PFR0\\_EL1](#).  
ID\_AA64PFR0\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64PFR0\_EL1 is a 64-bit register.

The ID\_AA64PFR0\_EL1 bit assignments are:

### Bits [63:28]

Reserved, RES0.

### GIC, bits [27:24]

GIC system register interface. Permitted values are:

- 0000 No GIC system registers are supported.
- 0001 GICv3 system registers are supported.

All other values are reserved.

### AdvSIMD, bits [23:20]

Advanced SIMD. Permitted values are:

- 0000 Advanced SIMD is implemented.
- 1111 Advanced SIMD is not implemented.

All other values are reserved.

### FP, bits [19:16]

Floating-point. Permitted values are:

- 0000 Floating-point is implemented.
- 1111 Floating-point is not implemented.

All other values are reserved.

**EL3, bits [15:12]**

EL3 exception level handling. Permitted values are:

- 0000 EL3 is not implemented.
  - 0001 EL3 can be executed in AArch64 state only.
  - 0010 EL3 can be executed in either AArch64 or AArch32 state.
- All other values are reserved.

**EL2, bits [11:8]**

EL2 exception level handling. Permitted values are:

- 0000 EL2 is not implemented.
  - 0001 EL2 can be executed in AArch64 state only.
  - 0010 EL2 can be executed in either AArch64 or AArch32 state.
- All other values are reserved.

**EL1, bits [7:4]**

EL1 exception level handling. Permitted values are:

- 0000 EL1 is not implemented.
  - 0001 EL1 can be executed in AArch64 state only.
  - 0010 EL1 can be executed in either AArch64 or AArch32 state.
- All other values are reserved.

**EL0, bits [3:0]**

EL0 exception level handling. Permitted values are:

- 0000 EL0 is not implemented.
  - 0001 EL0 can be executed in AArch64 state only.
  - 0010 EL0 can be executed in either AArch64 or AArch32 state.
- All other values are reserved.

**Accessing the ID\_AA64PFR0\_EL1:**

ID\_AA64PFR0\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD20

ID\_AA64PFR0\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD24

## H9.2.49 ID\_AA64PFR1\_EL1, Processor Feature Register 1

The ID\_AA64PFR1\_EL1 characteristics are:

### Purpose

Reserved for future expansion of information about implemented processor features in AArch64.  
This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

Default
RO

### Configurations

ID\_AA64PFR1\_EL1 is architecturally mapped to AArch64 register [ID\\_AA64PFR1\\_EL1](#).  
ID\_AA64PFR1\_EL1 is in the Debug power domain.

### Attributes

ID\_AA64PFR1\_EL1 is a 64-bit register.

The ID\_AA64PFR1\_EL1 bit assignments are:

### Bits [63:0]

Reserved, RES0.

### Accessing the ID\_AA64PFR1\_EL1:

ID\_AA64PFR1\_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD40

ID\_AA64PFR1\_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD44

## H9.2.50 MIDR\_EL1, Main ID Register

The MIDR\_EL1 characteristics are:

### Purpose

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

### Configurations

MIDR\_EL1 is architecturally mapped to AArch64 register [MIDR\\_EL1](#).

MIDR\_EL1 is architecturally mapped to AArch32 register [MIDR](#).

MIDR\_EL1 is in the Debug power domain.

### Attributes

MIDR\_EL1 is a 32-bit register.

The MIDR\_EL1 bit assignments are:

### Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation

Hex representation	ASCII representation	Implementer
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

#### Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

#### Architecture, bits [19:16]

The permitted values of this field are:

0001	ARMv4
0010	ARMv4T
0011	ARMv5 (obsolete)
0100	ARMv5T
0101	ARMv5TE
0110	ARMv5TEJ
0111	ARMv6
1111	Defined by CPUID scheme

All other values are reserved.

#### PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

#### Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

#### Accessing the MIDR\_EL1:

MIDR\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD00

## H9.2.51 OSLAR\_EL1, OS Lock Access Register

The OSLAR\_EL1 characteristics are:

### Purpose

Used to lock or unlock the OS lock.

This register is part of the Debug registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	SLK	Default
Error	Error	WI	WO

### Configurations

OSLAR\_EL1 is architecturally mapped to AArch64 register [OSLAR\\_EL1](#).

OSLAR\_EL1 is architecturally mapped to AArch32 register [DBGOSLAR](#).

OSLAR\_EL1 is in the Core power domain.

### Attributes

OSLAR\_EL1 is a 32-bit register.

The OSLAR\_EL1 bit assignments are:

### Bits [31:1]

Reserved, RES0.

### OSLK, bit [0]

On writes to OSLAR\_EL1, bit[0] is copied to the OS lock.

Use [EDPRSR.OSLK](#) to check the current status of the lock.

### Accessing the OSLAR\_EL1:

OSLAR\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x300

## H9.3 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers that are accessible through the external debug interface.

### H9.3.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

#### Purpose

Provides a control for external multiplexing of additional triggers into the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

ASICCTL is in the Debug power domain.

#### Attributes

ASICCTL is a 32-bit register.

The ASICCTL bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### ASICCTL, bits [7:0]

IMPLEMENTATION DEFINED ASIC control. Provides a control for external multiplexing of additional triggers into the CTI.

If external multiplexing of trigger signals is implemented then the number of multiplexed signals on each trigger must be reflected in [CTIDEVID.EXTMUXNUM](#).

If [CTIDEVID.EXTMUXNUM](#) is zero, this field is RAZ.

On IMPLEMENTATION DEFINED reset, the field resets to an IMPLEMENTATION DEFINED value.

#### Accessing the ASICCTL:

ASICCTL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x144

## H9.3.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

### Purpose

Clears bits of the Application Trigger register.

This register is part of the Cross-Trigger Interface registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	WO

### Configurations

CTIAPPCLEAR is in the Debug power domain.

### Attributes

CTIAPPCLEAR is a 32-bit register.

The CTIAPPCLEAR bit assignments are:

### APPCLEAR<x>, bit [x] for x = 0 to (N - 1)

Application trigger <x> disable.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Writing to this bit has the following effect:

0 No effect.

1 Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use [CTIAPPULSE](#).

### Accessing the CTIAPPCLEAR:

CTIAPPCLEAR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x018

### H9.3.3 CTIAPPULSE, CTI Application Pulse register

The CTIAPPULSE characteristics are:

**Purpose**

Causes event pulses to be generated on ECT channels.

This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	WO

**Configurations**

CTIAPPULSE is in the Debug power domain.

**Attributes**

CTIAPPULSE is a 32-bit register.

The CTIAPPULSE bit assignments are:

**APPULSE<x>, bit [x] for x = 0 to (N - 1)**

Generate event pulse on ECT channel <x>.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Writing to this bit has the following effect:

0 No effect.

1 Channel <x> event pulse generated for one clock period.

**Accessing the CTIAPPULSE:**

CTIAPPULSE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x01C

### H9.3.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

#### Purpose

Sets bits of the Application Trigger register.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

CTIAPPSET is in the Debug power domain.

#### Attributes

CTIAPPSET is a 32-bit register.

The CTIAPPSET bit assignments are:

#### APPSET<x>, bit [x] for x = 0 to (N - 1)

Application trigger <x> enable.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Possible values of this bit are:

- 0 Reading this means the application trigger is inactive. Writing this has no effect.
- 1 Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use [CTIAPPULSE](#).

On External debug reset, the field reset value is architecturally UNKNOWN.

#### Accessing the CTIAPPSET:

CTIAPPSET can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x014

### H9.3.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

#### Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

CTIAUTHSTATUS.{SNID,SID} are RAZ, because the CTI does not itself provide Secure authentication.

#### Attributes

CTIAUTHSTATUS is a 32-bit register.

The CTIAUTHSTATUS bit assignments are:

#### Bits [31:4]

Reserved, RES0.

#### NSNID, bits [3:2]

If EL3 is not implemented and the processor is Secure, holds the same value as [DBGAUTHSTATUS\\_EL1.SNID](#).

Otherwise, holds the same value as [DBGAUTHSTATUS\\_EL1.NSNID](#).

#### NSID, bits [1:0]

If EL3 is not implemented and the processor is Secure, holds the same value as [DBGAUTHSTATUS\\_EL1.SID](#).

Otherwise, holds the same value as [DBGAUTHSTATUS\\_EL1.NSID](#).

### Accessing the CTIAUTHSTATUS:

CTIAUTHSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFB8

### H9.3.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

**Purpose**

Provides the raw status of the ECT channel inputs to the CTI.  
This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	RO

**Configurations**

CTICHINSTATUS is in the Debug power domain.

**Attributes**

CTICHINSTATUS is a 32-bit register.

The CTICHINSTATUS bit assignments are:

**CHIN<n>, bit [x] for x = 0 to (N - 1)**

Input channel <n> status.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ.

Possible values of this bit are:

- 0 Input channel <n> is inactive.
- 1 Input channel <n> is active.

**Accessing the CTICHINSTATUS:**

CTICHINSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x138

### H9.3.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

**Purpose**

Provides the status of the ECT channel outputs from the CTI.  
This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	RO

**Configurations**

CTICHOUTSTATUS is in the Debug power domain.

**Attributes**

CTICHOUTSTATUS is a 32-bit register.

The CTICHOUTSTATUS bit assignments are:

**CHOUT<n>, bit [x] for x = 0 to (N - 1)**

Output channel <n> status.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ.

Possible values of this bit are:

- 0 Output channel <n> is inactive.
- 1 Output channel <n> is active.

**Accessing the CTICHOUTSTATUS:**

CTICHOUTSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x13C

### H9.3.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

**Purpose**

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	RO

**Configurations**

CTICIDR0 is in the Debug power domain.

CTICIDR0 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

**Attributes**

CTICIDR0 is a 32-bit register.

The CTICIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_0, bits [7:0]**

Preamble. Must read as 0x00.

**Accessing the CTICIDR0:**

CTICIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFF0

### H9.3.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTICIDR1 is in the Debug power domain.

CTICIDR1 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTICIDR1 is a 32-bit register.

The CTICIDR1 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

#### PRMBL\_1, bits [3:0]

Preamble. RAZ.

#### Accessing the CTICIDR1:

CTICIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFF4

### H9.3.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTICIDR2 is in the Debug power domain.

CTICIDR2 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTICIDR2 is a 32-bit register.

The CTICIDR2 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_2, bits [7:0]

Preamble. Must read as 0x05.

#### Accessing the CTICIDR2:

CTICIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFF8

### H9.3.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTICIDR3 is in the Debug power domain.

CTICIDR3 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTICIDR3 is a 32-bit register.

The CTICIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_3, bits [7:0]

Preamble. Must read as 0xB1.

#### Accessing the CTICIDR3:

CTICIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFFC

### H9.3.12 CTICLAIMCLR, CTI Claim Tag Clear register

The CTICLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.  
This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	RW

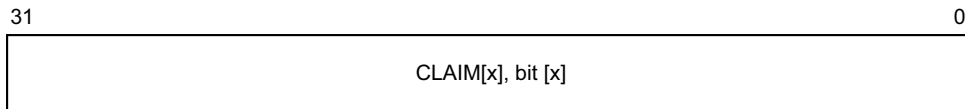

**Configurations**

CTICLAIMCLR is in the Debug power domain.  
CTICLAIMCLR is optional to implement in the external register interface.

**Attributes**

CTICLAIMCLR is a 32-bit register.

The CTICLAIMCLR bit assignments are:

**CLAIM[x], bit [x], bits [31:0]**

Clear CLAIM tag. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

Otherwise, reads return the value of CLAIM[x] and the behavior on writes is:

- 0 No action.
- 1 Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

**Accessing the CTICLAIMCLR:**

CTICLAIMCLR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFA4

### H9.3.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

#### Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

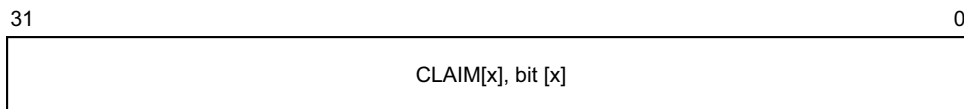

CTICLAIMSET is in the Debug power domain.

CTICLAIMSET is optional to implement in the external register interface.

#### Attributes

CTICLAIMSET is a 32-bit register.

The CTICLAIMSET bit assignments are:

#### CLAIM[x], bit [x], bits [31:0]

CLAIM tag set bit. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

Otherwise, the bit is RAO and the behavior on writes is:

- 0 No action.
- 1 Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

#### Accessing the CTICLAIMSET:

CTICLAIMSET can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFA0

### H9.3.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

#### Purpose

Controls whether the CTI is enabled.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

CTICONTROL is in the Debug power domain.

#### Attributes

CTICONTROL is a 32-bit register.

The CTICONTROL bit assignments are:

#### Bits [31:1]

Reserved, RES0.

#### GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

- 0 CTI mapping functions disabled.
- 1 CTI mapping functions enabled.

When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset.

On External debug reset, the field resets to 0.

#### Accessing the CTICONTROL:

CTICONTROL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x000

### H9.3.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

#### Purpose

Copy of the low half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the CTI component relates to.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVAFF0 is in the Debug power domain.

CTIDEVAFF0 is optional to implement in the external register interface.

#### Attributes

CTIDEVAFF0 is a 32-bit register.

The CTIDEVAFF0 bit assignments are:

#### Bits [31:0]

[MPIDR\\_EL1](#) low half. Read-only copy of the low half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

#### Accessing the CTIDEVAFF0:

CTIDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFA8

### H9.3.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

#### Purpose

Copy of the high half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the CTI component relates to.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVAFF1 is in the Debug power domain.

CTIDEVAFF1 is optional to implement in the external register interface.

#### Attributes

CTIDEVAFF1 is a 32-bit register.

The CTIDEVAFF1 bit assignments are:

#### Bits [31:0]

[MPIDR\\_EL1](#) high half. Read-only copy of the high half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

#### Accessing the CTIDEVAFF1:

CTIDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFAC

### H9.3.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

#### Purpose

Identifies the programmers' model architecture of the CTI component.  
This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVARCH is in the Debug power domain.  
CTIDEVARCH is optional to implement in the external register interface.

#### Attributes

CTIDEVARCH is a 32-bit register.

The CTIDEVARCH bit assignments are:

#### ARCHITECT, bits [31:21]

Defines the architecture of the component. For CTI, this is ARM Limited.  
Bits [31:28] are the JEP 106 continuation code, 0x4.  
Bits [27:21] are the JEP 106 ID code, 0x3B.

#### PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.  
This field is 1 in v8-A.

#### REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.  
For CTI, the revision defined by v8-A is 0x0.  
All other values are reserved.

#### ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, 0x1.
- Bits [11:0] are the architecture part number, 0xA14.

This corresponds to CTI architecture version CTIv2.

**Accessing the CTIDEVARCH:**

CTIDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

---

<b>Component</b>	<b>Offset</b>
CTI	0xFBC

---

### H9.3.18 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

#### Purpose

Describes the CTI component to the debugger.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVID is in the Debug power domain.

#### Attributes

CTIDEVID is a 32-bit register.

The CTIDEVID bit assignments are:

#### Bits [31:26]

Reserved, RES0.

#### INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ.

00 **CTIGATE** does not mask propagation of input events from external channels.

01 **CTIGATE** masks propagation of input events from external channels.

All other values are reserved.

#### Bits [23:22]

Reserved, RES0.

#### NUMCHAN, bits [21:16]

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For v8-A, valid values are:

000011 3 channels (0-2) implemented.

000100 4 channels (0-3) implemented.

000101 5 channels (0-4) implemented.

000110 6 channels (0-5) implemented.

and so on up to 0b100000, 32 channels (0-31) implemented.

All other values are reserved.

**Bits [15:14]**

Reserved, RES0.

**NUMTRIG, bits [13:8]**

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.

For v8-A, valid values are:

000011 Up to 3 triggers (0-2) implemented.

001000 Up to 8 triggers (0-7) implemented.

001001 Up to 9 triggers (0-8) implemented.

001010 Up to 10 triggers (0-9) implemented.

and so on up to 0b100000, 32 triggers (0-31) implemented.

All other values are reserved. If the Trace Extension is implemented, this field must be at least 001000. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

**Bits [7:5]**

Reserved, RES0.

**EXTMUXNUM, bits [4:0]**

Maximum number of external triggers available for multiplexing into the CTI. This relates only to additional external triggers outside those defined for v8-A.

**Accessing the CTIDEVID:**

CTIDEVID can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC8

### H9.3.19 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

#### Purpose

Reserved for future information about the CTI component to the debugger.  
This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVID1 is in the Debug power domain.

#### Attributes

CTIDEVID1 is a 32-bit register.

The CTIDEVID1 bit assignments are:

#### Bits [31:0]

Reserved, RES0.

#### Accessing the CTIDEVID1:

CTIDEVID1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC4

### H9.3.20 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

#### Purpose

Reserved for future information about the CTI component to the debugger.  
This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVID2 is in the Debug power domain.

#### Attributes

CTIDEVID2 is a 32-bit register.

The CTIDEVID2 bit assignments are:

#### Bits [31:0]

Reserved, RES0.

#### Accessing the CTIDEVID2:

CTIDEVID2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC0

### H9.3.21 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

#### Purpose

Indicates to a debugger that this component is part of a processor's cross-trigger interface.  
This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIDEVTYPE is in the Debug power domain.  
CTIDEVTYPE is optional to implement in the external register interface.

#### Attributes

CTIDEVTYPE is a 32-bit register.

The CTIDEVTYPE bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a processor component.

#### MAJOR, bits [3:0]

Major type. Must read as 0x4 to indicate this is a cross-trigger component.

#### Accessing the CTIDEVTYPE:

CTIDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFCC

### H9.3.22 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

#### Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

CTIGATE is in the Debug power domain.

#### Attributes

CTIGATE is a 32-bit register.

The CTIGATE bit assignments are:

#### GATE<x>, bit [x] for x = 0 to (N - 1)

Channel <x> gate enable.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Possible values of this bit are:

0 Disable output and, if [CTIDEVID.INOUT](#) == 0b01, input channel <x> propagation.

1 Enable output and, if [CTIDEVID.INOUT](#) == 0b01, input channel <x> propagation.

On External debug reset, the field reset value is architecturally UNKNOWN.

#### Accessing the CTIGATE:

CTIGATE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x140

### H9.3.23 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

#### Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

#### Configurations

CTIINEN<n> is in the Debug power domain.

#### Attributes

CTIINEN<n> is a 32-bit register.

The CTIINEN<n> bit assignments are:

#### INEN<x>, bit [x] for x = 0 to (N - 1)

Input trigger <n> to output channel <x> enable.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Possible values of this bit are:

0 Input trigger <n> will not generate an event on output channel <x>.

1 Input trigger <n> will generate an event on output channel <x>.

On External debug reset, the field reset value is architecturally UNKNOWN.

#### Accessing the CTIINEN<n>:

CTIINEN<n> can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x020 + 4n

### H9.3.24 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

#### Purpose

Can be used to create soft acknowledges for output triggers.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	WO

#### Configurations

CTIINTACK is in the Debug power domain.

#### Attributes

CTIINTACK is a 32-bit register.

The CTIINTACK bit assignments are:

#### ACK<n>, bit [x] for x = 0 to (N - 1)

Acknowledge for output trigger <n>.

N is the number of CTI triggers implemented as defined by the [CTIDEVID.NUMTRIG](#) field. Bits [31:N] are RAZ/WI.

If any of the following is true, writes to ACK<n> are ignored:

- $n \geq \text{CTIDEVID.NUMTRIG}$ , the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by [CTIOUTEN<n>](#), is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

- |   |                         |
|---|-------------------------|
| 0 | No effect               |
| 1 | Deactivate the trigger. |

### Accessing the CTIINTACK:

CTIINTACK can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x010

### H9.3.25 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

#### Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RW

#### Configurations

CTIITCTRL is in the Debug power domain.

CTIITCTRL is optional to implement in the external register interface.

#### Attributes

CTIITCTRL is a 32-bit register.

The CTIITCTRL bit assignments are:

#### Bits [31:1]

Reserved, RES0.

#### IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

#### Accessing the CTIITCTRL:

CTIITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xF00

### H9.3.26 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

#### Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.  
This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
WO

#### Configurations

CTILAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

CTILAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

#### Attributes

CTILAR is a 32-bit register.

The CTILAR bit assignments are:

#### KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

#### Accessing the CTILAR:

CTILAR can be accessed through the internal memory-mapped interface:

Component	Offset
CTI	0xFB0

### H9.3.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

**Purpose**

Indicates the current status of the software lock for CTI registers.  
This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

<b>Default</b>
RO

**Configurations**

CTILSR is in the Debug power domain.  
If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.  
CTILSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.  
The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.  
Software uses [CTILAR](#) to set or clear the lock, and CTILSR to check the current status of the lock.

**Attributes**

CTILSR is a 32-bit register.

The CTILSR bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**nTT, bit [2]**

Not thirty-two bit access required. RAZ.

**SLK, bit [1]**

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

0            Lock clear. Writes are permitted to this component's registers.

1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

**SLI, bit [0]**

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

0 Software lock not implemented or not memory-mapped access.

1 Software lock implemented and memory-mapped access.

**Accessing the CTILSR:**

CTILSR can be accessed through the internal memory-mapped interface:

Component	Offset
CTI	0xFB4

### H9.3.28 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

**Purpose**

Defines which input channels generate output trigger n.

This register is part of the Cross-Trigger Interface registers functional group.

**Usage constraints**

This register is accessible as shown below:

SLK	Default
RO	RW

**Configurations**

CTIOUTEN<n> is in the Debug power domain.

**Attributes**

CTIOUTEN<n> is a 32-bit register.

The CTIOUTEN<n> bit assignments are:

**OUTEN<x>, bit [x] for x = 0 to (N - 1)**

Input channel <x> to output trigger <n> enable.

N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Bits [31:N] are RAZ/WI.

Possible values of this bit are:

- 0 An event on input channel <x> will not cause output trigger <n> to be asserted.
- 1 An event on input channel <x> will cause output trigger <n> to be asserted.

On External debug reset, the field reset value is architecturally UNKNOWN.

**Accessing the CTIOUTEN<n>:**

CTIOUTEN<n> can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x0A0 + 4n

### H9.3.29 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIPIDR0 is in the Debug power domain.

CTIPIDR0 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR0 is a 32-bit register.

The CTIPIDR0 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PART\_0, bits [7:0]

Part number, least significant byte.

#### Accessing the CTIPIDR0:

CTIPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFE0

### H9.3.30 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIPIDR1 is in the Debug power domain.

CTIPIDR1 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR1 is a 32-bit register.

The CTIPIDR1 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### DES\_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

#### PART\_1, bits [3:0]

Part number, most significant nibble.

#### Accessing the CTIPIDR1:

CTIPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFE4

### H9.3.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIPIDR2 is in the Debug power domain.

CTIPIDR2 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR2 is a 32-bit register.

The CTIPIDR2 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

#### JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

#### DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

#### Accessing the CTIPIDR2:

CTIPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFE8

### H9.3.32 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIPIDR3 is in the Debug power domain.

CTIPIDR3 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR3 is a 32-bit register.

The CTIPIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVAND, bits [7:4]

Part minor revision. Parts using [CTIPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

#### CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

#### Accessing the CTIPIDR3:

CTIPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFEC

### H9.3.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

#### Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTIPIDR4 is in the Debug power domain.

CTIPIDR4 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR4 is a 32-bit register.

The CTIPIDR4 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SIZE, bits [7:4]

Size of the component. RAZ.  $\log_2$  of the number of 4KB pages from the start of the component to the end of the component ID registers.

#### DES\_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

#### Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFD0

### H9.3.34 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

#### Purpose

Provides the status of the trigger inputs.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTITRIGINSTATUS is in the Debug power domain.

#### Attributes

CTITRIGINSTATUS is a 32-bit register.

The CTITRIGINSTATUS bit assignments are:

#### TRIN<n>, bit [x] for x = 0 to (N - 1)

Trigger input <n> status.

N is the number of CTI triggers implemented as defined by the [CTIDEVID.NUMTRIG](#) field.

Bits [31:N] are RAZ.

Possible values of this bit are:

0 Input trigger n is inactive.

1 Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

#### Accessing the CTITRIGINSTATUS:

CTITRIGINSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x130

### H9.3.35 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

#### Purpose

Provides the status of the trigger outputs.

This register is part of the Cross-Trigger Interface registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

CTITRIGOUTSTATUS is in the Debug power domain.

#### Attributes

CTITRIGOUTSTATUS is a 32-bit register.

The CTITRIGOUTSTATUS bit assignments are:

#### TROUT<n>, bit [x] for x = 0 to (N - 1)

Trigger output <n> status.

N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

Bits [31:N] are RAZ.

If output trigger <n> is implemented and connected, possible values of this bit are:

0 Output trigger n is inactive.

1 Output trigger n is active.

Otherwise it is IMPLEMENTATION DEFINED whether TROUT<n> is RAZ or behaves as above.

#### Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x134

# Part I

## **Memory-mapped Components of the ARMv8 Architecture**

# Chapter I1

## Memory-Mapped System Register Descriptions

This chapter describes the memory-mapped system control registers.

It contains the following items:

- [Introduction on page I1-4598.](#)
- [Performance Monitors registers on page I1-4599.](#)
- [Generic Timer registers on page I1-4647.](#)

## I1.1 Introduction

The following sections describe the memory-mapped system control registers:

- [Performance Monitors registers](#) on page I1-4599.
- [Generic Timer registers](#) on page I1-4647.

## 11.2 Performance Monitors registers

This section describes the Performance Monitoring registers.

### 11.2.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

#### Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

PMAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

#### Attributes

PMAUTHSTATUS is a 32-bit register.

The PMAUTHSTATUS bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SNID, bits [7:6]

Holds the same value as [DBGAUTHSTATUS\\_EL1.SNID](#).

#### Bits [5:4]

Reserved, RES0.

#### NSNID, bits [3:2]

Holds the same value as [DBGAUTHSTATUS\\_EL1.NSNID](#).

#### Bits [1:0]

Reserved, RES0.

### Accessing the PMAUTHSTATUS:

PMAUTHSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFB8

## 11.2.2 PMCCFILTR\_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR\_EL0 characteristics are:

### Purpose

Determines the modes in which the Cycle Counter, [PMCCNTR\\_EL0](#), increments.  
This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMCCFILTR\_EL0 is architecturally mapped to AArch64 register [PMCCFILTR\\_EL0](#).  
PMCCFILTR\_EL0 is architecturally mapped to AArch32 register [PMCCFILTR](#).  
PMCCFILTR\_EL0 is in the Core power domain.

### Attributes

PMCCFILTR\_EL0 is a 32-bit register.

The PMCCFILTR\_EL0 bit assignments are:

### P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.
- 1 Do not count cycles in EL1.

### U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count cycles in EL0.
- 1 Do not count cycles in EL0.

### NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted. Otherwise, cycles in Non-secure EL1 are not counted.

**NSU, bit [28]**

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

**NSH, bit [27]**

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

**M, bit [26]**

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

**Bits [25:0]**

Reserved, RES0.

**Accessing the PMCCFILTR\_EL0:**

PMCCFILTR\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x47C

### 11.2.3 PMCCNTR\_EL0, Performance Monitors Cycle Counter

The PMCCNTR\_EL0 characteristics are:

#### Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.  
This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

PMCCNTR\_EL0 is architecturally mapped to AArch64 register [PMCCNTR\\_EL0](#).  
PMCCNTR\_EL0 is architecturally mapped to AArch32 register [PMCCNTR](#).  
PMCCNTR\_EL0 is in the Core power domain.

#### Attributes

PMCCNTR\_EL0 is a 64-bit register.

The PMCCNTR\_EL0 bit assignments are:

#### CCNT, bits [63:0]

Cycle count. Depending on the values of [PMCR\\_EL0](#).{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

The cycle count can be reset to zero by writing 1 to [PMCR\\_EL0.C](#).

#### Accessing the PMCCNTR\_EL0:

PMCCNTR\_EL0[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0F8

PMCCNTR\_EL0[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0FC

## I1.2.4 PMCEID0\_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0\_EL0 characteristics are:

### Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

### Configurations

PMCEID0\_EL0 is architecturally mapped to AArch64 register [PMCEID0\\_EL0](#).

PMCEID0\_EL0 is architecturally mapped to AArch32 register [PMCEID0](#).

PMCEID0\_EL0 is in the Core power domain.

### Attributes

PMCEID0\_EL0 is a 32-bit register.

The PMCEID0\_EL0 bit assignments are:

### CE[31:0], bits [31:0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For each bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
31	0x01F	L1D_CACHE_ALLOCATE
30	0x01E	CHAIN
29	0x01D	BUS_CYCLES
28	0x01C	TTBR_WRITE_RETIRED
27	0x01B	INST_SPEC
26	0x01A	MEMORY_ERROR
25	0x019	BUS_ACCESS
24	0x018	L2D_CACHE_WB
23	0x017	L2D_CACHE_REFILL

Bit	Event number	Event mnemonic
22	0x016	L2D_CACHE
21	0x015	L1D_CACHE_WB
20	0x014	L1I_CACHE
19	0x013	MEM_ACCESS
18	0x012	BR_PRED
17	0x011	CPU_CYCLES
16	0x010	BR_MIS_PRED
15	0x00F	UNALIGNED_LDST_RETIRED
14	0x00E	BR_RETURN_RETIRED
13	0x00D	BR_IMMED_RETIRED
12	0x00C	PC_WRITE_RETIRED
11	0x00B	CID_WRITE_RETIRED
10	0x00A	EXC_RETURN
9	0x009	EXC_TAKEN
8	0x008	INST_RETIRED
7	0x007	ST_RETIRED
6	0x006	LD_RETIRED
5	0x005	L1D_TLB_REFILL
4	0x004	L1D_CACHE
3	0x003	L1D_CACHE_REFILL
2	0x002	L1I_TLB_REFILL
1	0x001	L1I_CACHE_REFILL
0	0x000	SW_INCR

#### Accessing the PMCEID0\_EL0:

PMCEID0\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE20

## I1.2.5 PMCEID1\_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1\_EL0 characteristics are:

### Purpose

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

### Configurations

PMCEID1\_EL0 is architecturally mapped to AArch64 register [PMCEID1\\_EL0](#).

PMCEID1\_EL0 is architecturally mapped to AArch32 register [PMCEID1](#).

PMCEID1\_EL0 is in the Core power domain.

### Attributes

PMCEID1\_EL0 is a 32-bit register.

The PMCEID1\_EL0 bit assignments are:

### Bits [31:1]

Reserved, RES0.

### CE[32], bit [0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
0	0x020	L2D_CACHE_ALLOCATE

### Accessing the PMCEID1\_EL0:

PMCEID1\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE24

## I1.2.6 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

### Purpose

Contains PMU-specific configuration data.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

### Configurations

PMCFGR is in the Core power domain.

### Attributes

PMCFGR is a 32-bit register.

The PMCFGR bit assignments are:

### Bits [31:20]

Reserved, RES0.

### UEN, bit [19]

User-mode Enable Register supported. [PMUSERENR\\_ELO](#) is not visible in the external debug interface, so this bit is RES0.

### WT, bit [18]

This feature is not supported, so this bit is RES0.

### NA, bit [17]

This feature is not supported, so this bit is RES0.

### EX, bit [16]

Export supported. Value is IMPLEMENTATION DEFINED.

0 [PMCR\\_ELO.X](#) is RES0.

1 [PMCR\\_ELO.X](#) is read/write.

### CCD, bit [15]

Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RES0 otherwise.

0 [PMCR\\_ELO.D](#) is RES0.

1 [PMCR\\_ELO.D](#) is read/write.

**CC, bit [14]**

Dedicated cycle counter (counter 31) supported. This bit is RES1.

**SIZE, bits [13:8]**

Size of counters. This field determines the spacing of counters in the memory-map.

In v8-A the counters are at doubleword-aligned addresses, and the largest counter is 64-bits, so this field is `0b111111`.

**N, bits [7:0]**

Number of counters implemented in addition to the cycle counter, [PMCCNTR\\_ELO](#). The maximum number of event counters is 31, so bits[7:5] are always RES0.

`00000000` Only [PMCCNTR\\_ELO](#) implemented.

`00000001` [PMCCNTR\\_ELO](#) plus one event counter implemented.

and so on up to `0b00011111`, which indicates [PMCCNTR\\_ELO](#) and 31 event counters implemented.

**Accessing the PMCFGR:**

PMCFGR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE00

## I1.2.7 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMCIDR0 is in the Debug power domain.  
 PMCIDR0 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

### Attributes

PMCIDR0 is a 32-bit register.

The PMCIDR0 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### PRMBL\_0, bits [7:0]

Preamble. Must read as 0x00.

### Accessing the PMCIDR0:

PMCIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFF0

## 11.2.8 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMCIDR1 is in the Debug power domain.

PMCIDR1 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

### Attributes

PMCIDR1 is a 32-bit register.

The PMCIDR1 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

### PRMBL\_1, bits [3:0]

Preamble. RAZ.

### Accessing the PMCIDR1:

PMCIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFF4

## I1.2.9 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.  
This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMCIDR2 is in the Debug power domain.  
PMCIDR2 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

PMCIDR2 is a 32-bit register.

The PMCIDR2 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### PRMBL\_2, bits [7:0]

Preamble. Must read as 0x05.

### Accessing the PMCIDR2:

PMCIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFF8

### 11.2.10 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

PMCIDR3 is in the Debug power domain.  
 PMCIDR3 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

#### Attributes

PMCIDR3 is a 32-bit register.

The PMCIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_3, bits [7:0]

Preamble. Must read as 0xB1.

#### Accessing the PMCIDR3:

PMCIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFFC

## I1.2.11 PMCNTENCLR\_ELO, Performance Monitors Count Enable Clear register

The PMCNTENCLR\_ELO characteristics are:

### Purpose

Disables the Cycle Count Register, [PMCCNTR\\_ELO](#), and any implemented event counters [PMEVCNTR<x>](#). Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMCNTENCLR\_ELO is architecturally mapped to AArch64 register [PMCNTENCLR\\_ELO](#).

PMCNTENCLR\_ELO is architecturally mapped to AArch32 register [PMCNTENCLR](#).

PMCNTENCLR\_ELO is in the Core power domain.

### Attributes

PMCNTENCLR\_ELO is a 32-bit register.

The PMCNTENCLR\_ELO bit assignments are:

### C, bit [31]

[PMCCNTR\\_ELO](#) disable bit. Disables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter disable bit for [PMEVCNTR<x>](#).

N is the value in [PMCR\\_ELO.N](#). Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) is enabled. When written, disables [PMEVCNTR<x>](#).

### Accessing the PMCNTENCLR\_ELO:

PMCNTENCLR\_ELO can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC20

## I1.2.12 PMCNTENSET\_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET\_EL0 characteristics are:

### Purpose

Enables the Cycle Count Register, [PMCCNTR\\_EL0](#), and any implemented event counters [PMEVCNTR<x>](#). Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMCNTENSET\_EL0 is architecturally mapped to AArch64 register [PMCNTENSET\\_EL0](#).

PMCNTENSET\_EL0 is architecturally mapped to AArch32 register [PMCNTENSET](#).

PMCNTENSET\_EL0 is in the Core power domain.

### Attributes

PMCNTENSET\_EL0 is a 32-bit register.

The PMCNTENSET\_EL0 bit assignments are:

### C, bit [31]

[PMCCNTR\\_EL0](#) enable bit. Enables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter enable bit for [PMEVCNTR<x>](#).

N is the value in [PMCR\\_EL0.N](#). Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) event counter is enabled. When written, enables [PMEVCNTR<x>](#).

### Accessing the PMCNTENSET\_ELO:

PMCNTENSET\_ELO can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC00

## 11.2.13 PMCR\_ELO, Performance Monitors Control Register

The PMCR\_ELO characteristics are:

### Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMCR\_ELO is architecturally mapped to AArch64 register [PMCR\\_ELO](#).

PMCR\_ELO is architecturally mapped to AArch32 register [PMCR](#).

PMCR\_ELO is in the Core power domain.

Bits [31:11] of this register must be implemented as RAZ/WI despite the mapping to the internal [PMCR](#) system register. An external agent must use other means to discover this information, such as [PMCFGR](#) and the ID registers.

### Attributes

PMCR\_ELO is a 32-bit register.

The PMCR\_ELO bit assignments are:

### Bits [31:11]

Reserved, RAZ/WI.

### Bits [10:7]

Reserved, RES0.

### LC, bit [6]

Long cycle counter enable. Determines which [PMCCNTR\\_ELO](#) bit generates an overflow recorded by [PMOVSr](#)[31].

0 Cycle counter overflow on increment that changes [PMCCNTR\\_ELO](#)[31] from 1 to 0.

1 Cycle counter overflow on increment that changes [PMCCNTR\\_ELO](#)[63] from 1 to 0.

ARM deprecates use of `PMCR_ELO.LC = 0`.

### DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 [PMCCNTR\\_ELO](#), if enabled, counts when event counting is prohibited.

1 [PMCCNTR\\_ELO](#) does not count when event counting is prohibited.

Event counting is prohibited when `ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE`.

This bit is RW.

### X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0 Do not export events.
- 1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

### D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, [PMCCNTR\\_ELO](#) counts every clock cycle.
- 1 When enabled, [PMCCNTR\\_ELO](#) counts once every 64 clock cycles.

This bit is RW.

If [PMCR\\_ELO.LC](#) == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of [PMCR.D](#) = 1.

### C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset [PMCCNTR\\_ELO](#) to zero.

This bit is always RAZ.

Resetting [PMCCNTR\\_ELO](#) does not clear the [PMCCNTR\\_ELO](#) overflow bit to 0.

### P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset all event counters, not including [PMCCNTR\\_ELO](#), to zero.

This bit is always RAZ.

Resetting the event counters does not clear any overflow bits to 0.

### E, bit [0]

Enable. The possible values of this bit are:

- 0 All counters, including [PMCCNTR\\_ELO](#), are disabled.
- 1 All counters are enabled by [PMCNTENSET\\_ELO](#).

This bit is RW.

### Accessing the [PMCR\\_ELO](#):

[PMCR\\_ELO](#) can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE04

## I1.2.14 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

### Purpose

Copy of the low half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the Performance Monitor component relates to.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMDEVAFF0 is in the Debug power domain.

PMDEVAFF0 is optional to implement in the external register interface.

### Attributes

PMDEVAFF0 is a 32-bit register.

The PMDEVAFF0 bit assignments are:

### Bits [31:0]

[MPIDR\\_EL1](#) low half. Read-only copy of the low half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

### Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFA8

## 11.2.15 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

### Purpose

Copy of the high half of the processor [MPIDR\\_EL1](#) register that allows a debugger to determine which processor in a multiprocessor system the Performance Monitor component relates to.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMDEVAFF1 is in the Debug power domain.

PMDEVAFF1 is optional to implement in the external register interface.

### Attributes

PMDEVAFF1 is a 32-bit register.

The PMDEVAFF1 bit assignments are:

### Bits [31:0]

[MPIDR\\_EL1](#) high half. Read-only copy of the high half of [MPIDR\\_EL1](#), as seen from the highest implemented exception level.

### Accessing the PMDEVAFF1:

PMDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFAC

## I1.2.16 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

### Purpose

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMDEVARCH is in the Debug power domain.

PMDEVARCH is optional to implement in the external register interface.

### Attributes

PMDEVARCH is a 32-bit register.

The PMDEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, 0x4.

Bits [27:21] are the JEP 106 ID code, 0x3B.

### PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in v8-A.

### REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For Performance Monitors, the revision defined by v8-A is 0x0.

All other values are reserved.

### ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, 0x2.
- Bits [11:0] are the architecture part number, 0xA16.

This corresponds to Performance Monitors architecture version PMUv3.

### Accessing the PMDEVARCH:

PMDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFBC

## I1.2.17 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

### Purpose

Indicates to a debugger that this component is part of a processor's performance monitor interface.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMDEVTYPE is in the Debug power domain.  
 PMDEVTYPE is optional to implement in the external register interface.

### Attributes

PMDEVTYPE is a 32-bit register.

The PMDEVTYPE bit assignments are:

### Bits [31:8]

Reserved, RES0.

### SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a processor component.

### MAJOR, bits [3:0]

Major type. Must read as 0x6 to indicate this is a performance monitor component.

### Accessing the PMDEVTYPE:

PMDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFCC

## 11.2.18 PMEVCNTR<n>\_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>\_EL0 characteristics are:

### Purpose

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

External accesses to the performance monitors ignore [PMUSERENR\\_EL0](#) and, if implemented, [MDCR\\_EL2](#).{TPM, TPMCR, HPMN} and [MDCR\\_EL3](#).TPM. This means that all counters are accessible regardless of the current EL or privilege of the access.

### Configurations

PMEVCNTR<n>\_EL0 is architecturally mapped to AArch64 register [PMEVCNTR<n>\\_EL0](#).

PMEVCNTR<n>\_EL0 is architecturally mapped to AArch32 register [PMEVCNTR<n>](#).

PMEVCNTR<n>\_EL0 is in the Core power domain.

### Attributes

PMEVCNTR<n>\_EL0 is a 32-bit register.

The PMEVCNTR<n>\_EL0 bit assignments are:

### Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

### Accessing the PMEVCNTR<n>\_EL0:

PMEVCNTR<n>\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x000 + 8n

## 11.2.19 PMEVTYPER<n>\_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>\_EL0 characteristics are:

### Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMEVTYPER<n>\_EL0 is architecturally mapped to AArch64 register [PMEVTYPER<n>\\_EL0](#).

PMEVTYPER<n>\_EL0 is architecturally mapped to AArch32 register [PMEVTYPER<n>](#).

PMEVTYPER<n>\_EL0 is in the Core power domain.

### Attributes

PMEVTYPER<n>\_EL0 is a 32-bit register.

The PMEVTYPER<n>\_EL0 bit assignments are:

### P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

### U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

### NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

**NSU, bit [28]**

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

**NSH, bit [27]**

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

**M, bit [26]**

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Secure EL3 are counted.

Otherwise, events in Secure EL3 are not counted.

**Bits [25:10]**

Reserved, RES0.

**evtCount, bits [9:0]**

Event to count. The event number of the event that is counted by event counter [PMEVCNTR<n>\\_EL0](#).

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

**Accessing the PMEVTYPER<n>\_EL0:**

PMEVTYPER<n>\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x400 + 4n

## I1.2.20 PMINTENCLR\_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR\_EL1 characteristics are:

### Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR\\_ELO](#), and the event counters [PMEVCNTR<n>\\_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMINTENCLR\_EL1 is architecturally mapped to AArch64 register [PMINTENCLR\\_EL1](#).

PMINTENCLR\_EL1 is architecturally mapped to AArch32 register [PMINTENCLR](#).

PMINTENCLR\_EL1 is in the Core power domain.

### Attributes

PMINTENCLR\_EL1 is a 32-bit register.

The PMINTENCLR\_EL1 bit assignments are:

### C, bit [31]

[PMCCNTR\\_ELO](#) overflow interrupt request disable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow interrupt request disable bit for [PMEVCNTR<x>\\_ELO](#).

N is the value in [PMCR\\_ELO.N](#). Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<x>\\_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<x>\\_ELO](#) event counter interrupt request is enabled. When written, disables the [PMEVCNTR<x>\\_ELO](#) interrupt request.

### Accessing the PMINTENCLR\_EL1:

PMINTENCLR\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC60

## 11.2.21 PMINTENSET\_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET\_EL1 characteristics are:

### Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR\\_ELO](#), and the event counters [PMEVCNTR<n>\\_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMINTENSET\_EL1 is architecturally mapped to AArch64 register [PMINTENSET\\_EL1](#).

PMINTENSET\_EL1 is architecturally mapped to AArch32 register [PMINTENSET](#).

PMINTENSET\_EL1 is in the Core power domain.

### Attributes

PMINTENSET\_EL1 is a 32-bit register.

The PMINTENSET\_EL1 bit assignments are:

### C, bit [31]

[PMCCNTR\\_ELO](#) overflow interrupt request enable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow interrupt request enable bit for [PMEVCNTR<x>\\_ELO](#).

N is the value in [PMCR\\_ELO.N](#). Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<x>\\_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<x>\\_ELO](#) event counter interrupt request is enabled. When written, enables the [PMEVCNTR<x>\\_ELO](#) interrupt request.

### Accessing the PMINTENSET\_EL1:

PMINTENSET\_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC40

## I1.2.22 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

### Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

### Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is in the Core power domain or in the Debug power domain.

PMITCTRL is optional to implement in the external register interface.

### Attributes

PMITCTRL is a 32-bit register.

The PMITCTRL bit assignments are:

### Bits [31:1]

Reserved, RES0.

### IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

### Accessing the PMITCTRL:

PMITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xF00

## 11.2.23 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

### Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

WO

---

### Configurations

PMLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and [PMLSR](#) to check the current status of the lock.

### Attributes

PMLAR is a 32-bit register.

The PMLAR bit assignments are:

### KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

### Accessing the PMLAR:

PMLAR can be accessed through the internal memory-mapped interface:

Component	Offset
PMU	0xFB0

## I1.2.24 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

### Purpose

Indicates the current status of the software lock for Performance Monitors registers.  
This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

### Configurations

PMLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses [PMLAR](#) to set or clear the lock, and PMLSR to check the current status of the lock.

### Attributes

PMLSR is a 32-bit register.

The PMLSR bit assignments are:

### Bits [31:3]

Reserved, RES0.

### nTT, bit [2]

Not thirty-two bit access required. RAZ.

### SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

0 Lock clear. Writes are permitted to this component's registers.

1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

**SLI, bit [0]**

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

- 0 Software lock not implemented or not memory-mapped access.
- 1 Software lock implemented and memory-mapped access.

**Accessing the PMLSR:**

PMLSR can be accessed through the internal memory-mapped interface:

Component	Offset
PMU	0xFB4

## I1.2.25 PMOVSLR\_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSLR\_EL0 characteristics are:

### Purpose

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR\\_EL0](#), and each of the implemented event counters [PMEVCNTR<x>](#). Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMOVSLR\_EL0 is architecturally mapped to AArch64 register [PMOVSLR\\_EL0](#).

PMOVSLR\_EL0 is architecturally mapped to AArch32 register [PMOVSRR](#).

PMOVSLR\_EL0 is in the Core power domain.

### Attributes

PMOVSLR\_EL0 is a 32-bit register.

The PMOVSLR\_EL0 bit assignments are:

### C, bit [31]

[PMCCNTR\\_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR\_EL0.LC is used to control from which bit of [PMCCNTR\\_EL0](#) (bit 31 or bit 63) an overflow is detected.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow clear bit for [PMEVCNTR<x>](#).

N is the value in [PMCR\\_EL0.N](#). Bits [30:N] are RAZ/WI.

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<x>](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) has overflowed. When written, clears the [PMEVCNTR<x>](#) overflow bit to 0.

### Accessing the PMOVSLR\_EL0:

PMOVSLR\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC80

## I1.2.26 PMOVSET\_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSET\_EL0 characteristics are:

### Purpose

Sets the state of the overflow bit for the Cycle Count Register, [PMCCNTR\\_EL0](#), and each of the implemented event counters [PMEVCNTR<x>](#).

This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

### Configurations

PMOVSET\_EL0 is architecturally mapped to AArch64 register [PMOVSET\\_EL0](#).

PMOVSET\_EL0 is architecturally mapped to AArch32 register [PMOVSET](#).

PMOVSET\_EL0 is in the Core power domain.

### Attributes

PMOVSET\_EL0 is a 32-bit register.

The PMOVSET\_EL0 bit assignments are:

### C, bit [31]

[PMCCNTR\\_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow set bit for [PMEVCNTR<x>](#).

N is the value in [PMCR\\_EL0.N](#). Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that [PMEVCNTR<x>](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<x>](#) has overflowed. When written, sets the [PMEVCNTR<x>](#) overflow bit to 1.

### Accessing the PMOVSSET\_ELO:

PMOVSSET\_ELO can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xCC0

## I1.2.27 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.  
This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMPIDR0 is in the Debug power domain.  
PMPIDR0 is optional to implement in the external register interface.  
This register is required for CoreSight compliance.

### Attributes

PMPIDR0 is a 32-bit register.

The PMPIDR0 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### PART\_0, bits [7:0]

Part number, least significant byte.

### Accessing the PMPIDR0:

PMPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFE0

## 11.2.28 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMPIDR1 is in the Debug power domain.  
 PMPIDR1 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

### Attributes

PMPIDR1 is a 32-bit register.

The PMPIDR1 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### DES\_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

### PART\_1, bits [3:0]

Part number, most significant nibble.

### Accessing the PMPIDR1:

PMPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFE4

## I1.2.29 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

### Configurations

PMPIDR2 is in the Debug power domain.  
 PMPIDR2 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

### Attributes

PMPIDR2 is a 32-bit register.

The PMPIDR2 bit assignments are:

### Bits [31:8]

Reserved, RES0.

### REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

### JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

### DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

### Accessing the PMPIDR2:

PMPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFE8

### 11.2.30 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

PMPIDR3 is in the Debug power domain.  
 PMPIDR3 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

#### Attributes

PMPIDR3 is a 32-bit register.

The PMPIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVAND, bits [7:4]

Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

#### CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

#### Accessing the PMPIDR3:

PMPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFEC

### I1.2.31 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.  
 This register is part of the Performance Monitors registers functional group.

#### Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

#### Configurations

PMPIDR4 is in the Debug power domain.  
 PMPIDR4 is optional to implement in the external register interface.  
 This register is required for CoreSight compliance.

#### Attributes

PMPIDR4 is a 32-bit register.

The PMPIDR4 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SIZE, bits [7:4]

Size of the component. RAZ. Log<sub>2</sub> of the number of 4KB pages from the start of the component to the end of the component ID registers.

#### DES\_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

#### Accessing the PMPIDR4:

PMPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFD0

## 11.2.32 PMSWINC\_EL0, Performance Monitors Software Increment register

The PMSWINC\_EL0 characteristics are:

### Purpose

Increments a counter that is configured to count the Software increment event, event 0x00.  
 This register is part of the Performance Monitors registers functional group.

### Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	WO

### Configurations

PMSWINC\_EL0 is architecturally mapped to AArch64 register [PMSWINC\\_EL0](#).

PMSWINC\_EL0 is architecturally mapped to AArch32 register [PMSWINC](#).

PMSWINC\_EL0 is in the Core power domain.

PMSWINC\_EL0 is optional to implement in the external register interface.

If this register is implemented, use of it is deprecated.

If 1 is written to bit [x] from the external debug interface, it is CONstrained UNPREDICTABLE whether or not a SW\_INCR event is created for counter x. This is consistent with not implementing the register in the external debug interface.

### Attributes

PMSWINC\_EL0 is a 32-bit register.

The PMSWINC\_EL0 bit assignments are:

### Bit [31]

Reserved, RES0.

### P<x>, bit [x] for x = 0 to (N - 1)

Event counter software increment bit for PMEVCNTR<x>.

P<x> is WI if  $x \geq \text{PMCR\_EL0.N}$ , the number of implemented counters.

Otherwise, the effects of writing to this bit are:

0 No action. The write to this bit is ignored.

1 It is CONstrained UNPREDICTABLE whether a SW\_INCR event is generated for event counter x.

### Accessing the PMSWINC\_EL0:

PMSWINC\_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xCA0

## I1.3 Generic Timer registers

This section describes the Generic Timer registers.

### I1.3.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

#### Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible from Non-secure state.
- If frame CNTELOBaseN is implemented, the CNTELOACR in frame CNTBaseN provides additional control of accesses to frame CNTELOBaseN.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RW

---

In a system that implements both Secure and Non-secure states:

- This register is always accessible in Secure state.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible in Non-secure state.

#### Configurations

Implemented only if CNTTIDR.FI<n> is RAO.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

#### Attributes

CNTACR<n> is a 32-bit register.

The CNTACR<n> bit assignments are:

#### Bits [31:6]

Reserved, RES0.

**RWPT, bit [5]**

Read/write access to the EL1 Physical Timer registers [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the EL1 Physical Timer registers in frame <n>.

**RWVT, bit [4]**

Read/write access to the Virtual Timer register [CNTV\\_CVAL](#), [CNTV\\_TVAL](#), and [CNTV\\_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the Virtual Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the Virtual Timer registers in frame <n>.

**RVOFF, bit [3]**

Read-only access to [CNTVOFF](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVOFF](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVOFF](#) in frame <n>.

**RFRQ, bit [2]**

Read-only access to [CNTFRQ](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTFRQ](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTFRQ](#) in frame <n>.

**RVCT, bit [1]**

Read-only access to [CNTVCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVCT](#) in frame <n>.

**RPCT, bit [0]**

Read-only access to [CNTPCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTPCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTPCT](#) in frame <n>.

**Accessing the CNTACR<n>:**

CNTACR<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x040 + 4n

## I1.3.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

### Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

This register is part of the Generic Timer registers functional group.

### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RW

---

In a system that implements both Secure and Non-secure states, this register is only writable in Secure state.

### Configurations

There are no configuration notes.

### Attributes

CNTCR is a 32-bit register.

The CNTCR bit assignments are:

### FCREQ, bits [31:8]

Frequency change request. Indicates the number of the entry in the frequency table to select. Selecting an unimplemented entry, or the 0 entry (base frequency) has no effect on the counter. Resets to 0.

### Bits [7:2]

Reserved, RES0.

### HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

0 System counter ignores Halt-on-debug.

1 Asserted Halt-on-debug signal halts system counter update.

Reset value is architecturally UNKNOWN.

### EN, bit [0]

Enables the counter:

0 System counter disabled.

1 System counter enabled.

Resets to 0.

### Accessing the CNTCR:

CNTCR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x000

### I1.3.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

#### Purpose

Indicates the current count value.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

#### Default

---

RW in CNTControlBase, RO in CNTReadBase

---

#### Configurations

There are no configuration notes.

#### Attributes

CNTCV is a 64-bit register.

The CNTCV bit assignments are:

#### CountValue, bits [63:0]

Indicates the counter value.

#### Accessing the CNTCV:

CNTCV[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x008
Timer	CNTReadBase	0x000

CNTCV[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x00C
Timer	CNTReadBase	0x004

### 11.3.4 CNTELOACR, Counter-timer EL0 Access Control Register

The CNTELOACR characteristics are:

#### Purpose

An implementation of CNTELOACR in the frame at CNTBaseN controls whether the [CNTPCT](#), [CNTVCT](#), [CNTFRQ](#), EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTELOBaseN.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RW

---

#### Configurations

CNTELOACR is optional to implement in the external register interface.

In each implemented CNTBaseN frame, CNTELOACR is optional. If it is not implemented:

- Its location is RAZ/WI.
- The registers it controls are not visible in the corresponding CNTELOBaseN frame.

#### Attributes

CNTELOACR is a 32-bit register.

The CNTELOACR bit assignments are:

#### Bits [31:10]

Reserved, RES0.

#### EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTELOBaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

#### EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the [CNTV\\_CVAL](#), [CNTV\\_TVAL](#), and [CNTV\\_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTELOBaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTELOBaseN frame, regardless of the value of this bit.

#### Bits [7:2]

Reserved, RES0.

#### EL0VCTEN, bit [1]

Second view read access control for [CNTVCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTVCT](#) is not visible in the second view.  
If EL0PCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTVCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

#### EL0PCTEN, bit [0]

Second view read access control for [CNTPCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTPCT](#) is not visible in the second view.  
If EL0VCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTPCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

#### Accessing the CNTELOACR:

CNTELOACR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x014

### 11.3.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

#### Purpose

Indicates the base frequency of the system counter.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO or RW

---

#### Configurations

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialise the table entries as part of its start-up sequence.

If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

#### Attributes

CNTFID0 is a 32-bit register.

The CNTFID0 bit assignments are:

#### Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

#### Accessing the CNTFID0:

CNTFID0 can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020

### I1.3.6 CNTFID<n>, Counter Frequency IDs, n = 1 - 23

The CNTFID<n> characteristics are:

#### Purpose

Indicates alternative system counter update frequencies.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO or RW

---

#### Configurations

CNTFID<n> is optional to implement in the external register interface.

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table. The only required entry in the table is the entry for CNTFID0.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialise the table entries as part of its start-up sequence.

If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

#### Attributes

CNTFID<n> is a 32-bit register.

The CNTFID<n> bit assignments are:

#### Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. ARM strongly recommends that all frequency values in the table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

$$\text{increment} = (\text{base frequency}) / \text{selected frequency}$$

#### Accessing the CNTFID<n>:

CNTFID<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020 + 4n

### 11.3.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

#### Purpose

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

In a system that implements both Secure and Non-secure states, this register is only accessible in Secure state.

#### Configurations

CNTFRQ is architecturally mapped to AArch64 register [CNTFRQ\\_ELO](#).

CNTFRQ is architecturally mapped to AArch32 register [CNTFRQ](#).

#### Attributes

CNTFRQ is a 32-bit register.

The CNTFRQ bit assignments are:

#### Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

#### Accessing the CNTFRQ:

CNTFRQ can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x010
Timer	CNTELOBaseN	0x010
Timer	CNTCTLBase	0x000

### 11.3.8 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

**Purpose**

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

<b>Default</b>
RW

In a system that implements both Secure and Non-secure states, this register is only accessible in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTNSAR is a 32-bit register.

The CNTNSAR bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**NS<n>, bit [n], for n = 0 to 7**

Non-secure access to frame n. The possible values of this bit are:

- 0 Secure access only. Behaves as RES0 to Non-secure accesses.
- 1 Secure and Non-secure accesses permitted.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Non-secure accesses, then NS<n> is RES1.

### Accessing the CNTNSAR:

CNTNSAR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x004

### I1.3.9 CNTP\_CTL, Counter-timer Physical Timer Control

The CNTP\_CTL characteristics are:

#### Purpose

Control register for the physical timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RW

[CNTACR<n>](#).RWPT enables access to this register in frame <n>.

#### Configurations

CNTP\_CTL is architecturally mapped to AArch64 register [CNTP\\_CTL\\_ELO](#).

CNTP\_CTL is architecturally mapped to AArch32 register [CNTP\\_CTL](#).

#### Attributes

CNTP\_CTL is a 32-bit register.

The CNTP\_CTL bit assignments are:

#### Bits [31:3]

Reserved, RES0.

#### ISTATUS, bit [2]

The status of the timer interrupt:

0 Interrupt not asserted.

1 Interrupt asserted.

This bit is read-only.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked.

1 Timer interrupt is masked.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0           Timer disabled.

1           Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

**Accessing the CNTP\_CTL:**

CNTP\_CTL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x02C
Timer	CNTELOBaseN	0x02C

### 11.3.10 CNTP\_CVAL, Counter-timer Physical Timer CompareValue

The CNTP\_CVAL characteristics are:

#### Purpose

Holds the 64-bit compare value for the EL1 physical timer.  
 This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RW

[CNTACR<n>](#).RWPT enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the CNTP\_CVAL register must be accessible as an atomic 64-bit value.

#### Configurations

CNTP\_CVAL is architecturally mapped to AArch64 register [CNTP\\_CVAL\\_EL0](#).

CNTP\_CVAL is architecturally mapped to AArch32 register [CNTP\\_CVAL](#).

#### Attributes

CNTP\_CVAL is a 64-bit register.

The CNTP\_CVAL bit assignments are:

#### Bits [63:0]

EL1 physical timer compare value.

#### Accessing the CNTP\_CVAL:

CNTP\_CVAL[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x020
Timer	CNTEL0BaseN	0x020

CNTP\_CVAL[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x024
Timer	CNTEL0BaseN	0x024

### I1.3.11 CNTP\_TVAL, Counter-timer Physical Timer TimerValue

The CNTP\_TVAL characteristics are:

#### Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.  
 This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RW

[CNTACR<n>](#).RWPT enables access to this register in frame <n>.

#### Configurations

CNTP\_TVAL is architecturally mapped to AArch64 register [CNTP\\_TVAL\\_ELO](#).

CNTP\_TVAL is architecturally mapped to AArch32 register [CNTP\\_TVAL](#).

#### Attributes

CNTP\_TVAL is a 32-bit register.

The CNTP\_TVAL bit assignments are:

#### Bits [31:0]

EL1 physical timer value.

#### Accessing the CNTP\_TVAL:

CNTP\_TVAL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x028
Timer	CNTELOBaseN	0x028

### I1.3.12 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

#### Purpose

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RO

[CNTACR<n>.RPCT](#) enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

#### Configurations

CNTPCT is architecturally mapped to AArch64 register [CNTPCT\\_EL0](#).

CNTPCT is architecturally mapped to AArch32 register [CNTPCT](#).

#### Attributes

CNTPCT is a 64-bit register.

The CNTPCT bit assignments are:

#### Bits [63:0]

Physical count value.

#### Accessing the CNTPCT:

CNTPCT[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x000
Timer	CNTELOBaseN	0x000

CNTPCT[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x004
Timer	CNTELOBaseN	0x004

### 11.3.13 CNTSR, Counter Status Register

The CNTSR characteristics are:

#### Purpose

Provides counter frequency status information.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RO

#### Configurations

There are no configuration notes.

#### Attributes

CNTSR is a 32-bit register.

The CNTSR bit assignments are:

#### FCACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the frequency table.

Selecting an unimplemented entry, or the 0 entry (base frequency) has no effect on the counter.

Resets to 0.

#### Bits [7:2]

Reserved, RES0.

#### DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-Debug signal is asserted:

0 Counter is not halted.

1 Counter is halted.

Reset value is architecturally UNKNOWN.

#### Bit [0]

Reserved, RES0.

### Accessing the CNTSR:

CNTSR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x004

### 11.3.14 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

#### Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RO

---

#### Configurations

There are no configuration notes.

#### Attributes

CNTTIDR is a 32-bit register.

The CNTTIDR bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Frame7	Frame6	Frame5	Frame4	Frame3	Frame2	Frame1	Frame0	

#### Frame<n>, bits [4n+3:4n], for n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2] indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0	Frame <n> does not have a second view. CNTEL0Base<n> is RES0.
1	Frame <n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1] indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV\_CVAL, CNTV\_TVAL, and CNTV\_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

The possible values of bit[1] are:

Bit[1]	Meaning
0	Frame <n> does not have virtual capability. The virtual time and offset registers are RES0.
1	Frame <n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0] indicates whether frame <n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0	Frame <n> not implemented. All registers associated with the frame are RES0.
1	Frame <n> is implemented.

#### Accessing the CNTTIDR:

CNTTIDR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x008

### 11.3.15 CNTV\_CTL, Counter-timer Virtual Timer Control

The CNTV\_CTL characteristics are:

#### Purpose

Control register for the virtual timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

---

RW

---

Bit [1] of [CNTTIDR.Frame<n>](#) indicates whether CNTV\_CTL is implemented for frame <n>.

If CNTV\_CTL is implemented, [CNTACR<n>.RWVT](#) enables access to the register in frame <n>.

If CNTV\_CTL is not implemented, the register location is RAZ/WI.

#### Configurations

CNTV\_CTL is architecturally mapped to AArch64 register [CNTV\\_CTL\\_EL0](#).

CNTV\_CTL is architecturally mapped to AArch32 register [CNTV\\_CTL](#).

CNTV\_CTL is optional to implement in the external register interface.

#### Attributes

CNTV\_CTL is a 32-bit register.

The CNTV\_CTL bit assignments are:

#### Bits [31:3]

Reserved, RES0.

#### ISTATUS, bit [2]

The status of the timer interrupt:

0 Interrupt not asserted.

1 Interrupt asserted.

This bit is read-only.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked.

1 Timer interrupt is masked.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0           Timer disabled.

1           Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

**Accessing the CNTV\_CTL:**

CNTV\_CTL can be accessed through the internal memory-mapped interface:

<b>Component</b>	<b>Frame</b>	<b>Offset</b>
Timer	CNTBaseN	0x03C
Timer	CNTELOBaseN	0x03C

### 11.3.16 CNTV\_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV\_CVAL characteristics are:

#### Purpose

Holds the 64-bit compare value for the virtual timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RW

Bit [1] of [CNTTIDR](#).Frame<n> indicates whether CNTV\_CVAL is implemented for frame <n>. If CNTV\_CVAL is implemented, [CNTACR](#)<n>.RWVT enables access to the register in frame <n>. If CNTV\_CVAL is not implemented, the register location is RAZ/WI. If the implementation supports 64-bit atomic accesses, then the CNTV\_CVAL register must be accessible as an atomic 64-bit value.

#### Configurations

CNTV\_CVAL is architecturally mapped to AArch64 register [CNTV\\_CVAL\\_EL0](#).

CNTV\_CVAL is architecturally mapped to AArch32 register [CNTV\\_CVAL](#).

CNTV\_CVAL is optional to implement in the external register interface.

#### Attributes

CNTV\_CVAL is a 64-bit register.

The CNTV\_CVAL bit assignments are:

#### Bits [63:0]

Virtual timer compare value.

#### Accessing the CNTV\_CVAL:

CNTV\_CVAL[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x030
Timer	CNTELOBaseN	0x030

CNTV\_CVAL[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x034
Timer	CNTELOBaseN	0x034

### 11.3.17 CNTV\_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV\_TVAL characteristics are:

#### Purpose

Holds the timer value for the virtual timer.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

<b>Default</b>
RW

Bit [1] of [CNTTIDR.Frame<n>](#) indicates whether CNTV\_TVAL is implemented for frame <n>. If CNTV\_TVAL is implemented, [CNTACR<n>.RWVT](#) enables access to the register in frame <n>. If CNTV\_TVAL is not implemented, the register location is RAZ/WI.

#### Configurations

CNTV\_TVAL is architecturally mapped to AArch64 register [CNTV\\_TVAL\\_EL0](#).

CNTV\_TVAL is architecturally mapped to AArch32 register [CNTV\\_TVAL](#).

CNTV\_TVAL is optional to implement in the external register interface.

#### Attributes

CNTV\_TVAL is a 32-bit register.

The CNTV\_TVAL bit assignments are:

#### Bits [31:0]

Virtual timer value.

#### Accessing the CNTV\_TVAL:

CNTV\_TVAL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x038
Timer	CNTEL0BaseN	0x038

### I1.3.18 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

#### Purpose

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RO

[CNTACR<n>.RVCT](#) enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the [CNTPCT](#) register must be accessible as an atomic 64-bit value.

#### Configurations

CNTVCT is architecturally mapped to AArch64 register [CNTVCT\\_EL0](#).

CNTVCT is architecturally mapped to AArch32 register [CNTVCT](#).

#### Attributes

CNTVCT is a 64-bit register.

The CNTVCT bit assignments are:

#### Bits [63:0]

Virtual count value.

#### Accessing the CNTVCT:

CNTVCT[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x008
Timer	CNTELOBaseN	0x008

CNTVCT[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x00C
Timer	CNTELOBaseN	0x00C

### 11.3.19 CNTVOFF, Counter-timer Virtual Offset

The CNTVOFF characteristics are:

#### Purpose

Holds the 64-bit virtual offset.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RO

If the implementation supports 64-bit atomic accesses, then the CNTVOFF register must be accessible as an atomic 64-bit value.

#### Configurations

CNTVOFF is architecturally mapped to AArch64 register [CNTVOFF\\_EL2](#).

CNTVOFF is architecturally mapped to AArch32 register [CNTVOFF](#).

[CNTACR<n>.RVOFF](#) enables access to this register for frame CNTBase<n>.

#### Attributes

CNTVOFF is a 64-bit register.

The CNTVOFF bit assignments are:

#### Bits [63:0]

Virtual offset.

#### Accessing the CNTVOFF:

CNTVOFF[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x018

CNTVOFF[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x01C

### I1.3.20 CNTVOFF<n>, Counter-timer Virtual Offsets, n = 0 - 7

The CNTVOFF<n> characteristics are:

#### Purpose

Holds the 64-bit virtual offset for frame CNTBase<n>.

This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

Default
RW

If the implementation supports 64-bit atomic accesses, then the CNTVOFF<n> registers must be accessible as atomic 64-bit values.

#### Configurations

CNTVOFF<n> is architecturally mapped to AArch64 register [CNTVOFF\\_EL2](#).

CNTVOFF<n> is architecturally mapped to AArch32 register [CNTVOFF](#).

CNTVOFF<n> is optional to implement in the external register interface.

CNTVOFF<n> is accessible in the CNTCTLBase register map if [CNTACR<n>.RVOFF](#) is 1 and bit [1] of [CNTTIDR.Frame<n>](#) is 1.

If bit [1] of [CNTTIDR.Frame<n>](#) is 0, or [CNTACR<n>.RVOFF](#) is 1, CNTVOFF<n> is RAZ/WI.

#### Attributes

CNTVOFF<n> is a 64-bit register.

The CNTVOFF<n> bit assignments are:

#### Bits [63:0]

Virtual offset.

#### Accessing the CNTVOFF<n>:

CNTVOFF<n>[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x080 + 8n

CNTVOFF<n>[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x084 + 8n

### 11.3.21 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

#### Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.  
This register is part of the Generic Timer registers functional group.

#### Usage constraints

This register is accessible as shown below:

---

**Default**

RO

---

#### Configurations

These registers are implemented independently in each of the frames accessed through the different memory maps.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the ARM Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of 0xF.

#### Attributes

CounterID<n> is a 32-bit register.

The CounterID<n> bit assignments are:

#### Accessing the CounterID<n>:

CounterID<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0xFD0 + 4n
Timer	CNTReadBase	0xFD0 + 4n
Timer	CNTBaseN	0xFD0 + 4n
Timer	CNTELOBaseN	0xFD0 + 4n
Timer	CNTCTLBase	0xFD0 + 4n

# Chapter I2

## System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the optional Generic Timer. It contains the following sections:

- *About the Generic Timer specification* on page I2-4680.
- *Memory-mapped counter module* on page I2-4681.
- *Counter module control and status register summary* on page I2-4684.
- *About the memory-mapped view of the counter and timer* on page I2-4686.
- *The CNTBaseN and CNTPL0BaseN frames* on page I2-4687.
- *The CNTCTLBase frame* on page I2-4689.
- *Providing a complete set of counter and timer features* on page I2-4690.
- *Gray-count scheme for timer distribution scheme* on page I2-4692.

---

### Note

- *Generic Timer registers* on page I1-4647 describes the System level Generic Timer registers. These registers are memory-mapped.
  - *Chapter D7 The Generic Timer* gives a general description of the Generic Timer, and describes the system control register interface to the Generic Timer.
-

## I2.1 About the Generic Timer specification

[Chapter D7 The Generic Timer](#) describes the ARM Generic Timer, and its implementation as an optional extension to an ARMv8 processor implementation. [Chapter D7](#) includes the definition of the low-latency System register interface to the Generic Timer Extension. However, the ARM Generic Timer architecture requires the implementation of some parts of the timer at the system level. This system level implementation includes a memory-mapped interface to the timer that:

- Provides some top-level management of the Generic Timer, that is not available from the System register interface from any PE in the system.
- Provides memory-mapped access to Generic Timer features, for system components that cannot implement a System register interface to the timer. The latency of this memory-mapped access can be significantly higher than the latency of System register accesses.

The Generic Timer architecture defines both a counter and a timer. The counter and timer work in combination, but each has a distinct purpose:

- The counter counts the passing of time.
- The timer schedules the triggering of events.

See [About the Generic Timer on page D7-1856](#) for more information about the timer and the counter. [Generic Timer example on page D7-1856](#) shows a system-wide implementation of the Generic Timer.

Most of this chapter describes the system level implementation of the Generic Timer. [Gray-count scheme for timer distribution scheme on page I2-4692](#) describes a possible scheme for distributing the counter value across this system.

### I2.1.1 The memory-mapped view of the Generic Timer

The memory-mapped view of the Generic Timer provides:

- Access to the system level features of the Generic Timer:
  - [Memory-mapped counter module on page I2-4681](#) describes these features.
  - [Counter module control and status register summary on page I2-4684](#) describes the memory-mapped interface to those features.
- Memory-mapped access to the Generic Timer features defined in [Chapter D7 The Generic Timer](#). This provides memory-mapped access to different views of the system control registers described in that chapter. [About the memory-mapped view of the counter and timer on page I2-4686](#) describes this access.

## I2.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. It provides:

- A RW control register [CNTCR](#), that provides:
  - An enable bit for the system counter.
  - An enable bit for Halt-on-Debug. When this is enabled, if the debug halt signal into the system counter is asserted, it halts the system counter. Otherwise, the system counter ignores the state of this halt signal. For more information about Halt-on-Debug, contact ARM.
  - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. For more information see [Control of counter operating frequency and increment on page I2-4682](#).

Writes to this register are rare. In a system that uses security, this register is writable only by Secure writes.

- A RO status register, [CNTSR](#), that provides:
  - A bit that indicates whether the system counter is halted because of an asserted Halt-on-Debug signal.
  - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.
- Two contiguous RW registers that hold the current system counter value, [CNTCV](#). If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

Writes to these registers are rare. In a system that uses security, these registers are writable only by Secure writes.

- A table of one or more 32-bit entries, where:
  - The first entry defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
  - Each subsequent entry defines an alternative frequency of the system counter, and must be an exact divisor of the base frequency.

A 32-bit zero entry immediately follows the last table entry.

This table can be WO or RW. For more information, see [The frequency modes table on page I2-4682](#).

- Two contiguous RO registers that hold the current system counter value, [CNTCV](#). If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

These registers are located in two memory *frames*, identified by different base addresses:

- The locations of the RO copies of [CNTCV](#) are defined relative to the CNTReadBase base address.
- The locations of all the other registers are defined relative to the CNTControlBase base address.

### ———— **Note** —————

The final twelve words of the first or only 4KB block of a register memory frame is an ID block.

[Counter module control and status register summary on page I2-4684](#) describes CNTReadBase and CNTControlBase memory maps, and the registers in each frame.

## I2.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see [System counter on page D7-1857](#). However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- [The frequency modes table](#)
- [Changing the system counter and increment](#).

### The frequency modes table

The frequency modes table starts at offset 0x20 from CNTControlBase.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

To ensure overall counter accuracy is maintained, any subsequent entries in the table must be exact divisors of the base frequency. That is, ARM strongly recommends that all frequency values in the table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

$$\text{increment} = (\text{base\_frequency}) / (\text{selected\_frequency})$$

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the frequency modes table are in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the CNTControlBase memory map shows the table region as RO or RW.

ARM strongly recommends that the frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the frequency modes table, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

#### ———— **Note** —————

ARM considers it unlikely that implementations will require significantly fewer entries than the architectural limit.

### Changing the system counter and increment

The CNTCR.FREQ field defines which frequency modes table entry specifies the system counter update frequency. The value in the FCREQ specifies the entry.

Changing the value of CNTCR.FREQ requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, it is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.
- When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.

2. Makes the counter increment required for operation at that lower frequency.
3. Switches to operating at the higher frequency.

When the frequency has changed, **CNTSR** is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll **CNTSR** to detect the change.

## I2.3 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory frames:

- A control frame, with base address CNTControlBase.
- A status frame, with base address CNTReadBase.

Each of these register memory frames is at least 4KB in size, or is at least the size of the memory protection granule if this granule size is larger than 4KB. Similarly, each base address must be aligned to 4KB, or to the memory protection granule if that is larger than 4KB.

———— **Note** —————

The memory protection granule is either 4KB or 64KB.

In each register memory frame, the memory at offset 0xFD0-0xFFF is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the [CounterID<n>](#) register descriptions for more information.

The counter is assumed to be little-endian.

In an implementation that supports Secure and Non-secure memory spaces, CNTControlBase is implemented only in the Secure memory space.

[Table I2-1](#) shows the CNTControlBase control registers, in order of their offsets from CNTControlBase. [Generic Timer registers on page I1-4647](#) describes each of these registers.

**Table I2-1 CNTControlBase memory map**

Offset	Name	Type	Description
0x000	<a href="#">CNTCR</a>	RW	Counter Control Register.
0x004	<a href="#">CNTSR</a>	RO	Counter Status Register.
0x008	<a href="#">CNTCV[31:0]</a>	RW	Counter Count Value register.
0x00C	<a href="#">CNTCV[63:32]</a>	RW	
0x010-0x01C	-	RES0	Reserved.
0x020	<a href="#">CNTFID0</a>	RO or RW	Frequency modes table, and end marker.
0x020+4n	<a href="#">CNTFIDn</a>	RO or RW	CNTFID0 is the base frequency, and each CNTFIDn is an alternative frequency. For more information see <a href="#">The frequency modes table on page I2-4682</a> .
0x024+4n	-	RO or RW	
(0x024+4n)-0x0BC	-	RES0	Reserved.
0x0C0-0x0FC	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
0x100-0xFCC	-	RES0	Reserved.
0xFD0-0xFFC	<a href="#">CounterID&lt;n&gt;</a>	RO	Counter ID registers 0-11.

Table I2-2 shows the CNTReadBase control registers, in order of their offsets from CNTReadBase. *Generic Timer registers* on page I1-4647 describes each of these registers.

**Table I2-2 CNTReadBase memory map**

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

## I2.4 About the memory-mapped view of the counter and timer

To provide the Generic Timer functionality to any programmable system components that cannot implement a coprocessor interface to the Generic Timer, the Generic Timer specification defines a memory-mapped component that can be placed close to such a component. ARM recommends that the system implementation includes an instance of this memory-mapped structure for each system component requiring memory-mapped access to the Generic Timer.

The memory map consists of up to 8 timer *frames*. Each timer frame:

- Provides its own set of timers and associated interrupts.
- Is in its own memory protection region that is:
  - In its own memory protection region, with a system-defined size of 4KB or 64KB.
  - At a start address that is aligned to 4KB.

———— **Note** —————

The 4KB alignment requirement applies regardless of the memory protection region size.

The base address of a frame is  $CNTBaseN$ , where  $N$  numbers from 0 up to a maximum permitted value of 7.

The system provides a second view of each implemented  $CNTBaseN$  frame. The base address of the second view of the  $CNTBaseN$  frame is  $CNTPL0BaseN$ , and in this view:

- All registers visible in  $CNTBaseN$  are visible, except for [CNTVOFF](#) and [CNTELOACR](#).
- The offsets of all visible registers are the same as their offsets in the  $CNTBaseN$  frame.

In addition, the system provides a control frame at base address  $CNTCTLBase$ .

The memory protection region and alignment requirements for the  $CNTPL0BaseN$  and  $CNTCTLBase$  frames are the same as the requirements for the  $CNTBaseN$  frames.

The system defines the position of each frame in the memory map. This means the values of each of the  $CNTBaseN$ ,  $CNTPL0BaseN$ , and  $CNTCTLBase$  base addresses is IMPLEMENTATION DEFINED.

The memory-mapped timers are assumed to be little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- [The  \$CNTBaseN\$  and  \$CNTPL0BaseN\$  frames on page I2-4687.](#)
- [The  \$CNTCTLBase\$  frame on page I2-4689.](#)
- [Providing a complete set of counter and timer features on page I2-4690.](#)

## 12.5 The CNTBaseN and CNTPL0BaseN frames

Table I2-3 shows the CNTBaseN registers, in order of their offsets from CNTBaseN. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not then memory at offsets 0x030-0x03C is RAZ/WI. Except for CNTELOACR and the CounterID<n> registers, these registers are also implemented in the system control register interface to the Generic Timer.

Generic Timer registers on page I1-4647 describes each of these registers.

Table I2-3 CNTBaseN memory map

Offset	Register, VMSA	Type	Description
0x000	CNTPCT[31:0] <sup>a</sup>	RO	Physical Count register
0x004	CNTPCT[63:32] <sup>a</sup>	RO	
0x008	CNTVCT[31:0] <sup>a</sup>	RO	Virtual Count register
0x00C	CNTVCT[63:32] <sup>a</sup>	RO	
0x010	CNTRFQ <sup>a</sup>	RO <sup>b</sup>	Counter Frequency register
0x014	CNTELOACR	RW <sup>c</sup>	Counter EL0 Access Control Register, optional in the CNTBaseN memory map
0x018	CNTVOFF[31:0] <sup>a</sup>	RO <sup>d</sup>	Virtual Offset register, if implementation includes EL2
0x01C	CNTVOFF[63:32] <sup>a</sup>	RO <sup>d</sup>	
0x020	CNTP_CVAL[31:0] <sup>a</sup>	RW	EL1 Physical Timer CompareValue register
0x024	CNTP_CVAL[63:32] <sup>a</sup>	RW	
0x028	CNTP_TVAL <sup>a</sup>	RW	EL1 Physical TimerValue register
0x02C	CNTP_CTL <sup>a</sup>	RW	EL1 Physical Timer Control register
0x030	CNTV_CVAL[31:0] <sup>a</sup>	RW <sup>c</sup>	Virtual Timer CompareValue register, optional in the CNTBaseN memory map
0x034	CNTV_CVAL[63:32] <sup>a</sup>	RW <sup>c</sup>	
0x038	CNTV_TVAL <sup>a</sup>	RW <sup>c</sup>	Virtual TimerValue register, optional in the CNTBaseN memory map
0x03C	CNTV_CTL <sup>a</sup>	RW <sup>c</sup>	Virtual Timer Control register, optional in the CNTBaseN memory map
0x040-0xFCF	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D8-2170 and *Generic Timer registers* on page G4-4208. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. But must be writable for initial configuration.

c. Address is reserved, RAZ/WI if register not implemented

d. The CNTCTLBase frame includes a RW view of this register.

For any value of N, the layout of the registers in the frame at CNTPL0BaseN is identical to that at CNTBaseN, except that:

- CNTVOFF is not visible, and the memory at 0x018-0x01C is RAZ/WI.
- CNTELOACR is never visible, and the memory at 0x014 is always RAZ/WI.

- If implemented in the frame at CNTBaseN, CNTELOACR controls whether CNTPCT, CNTVCT, CNTFRQ, the EL1 Physical Timer, and the Virtual Timer registers are visible in the frame at CNTPL0BaseN. If CNTELOACR is not implemented then these registers are not visible in the frame at CNTPL0BaseN, and their addresses are RAZ/WI.
- If CNTFRQ is visible it is always RO. That is, it is not RW for initial configuration.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP\_CVAL, and CNTV\_CVAL must be accessible as atomic 64-bit values.

## I2.6 The CNTCTLBase frame

The CNTCTLBase frame contains an identification register for the features of the memory-mapped counter and timer implementation, access controls for each CNTBase $N$  frame, and a virtual offset register for frames that implement a virtual timer. Table I2-4 shows the CNTCTLBase registers, in order of their offsets from CNTCTLBase. The CNTFRQ and CNTVOFF registers are also implemented in the Secure system control register interface to the Generic Timer.

*Generic Timer registers on page I1-4647* describes each of these registers.

**Table I2-4 CNTCTLBase memory map**

Offset	Register	Type	Security	Description
0x000	CNTFRQ <sup>a</sup>	RW	Secure	Counter Frequency register.
0x004	CNTNSAR	RW	Secure	Counter Non-Secure Access Register.
0x008	CNTTIDR	RO	Both	Counter Timer ID Register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4 $N$ <sup>b</sup>	CNTACR< $n$ >	RW	Configurable <sup>c</sup>	Counter Access Control Register $N$ .
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8 $N$ <sup>b</sup>	CNTVOFF< $n$ >[31:0] <sup>a</sup>	RW <sup>d</sup>	Configurable <sup>c</sup>	Virtual Offset register, if implementation includes EL2. Optional in the CNTCTLBase memory map
0x084+8 $N$ <sup>b</sup>	CNTVOFF< $n$ >[63:32] <sup>a</sup>	RW <sup>d</sup>		
0x0C0- 0xFCF	-	RES0	-	Reserved.
0xFD0- 0xFFC	CounterID< $n$ >	RO	Both	Counter ID registers 0-11.

- These registers are also defined in the Secure System registers interface to the Generic Timer, and therefore are also described in *Generic Timer registers on page D8-2170* and *Generic Timer registers on page G4-4208*. The bit assignments of the registers are identical in the System registers interface and in the memory-mapped system level interface.
- Implemented for each value of  $N$  from 0 to 7.
- The CNTNSAR determines the Non-secure accessibility of the CNTACR< $n$ >s and the CNTVOFF< $n$ >s in the CNTCTLBase frame. For more information, see the register descriptions.
- Address is reserved, RAZ/WI if register not implemented.

## I2.7 Providing a complete set of counter and timer features

Using the general model for implementing a memory-mapped interface to the Generic Timer described in this section, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLBase control frame.
- The following CNTBase $N$  timer frames:
  - Frame 0** Accessible from Non-secure state, with second view and virtual capability. This provide the Non-secure EL1&0 timers.
  - Frame 1** Accessible from Non-secure state, with no second view and no virtual capability. This provide the Non-secure EL2 timers.
  - Frame 2** Accessible only Secure state, with a second view but no virtual capability. This provide the Secure EL1&0 timers.

In this implementation, the full set of implemented frames, and their configuration in the memory map, is as follows:

### CNTCTLBase

The control frame. This frame is located in both Secure and Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase0** The first view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

### CNTPL0Base0

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame can be accessible at EL1, or at EL1 and EL0, but this is not required.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

**CNTBase1** The first and only view of the Non-secure EL2 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase2** The first view of the Secure EL1&0 timers. This frame is located only in Secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

### CNTPL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0 timers. This frame is located only in Secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

———— **Note** —————

[About VMSAv8-32 on page G3-3562](#) describes the translation regimes.

---

## I2.8 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

$$\text{Gray}[N] = \text{Count}[N]$$

$$\text{Gray}[i] = (\text{XOR}(\text{Gray}[N:i+1])) \text{ XOR } \text{Count}[i] \text{ for } N-1 \geq i \geq 0$$

$$\text{Count}[i] = \text{XOR}(\text{Gray}[N:i]) \text{ for } N \geq i \geq 0$$

This is for an N+1 bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

———— **Note** —————

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be  $2^n$ , where n is an integer. A switch-over can occur only on the  $2n+1$  boundary to avoid losing the Gray-coding property on a switch-over.

---

# Chapter I3

## Recommended Memory-mapped Interfaces to the Performance Monitors

This chapter describes the recommended memory-mapped and external debug interfaces to the Performance Monitors. It contains the following section:

- [About the memory-mapped views of the Performance Monitors registers on page I3-4694.](#)

———— **Note** —————

[Performance Monitors registers on page I1-4599](#) describes the memory-mapped registers for the Performance Monitors.

—————

## I3.1 About the memory-mapped views of the Performance Monitors registers

An implementation can provide:

- Memory-mapped access to the Performance Monitors registers. Software running on any processor in a system can use this interface to access counters in the Performance Monitors.
- Access to the Performance Monitors registers through an external debug interface. A debugger can use this interface to access counters in the Performance Monitors.

ARM recommends that any external debug interface is implemented as defined in the *ARM Debug Interface v5 Architecture Specification*.

An external debug interface provides a memory-mapped view of the Performance Monitors registers.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- [Differences in the memory-mapped views of the Performance Monitors registers](#).
- [Synchronization of changes to the memory-mapped views](#).
- [Performance Monitors memory-mapped register views](#).
- [Access permissions for memory-mapped views of the Performance Monitors on page I3-4695](#).

In this appendix, unless the context explicitly indicates otherwise, any reference to a *memory-mapped view* applies equally to a register view using:

- A access through an external debug interface.
- A memory-mapped access.

### I3.1.1 Differences in the memory-mapped views of the Performance Monitors registers

A memory-mapped view of the Performance Monitors registers accesses the same registers as the System registers interface described in [Performance Monitors Extension registers on page D6-1851](#), except that:

1. The **PMSELR** is accessible only in the System registers interface.
2. The **PMCFGR**, **PMLAR**, **PMLSR**, **PMAUTHSTATUS**, **PMDEVTYPE**, **PMPIDR0**, **PMPIDR1**, **PMPIDR2**, **PMPIDR3**, **PMPIDR4**, **PMCIDR0**, **PMCIDR1**, **PMCIDR2** and **PMCIDR3** registers are accessible only in memory-mapped views. [Performance Monitors registers on page I1-4599](#) describes these registers.
3. The following controls do not affect the memory-mapped view:
  - **PMSELR**.
  - **PMUSERENR**.
  - **HDCR**.{TPM, TPMCR, HPMN}.

Instead, see the register descriptions in [Chapter I1 Memory-Mapped System Register Descriptions](#).

### I3.1.2 Synchronization of changes to the memory-mapped views

If a Performance Monitor is visible in both system register and a memory-mapped views, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see [Synchronization of changes to the external debug registers on page H8-4445](#).

### I3.1.3 Performance Monitors memory-mapped register views

[Table I3-1 on page I3-4695](#) shows the memory-mapped view of the Performance Monitors registers. All other entries are reserved.

———— **Note** —————

- Counters that are reserved because **HDCR.HPMN** has been changed from its reset value remain visible in any memory-mapped view.

- The registers that relate to an implemented event counter, PMN<sub>x</sub>, are [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#).

**Table I3-1 Performance Monitors memory-mapped register views**

Offset	Type	Name	Description
0x000+8xn	RW	<a href="#">PMEVCNTR&lt;n&gt;_EL0<sup>a</sup></a>	Performance Monitors Event Counter Register.
0x0F8-0x0FC	RW	<a href="#">PMCCNTR_EL0[31:0]<sup>aP</sup></a> <a href="#">MCCNTR_EL0[63:32]<sup>a</sup></a>	Performance Monitors Cycle Counter Register <sup>b</sup>

0x47C	RW	<a href="#">PMCCFILTR_EL0<sup>a</sup></a>	Performance Monitors Cycle Counter Filter Register
0x600-0x6FC	-	-	IMPLEMENTATION DEFINED
0xA00-0xBFC	-	-	IMPLEMENTATION DEFINED
0xC00	RW	<a href="#">PMCNTENSET_EL0<sup>a</sup></a>	Performance Monitors Count Enable Set register
0xC20	RW	<a href="#">PMCNTENCLR_EL0<sup>a</sup></a>	Performance Monitors Count Enable Clear register
0xC40	RW	<a href="#">PMINTENSET_EL1<sup>a</sup></a>	Performance Monitors Interrupt Enable Set register
0xC60	RW	<a href="#">PMINTENCLR_EL1<sup>a</sup></a>	Performance Monitors Interrupt Enable Clear register
0xC80	RW	<a href="#">PMOVSCLR_EL0<sup>a</sup></a>	Performance Monitors Overflow Flag Status Clear register
0xCA0	WO	<a href="#">PMSWINC_EL0<sup>a</sup></a>	Performance Monitors Software Increment register
0xCC0	RW	<a href="#">PMOVSSSET_EL0<sup>a</sup></a>	Performance Monitors Overflow Flag Status Set register
0xD80-0xDFC	-	-	IMPLEMENTATION DEFINED
0xE00	RO	<a href="#">PMCFGR<sup>c</sup></a>	Performance Monitors Configuration Register
0xE04	RW	<a href="#">PMCR_EL0<sup>a</sup></a>	Performance Monitors Control Register
0xE20	RO	<a href="#">PMCEID0_EL0<sup>a</sup></a>	Performance Monitors Common Event Identification register 0
0xE24	RO	<a href="#">PMCEID1_EL0<sup>a</sup></a>	Performance Monitors Common Event Identification register 1
0xE80-0xEFC	-	-	IMPLEMENTATION DEFINED
0xF00-0xFFC	-	-	<i>Management registers and CoreSight compliance on page AppxB-4782</i>

- These registers are also defined in the System registers interface to the Performance Monitors.
- The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.
- These registers are defined only in the memory-mapped views of the Performance Monitors.

### 13.1.4 Access permissions for memory-mapped views of the Performance Monitors

For more information, see [External debug interface register access permissions on page H8-4451](#).

[Table I3-2 on page I3-4696](#) shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

**DLK** When the OS Double Lock is locked, `EDPRSR.DLK == 1`, accesses to some registers produce an error. Applies to both interfaces.

- EPMAD** When AllowExternalPMUAccess() == FALSE, external debug access is disabled. See also *Behavior of a not permitted memory-mapped access* on page H8-4450.
- Error** Indicates that the access gives an error response.
- Default** This shows the default access permissions, if none of the conditions in this list prevent access to the register.
- Off** When EDPRSR.PU == 0, the Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed.
- **Note** —————
- If debug power is off, then all external debug interface accesses return an error.
- 
- OSLK** When the OS Lock is locked, OSLAR\_EL1.OSLK == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.
- SLK** This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4449.
- For all other accesses, this column is ignored.
- Indicates that the control has no effect on the behavior of the access:
- If no other control affects the behavior, the Default access behavior applies.
  - However, another control might determine the behavior.

**Table I3-2 Access permissions for the Performance Monitors registers**

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0 <sup>a</sup>	Core	Error	Error	Error	Error	RW	RO
0x0F8	PMCCNTR_EL0[31:0]	Core	Error	Error	Error	Error	RW	RO
0x0FC	PMCCNTR_EL0[63:32]	Core	Error	Error	Error	Error	RW	RO
0x400+4xn	PMEVTYPER<n>_EL0 <sup>a</sup>	Core	Error	Error	Error	Error	RW	RO
0x47C	PMCCFILTR_EL0	Core	Error	Error	Error	Error	RW	RO

0xA00-0xBFC	-	-	Access is IMPLEMENTATION DEFINED					
0xC00	PMCNTENSET_EL0	Core	Error	Error	Error	Error	RW	RO
0xC20	PMCNTENCLR_EL0	Core	Error	Error	Error	Error	RW	RO
0xC40	PMINTENSET_EL1	Core	Error	Error	Error	Error	RW	RO
0xC60	PMINTENCLR_EL1	Core	Error	Error	Error	Error	RW	RO
0xC80	PMOVSLR_EL0	Core	Error	Error	Error	Error	RW	RO
0xCA0	PMSWINC_EL0 <sup>b</sup>	Core	Error	Error	Error	Error	WO	WI
0xCC0	PMOVSSSET_EL0	Core	Error	Error	Error	Error	RW	RO
0xD80-0xDFC	-	-	Access is IMPLEMENTATION DEFINED					
0xE00	PMCFGR	Core	Error	Error	Error	Error	RO	RO
0xE04	PMCR_EL0	Core	Error	Error	Error	Error	RW	RO

**Table I3-2 Access permissions for the Performance Monitors registers (continued)**

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0xE20	<a href="#">PMCEID0_EL0</a>	Core	Error	Error	Error	Error	RO	RO
0xE24	<a href="#">PMCEID1_EL0</a>	Core	Error	Error	Error	Error	RO	RO
0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	<a href="#">Management registers and CoreSight compliance on page AppxB-4782</a>							

- a. Implemented counters only. *n* is the counter number.
- b. Only if the OPTIONAL PMSWINC\_EL0 register is implemented in the external debug interface.

### 13.1.5 Power domains and Performance Monitors registers reset

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see [Chapter H6 Debug Reset and Powerdown Support](#).

[Table I3-3](#) shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

- 64** This is the architectural reset value when resetting into AArch64 state.
- 32** This is the architectural reset value when resetting into AArch32 state.
- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

———— **Note** —————

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is [PMCR\\_EL0.N](#).
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is [PMSWINC\\_EL0](#).
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

**Table I3-3 Performance Monitors system register resets**

Register	Domain	Field	64	32	Description
<a href="#">PMCR_EL0</a>	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable

**Table I3-3 Performance Monitors system register resets (continued)**

Register	Domain	Field	64	32	Description

## Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- [AArch32 CONSTRAINED UNPREDICTABLE behaviors on page AppxA-4702.](#)
- [Constraints on AArch64 state UNPREDICTABLE behaviors on page AppxA-4765.](#)

## A.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- [Overview of the constraints on ARMv7 UNPREDICTABLE behaviors.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions.](#)
- [CONSTRAINED UNPREDICTABLE behavior, A32 and T32 system instructions on page AppxA-4753.](#)
- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page AppxA-4759.](#)
- [Using R13 on page AppxA-4759.](#)
- [Using R15 on page AppxA-4760.](#)
- [SBZ or SBO fields in instructions on page AppxA-4760.](#)
- [CONSTRAINED UNPREDICTABLE behavior in an IT block on page AppxA-4761.](#)
- [Branching into an IT block on page AppxA-4762.](#)
- [Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page AppxA-4762.](#)
- [Unallocated values in register fields of CP14 and CP 15 registers and translation table entries on page AppxA-4762.](#)
- [Unallocated CP14 and CP15 instructions on page AppxA-4763.](#)
- [Loads and Stores to unaligned locations on page AppxA-4763.](#)
- [Branching to an unaligned PC on page AppxA-4763.](#)
- [Unpredictable CPACR and NSACR settings on page AppxA-4763.](#)
- [Instruction fetches from Device memory on page AppxA-4764.](#)
- [Multi-access instructions that load the PC from Device memory on page AppxA-4764.](#)
- [Out of range virtual address on page AppxA-4764.](#)
- [Translation Table Base Address alignment on page AppxA-4764.](#)

### A.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

———— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

### A.1.2 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 instructions listed in [Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534](#) and [Alphabetical list of floating-point and Advanced SIMD instructions on page F8-3076](#).

#### **BFC**

For a description of these instructions and the encodings, see [BFC on page F7-2568](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If  $msbit < 1sbit$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The output value is the registers in UNKNOWN.

## BFI

For a description of these instructions and the encodings, see [BFI on page F7-2569](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $msbit < 1sbit$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The output value is the registers in UNKNOWN.

## BKPT

For a description of this instruction and the encoding, see [BKPT on page F7-2575](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $cond \neq '1110'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction executes unconditionally.
  - The instruction executes conditionally.

## CLZ

For a description of this instruction and the encoding, see [CLZ on page F7-2585](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If  $!consistent(Rm)$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register specified by  $hw1[3:0]$  is used as the source register.
  - The register specified by  $hw2[3:0]$  is used as the source register.
  - The value in the destination register is UNKNOWN.

## CMP (register)

For a description of this instruction and the encoding, see [CMP \(register\) on page F7-2590](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T2 encoding:

- If  $n < 8$  &&  $m < 8$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the comparison between  $Rn$  and  $Rm$ .
  - The condition flags become UNKNOWN.

## CRC32, CRC32C

For a description of this instruction and the encoding, see [CRC32, CRC32C](#) on page F7-2594.

### CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction behaves as if `sz == '10'`.

For the A1 encoding:

- If `cond! = '1110'`, then one of the following behaviors can occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction is executed unconditionally.
- The instruction is executed conditionally.

## HLT

For a description of this instruction and the encoding, see [HLT](#) on page F7-2608.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `cond != '1110'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction is executed unconditionally.
  - The instruction is executed conditionally.

## IT

For a description of this instruction and the encoding, see [IT](#) on page F7-2610.

### CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)` then one of the following behaviors occurs:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - `firstcond == '1111'` is treated the same as `firstcond == '1110'`, meaning the always condition, and the ITSTATE state machine is progressed in the same way as for any other `cond_base` value.

## LDC/LDC2 (literal)

For a description of this instruction and the encoding, see [LDC, LDC2 \(literal\)](#) on page F7-2622.

### CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_ARM)`, then one of the following behaviors can occur:

- The instruction is undefined.
- The instruction executes as a NOP.
- The load instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

### LDM/LDMIA/LDMFD (T32)

For a description of this instruction and the encoding, see [LDM/LDMIA/LDMFD \(T32\)](#) on page F7-2624.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If  $\text{BitCount}(\text{registers}) < 2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If  $\text{hw2}[13]$  is set to 1, then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [SBZ or SBO fields in instructions](#) on page AppxA-4760.

- If  $P == '1' \ \&\& \ M == '1'$ , then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.
- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back in UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### LDM/LDMIA/LDMFD (A32)

For a description of this instruction and the encoding, see [LDM/LDMIA/LDMFD \(A32\)](#) on page F7-2626.

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back in UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### **LMDMA/LDMFA**

For a description of this instruction and the encoding, see [LMDMA/LDMFA on page F7-2628](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back in UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

### **LDMIB/LDMED**

For a description of this instruction and the encoding, see [LDMIB/LDMED on page F7-2632](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back in UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

## LDMDB/LDMEA

For a description of this instruction and the encoding, see [LDMDB/LDMEA on page F7-2630](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $wback \ \&\& \ registers\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the A1 encoding:

- If  $BitCount(registers) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.

For the T1 encoding:

- If  $BitCount(registers) < 2$ , one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If  $hw2[13]$  is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

#### Note

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If  $P == '1' \ \&\& \ M == '1'$ , then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a NOP.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

## LDR (immediate, T32)

For a description of this instruction and the encoding, see [LDR \(immediate, T32\) on page F7-2634](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T4 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDR (immediate, A32)**

For a description of this instruction and the encoding, see [LDR \(immediate, A32\)](#) on page F7-2636.

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDR (register, A32)**

For a description of this instruction and the encoding, see [LDR \(register, A32\)](#) on page F7-2642.

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRB (immediate, T32)**

For a description of this instruction and the encoding, see [LDRB \(immediate, T32\)](#) on page F7-2644.

### **CONSTRAINED UNPREDICTABLE behavior**

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

## LDRB (immediate, A32)

For a description of this instruction and the encoding, see [LDRB \(immediate, A32\)](#) on page F7-2646.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

## LDRB (register)

For a description of this instruction and the encoding, see [LDRB \(register\)](#) on page F7-2650.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

## LDRBT

For a description of this instruction and the encoding, see [LDRBT](#) on page F7-2652.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

#### ———— Note —————

Pre-indexed and post-indexed addressing implies writeback.

- When the `Rn` field specifies R15, then this instruction can be treated either as described in this section or as described in [LDRB \(literal\)](#) on page AppxA-4713.

## LDRH (immediate, T32)

For a description of this instruction and the encoding, see [LDRH \(immediate, T32\)](#) on page F7-2664.

### **CONSTRAINED UNPREDICTABLE behavior**

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRH (immediate, A32)**

For a description of this instruction and the encoding, see [LDRH \(immediate, A32\) on page F7-2666](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRH (register)**

For a description of this instruction and the encoding, see [LDRH \(register\) on page F7-2670](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRHT**

For a description of this instruction and the encoding, see [LDRHT on page F7-2672](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in [LDRH \(literal\)](#) on page AppxA-4714.

### **LDRSB (immediate)**

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#) on page F7-2674.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRSB (register)**

For a description of this instruction and the encoding, see [LDRSB \(register\)](#) on page F7-2678.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRSBT**

For a description of this instruction and the encoding, see [LDRSBT](#) on page F7-2680.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 and A2 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in [LDRSB \(literal\)](#) on page AppxA-4714.

### **LDRSH (immediate)**

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#) on page F7-2682.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the T2 and A1 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRSH (register)**

For a description of this instruction and the encoding, see [LDRSH \(register\)](#) on page F7-2686.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

### **LDRSHT**

For a description of this instruction and the encoding, see [LDRSHT](#) on page F7-2688.

For the A1 and A2 encoding:

- If wback && n == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in [LDRSB \(literal\)](#) on page AppxA-4714.

## LDRT

For a description of this instruction and the encoding, see [LDRT on page F7-2690](#).

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

---

**Note**

Pre-indexed and post-indexed addressing implies writeback.

---

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in [LDRSB \(literal\) on page AppxA-4714](#).

## LDR (literal)

For a description of this instruction and the encoding, see [LDR \(literal\) on page F7-2638](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

---

**Note**

This is an exception to the principle in [SBZ or SBO fields in instructions on page AppxA-4760](#).

---

- If `bit[24] == 0` and `bit[21] == 1`, then the instruction can be handled according to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#) or the requirements described in [LDR \(immediate, T32\) on page AppxA-4707](#).

## LDRB (literal)

For a description of this instruction and the encoding, see [LDRB \(literal\) on page F7-2648](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.

- The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

This is an exception to the principle in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#) or the requirements described in [LDRB \(immediate, T32\) on page AppxA-4708](#).

### LDRH (literal)

For a description of this instruction and the encoding, see [LDRH \(literal\) on page F7-2668](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

This is an exception to the principle in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#) or the requirements described in [LDRH \(immediate, T32\) on page AppxA-4709](#).

### LDRSB (literal)

For a description of this instruction and the encoding, see [LDRSB \(literal\) on page F7-2676](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

This is an exception to the principle in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#) or the requirements described in [LDRSB \(immediate\) on page AppxA-4711](#).

## LDRSH (literal)

For a description of this instruction and the encoding, see [LDRSH \(literal\)](#) on page F7-2684.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15](#) on page AppxA-4760 apply.

———— **Note** —————

This is an exception to the principle in [SBZ or SBO fields in instructions](#) on page AppxA-4760.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in [SBZ or SBO fields in instructions](#) on page AppxA-4760 or the requirements described in [LDRSH \(immediate\)](#) on page AppxA-4712.

## LDRD (immediate)

For a description of this instruction and the encoding, see [LDRD \(immediate\)](#) on page F7-2654.

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If wback && (n == t || n == t2), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the T1 encoding:

- If t == t2, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If P == '0' && W == '1' then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if the values of P and W were as follows:
    - P == '1' && W == '0'
    - P == '1' && W == '1'
    - P == '0' && W == '0'

- If  $Rt<0> == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt<0> == '0'$ .
  - The registers accessed are both specified by  $Rt$ . This means that  $Rt$  and  $Rt+1$  are the same, and both have  $bit[0] == 1$ .
  - The registers accessed are specified by  $Rt$  and  $Rt+1$ .

———— **Note** —————

This does not apply if  $Rt == '1111'$ .

---

## LDRD (register)

For a description of this instruction and the encoding, see [LDRD \(register\)](#) on page F7-2658.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If  $wback \ \&\& \ (n == t \ || \ n == t2)$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.
- If  $P == '0' \ \&\& \ W == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if the values of  $P$  and  $W$  were as follows:
    - $P == '1' \ \&\& \ W == '0'$
    - $P == '1' \ \&\& \ W == '1'$
    - $P == '0' \ \&\& \ W == '0'$
- If  $m == t \ || \ m == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction loads register  $Rm$  with an UNKNOWN value.
- If  $Rt<0> == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt<0> == '0'$ .
  - The registers accessed are both specified by  $Rt$ . This means that  $Rt$  and  $Rt+1$  are the same, and in both cases  $bit[0] == 1$ .
  - The registers accessed are specified by  $Rt$  and  $Rt+1$ .

———— **Note** —————

This does not apply if  $Rt == '1111'$ .

---

## LDRD (literal)

For a description of this instruction and the encoding, see [LDRD \(literal\)](#) on page F7-2656.

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] and bit[21] do not have their *should be* values, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction is treated as if the bits had their *should be* values.
- If  $Rt_{<0>} == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt_{<0>} == '0'$ .
  - The registers accessed are both specified by  $Rt$ . This means that  $Rt$  and  $Rt+1$  are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by  $Rt$  and  $Rt+1$ .

**Note**

This does not apply if  $Rt == '1111'$ .

For the T1 encoding:

- If  $t == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.
- If  $W == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction is treated as if  $W == '0'$ .
  - The instruction uses the P and W bits as described for [LDRD \(immediate\)](#) on page AppxA-4715.

## LDREX

For a description of this instruction and the encoding, see [LDREX](#) on page F7-2660.

### CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDREXH

For a description of this instruction and the encoding, see [LDREXH](#) on page F7-2663.

### CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDREXB

For a description of this instruction and the encoding, see [LDREXB on page F7-2661](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDAEX

For a description of this instruction and the encoding, see [LDAEX on page F7-2614](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDAEXH

For a description of this instruction and the encoding, see [LDAEXH on page F7-2617](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDAEXB

For a description of this instruction and the encoding, see [LDAEXB on page F7-2615](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

## LDREXD

For a description of this instruction and the encoding, see [LDREXD on page F7-2662](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

For the T1 encoding:

- If  $t_1 == t_2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If  $Rt_{<0>} == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

- The behavior is the same as if the  $Rt<0>== '0'$ .
- The registers accessed are both specified by  $Rt$ . This means that  $Rt$  and  $Rt+1$  are the same, and both have  $bit[0] == 1$ .
- The registers accessed are specified by  $Rt$  and  $Rt+1$ .

———— **Note** —————

If  $t2 == 15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

---

## LDAEXD

For a description of this instruction and the encoding, see [LDAEXD on page F7-2616](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

For the T1 encoding:

- If  $t == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If  $Rt<0>== '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if the  $Rt<0>== '0'$ .
  - The registers accessed are both specified by  $Rt$ . This means that  $Rt$  and  $Rt+1$  are the same, and both have  $bit[0] == 1$ .
  - The registers accessed are specified by  $Rt$  and  $Rt+1$ .

———— **Note** —————

If  $t2 == 15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

---

## MOV (register, T32)

For a description of this instruction and the encoding, see [MOV \(register, T32\) on page F7-2710](#).

### CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If  $InITBlock()$ , then one of the following behaviors can occur:
  - The instruction generates an UNDEFINED exception.
  - The instruction is executed as if it passed its condition code check.
  - The instruction executes as a NOP. That is, it behaves as if it failed its condition code check.
  - The instruction is treated as MOV Rd, Rm.

---

**Note**

---

This is an exception to the general behavior described in *CONSTRAINED UNPREDICTABLE behavior in an IT block* on page AppxA-4761.

---

### **MRRC, MRRC2**

For a description of this instruction and the encoding, see *MRRC, MRRC2* on page F7-2718.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $t == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register that is transferred takes an UNKNOWN value.

### **MSR (register)**

For a description of this instruction and the encoding, see *MSR (register)* on page F7-2724.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $mask == '00'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

### **POP (T32)**

For a description of this instruction and the encoding, see *POP (T32)* on page F7-2756.

#### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If  $BitCount(registers) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a POP with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If  $BitCount(registers) < 2$ , one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If  $hw2\ bit[13]$  is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

- The instruction performs all of the loads using the specified addressing mode but R13 is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If  $P == '1'$  &&  $M == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For the T3 encoding:

- If  $t == 13$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the load using the specified addressing mode but R15 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [Using R13 on page AppxA-4759](#).

## POP (A32)

For a description of this instruction and the encoding, see [POP \(A32\) on page F7-2758](#).

### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[13] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode but R13 is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the A2 encoding:

- If  $t == 13$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the load using the specified addressing mode but R15 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [Using R13 on page AppxA-4759](#).

## PUSH

For a description of this instruction and the encoding, see [PUSH on page F7-2760](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a PUSH with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If  $\text{BitCount}(\text{registers}) < 2$ , one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction stores a single register using the specified addressing modes.
  - The instruction operates as a PUSH with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If hw2 bit[13] is set, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode but R13 is UNKNOWN.

**Note**

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

- If hw2 bit[15] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode, but R15 is UNKNOWN.

### **RBIT**

For a description of this instruction and the encoding, see [RBIT on page F7-2772](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If  $\text{! Consistent}(\text{Rm})$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2] is used as the source register.
  - The value in the destination register is UNKNOWN.

### **REV**

For a description of this instruction and the encoding, see [REV on page F7-2773](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T2 encoding:

- If ! Consistent(Rm), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

### **REV16**

For a description of this instruction and the encoding, see [REV16 on page F7-2774](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T2 encoding:

- If ! Consistent(Rm), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

### **REVSH**

For a description of this instruction and the encoding, see [REVSH on page F7-2775](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T2 encoding:

- If ! Consistent(Rm), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

### **SBFX**

For a description of this instruction and the encoding, see [SBFX on page F7-2798](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If msbit > 31, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The output value in the register is UNKNOWN.

### **UBFX**

For a description of this instruction and the encoding, see [UBFX on page F7-2960](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $\text{msbit} > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The output value in the register is UNKNOWN.

### **SDIV**

For a description of this instruction and the encoding, see [SDIV on page F7-2800](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If halfword 2 bits[15:12] != '1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

#### **Note**

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

### **UDIV**

For a description of this instruction and the encoding, see [UDIV on page F7-2964](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If halfword 2 bits[15:12] != '1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

#### **Note**

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

### **SMULL**

For a description of this instruction and the encoding, see [SMULL on page F7-2838](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $\text{dHi} == \text{dLo}$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

## SMLAL

For a description of this instruction and the encoding, see [SMLAL on page F7-2816](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

## SMLALBB, SMLALBT, SMLALTB, SMLALTT

For a description of this instruction and the encoding, see [SMLALBB](#), [SMLALBT](#), [SMLALTB](#), [SMLALTT](#) on page F7-2818.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

## SMLALD

For a description of this instruction and the encoding, see [SMLALD on page F7-2820](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

## SMLS LD

For a description of this instruction and the encoding, see [SMLS LD on page F7-2826](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

## UMULL

For a description of this instruction and the encoding, see [UMULL on page F7-2982](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

### **UMAAL**

For a description of this instruction and the encoding, see [UMAAL on page F7-2978](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

### **UMLAL**

For a description of this instruction and the encoding, see [UMLAL on page F7-2980](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $dHi == dLo$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The target register takes an UNKNOWN value.

### **STC, STC2**

For a description of this instruction and the encoding, see [STC, STC2 on page F7-2854](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $n == 15$  && ( $wback || CurrentInstrSet() != InstrSet\_A32$ ), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

- The instruction set uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

For the T1 and T2 encoding:

- The value used by stores using R15 as a base register follows the requirements described in [Using R15 on page AppxA-4760](#).

## STM (STMIA, STMEA)

For a description of this instruction and the encoding, see [STM \(STMIA, STMEA\)](#) on page F7-2870.

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in [Using R15](#) on page AppxA-4760.

For the T1 and A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If  $\text{BitCount}(\text{registers}) < 2$ , then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction stores a single register using the specified addressing modes.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If hw2 bit[13] is set, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the stores using the specified addressing mode but the value of R13 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [SBZ or SBO fields in instructions](#) on page AppxA-4760.

- If hw2 bit[15] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [SBZ or SBO fields in instructions](#) on page AppxA-4760.

- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.

## STMDA (STMED)

For a description of this instruction and the encoding, see [STMDA \(STMED\)](#) on page F7-2872.

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

### **STMIB (STMFA)**

For a description of this instruction and the encoding, see [STMIB \(STMFA\) on page F7-2876](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

### **STMDB (STMFD)**

For a description of this instruction and the encoding, see [STMDB \(STMFD\) on page F7-2874](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the A1 encoding:

- If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T1 encoding:

- If  $\text{BitCount}(\text{register}) < 2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction stores a single register using the specified addressing mode.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If  $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

- The instruction executes as a NOP.
- The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.
- If hw2 bit[13] is set to 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

———— **Note** —————

This is an exception to the requirements described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

---

- If hw2 bit[15] is set to 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

———— **Note** —————

This is an exception to the requirement described in [SBZ or SBO fields in instructions on page AppxA-4760](#).

---

### STR (immediate, T32)

For a description of this instruction and the encoding, see [STR \(immediate, T32\) on page F7-2878](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the T4 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

### STR (immediate, A32)

For a description of this instruction and the encoding, see [STR \(immediate, A32\) on page F7-2880](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

## STR (register)

For a description of this instruction and the encoding, see [STR \(register\)](#) on page F7-2882.

### CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the A1 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.
    - **Note** —————
    - This is consistent with ignoring writes to the PC.
  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.
    - **Note** —————
    - Pre-indexed and post-indexed addressing implies writeback.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

## STRB (immediate, T32)

For a description of this instruction and the encoding, see [STRB \(immediate, T32\)](#) on page F7-2884.

### CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

**Note**

This is consistent with ignoring writes to the PC.

---

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

**Note**

Pre-indexed and post-indexed addressing implies writeback.

---
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

### STRB (immediate, A32)

For a description of this instruction and the encoding, see [STRB \(immediate, A32\) on page F7-2886](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

**Note**

This is consistent with ignoring writes to the PC.

---

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

## STRB (register)

For a description of this instruction and the encoding, see [STRB \(register\) on page F7-2888](#).

### CONSTRAINED UNPREDICTABLE behavior

For the A1 and T2 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

---

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

## STRBT

For a description of this instruction and the encoding, see [STRBT on page F7-2890](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the T4 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
  - If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The store instruction operates without writeback.  
  
———— **Note** —————  
This is consistent with ignoring writes to the PC.  
—————
      - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.
- **Note** —————  
Pre-indexed and post-indexed addressing implies writeback.  
—————

### STRH (immediate, T32)

For a description of this instruction and the encoding, see [STRH \(immediate, T32\) on page F7-2904](#).

### CONSTRAINED UNPREDICTABLE behavior

For the T3 and T4 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the T4 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

- The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
  - If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The store instruction operates without writeback.
- **Note** —————
- This is consistent with ignoring writes to the PC.
- 
- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.
- **Note** —————
- Pre-indexed and post-indexed addressing implies writeback.
- 

### STRH (immediate, A32)

For a description of this instruction and the encoding, see [STRH \(immediate, A32\) on page F7-2906](#).

#### CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
  - If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
  - If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.
    - The store instruction operates without writeback.
- **Note** —————
- This is consistent with ignoring writes to the PC.
- 
- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.
- **Note** —————
- Pre-indexed and post-indexed addressing implies writeback.
- 
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

## STRH (register)

For a description of this instruction and the encoding, see [STRH \(register\)](#) on page F7-2908.

### CONSTRAINED UNPREDICTABLE behavior

For the T2 and A1 encoding:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the A1 encoding:

- If  $wback \ \&\& \ n == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.
    - **Note** —————
    - This is consistent with ignoring writes to the PC.
  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.
    - **Note** —————
    - Pre-indexed and post-indexed addressing implies writeback.

## STRHT

For a description of this instruction and the encoding, see [STRHT](#) on page F7-2910.

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $t == 15$  is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

**Note**

This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

**Note**

Pre-indexed and post-indexed addressing implies writeback.

## STRT

For a description of this instruction and the encoding, see [STRT on page F7-2912](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For the T1 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

**Note**

This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

### STRD (immediate)

For a description of this instruction and the encoding, see [STRD \(immediate\) on page F7-2892](#).

#### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $t == 15$  or  $t2 == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If  $wback \ \&\& \ (n == t \ || \ n == t2)$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15 on page AppxA-4760](#).

For the A1 encoding:

- If  $wback \ \&\& \ n == 15$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

---

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

- If  $Rt<0> == '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt<0> == '0'$ .
  - The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

———— **Note** —————

This does not apply if Rt=='1111'.

- If P == '0' && W == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction behaves as if the values of P and W were one of:
    - P == '1' && W == '0'
    - P == '1' && W == '1'
    - P == '0' && W == '0'

### STRD (register)

For a description of this instruction and the encoding, see [STRD \(register\)](#) on page F7-2894.

#### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If t2 == 15, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If wback && (n == t || n == t2), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in [Using R15](#) on page AppxA-4760.
- If wback && n == 15, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates without writeback.

———— **Note** —————

This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in [Using R15](#) on page AppxA-4760 apply.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

- If Rt<0>=='1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if Rt<0>=='0'.

- The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
- The registers accessed are specified by Rt and Rt+1.

————— **Note** —————

This does not apply if Rt== '1111'.

---

- If P == '0' && W == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction behaves as if the values of P and W were one of:
    - P == '1' && W == '0'
    - P == '1' && W == '1'
    - P == '0' && W == '0'

## STREX

For a description of this instruction and the encoding, see [STREX on page F7-2896](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If d == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If d == n, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that t2==15, then the requirements described in [Using R15 on page AppxA-4760](#) apply.

## STREXB

For a description of this instruction and the encoding, see [STREXB on page F7-2898](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If d == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If d == n, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.

- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2==15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

## STREXD

For a description of this instruction and the encoding, see [STREXD on page F7-2900](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2==15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

For the A1 encoding:

- If  $Rt<0>== '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt<0>== '0'$ .
  - The register accessed are both specified by  $Rt$ . For example,  $Rt$  and  $Rt+1$  are the same, and both have  $bit[0] == 1$ .
  - The registers accessed are specified by  $Rt$  and  $R+1$ .

## STREXH

For a description of this instruction and the encoding, see [STREXH on page F7-2902](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.

- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2=15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

## STLEX

For a description of this instruction and the encoding, see [STLEX on page F7-2860](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2=15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

## STLEXB

For a description of this instruction and the encoding, see [STLEXB on page F7-2862](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2=15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

## STLEXD

For a description of this instruction and the encoding, see [STLEXD on page F7-2864](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2==15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

For the A1 encoding:

- If  $Rt<0>== '1'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if  $Rt<0>== '0'$ .
  - The register accessed are both specified by  $Rt$ . For example,  $Rt$  and  $Rt+1$  are the same, and both have  $bit[0] == 1$ .
  - The registers accessed are specified by  $Rt$  and  $R+1$ .

### **STLEXH**

For a description of this instruction and the encoding, see [STLEXH on page F7-2866](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d == t$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If  $d == n$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that  $t2==15$ , then the requirements described in [Using R15 on page AppxA-4760](#) apply.

### **VCVT (between floating-point and fixed-point)**

For a description of this instruction and the encoding, see [VCVT \(between floating-point and fixed-point, floating-point\) on page F8-3148](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $\text{frac\_bits} < 0$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The result of the conversion is UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD1 (multiple single elements)**

For a description of this instruction and the encoding, see [VLD1 \(multiple single elements\)](#) on page F8-3174.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d+\text{regs} > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD1 (single element to all lanes)**

For a description of this instruction and the encoding, see [VLD1 \(single element to all lanes\)](#) on page F8-3178.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d+\text{regs} > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see [VLD2 \(multiple 2-element structures\)](#) on page F8-3180.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d2 + \text{regs} > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD2 (single 2-element structure to one lane)**

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to one lane\) on page F8-3182](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d2 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD2 (single 2-element structure to all lanes)**

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to all lanes\) on page F8-3184](#).

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d2 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VLD3 \(multiple 3-element structures\)](#) on page F8-3186.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d3 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD3 (single 3-element structure to one lane)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to one lane\)](#) on page F8-3188.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d3 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD3 (single 3-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to all lanes\)](#) on page F8-3190.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d+regs > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VLD4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VLD4 \(multiple 4-element structures\)](#) on page F8-3192.

### **CONSTRAINED UNPREDICTABLE behavior**

If  $d3 > 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VLD4 (single 4-element structure to one lane)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to one lane\)](#) on page F8-3194.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d4 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VLD4 (single 4-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to all lanes\)](#) on page F8-3196.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d4 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VLDM

For a description of this instruction and the encoding, see [VLDM on page F8-3198](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a VLDM or a VPOP with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

#### Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register greater than D16 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VPOP

For a description of this instruction and the encoding, see [VPOP on page F8-3268](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a VLDM or a VPOP with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

#### Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register greater than D16 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and two single-precision registers\)](#) on page F8-3224.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $to\_arm\_registers \ \&\& \ t == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The destination register becomes UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

- If  $m == 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD&FP single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

### **VMOV (between two general-purpose registers and a doubleword extension register)**

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and a doubleword extension register\)](#) on page F8-3226.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $to\_arm\_registers \ \&\& \ t == t2$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The destination register becomes UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST1 (multiple single elements)**

For a description of this instruction and the encoding, see [VST1 \(multiple single elements\)](#) on page F8-3356.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d+regs > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see [VST2 \(multiple 2-element structures\)](#) on page F8-3360.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d2+regs > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST2 (single 2-element structure from one lane)**

For a description of this instruction and the encoding, see [VST2 \(single 2-element structure from one lane\)](#) on page F8-3362.

### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d2 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VST3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VST3 \(multiple 3-element structures\)](#) on page F8-3364.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d3 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VST3 (single 3-element structure from one lane)

For a description of this instruction and the encoding, see [VST3 \(single 3-element structure from one lane\)](#) on page F8-3366.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d3 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VST4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VST4 \(multiple 4-element structures\)](#) on page F8-3368.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If  $d4 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VST4 (single 4-element structure from one lane)

For a description of this instruction and the encoding, see [VST4 \(single 4-element structure from one lane\)](#) on page F8-3370.

#### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $d4 > 31$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VSTM

For a description of this instruction and the encoding, see [VSTM](#) on page F8-3372.

#### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $regs == 0$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a VSTM or VPUSH with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

#### ————— Note —————

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register greater than D16 with an odd value of  $imm8$ .

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VPUSH

For a description of this instruction and the encoding, see [VPUSH on page F8-3270](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $\text{regs} == 0$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as a VSTM or VPUSH with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

#### ———— Note —————

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register greater than D16 with an odd value of  $\text{imm8}$ .

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## VTBL, VTBX

For a description of this instruction and the encoding, see [VTBL, VTBX on page F8-3386](#).

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If  $n + \text{length} > 32$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - One or more of the SIMD&FP registers become UNKNOWN. This behavior does not affect any general-purpose registers.

### A.1.3 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 system instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions listed in [Alphabetical list of system instructions on page F7-3033](#) in alphabetical order. Unless specifically stated otherwise, the CONSTRAINED UNPREDICTABLE behavior applies to all encodings that can result in CONSTRAINED UNPREDICTABLE behavior,

## CPS (A32)

For a description of this instruction and the encoding, see [CPS \(A32\) on page F7-3036](#).

### CONSTRAINED UNPREDICTABLE behavior

If the instruction transfers an illegal mode encoding to the **CPSR** mode field, then this invokes the Illegal Exception Return mechanism by not the changing the mode, and setting **CPSR.IL**.

#### ———— Note ————

- An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.
- CPS executed from User mode acts as a NOP.

For the A1 encoding:

- If  $(\text{imod} == '00 \ \&\& \ M == '0') \ || \ \text{imod} == '01'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If  $\text{mode} != '00000' \ \&\& \ M == '0'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as if  $M == '1'$ .
  - The instruction operates as if  $\text{mode} == '0000'$ .
- If  $(\text{imod}<1> == '1' \ \&\& \ A:I:F == '000')$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if  $\text{imod}<1> == '0'$ .
  - The instruction behaves as if A:I:F had an UNKNOWN nonzero value.
- If  $(\text{imod}<1> == '0' \ \&\& \ A:I:F != 000)$  then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if  $\text{imod}<1> == '1'$ .
  - The instruction behaves as if  $A:I:F == 000$ .

## CPS (T32)

For a description of this instruction and the encoding, see [CPS \(T32\) on page F7-3034](#).

### CONSTRAINED UNPREDICTABLE behavior

If the instruction transfers an illegal mode encoding to the **CPSR** mode field, then this invokes the Illegal Exception Return mechanism by not the changing the mode, and setting **CPSR.IL**.

#### ———— Note ————

- An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.
- CPS executed from User mode acts as a NOP.

For the T1 encoding:

- If  $A:I:F == '000'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

For the T2 encoding:

- If  $\text{imod} == '01'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If  $\text{mode} != '00000' \ \&\& \ M == '0'$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as if  $M == '1'$ .
  - The instruction behaves as if  $\text{mode} == '0000'$ .
- If  $(\text{imod}<1> == '1' \ \&\& \ A:I:F == '000')$ , then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if  $\text{imod}<1> == '0'$ .
  - The instruction behaves as if A:I:F had an UNKNOWN nonzero value.
- If  $(\text{imod}<1> == '0' \ \&\& \ A:I:F != '000')$  then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if  $\text{imod}<1> == '1'$ .
  - The instruction behaves as if A:I:F == '000'.

### LDM (exception return)

For a description of this instruction and the encoding, see [LDM \(exception return\) on page F7-3042](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If  $\text{wback} \ \&\& \ \text{registers}<n> == '1'$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the Illegal Exception Return mechanism.

#### ———— **Note** ————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

### LDM (User registers)

For a description of this instruction and the encoding, see [LDM \(User registers\) on page F7-3044](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:

- The instruction is undefined.
- The instruction executes as a NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

### **MRS**

For a description of this instruction and the encoding, see [MRS on page F7-3046](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode and is accessing the [SPSR](#), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

### **MSR (immediate)**

For a description of this instruction and the encoding, see [MSR \(immediate\) on page F7-3052](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode and is accessing the [SPSR](#), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If  $\text{mask} == '0000'$  &&  $R == '1'$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the [CPSR](#) mode field, then this invokes the Illegal Exception Return mechanism by not the changing the mode, and setting [CPSR.IL](#).

#### ———— **Note** —————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

### **MSR (register)**

For a description of this instruction and the encoding, see [MSR \(register\) on page F7-3054](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode and is accessing the [SPSR](#), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If mask == '0000', then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the [CPSR](#) mode field, then this invokes the Illegal Exception Return mechanism by not the changing the mode, and setting [CPSR.IL](#).

———— **Note** —————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

---

### **RFE**

For a description of this instruction and the encoding, see [RFE on page F7-3056](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in T32EE state, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the [CPSR](#) mode field, then this invokes the Illegal Exception Return mechanism.

———— **Note** —————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

---

### **SRS (T32)**

For a description of this instruction and the encoding, see [SRS \(T32\) on page F7-3060](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode, or the instruction is executed in T32EE state, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction specifies an illegal mode field, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- R13 of the current mode is used.
- The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become unknown.

## SRS (A32)

For a description of this instruction and the encoding, see [SRS \(A32\) on page F7-3062](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction specifies an illegal mode field, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- R13 of the current mode is used.
- The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become unknown.

## STM (User registers)

For a description of this instruction and the encoding, see [STM \(User registers\) on page F7-3064](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $\text{BitCount}(\text{registers}) < 1$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If the instruction is executed from User mode or System mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

## SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If this instruction is executed in User mode or in System mode, or the instructions are executed in T32EE state, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the Illegal Exception Return mechanism.

#### ———— **Note** —————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

## SUBS PC. LR and related instructions (A32)

For a description of this instruction and the encoding, see [SUBS PC, LR and related instructions \(A32\)](#) on page F7-3068.

### CONSTRAINED UNPREDICTABLE behavior

If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the Illegal Exception Return mechanism.

#### ———— Note —————

An illegal mode encoding is either an UNALLOCATED mode encoding or one that is not accessible at the current Exception level.

## VMRS

For a description of this instruction and the encoding, see [VMRS](#) on page F7-3070.

### CONSTRAINED UNPREDICTABLE behavior

If  $t == 15$  &&  $reg != '0001'$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction transfers an UNKNOWN value to the specified general-purpose register.

In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for the CONSTRAINED UNPREDICTABLE cases.

## VMSR

For a description of this instruction and the encoding, see [VMSR](#) on page F7-3072.

### CONSTRAINED UNPREDICTABLE behavior

If  $reg == "001x" || reg == "01xx"$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for the CONSTRAINED UNPREDICTABLE cases.

### A.1.4 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state](#) on page H2-4341 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

### A.1.5 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

## A.1.6 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual can do one of the following:

- Cause the instruction to be treated as an UNDEFINED instruction.
- Cause the instruction to execute as a NOP.
- Read the PC with the standard offset that applies for the current instruction set.
- Read the PC with the standard offset that applies for the current instruction set with alignment to a word boundary.
- Read 0.
- Read an UNKNOWN value.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual can do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of CPSR.NZCV, CPSR.Q, and CPSR.GE when the register specifier is not R15, if the instruction is CONSTRAINED UNPREDICTABLE when the register specifier is R15, then the flags that the instruction would affect become UNKNOWN.

In addition, for MRC instructions for CP14 and CP15 that use R15 as the destination register descriptor, and thereby target APSR.NZCV, where these are described as being CONSTRAINED UNPREDICTABLE, ASPR.NZCV becomes UNKNOWN.

## A.1.7 SBZ or SBO fields in instructions

[Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. Except for the specific cases called out in [CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions on page AppxA-4702](#), if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.

The exceptions to this rule are:

- [LDM/LDMIA/LDMFD \(T32\) on page AppxA-4705](#).
- [LDMDB/LDMEA on page AppxA-4707](#).
- [LDR \(literal\) on page AppxA-4713](#).
- [LDRB \(literal\) on page AppxA-4713](#).
- [LDRH \(literal\) on page AppxA-4714](#).

- [LDRSB \(literal\)](#) on page AppxA-4714.
- [LDRSH \(literal\)](#) on page AppxA-4715.
- [LDRD \(immediate\)](#) on page AppxA-4715.
- [LDRD \(register\)](#) on page AppxA-4716.
- [LDRD \(literal\)](#) on page AppxA-4717.
- [POP \(T32\)](#) on page AppxA-4720.
- [POP \(A32\)](#) on page AppxA-4721.
- [PUSH](#) on page AppxA-4721.
- [SDIV](#) on page AppxA-4724.
- [UDIV](#) on page AppxA-4724.
- [STM \(STMIA, STMEA\)](#) on page AppxA-4727.
- [STMDB \(STMTD\)](#) on page AppxA-4728.

### A.1.8 CONSTRAINED UNPREDICTABLE behavior in an IT block

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction in an IT block other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed their condition code.
- The instructions are treated as NOPS. This means that they behave as if they had failed the condition code.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the [CPSR.ITSTATE](#) state machine can:

- Clear [CPSR.ITSTATE](#).
- Advance [CPSR.ITSTATE](#) for either a sequential or a nonsequential change of the PC in the same way as they would do for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

#### ———— **Note** ————

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC can be:

- Executed as if they had passed the condition code check for the remaining iterations of the [CPSR.ITSTATE](#) state machine.
- Executed as NOPS. That is, they behave as if they failed the condition code check for the remaining iterations of the [CPSR.ITSTATE](#) state machine.
- Executed as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior in [Branching into an IT block on page AppxA-4762](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause [CPSR.ITSTATE](#) to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in [CPSR.ITSTATE](#), the ITSTATE bits are forced to 00000000.

The reserved values are:

```
ITState[7:4] != '0000' && ITState[3:0] = '0000'  
ITState[2:0] != '000' when SCTLR/SCTLR_EL1.ITD == '1'
```

Exception returns or Debug state exits that set **CPSR.ITSTATE** to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with **ITSTATE** set to a value other than `0b00000000`.
- Inside an IT block, but with a different value of **ITSTATE** than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit can:

- Execute as if they passed the condition code check for the remaining iterations of the **ITSTATE** state machine.
- Execute as NOPs. That is, they behave as if they failed the condition code check for the remaining iterations of the **ITState** state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block*.

The remaining iterations of the **CPSR.ITSTATE** state machine can behave as follows:

- The **ITSTATE** state machine advances as if it were in an IT block.
- The **ITSTATE** bits are ignored.
- The **ITSTATE** bits are forced to `00000000`.

### A.1.9 Branching into an IT block

Branching into an IT block leads to **CONSTRAINED UNPREDICTABLE** behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed its condition code checks.

### A.1.10 Syndrome register handling for **CONSTRAINED UNPREDICTABLE** instructions treated as **UNDEFINED**

When a **CONSTRAINED UNPREDICTABLE** instruction is treated as **UNDEFINED**, this generates an **UNDEFINED** instruction exception:

- If this exception is taken in AArch64, then **ESR\_ELx** is **UNKNOWN**.
- If this exception is taken at EL2 in AArch32, then **HSR** is **unknown**.

———— **Note** ————

The value written in **ESR** or **HSR** must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not **CONSTRAINED UNPREDICTABLE** at that Exception level. This is to avoid a possible privilege violation.

### A.1.11 Unallocated values in register fields of CP14 and CP 15 registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within CP15 registers and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause **CONSTRAINED UNPREDICTABLE** behavior.

- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

### A.1.12 Unallocated CP14 and CP15 instructions

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.

### A.1.13 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

### A.1.14 Branching to an unaligned PC

If branching to an address in A32 state which is not word aligned is defined to be UNPREDICTABLE, then one of the following behaviors can occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates a Prefetch Abort exception on the first instruction using the unaligned PC value. If this is executed in EL0 when EL2 is using AArch32 and `HCR.TGE == 1`, or EL2 is using AArch64 and `HCR_EL2.TGE == 1`, then the exception is taken to EL2.

Where the exception is taken to EL1 or EL3 using AArch32:

- If `TTBCR.EAE == 0`, `IFSR[10, 3:0]` takes the value 00001.
- If `TTBCR.EAE == 1`, `IFSR[5:0]` takes the value 100001.

If the exception is taken to EL2 using AArch32, then:

- The `HCR.EC` code of `0x22` is used.
- `HSR.IL` is UNKNOWN
- `HCR.ISS [24:0]` is RES0.

The `IFAR` or `HIFAR` takes the value of the address that faulted, including the misaligned low order bit[1].

The `R14_abt/ELR` holds the address that faulted, including the misaligned low order bit[1] with the standard offset associated with that exception.

———— **Note** —————

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of `IFAR` or `HIFAR` is 0 for all these cases.

### A.1.15 Unpredictable CPACR and NSACR settings

If `CPACR.cp<n>` contains the encoding `0b10`, then one of the following behaviors can occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

———— **Note** —————

In ARMv7, `CPACR` had a `D32DIS` bit, and `NSACR` had a `NSD32DIS` bit. There is no `CPACR.D32DIS` or `NSACR.NSD32DIS` in ARMv8-A, and the corresponding bits in the two registers are RES0.

### A.1.16 Instruction fetches from Device memory

Instruction fetches from Device memory are UNPREDICTABLE.

If a location in memory with the Device attribute is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when the MMU is enabled.

If branches cause the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation can perform one of the following behaviors:

- It can treat the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It can take a permission fault.

### A.1.17 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when the MMU is enabled are unpredictable in AArch32 state. In the ARMv8-A architecture in AArch32, an implementation can perform one of the following behaviors:

- It can load the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It can take a permission fault.

### A.1.18 Out of range virtual address

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFFFFFF and 0x00000000, then the bytes that wrap around and appear to be from 0x00000000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFFFFFF and 0x00000000, then the bytes that wrap around and appear to be from 0x00000000 onwards come from an UNKNOWN address.

### A.1.19 Translation Table Base Address alignment

An misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and **TTBR0**[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and **TTBR0**[x-1:3], **TTBR1**[x-1:3], **HTTBR**[x-1:3], or **VTTBR**[x-1:3], which are defined to be RES0, contain one or more nonzero values.

If a misaligned Translation Table Base Address occurs, then one of the following behaviors can occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register can be corrupted in those bits that are nonzero.

## A.2 Constraints on AArch64 state UNPREDICTABLE behaviors

It contains the following sections:

- [Overview of the constraints on AArch64 UNPREDICTABLE behaviors.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A64 instructions.](#)

### A.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

———— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

---

### A.2.2 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in [Chapter C5 A64 Base Instruction Descriptions](#) and [Chapter C6 A64 SIMD and Floating-point Instruction Descriptions](#).

#### **LDR (immediate)**

For a description of this instruction and the encoding, see [LDR \(immediate\) on page C5-517](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

#### **LDRB (immediate)**

For a description of this instruction and the encoding, see [LDRB \(immediate\) on page C5-524](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

### **LDRH (immediate)**

For a description of this instruction and the encoding, see [LDRH \(immediate\)](#) on page C5-530.

#### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

### **LDRSB (immediate)**

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#) on page C5-536.

#### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

### **LDRSH (immediate)**

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#) on page C5-542.

#### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

## LDRSW (immediate)

For a description of this instruction and the encoding, see [LDRSW \(immediate\)](#) on page C5-548.

### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &&  $n != 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

#### ———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

## LDP

For a description of this instruction and the encoding, see [LDP](#) on page C5-511.

### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n || t2 == n)$  &&  $n != 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

#### ———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

## LDPSW

For a description of this instruction and the encoding, see [LDPSW](#) on page C5-514.

### **CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n || t2 == n)$  &&  $n != 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.

- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

---

### **LDNP (SIMD&FP)**

For a description of this instruction and the encoding, see [LDNP \(SIMD&FP\) on page C6-1052](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

### **LDP (SIMD&FP)**

For a description of this instruction and the encoding, see [LDP \(SIMD&FP\) on page C6-1054](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

### **LDAXP**

For a description of this instruction and the encoding, see [LDAXP on page C5-497](#)[LDP on page C5-511](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

### **LDXP**

For a description of this instruction and the encoding, see [LDXP on page C5-579](#).

#### **CONSTRAINED UNPREDICTABLE behavior**

If  $t == t2$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## STR (immediate)

For a description of this instruction and the encoding, see [STR \(immediate\)](#) on page C5-694.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ———— Note —————

Pre-indexed and post-indexed addressing implies writeback.

---

## STRB (immediate)

For a description of this instruction and the encoding, see [STRB \(immediate\)](#) on page C5-700.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ———— Note —————

Pre-indexed and post-indexed addressing implies writeback.

---

## STRH (immediate)

For a description of this instruction and the encoding, see [STRH \(immediate\)](#) on page C5-706.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ———— Note —————

Pre-indexed and post-indexed addressing implies writeback.

---

## STP

For a description of this instruction and the encoding, see [STP](#) on page C5-691.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n \ || \ t2 == n) \ \&\& \ n \neq 31$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed and post-indexed addressing implies writeback.

—————

## STLXR

For a description of this instruction and the encoding, see [STLXR on page C5-680](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t$  || (pair &&  $s == t2$ ), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &&  $n != 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STLXRB

For a description of this instruction and the encoding, see [STLXRB on page C5-683](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t$  || (pair &&  $s == t2$ ), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &&  $n != 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STLXRH

For a description of this instruction and the encoding, see [STLXRH on page C5-686](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t$  || (pair &&  $s == t2$ ), then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &&  $n != 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STXR

For a description of this instruction and the encoding, see [STXR on page C5-727](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t \parallel (\text{pair } \&\& s == t2)$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \ \&\& n \neq 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

### **STXRB**

For a description of this instruction and the encoding, see [STXRB on page C5-730](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t \parallel (\text{pair } \&\& s == t2)$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \ \&\& n \neq 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

### **STXRH**

For a description of this instruction and the encoding, see [STXRH on page C5-733](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t \parallel (\text{pair } \&\& s == t2)$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \ \&\& n \neq 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

### **STLXP**

For a description of this instruction and the encoding, see [STLXP on page C5-677](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t \parallel (\text{pair } \&\& s == t2)$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \ \&\& n \neq 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs the store to an UNKNOWN address.

## STXP

For a description of this instruction and the encoding, see [STXP on page C5-724](#).

### **CONSTRAINED UNPREDICTABLE behavior**

If  $s == t \ || \ (\text{pair} \ \&\& \ s == t2)$ , then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \ \&\& \ n \ != \ 31$  then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

# Appendix B

## Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- [About the recommended external debug interface on page AppxB-4774.](#)
- [PMUEVENT bus on page AppxB-4777.](#)
- [DBGCPUDONE on page AppxB-4778.](#)
- [Recommended authentication interface on page AppxB-4779.](#)
- [Management registers and CoreSight compliance on page AppxB-4782.](#)

———— **Note** —————

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

---

## B.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. The connection between components, such as between the PE and Trace extension or between the PE and the CTI, is not described here. [Table B-1](#) shows the signals in the recommended interface.

**Table B-1 Recommended debug interface signals**

Name	Direction	Description	Notes
<b>DBGGEN</b>	In	External debug enable	-
<b>SPIDEN</b>	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by <a href="#">MDCR_EL3.SPD32</a>
<b>NIDEN</b>	In	External profiling and trace enable	-
<b>SPNIDEN</b>	In	Secure external profiling and trace enable	-
<b>DBGRESTART</b>	In	External debug restart	
<b>DBGRESTARTED</b>	Out	External debug restart acknowledge	
<b>EDBGRQ</b>	In	External halt request	Provided for legacy connections only.
<b>DBGACK</b>	Out	External halt request acknowledge	
<b>DBGTRIGGER</b>	Out	External trigger notification	
<b>DBGTRIGGERACK</b>	In	External trigger notification acknowledge	
<b>DBGCPUDONE</b>	Out	PE is in Debug state	See <a href="#">DBGCPUDONE</a> on page AppxB-4778
<b>COMMIRQ</b>	Out	DCC interrupt	Interface to an interrupt controller. See <a href="#">Interrupt-driven use of the DCC</a> on page H4-4402 and the pseudocode for function <code>CheckForDCCInterrupts()</code> in <a href="#">Pseudocode details for the operation of the DCC and ITR registers</a> on page H4-4403.
<b>PMUIRQ</b>	Out	Performance Monitor overflow	Interface to an interrupt controller. See <a href="#">Behavior on overflow</a> on page D6-1826.
<b>COMMRX</b>	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See <a href="#">Interrupt-driven use of the DCC</a> on page H4-4402 and the pseudocode for function <code>CheckForDCCInterrupts()</code> in <a href="#">Pseudocode details for the operation of the DCC and ITR registers</a> on page H4-4403.
<b>COMMTX</b>	Out	DTRTX is empty	
<b>PMUEVENT[n:0]</b>	Out	Performance Monitors event bus	See <a href="#">PMUEVENT bus</a> on page AppxB-4777

**Table B-1 Recommended debug interface signals (continued)**

Name	Direction	Description	Notes
DBGNOPWRDWN	Out	Core no powerdown request	Interface to a power controller. See <a href="#">DBGPRCR_EL1.CORENPDRQ</a> .
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See <a href="#">EDPRCR.COREPURQ</a> .
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See <a href="#">EDPRCR.CWRR</a> .
DBGBUSCANCELREQ	Out	All asynchronous entry to Debug state	Extension to the bus interface. See <a href="#">EDPRCR.CBRRQ</a> .
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See <a href="#">EDPRSR.PU</a> .
DBGROMADDR[n:12]	In	<a href="#">MDRAR_EL1.ROMADDR</a>	<i>n</i> depends on the size of the physical address space.
DBGROMADDRV	In	<a href="#">MDRAR_EL1.Valid</a>	-
PRESETDBG	In	External debug reset	-
CPUPORESET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In		
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		For details see <i>AMBA APB3</i> . ARM recommends a single slave port for all integrated debug components. <b>PADDRDBG31</b> distinguishes memory-mapped and DAP accesses: <b>0</b> Memory-mapped access <b>1</b> DAP access
PWDATADBG[31:0]	In	Debug APB slave port	
PADDRDBG[n:2] <sup>a</sup>	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		

a. The value of *n* depends on the size of the address space occupied by the Debug port.

Figure B-1 on page AppxB-4776 shows the recommended debug interface.

Figure B-1 Recommended external debug interface, including the APB3 slave port

In Figure B-1, signals with a lower-case n suffix are active LOW and all other signals are active HIGH.

## B.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or non-zero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSEL multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

### B.3 DBGCPUDONE

The PE asserts **DBGCPUDONE** only after it has completed all Non-debug state memory accesses. Therefore, the system can use **DBGCPUDONE** as an indicator that all memory accesses issued by the PE result from operations performed by a debugger.

## B.4 Recommended authentication interface

The details of the debug authentication interface are IMPLEMENTATION DEFINED.

ARM recommends the use of the CoreSight interface, which has four signals for external debug authentication:

- **DBGEN**,
- **SPIDEN**.
- **NIDEN**.
- **SPNIDEN**.

CoreSight forbids asserting **SPIDEN** without also asserting **DBGEN**. CoreSight also forbids asserting **SPNIDEN** without also asserting **NIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted secure debug authentication if either:

- EL3 is using AArch32 and `SDCR.SPD == 0b00`.
- Secure EL1 is using AArch32 and `MDCR_EL3.SPD32 == 0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

Table B-2 shows the debug authentication pseudocode functions and the recommended implementations.

**Table B-2 Recommended implementation of debug enable pseudocode functions**

Pseudocode function	Description	Implementation
<code>AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()</code> See <i>Pseudocode details for AArch32 Self-Hosted Secure Privileged Invasive Debug Enabled</i> on page AppxB-4780	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	<b>(DBGEN AND SPIDEN)</b>
<code>ExternalSecureNoninvasiveDebugEnabled()</code> See <i>Pseudocode details for External Invasive Debug Enabled</i> on page AppxB-4780	Secure non-invasive debug enabled	<b>(DBGEN OR NIDEN) AND (SPIDEN OR SPNIDEN)</b>
<code>ExternalSecureInvasiveDebugEnabled()</code> See <i>Pseudocode details for External Secure Invasive Debug Enabled</i> on page AppxB-4780	Secure invasive debug enabled	<b>(DBGEN AND SPIDEN)</b>
<code>ExternalNoninvasiveDebugEnabled()</code> See <i>Pseudocode details for External Non-invasive Debug Enabled</i> on page AppxB-4781	Non-secure non-invasive debug enabled	<b>(DBGEN OR NIDEN)</b>
<code>ExternalInvasiveDebugEnabled()</code> See <i>Pseudocode details for External Secure Non-invasive Debug Enabled</i> on page AppxB-4781	Non-secure invasive debug enabled	<b>DBGEN</b>

The following assertions must apply to all implementations:

```
if !ExternalInvasiveDebugEnabled() then assert !ExternalSecureInvasiveDebugEnabled()
```

```
if !ExternalNoninvasiveDebugEnabled() then assert !ExternalSecureNoninvasiveDebugEnabled()
```

```
if ExternalInvasiveDebugEnabled() then assert ExternalNoninvasiveDebugEnabled()  
if ExternalSecureInvasiveDebugEnabled() then assert ExternalSecureNoninvasiveDebugEnabled()
```

The definition for the Debug\_authentication() function is as follows:

```
signal DBGEN;
```

```
signal NIDEN;
```

```
signal SPIDEN;
```

```
signal SPNIDEN;
```

#### B.4.1 Pseudocode details for AArch32 Self-Hosted Secure Privileged Invasive Debug Enabled

The pseudocode for the AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled() function is as follows:

```
// AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()  
// =====  
  
boolean AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()  
    // In the recommended interface, AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled returns  
    // the state of the (DBGEN AND SPIDEN) signal.  
    if !HaveEL(EL3) && !IsSecure() then return FALSE;  
    return DBGEN == HIGH && SPIDEN == HIGH;
```

#### B.4.2 Pseudocode details for External Invasive Debug Enabled

The pseudocode for the ExternalInvasiveDebugEnabled() function is as follows:

```
// ExternalInvasiveDebugEnabled()  
// =====  
  
boolean ExternalInvasiveDebugEnabled()  
    // In the recommended interface, ExternalInvasiveDebugEnabled returns the state of the DBGEN  
    // signal.  
    return DBGEN == HIGH;
```

#### B.4.3 Pseudocode details for External Secure Invasive Debug Enabled

The pseudocode for the ExternalSecureInvasiveDebugEnabled() function is as follows:

```
// ExternalSecureInvasiveDebugEnabled()  
// =====  
  
boolean ExternalSecureInvasiveDebugEnabled()
```

```
// In the recommended interface, ExternalSecureInvasiveDebugEnabled returns the state of the
// (DBGEN AND SPIDEN) signal.
// CoreSight allows asserting SPIDEN without also asserting DBGEN, but this is not recommended.
if !HaveEL(EL3) && !IsSecure() then return FALSE;
return ExternalInvasiveDebugEnabled() && SPIDEN == HIGH;
```

#### B.4.4 Pseudocode details for External Non-invasive Debug Enabled

The pseudocode for the ExternalNoninvasiveDebugEnabled() function is as follows:

```
// ExternalNoninvasiveDebugEnabled()
// =====

boolean ExternalNoninvasiveDebugEnabled()
    // In the recommended interface, ExternalNoninvasiveDebugEnabled returns the state of the (DBGEN
    // OR NIDEN) signal.
    return ExternalInvasiveDebugEnabled() || NIDEN == HIGH;
```

#### B.4.5 Pseudocode details for External Secure Non-invasive Debug Enabled

The pseudocode for the ExternalSecureNoninvasiveDebugEnabled() function is as follows:

```
// ExternalSecureNoninvasiveDebugEnabled()
// =====

boolean ExternalSecureNoninvasiveDebugEnabled()
    // In the recommended interface, ExternalSecureNoninvasiveDebugEnabled returns the state of the
    // (DBGEN OR NIDEN) AND (SPIDEN OR SPNIDEN) signal.
    if !HaveEL(EL3) && !IsSecure() then return FALSE;
    return ExternalNoninvasiveDebugEnabled() && (SPIDEN == HIGH || SPNIDEN == HIGH);
```

## B.5 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

### B.5.1 CoreSight interface register map

Table B-3 shows the external management register maps for the following registers:

- ED** These are the external debug register.
- CTI** These are the Cross-trigger interface registers.
- PMU** These are the Performance Monitors registers.

**Table B-3 CoreSight interface register map**

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xF00	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
0xF04-0xF8C	-	-	-	Reserved, RES0
0xFA0	DBGCLAIMSET_EL1 <sup>a</sup>	CTICLAIMSET <sup>b</sup>	-	Claim Tag Set registers
0xFA4	DBGCLAIMCLR_EL1 <sup>a</sup>	CTICLAIMCLR <sup>b</sup>	-	Claim Tag Clear registers
0xFA8	EDDEVAFF0 <sup>a</sup>	CTIDEVAFF0 <sup>c</sup>	PMDEVAFF0	Device Affinity registers
0xFAC	EDDEVAFF1 <sup>a</sup>	CTIDEVAFF1 <sup>c</sup>	PMDEVAFF0	
0xFB0	EDLAR <sup>d</sup>	CTILAR <sup>d</sup>	PMLAR <sup>d</sup>	Lock Access register
0xFB4	EDLSR <sup>d</sup>	CTILSR <sup>d</sup>	PMLSR <sup>d</sup>	Lock Status register
0xFB8	DBGAUTHSTATUS_EL1 <sup>a</sup>	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
0xFBC	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
0xFC0	EDDEVID2 <sup>a</sup>	CTIDEVID2 <sup>a</sup>	-	Device ID register
0xFC4	EDDEVID1 <sup>a</sup>	CTIDEVID1 <sup>a</sup>	-	
0xFC8	EDDEVID <sup>a</sup>	CTIDEVID <sup>a</sup>	-	
0xFCC	EDDEVTYPE	CTIDEVTYPE	PMDEVTYPE	Device Type register
0xFD0	EDPIDR4	CTIPIDR4	PMPIDR4	Peripheral ID registers
0xFD4-0xFDC	-	-	-	Reserved, RES0
0xFE0	EDPIDR0	CTIPIDR0	PMPIDR0	Peripheral ID registers
0xFE4	EDPIDR1	CTIPIDR1	PMPIDR1	
0xFE8	EDPIDR2	CTIPIDR2	PMPIDR2	
0xFEC	EDPIDR3	CTIPIDR3	PMPIDR3	

Table B-3 CoreSight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

- This register must always be implemented, regardless of whether the component is CoreSight compliant.
- If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
- If the CTI implements CTIV1, this register is not implemented. See the register description for details.
- The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

### B.5.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, [Table B-4 on page AppxB-4784](#), [Table B-5 on page AppxB-4785](#), and [Table B-6 on page AppxB-4786](#) show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see [External debug interface register access permissions summary on page H8-4453](#).

#### ———— Note ————

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

[Table B-4 on page AppxB-4784](#), [Table B-5 on page AppxB-4785](#), and [Table B-6 on page AppxB-4786](#) include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in [Reserved and unallocated registers on page H8-4454](#) does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-4449](#).

The terms in [Table B-4 on page AppxB-4784](#), [Table B-5 on page AppxB-4785](#), and [Table B-6 on page AppxB-4786](#) are defined as follows:

**Domain** This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

**Conditions** This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

**Off** [EDPRSR.PU == 0](#). The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

#### ———— Note ————

If debug power is off, then all external debug interface accesses return an error.

<b>DLK</b>	DoubleLockStatus() == TRUE. The OS Double Lock is locked, that is, <a href="#">EDPRSR.DLK == 1</a> .
<b>OSLK</b>	<a href="#">OSLSR.OSLK == 1</a> . The OS Lock is locked.
<b>Default</b>	This provides the default access permissions, if there are no conditions that prevent access to the register.
<b>SLK</b>	This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See <a href="#">Register access permissions for memory-mapped accesses on page H8-4449</a> . For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
- RO** This means that the register or field is read-only.
- RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.
- RC** This means that the bit clears to 0 after a read.
- (SE)** This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.
- WO** This means that the register or field is write-only.
- WI** This means that the register or field ignores writes.
- IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

**Table B-4 External debug interface access permissions, CoreSight registers (debug)**

Offset	Register	Domain	Conditions (priority left to right)				Default	SLK

### B.5.3 Management register resets

Table B-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table B-7 shows a summary of the management register resets.

**Table B-7 Management register resets**

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1 CTICLAIMCLR <sup>a</sup>	External debug	CLAIM	0x0	Claim tags
CTILSR <sup>b</sup> EDLSR <sup>b</sup> PMLSR <sup>b</sup>	External debug	SLK	1	Software Lock

a. CTICLAIMCLR only if implemented. For DBGCLAIMCLR\_EL1, see *DBGCLAIMCLR\_EL1, Debug Claim Tag Clear register* on page H9-4477.

b. Only if the OPTIONAL Software Lock is implemented

# Appendix C

## Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following section:

- [ARM recommendations for IMPLEMENTATION DEFINED event numbers on page AppxC-4790.](#)
- [Summary of events taken to an Exception Level using AArch64 on page AppxC-4801.](#)

## C.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.
- Include cumulative occupancy for resource queues such as data access queues, and entry/exit counts, so that average latencies can be determined and counts for key resources that might exist can be separated.
- Provide registers in the IMPLEMENTATION DEFINED space to further extend such counts by, for example, specifying a minimum latency for an event to be counted.
- Use cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist:
  - An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, by, for example specifying a minimum latency for an event to be counted.

Table C-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

**Table C-1 PMU IMPLEMENTATION DEFINED event numbers**

Event number	Event mnemonic	Description
0x40	L1D_CACHE_LD	Level 1 data cache access, read
0x41	L1D_CACHE_ST	Level 1 data cache access, write
0x42	L1D_CACHE_REFILL_LD	Level 1 data cache refill, read
0x43	L1D_CACHE_REFILL_ST	Level 1 data cache refill, write
0x44	L1D_CACHE_REFILL_INNER	Level 1 data cache refill, inner
0x45	L1D_CACHE_REFILL_OUTER	Level 1 data cache refill, outer
0x46	L1D_CACHE_WB_VICTIM	Level 1 data cache write-back, victim
0x47	L1D_CACHE_WB_CLEAN	Level 1 data cache write-back, cleaning and coherency
0x48	L1D_CACHE_INVALID	Level 1 data cache invalidate
0x49-0x4B	-	Reserved
0x4C	L1D_TLB_REFILL_LD	Level 1 data TLB refill, read
0x4D	L1D_TLB_REFILL_ST	Level 1 data TLB refill, write
0x4E-0x4F	-	Reserved
0x50	L2D_CACHE_LD	Level 2 data cache access, read
0x51	L2D_CACHE_ST	Level 2 data cache access, write
0x52	L2D_CACHE_REFILL_LD	Level 2 data cache refill, read
0x53	L2D_CACHE_REFILL_ST	Level 2 data cache refill, write
0x54-0x55	-	Reserved
0x56	L2D_CACHE_WB_VICTIM	Level 2 data cache write-back, victim
0x57	L2D_CACHE_WB_CLEAN	Level 2 data cache write-back, cleaning and coherency

**Table C-1 PMU IMPLEMENTATION DEFINED event numbers (continued)**

Event number	Event mnemonic	Description
0x58	L2D_CACHE_INVALID	Level 2 data cache invalidate
0x59-0x5F	-	Reserved
0x60	BUS_ACCESS_LD	Bus access, read
0x61	BUS_ACCESS_ST	Bus access, write
0x62	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x63	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x64	BUS_ACCESS_NORMAL	Bus access, normal
0x65	BUS_ACCESS_PERIPH	Bus access, peripheral
0x66	MEM_ACCESS_LD	Data memory access, read
0x67	MEM_ACCESS_ST	Data memory access, write
0x68	UNALIGNED_LD_SPEC	Unaligned access, read
0x69	UNALIGNED_ST_SPEC	Unaligned access, write
0x6A	UNALIGNED_LDST_SPEC	Unaligned access
0x6B	-	Reserved
0x6C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x6D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x6E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x6F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x70	LD_SPEC	Operation speculatively executed, load
0x71	ST_SPEC	Operation speculatively executed, store
0x72	LDST_SPEC	Operation speculatively executed, load or store
0x73	DP_SPEC	Operation speculatively executed, integer data-processing
0x74	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x75	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x76	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x77	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x78	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x79	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x7A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x7B	-	Reserved
0x7C	ISB_SPEC	Barrier speculatively executed, ISB
0x7D	DSB_SPEC	Barrier speculatively executed, DSB

**Table C-1 PMU IMPLEMENTATION DEFINED event numbers (continued)**

Event number	Event mnemonic	Description
0x7E	DMB_SPEC	Barrier speculatively executed, DMB
0x7F-0x80	-	Reserved
0x81	EXC_UNDEF	Exception taken, Other synchronous
0x82	EXC_SVC	Exception taken, Supervisor Call
0x83	EXC_PABORT	Exception taken, Instruction Abort
0x84	EXC_DABORT	Exception taken, Data Abort and SError
0x85	-	Reserved
0x86	EXC_IRQ	Exception taken, IRQ
0x87	EXC_FIQ	Exception taken, FIQ
0x88	EXC_SMC	Exception taken, Secure Monitor Call
0x89	-	Reserved
0x8A	EXC_HVC	Exception taken, Hypervisor Call
0x8B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not taken locally
0x8C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not taken locally
0x8D	EXC_TRAP_OTHER	Exception taken, Other traps not taken locally
0x8E	EXC_TRAP_IRQ	Exception taken, IRQ not taken locally
0x8F	EXC_TRAP_FIQ	Exception taken, FIQ not taken locally
0x90	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x91	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release

**0x40, Level 1 data cache access, read**

This event is similar to Level 1 data cache access but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

**0x41, Level 1 data cache access, write**

This event is similar to Level 1 data cache access but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x42, Level 1 data cache refill, read**

This event is similar to Level 1 data cache refill but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

**0x43, Level 1 data cache refill, write**

This event is similar to Level 1 data cache refill but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x44, Level 1 data cache refill, inner**

This event is similar to Level 1 data cache refill but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

———— **Note** ————

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

**0x45, Level 1 data cache refill, outer**

This event is similar to Level 1 data cache refill but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

**0x46, Level 1 data cache write-back, victim**

This event is similar to Level 1 data cache write-back but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

CP15 cache maintenance operations do not count as events.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

**0x47, Level 1 data cache write-back, cleaning and coherency**

This event is similar to Level 1 data cache write-back but the counter counts only write-backs that are a result of a coherency operation made by another PE or from a CP15 cache maintenance operation. Whether write-backs made as a result of CP15 cache maintenance operations are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

———— **Note** ————

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

**0x48, Level 1 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed CP15 cache set/way maintenance operations.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

**0x4C, Level 1 data TLB refill, read**

This event is similar to Level 1 data TLB refill but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

**0x4D, Level 1 data TLB refill, write**

This event is similar to Level 1 data TLB refill but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

The counter counts [DC ZVA](#) as a store instruction.

**0x50, Level 2 data cache access, read**

This event is similar to Level 2 data cache access but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

**0x51, Level 2 data cache access, write**

This event is similar to Level 2 data cache access but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x52, Level 2 data cache refill, read**

This event is similar to Level 2 data cache refill but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

**0x53, Level 2 data cache refill, write**

This event is similar to Level 2 data cache refill but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x56, Level 2 data cache write-back, victim**

This event is similar to Level 2 data cache write-back but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

CP15 cache maintenance operations do not count as events.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

**0x57, Level 2 data cache write-back, cleaning and coherency**

This event is similar to Level 2 data cache write-back but the counter counts only write-backs that are a result of a coherency operation made by another PE or CP15 cache maintenance operation. Whether write-backs made as a result of CP15 cache maintenance operations are counted is IMPLEMENTATION DEFINED.

———— **Note** —————

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

—————

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

**0x58, Level 2 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed CP15 set/way cache maintenance operations.

———— **Note** —————

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

—————

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

**0x60, Bus access, read**

This event is similar to bus access but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

**0x61, Bus access, write**

This event is similar to bus access but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

**0x62, Bus access, Normal, Cacheable, Shareable**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

———— **Note** —————

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either Shareable or Not Shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as Shareable for the purposes of defining this event.

**0x63, Bus access, not Normal, Cacheable, Shareable**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Not Shareable.
- Normal, Not Cacheable.
- Device.

———— **Note** —————

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either Shareable or Not Shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as Shareable for the purposes of defining this event.

**0x64, Bus access, normal**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Not Cacheable accesses but does not count Device accesses.

**0x65, Bus access, peripheral**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

**0x66, Data memory access, read**

This event is similar to data memory access but the counter counts only memory-read operations that the PE made.

**0x67, Data memory access, write**

This event is similar to data memory access but the counter counts only memory-write operations made by the PE.

**0x68, Unaligned access, read**

This event is similar to data memory access but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x69, Unaligned access, write**

This event is similar to data memory access but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x6A, Unaligned access**

This event is similar to data memory access but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x6C, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x6D, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

**0x6E, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

**0x6F, Exclusive operation speculatively executed, Store-Exclusive**

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the exclusive operation speculatively executed, Load-Exclusive event.

**0x70, Operation speculatively executed, load**

This event is similar to the operation speculatively executed but the counter counts only memory-reading instructions. Defined by the instruction architecturally executed, condition code check pass, load event, see [Common event numbers on page D6-1839](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

#### 0x71, Operation speculatively executed, store

This event is similar to the operation speculatively executed but the counter counts only memory-writing instructions. Defined by the instruction architecturally executed, condition code check pass, store event, see [Common event numbers on page D6-1839](#).

The counter counts [DC ZVA](#) as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

#### 0x72, Operation speculatively executed, load or store

This event is similar to the operation speculatively executed but the counter counts only memory-reading instructions and memory-writing instructions. Defined by the instruction architecturally executed, condition code check pass, load and instruction architecturally executed, condition code check pass, store events, see [Common event numbers on page D6-1839](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

#### 0x73, Operation speculatively executed, integer data-processing

This event is similar to the operation speculatively executed but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, [Data processing - immediate on page C2-140](#) and [Data processing - register on page C2-145](#).
- In AArch32 state, [Data-processing instructions on page F1-2383](#).

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, [System register instructions on page C2-126](#), [System instructions on page C2-126](#), and [Hint instructions on page C2-127](#).
- In AArch32 state, [Status register access instructions on page F1-2391](#), [Banked register access instructions on page F1-2391](#), [Miscellaneous instructions on page F1-2395](#), other than ISB and preloads, and [Coprocessor instructions on page F1-2397](#), other than coprocessor load and store instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - FMOV (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - DUP (general).
  - SMOV.
  - UMOV.
  - INS (general).

- In AArch32 state:
  - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - VMRS.
  - VMSR.

#### 0x74, Operation speculatively executed, Advanced SIMD

This event is similar to the operation speculatively executed but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in [Data processing - SIMD and floating-point on page C2-152](#)
- For AArch32 state, [Advanced SIMD data-processing instructions on page F1-2401](#)

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

#### 0x75, Operation speculatively executed, floating-point

This event is similar to the operation speculatively executed but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, the floating-point operations listed in [Data processing - SIMD and floating-point on page C2-152](#).
- In AArch32 state, [Floating-point data-processing instructions on page F1-2408](#).

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data-processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

#### 0x76, Operation speculatively executed, software change of the PC

This event is similar to the operation speculatively executed but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see [Common event numbers on page D6-1839](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

See also PC\_WRITE\_RETIRED in [Table D6-6 on page D6-1839](#).

**0x77, Operation speculatively executed, Cryptographic instruction**

This event is similar to the operation speculatively executed but the counter counts only Cryptographic instructions, except PMULL and VMULL, see [Cryptography extensions on page C2-169](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

**0x78, Branch speculatively executed, immediate branch**

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see [Common event numbers on page D6-1839](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR\_IMMED\_RETIRED in [Table D6-6 on page D6-1839](#).

**0x79, Branch speculatively executed, procedure return**

The counter counts procedure return instructions speculatively executed. Defined by the instruction architecturally executed, condition code check pass, procedure return event, see [Common event numbers on page D6-1839](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR\_RETURN\_RETIRED in [Table D6-6 on page D6-1839](#).

**0x7A, Branch speculatively executed, indirect branch**

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x7C, Barrier speculatively executed, ISB**

The counter counts instruction synchronization barrier instructions speculatively executed, including [CP15ISB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x7D, Barrier speculatively executed, DSB**

The counter counts data synchronization barrier instructions speculatively executed, including [CP15DSB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x7E, Barrier speculatively executed, DMB**

The counter counts data memory barrier instructions speculatively executed, including [CP15DSB](#). It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x81, Exception taken, other synchronous**

This event is similar to exception taken but the counter counts only synchronous exceptions that are not counted by the other Exception taken events. This event counts only exceptions taken locally.

**0x82, Exception taken, Supervisor Call**

This event is similar to exception taken but the counter counts only Supervisor Call exceptions. This event counts only exceptions taken locally.

**0x83, Exception taken, Instruction Abort**

This event is similar to exception taken but the counter counts only Instruction Abort exceptions. This event counts only exceptions taken locally.

**0x84, Exception taken, Data Abort or SError**

This event is similar to exception taken but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions taken locally.

**0x86, Exception taken, IRQ**

This event is similar to exception taken but the counter counts only IRQ exceptions. The counter counts only exceptions taken locally, including Virtual IRQ exceptions.

**0x87, Exception taken, FIQ**

This event is similar to exception taken but the counter counts only FIQ exceptions. The counter counts only exceptions taken locally, including Virtual FIQ exceptions.

**0x88, Exception taken, Secure Monitor Call**

This event is similar to exception taken but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

**0x8A, Exception taken, Hypervisor Call**

This event is similar to exception taken but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions taken locally in the hypervisor and those taken as an exception from Non-secure EL1.

**0x8B, Exception taken, Instruction Abort not taken locally**

This event is similar to exception taken but the counter counts only Instruction Abort exceptions not taken locally.

**0x8C, Exception taken, Data Abort or SError not taken locally**

This event is similar to exception taken but the counter counts only Data Abort or SError interrupt exceptions not taken locally.

**0x8D, Exception taken, other traps not taken locally**

This event is similar to exception taken but the counter counts only those traps that are not counted as:

- Exception taken, Hypervisor Call.
- Exception taken, Instruction Abort not taken locally.
- Exception taken, Data Abort or SError not taken locally.
- Exception taken, IRQ not taken locally.
- Exception taken, FIQ not taken locally.

**0x8E, Exception taken, IRQ not taken locally**

This event is similar to exception taken but the counter counts only IRQ exceptions not taken locally.

**0x8F, Exception taken, FIQ not taken locally**

This event is similar to exception taken but the counter counts only FIQ exceptions not taken locally.

**0x90, Release consistency operation speculatively executed, Load-Acquire**

The counter counts Load-Acquire operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x91, Release consistency operation speculatively executed, Store-Release**

The counter counts Store-Release operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

## C.2 Summary of events taken to an Exception Level using AArch64

Table C-2 shows the events for exceptions taken to an Exception level using AArch64.

**Table C-2 Events for exceptions taken to an EL using AArch64**

ESR.EC	Description	Event number and classification for exception taken to	
		EL1, or the current EL	EL2 or EL3, from below
0x00	Unknown or uncategorized	0x081, Other synchronous	0x08D, Other traps not taken locally
0x01	WFE/WFI traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x03	AArch32 CP15 MCR/MRC traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x04	AArch32 CP15 MCRR/MRRC traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x05	AArch32 CP14 MCR/MRC traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x06	AArch32 CP14 LDC/STC traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x07	Advanced SIMD or FP traps	0x081, Other synchronous	0x08D, Other traps not taken locally
0x08	AArch32 MVFR* and FPSID traps	-	0x08D, Other traps not taken locally

-	FIQ interrupt	0x087, FIQ	0x08F, FIQ not taken locally

———— **Note** —————

In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See [Exception levels on page D1-1408](#) for more information.

# Appendix D

## Example OS Save and Restore sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

- [Save Debug registers on page AppxD-4804.](#)
- [Restore Debug registers on page AppxD-4806.](#)

## D.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.

; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

; (1) Set OS lock.

MOV X2,#1 ; Set the OS lock. In AArch64 state, the OS lock

MSR OSLAR\_EL1,X2 ; is writable via OSLAR.

ISB ; Context synchronization operation

; (2) Walk through the registers, saving them

MRS X1,OSDTRRX\_EL1 ; Read DTRRX

MRS X2,OSDTRTX\_EL1 ; Read DTRTX

STP W1,W2,[X0],#8 ; Save { DTRRX, DTRTX }

MRS X1,MDSR\_EL1 ; Read DSCR

MRS X2,OSECCR\_EL1 ; Read ECCR

STP W1,W2,[X0],#8 ; Save { DSCR, ECCR }

[ AARCH32\_SUPPORTED

MRS X1,DBGVCR32\_EL2 ; Read DBGVCR

MRS X2,DBGCLAIMCLR\_EL1 ; Read CLAIM - note, have to read via CLAIMCLR

STP W1,W2,[X0],#8 ; Save { VCR, CLAIM }

]

;; Macros for saving off a "register pair"

;; \$WB is W for watchpoint, B for breakpoint

;; \$num is the pair's number

;; X0 contains a pointer for the value words

;; X1 contains a pointer for the control words

;; W2 contains the max index

MACRO

SaveRP \$WB,\$num, \$exit

MRS X3,DBG\$WB.VR\$num.\_EL1 ; Read DBGxVRn

STR X3,[X0],#8 ; Save { xVRn }

MRS X3,DBG\$WB.CR\$num.\_EL1 ; Read DBGxCrN

STR W3,[X0],#4 ; Save { xCrN }.

[ \$num > 1 :LAND: \$num < 15

```
CMP    W1, # $num
BEQ    $exit
]
MEND
```

```
; (3) Breakpoints
```

```
MRS    X1, ID_AA64DFR0_EL1
UBFX   W1, W1, #12, #4           ; Extract BRPs field
```

```
MACRO
```

```
SaveBRP $num                    ; Save a Breakpoint Register Pair
```

```
SaveRP B, $num, SaveDebugRegisters_Watchpoints
```

```
MEND
```

```
SaveBRP 0
```

```
SaveBRP 1
```

```
SaveBRP 2
```

```
;; and so on to ...
```

```
SaveBRP 15
```

```
SaveDebugRegisters_Watchpoints
```

```
; (4) Watchpoints
```

```
MRS    X1, ID_AA64DFR0_EL1       ; Read DBGDIDR
```

```
UBFX   W1, W1, #20, #4           ; Extract WRPs field
```

```
MACRO
```

```
SaveWRP $num                    ; Save a Watchpoint Register Pair
```

```
SaveRP W, $num, SaveDebugRegisters_Exit
```

```
MEND
```

```
SaveWRP 0
```

```
SaveWRP 1
```

```
SaveWRP 2
```

```
;; and so on to ...
```

```
SaveWRP 15
```

```
SaveDebugRegisters_Exit
```

```
; (5) Return the pointer to first word not read. This pointer is already in X0, so
```

```
; all that is needed is to return from this function. The OS double-lock (OSDLR_EL1.DLK) is
```

```
; locked later, just before the final entry to WFI state.
```

```
RET
```

## D.2 Restore Debug registers

This section shows how to restore the registers that are used by an external debugger.

; On entry, X0 points to a block of saved debug registers.

; Returns the pointer beyond the block and corrupts R1-R3,R12.

RestoreDebugRegisters

; (1) Lock OS lock. The lock will already be set, but this write is included to ensure it  
; is locked.

MOV X2,#1 ; Lock the OS lock. In AArch64 state, the OS lock

MSR OSLAR\_EL1,X2 ; is writable via OSLAR.

ISB ; Context synchronization operation

; (2) Walk through the registers, restoring them

LDP W1,W2,[X0],#8 ; Read { DTRRX,DTRTX }

MSR OSDTRRX\_EL1,X1 ; Restore DTRRX

MSR OSDTRTX\_EL1,X2 ; Restore DTRTX

LDP W1,W2,[X0],#8 ; Read { DSCR, ECCR }

MSR MDSCR\_EL1,X1 ; Restore DSCR

MSR OSECCR\_EL1,X2 ; Restore ECCR

[ AARCH32\_SUPPORTED

LDP W1,W2,[X0],#8 ; Read { VCR,CLAIM }

MSR DBGVCR32\_EL2,X1 ; Restore DBGVCR

MSR DBGCLAIMSET\_EL1,X2 ; Restore CLAIM – note, writes CLAIMSET

]

;; Macro for restoring a “register pair”

MACRO

RestoreRP \$WB,\$num,\$exit

LDR X3,[X0],#8 ; Read { xVRn }

MSR DBG\$WB.VR\$num.\_EL1,X3 ; Restore DBGxVRn

LDR W3,[X0],#4 ; Read { xCRn }

MSR DBG\$WB.CR\$num.\_EL1,X3 ; Restore DBGxCRn

[ \$num >= 1 :LAND: \$num < 15

CMP W1,#\$num

BEQ \$exit

]

MEND

```
; (3) Breakpoints
MRS    X1, ID_AA64DFR0_EL1
UBFX   W1, W1, #12, #4           ; Extract BRPs field

; (5) Clear the OS lock.
ISB
MOV    X2, #0                    ; Clear the OS lock. In AArch64 state, the OS lock
MSR    OSLAR_EL1, X2            ; is writable via OSLAR.

; (6) A final ISB guarantees the restored register values are visible to subsequent
; instructions.
ISB
```

```
; (7) Return the pointer to first word not read. This pointer is already in X0, so  
; all that is needed is to return from this function.  
RET
```

# Appendix E

## Additional Guidance

This chapter provides information about implementing and using the ARM architecture. It contains the following sections:

- *Implementation guidance for multiple views of Debug registers* on page AppxE-4810.
- *AArch32 equivalent Advanced SIMD Mnemonics* on page AppxE-4813.
- *Identifying the cache resources in ARMv8* on page AppxE-4821.
- *Memory access mode in Debug state* on page AppxE-4822.

———— **Note** —————

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

---

## E.1 Implementation guidance for multiple views of Debug registers

Table E-1 and Table E-2 on page AppxE-4811 show the aliases and list the access permissions for each of the bits in the Debug System Control Registers.

For definitions of each system register bit see [MDSCR\\_EL1](#)[18:15, 13:12, 5:2, 0], and [EDSCR](#)[30:29, 27:26, 23:21, 14, 6]. All other bits are reserved, RES0.

Table E-1 shows the implementation requirements for Debug system control registers in AArch64 state, but software must not rely on reserved fields being RAZ or RAZ/WI.

**Table E-1 Implementation requirements for Debug system control registers (AArch64 state)**

Bits	Physical register or status value for system register views	EDSCR	MDCCSR_ELO (read-only)	MDSCR_EL1	
				OSLK == 0	OSLK == 1
31	Reserved	RAZ/WI	RAZ	RAZ/WI	RAZ/WI
30	<a href="#">EDSCR.RXfull</a>	RO	RO	RO <sup>a</sup>	R/W
29	<a href="#">EDSCR.TXfull</a>	RO	RO	RO <sup>a</sup>	RO
28	Reserved	(ITO) <sup>b</sup>	RAZ	RAZ/WI	RAZ/WI
27	<a href="#">EDSCR.RXO</a>	RO	RAZ	RO <sup>a</sup>	R/W <sup>c</sup>

- a. ARM deprecates the use of this field.
- b. This field does not map to a system register view. See [EDSCR, External Debug Status and Control Register](#) on page H9-4531.
- c. Software must treat this value as an UNKNOWN value on save. It must be preserved on restore.
- d. UNKNOWN at EL0.
- e. Software must not rely on this bit ignoring writes when OSLK == 0, and must treat the value read as UNKNOWN.
- f. UNKNOWN at EL0. ARM deprecates the use of this field.
- g. See [RES0](#) for details of how RES0 applies to this bit.

## E.2 AArch32 equivalent Advanced SIMD Mnemonics

Table E-3 shows a comparison of the AArch32 instructions and their AArch64 counterparts. It also lists instructions that are new to AArch64.

———— **Note** ————

All Advanced SIMD floating-point functionality changes implicitly to comply with the FPCR rounding mode field, the Default NaN control, the Flush-to-Zero control, and, where supported by the implementation, the Exception trap enable bits.

**Table E-3 AArch32 equivalent SIMD mnemonics**

AArch32	AArch64					Description
	Agnostic	Integer		Floating-point	Polynomial	
		Unsigned	Signed			
VABA	-	UABA	SABA	-	-	Integer vector absolute difference and accumulate
VABAL	-	UBAL UABAL2	SABAL SABAL2	-	-	Integer vector absolute difference and accumulate long
VABD	-	UABD	SABD	FABD	-	Vector absolute difference
VABDL	-	UABDL UABDL2	SABDL SABDL2	-	-	Integer vector absolute difference long
VABS	-	-	ABS	FABS	-	Vector absolute value
VACGE	-	-	-	FACGE	-	Floating-point vector absolute compare greater than or equal
VACGT	-	-	-	FACGT	-	Floating-point vector absolute compare greater than
VACLE	-	-	-	FACLE	-	Floating-point vector absolute compare less than or equal
VACLT	-	-	-	FACTL	-	Floating-point vector absolute compare less than
VADD	ADD	-	-	FADD	-	Vector add
VADDHN	ADDHN ADDHN2	-	-	-	-	Integer vector add returning high narrow
VADDL	-	UADDL UADDL2	SADDL SADDL2	-	-	Integer vector add long
VADDW	-	UADDW UADDW2	SADDW SADDW2	-	-	Integer vector add wide
VAND	AND	-	-	-	-	Bitwise vector AND

Table E-3 AArch32 equivalent SIMD mnemonics (continued)

AArch64						
AArch32	Integer					Description
	Agnostic	Unsigned	Signed	Floating-point	Polynomial	
VBIC	BIC	-	-	-	-	Bitwise vector bit clear
VBIF	BIF	-	-	-	-	Bitwise vector insert if false
VBIT	BIT	-	-	-	-	Bitwise vector insert if true
VBSL	BSL	-	-	-	-	Bitwise vector select
VCEQ	CMEQ	-	-	FCMEQ	-	Vector compare equal
VCGE	-	CMHS	CMGE	FCMGE	-	Vector compare greater than or equal
VCGT	-	CMHI	CMGT	FCMGT	-	Vector compare greater than
VCLE	-	CMLS	CMLE	FCMLE	-	Vector compare less than or equal
VCLS	CLS	-	-	-	-	Integer vector count leading sign bits
VCLT	-	CML0	CMLT	FCMLT	-	Vector compare less than
VCLZ	CLZ	-	-	-	-	Integer vector count leading zero bits
VCMP	-	-	-	FCMP	-	Floating-point compare
VCMPE	-	-	-	FCMPE	-	Floating-point compare (exception on quiet NaNs)
VCNT	CNT	-	-	-	-	Vector count non-zero bits
VCVT.s32.f32	-	-	-	FCVTZS	-	Vector floating-point convert to signed integer (round to zero)
new	-	-	-	FCVTxS	-	Vector floating-point convert to signed integer (round to x)
VCVT.u32.f32	-	-	-	FCVTZU	-	Vector floating-point convert to unsigned integer (round to zero)
new	-	-	-	FCVTxU	-	Vector floating-point convert to unsigned integer (round to x)
VCVT.f32.i32	-	UCVTF	SCVTF	-	-	Vector integer convert to floating-point
VCVT.f*.f*	-	-	-	FCVTN FCVTL	-	Vector convert floating-point precision

Table E-3 AArch32 equivalent SIMD mnemonics (continued)

AArch64						
AArch32	Integer					Description
	Agnostic	Unsigned	Signed	Floating-point	Polynomial	
new	-	-	-	FCVTXN	-	Vector convert double-precision to single-precision (rounding to odd)
new	-	-	-	FRINTx	-	Vector floating-point round to integral floating-point value (towards x)
new	-	-	-	FDIV	-	Vector floating point divide
VDUP	DUP	-	-	-	-	Duplicate single vector element to all elements
new	INS	-	-	-	-	Insert single element in another element
VEOR	EOR	-	-	-	-	Bitwise exclusive OR
VEXT	EXT	-	-	-	-	Bitwise vector extract
VHADD	-	UHADD	SHADD	-	-	Integer vector halving add
VHSUB	-	UHSUB	SHSUB	-	-	Integer vector halving subtract
VLD1..4	LD1..4	-	-	-	-	Vector structure/element load
VLD1..4R	LD1..4R	-	-	-	-	Vector replicated element load
VLDM/VLDR	LDP/LDR	-	-	-	-	Vector load pair/register
VMAX	-	UMAX	SMAX	FMAX	-	Vector maximum
new	-	-	-	FMAXNM	-	Floating-point vector maxNum
VMIN	-	UMIN	SMIN	FMIN	-	Vector minimum
new	-	-	-	FMINNM	-	Floating-point vector minNum
VMLA	MLA	-	-	n/a	-	Vector chained multiply-add
VFMA	-	-	-	FMLA	-	Vector fused multiply-add
VMLAL	-	UMLAL UMLAL2	SMLAL SMLAL2	-	-	Integer vector multiply-add long
VMLS	MLS	-	-	n/a	-	Vector chained multiply-subtract

Table E-3 AArch32 equivalent SIMD mnemonics (continued)

AArch64						
AArch32	Integer					Description
	Agnostic	Unsigned	Signed	Floating-point	Polynomial	
VFMS	-	-	-	FMLS	-	Vector fused multiply-subtract
VMLS	-	UMLS UMLS2	SMLS SMLS2	-	-	Integer vector multiply-subtract long
VMOV	MOV	UMOV	SMOV	FMOV	-	Vector move
VMOVL	-	UXTL UXTL2	SXTL SXTL2	-	-	Integer vector lengthen (pseudo for USHL#0 or SSHL#0)
VMOVN	XTN	-	-	-	-	Integer vector narrow
VMUL	MUL	-	-	FMUL	PMUL	Vector multiply
new	-	-	-	FMULX	-	Floating-point vector multiply extended (0xINF → 2)
VMULL	-	UMULL UMULL2	SMULL SMULL2	-	PMULL PMULL2	Vector multiply long
VMVN	MVN	-	-	-	-	Bitwise vector NOT
VNEG	-	-	NEG	FNEG	-	Vector negate
VORN	ORN	-	-	-	-	Bitwise vector OR NOT
VORR	ORR	-	-	-	-	Bitwise vector OR
VPADAL	-	UADALP	SADALP	-	-	Integer vector add and accumulate long pair

## E.3 Identifying the cache resources in ARMv8

In ARMv8 the architecture defines support for multiple levels of cache, up to a maximum of seven levels. This complicates the process of identifying the cache resources available to a PE on an ARMv8 implementation. To obtain this information, software must:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance operations.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also provides the Level of Unification and the Level of Coherency for the cache implementation.
3. For each cache identified at stage 2:
  - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
    - An instruction cache.
    - A data or unified cache.
  - Read the Cache Size ID Register to find details of the cache.

## E.4 Memory access mode in Debug state

The following subsections provide information about memory access modes in Debug state:

- [Alignment constraints](#).
- [Using memory access mode in AArch64 state](#).

This information is an addition to the information provided in [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

### E.4.1 Alignment constraints

If the address in X0 or R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to X0 or R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to  $\text{Align}(X[0],4)$  in AArch64 state, or  $\text{Align}(R[0],4)$  in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.
- Following each memory access, if there is no Data Abort, X0 or R0 is updated with an UNKNOWN value.
- For external writes to [DBGDTRRX\\_EL0](#), if the PE writes to memory, an UNKNOWN value is written.
- For external reads of [DBGDTRTX\\_EL0](#) an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a [DBGDTRTX\\_EL0](#) read can trigger a TX underrun, and a [DBGDTRRX\\_EL0](#) write can trigger an RX overrun.

The ARM preferred implementation is:

- The PE makes an unaligned memory access to X0 or R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
- Following each memory access, if there is no Data Abort, X0 is updated with  $X0 + 4$  or R0 is updated with  $R0 + 4$ .
- For external writes to [DBGDTRRX\\_EL0](#), if the PE writes to memory, the word written to [DBGDTRRX\\_EL0](#) is written.
- For external reads of [DBGDTRTX\\_EL0](#), the result of the unaligned load is returned.
- The RXfull and TXfull flags are updated as normal.

### E.4.2 Using memory access mode in AArch64 state

[Figure E-1 on page AppxE-4823](#) and [Figure E-2 on page AppxE-4824](#) show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer  $n$  words of data:

- The download sequence needs  $n+6$  accesses by the external debug interface.
- The upload sequence needs  $n+8$  accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling [EDSCR](#) after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the [EDSCR.ERR](#) flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the [EDSCR.ERR](#) flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. [EDSCR.ERR](#) might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

**Note**

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

**Figure E-1 Fast code download in AArch64 (external host to target)**

In [Figure E-1](#), the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
  - a. Write address [31:0] to `DBGDTRRX_EL0`.
  - b. Write address [63:32] to `DBGDTRTX_EL0`.
  - c. Write `MRS X0, DBGDTR_EL0` to `EDITR`. The PE executes this instruction.
  - d. Set `EDSCR.MA` to 1.
2. Loop  $n$  times. From the external debug interface:
  - a. Write to `DBGDTRRX_EL0`. The PE reads the word from `DTRRX` and stores it to memory. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
  - a. Clear `EDSCR.MA` to 0.
  - b. Read `EDSCR` to check for overruns or Data Aborts during download.

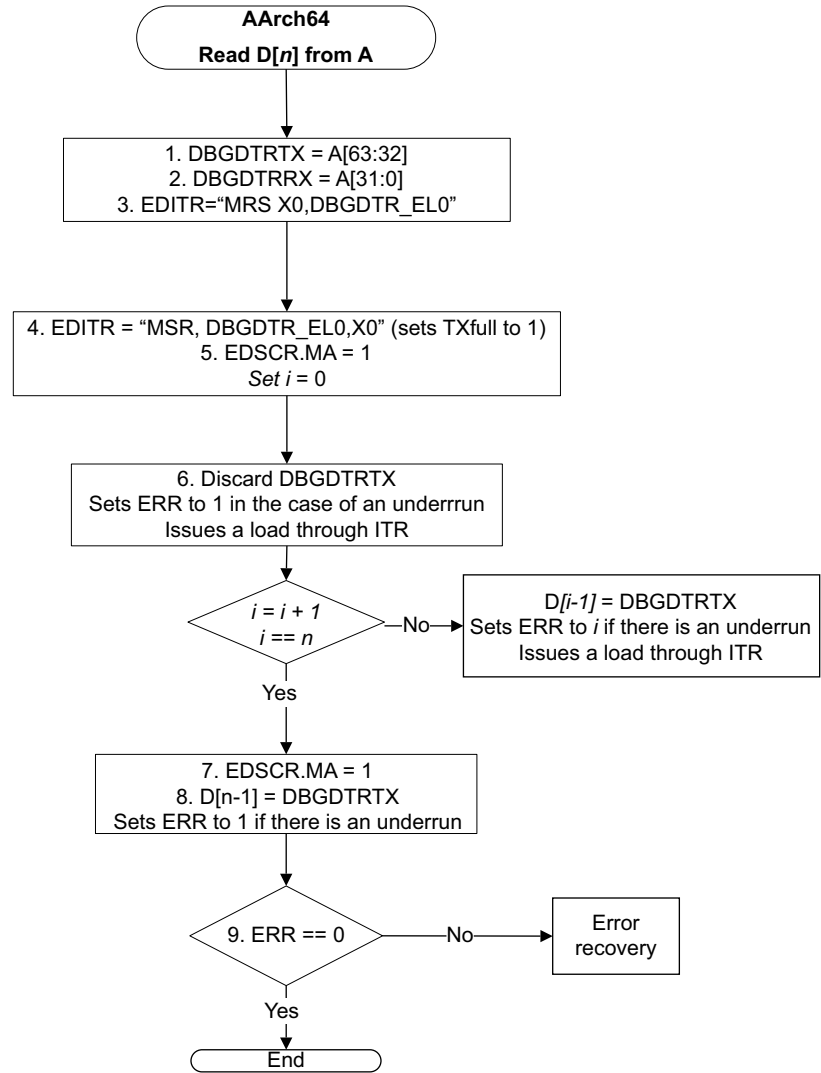

Figure E-2 Fast data upload in AArch64 (target to external host)

In Figure E-2, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
  - a. Write address [31:0] to `DBGDTRRX_EL0`.
  - b. Write address [63:32] to `DBGDTRTX_EL0`.
  - c. Write `MRS X0, DBGDTR_EL0` to `EDITR`.
  - d. Write `MSR DBGDTR_EL0, X0` to `EDITR`. This dummy operation ensures `EDSCR.TXfull == 1`.
  - e. Set `EDSCR.MA` to 1.
  - f. Read `DBGDTRTX_EL0` and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments `X0` by 4.
2. Loop  $n-1$  times. From the external debug interface:
  - a. Read `DBGDTRTX_EL0`. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
  - a. Clear `EDSCR.MA` to 0.
  - b. Read `DBGDTRTX_EL0` for the  $n^{\text{th}}$  value.

- c. Read [EDSCR](#) to check for underruns, overruns or Data Aborts during upload.

# Appendix F

## Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- [Introduction on page AppxF-4828.](#)
- [Load-Acquire, Store-Release and barriers on page AppxF-4831.](#)
- [Load-Acquire Exclusive, Store-Release Exclusive and barriers on page AppxF-4839.](#)
- [Using a mailbox to send an interrupt on page AppxF-4845.](#)
- [Cache and TLB maintenance operations and barriers on page AppxF-4846.](#)
- [ARMv7 compatible approaches for ordering, using DMB and DSB barriers on page AppxF-4859.](#)

---

**Note**

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

---

## F.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

### F.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM).

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to system control registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate in memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

### F.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

**DMB** See [Data Memory Barrier \(DMB\)](#) on page B2-85.

**DSB** See [Data Synchronization Barrier \(DSB\)](#) on page B2-86.

**ISB** See [Instruction Synchronization Barrier \(ISB\)](#) on page B2-85.

#### **Observer, Completion**

See [Observability and completion](#) on page B2-82.

**Program order**

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

**F.1.3 Conventions**

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

**AArch32**

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
    LDR R12, [Rx]
    CMP R12, #1
    BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
loop
    LDA R12, [Rx]      ; load acquire ensures it is ordered before subsequent loads/stores
    CMP R12, #1
    BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

**AArch64**

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
    LDR W12, [Xx]
    CMP W12, #1
    B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
loop
    LDAR W12, [Xx]    ; load acquire ensures it is ordered before subsequent loads/stores
    CMP W12, #1
    B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1...Px refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1...Ex refer to non-caching observers, that do not participate in the coherency protocol, but execute ARM instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

———— **Note** ————

Throughout this appendix, *ARM instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Results are expressed in terms of <agent>:<register>, such as P0:R5. The results can be described as:

- |                        |  |
|------------------------|--|
| <b>Permissible</b>     | This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues. |
| <b>Not permissible</b> | Results that the architecture expressly forbids.   |
| <b>Required</b>        | Results that the architecture expressly requires.  |

The examples omit the required shareability domain arguments of DMB and DSB instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a DMB ST, that is a barrier to stores only, this is shown by the use of DMB [ST]. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations DMB ST is faster than DMB.

For AArch64 code, the shareability domain of the DMB or DSB must be included. This is shown in this document using the notation DMB <domain> and DSB <domain> respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are Shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an STR instruction, 0x55, 0x66, 0x77, and 0x88 respectively.
  - When used with an LDR instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance operations. The following tables describe the mnemonics:

- [Cache maintenance operations, functional group on page G3-3743](#)
- [TLB maintenance operations, functional group on page G3-3744](#).

### Notes on timing effects

The ARMv8 architecture makes no statement about when an instruction will occur. In particular, stores may take an unbounded time to be observed by other observers. Therefore the WAIT loop waiting for the result of that store may take an unbounded time to move forward.

In cases that it is necessary to guarantee the completion of a store, a DSB instruction can be used to force this drain.

In general, the examples in this document associated with ordering assume that stores will become observable over time and so a final DSB barrier to ensure the completion of stores is omitted.

## F.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in *Load-Acquire, Store-Release* on page B2-87.

The following sections show that most of the examples in sections *Simple ordering and barrier cases* on page AppxF-4859 and *Load-Exclusive, Store-Exclusive and barriers* on page AppxF-4866 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

### F.2.1 Message passing

The following sections describe:

- *Resolving weakly-ordered message passing by using Acquire and Release.*
- *Resolving message passing by the use of Store-Release and address dependency on page AppxF-4832.*

#### Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in *Weakly-ordered message passing problem* on page AppxF-4859 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

##### AArch32

###### P1

```
STR R5, [R1]          ; set new data
STL R0, [R2]          ; send flag indicating data ready, which is ordered after all
```

###### P2

```
WAIT_ACQ([R2]==1)    ; wait on flag
LDR R5, [R1]
```

##### AArch64

###### P1

```
STR W5, [X1]          ; set new data
STL W0, [X2]          ; send flag indicating data ready, which is ordered after all
```

###### P2

```
WAIT_ACQ([X2]==1)    ; wait on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

##### AArch32

###### P3

```
WAIT_ACQ([R2]==1)    ; wait on flag
LDR R5, [R1]
```

### **AArch64**

#### P3

```
WAIT_ACQ([X2]==1)    ; wait on flag  
LDR W5, [X1]
```

### **Resolving message passing by the use of Store-Release and address dependency**

The lack of ordering of stores discussed in [Message passing with multiple observers on page AppxF-4861](#) can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

### **AArch32**

#### P1

```
STR R5, [R1]         ; set new data  
STL R0, [R2]         ; send flag indicating data ready using a Store Release
```

#### P2

```
WAIT([R2]==1)  
AND R12, R12, #0    ; R12 is destination of LDR in WAIT macro  
LDR R5, [R1, R12]  ; Load is dependent and so is ordered after the flag has been seen
```

### **AArch64**

#### P1

```
STR W5, [X1]         ; set new data  
STLR W0, [X2]        ; send flag indicating data ready using a Store Release
```

#### P2

```
WAIT([X2]==1)  
AND W12, W12, WZR    ; R12 is destination of LDR in WAIT macro  
LDR W5, [X1, X12]   ; Load is dependent and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

### **AArch32**

#### P3

```
WAIT([R2]==1)  
AND R12, R12, #0    ; R12 is destination of LDR in WAIT macro  
LDR R5, [R1, R12]  ; Load is dependent and so is ordered after the flag has been seen
```

#### **AArch64**

##### P3

```
WAIT([X2]==1)
AND W12, W12, WZR ; R12 is destination of LDR in WAIT macro
LDR W5, [X1, X12] ; Load is dependent and so is ordered after the flag has been seen
```

## **F.2.2 Address dependency with object construction**

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

#### **AArch32**

##### P1

```
STR R5, [R1, #offset] ; set new data in a field
STL R1, [R2] ; update base address
```

##### P2

```
LDR R1, [R2] ; read for base address
CMP R1, #0 ; check if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; use base address to read field
```

#### **AArch64**

##### P1

```
STR W5, [X1, #offset] ; set new data in a field
STLR X1, [X2] ; update base address
```

##### P2

```
LDR X1, [X2] ; read for base address
CMP X1, #0 ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; use base address to read field
```

It is required that P2:R5==0x55 if the null\_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

### F.2.3 Causal consistency issues with multiple observers

The cause consistent problem discussed in *Causal consistency issues with multiple observers* on page AppxF-4862 can be addressed by the use of a Store-Release, as this requires that the store is multicopy atomic in the case of a Load-Acquire. In addition, a Store-Release has an effect on the observation order of any stores observed by the observer executing the Store-Release.

The following sequences guarantee causal consistency:

- *Using multi-copy atomicity of the Store-Release when observed by Load-Acquire.*
- *Using ordering property of Store-Release on stores observed by the PE on page AppxF-4835.*

#### Using multi-copy atomicity of the Store-Release when observed by Load-Acquire

##### AArch32

###### P1

```
STL R0, [R2]      ; set new data
                  ; this is made multi-copy atomic
```

###### P2

```
WAIT_ACQ([R2]==1) ; wait to see new data from P1
STR R0, [R3]      ; send flag
                  ; must be after the new data has been by P2 as stores must not be speculative
                  ; this does not need to be a store release, though it could be a store
release
```

###### P3

```
WAIT([R3]==1)    ; wait for P2 flag
                  ; this does not need to be a WAIT_ACQ, although
                  ; it could be a WAIT_ACQ (at which point the dependency is not needed)
AND R12, R12, #0 ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
LDA R0, [R2, R12] ; read P1 data using a Load-Acquire
```

##### AArch64

###### P1

```
STLR W0, [X2]    ; set new data
                  ; this is made multi-copy atomic
```

###### P2

```
WAIT_ACQ([X2]==1) ; wait to see new data from P1
STR W0, [X3]      ; send flag
                  ; must be after the new data has been by P2 as stores
                  ; must not be speculative
                  ; this does not need to be a store release, though it could be a
                  ; store release
```

###### P3

```
WAIT([X3]==1)    ; wait for P2 flag
                  ; this does not need to be a WAIT_ACQ, though
```

```
                                ; it could be a WAIT_ACQ (at which point the dependency is not needed)
AND W12, W12, WZR                ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
LDAR W0, [X2, X12]              ; read P1 data using a Load-Acquire
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 using a Load-Acquire.

## Using ordering property of Store-Release on stores observed by the PE

### AArch32

#### P1

```
STR R0, [R2]                    ; set new data
                                ; this does not have to be a store release, though it
                                ; could be a store release
```

#### P2

```
WAIT ([R2]==1)                 ; wait to see new data from P1
                                ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
STL R0, [R3]                   ; send flag
                                ; must be after the new data has been by P2 as stores must not be speculative
                                ; as a store release, this orders P1 store
```

#### P3

```
WAIT([R3]==1)                 ; wait for P2 flag
                                ; this does not need to be a WAIT_ACQ, although it could be a WAIT_ACQ
                                ; (at which point the dependency is not needed)
AND R12, R12, #0               ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
LDR R0, [R2, R12]             ; read P1 data
```

### AArch64

#### P1

```
STR W0, [X2]                   ; set new data
                                ; this does not have to be a store release, though it
                                ; could be a store release
```

#### P2

```
WAIT ([X2]==1)                 ; wait to see new data from P1
                                ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
STLR W0, [X3]                  ; send flag
                                ; must be after the new data has been by P2 as stores must not be speculative
                                ; as a store release, this orders P1 store
```

#### P3

```
WAIT([X3]==1)                 ; wait for P2 flag
                                ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
```

```
                                ; at which point the dependency is not needed  
AND W12, W12, WZR              ; dependency to ensure order  
                                ; only needed for a WAIT, not WAIT_ACQ  
LDR W0, [X2, X12]              ; read P1 data
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 using a Load-Acquire.

———— **Note** —————

The use of dependency by P3 could be replaced by a Load-Acquire.

## F.2.4 Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders as was shown in [Multiple observers of writes to multiple locations on page AppxF-4863](#), but the use of Load-Acquire and Store-Release can resolve this. In this case, the loads by P3 and P4 must be Load-Acquire in order to ensure the perceived multi-copy atomicity of the stores:

### AArch32

#### P1

```
STL R0, [R1]                    ; set new data
```

#### P2

```
STL R0, [R2]                    ; set new data
```

#### P3

```
LDA R10, [R2]                   ; read P2 data before P1  
LDA R9, [R1]                    ;  
BIC R9, R10, R9                 ; R9 <- R10 & ~R9  
                                ; R9 contains 1 if read from [R2] is observed to be 1 and  
                                ; read from [R1] is observed to be 0
```

#### P4

```
LDA R9, [R1]  
LDA R10, [R2]  
BIC R9, R9, R10                 ; R9 <- R9 & ~R10  
                                ; R9 contains 1 if read from [R2] is observed to be 0 and  
                                ; read from [R1] is observed to be 1
```

### AArch64

#### P1

```
STLR W0, [X1]                   ; set new data
```

#### P2

```
STLR W0, [X2]                   ; set new data
```

#### P3

```
LDAR W10, [X2]                  ; read P2 data before P1
```

```
LDAR W9, [X1]      ;
BIC W9, W10, W9    ; W9 <- W10 & ~W9
                   ; W9 contains 1 if read from [X2] is observed to be 1 and
                   ; read from [X1] is observed to be 0
```

P4

```
LDAR W9, [X1]
LDAR W10, [X2]
BIC W9, W9, W10    ; W9 <- W9 & ~W10
                   ; W9 contains 1 if read from [X2] is observed to be 0 and
                   ; read from [X1] is observed to be 1
```

In this case, the result P3:R9==1 and P4:R9==1 is not permissible, as the stores from P1 and P2 are multi-copy atomic when read by Load-Acquire.

Therefore, if P3 gets R10==1, then we know that the P3 load of R9 can only be observed after we know that P4 has also observed the P2 store to [R2]. Similarly, if the P4 load of R9 returns 1, and the P3 load of R9 returns 0, then the P3 load must have occurred before the P4 load.

Therefore, if the P3 load of R10 returns 1 and the P3 load of R9 returns 0, then we know that if the P4 load of R9 returns 1, it must have happened after P4 has observed the P2 store to [R2], so the P4 load of R10 must return 1.

This shows that, of the 4 possible values for {P3:R9, P4:R9}, the use of these instructions makes the result {1,1} impossible.

## F.2.5 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page AppxF-4864](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

### AArch32

P1

```
STR R0, [R2]
DSB
Loop
WFI
B Loop
```

### AArch64

P1

```
STR W0, [X2]
DSB <domain>
Loop
```

WFI

B Loop

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

## F.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using LDREX and STREX).
- Acquire only semantics (using LDAEX and STREX).
- Release only semantics (using LDREX and STLEX).
- Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of WFE, by removing the need for a DSB barrier and SEV instruction.

### F.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

#### AArch32

##### Px

```
    PLDW[R1]          ; preload into cache in unique state
```

Loop

```
    LDAEX R5, [R1]    ; read lock with acquire
    CMP R5, #0        ; check if 0
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0      ; test if store succeeded
    BNE Loop          ; retry if not
```

```
    ; loads and stores in the critical region can now be performed
```

#### AArch64

##### Px

```
    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
```

Loop

```
    LDAXR W5, [X1]    ; read lock with acquire
    CBNZ W5, Loop     ; check if 0
    STXR W5, W0, [X1] ; attempt to store new value
    CBNZ W5, Loop     ; test if store succeeded and retry if not
```

```
    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

### F.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

#### AArch32

##### Px

```
    ; loads and stores in the critical region  
    MOV R0, #0  
    STL R0, [R1]          ; clear the lock with release semantics
```

#### AArch64

##### Px

```
    ; loads and stores in the critical region  
    STLR WZR, [X1]       ; clear the lock with release semantics
```

### F.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

#### ———— Note ————

The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

This is shown in the implementation below:

#### AArch32

##### Px

```
    ; R1 holds two 16 bit quantities  
    ; the lower halfword holds the current ticket number  
    ; the higher halfword holds the next ticket number  
  
    PLDW[R1]          ; preload into cache in unique state  
Loop1  
    LDAEX R5, [R1]    ; read current and next
```

```
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start
Loop2
LDAH R6, [R1] ; read current value
CMP R6, R5, LSR #16 ; compare it with our allocated ticket
BNE Loop2 ; retry (spin) if it is not the same
block_start
```

## AArch64

### Px

```
; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
LDAXR W5, [X1] ; read current and next
ADD W5, W5, #0x10000 ; increment the next number
STXR W6, W5, [X1] ; and update the value
CBNZ W6, Loop1 ; did the exclusive pass - retry if not

AND W6, W5, #0xFFFF
CMP W6, W5, LSR #16 ; is the current ticket ours
B.EQ block_start
Loop2
LDARH W6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
B.NE Loop2 ; retry (spin) if it isn't the same
block_start
```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

### AArch32

```
ADD R6, R6, #1
```

```
STLH R6, [R1]
```

#### AArch64

```
ADD W6, W6, #1
```

```
STLRH W6, [X1]
```

### F.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

#### Simple lock

The following is an example of lock acquire code using WFE:

#### AArch32

##### Px

```
PLDW[R1] ; preload into cache in unique state
```

Loop

```
LDAEX R5, [R1] ; read lock with acquire
```

```
CMP R5, #0 ; check if 0
```

```
WFENE ; sleep if the lock is held
```

```
STREXEQ R5, R0, [R1] ; attempt to store new value
```

```
CMPEQ R5, #0 ; test if store succeeded
```

```
BNE Loop ; retry if not
```

#### AArch64

##### Px

```
SEVL ; invalidates the WFE on the first loop iteration
```

```
PRFM PSTL1KEEP, [X1] ; allocate into cache in unique state
```

Loop

```
WFE
```

```
LDAXR W5, [X1] ; read lock with acquire
```

```
CBNZ W5, Loop ; check if 0
```

```
STXR W5, W0, [X1] ; attempt to store new value
```

```
CBNZ W5, Loop ; test if store succeeded and retry if not
```

```
; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code:

#### AArch32

Px

```
; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock
```

**AArch64**

Px

```
; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock
```

**Ticket lock**

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

**AArch32**

Px

```
; R1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PLDW[R1] ; preload into cache in unique state
Loop1
LDAEX R5, [R1] ; read current and next
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start
SEVL
Loop2
WFE ; wait if there has not been a change to the count since last
; read
LDAEXH R6, [R1] ; check the current count
CMP R6, R5, LSR #16 ; check if it is equal
BNE Loop2
block_start
```

**AArch64**

Px

```
; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
LDAXR W5, [X1] ; read current and next
ADD W5, W5, #0x10000 ; increment the next number
STXR W6, W5, [X1] ; and update the value
CBNZ W6, Loop1 ; did the exclusive pass - retry if not

AND W6, W5, 0xFFFF
CMP W6, W5, LSR #16 ; is the current ticket ours
```

*Appendix F Barrier Litmus Tests*  
*F.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers*

```
B.EQ block_start
SEVL
Loop2
WFE
LDAXRH W6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with our allocated ticket
B.NE Loop2 ; retry (spin) if it is not the same
block_start
```

## F.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

### **AArch32**

#### P1

```
STR R5, [R1]          ; message stored to shared memory location
```

```
DSB ST
```

```
STR R0, [R4]          ; R4 contains the address of a mailbox
```

#### P2

```
; interrupt service routine
```

```
LDR R5, [R1]
```

### **AArch64**

#### P1

```
STR W5, [X1]          ; message stored to shared memory location
```

```
DSB ST
```

```
STR W0, [X4]          ; R4 contains the address of a mailbox
```

#### P2

```
; interrupt service routine
```

```
LDR W5, [X1]
```

These rules are required in connection to the ARM Generic Interrupt Controller (GIC).

## F.5 Cache and TLB maintenance operations and barriers

The following sections describe the use of barriers with cache and TLB maintenance operations:

- [Data cache maintenance operations](#)
- [Instruction cache maintenance operations](#) on page AppxF-4851
- [TLB maintenance operations and barriers](#) on page AppxF-4854.

### F.5.1 Data cache maintenance operations

The following sections describe the use of barriers with data cache maintenance operations:

- [Message passing to non-caching observers](#)
- [Multiprocessing message passing to non-caching observers](#) on page AppxF-4847
- [Invalidating DMA buffers, non-functional example](#) on page AppxF-4848
- [Invalidating DMA buffers, functional example with single PE](#) on page AppxF-4849
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page AppxF-4850.

#### Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance operations and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance operation. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

##### AArch32

###### P1

```
STR R5, [R1]          ; update data (assumed to be in P1 cache)
DCCMVAC R1            ; clean cache to point of coherency
DMB                   ; ensure effects of the clean will be observed before the
                       ; flag is set
STR R0, [R4]          ; send flag to external agent (Non-cacheable location)
```

###### E1

```
WAIT_ACQ ([R4] == 1) ; wait for the flag (with order)
LDR R5, [R1]          ; read the data
```

##### AArch64

###### P1

```
STR W5, [X1]          ; update data (assumed to be in P1 cache)
DC CVAC, X1           ; clean cache to point of coherency
DMB ISH               ; ensure effects of the clean will be observed before the
                       ; flag is set
STR W0, [X4]          ; send flag to external agent (Non-cacheable location)
```

###### E1

```
WAIT_ACQ ([X4] == 1) ; wait for the flag (with order)
LDR W5, [X1]          ; read the data
```

In this example, it is required that E1:R5==0x55.

## Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance operations combined with properties of barriers, means that the message passing principle for non-caching observers is:

### AArch32

#### P1

```
STR R5, [R1]          ; update data (assumed to be in P1 cache)
STL R0, [R2]          ; send a flag for P2 (ordered by the store release)
```

#### P2

```
WAIT ([R2] == 1)     ; wait for P1 flag
DMB                  ; ensure cache clean is observed after P1 flag is observed
DCCMVA R1            ; clean cache to point of coherency ?will clean P1 cache
DMB                  ; ensure effects of the clean will be observed before the
                    ; flag to E1 is set
STR R0, [R4]         ; send flag to E1
```

#### E1

```
WAIT_ACQ ([R4] == 1) ; wait for P2 flag (ordered)
LDR R5, [R1]         ; read data
```

### AArch64

#### P1

```
STR W5, [X1]          ; update data (assumed to be in P1 cache)
STLR W0, [X2]         ; send a flag for P2 (ordered)
```

#### P2

```
WAIT ([X2] == 1)     ; wait for P1 flag
DMB SY               ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1         ; clean cache to point of coherency, will clean P1 cache
DMB SY               ; ensure effects of the clean will be observed before the
                    ; flag to E1 is set
STR W0, [X4]         ; send flag to E1
```

#### E1

```
WAIT_ACQ ([X4] == 1) ; wait for P2 flag
LDR W5, [X1]         ; read data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

———— **Note** —————

The cache maintenance operations are not ordered by the Load-Acquire and Store-Release instructions.

### Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

#### AArch32

##### P1

```
DCIMVAC R1          ; ensure cache clean wrt memory. A clean operation could be used
                    ; but as the DMA will subsequently overwrite this region an
                    ; invalidate operation is sufficient and usually more efficient

DMB                 ; ensures cache invalidation is observed before the next store
                    ; is observed

STR R0, [R3]        ; send flag to external agent

WAIT_ACQ ([R4]==1) ; wait for a different flag from an external agent

LDR R5, [R1]
```

##### E1

```
WAIT ([R3] == 1)   ; wait for flag

STR R5, [R1]       ; store new data

STL R0, [R4]       ; send a flag
```

#### AArch64

##### P1

```
DC IVAC, X1        ; ensure cache clean wrt memory. A clean operation could be used
                    ; but as the DMA will subsequently overwrite this region an
                    ; invalidate operation is sufficient and usually more efficient

DMB SY             ; ensures cache invalidation is observed before the next store
                    ; is observed

STR W0, [X3]       ; send flag to external agent

WAIT_ACQ ([X4]==1) ; wait for a different flag from an external agent

LDR W5, [X1]
```

##### E1

```
WAIT ([X3] == 1)   ; wait for flag

STR W5, [X1]       ; store new data

STLR W0, [X4]      ; send a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

## Invalidating DMA buffers, functional example with single PE

### AArch32

#### P1

```
DCIMVAC R1          ; ensure cache clean wrt memory. A clean operation could be used
                    ; but as the DMA will subsequently overwrite this region an
                    ; invalidate operation is sufficient and usually more efficient

DMB                 ; ensures cache invalidation is observed before the next store
                    ; is observed

STR R0, [R3]        ; send flag to external agent

WAIT ([R4]==1)      ; wait for a different flag from an external agent

DMB                 ; ensure that cache invalidate is observed after the flag
                    ; from external agent is observed

DCIMVAC R1          ; ensure cache discards stale copies before use

LDR R5, [R1]
```

#### E1

```
WAIT ([R3] == 1)    ; wait for flag

STR R5, [R1]        ; store new data

STL R0, [R4]        ; send a flag
```

### AArch64

#### P1

```
DC IVAC, X1         ; ensure cache clean wrt memory. A clean operation could be used
                    ; but as the DMA will subsequently overwrite this region an
                    ; invalidate operation is sufficient and usually more efficient

DMB SY              ; ensures cache invalidation is observed before the next store
                    ; is observed

STR W0, [X3]        ; send flag to external agent

WAIT ([X4]==1)      ; wait for a different flag from an external agent

DMB SY              ; ensure that cache invalidate is observed after the flag
                    ; from external agent is observed

DC IVAC, X1         ; ensure cache discards stale copies before use

LDR W5, [X1]
```

#### E1

```
WAIT ([X3] == 1)    ; wait for flag

STR W5, [X1]        ; store new data

STLR W0, [X4]       ; send a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

## Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance operations, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

### AArch32

#### P0

(Use data from [R1], potentially using [R1] as scratch space)

```
STL R0, [R2]          ; signal release of [R1]
WAIT_ACQ ([R2] == 0) ; wait for new value from DMA
LDR R5, [R1]
```

#### P1

```
WAIT ([R2] == 1)      ; wait for release of [R1] by P0
DCIMVAC R1            ; ensure caches are clean wrt memory, invalidate is sufficient
DMB
STR R0, [R3]          ; request new data for [R1]
WAIT ([R4] == 1)      ; wait for new data
DMB
DCIMVAC R1            ; ensure caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]          ; signal availability of new [R1]
```

#### E1

```
WAIT ([R3] == 1)      ; wait for new data request
STR R5, [R1]          ; send new [R1]
DMB [ST]
STR R0, [R4]          ; indicate new data available to P1
```

### AArch64

#### P0

(Use data from [X1], potentially using [X1] as scratch space)

```
STLR W0, [X2]         ; signal release of [X1]
WAIT_ACQ ([X2] == 0) ; wait for new value from DMA
LDR W5, [X1]
```

#### P1

```
WAIT ([X2] == 1)      ; wait for release of [R1] by P0
DC IVAC, X1           ; ensure caches are clean wrt memory, invalidate is sufficient
DMB SY
STR W0, [X3]          ; request new data for [R1]
WAIT ([X4] == 1)      ; wait for new data
```

```

DMB SY
DCIMVAC X1          ; ensure caches discard stale copies before use
DMB SY
STR WZR, [X2]       ; signal availability of new [R1]
  
```

E1

```

WAIT ([X3] == 1)    ; wait for new data request
STR W5, [X1]        ; send new [R1]
STR W0, [X4]        ; indicate new data available to P1
  
```

In this example, the result  $P0:R5 == 0x55$  is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

## F.5.2 Instruction cache maintenance operations

The following sections describe the use of barriers with instruction cache maintenance operations:

- [Ensuring the visibility of updates to instructions for a uniprocessor](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor on page AppxF-4852.](#)

### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance operations are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

#### AArch32

P1

```

STR R11, [R1]       ; R11 contains a new instruction to stored in program memory
DCMVAU R1           ; clean to PoU makes visible to instruction cache
DSB
ICIMVAU R1          ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DSB                 ; ensure completion of the invalidation
ISB                 ; ensure instruction fetch path sees new I cache state
BX R1
  
```

In AArch64, the branch predictor maintenance is not required.

#### AArch64

P1

```

STR W11, [X1]       ; W11 contains a new instruction to stored in program memory
DC CVAU, X1         ; clean to PoU makes visible to instruction cache
  
```

```
DSB ISH
IC IVAU, X1      ; ensure instruction cache/branch predictor discard stale data
DSB ISH          ; ensure completion of the invalidation
ISB              ; ensure instruction fetch path sees new I cache state
BR X1
```

———— **Note** ————

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

### Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that performs an instruction cache maintenance operation to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance operation is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

#### **AArch32**

##### P1

```
STR R11, [R1]    ; R11 contains a new instruction to stored in program memory
DCCMVAU R1      ; clean to PoU makes visible to instruction cache
DSB             ; ensure completion of the clean on all processors
ICIMVAU R1      ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DSB             ; ensure completion of the ICache and branch predictor
                ; invalidation on all processors
STR R0, [R2]    ; set flag to signal completion
ISB             ; synchronize context on this processor
BX R1           ; branch to new code
```

##### P2-Px

```
WAIT ([R2] == 1) ; wait for flag signalling completion
ISB             ; synchronize context on this processor
BX R1           ; branch to new code
```

#### **AArch64**

##### P1

```
STR X11, [X1]   ; X11 contains a new instruction to stored in program memory
DC CVAU, X1     ; clean to PoU makes visible to instruction cache
DSB ISH        ; ensure completion of the clean on all processors
IC IVAU, X1     ; ensure instruction cache/branch predictor discard stale data
DSB ISH        ; ensure completion of the ICache and branch predictor
```

```

; invalidation on all processors
STR W0, [X2] ; set flag to signal completion
ISB ; synchronize context on this processor
BR R1 ; branch to new code

```

P2-Px

```

WAIT ([X2] == 1) ; wait for flag signalling completion
ISB ; synchronize context on this processor
BR X1 ; branch to new code

```

**Nonfunctional approach**

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance operations that other PEs issue:

**AArch32**

P1

```

STR R11, [R1] ; R11 contains a new instruction to stored in program memory
DCCMVAU R1 ; clean to PoU makes visible to instruction cache
DSB ; ensure completion of the clean on all processors
ICIMVAU R1 ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DMB ; ensure ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other processors
STR R0, [R2] ; set flag to signal completion
DSB ; ensure completion of the invalidation on all processors
ISB ; synchronize context on this processor
BX R1 ; branch to new code

```

P2-Px

```

WAIT ([R2] == 1) ; wait for flag signalling completion
DSB ; this DSB does not guarantee completion of P1
; ICIMVAU/BPIMVA
ISB
BX R1

```

**AArch64**

P1

```

STR W11, [X1] ; W11 contains a new instruction to stored in program memory
DC CVAU, X1 ; clean to PoU makes visible to instruction cache
DSB ISH ; ensure completion of the clean on all processors
IC IVAU, X1 ; ensure instruction cache/branch predictor discard stale data

```

```
DMB ISH          ; ensure ordering of the store after the invalidation
                 ; DOES NOT guarantee completion of instruction cache/branch
                 ; predictor on other processors

STR W0, [X2]     ; set flag to signal completion

DSB ISH          ; ensure completion of the invalidation on all processors

ISB              ; synchronize context on this processor

BR X1            ; branch to new code
```

#### P2-Px

```
WAIT ([X2] == 1) ; wait for flag signalling completion

DSB ISH          ; this DSB does not guarantee completion of P1
                 ; ICIMVAU/BPIMVA

ISB

BR X1
```

In this example, P2...Px might not see the updated region of code at R1.

### F.5.3 TLB maintenance operations and barriers

The following sections describe the use of barriers with TLB maintenance operations:

- [Ensuring the visibility of updates to translation tables for a uniprocessor](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page AppxF-4855](#)
- [Paging memory in and out on page AppxF-4856.](#)

#### **Ensuring the visibility of updates to translation tables for a uniprocessor**

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

#### **AArch32**

##### P1

```
STR R11, [R1]    ; update the translation table entry

DSB              ; ensure visibility of the update to translation table walks

TLBIMVA R10

BPIALL

DSB              ; ensure completion of the BP and TLB invalidation

ISB              ; synchronise context on this processor

                 ; new translation table entry can be relied upon at this point and all accesses
                 ; generated by this observer using
                 ; the old mapping have been completed
```

## **AArch64**

### P1

```
STR X11, [X1]      ; update the translation table entry
DSB ISH            ; ensure visibility of the update to translation table walks
TLBI VAE1, X10    ; assumes we are in the EL1
DSB ISH            ; ensure completion of the TLB invalidation
ISB                ; synchronise context on this processor
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

## **Ensuring the visibility of updates to translation tables for a multiprocessor**

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that performs a TLB maintenance operation to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance operation is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance operation ensures that all accesses that used the old mapping have completed.

## **AArch32**

### P1

```
STR R11, [R1]     ; update the translation table entry
DSB               ; ensure visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB               ; ensure completion of the BP and TLB invalidation
ISB               ; Note ISB is not broadcast and must be executed locally
                  ; on other processors
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

## **AArch64**

### P1

```
STR X11, [X1]     ; update the translation table entry
DSB ISH           ; ensure visibility of the update to translation table walks
TLBI VAE1IS, X10
```

```
DSB ISH          ; ensure completion of the TLB invalidation
ISB              ; Note ISB is not broadcast and must be executed locally
                ; on other processors
                ; new translation table entry can be relied upon at this point and all accesses
                ; generated by any observers affected by the broadcast TLBIMVAIS operation using
                ; the old mapping have been completed
```

The completion of the TLB maintenance operation is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance operation. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance operation is observed by that different observer.

## Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

### AArch32

#### P1

```
STR R11, [R1]    ; update the translation table for the region being paged out
DSB              ; ensure visibility of the update to translation table walks
TLBIMVAIS R10    ; invalidate the old entry
DSB              ; ensure completion of the invalidation on all processors
ISB              ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB              ; ensure completion of the memory transfer (this could be part of
                ; LoadMemoryFromBackingStore
ICIALLUIS        ; also invalidates the branch predictor
STR R9, [R1]     ; create a new translation table entry with a new mapping
DSB              ; ensure completion of the I Cache & Branch Predictor invalidation
                ; AND ensure visibility of the new translation table mapping
ISB              ; ensure synchronisation of this instruction stream
```

### AArch64

#### P1

```
STR X11, [X1]    ; update the translation table for the region being paged out
DSB ISH          ; ensure visibility of the update to translation table walks
```

```

TLBI VAE1IS, X10      ; invalidate the old entry
DSB ISH                ; ensure completion of the invalidation on all processors
ISB                    ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH                ; ensure completion of the memory transfer (this could be part of
                       ; LoadMemoryFromBackingStore
IC IALLUIS             ; also invalidates the branch predictor
STR X9, [X1]           ; create a new translation table entry with a new mapping
DSB ISH                ; ensure completion of the I Cache & Branch Predictor invalidation
                       ; AND ensure visibility of the new translation table mapping
ISB                    ; ensure synchronisation of this instruction stream
  
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `IC IALLUIS` in AArch32 and `IC IALLUIS` in AArch64 to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` and `IC IVAU` operations in AArch32 and AArch64 respectively. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

#### F.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a Processing Element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the Processing Element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the Processing Element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a `DSB <domain>` instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

##### **AArch32**

###### P1

```

STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
  
```

##### **AArch64**

###### P1

```

STR W5, [X2]          ; data written to the data buffer
  
```

```
DSB <domain>  
STR W0, [X4] ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the Processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

### **AArch32**

#### P1

```
WAIT ([R4] == 1) ; R4 contains the address of the status register,  
; and the value '1' indicates completion of the DMA transfer  
DSB  
LDR R5, [R2] ; read data from the data buffer
```

### **AArch64**

#### P1

```
WAIT ([X4] == 1) ; X4 contains the address of the status register,  
; and the value '1' indicates completion of the DMA transfer  
DSB <domain>  
LDR W5, [X2] ; read data from the data buffer
```

## F.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- [Simple ordering and barrier cases](#).
- [Load-Exclusive, Store-Exclusive and barriers](#) on page AppxF-4866.
- [Using a mailbox to send an interrupt](#) on page AppxF-4868.
- [Cache and TLB maintenance operations and barriers](#) on page AppxF-4868.

### F.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

#### Simple weakly consistent ordering example

```
P1
    STR R5, [R1]
    LDR R6, [R2]

P2
    STR R6, [R2]
    LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

#### Message passing

The following sections describe:

- [Weakly-ordered message passing problem](#)
- [Message passing with multiple observers](#) on page AppxF-4861.

#### Weakly-ordered message passing problem

```
P1
    STR R5, [R1]           ; set new data
    STR R0, [R2]           ; send flag indicating data ready

P2
    WAIT([R2]==1)         ; wait on flag
    LDR R5, [R1]           ; read new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

#### Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

```
P1
    STR R5, [R1]           ; set new data
    DMB [ST]               ; ensure all observers observe data before the flag
```

```

    STR R0, [R2]           ; send flag indicating data ready

P2

    WAIT([R2]==1)        ; wait on flag

    DMB                   ; ensure that the load of data is after the flag has been observed

    LDR R5, [R1]
  
```

### Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.  
 Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.  
 This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.  
 Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table F-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table F-1 Dependency examples

Address dependency		Control dependency		Address and control dependency <sup>a</sup>
(a)	(b)	(c)	(d)	(e)
LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]
LDR r2, [r1]	AND r1, r1, #0	CMP r1, #55	CMP r1, #55	CMP r1, #0
	LDR r2, [r3, r1]	LDRNE r2, [r3]	MOVNE r4, #22	LDRNE r2, [r1]
			LDR r2, [r3, r4]	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page AppxF-4859 can also be satisfied as shown in the following example:

```

P1

    STR R5, [R1]           ; set new data

    DMB [ST]              ; ensure all observers observe data before the flag

    STR R0, [R2]           ; send flag indicating data ready

P2

    WAIT([R2]==1)

    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro

    LDR R5, [R1, R12]     ; Load is dependent and so is ordered after the flag has been seen
  
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

### **Message passing with multiple observers**

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

```
P1
    STR R5, [R1]           ; set new data
    STR R0, [R2]           ; send flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; Load is dependent and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; Load is dependent and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

### **Resolving by the addition of barriers**

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

```
P1
    STR R5, [R1]           ; set new data
    DMB [ST]               ; ensure all observers observe data before the flag
    STR R0, [R2]           ; send flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; Load is dependent and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; Load is dependent and so is ordered after the flag has been seen
```

### **Address dependency with object construction**

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

```
P1
    STR R5, [R1, #offset]  ; set new data in a field
```

```
DMB [ST]           ; ensure all observers observe data before base address is updated
STR R1, [R2]       ; update base address
P2
LDR R1, [R2]       ; read for base address
CMP R1, #0         ; check if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; use base address to read field
```

If the `null_trap` is not taken, it is required that `P2:R5==0x55`. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

### Causal consistency issues with multiple observers

The fact that different observers can observe memory accesses in different orders extends, in the absence of barriers, to behaviors that do not fit naturally expected causal properties, as the following example shows:

```
P1
STR R0, [R2]       ; set new data
P2
WAIT([R2]==1)     ; wait to see new data from P1
STR R0, [R3]       ; send flag, must be after the new data has been by P2 as stores
                   ; must not be speculative
P3
WAIT([R3]==1)     ; wait for P2's flag
AND R12, R12, #0  ; dependency to ensure order
LDR R0, [R2, R12] ; read P1's data
```

In this example, `P3:R0==0` is permissible. P3 is not guaranteed to see the stores from P1 and P2 in any particular order. This applies despite the fact that the store from P2 can only happen after P2 has observed the store from P1.

This example shows that the ARM memory order model for Normal memory does not conform to *causal consistency*. This means that the apparently transitive causal relationship between two variables is not guaranteed to be transitive.

The following example shows the insertion of a barrier by P2 to create causal consistency:

```
P1
STR R0, [R2]       ; set new data
P2
WAIT([R2]==1)     ; wait to see new data from P1
DMB               ; ensure P1's data is observed by all observers before any following store
STR R0, [R3]       ; send flag
P3
WAIT([R3]==1)     ; wait for P2's flag
AND R12, R12, #0  ; dependency to ensure order
```

```
LDR R0, [R2, R12] ; read P1's data
```

This creates causal consistency because a DMB is required to order all accesses that the executing PE observed before the DMB, not only those it issued, before any of the accesses that follow the DMB.

### Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders, as the following example shows:

P1

```
STR R0, [R1] ; set new data
```

P2

```
STR R0, [R2] ; set new data
```

P3

```
LDR R10, [R2] ; read P2's data before P1's
LDR R9, [R1] ;
BIC R9, R10, R9 ; R9 <- R10 && ~R9
                ; R9 contains 1 iff read from [R2] is observed to be 1 and
                ; read from [R1] is observed to be 0.
```

P4

```
LDR R9, [R1]
LDR R10, [R2]
BIC R9, R9, R10 ; R9 <- R9 && ~R10
                ; R9 contains 1 iff read from [R2] is observed to be 0 and
                ; read from [R1] is observed to be 1.
```

In this example, the result P3:R9==1 and P4:R9==1 is permissible. This means that P3 and P4 observed the stores from P1 and P2 in different orders.

The following example shows the use of DMB instructions to ensure sequential consistency:

P1

```
STR R0, [R1] ; set new data
```

P2

```
STR R0, [R2] ; set new data
```

P3

```
LDR R10, [R2] ; read P2's data before P1's
DMB
LDR R9, [R1]
BIC R9, R10, R9 ; R9 <- R10 && ~R9
                ; R9 contains 1 iff read from [R2] is observed to be 1 and
                ; read from [R1] is observed to be 0.
```

P4

```
LDR R9, [R1] ; read P1's data before P2's
```

```
DMB
LDR R10, [R2]
BIC R9, R9, R10      ; R9 <- R9 && ~R10
                     ; R9 contains 1 iff read from [R2] is observed to be 0 and
                     ; read from [R1] is observed to be 1.
```

In this example:

- the DMB executed by P3 ensures that, if the P3 load from [R2] observes the P2 store to [R2], then all observers observe the P2 store to [R2] before they observe the P3 load from [R1]
- the DMB executed by P4 ensures that, if the P4 load from [R1] observes the P1 store to [R1], then all observers observe the P1 store to [R1] before they observe the P4 load from [R2].

If the P3 load from [R1] returns 0, then it has not observed the P1 store to [R1]. Also, if the P3 load of [R2] returns 1, then all observers must have observed the P2 store to [R2] before they observed the P1 store to [R1]. This means that P4 cannot observe the P1 store to [R1] without also observing the P2 store to [R2].

Alternatively, if the P4 load from [R2] returns 0, then it has not observed the P2 store to [R2]. If, also, the P4 load of [R1] returns 1, then all observers must have observed the P1 store to [R1] before they observed the P2 store to [R2]. This means that P3 cannot observe the P2 store to [R2] without also observing the P1 store to [R1].

This shows that, of the four possible results for {P3:R9, P4:R9}, the insertion of these barriers makes the result {1, 1} impossible.

### Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

```
P1
STR R0, [R2]
WAIT ([R3]==1)

P2
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a DMB instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

```
P1
STR R0, [R2]
DMB
WAIT ([R3]==1)

P2
WAIT ([R2]==1)
STR R0, [R3]
```

The DMB executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

```
P1
    STR R0, [R2]
    WAIT ([R2]==2)

P2
    WAIT ([R2]==1)
    LDR R0, [R2]
    ADD R0, R0, #1
    STR R0, [R2]
```

In this example, the same deadlock can occur, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a DMB instruction prevents this deadlock:

```
P1
    STR R0, [R2]
    DMB
    WAIT ([R2]==2)

P2
    WAIT ([R2]==1)
    LDR R0, [R2]
    ADD R0, R0, #1
    STR R0, [R2]
```

### WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page AppxF-4864](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

```
P1
    STR R0, [R2]
    DSB

Loop
    WFI
    B Loop
```

However, if the example in [Posting a store before polling for acknowledgement on page AppxF-4864](#) is extended to include a WFE, there is no risk of a deadlock. The extended example is:

```
P1
```

```
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop
P2
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- the DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1
- the dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see [Use of Wait For Event \(WFE\) and Send Event \(SEV\) with locks on page AppxF-4867](#).

## F.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in [Synchronization and semaphores on page B2-100](#), are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

### Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

```
Px
Loop
    LDREX R5, [R1]      ; read lock
    CMP R5, #0         ; check if 0
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0       ; test if store succeeded
    BNE Loop           ; retry if not
    DMB                ; ensures that all subsequent accesses are observed after the
                       ; gaining of the lock is observed
```

; loads and stores in the critical region can now be performed

### Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

Px

```

; loads and stores in the critical region
MOV R0, #0
DMB                ; ensure all previous accesses are observed before the lock is cleared
STR R0, [R1]      ; clear the lock

```

### Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

Px

```

Loop
LDREX R5, [R1]    ; read lock
CMP R5, #0        ; check if 0
WFENE             ; sleep if the lock is held
STREXEQ R5, R0, [R1] ; attempt to store new value
CMPEQ R5, #0      ; test if store succeeded
BNE Loop          ; retry if not
DMB               ; ensures that all subsequent accesses are observed after the
                  ; gaining of the lock is observed
; loads and stores in the critical region can now be performed

```

And the following is an example of lock release code using SEV:

Px

```

; loads and stores in the critical region
MOV R0, #0
DMB                ; ensure all previous accesses are observed before the lock is cleared
STR R0, [R1]      ; clear the lock
DSB                ; ensure completion of the store that cleared the lock before

```

```
                                ; sending the event  
  
SEV
```

### F.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

```
P1  
  
    STR R5, [R1]                ; message stored to shared memory location  
  
    DSB [ST]  
  
    STR R1, [R4]                ; R4 contains the address of a mailbox  
  
P2  
  
    ; interrupt service routine  
  
    LDR R5, [R1]
```

———— **Note** —————

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

### F.6.4 Cache and TLB maintenance operations and barriers

The following sections describe the use of barriers with cache and TLB maintenance operations:

- [Data cache maintenance operations](#)
- [Instruction cache maintenance operations](#) on page AppxF-4871
- [TLB maintenance operations and barriers](#) on page AppxF-4873.

#### Data cache maintenance operations

The following sections describe the use of barriers with data cache maintenance operations:

- [Message passing to non-caching observers](#)
- [Multiprocessing message passing to non-caching observers](#) on page AppxF-4869
- [Invalidating DMA buffers, non-functional example](#) on page AppxF-4869
- [Invalidating DMA buffers, functional example with single PE](#) on page AppxF-4870
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page AppxF-4870.

#### Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance operations and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

```
P1  
  
    STR R5, [R1]                ; update data (assumed to be in P1's cache)  
  
    DCCMVA R1                  ; clean cache to point of coherency
```

```

DMB                ; ensure effects of the clean will be observed before the flag is set
STR R0, [R4]       ; send flag to external agent (Non-cacheable location)
E1
WAIT ([R4] == 1)   ; wait for the flag
DMB                ; ensure that flag has been seen before reading data
LDR R5, [R1]       ; read the data

```

In this example, it is required that E1:R5==0x55.

### **Multiprocessing message passing to non-caching observers**

The broadcast nature of the cache maintenance operations in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

```

P1
STR R5, [R1]       ; update data (assumed to be in P1's cache)
DMB [ST]          ; ensure new data is observed before the flag to P2 is set
STR R0, [R2]       ; send flag to P2
P2
WAIT ([R2] == 1)   ; wait for flag from P1
DMB              ; ensure cache clean is observed after P1's flag is observed
DCCMVA R1         ; clean cache to point of coherency - this cleans the cache of P1
DMB              ; ensure effects of the clean are observed before the flag to E1 is set
STR R0, [R4]       ; send flag to E1
E1
WAIT ([R4] == 1)   ; wait for flag from P2
DMB              ; ensure that flag has been observed before reading the data
LDR R5, [R1]       ; read the data

```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

### **Invalidating DMA buffers, non-functional example**

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

```

P1
DCIMVA R1         ; ensure cache clean with respect to memory. A clean operation could be
                  ; used but the DMA overwrites this region so an invalidate operation
                  ; is sufficient and usually more efficient
DMB              ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]       ; send flag to external agent
WAIT ([R4]==1)    ; wait for a different flag from an external agent

```

```
DMB ; observe flag from external agent before reading new data. However [R1]
; could have been brought into cache earlier

LDR R5, [R1]
E1
WAIT ([R3] == 1) ; wait for flag
STR R5, [R1] ; store new data
DMB
STR R0, [R4] ; send a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

### ***Invalidating DMA buffers, functional example with single PE***

```
P1
DCIMVAC R1 ; ensure cache clean with respect to memory. A clean operation could be
; used but the DMA overwrites this region so an invalidate operation
; is sufficient and usually more efficient

DMB ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; send flag to external agent
WAIT ([R4]==1) ; wait for a different flag from an external agent
DMB ; ensure that cache invalidate is observed after the flag
; from external agent is observed

DCIMVAC R1 ; ensure cache discards stale copies before use
LDR R5, [R1]
E1
WAIT ([R3] == 1) ; wait for flag
STR R5, [R1] ; store new data
DMB [ST]
STR R0, [R4] ; send a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

### ***Invalidating DMA buffers, functional example with multiple coherent PEs***

The broadcasting of cache maintenance operations, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

```
P0
(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2] ; signal release of [R1]
WAIT ([R2] == 0) ; wait for new value from DMA
```

```

DMB
LDR R5, [R1]
P1
WAIT ([R2] == 1)      ; wait for release of [R1] by P0
DCIMVAC R1           ; ensure caches are clean with respect to memory, invalidate is sufficient
DMB
STR R0, [R3]         ; request new data for [R1]
WAIT ([R4] == 1)     ; wait for new data
DMB
DCIMVAC R1           ; ensure caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]         ; signal availability of new [R1]
E1
WAIT ([R3] == 1)     ; wait for new data request
STR R5, [R1]         ; send new [R1]
DMB [ST]
STR R0, [R4]         ; indicate new data available to P1

```

In this example, the result  $P0:R5 == 0x55$  is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

### Instruction cache maintenance operations

The following sections describe the use of barriers with instruction cache maintenance operations:

- [Ensuring the visibility of updates to instructions for a uniprocessor](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor on page AppxF-4872.](#)

#### ***Ensuring the visibility of updates to instructions for a uniprocessor***

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance operations are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

```

P1
STR R11, [R1]        ; R11 contains a new instruction to store in program memory
DCCMVAU R1          ; clean to PoU makes visible to instruction cache
DSB
ICIMVAU R1          ; ensure instruction cache and branch predictor discards stale data
BPIMVA R1

```

```
DSB                ; ensure completion of the invalidation
ISB                ; ensure instruction fetch path observes new instruction cache state
BX R1
```

### **Ensuring the visibility of updates to instructions for a multiprocessor**

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that performs an instruction cache maintenance operation to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance operation is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

```
P1
STR R11, [R1]      ; R11 contains a new instruction to store in program memory
DCCMVAU R1        ; clean to PoU makes visible to instruction cache
DSB               ; ensure completion of the clean on all processors
ICIMVAU R1       ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DSB               ; ensure completion of the ICache and branch predictor
                 ; invalidation on all processors
STR R0, [R2]     ; set flag to signal completion
ISB               ; synchronize context on this processor
BX R1            ; branch to new code

P2-Px
WAIT ([R2] == 1) ; wait for flag signaling completion
ISB               ; synchronize context on this processor
BX R1            ; branch to new code
```

### **Nonfunctional approach**

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance operations that other PEs issue:

```
P1
STR R11, [R1]      ; R11 contains a new instruction to store in program memory
DCCMVAU R1        ; clean to PoU makes visible to instruction cache
DSB               ; ensure completion of the clean on all processors
ICIMVAU R1       ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB               ; ensure ordering of the store after the invalidation
                 ; DOES NOT guarantee completion of instruction cache/branch
                 ; predictor on other processors
STR R0, [R2]     ; set flag to signal completion
```

```
DSB                ; ensure completion of the invalidation on all processors
ISB                ; synchronize context on this processor
BX R1              ; branch to new code

P2-Px

WAIT ([R2] == 1)   ; wait for flag signaling completion
DSB                ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1
```

In this example, P2...Px might not see the updated region of code at R1.

## TLB maintenance operations and barriers

The following sections describe the use of barriers with TLB maintenance operations:

- [Ensuring the visibility of updates to translation tables for a uniprocessor](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page AppxF-4874](#)
- [Paging memory in and out on page AppxF-4874.](#)

### **Ensuring the visibility of updates to translation tables for a uniprocessor**

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

```
P1

STR R11, [R1]      ; update the translation table entry
DSB                ; ensure visibility of the update to translation table walks
TLBIMVA R10
BPIALL

DSB                ; ensure completion of the BP and TLB invalidation
ISB                ; synchronize context on this processor
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

### **Ensuring the visibility of updates to translation tables for a multiprocessor**

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that performs a TLB maintenance operation must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance operation is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance operation ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]          ; update the translation table entry
DSB                    ; ensure visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                    ; ensure completion of the BP and TLB invalidation
ISB                    ; Note ISB is not broadcast and must be executed locally on other processors
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance operation is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance operation. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance operation is observed by that different observer.

### **Paging memory in and out**

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]          ; update the translation table for the region being paged out
DSB                    ; ensure visibility of the update to translation table walks
TLBIMVAIS R10          ; invalidate the old entry
DSB                    ; ensure completion of the invalidation on all processors
ISB                    ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                    ; ensure completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore
ICIALLUIS              ; also invalidates the branch predictor
```

```
STR R9, [R1]      ; create a new translation table entry with a new mapping
DSB               ; ensure completion of instruction cache and branch predictor invalidation
                 ; and ensure visibility of the new translation table mapping
ISB               ; ensure synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIALLUIS` to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` operations. This invalidation must be done when the mapping used for the `ICIMVAU` operations is valid but not executable.

# Appendix G

## ARMv8 Pseudocode Library

This appendix contains the ARMv8 pseudocode library. It contains the following sections:

- [Library pseudocode for AArch64 on page AppxG-4878.](#)
- [Library pseudocode for AArch32 on page AppxG-4927.](#)
- [Common library pseudocode on page AppxG-4986.](#)

---

### **Note**

#### **Status of this appendix in the beta release document**

ARM is currently working to improve the organization and presentation of the pseudocode in this document, including providing improved linking within the pseudocode. Currently, this chapter contains the complete pseudocode library for ARMv8, split between:

- Functions, or versions of functions, that are specific to execution in AArch64 state.
- Functions, or versions of functions, that are specific to execution in AArch32state.
- Functions that apply to execution in either Execution state.

Many pseudocode functions are included elsewhere in the document, to accompany the description of the associated functionality. Currently, those functions are repeated in this appendix.

---

## G.1 Library pseudocode for AArch64

This section holds the pseudocode for execution in AArch64 state. Functions listed in this section are identified as AArch64.FunctionName. Some of these functions have an equivalent AArch32 function, AArch32.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch64/debug/breakpoint.

### G.1.1 aarch64/debug

This section contains the pseudocode for AArch64 state that relates to debug.

#### aarch64/debug/breakpoint

```
// Breakpoints in an AArch64 translation regime

// AArch64.BreakpointValueMatch()
// =====
boolean AArch64.BreakpointValueMatch(integer n, bits(64) vaddress, boolean linked_to)

    // "n" is the identity of the breakpoint unit to match against
    // "vaddress" is the current instruction address, ignored if linked_to is TRUE and Context
    // matching breakpoints.
    // "linked_to" is TRUE if this is a call from StateMatch for linking.

    // If a non-existent breakpoint then it is CONSTRAINED UNPREDICTABLE whether this gives
    // no match or the breakpoint is mapped to another UNKNOWN implemented breakpoint.
    if n > UInt(ID_AA64DFR0_EL1.BRPs) then
        (c, n) = ConstrainUnpredictableInteger(0, UInt(ID_AA64DFR0_EL1.BRPs));
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return FALSE;

    // If this breakpoint is not enabled, it cannot generate a match. (This could also happen on a
    // call from StateMatch for linking.)
    if DBGBCR_EL1[n].E == '0' then return FALSE;

    // Return FALSE if BT is set to a reserved type.
    if DBGBCR_EL1[n].BT IN {'011x', '11xx'} then return FALSE;

    // Determine what to compare against.
    match_addr = DBGBCR_EL1[n].BT<3,1> == '00';
    match_vmid = DBGBCR_EL1[n].BT<3> == '1';
    match_cid = DBGBCR_EL1[n].BT<1> == '1';
    linked     = DBGBCR_EL1[n].BT<0> == '1';

    // Assertions based on the definition of DBGBCR_EL1[n].BT.
    // Unless this breakpoint is context-aware, BT<3,1> are RAZ, and
    // doesn't match VMID or CONTEXTIDR
    assert (n >= UInt(ID_AA64DFR0_EL1.BRPs) - UInt(ID_AA64DFR0_EL1.CTX_CMPs) ||
           (IsZero(DBGBCR_EL1[n].BT<3,1>) && !match_vmid && !match_cid));

    // Must be matching either address, or one or both of CONTEXTIDR and VMID. This assertion is
    // obviously true given the definition of these variables.
    assert ((match_addr && !match_cid && !match_vmid) ||
           (!match_addr && match_cid) || (!match_addr && match_vmid));

    // VMID matching is not possible/allowable if no EL2 support.
    assert HaveEL(EL2) || !match_vmid;

    // If this is a call from StateMatch, return FALSE if the breakpoint is not programmed for a
    // VMID and/or context ID match, or if not context-aware. The above assertions mean that the
    // code can just test for match_addr == TRUE to confirm all these things.
    if linked_to && (!linked || match_addr) then return FALSE;

    // If this is a call from BreakpointMatch return FALSE for Linked context ID and/or
    // VMID matches.
    if !linked_to && linked && !match_addr then return FALSE;
```

```

// Do the comparison.
if match_addr then
    top = AddrTop(vaddress);
    byte_select_match = (DBGBCR_EL1[n].BAS<0> != '0');

## G.2 Library pseudocode for AArch32

This section holds the pseudocode for execution in AArch32 state. Functions listed in this section are identified as AArch32.FunctionName. Some of these functions have an equivalent AArch64 function, AArch64.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch32/debug/breakpoint.

### G.2.1 aarch32/debug

This section contains the pseudocode for AArch32 state that relates to debug.

#### aarch32/debug/VCRMatch

## G.3 Common library pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

### G.3.1 shared/debug

This section contains the pseudocode that relates to debug and is common to AArch32 state and AArch64 state.

#### shared/debug/CONTEXTIDR\_GEN

```
// CONTEXTIDR_GEN()
// =====

bits(32) CONTEXTIDR_GEN[]
// AArch32 CONTEXTIDR is Banked, but there is no banking in AArch64.
return (if ELUsingAArch32(EL3) && IsSecure() then CONTEXTIDR_S else CONTEXTIDR_EL1);
```

#### shared/debug/ClearStickyErrors

```
// ClearStickyErrors()
// =====

ClearStickyErrors()
    EDSCR.TXU = '0';           // Clear TX underrun flag
    EDSCR.RXO = '0';           // Clear RX overrun flag
    if Halted() then         // in Debug state
        EDSCR.ITO = '0';       // Clear ITR overrun flag
    EDSCR.ERR = '0';           // Clear cumulative error flag
    return;
```

#### shared/debug/DebugTarget

```
// DebugTargetFrom()
// =====

bits(2) DebugTargetFrom(boolean secure)
// Returns the debug exception target EL
route_to_el2 = HaveEL(EL2) && !secure && (MDCR_EL2.TDE == '1' || HCR_EL2.TGE == '1');

if route_to_el2 then
    target = EL2;
elseif HaveEL(EL3) && HighestELUsingAArch32() && secure then
    target = EL3;
else
    target = EL1;

return target;

// DebugTarget()
// =====

bits(2) DebugTarget()
    secure = IsSecure();
    return DebugTargetFrom(secure);
```

#### shared/debug/DoubleLockStatus

```
// DoubleLockStatus()
// =====
```

```

boolean DoubleLockStatus()
    // Returns the value of EDPRSR.DLK:
    // FALSE if OSDLR_EL1.DLK == 0 or DBGPRCR_EL1.CORENPDRQ == 1 or the processor is in Debug state.
    // TRUE if OSDLR_EL1.DLK == 1 and DBGPRCR_EL1.CORENPDRQ == 0 and the processor is in Non-debug
    // state.
    return OSDLR_EL1.DLK == '1' && DBGPRCR_EL1.CORENPDRQ == '0' && !Halted();

```

### shared/debug/FindWatchpoint

```

// FindWatchpoint()
// =====

integer FindWatchpoint()
    address = FAR[];
    base = Align(address, ZVAGranuleSize());
    limit = base + ZVAGranuleSize();
    repeat
        for i = 0 to UInt(ID_AA64DFR0_EL1.WRPs)
            if WatchpointByteMatch(i, address) then // Candidate found
                return i;
            address = address + 1;
            if address == limit then address = base; // Wrap round, as this must be a DC ZVA
    while address != FAR[];
    return -1; // No candidate found (should not happen)

```

### shared/debug/authentication

```

// Debug authentication
// ~~~~~

// Debug_authentication signals
// =====

signal DBGEN;
signal NIDEN;
signal SPIDEN;
signal SPNIDEN;

// AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()
// =====

### G.3.2 shared/exceptions

This section contains the pseudocode that relates to exception handling and is common to AArch32 state and AArch64 state.

#### shared/exceptions/exceptions

```

// ~~~~~
// Shared Exception Model
// ~~~~~

// Typical flow through a translation for EL0 using AArch32 under EL1 using AArch64
// is as follows:
//
//
// WFE instruction pseudocode (AArch32)
// |
// '-> AArch32.WFxTrap(EL2)
// |
// '-> AArch32.TakeHypTrapException()
// |
// '-> AArch32.EnterHypMode()
// |
// |-> AArch32.ReportHypEntry()
// |
// '-> AArch32.BranchTo(HVBAR + offset)
//

```

```
// However, as necessary the exception handlers are marshalled to the correct
// exception regime for the exception type:
//
// WFE instruction pseudocode (AArch32)
// |
// `-> AArch32.WFxTrap(EL2)
// |
// `-> AArch64.WFxTrap(EL2)
// |
// `-> AArch64.TakeException(EL2)
// |
// |-> MaybeZeroRegisterUppers()
// |
// |-> AArch64.ReportException()
// |
// `-> AArch64.BranchTo(VBAR[EL2] + offset)
//
// Syndrome handling is different in the two worlds, and this is deliberate (though
// not necessarily fortunate). AArch64 passes the syndrome down to the exception
// entry which writes ESR and FAR; AArch32 does this for Hyp entries but otherwise
// writes these before calling the entry point. This is necessary in the AArch32
// case because of the variance due to descriptor format, eventual destination of
// the exception, etc.

// Exception
// =====
// Classes of exception

enumeration Exception {Exception_Uncategorized, // Uncategorized or unknown reason

## shared/translation/translation

```

// ~~~~~
// Shared Translation System
// ~~~~~
// Shared exception model and translation table walking code.
//
// Typical flow through a translation for EL0 using AArch32 under EL1 using AArch64
// is as follows:
//
// AArch32.TranslateAddress(bits(32) vaddress)
// |
// |--> AArch64.TranslateAddress(ZeroExtend(vaddress, 64))
// |
// |--> AArch64.FirstStageTranslate(vaddress)
// |
// |--> AArch64.TranslationTableWalkLD()
// |
// |--> AArch64.SecondStageWalk()
// |
// |--> AArch64.SecondStageTranslate()
// |
// |--> AArch64.TranslationTableWalkLD()
// |
// |--> AArch64.SecondStageTranslate(vaddress)
// |
// |--> AArch64.TranslationTableWalkLD()
//
// In ARMv7 "SecondStageTranslate" was used only for the recursive call from
// TranslationTableWalk{SD|LD}. For ARMv8 it is extended to deal with all
// second stage translations, so as to support EL0 and EL1 using AArch32
// under EL2 using AArch64:
//
// AArch32.TranslateAddress(bits(32) vaddress)
// |
// |--> AArch32.FirstStageTranslate(vaddress)
// |
// |--> AArch32.TranslationTableWalkLD()
// |
// |--> AArch32.SecondStageWalk()
// |
// |--> AArch32.SecondStageTranslate()

# Appendix H

## ARM Pseudocode Definition

This appendix provides a definition of the pseudocode used in this manual, and defines some *helper* procedures and functions used by pseudocode. It contains the following sections:

- [About the ARM pseudocode on page AppxH-5060.](#)
- [Pseudocode for instruction descriptions on page AppxH-5061.](#)
- [Data types on page AppxH-5063.](#)
- [Expressions on page AppxH-5067.](#)
- [Operators and built-in functions on page AppxH-5069.](#)
- [Statements and program structure on page AppxH-5074.](#)
- [Miscellaneous helper procedures and functions on page AppxH-5078.](#)

———— **Note** —————

**Status of this appendix in the beta release document**

ARM is currently working to improve the organization and presentation of the pseudocode in this document. Currently, this chapter contains the ARMv7 definition, and needs updating to incorporate changes and extensions to the pseudocode made for ARMv8. These updates will appear in the next issue of this manual.

The pseudocode in this manual describes ARMv8 execution in both AArch32 state and AArch64 state. It does not describe differences in earlier versions of the architecture.

## H.1 About the ARM pseudocode

See the *Note* on the front page of this appendix, [Status of this appendix in the beta release document on page AppxH-5059](#).

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. [Pseudocode for instruction descriptions on page AppxH-5061](#) gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- [Data types on page AppxH-5063](#).
- [Expressions on page AppxH-5067](#).
- [Operators and built-in functions on page AppxH-5069](#).
- [Statements and program structure on page AppxH-5074](#).

[Miscellaneous helper procedures and functions on page AppxH-5078](#) describes some pseudocode helper functions, that are used by the pseudocode functions that are described elsewhere in this manual. [Appendix I](#) contains the indexes to the pseudocode.

### H.1.1 General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION\_DEFINED, SEE, SUBARCHITECTURE\_DEFINED, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs. This means that these statements terminate pseudocode execution.

For more information, see [Simple statements on page AppxH-5074](#).

## H.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in *General limitations of ARM pseudocode* on page AppxH-5060 and *Limitations of the instruction pseudocode* on page AppxH-5062.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. *Instruction encoding diagrams and instruction pseudocode* gives more information about the pseudocode provided for each instruction.

### H.2.1 Instruction encoding diagrams and instruction pseudocode

———— **Note** —————

Currently this appendix only describes A32/T32 instruction pseudocode. This information is only partially applicable to the A64 instruction descriptions. This will be corrected in the next issue of the document.

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed()` then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is UNPREDICTABLE. For more information, see *SBZ or SBO fields in instructions* on page AppxA-4760.
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.

3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is `UNPREDICTABLE`. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as `UNPREDICTABLE`.
5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

## H.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see [Ordering requirements on page E2-2351](#).
- Pseudocode does not describe the exact rules when an `UNDEFINED` instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then ...` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a `NOP`. [Conditional execution of undefined instructions on page G1-3478](#) describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. [Combinations of exceptions on page E1-2309](#) describes the exact rules.

### ————— **Note** —————

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

## H.3 Data types

This section describes:

- [General data type rules](#).
- [Bitstrings](#).
- [Integers](#) on page AppxH-5064.
- [Reals](#) on page AppxH-5064.
- [Booleans](#) on page AppxH-5064.
- [Enumerations](#) on page AppxH-5064.
- [Lists](#) on page AppxH-5065.
- [Arrays](#) on page AppxH-5066.

### H.3.1 General data type rules

ARM architecture pseudocode is a strongly-typed language. Every constant and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- List.
- Array.

The type of a constant is determined by its syntax. The type of a variable is normally determined by assignment to the variable, with the variable being implicitly declared to be of the same type as whatever is assigned to it. For example, the assignments  $x = 1$ ,  $y = '1'$ , and  $z = \text{TRUE}$  implicitly declare the variables  $x$ ,  $y$  and  $z$  to have types integer, bitstring of length 1, and Boolean, respectively.

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

### H.3.2 Bitstrings

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 1.

The type name for bitstrings of length  $N$  is `bits(N)`. A synonym of `bits(1)` is `bit`.

Bitstring constants are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants of type `bit` are `'0'` and `'1'`. Spaces can be included in bitstrings for clarity.

A special form of bitstring constant with `'x'` bits is permitted in bitstring comparisons, see [Equality and non-equality testing](#) on page AppxH-5069.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length  $N$  is bit  $(N-1)$  and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings derived from encoding diagrams, this order matches the way they are printed.

Bitstrings are the only concrete data type in pseudocode, in the sense that they correspond directly to the contents of registers, memory locations, instructions, and so on. All of the remaining data types are abstract.

### H.3.3 Integers

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable functions to interpret those bitstrings as integers.

The type name for integers is `integer`.

Integer constants are normally written in decimal, such as `0`, `15`, `-1234`. They can also be written in C-style hexadecimal, such as `0x55` or `0x80000000`. Hexadecimal integer constants are treated as positive unless they have a preceding minus sign. For example, `0x80000000` is the integer  $+2^{31}$ . If  $-2^{31}$  needs to be written in hexadecimal, it must be written as `-0x80000000`.

### H.3.4 Reals

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable functions to interpret those bitstrings as reals.

The type name for reals is `real`.

Real constants are written in decimal with a decimal point. This means `0` is an integer constant, but `0.0` is a real constant.

### H.3.5 Booleans

A Boolean is a logical TRUE or FALSE value.

The type name for Booleans is `boolean`. This is not the same type as `bit`, which is a length-1 bitstring. Boolean constants are TRUE and FALSE.

### H.3.6 Enumerations

An enumeration is a defined set of symbolic constants, such as:

```
enumeration InstrSet {InstrSet_ARM, InstrSet_Thumb, InstrSet_Jazelle, InstrSet_ThumbEE};
```

An enumeration always contains at least one symbolic constant, and a symbolic constant must not be shared between enumerations.

Enumerations must be declared explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the symbolic constants to it. By convention, each of the symbolic constants starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the symbolic constants are its possible *constants*.

———— **Note** —————

A `boolean` is a pre-declared enumeration that does not follow the normal naming convention and that has a special role in some pseudocode constructs, such as `if` statements. This means the enumeration of a `boolean` is:

```
enumeration boolean {FALSE, TRUE};
```

---

### H.3.7 Lists

A list is an ordered set of other data items, separated by commas and enclosed in parentheses, for example:

```
(bits(32) shifter_result, bit shifter_carry_out)
```

A list always contains at least one data item.

Lists are often used as the return type for a function that returns multiple results. For example, the list at the start of this section is the return type of the function `Shift_C()` that performs a standard A32/T32 shift or rotation, when its first operand is of type `bits(32)`.

Some specific pseudocode operators use lists surrounded by other forms of bracketing than the (...) parentheses. These are:

- Bitstring extraction operators, that use lists of bit numbers or ranges of bit numbers surrounded by angle brackets `<...>`.
- Array indexing, that uses lists of array indexes surrounded by square brackets `[...]`.
- Array-like function argument passing, that uses lists of function arguments surrounded by square brackets `[...]`.

Each combination of data types in a list is a separate type, with type name given by listing the data types. This means that the example list at the start of this section is of type `(bits(32), bit)`. The general principle that types can be declared by assignment extends to the types of the individual list items in a list. For example:

```
(shift_t, shift_n) = ('00', 0);
```

implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be of type `(bits(2), integer)`.

A list type can also be explicitly named, with explicitly named elements in the list. For example:

```
type ShiftSpec is (bits(2) shift, integer amount);
```

After this definition and the declaration:

```
ShiftSpec abc;
```

The elements of the resulting list can then be referred to as `abc.shift` and `abc.amount`. This qualified naming of list elements is only permitted for variables that have been explicitly declared, not for those that have been declared by assignment only.

Explicitly naming a type does not alter what type it is. For example, after the above definition of `ShiftSpec`, `ShiftSpec` and `(bits(2), integer)` are two different names for the same type, not the names of two different types. To avoid ambiguity in references to list elements, it is an error to declare a list variable multiple times using different names of its type or to qualify it with list element names not associated with the name by which it was declared.

An item in a list that is being assigned to can be written as “-” to indicate that the corresponding item of the assigned list value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

List constants are written as a list of constants of the appropriate types, for example the `('00', 0)` in the earlier example.

### H.3.8 Arrays

Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant array. Arrays always contain at least one element, because:

- Enumerations always contain at least one symbolic constant.
- Integer ranges always contain at least one integer.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing.

## H.4 Expressions

This section describes:

- [General expression syntax.](#)
- [Operators and functions - polymorphism and prototypes on page AppxH-5068.](#)
- [Precedence rules on page AppxH-5068.](#)

### H.4.1 General expression syntax

An expression is one of the following:

- A constant.
- A variable, optionally preceded by a data type name to declare its type.
- The word UNKNOWN preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register described in the text is to be regarded as declaring a correspondingly named bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as 0 and ignore writes.

An expression like bits(32) UNKNOWN indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

#### ———— Note —————

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.  
The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Every expression has a data type.

- For a constant, this data type is determined by the syntax of the constant.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.
  - A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

#### H.4.2 Operators and functions - polymorphism and prototypes

Operators and functions in pseudocode can be polymorphic, producing different functionality when applied to different data types. Each resulting form of an operator or function has a different prototype definition. For example, the operator + has forms that act on various combinations of integers, reals and bitstrings.

One particularly common form of polymorphism is between bitstrings of different lengths. This is represented by using `bits(N)`, `bits(M)`, or similar, in the prototype definition.

#### H.4.3 Precedence rules

The precedence rules for expressions are:

1. Constants, variables and function invocations are evaluated with higher priority than any operators using their results.
2. Expressions on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if `i`, `j` and `k` are integer variables, `i > 0 && j > 0 && k > 0` is acceptable, but `i > 0 && j > 0 || k > 0` is not.

## H.5 Operators and built-in functions

This section describes:

- [Operations on generic types.](#)
- [Operations on Booleans.](#)
- [Bitstring manipulation.](#)
- [Arithmetic on page AppxH-5072.](#)

### H.5.1 Operations on generic types

The following operations are defined for all types.

#### Equality and non-equality testing

Any two values  $x$  and  $y$  of the same type can be tested for equality by the expression  $x == y$  and for non-equality by the expression  $x != y$ . In both cases, the result is of type `boolean`.

A special form of comparison is defined with a bitstring constant that includes 'x' bits as well as '0' and '1' bits. The bits corresponding to the 'x' bits are ignored in determining the result of the comparison. For example, if opcode is a 4-bit bitstring,  $opcode == '1x0x'$ , this matches the values '1000', '1100', '1001' and '1101'.

———— **Note** —————

This special form is permitted in the implied equality comparisons in when parts of case ... of ... structures.

---

#### Conditional selection

If  $x$  and  $y$  are two values of the same type and  $t$  is a value of type `boolean`, then `if t then x else y` is an expression of the same type as  $x$  and  $y$  that produces  $x$  if  $t$  is `TRUE` and  $y$  if  $t$  is `FALSE`.

### H.5.2 Operations on Booleans

If  $x$  is a `boolean`, then `!x` is its logical inverse.

If  $x$  and  $y$  are `booleans`, then  $x \&\& y$  is the result of ANDing them together. As in the C language, if  $x$  is `FALSE`, the result is determined to be `FALSE` without evaluating  $y$ .

If  $x$  and  $y$  are `booleans`, then  $x \|\| y$  is the result of ORing them together. As in the C language, if  $x$  is `TRUE`, the result is determined to be `TRUE` without evaluating  $y$ .

———— **Note** —————

If  $x$  and  $y$  are `booleans`, then the result of  $x != y$  is the same as the result of exclusive-ORing  $x$  and  $y$  together.

---

### H.5.3 Bitstring manipulation

The following bitstring manipulation functions are defined:

#### Bitstring length and most significant bit

If  $x$  is a bitstring:

- The bitstring length function `Len(x)` returns the length of  $x$  as an integer.
- `TopBit(x)` is the leftmost bit of  $x$ . Using bitstring extraction, this means:  
`TopBit(x) = x <Len(x)-1>`.

## Bitstring concatenation and replication

If  $x$  and  $y$  are bitstrings of lengths  $N$  and  $M$  respectively, then  $x:y$  is the bitstring of length  $N+M$  constructed by concatenating  $x$  and  $y$  in left-to-right order.

If  $x$  is a bitstring and  $n$  is an integer with  $n > 0$ :

- $\text{Replicate}(x, n)$  is the bitstring of length  $n \cdot \text{Len}(x)$  consisting of  $n$  copies of  $x$  concatenated together.
- $\text{Zeros}(n) = \text{Replicate}('0', n)$ ,  $\text{Ones}(n) = \text{Replicate}('1', n)$ .

## Bitstring extraction

The bitstring extraction operator extracts a bitstring from either another bitstring or an integer. Its syntax is  $x\langle\text{integer\_list}\rangle$ , where  $x$  is the integer or bitstring being extracted from, and  $\langle\text{integer\_list}\rangle$  is a list of integers enclosed in angle brackets rather than the usual parentheses. The length of the resulting bitstring is equal to the number of integers in  $\langle\text{integer\_list}\rangle$ . In  $x\langle\text{integer\_list}\rangle$ , each of the integers in  $\langle\text{integer\_list}\rangle$  must be:

- $\geq 0$ .
- $< \text{Len}(x)$  if  $x$  is a bitstring.

The definition of  $x\langle\text{integer\_list}\rangle$  depends on whether  $\text{integer\_list}$  contains more than one integer:

- If  $\text{integer\_list}$  contains more than one integer,  $x\langle i, j, k, \dots, n \rangle$  is defined to be the concatenation:  
 $x\langle i \rangle : x\langle j \rangle : x\langle k \rangle : \dots : x\langle n \rangle$ .
- If  $\text{integer\_list}$  consists of just one integer  $i$ ,  $x\langle i \rangle$  is defined to be:
  - If  $x$  is a bitstring, '0' if bit  $i$  of  $x$  is a zero and '1' if bit  $i$  of  $x$  is a one.
  - If  $x$  is an integer, let  $y$  be the unique integer in the range  $0$  to  $2^{i+1}-1$  that is congruent to  $x$  modulo  $2^{i+1}$ . Then  $x\langle i \rangle$  is '0' if  $y < 2^i$  and '1' if  $y \geq 2^i$ .  
Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

In  $\langle\text{integer\_list}\rangle$ , the notation  $i:j$  with  $i \geq j$  is shorthand for the integers in order from  $i$  down to  $j$ , with both end values included. For example,  $\text{instr}\langle 31:28 \rangle$  is shorthand for  $\text{instr}\langle 31, 30, 29, 28 \rangle$ .

The expression  $x\langle\text{integer\_list}\rangle$  is assignable provided  $x$  is an assignable bitstring and no integer appears more than once in  $\langle\text{integer\_list}\rangle$ . In particular,  $x\langle i \rangle$  is assignable if  $x$  is an assignable bitstring and  $0 \leq i < \text{Len}(x)$ .

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the [APSR](#) shows its  $\text{bit}\langle 31 \rangle$  as  $N$ . In such cases, the syntax  $\text{APSR}.N$  is used as a more readable synonym for  $\text{APSR}\langle 31 \rangle$ .

## Logical operations on bitstrings

If  $x$  is a bitstring,  $\text{NOT}(x)$  is the bitstring of the same length obtained by logically inverting every bit of  $x$ .

If  $x$  and  $y$  are bitstrings of the same length,  $x \text{ AND } y$ ,  $x \text{ OR } y$ , and  $x \text{ EOR } y$  are the bitstrings of that same length obtained by logically ANDing, ORing, and exclusive-ORing corresponding bits of  $x$  and  $y$  together.

## Bitstring count

If  $x$  is a bitstring,  $\text{BitCount}(x)$  produces an integer result equal to the number of bits of  $x$  that are ones.

## Testing a bitstring for being all zero or all ones

If  $x$  is a bitstring:

- $\text{IsZero}(x)$  produces TRUE if all of the bits of  $x$  are zeros and FALSE if any of them are ones
- $\text{IsZeroBit}(x)$  produces '1' if all of the bits of  $x$  are zeros and '0' if any of them are ones.

$\text{IsOnes}(x)$  and  $\text{IsOnesBit}(x)$  work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)   = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

## Lowest and highest set bits of a bitstring

If  $x$  is a bitstring, and  $N = \text{Len}(x)$ :

- $\text{LowestSetBit}(x)$  is the minimum bit number of any of its bits that are ones. If all of its bits are zeros,  $\text{LowestSetBit}(x) = N$ .
- $\text{HighestSetBit}(x)$  is the maximum bit number of any of its bits that are ones. If all of its bits are zeros,  $\text{HighestSetBit}(x) = -1$ .
- $\text{CountLeadingZeroBits}(x)$  is the number of zero bits at the left end of  $x$ , in the range 0 to  $N$ . This means:  
 $\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)$ .
- $\text{CountLeadingSignBits}(x)$  is the number of copies of the sign bit of  $x$  at the left end of  $x$ , excluding the sign bit itself, and is in the range 0 to  $N-1$ . This means:  
 $\text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x \ll N-1) \text{ EOR } x \ll N-2$ .

## Zero-extension and sign-extension of bitstrings

If  $x$  is a bitstring and  $i$  is an integer, then  $\text{ZeroExtend}(x, i)$  is  $x$  extended to a length of  $i$  bits, by adding sufficient zero bits to its left. That is, if  $i = \text{Len}(x)$ , then  $\text{ZeroExtend}(x, i) = x$ , and if  $i > \text{Len}(x)$ , then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If  $x$  is a bitstring and  $i$  is an integer, then  $\text{SignExtend}(x, i)$  is  $x$  extended to a length of  $i$  bits, by adding sufficient copies of its leftmost bit to its left. That is, if  $i = \text{Len}(x)$ , then  $\text{SignExtend}(x, i) = x$ , and if  $i > \text{Len}(x)$ , then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either  $\text{ZeroExtend}(x, i)$  or  $\text{SignExtend}(x, i)$  in a context where it is possible that  $i < \text{Len}(x)$ .

## Converting bitstrings to integers

If  $x$  is a bitstring,  $\text{SInt}(x)$  is the integer whose two's complement representation is  $x$ :

```
// SInt()
```

```
// =====
```

```
integer SInt(bits(N) x)
```

```
    result = 0;
```

```
    for i = 0 to N-1
```

```
        if x<i> == '1' then result = result + 2∧i;
```

```
    if x<N-1> == '1' then result = result - 2∧N;
```

```
return result;
```

UInt(x) is the integer whose unsigned representation is x:

```
// UInt()  
// =====
```

```
integer UInt(bits(N) x)  
  
    result = 0;  
    for i = 0 to N-1  
        if x<i> == '1' then result = result + 2i;  
    return result;
```

Int(x, unsigned) returns either SInt(x) or UInt(x) depending on the value of its second argument:

```
// Int()  
// =====
```

```
integer Int(bits(N) x, boolean unsigned)  
  
    result = if unsigned then UInt(x) else SInt(x);  
    return result;
```

## H.5.4 Arithmetic

Most pseudocode arithmetic is performed on integer or real values, with operands being obtained by conversions from bitstrings and results converted back to bitstrings afterwards. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

### Unary plus, minus and absolute value

If x is an integer or real, then +x is x unchanged, -x is x with its sign reversed, and Abs(x) is the absolute value of x. All three are of the same type as x.

### Addition and subtraction

If x and y are integers or reals, x+y and x-y are their sum and difference. Both are of type integer if x and y are both of type integer, and real otherwise.

Addition and subtraction are particularly common arithmetic operations in pseudocode, and so it is also convenient to have definitions of addition and subtraction acting directly on bitstring operands.

If x and y are bitstrings of the same length N, so that  $N = \text{Len}(x) = \text{Len}(y)$ , then x+y and x-y are the least significant N bits of the results of converting them to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

```
x+y = (SInt(x) + SInt(y))<N-1:0>  
     = (UInt(x) + UInt(y))<N-1:0>  
x-y = (SInt(x) - SInt(y))<N-1:0>  
     = (UInt(x) - UInt(y))<N-1:0>
```

If x is a bitstring of length N and y is an integer, x+y and x-y are the bitstrings of length N defined by  $x+y = x + y<N-1:0>$  and  $x-y = x - y<N-1:0>$ . Similarly, if x is an integer and y is a bitstring of length M, x+y and x-y are the bitstrings of length M defined by  $x+y = x<M-1:0> + y$  and  $x-y = x<M-1:0> - y$ .

## Comparisons

If  $x$  and  $y$  are integers or reals, then  $x == y$ ,  $x != y$ ,  $x < y$ ,  $x <= y$ ,  $x > y$ , and  $x >= y$  are equal, not equal, less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results. In the case of  $==$  and  $!=$ , this extends the generic definition applying to any two values of the same type to also act between integers and reals.

## Multiplication

If  $x$  and  $y$  are integers or reals, then  $x * y$  is the product of  $x$  and  $y$ . It is of type `integer` if  $x$  and  $y$  are both of type `integer`, and `real` otherwise.

## Division and modulo

If  $x$  and  $y$  are integers or reals, then  $x/y$  is the result of dividing  $x$  by  $y$ , and is always of type `real`.

If  $x$  and  $y$  are integers, then  $x \text{ DIV } y$  and  $x \text{ MOD } y$  are defined by:

$$x \text{ DIV } y = \text{RoundDown}(x/y)$$

$$x \text{ MOD } y = x - y * (x \text{ DIV } y)$$

It is a pseudocode error to use any of  $x/y$ ,  $x \text{ MOD } y$ , or  $x \text{ DIV } y$  in any context where  $y$  can be zero.

## Square root

If  $x$  is an integer or a real,  $\text{Sqrt}(x)$  is its square root, and is always of type `real`.

## Rounding and aligning

If  $x$  is a real:

- $\text{RoundDown}(x)$  produces the largest integer  $n$  such that  $n \leq x$ .
- $\text{RoundUp}(x)$  produces the smallest integer  $n$  such that  $n \geq x$ .
- $\text{RoundTowardsZero}(x)$  produces  $\text{RoundDown}(x)$  if  $x > 0.0$ ,  $0$  if  $x == 0.0$ , and  $\text{RoundUp}(x)$  if  $x < 0.0$ .

If  $x$  and  $y$  are both of type `integer`,  $\text{Align}(x, y) = y * (x \text{ DIV } y)$  is of type `integer`.

If  $x$  is of type `bitstring` and  $y$  is of type `integer`,  $\text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) \langle \text{Len}(x) - 1 : 0 \rangle$  is a bitstring of the same length as  $x$ .

It is a pseudocode error to use either form of  $\text{Align}(x, y)$  in any context where  $y$  can be 0. In practice,  $\text{Align}(x, y)$  is only used with  $y$  a constant power of two, and the bitstring form used with  $y = 2^n$  has the effect of producing its argument with its  $n$  low-order bits forced to zero.

## Scaling

If  $x$  and  $n$  are of type `integer`, then:

- $x \ll n = \text{RoundDown}(x * 2^n)$ .
- $x \gg n = \text{RoundDown}(x * 2^{(-n)})$ .

## Maximum and minimum

If  $x$  and  $y$  are integers or reals, then  $\text{Max}(x, y)$  and  $\text{Min}(x, y)$  are their maximum and minimum respectively. Both are of type `integer` if  $x$  and  $y$  are both of type `integer`, and `real` otherwise.

## Raising to a power

If  $x$  is an integer or a real and  $n$  is an integer then  $x^n$  is the result of raising  $x$  to the power of  $n$ , and:

- If  $x$  is of type `integer` then  $x^n$  is of type `integer`.
- If  $x$  is of type `real` then  $x^n$  is of type `real`.

## H.6 Statements and program structure

This section describes the control statements used in the pseudocode.

### H.6.1 Simple statements

Each of the following simple statements must be terminated with a semicolon, as shown.

#### Assignments

An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

#### Procedure calls

A procedure call takes the form:

```
<procedure_name>(<arguments>;
```

#### Return statements

A procedure return takes the form:

```
return;
```

And a function return takes the form:

```
return <expression>;
```

where <expression> is of the type declared in the function prototype line.

#### UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

#### UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

#### SEE...

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

## IMPLEMENTATION\_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {<text>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION\_DEFINED. An optional <text> field can give more information.

## SUBARCHITECTURE\_DEFINED

This subsection describes the statement:

```
SUBARCHITECTURE_DEFINED {<text>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is SUBARCHITECTURE\_DEFINED. An optional <text> field can give more information.

## H.6.2 Compound statements

Indentation normally indicates the structure in compound statements. The statements contained in structures such as if ... then ... else ... or procedure and function definitions are indented more deeply than the statement itself, and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level.

### if ... then ... else ...

A multi-line if ... then ... else ... structure takes the form:

```
if <boolean_expression> then
    <statement 1>
    <statement 2>
    ...
    <statement n>
elseif <boolean_expression> then
    <statement a>
    <statement b>
    ...
    <statement z>
else
    <statement A>
    <statement B>
    ...
    <statement Z>
```

The block of lines consisting of elseif and its indented statements is optional, and multiple elseif blocks can be used.

The block of lines consisting of else and its indented statements is optional.

Abbreviated one-line forms can be used when there are only simple statements in the then part and in the else part, if it is present, such as:

```
if <boolean_expression> then <statement 1>
if <boolean_expression> then <statement 1> else <statement A>
if <boolean_expression> then <statement 1> <statement 2> else <statement A>
```

### ————— Note —————

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the else part is optional are differences from the if ... then ... else ... expression.

### repeat ... until ...

A repeat ... until ... structure takes the form:

```
repeat
  <statement 1>
  <statement 2>
  ...
  <statement n>
until <boolean_expression>;
```

### while ... do

A while ... do structure takes the form:

```
while <boolean_expression> do
  <statement 1>
  <statement 2>
  ...
  <statement n>
```

### for ...

A for ... structure takes the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>
  <statement 2>
  ...
  <statement n>
```

### case ... of ...

A case ... of ... structure takes the form:

```
case <expression> of
  when <constant values>
    <statement 1>
    <statement 2>
    ...
    <statement n>
  ... more "when" groups ...
  otherwise
    <statement A>
    <statement B>
    ...
    <statement Z>
```

In this structure, <constant values> consists of one or more constant values of the same type as <expression>, separated by commas. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, <constant values> can also include bitstring constants containing 'x' bits. For details see [Equality and non-equality testing on page AppxH-5069](#).

## Procedure and function definitions

A procedure definition takes the form:

```
<procedure name>(<argument prototypes>)  
  <statement 1>  
  <statement 2>  
  ...  
  <statement n>
```

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

### ————— **Note** —————

This first prototype line is not terminated by a semicolon. This helps to distinguish it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)  
  <statement 1>  
  <statement 2>  
  ...  
  <statement n>
```

An array-like function is similar, but with square brackets:

```
<return type> <function name>[<argument prototypes>]  
  <statement 1>  
  <statement 2>  
  ...  
  <statement n>
```

An array-like function also usually has an assignment prototype:

```
<function name>[<argument prototypes>] = <value prototypes>  
  <statement 1>  
  <statement 2>  
  ...  
  <statement n>
```

## H.6.3 Comments

Two styles of pseudocode comment exist:

- // starts a comment that is terminated by the end of the line.
- /\* starts a comment that is terminated by \*/.

## H.7 Miscellaneous helper procedures and functions

The functions described in this section are not part of the pseudocode specification. They are miscellaneous *helper* procedures and functions used by pseudocode that are not described elsewhere in this manual. Each has a brief description and a pseudocode prototype, except that the prototype is omitted where it is identical to the section title.

### H.7.1 ArchVersion()

This function returns the major version number of the architecture.

```
// ArchVersion()  
// =====
```

```
integer ArchVersion()  
    return 8;
```

### H.7.2 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

### H.7.3 GenerateAlignmentException()

This procedure generates the appropriate exception for an alignment error.

In all architecture variants and profiles described in this manual, `GenerateAlignmentException()` generates a Data Abort exception.

### H.7.4 GenerateCoproprocessorException()

This procedure generates the appropriate exception for a rejected coprocessor instruction.

In all architecture variants and profiles described in this manual, `GenerateCoproprocessorException()` generates an Undefined Instruction exception.

### H.7.5 Hint\_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

### H.7.6 Hint\_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

### H.7.7 Hint\_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

### H.7.8 Hint\_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

### H.7.9 Hint\_Yield()

This procedure performs a *Yield* hint.

```
Hint_Yield();
```

### H.7.10 IntegerZeroDivideTrappingEnabled()

This function returns TRUE if the trapping of divisions by zero in the integer division instructions SDIV and UDIV is enabled, and FALSE otherwise.

The A-profile SDIV and UDIV implementation does not support trapping of integer division by zero and therefore this function always returns FALSE.

```
boolean IntegerZeroDivideTrappingEnabled();
```

### H.7.11 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an external abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)
```

```
    assert type != Fault_None;
```

```
boolean IsExternalAbort(FaultRecord fault);
```

### H.7.12 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
```

```
    assert type != Fault_None;
```

```
boolean IsAsyncAbort(FaultRecord fault);
```

### H.7.13 JazelleAcceptsExecution()

This function indicates whether Jazelle hardware will take over execution when a BXJ instruction is executed.

```
boolean JazelleAcceptsExecution();
```

### H.7.14 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the [HSR](#).

```
bits(11) LSInstructionSyndrome();
```

### H.7.15 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

#### H.7.16 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```
boolean RemapRegsHaveResetValues();
```

#### H.7.17 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

———— **Note** —————

Currently, this function is used only on 32-bit instruction encodings.

#### H.7.18 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

# Appendix I

## Pseudocode Index

This appendix provides indexes to pseudocode definitions and to the pseudocode functions. It contains the following sections:

- [Pseudocode operators and keywords on page AppxI-5082.](#)
- [Pseudocode indexes on page AppxI-5085.](#)

---

### **Note**

#### **Status of this appendix in the beta release document**

ARM is currently working to improve the organization of the pseudocode in this document, including providing improved linking within the pseudocode. The pseudocode indexes will be added as part of this work. At present, this chapter contains only a list of the pseudocode operators and keywords.

---

## I.1 Pseudocode operators and keywords

Table I-1 shows the pseudocode operators and keywords.

**Table I-1 Pseudocode operators and keywords**

Operator	Meaning
-	Unary minus on integers or reals
-	Subtraction of integers, reals and bitstrings
+	Unary plus on integers or reals
+	Addition of integers, reals and bitstrings
.	Extract named member from a list
.	Extract named bit or field from a register
:	Bitstring concatenation
:	Integer range in bitstring extraction operator
!	Boolean NOT
!=	Compare for non-equality (any type)
!=	Compare for non-equality (between integers and reals)
(...)	Around arguments of procedure
(...)	Around arguments of function
[...]	Around array index
[...]	Around arguments of array-like function
*	Multiplication of integers and reals
/	Division of integers and reals (real result)
/*...*/	Comment delimiters
//	Introduces comment terminated by end of line
&&	Boolean AND
<	<i>Less than</i> comparison of integers and reals
<...>	Extraction of specified bits of bitstring or integer
<<	Multiply integer by power of 2 (with rounding towards -infinity)
<=	<i>Less than or equal</i> comparison of integers and reals
=	Assignment
==	Compare for equality (any type)
==	Compare for equality (between integers and reals)
>	<i>Greater than</i> comparison of integers and reals
>=	<i>Greater than or equal</i> comparison of integers and reals
>>	Divide integer by power of 2 (with rounding towards -infinity)

**Table I-1 Pseudocode operators and keywords (continued)**

<b>Operator</b>	<b>Meaning</b>
	Boolean OR
x <sup>N</sup>	N <sup>th</sup> integer power of integers or real <sup>a</sup>
AND	Bitwise AND of bitstrings
array	Keyword introducing array type definition
bit	Bitstring type of length 1
bits(N)	Bitstring type of length N
boolean	Boolean type
case ... of ...	Control structure
DIV	Quotient from integer division
enumeration	Keyword introducing enumeration type definition
EOR	Bitwise EOR of bitstrings
FALSE	Boolean constant
for ...	Control structure
for ... downto	Counts down
if ... then ... else ...	Expression selecting between two values
if ... then ... else ...	Control structure
IN	Tests membership of a set of values
IMPLEMENTATION_DEFINED	Describes IMPLEMENTATION DEFINED behavior
integer	Unbounded integer type
MOD	Remainder from integer division
OR	Bitwise OR of bitstrings
otherwise	Introduces default case in case ... of ... control structure
real	Real number type
repeat ... until ...	Control structure
return	Procedure or function return
SEE	Points to other pseudocode to use instead
SUBARCHITECTURE_DEFINED	Describes SUBARCHITECTURE DEFINED behavior
TRUE	Boolean constant
type	Names a type
UNDEFINED	Cause Undefined Instruction exception
UNKNOWN	Unspecified value

**Table I-1 Pseudocode operators and keywords (continued)**

<b>Operator</b>	<b>Meaning</b>
UNPREDICTABLE	Unspecified behavior
when	Introduces specific case in case ... of ... control structure
while ... do ...	Control structure

a.  $N$  must be an integer,  $x$  can be an integer or a real.

## I.2 Pseudocode indexes

———— **Note** —————

ARM is continuing to work on the structuring and linking of the pseudocode in this document. The next release of this manual will include a pseudocode index by function or procedure name.

---

# Appendix J

## Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation on page AppxJ-5088.*
- *Alphabetical index of AArch64 registers and system instructions on page AppxJ-5092.*
- *Functional index of AArch64 registers and system instructions on page AppxJ-5102.*
- *Alphabetical index of AArch32 registers and system instructions on page AppxJ-5113.*
- *Functional index of AArch32 registers and system instructions on page AppxJ-5122.*
- *Alphabetical index of memory-mapped registers on page AppxJ-5133.*
- *Functional index of memory-mapped registers on page AppxJ-5138.*

## J.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 system registers or AArch64 system registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, `_EL0`, `_EL1`, `_EL2`, or `_EL3`.

The following sections disambiguate the general register names:

- [Register name disambiguation by Execution state.](#)
- [Register name disambiguation by Exception level on page AppxJ-5091.](#)

### J.1.1 Register name disambiguation by Execution state

[Table J-1](#) disambiguates the general names of the registers by Execution state.

**Table J-1 Disambiguation of general names of registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>
DBGBVR	Debug Breakpoint Value Registers	DBGBVR<n>_EL1	DBGBVR<n> DBGBXR<n>
DBGCLAIMCLR	Debug Claim Tag Clear register	DBGCLAIMCLR_EL1	DBGCLAIMCLR
DBGCLAIMSET	Debug Claim Tag Set register	DBGCLAIMSET_EL1	DBGCLAIMSET
DBGDTRRX	Debug Data Transfer Register, Receive	DBGDTRRX_EL0	DBGDTRRXint
DBGDTRTX	Debug Data Transfer Register, Transmit	DBGDTRTX_EL0	DBGDTRTXint
DBGPRCR	Debug Power Control Register	DBGPRCR_EL1	DBGPRCR
DBGVCR	Debug Vector Catch Register	DBGVCR32_EL2	DBGVCR
DBGWCR	Debug Watchpoint Control Registers	DBGWCR<n>_EL1	DBGWCR<n>
DBGWVR	Debug Watchpoint Value Registers	DBGWVR<n>_EL1	DBGWVR<n>
DCCINT	Debug Comms Channel Interrupt Enable Register	MDCCINT_EL1	DBGDCCINT
DCCSR	Debug Comms Channel Status Register	MDCCSR_EL0	DBGDSCRint
DBGAUTHSTATUS	Debug Authentication Status	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS
DLR	Debug Link Register	DLR_EL0[31:0]	DLR
DSCR	Debug System Control Register	MDSCR_EL1	DBGDSCRext
DSPSR	Debug Saved PE State Register	DSPSR_EL0	DSPSR
FAR	Fault Address Register	FAR_EL1 FAR_EL2 FAR_EL3 HPFAR_EL2	DFAR, IFAR HDFAR, HIFAR FAR_EL3 HPFAR

**Table J-1 Disambiguation of general names of registers by Execution state (continued)**

General name	Short description	AArch64 register	AArch32 register
HCR	Hypervisor Configuration Register	HCR_EL2	HCR HCR2
HDCR	Hyp or EL2 Debug Control Register	MDCR_EL2	HDCR
HSCTLR	Hypervisor System Control Register	SCTLR_EL2	HSCTLR
HTTBR	EL2 Translation Table Base Register	TTBR0_EL2	HTTBR
ISR	Interrupt Status Register	ISR_EL1	ISR
OSDLR	OS Double-Lock Register	OSDLR_EL1	DBGOSDLR
OSDTRRX	OS Lock Data Transfer Register, Receive	OSDTRRX_EL1	DBGDTRRXext
OSDTRTX	OS Lock Data Transfer Register, Transmit	OSDTRTX_EL1	DBGDTRTXext
OSECCR	OS Lock Exception Catch Control Register	OSECCR_EL1	DBGOSECCR
OSLAR	OS Lock Access Register	OSLAR_EL1	DBGOSLAR
OSLSR	OS Lock Status Register	OSLSR_EL1	DBGOSLSR
SCR	EL3 Debug Control Register	SCR_EL3	SCR
SCTLR	System Control Register	SCTLR_EL1 SCTLR_EL2 SCTLR_EL3	SCTLR (NS) HSCTLR SCTLR (S)
SDCR	Secure or EL3 Debug Configuration Register	MDCR_EL3	SDCR
SDER	Secure Debug Enable Register	SDER32_EL3	SDER
SPSR	Saved Program Status Register	SPSR_EL1 SPSR_EL2 SPSR_EL3	SPSR
TCR	Translation Control Register	TCR_EL1 TCR_EL2 TCR_EL3	TTBCR(NS) HTCR TTBCR(S)
TTBR	Translation Table Base Register	TTBR0_EL1 TTBR0_EL2 TTBR1_EL1	TTBR0 TTBR1
VCR	EL1&0 stage 2 Translation Control Register	VTCR_EL2	VTCR
VTTBR	EL1&0 stage 2 Translation Table Base Register	VTTBR_EL2	VTTBR

Table J-2 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

**Table J-2 Disambiguation of general names of the Performance Monitors System registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
PMCCFILTR	Cycle Count Filter Register	PMCCFILTR_EL0	PMCCFILTR
PMCCNTR	Cycle Count Register	PMCCNTR_EL0	PMCCNTR
PMCEID0	Performance Monitors Cycle Count Filter Register 0	PMCEID0_EL0	PMCEID0
PMCEID1	Performance Monitors Cycle Count Filter Register 1	PMCEID1_EL0	PMCEID1
PMCNTENCLR	Performance Monitors Count Enable Clear register	PMCNTENCLR_EL0	PMINTENCLR
PMCNTENSET	Performance Monitors Count Enable Set register	PMCNTENSET_EL0	PMCNTENSET
PMCR	Performance Monitors Control Register	PMCR_EL0	PMCR
PMEVCNTR<n>	Performance Monitors Event Count Registers, n = 0-30	PMEVCNTR<n>_EL0	PMEVCNTR<n>
PMEVTYPER<n>	Performance Monitors Event Type Registers, n = 0-30	PMEVTYPER<n>_EL0	PMEVTYPER<n>
PMINTENCLR	Performance Monitors Interrupt Enable Clear register	PMINTENCLR_EL1	PMINTENCLR
PMINTENSET	Performance Monitors Interrupt Enable Set register	PMINTENSET_EL1	PMINTENSET
PMOVSCLR	Performance Monitors Overflow Flag Status Register	PMOVSCLR_EL0	PMOVSR
PMOVSSET	Performance Monitors Overflow Flag Status Set register	PMOVSSET_EL0	PMOVSSET
PMSELR	Performance Monitors Event Counter Selection Register	PMSELR_EL0	PMSELR
PMSWINC	Performance Monitors Software Increment register	PMSWINC_EL0	PMSWINC
PMUSERENR	Performance Monitors User Enable Register	PMUSERENR_EL0	PMUSERENR
PMXEVCNTR	Performance Monitors Selected Event Count Register	PMXEVCNTR_EL0	PMXEVCNTR
PMXEVTYPER	Performance Monitors Selected Event Type Register	PMXEVTYPER_EL0	PMXEVTYPER

Table J-3 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

**Table J-3 Disambiguation of general names of the Generic Timer System registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
CNTRFQ	Counter-timer Frequency register	CNTRFQ_EL0	CNTRFQ
CNTHCTL	Counter-timer Hypervisor Control register	CNTHCTL_EL2	CNTHCTL
CNTHP_CTL	Counter-timer Hypervisor Physical Timer Control register	CNTHP_CTL_EL2	CNTHP_CTL
CNTHP_CVAL	Counter-timer Hypervisor Physical Timer Compare Value register	CNTHP_CVAL_EL2	CNTHP_CVAL
CNTHP_TVAL	Counter-timer Hypervisor Physical Timer Timer Value register	CNTHP_TVAL_EL2	CNTHP_TVAL
CNTKCTL	Counter-timer Kernel Control register	CNTKCTL_EL1	CNTKCTL

**Table J-3 Disambiguation of general names of the Generic Timer System registers by Execution state (continued)**

General name	Short description	AArch64 register	AArch32 register
CNTP_CTL	Counter-timer Physical Timer Control register	CNTP_CTL_EL0	CNTP_CTL
CNTP_CVAL	Counter-timer Physical Timer CompareValue register	CNTP_CVAL_EL0	CNTP_CVAL
CNTP_TVAL	Counter-timer Physical Timer TimerValue register	CNTP_TVAL_EL0	CNTP_TVAL
CNTPCT	Counter-timer Physical Count register	CNTPCT_EL0	CNTPCT
CNTPS_CTL	Counter-timer Physical Secure Timer Control register	CNTPS_CTL_EL1	-
CNTPS_CVAL	Counter-timer Physical Secure Timer CompareValue register	CNTPS_CVAL_EL1	-
CNTPS_TVAL	Counter-timer Physical Secure Timer TimerValue register	CNTPS_TVAL_EL1	-
CNTV_CTL	Counter-timer Virtual Timer Control register	CNTV_CTL_EL0	CNTV_CTL
CNTV_CVAL	Counter-timer Virtual Timer CompareValue register	CNTV_CVAL_EL0	CNTV_CVAL
CNTV_TVAL	Counter-timer Virtual Timer TimerValue register	CNTV_TVAL_EL0	CNTV_TVAL
CNTVCT	Counter-timer Virtual Count register	CNTVCT_EL0	CNTVCT
CNTVOFF	Counter-timer Virtual Offset register	CNTVOFF_EL2	CNTVOFF

### J.1.2 Register name disambiguation by Exception level

Table J-4 disambiguates the general names of the AArch64 System registers by Exception level.

**Table J-4 Disambiguation of AArch64 system registers by Exception level**

General form	EL0	EL1	EL2	EL3
AFSR0_ELx	-	AFSR0_EL1	AFSR0_EL2	AFSR0_EL3
AFSR1_ELx	-	AFSR1_EL1	AFSR1_EL2	AFSR1_EL3
ELR_ELx	-	ELR_EL1	ELR_EL2	ELR_EL3
ESR_ELx	-	ESR_EL1	ESR_EL2	ESR_EL3
FAR_ELx	-	FAR_EL1	FAR_EL2	FAR_EL3
MAIR_ELx	-	MAIR_EL1	MAIR_EL2	MAIR_EL3
RMR_ELx	-	RMR_EL1	RMR_EL2	RMR_EL3
RVBAR_ELx	-	RVBAR_EL1	RVBAR_EL2	RVBAR_EL3
SCTLR_ELx	-	SCTLR_EL1	SCTLR_EL2	SCTLR_EL3
SP_ELx	SP_EL0	SP_EL1	SP_EL2	SP_EL3
SPSR_ELx	-	SPSR_EL1	SPSR_EL2	SPSR_EL3
TCR_ELx	-	TCR_EL1	TCR_EL2	TCR_EL3
VBAR_ELx	-	VBAR_EL1	VBAR_EL2	VBAR_EL3

## J.2 Alphabetical index of AArch64 registers and system instructions

This section is an index of AArch64 registers and system instructions in alphabetical order.

**Table J-5 Alphabetical index of AArch64 Registers**

<b>Register</b>	<b>Description, see</b>
ACTLR_EL1	<i>ACTLR_EL1, Auxiliary Control Register (EL1) on page D8-1870</i>
ACTLR_EL2	<i>ACTLR_EL2, Auxiliary Control Register (EL2) on page D8-1871</i>
ACTLR_EL3	<i>ACTLR_EL3, Auxiliary Control Register (EL3) on page D8-1872</i>
AFSR0_EL1	<i>AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1) on page D8-1873</i>
AFSR0_EL2	<i>AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2) on page D8-1874</i>
AFSR0_EL3	<i>AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3) on page D8-1875</i>
AFSR1_EL1	<i>AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1) on page D8-1876</i>
AFSR1_EL2	<i>AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2) on page D8-1877</i>
AFSR1_EL3	<i>AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3) on page D8-1878</i>
AIDR_EL1	<i>AIDR_EL1, Auxiliary ID Register on page D8-1879</i>
AMAIR_EL1	<i>AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1) on page D8-1880</i>
AMAIR_EL2	<i>AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2) on page D8-1881</i>
AMAIR_EL3	<i>AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3) on page D8-1882</i>
AT S12E0R	<i>AT S12E0R, Address Translate Stages 1 and 2 EL0 Read on page C4-323</i>
AT S12E0W	<i>AT S12E0W, Address Translate Stages 1 and 2 EL0 Write on page C4-324</i>
AT S12E1R	<i>AT S12E1R, Address Translate Stages 1 and 2 EL1 Read on page C4-325</i>
AT S12E1W	<i>AT S12E1W, Address Translate Stages 1 and 2 EL1 Write on page C4-326</i>
AT S1E0R	<i>AT S1E0R, Address Translate Stage 1 EL0 Read on page C4-327</i>
AT S1E0W	<i>AT S1E0W, Address Translate Stage 1 EL0 Write on page C4-328</i>
AT S1E1R	<i>AT S1E1R, Address Translate Stage 1 EL1 Read on page C4-329</i>
AT S1E1W	<i>AT S1E1W, Address Translate Stage 1 EL1 Write on page C4-330</i>
AT S1E2R	<i>AT S1E2R, Address Translate Stage 1 EL2 Read on page C4-331</i>
AT S1E2W	<i>AT S1E2W, Address Translate Stage 1 EL2 Write on page C4-332</i>
AT S1E3R	<i>AT S1E3R, Address Translate Stage 1 EL3 Read on page C4-333</i>
AT S1E3W	<i>AT S1E3W, Address Translate Stage 1 EL3 Write on page C4-334</i>
CCSIDR_EL1	<i>CCSIDR_EL1, Current Cache Size ID Register on page D8-1883</i>
CLIDR_EL1	<i>CLIDR_EL1, Cache Level ID Register on page D8-1885</i>
CNTFRQ_EL0	<i>CNTFRQ_EL0, Counter-timer Frequency register on page D8-2170</i>
CNTHCTL_EL2	<i>CNTHCTL_EL2, Counter-timer Hypervisor Control register on page D8-2171</i>
CNTHP_CTL_EL2	<i>CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register on page D8-2173</i>

**Table J-5 Alphabetical index of AArch64 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
CNTHP_CVAL_EL2	<i>CNTHP_CVAL_EL2</i> , Counter-timer Hypervisor Physical Timer CompareValue register on page D8-2175
CNTHP_TVAL_EL2	<i>CNTHP_TVAL_EL2</i> , Counter-timer Hypervisor Physical Timer TimerValue register on page D8-2176
CNTKCTL_EL1	<i>CNTKCTL_EL1</i> , Counter-timer Kernel Control register on page D8-2177
CNTP_CTL_EL0	<i>CNTP_CTL_EL0</i> , Counter-timer Physical Timer Control register on page D8-2179
CNTP_CVAL_EL0	<i>CNTP_CVAL_EL0</i> , Counter-timer Physical Timer CompareValue register on page D8-2181
CNTP_TVAL_EL0	<i>CNTP_TVAL_EL0</i> , Counter-timer Physical Timer TimerValue register on page D8-2182
CNTPCT_EL0	<i>CNTPCT_EL0</i> , Counter-timer Physical Count register on page D8-2183
CNTPS_CTL_EL1	<i>CNTPS_CTL_EL1</i> , Counter-timer Physical Secure Timer Control register on page D8-2184
CNTPS_CVAL_EL1	<i>CNTPS_CVAL_EL1</i> , Counter-timer Physical Secure Timer CompareValue register on page D8-2186
CNTPS_TVAL_EL1	<i>CNTPS_TVAL_EL1</i> , Counter-timer Physical Secure Timer TimerValue register on page D8-2187
CNTV_CTL_EL0	<i>CNTV_CTL_EL0</i> , Counter-timer Virtual Timer Control register on page D8-2188
CNTV_CVAL_EL0	<i>CNTV_CVAL_EL0</i> , Counter-timer Virtual Timer CompareValue register on page D8-2190
CNTV_TVAL_EL0	<i>CNTV_TVAL_EL0</i> , Counter-timer Virtual Timer TimerValue register on page D8-2191
CNTVCT_EL0	<i>CNTVCT_EL0</i> , Counter-timer Virtual Count register on page D8-2192
CNTVOFF_EL2	<i>CNTVOFF_EL2</i> , Counter-timer Virtual Offset register on page D8-2193
CONTEXTIDR_EL1	<i>CONTEXTIDR_EL1</i> , Context ID Register on page D8-1887
CPACR_EL1	<i>CPACR_EL1</i> , Architectural Feature Access Control Register on page D8-1888
CPTR_EL2	<i>CPTR_EL2</i> , Architectural Feature Trap Register (EL2) on page D8-1890
CPTR_EL3	<i>CPTR_EL3</i> , Architectural Feature Trap Register (EL3) on page D8-1892
CSSELR_EL1	<i>CSSELR_EL1</i> , Cache Size Selection Register on page D8-1894
CTR_EL0	<i>CTR_EL0</i> , Cache Type Register on page D8-1895
CurrentEL	<i>CurrentEL</i> , Current Exception Level on page C4-252
DACR32_EL2	<i>DACR32_EL2</i> , Domain Access Control Register on page D8-1897
DAIF	<i>DAIF</i> , Interrupt Mask Bits on page C4-254
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1</i> , Debug Authentication Status register on page D8-2077
DBGBCR<n>_EL1	<i>DBGBCR&lt;n&gt;_EL1</i> , Debug Breakpoint Control Registers, <i>n</i> = 0 - 15 on page D8-2079
DBGBVR<n>_EL1	<i>DBGBVR&lt;n&gt;_EL1</i> , Debug Breakpoint Value Registers, <i>n</i> = 0 - 15 on page D8-2082
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1</i> , Debug Claim Tag Clear register on page D8-2085
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1</i> , Debug Claim Tag Set register on page D8-2086
DBGDTR_EL0	<i>DBGDTR_EL0</i> , Debug Data Transfer Register, half-duplex on page D8-2087

**Table J-5 Alphabetical index of AArch64 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
DBGDTRRX_EL0	<i>DBGDTRRX_EL0, Debug Data Transfer Register, Receive</i> on page D8-2089
DBGDTRTX_EL0	<i>DBGDTRTX_EL0, Debug Data Transfer Register, Transmit</i> on page D8-2091
DBGPRCR_EL1	<i>DBGPRCR_EL1, Debug Power Control Register</i> on page D8-2093
DBGVCR32_EL2	<i>DBGVCR32_EL2, Debug Vector Catch Register</i> on page D8-2094
DBGWCR<n>_EL1	<i>DBGWCR&lt;n&gt;_EL1, Debug Watchpoint Control Registers, n = 0 - 15</i> on page D8-2098
DBGWVR<n>_EL1	<i>DBGWVR&lt;n&gt;_EL1, Debug Watchpoint Value Registers, n = 0 - 15</i> on page D8-2101
DC CISW	<i>DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way</i> on page C4-307
DC CIVAC	<i>DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC</i> on page C4-309
DC CSW	<i>DC CSW, Data or unified Cache line Clean by Set/Way</i> on page C4-310
DC CVAC	<i>DC CVAC, Data or unified Cache line Clean by VA to PoC</i> on page C4-312
DC CVAU	<i>DC CVAU, Data or unified Cache line Clean by VA to PoU</i> on page C4-313
DC ISW	<i>DC ISW, Data or unified Cache line Invalidate by Set/Way</i> on page C4-314
DC IVAC	<i>DC IVAC, Data or unified Cache line Invalidate by VA to PoC</i> on page C4-316
DC ZVA	<i>DC ZVA, Data Cache Zero by VA</i> on page C4-317
DCZID_EL0	<i>DCZID_EL0, Data Cache Zero ID register</i> on page D8-1898
DLR_EL0	<i>DLR_EL0, Debug Link Register</i> on page D8-2103
DSPSR_EL0	<i>DSPSR_EL0, Debug Saved Program Status Register</i> on page D8-2104
ELR_EL1	<i>ELR_EL1, Exception Link Register (EL1)</i> on page C4-258
ELR_EL2	<i>ELR_EL2, Exception Link Register (EL2)</i> on page C4-259
ELR_EL3	<i>ELR_EL3, Exception Link Register (EL3)</i> on page C4-260
ESR_EL1	<i>ESR_EL1, Exception Syndrome Register (EL1)</i> on page D8-1899
ESR_EL2	<i>ESR_EL2, Exception Syndrome Register (EL2)</i> on page D8-1904
ESR_EL3	<i>ESR_EL3, Exception Syndrome Register (EL3)</i> on page D8-1909
FAR_EL1	<i>FAR_EL1, Fault Address Register (EL1)</i> on page D8-1914
FAR_EL2	<i>FAR_EL2, Fault Address Register (EL2)</i> on page D8-1915
FAR_EL3	<i>FAR_EL3, Fault Address Register (EL3)</i> on page D8-1917
FPCR	<i>FPCR, Floating-point Control Register</i> on page C4-261
FPEXC32_EL2	<i>FPEXC32_EL2, Floating-point Exception Control register</i> on page D8-1918
FPSR	<i>FPSR, Floating-point Status Register</i> on page C4-264
HACR_EL2	<i>HACR_EL2, Hypervisor Auxiliary Control Register</i> on page D8-1922
HCR_EL2	<i>HCR_EL2, Hypervisor Configuration Register</i> on page D8-1923
HPFAR_EL2	<i>HPFAR_EL2, Hypervisor IPA Fault Address Register</i> on page D8-1930

**Table J-5 Alphabetical index of AArch64 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
HSTR_EL2	<i>HSTR_EL2, Hypervisor System Trap Register on page D8-1931</i>
IC IALLU	<i>IC IALLU, Instruction Cache Invalidate All to PoU on page C4-319</i>
IC IALLUIS	<i>IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable on page C4-320</i>
IC IVAU	<i>IC IVAU, Instruction Cache line Invalidate by VA to PoU on page C4-321</i>
ICC_AP0R0_EL1	<i>ICC_AP0R0_EL1, Interrupt Controller Active Priorities Register (0,0) on page D8-2194</i>
ICC_AP0R1_EL1	<i>ICC_AP0R1_EL1, Interrupt Controller Active Priorities Register (0,1) on page D8-2196</i>
ICC_AP0R2_EL1	<i>ICC_AP0R2_EL1, Interrupt Controller Active Priorities Register (0,2) on page D8-2198</i>
ICC_AP0R3_EL1	<i>ICC_AP0R3_EL1, Interrupt Controller Active Priorities Register (0,3) on page D8-2200</i>
ICC_AP1R0_EL1	<i>ICC_AP1R0_EL1, Interrupt Controller Active Priorities Register (1,0) on page D8-2202</i>
ICC_AP1R1_EL1	<i>ICC_AP1R1_EL1, Interrupt Controller Active Priorities Register (1,1) on page D8-2204</i>
ICC_AP1R2_EL1	<i>ICC_AP1R2_EL1, Interrupt Controller Active Priorities Register (1,2) on page D8-2206</i>
ICC_AP1R3_EL1	<i>ICC_AP1R3_EL1, Interrupt Controller Active Priorities Register (1,3) on page D8-2208</i>
ICC_ASGI1R_EL1	<i>ICC_ASGI1R_EL1, Interrupt Controller Alias Software Generated Interrupt group 1 Register on page D8-2210</i>
ICC_BPR0_EL1	<i>ICC_BPR0_EL1, Interrupt Controller Binary Point Register 0 on page D8-2212</i>
ICC_BPR1_EL1	<i>ICC_BPR1_EL1, Interrupt Controller Binary Point Register 1 on page D8-2214</i>
ICC_CTLR_EL1	<i>ICC_CTLR_EL1, Interrupt Controller Control Register (EL1) on page D8-2216</i>
ICC_CTLR_EL3	<i>ICC_CTLR_EL3, Interrupt Controller Control Register (EL3) on page D8-2219</i>
ICC_DIR_EL1	<i>ICC_DIR_EL1, Interrupt Controller Deactivate Interrupt Register on page D8-2222</i>
ICC_EOIR0_EL1	<i>ICC_EOIR0_EL1, Interrupt Controller End Of Interrupt Register 0 on page D8-2223</i>
ICC_EOIR1_EL1	<i>ICC_EOIR1_EL1, Interrupt Controller End Of Interrupt Register 1 on page D8-2225</i>
ICC_HPPIR0_EL1	<i>ICC_HPPIR0_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 0 on page D8-2226</i>
ICC_HPPIR1_EL1	<i>ICC_HPPIR1_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 1 on page D8-2228</i>
ICC_IAR0_EL1	<i>ICC_IAR0_EL1, Interrupt Controller Interrupt Acknowledge Register 0 on page D8-2229</i>
ICC_IAR1_EL1	<i>ICC_IAR1_EL1, Interrupt Controller Interrupt Acknowledge Register 1 on page D8-2231</i>
ICC_IGRPEN0_EL1	<i>ICC_IGRPEN0_EL1, Interrupt Controller Interrupt Group 0 Enable register on page D8-2232</i>
ICC_IGRPEN1_EL1	<i>ICC_IGRPEN1_EL1, Interrupt Controller Interrupt Group 1 Enable register on page D8-2234</i>
ICC_IGRPEN1_EL3	<i>ICC_IGRPEN1_EL3, Interrupt Controller Interrupt Group 1 Enable register (EL3) on page D8-2236</i>
ICC_PMR_EL1	<i>ICC_PMR_EL1, Interrupt Controller Interrupt Priority Mask Register on page D8-2238</i>
ICC_RPR_EL1	<i>ICC_RPR_EL1, Interrupt Controller Running Priority Register on page D8-2240</i>
ICC_SEIEN_EL1	<i>ICC_SEIEN_EL1, Interrupt Controller System Error Interrupt Enable register on page D8-2241</i>

ID_ISAR2_EL1	<i>ID_ISAR2_EL1</i> , AArch32 Instruction Set Attribute Register 2 on page D8-1955
ID_ISAR3_EL1	<i>ID_ISAR3_EL1</i> , AArch32 Instruction Set Attribute Register 3 on page D8-1958
ID_ISAR4_EL1	<i>ID_ISAR4_EL1</i> , AArch32 Instruction Set Attribute Register 4 on page D8-1961
ID_ISAR5_EL1	<i>ID_ISAR5_EL1</i> , AArch32 Instruction Set Attribute Register 5 on page D8-1964
ID_MMFR0_EL1	<i>ID_MMFR0_EL1</i> , AArch32 Memory Model Feature Register 0 on page D8-1966
ID_MMFR1_EL1	<i>ID_MMFR1_EL1</i> , AArch32 Memory Model Feature Register 1 on page D8-1969
ID_MMFR2_EL1	<i>ID_MMFR2_EL1</i> , AArch32 Memory Model Feature Register 2 on page D8-1973
ID_MMFR3_EL1	<i>ID_MMFR3_EL1</i> , AArch32 Memory Model Feature Register 3 on page D8-1976
ID_PFR0_EL1	<i>ID_PFR0_EL1</i> , AArch32 Processor Feature Register 0 on page D8-1979
ID_PFR1_EL1	<i>ID_PFR1_EL1</i> , AArch32 Processor Feature Register 1 on page D8-1981
IFSR32_EL2	<i>IFSR32_EL2</i> , Instruction Fault Status Register (EL2) on page D8-1984
ISR_EL1	<i>ISR_EL1</i> , Interrupt Status Register on page D8-1988
MAIR_EL1	<i>MAIR_EL1</i> , Memory Attribute Indirection Register (EL1) on page D8-1990
MAIR_EL2	<i>MAIR_EL2</i> , Memory Attribute Indirection Register (EL2) on page D8-1992
MAIR_EL3	<i>MAIR_EL3</i> , Memory Attribute Indirection Register (EL3) on page D8-1994
MDCCINT_EL1	<i>MDCCINT_EL1</i> , Monitor DCC Interrupt Enable Register on page D8-2110
MDCCSR_EL0	<i>MDCCSR_EL0</i> , Monitor DCC Status Register on page D8-2112
MDCR_EL2	<i>MDCR_EL2</i> , Monitor Debug Configuration Register (EL2) on page D8-2114
MDCR_EL3	<i>MDCR_EL3</i> , Monitor Debug Configuration Register (EL3) on page D8-2117
MDRAR_EL1	<i>MDRAR_EL1</i> , Monitor Debug ROM Address Register on page D8-2120
MDSCR_EL1	<i>MDSCR_EL1</i> , Monitor Debug System Control Register on page D8-2122
MIDR_EL1	<i>MIDR_EL1</i> , Main ID Register on page D8-1996
MPIDR_EL1	<i>MPIDR_EL1</i> , Multiprocessor Affinity Register on page D8-1998
MVFR0_EL1	<i>MVFR0_EL1</i> , Media and VFP Feature Register 0 on page D8-2000
MVFR1_EL1	<i>MVFR1_EL1</i> , Media and VFP Feature Register 1 on page D8-2003
MVFR2_EL1	<i>MVFR2_EL1</i> , Media and VFP Feature Register 2 on page D8-2006
NZCV	<i>NZCV</i> , Condition Flags on page C4-267
OSDLR_EL1	<i>OSDLR_EL1</i> , OS Double Lock Register on page D8-2125

**Table J-5 Alphabetical index of AArch64 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
OSDTRRX_EL1	<i>OSDTRRX_EL1, OS Lock Data Transfer Register, Receive</i> on page D8-2126
OSDTRTX_EL1	<i>OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit</i> on page D8-2127
OSECCR_EL1	<i>OSECCR_EL1, OS Lock Exception Catch Control Register</i> on page D8-2128
OSLAR_EL1	<i>OSLAR_EL1, OS Lock Access Register</i> on page D8-2129
OSLSR_EL1	<i>OSLSR_EL1, OS Lock Status Register</i> on page D8-2130
PAR_EL1	<i>PAR_EL1, Physical Address Register</i> on page D8-2008
PMCCFILTR_EL0	<i>PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register</i> on page D8-2134
PMCCNTR_EL0	<i>PMCCNTR_EL0, Performance Monitors Cycle Count Register</i> on page D8-2136
PMCEID0_EL0	<i>PMCEID0_EL0, Performance Monitors Common Event Identification register 0</i> on page D8-2138
PMCEID1_EL0	<i>PMCEID1_EL0, Performance Monitors Common Event Identification register 1</i> on page D8-2140
PMCNTENCLR_EL0	<i>PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register</i> on page D8-2142
PMCNTENSET_EL0	<i>PMCNTENSET_EL0, Performance Monitors Count Enable Set register</i> on page D8-2144
PMCR_EL0	<i>PMCR_EL0, Performance Monitors Control Register</i> on page D8-2146
PMEVCNTR<n>_EL0	<i>PMEVCNTR&lt;n&gt;_EL0, Performance Monitors Event Count Registers, n = 0 - 30</i> on page D8-2149
PMEVTYPER<n>_EL0	<i>PMEVTYPER&lt;n&gt;_EL0, Performance Monitors Event Type Registers, n = 0 - 30</i> on page D8-2151
PMINTENCLR_EL1	<i>PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register</i> on page D8-2154
PMINTENSET_EL1	<i>PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register</i> on page D8-2156
PMOVSLR_EL0	<i>PMOVSLR_EL0, Performance Monitors Overflow Flag Status Clear Register</i> on page D8-2158
PMOVSSET_EL0	<i>PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register</i> on page D8-2160
PMSELR_EL0	<i>PMSELR_EL0, Performance Monitors Event Counter Selection Register</i> on page D8-2162
PMSWINC_EL0	<i>PMSWINC_EL0, Performance Monitors Software Increment register</i> on page D8-2164
PMUSERENR_EL0	<i>PMUSERENR_EL0, Performance Monitors User Enable Register</i> on page D8-2166
PMXVCNTR_EL0	<i>PMXVCNTR_EL0, Performance Monitors Selected Event Count Register</i> on page D8-2168
PMXEVTYPER_EL0	<i>PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register</i> on page D8-2169
REVIDR_EL1	<i>REVIDR_EL1, Revision ID Register</i> on page D8-2011
RMR_EL1	<i>RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented)</i> on page D8-2012
RMR_EL2	<i>RMR_EL2, Reset Management Register (if EL3 not implemented)</i> on page D8-2014
RMR_EL3	<i>RMR_EL3, Reset Management Register (if EL3 implemented)</i> on page D8-2016
RVBAR_EL1	<i>RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)</i> on page D8-2018

**Table J-5 Alphabetical index of AArch64 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
RVBAR_EL2	<i>RVBAR_EL2</i> , Reset Vector Base Address Register (if EL3 not implemented) on page D8-2019
RVBAR_EL3	<i>RVBAR_EL3</i> , Reset Vector Base Address Register (if EL3 implemented) on page D8-2020
S3_<op1>_<Cn>_<Cm>_<op2>	<i>S3_&lt;op1&gt;_&lt;Cn&gt;_&lt;Cm&gt;_&lt;op2&gt;</i> , IMPLEMENTATION DEFINED registers on page D8-2021

VTCR_EL2	<i>VTCR_EL2, Virtualization Translation Control Register on page D8-2072</i>
VTTBR_EL2	<i>VTTBR_EL2, Virtualization Translation Table Base Register on page D8-2075</i>

## J.3 Functional index of AArch64 registers and system instructions

This section is an index of the AArch64 registers and system instructions, divided by functional group.

### J.3.1 Special-purpose registers

This section is an index to the registers in the Special purpose and Processor state functional groups.

**Table J-6 Special-purpose registers**

Register	Description, see
DLR_EL0	<i>DLR_EL0, Debug Link Register</i> on page D8-2103
DSPSR_EL0	<i>DSPSR_EL0, Debug Saved Program Status Register</i> on page D8-2104
ELR_EL1	<i>ELR_EL1, Exception Link Register (EL1)</i> on page C4-258
ELR_EL2	<i>ELR_EL2, Exception Link Register (EL2)</i> on page C4-259
ELR_EL3	<i>ELR_EL3, Exception Link Register (EL3)</i> on page C4-260
FPCR	<i>FPCR, Floating-point Control Register</i> on page C4-261
FPSR	<i>FPSR, Floating-point Status Register</i> on page C4-264
SP_EL0	<i>SP_EL0, Stack Pointer (EL0)</i> on page C4-269
SP_EL1	<i>SP_EL1, Stack Pointer (EL1)</i> on page C4-270
SP_EL2	<i>SP_EL2, Stack Pointer (EL2)</i> on page C4-271
SP_EL3	<i>SP_EL3, Stack Pointer (EL3)</i> on page C4-272
SPSR_abt	<i>SPSR_abt, Saved Program Status Register (Abort mode)</i> on page C4-274
SPSR_EL1	<i>SPSR_EL1, Saved Program Status Register (EL1)</i> on page C4-278
SPSR_EL2	<i>SPSR_EL2, Saved Program Status Register (EL2)</i> on page C4-283
SPSR_EL3	<i>SPSR_EL3, Saved Program Status Register (EL3)</i> on page C4-288
SPSR_fiq	<i>SPSR_fiq, Saved Program Status Register (FIQ mode)</i> on page C4-294
SPSR_irq	<i>SPSR_irq, Saved Program Status Register (IRQ mode)</i> on page C4-298
SPSR_und	<i>SPSR_und, Saved Program Status Register (Undefined mode)</i> on page C4-302

### J.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control functional group.

**Table J-7 VMSA-specific registers**

Register	Description, see
AMAIR_EL1	<i>AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)</i> on page D8-1880
AMAIR_EL2	<i>AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)</i> on page D8-1881
AMAIR_EL3	<i>AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)</i> on page D8-1882
CONTEXTIDR_EL1	<i>CONTEXTIDR_EL1, Context ID Register</i> on page D8-1887
DACR32_EL2	<i>DACR32_EL2, Domain Access Control Register</i> on page D8-1897

**Table J-7 VMSA-specific registers (continued)**

Register	Description, see
MAIR_EL1	<i>MAIR_EL1, Memory Attribute Indirection Register (EL1)</i> on page D8-1990
MAIR_EL2	<i>MAIR_EL2, Memory Attribute Indirection Register (EL2)</i> on page D8-1992
MAIR_EL3	<i>MAIR_EL3, Memory Attribute Indirection Register (EL3)</i> on page D8-1994
TCR_EL1	<i>TCR_EL1, Translation Control Register (EL1)</i> on page D8-2038
TCR_EL2	<i>TCR_EL2, Translation Control Register (EL2)</i> on page D8-2043
TCR_EL3	<i>TCR_EL3, Translation Control Register (EL3)</i> on page D8-2046
TTBR0_EL1	<i>TTBR0_EL1, Translation Table Base Register 0 (EL1)</i> on page D8-2057
TTBR0_EL2	<i>TTBR0_EL2, Translation Table Base Register 0 (EL2)</i> on page D8-2059
TTBR0_EL3	<i>TTBR0_EL3, Translation Table Base Register 0 (EL3)</i> on page D8-2061
TTBR1_EL1	<i>TTBR1_EL1, Translation Table Base Register 1</i> on page D8-2063
VTCR_EL2	<i>VTCR_EL2, Virtualization Translation Control Register</i> on page D8-2072
VTTBR_EL2	<i>VTTBR_EL2, Virtualization Translation Table Base Register</i> on page D8-2075

### J.3.3 ID registers

This section is an index to the registers in the Identification functional group.

**Table J-8 ID registers**

Register	Description, see
AIDR_EL1	<i>AIDR_EL1, Auxiliary ID Register</i> on page D8-1879
CCSIDR_EL1	<i>CCSIDR_EL1, Current Cache Size ID Register</i> on page D8-1883
CLIDR_EL1	<i>CLIDR_EL1, Cache Level ID Register</i> on page D8-1885
CSSELR_EL1	<i>CSSELR_EL1, Cache Size Selection Register</i> on page D8-1894
CTR_EL0	<i>CTR_EL0, Cache Type Register</i> on page D8-1895
DCZID_EL0	<i>DCZID_EL0, Data Cache Zero ID register</i> on page D8-1898
ID_AA64AFR0_EL1	<i>ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0</i> on page D8-1933
ID_AA64AFR1_EL1	<i>ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1</i> on page D8-1934
ID_AA64DFR0_EL1	<i>ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0</i> on page D8-1935
ID_AA64DFR1_EL1	<i>ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1</i> on page D8-1937
ID_AA64ISAR0_EL1	<i>ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0</i> on page D8-1938
ID_AA64ISAR1_EL1	<i>ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1</i> on page D8-1940
ID_AA64MMFR0_EL1	<i>ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0</i> on page D8-1941
ID_AA64MMFR1_EL1	<i>ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1</i> on page D8-1943
ID_AA64PFR0_EL1	<i>ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0</i> on page D8-1944

**Table J-8 ID registers (continued)**

<b>Register</b>	<b>Description, see</b>
ID_AA64PFR1_EL1	<i>ID_AA64PFR1_EL1</i> , AArch64 Processor Feature Register 1 on page D8-1946
ID_AFR0_EL1	<i>ID_AFR0_EL1</i> , AArch32 Auxiliary Feature Register 0 on page D8-1947
ID_DFR0_EL1	<i>ID_DFR0_EL1</i> , AArch32 Debug Feature Register 0 on page D8-1948
ID_ISAR0_EL1	<i>ID_ISAR0_EL1</i> , AArch32 Instruction Set Attribute Register 0 on page D8-1950
ID_ISAR1_EL1	<i>ID_ISAR1_EL1</i> , AArch32 Instruction Set Attribute Register 1 on page D8-1952
ID_ISAR2_EL1	<i>ID_ISAR2_EL1</i> , AArch32 Instruction Set Attribute Register 2 on page D8-1955
ID_ISAR3_EL1	<i>ID_ISAR3_EL1</i> , AArch32 Instruction Set Attribute Register 3 on page D8-1958
ID_ISAR4_EL1	<i>ID_ISAR4_EL1</i> , AArch32 Instruction Set Attribute Register 4 on page D8-1961
ID_ISAR5_EL1	<i>ID_ISAR5_EL1</i> , AArch32 Instruction Set Attribute Register 5 on page D8-1964
ID_MMFR0_EL1	<i>ID_MMFR0_EL1</i> , AArch32 Memory Model Feature Register 0 on page D8-1966
ID_MMFR1_EL1	<i>ID_MMFR1_EL1</i> , AArch32 Memory Model Feature Register 1 on page D8-1969
ID_MMFR2_EL1	<i>ID_MMFR2_EL1</i> , AArch32 Memory Model Feature Register 2 on page D8-1973
ID_MMFR3_EL1	<i>ID_MMFR3_EL1</i> , AArch32 Memory Model Feature Register 3 on page D8-1976
ID_PFR0_EL1	<i>ID_PFR0_EL1</i> , AArch32 Processor Feature Register 0 on page D8-1979
ID_PFR1_EL1	<i>ID_PFR1_EL1</i> , AArch32 Processor Feature Register 1 on page D8-1981
MIDR_EL1	<i>MIDR_EL1</i> , Main ID Register on page D8-1996
MPIDR_EL1	<i>MPIDR_EL1</i> , Multiprocessor Affinity Register on page D8-1998
MVFR0_EL1	<i>MVFR0_EL1</i> , Media and VFP Feature Register 0 on page D8-2000
MVFR1_EL1	<i>MVFR1_EL1</i> , Media and VFP Feature Register 1 on page D8-2003
MVFR2_EL1	<i>MVFR2_EL1</i> , Media and VFP Feature Register 2 on page D8-2006
REVIDR_EL1	<i>REVIDR_EL1</i> , Revision ID Register on page D8-2011
VMPIDR_EL2	<i>VMPIDR_EL2</i> , Virtualization Multiprocessor ID Register on page D8-2068
VPIDR_EL2	<i>VPIDR_EL2</i> , Virtualization Processor ID Register on page D8-2070

### J.3.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors functional group.

**Table J-9 Performance monitors registers**

<b>Register</b>	<b>Description, see</b>
PMCCFILTR_EL0	<i>PMCCFILTR_EL0</i> , Performance Monitors Cycle Count Filter Register on page D8-2134
PMCCNTR_EL0	<i>PMCCNTR_EL0</i> , Performance Monitors Cycle Count Register on page D8-2136
PMCEID0_EL0	<i>PMCEID0_EL0</i> , Performance Monitors Common Event Identification register 0 on page D8-2138
PMCEID1_EL0	<i>PMCEID1_EL0</i> , Performance Monitors Common Event Identification register 1 on page D8-2140

**Table J-9 Performance monitors registers (continued)**

Register	Description, see
PMCNTENCLR_ELO	<i>PMCNTENCLR_ELO, Performance Monitors Count Enable Clear register on page D8-2142</i>
PMCNTENSET_ELO	<i>PMCNTENSET_ELO, Performance Monitors Count Enable Set register on page D8-2144</i>
PMCR_ELO	<i>PMCR_ELO, Performance Monitors Control Register on page D8-2146</i>
PMEVCNTR<n>_ELO	<i>PMEVCNTR&lt;n&gt;_ELO, Performance Monitors Event Count Registers, n = 0 - 30 on page D8-2149</i>
PMEVTYPER<n>_ELO	<i>PMEVTYPER&lt;n&gt;_ELO, Performance Monitors Event Type Registers, n = 0 - 30 on page D8-2151</i>
PMINTENCLR_EL1	<i>PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register on page D8-2154</i>
PMINTENSET_EL1	<i>PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register on page D8-2156</i>
PMOVSCLR_ELO	<i>PMOVSCLR_ELO, Performance Monitors Overflow Flag Status Clear Register on page D8-2158</i>
PMOVSSET_ELO	<i>PMOVSSET_ELO, Performance Monitors Overflow Flag Status Set register on page D8-2160</i>
PMSELR_ELO	<i>PMSELR_ELO, Performance Monitors Event Counter Selection Register on page D8-2162</i>
PMSWINC_ELO	<i>PMSWINC_ELO, Performance Monitors Software Increment register on page D8-2164</i>
PMUSERENR_ELO	<i>PMUSERENR_ELO, Performance Monitors User Enable Register on page D8-2166</i>
PMXEVCNTR_ELO	<i>PMXEVCNTR_ELO, Performance Monitors Selected Event Count Register on page D8-2168</i>
PMXEVTYPER_ELO	<i>PMXEVTYPER_ELO, Performance Monitors Selected Event Type Register on page D8-2169</i>

### J.3.5 Debug registers

This section is an index to the registers in the Debug functional group.

**Table J-10 Debug registers**

Register	Description, see
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1, Debug Authentication Status register on page D8-2077</i>
DBGBCR<n>_EL1	<i>DBGBCR&lt;n&gt;_EL1, Debug Breakpoint Control Registers, n = 0 - 15 on page D8-2079</i>
DBGBVR<n>_EL1	<i>DBGBVR&lt;n&gt;_EL1, Debug Breakpoint Value Registers, n = 0 - 15 on page D8-2082</i>
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1, Debug Claim Tag Clear register on page D8-2085</i>
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1, Debug Claim Tag Set register on page D8-2086</i>
DBGDTR_ELO	<i>DBGDTR_ELO, Debug Data Transfer Register, half-duplex on page D8-2087</i>
DBGDTRRX_ELO	<i>DBGDTRRX_ELO, Debug Data Transfer Register, Receive on page D8-2089</i>
DBGDTRTX_ELO	<i>DBGDTRTX_ELO, Debug Data Transfer Register, Transmit on page D8-2091</i>
DBGPRCR_EL1	<i>DBGPRCR_EL1, Debug Power Control Register on page D8-2093</i>
DBGVCR32_EL2	<i>DBGVCR32_EL2, Debug Vector Catch Register on page D8-2094</i>
DBGWCR<n>_EL1	<i>DBGWCR&lt;n&gt;_EL1, Debug Watchpoint Control Registers, n = 0 - 15 on page D8-2098</i>
DBGWVR<n>_EL1	<i>DBGWVR&lt;n&gt;_EL1, Debug Watchpoint Value Registers, n = 0 - 15 on page D8-2101</i>
DLR_ELO	<i>DLR_ELO, Debug Link Register on page D8-2103</i>

**Table J-10 Debug registers (continued)**

Register	Description, see
DSPSR_EL0	<i>DSPSR_EL0</i> , Debug Saved Program Status Register on page D8-2104
MDCCINT_EL1	<i>MDCCINT_EL1</i> , Monitor DCC Interrupt Enable Register on page D8-2110
MDCCSR_EL0	<i>MDCCSR_EL0</i> , Monitor DCC Status Register on page D8-2112
MDCR_EL2	<i>MDCR_EL2</i> , Monitor Debug Configuration Register (EL2) on page D8-2114
MDCR_EL3	<i>MDCR_EL3</i> , Monitor Debug Configuration Register (EL3) on page D8-2117
MDRAR_EL1	<i>MDRAR_EL1</i> , Monitor Debug ROM Address Register on page D8-2120
MDSCR_EL1	<i>MDSCR_EL1</i> , Monitor Debug System Control Register on page D8-2122
OSDLR_EL1	<i>OSDLR_EL1</i> , OS Double Lock Register on page D8-2125
OSDTRRX_EL1	<i>OSDTRRX_EL1</i> , OS Lock Data Transfer Register, Receive on page D8-2126
OSDTRTX_EL1	<i>OSDTRTX_EL1</i> , OS Lock Data Transfer Register, Transmit on page D8-2127
OSECCR_EL1	<i>OSECCR_EL1</i> , OS Lock Exception Catch Control Register on page D8-2128
OSLAR_EL1	<i>OSLAR_EL1</i> , OS Lock Access Register on page D8-2129
OSLSR_EL1	<i>OSLSR_EL1</i> , OS Lock Status Register on page D8-2130
SDER32_EL3	<i>SDER32_EL3</i> , AArch32 Secure Debug Enable Register on page D8-2132

### J.3.6 Generic timer registers

This section is an index to the registers in the Generic Timer functional group.

**Table J-11 Generic timer registers**

Register	Description, see
CNTRFQ_EL0	<i>CNTRFQ_EL0</i> , Counter-timer Frequency register on page D8-2170
CNTHCTL_EL2	<i>CNTHCTL_EL2</i> , Counter-timer Hypervisor Control register on page D8-2171
CNTHP_CTL_EL2	<i>CNTHP_CTL_EL2</i> , Counter-timer Hypervisor Physical Timer Control register on page D8-2173
CNTHP_CVAL_EL2	<i>CNTHP_CVAL_EL2</i> , Counter-timer Hypervisor Physical Timer CompareValue register on page D8-2175
CNTHP_TVAL_EL2	<i>CNTHP_TVAL_EL2</i> , Counter-timer Hypervisor Physical Timer TimerValue register on page D8-2176
CNTKCTL_EL1	<i>CNTKCTL_EL1</i> , Counter-timer Kernel Control register on page D8-2177
CNTP_CTL_EL0	<i>CNTP_CTL_EL0</i> , Counter-timer Physical Timer Control register on page D8-2179
CNTP_CVAL_EL0	<i>CNTP_CVAL_EL0</i> , Counter-timer Physical Timer CompareValue register on page D8-2181
CNTP_TVAL_EL0	<i>CNTP_TVAL_EL0</i> , Counter-timer Physical Timer TimerValue register on page D8-2182
CNTPCT_EL0	<i>CNTPCT_EL0</i> , Counter-timer Physical Count register on page D8-2183
CNTPS_CTL_EL1	<i>CNTPS_CTL_EL1</i> , Counter-timer Physical Secure Timer Control register on page D8-2184
CNTPS_CVAL_EL1	<i>CNTPS_CVAL_EL1</i> , Counter-timer Physical Secure Timer CompareValue register on page D8-2186

**Table J-11 Generic timer registers (continued)**

Register	Description, see
CNTPS_TVAL_EL1	<i>CNTPS_TVAL_EL1</i> , Counter-timer Physical Secure Timer TimerValue register on page D8-2187
CNTV_CTL_EL0	<i>CNTV_CTL_EL0</i> , Counter-timer Virtual Timer Control register on page D8-2188
CNTV_CVAL_EL0	<i>CNTV_CVAL_EL0</i> , Counter-timer Virtual Timer CompareValue register on page D8-2190
CNTV_TVAL_EL0	<i>CNTV_TVAL_EL0</i> , Counter-timer Virtual Timer TimerValue register on page D8-2191
CNTVCT_EL0	<i>CNTVCT_EL0</i> , Counter-timer Virtual Count register on page D8-2192
CNTVOFF_EL2	<i>CNTVOFF_EL2</i> , Counter-timer Virtual Offset register on page D8-2193

### J.3.7 Generic Interrupt Controller CPU interface registers

This section is an index to the registers in the GIC functional group.

**Table J-12 Generic Interrupt Controller CPU interface registers**

Register	Description, see
ICC_AP0R0_EL1	<i>ICC_AP0R0_EL1</i> , Interrupt Controller Active Priorities Register (0,0) on page D8-2194
ICC_AP0R1_EL1	<i>ICC_AP0R1_EL1</i> , Interrupt Controller Active Priorities Register (0,1) on page D8-2196
ICC_AP0R2_EL1	<i>ICC_AP0R2_EL1</i> , Interrupt Controller Active Priorities Register (0,2) on page D8-2198
ICC_AP0R3_EL1	<i>ICC_AP0R3_EL1</i> , Interrupt Controller Active Priorities Register (0,3) on page D8-2200
ICC_APIR0_EL1	<i>ICC_APIR0_EL1</i> , Interrupt Controller Active Priorities Register (1,0) on page D8-2202
ICC_APIR1_EL1	<i>ICC_APIR1_EL1</i> , Interrupt Controller Active Priorities Register (1,1) on page D8-2204
ICC_APIR2_EL1	<i>ICC_APIR2_EL1</i> , Interrupt Controller Active Priorities Register (1,2) on page D8-2206
ICC_APIR3_EL1	<i>ICC_APIR3_EL1</i> , Interrupt Controller Active Priorities Register (1,3) on page D8-2208
ICC_ASGIIR_EL1	<i>ICC_ASGIIR_EL1</i> , Interrupt Controller Alias Software Generated Interrupt group 1 Register on page D8-2210
ICC_BPR0_EL1	<i>ICC_BPR0_EL1</i> , Interrupt Controller Binary Point Register 0 on page D8-2212
ICC_BPR1_EL1	<i>ICC_BPR1_EL1</i> , Interrupt Controller Binary Point Register 1 on page D8-2214
ICC_CTLR_EL1	<i>ICC_CTLR_EL1</i> , Interrupt Controller Control Register (EL1) on page D8-2216
ICC_CTLR_EL3	<i>ICC_CTLR_EL3</i> , Interrupt Controller Control Register (EL3) on page D8-2219
ICC_DIR_EL1	<i>ICC_DIR_EL1</i> , Interrupt Controller Deactivate Interrupt Register on page D8-2222
ICC_EOIR0_EL1	<i>ICC_EOIR0_EL1</i> , Interrupt Controller End Of Interrupt Register 0 on page D8-2223
ICC_EOIR1_EL1	<i>ICC_EOIR1_EL1</i> , Interrupt Controller End Of Interrupt Register 1 on page D8-2225
ICC_HPPIR0_EL1	<i>ICC_HPPIR0_EL1</i> , Interrupt Controller Highest Priority Pending Interrupt Register 0 on page D8-2226
ICC_HPPIR1_EL1	<i>ICC_HPPIR1_EL1</i> , Interrupt Controller Highest Priority Pending Interrupt Register 1 on page D8-2228
ICC_IAR0_EL1	<i>ICC_IAR0_EL1</i> , Interrupt Controller Interrupt Acknowledge Register 0 on page D8-2229
ICC_IAR1_EL1	<i>ICC_IAR1_EL1</i> , Interrupt Controller Interrupt Acknowledge Register 1 on page D8-2231
ICC_IGRPEN0_EL1	<i>ICC_IGRPEN0_EL1</i> , Interrupt Controller Interrupt Group 0 Enable register on page D8-2232

**Table J-12 Generic Interrupt Controller CPU interface registers (continued)**

<b>Register</b>	<b>Description, see</b>
ICC_IGRPEN1_EL1	<i>ICC_IGRPEN1_EL1, Interrupt Controller Interrupt Group 1 Enable register on page D8-2234</i>
ICC_IGRPEN1_EL3	<i>ICC_IGRPEN1_EL3, Interrupt Controller Interrupt Group 1 Enable register (EL3) on page D8-2236</i>
ICC_PMR_EL1	<i>ICC_PMR_EL1, Interrupt Controller Interrupt Priority Mask Register on page D8-2238</i>
ICC_RPR_EL1	<i>ICC_RPR_EL1, Interrupt Controller Running Priority Register on page D8-2240</i>
ICC_SEIEN_EL1	<i>ICC_SEIEN_EL1, Interrupt Controller System Error Interrupt Enable register on page D8-2241</i>
ICC_SGI0R_EL1	<i>ICC_SGI0R_EL1, Interrupt Controller Software Generated Interrupt group 0 Register on page D8-2242</i>
ICC_SGI1R_EL1	<i>ICC_SGI1R_EL1, Interrupt Controller Software Generated Interrupt group 1 Register on page D8-2244</i>
ICC_SRE_EL1	<i>ICC_SRE_EL1, Interrupt Controller System Register Enable register (EL1) on page D8-2246</i>
ICC_SRE_EL2	<i>ICC_SRE_EL2, Interrupt Controller System Register Enable register (EL2) on page D8-2248</i>
ICC_SRE_EL3	<i>ICC_SRE_EL3, Interrupt Controller System Register Enable register (EL3) on page D8-2250</i>
ICH_AP0R0_EL2	<i>ICH_AP0R0_EL2, Interrupt Controller Hyp Active Priorities Register (0,0) on page D8-2252</i>
ICH_AP0R1_EL2	<i>ICH_AP0R1_EL2, Interrupt Controller Hyp Active Priorities Register (0,1) on page D8-2254</i>
ICH_AP0R2_EL2	<i>ICH_AP0R2_EL2, Interrupt Controller Hyp Active Priorities Register (0,2) on page D8-2256</i>
ICH_AP0R3_EL2	<i>ICH_AP0R3_EL2, Interrupt Controller Hyp Active Priorities Register (0,3) on page D8-2258</i>
ICH_AP1R0_EL2	<i>ICH_AP1R0_EL2, Interrupt Controller Hyp Active Priorities Register (1,0) on page D8-2260</i>
ICH_AP1R1_EL2	<i>ICH_AP1R1_EL2, Interrupt Controller Hyp Active Priorities Register (1,1) on page D8-2262</i>
ICH_AP1R2_EL2	<i>ICH_AP1R2_EL2, Interrupt Controller Hyp Active Priorities Register (1,2) on page D8-2264</i>
ICH_AP1R3_EL2	<i>ICH_AP1R3_EL2, Interrupt Controller Hyp Active Priorities Register (1,3) on page D8-2266</i>
ICH_EISR_EL2	<i>ICH_EISR_EL2, Interrupt Controller End of Interrupt Status Register on page D8-2268</i>
ICH_ELSR_EL2	<i>ICH_ELSR_EL2, Interrupt Controller Empty List Register Status Register on page D8-2270</i>
ICH_HCR_EL2	<i>ICH_HCR_EL2, Interrupt Controller Hyp Control Register on page D8-2272</i>
ICH_LR<n>_EL2	<i>ICH_LR&lt;n&gt;_EL2, Interrupt Controller List Registers, n = 0 - 15 on page D8-2275</i>
ICH_MISR_EL2	<i>ICH_MISR_EL2, Interrupt Controller Maintenance Interrupt State Register on page D8-2277</i>
ICH_VMCR_EL2	<i>ICH_VMCR_EL2, Interrupt Controller Virtual Machine Control Register on page D8-2279</i>
ICH_VSEIR_EL2	<i>ICH_VSEIR_EL2, Interrupt Controller Virtual System Error Interrupt Register on page D8-2281</i>
ICH_VTR_EL2	<i>ICH_VTR_EL2, Interrupt Controller VGIC Type Register on page D8-2282</i>

### J.3.8 Cache maintenance system instructions

This section is an index to the system instructions in the Cache maintenance functional group.

**Table J-13 Cache maintenance system instructions**

Register	Description, see
DC CISW	<i>DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way on page C4-307</i>
DC CIVAC	<i>DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC on page C4-309</i>
DC CSW	<i>DC CSW, Data or unified Cache line Clean by Set/Way on page C4-310</i>
DC CVAC	<i>DC CVAC, Data or unified Cache line Clean by VA to PoC on page C4-312</i>
DC CVAU	<i>DC CVAU, Data or unified Cache line Clean by VA to PoU on page C4-313</i>
DC ISW	<i>DC ISW, Data or unified Cache line Invalidate by Set/Way on page C4-314</i>
DC IVAC	<i>DC IVAC, Data or unified Cache line Invalidate by VA to PoC on page C4-316</i>
DC ZVA	<i>DC ZVA, Data Cache Zero by VA on page C4-317</i>
IC IALLU	<i>IC IALLU, Instruction Cache Invalidate All to PoU on page C4-319</i>
IC IALLUIS	<i>IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable on page C4-320</i>
IC IVAU	<i>IC IVAU, Instruction Cache line Invalidate by VA to PoU on page C4-321</i>

### J.3.9 Address translation system instructions

This section is an index to the system instructions in the Address translation functional group.

**Table J-14 Address translation system instructions**

Register	Description, see
AT S12E0R	<i>AT S12E0R, Address Translate Stages 1 and 2 EL0 Read on page C4-323</i>
AT S12E0W	<i>AT S12E0W, Address Translate Stages 1 and 2 EL0 Write on page C4-324</i>
AT S12E1R	<i>AT S12E1R, Address Translate Stages 1 and 2 EL1 Read on page C4-325</i>
AT S12E1W	<i>AT S12E1W, Address Translate Stages 1 and 2 EL1 Write on page C4-326</i>
AT S1E0R	<i>AT S1E0R, Address Translate Stage 1 EL0 Read on page C4-327</i>
AT S1E0W	<i>AT S1E0W, Address Translate Stage 1 EL0 Write on page C4-328</i>
AT S1E1R	<i>AT S1E1R, Address Translate Stage 1 EL1 Read on page C4-329</i>
AT S1E1W	<i>AT S1E1W, Address Translate Stage 1 EL1 Write on page C4-330</i>
AT S1E2R	<i>AT S1E2R, Address Translate Stage 1 EL2 Read on page C4-331</i>
AT S1E2W	<i>AT S1E2W, Address Translate Stage 1 EL2 Write on page C4-332</i>
AT S1E3R	<i>AT S1E3R, Address Translate Stage 1 EL3 Read on page C4-333</i>
AT S1E3W	<i>AT S1E3W, Address Translate Stage 1 EL3 Write on page C4-334</i>

### J.3.10 TLB maintenance system instructions

This section is an index to the system instructions in the TLB maintenance functional group.

**Table J-15 TLB maintenance system instructions**

Register	Description, see
TLBI ALLE1	<i>TLBI ALLE1, TLB Invalidate All entries, EL1 on page C4-336</i>
TLBI ALLE1IS	<i>TLBI ALLE1IS, TLB Invalidate All entries, EL1, Inner Shareable on page C4-337</i>
TLBI ALLE2	<i>TLBI ALLE2, TLB Invalidate All entries, EL2 on page C4-338</i>
TLBI ALLE2IS	<i>TLBI ALLE2IS, TLB Invalidate All entries, EL2, Inner Shareable on page C4-339</i>
TLBI ALLE3	<i>TLBI ALLE3, TLB Invalidate All entries, EL3 on page C4-340</i>
TLBI ALLE3IS	<i>TLBI ALLE3IS, TLB Invalidate All entries, EL3, Inner Shareable on page C4-341</i>
TLBI ASIDE1	<i>TLBI ASIDE1, TLB Invalidate by ASID, EL1 on page C4-342</i>
TLBI ASIDE1IS	<i>TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable on page C4-343</i>
TLBI IPAS2E1	<i>TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1 on page C4-344</i>
TLBI IPAS2E1IS	<i>TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable on page C4-345</i>
TLBI IPAS2LE1	<i>TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1 on page C4-346</i>
TLBI IPAS2LE1IS	<i>TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable on page C4-347</i>
TLBI VAAE1	<i>TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1 on page C4-348</i>
TLBI VAAE1IS	<i>TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable on page C4-350</i>
TLBI VAALE1	<i>TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1 on page C4-352</i>
TLBI VAALE1IS	<i>TLBI VAALE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable on page C4-354</i>
TLBI VAE1	<i>TLBI VAE1, TLB Invalidate by VA, EL1 on page C4-356</i>
TLBI VAE1IS	<i>TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable on page C4-358</i>
TLBI VAE2	<i>TLBI VAE2, TLB Invalidate by VA, EL2 on page C4-360</i>
TLBI VAE2IS	<i>TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable on page C4-362</i>
TLBI VAE3	<i>TLBI VAE3, TLB Invalidate by VA, EL3 on page C4-364</i>
TLBI VAE3IS	<i>TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable on page C4-366</i>
TLBI VALE1	<i>TLBI VALE1, TLB Invalidate by VA, Last level, EL1 on page C4-368</i>
TLBI VALE1IS	<i>TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable on page C4-370</i>
TLBI VALE2	<i>TLBI VALE2, TLB Invalidate by VA, Last level, EL2 on page C4-372</i>
TLBI VALE2IS	<i>TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable on page C4-374</i>
TLBI VALE3	<i>TLBI VALE3, TLB Invalidate by VA, Last level, EL3 on page C4-376</i>
TLBI VALE3IS	<i>TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable on page C4-378</i>

**Table J-15 TLB maintenance system instructions (continued)**

Register	Description, see
TLBI VMALLE1	<i>TLBI VMALLE1, TLB Invalidate by VMID, All entries at stage 1, EL1</i> on page C4-380
TLBI VMALLE1IS	<i>TLBI VMALLE1IS, TLB Invalidate by VMID, All entries at stage 1, EL1, Inner Shareable</i> on page C4-381
TLBI VMALLS12E1	<i>TLBI VMALLS12E1, TLB Invalidate by VMID, All entries at Stage 1 and 2, EL1</i> on page C4-382
TLBI VMALLS12E1IS	<i>TLBI VMALLS12E1IS, TLB Invalidate by VMID, All entries at Stage 1 and 2, EL1, Inner Shareable</i> on page C4-383

### J.3.11 Base system registers

This section is an index to the registers that are not a part of any of the other functional groups in this index.

**Table J-16 Base system registers**

Register	Description, see
ACTLR_EL1	<i>ACTLR_EL1, Auxiliary Control Register (EL1)</i> on page D8-1870
ACTLR_EL2	<i>ACTLR_EL2, Auxiliary Control Register (EL2)</i> on page D8-1871
ACTLR_EL3	<i>ACTLR_EL3, Auxiliary Control Register (EL3)</i> on page D8-1872
AFSR0_EL1	<i>AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)</i> on page D8-1873
AFSR0_EL2	<i>AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)</i> on page D8-1874
AFSR0_EL3	<i>AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)</i> on page D8-1875
AFSR1_EL1	<i>AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)</i> on page D8-1876
AFSR1_EL2	<i>AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)</i> on page D8-1877
AFSR1_EL3	<i>AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)</i> on page D8-1878
CPACR_EL1	<i>CPACR_EL1, Architectural Feature Access Control Register</i> on page D8-1888
CPTR_EL2	<i>CPTR_EL2, Architectural Feature Trap Register (EL2)</i> on page D8-1890
CPTR_EL3	<i>CPTR_EL3, Architectural Feature Trap Register (EL3)</i> on page D8-1892
CurrentEL	<i>CurrentEL, Current Exception Level</i> on page C4-252
DAIF	<i>DAIF, Interrupt Mask Bits</i> on page C4-254
ESR_EL1	<i>ESR_EL1, Exception Syndrome Register (EL1)</i> on page D8-1899
ESR_EL2	<i>ESR_EL2, Exception Syndrome Register (EL2)</i> on page D8-1904
ESR_EL3	<i>ESR_EL3, Exception Syndrome Register (EL3)</i> on page D8-1909
FAR_EL1	<i>FAR_EL1, Fault Address Register (EL1)</i> on page D8-1914
FAR_EL2	<i>FAR_EL2, Fault Address Register (EL2)</i> on page D8-1915
FAR_EL3	<i>FAR_EL3, Fault Address Register (EL3)</i> on page D8-1917
FPEXC32_EL2	<i>FPEXC32_EL2, Floating-point Exception Control register</i> on page D8-1918
HACR_EL2	<i>HACR_EL2, Hypervisor Auxiliary Control Register</i> on page D8-1922

**Table J-16 Base system registers (continued)**

<b>Register</b>	<b>Description, see</b>
HCR_EL2	<i>HCR_EL2, Hypervisor Configuration Register on page D8-1923</i>
HPFAR_EL2	<i>HPFAR_EL2, Hypervisor IPA Fault Address Register on page D8-1930</i>
HSTR_EL2	<i>HSTR_EL2, Hypervisor System Trap Register on page D8-1931</i>
IFSR32_EL2	<i>IFSR32_EL2, Instruction Fault Status Register (EL2) on page D8-1984</i>
ISR_EL1	<i>ISR_EL1, Interrupt Status Register on page D8-1988</i>
NZCV	<i>NZCV, Condition Flags on page C4-267</i>
PAR_EL1	<i>PAR_EL1, Physical Address Register on page D8-2008</i>
RMR_EL1	<i>RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented) on page D8-2012</i>
RMR_EL2	<i>RMR_EL2, Reset Management Register (if EL3 not implemented) on page D8-2014</i>
RMR_EL3	<i>RMR_EL3, Reset Management Register (if EL3 implemented) on page D8-2016</i>
RVBAR_EL1	<i>RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented) on page D8-2018</i>
RVBAR_EL2	<i>RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented) on page D8-2019</i>
RVBAR_EL3	<i>RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented) on page D8-2020</i>
S3_<op1>_<Cn>_<Cm>_<op2>	<i>S3_&lt;op1&gt;_&lt;Cn&gt;_&lt;Cm&gt;_&lt;op2&gt;, IMPLEMENTATION DEFINED registers on page D8-2021</i>
SCR_EL3	<i>SCR_EL3, Secure Configuration Register on page D8-2022</i>
SCTLR_EL1	<i>SCTLR_EL1, System Control Register (EL1) on page D8-2025</i>
SCTLR_EL2	<i>SCTLR_EL2, System Control Register (EL2) on page D8-2031</i>
SCTLR_EL3	<i>SCTLR_EL3, System Control Register (EL3) on page D8-2035</i>
SPSel	<i>SPSel, Stack Pointer Select on page C4-273</i>
TPIDR_EL0	<i>TPIDR_EL0, Thread Pointer / ID Register (EL0) on page D8-2052</i>
TPIDR_EL1	<i>TPIDR_EL1, Thread Pointer / ID Register (EL1) on page D8-2053</i>
TPIDR_EL2	<i>TPIDR_EL2, Thread Pointer / ID Register (EL2) on page D8-2054</i>
TPIDR_EL3	<i>TPIDR_EL3, Thread Pointer / ID Register (EL3) on page D8-2055</i>
TPIDRRO_EL0	<i>TPIDRRO_EL0, Thread Pointer / ID Register, Read-Only (EL0) on page D8-2056</i>
VBAR_EL1	<i>VBAR_EL1, Vector Base Address Register (EL1) on page D8-2065</i>
VBAR_EL2	<i>VBAR_EL2, Vector Base Address Register (EL2) on page D8-2066</i>
VBAR_EL3	<i>VBAR_EL3, Vector Base Address Register (EL3) on page D8-2067</i>

## J.4 Alphabetical index of AArch32 registers and system instructions

This section is an index of AArch32 registers and system instructions in alphabetical order.

**Table J-17 Alphabetical index of AArch32 Registers**

<b>Register</b>	<b>Description, see</b>
ACTLR	<i>ACTLR, Auxiliary Control Register on page G4-3773</i>
ADFSR	<i>ADFSR, Auxiliary Data Fault Status Register on page G4-3775</i>
AIDR	<i>AIDR, Auxiliary ID Register on page G4-3777</i>
AIFSR	<i>AIFSR, Auxiliary Instruction Fault Status Register on page G4-3778</i>
AMAIRO	<i>AMAIRO, Auxiliary Memory Attribute Indirection Register 0 on page G4-3780</i>
AMAIR1	<i>AMAIR1, Auxiliary Memory Attribute Indirection Register 1 on page G4-3782</i>
APSR	<i>APSR, Application Program Status Register on page G4-3784</i>
ATS12NSOPR	<i>ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read on page G4-3786</i>
ATS12NSOPW	<i>ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write on page G4-3787</i>
ATS12NSOUR	<i>ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read on page G4-3788</i>
ATS12NSOUW	<i>ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write on page G4-3789</i>
ATS1CPR	<i>ATS1CPR, Address Translate Stage 1 Current state PL1 Read on page G4-3790</i>
ATS1CPW	<i>ATS1CPW, Address Translate Stage 1 Current state PL1 Write on page G4-3791</i>
ATS1CUR	<i>ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read on page G4-3792</i>
ATS1CUW	<i>ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write on page G4-3793</i>
ATS1HR	<i>ATS1HR, Address Translate Stage 1 Hyp mode Read on page G4-3794</i>
ATS1HW	<i>ATS1HW, Address Translate Stage 1 Hyp mode Write on page G4-3795</i>
BPIALL	<i>BPIALL, Branch Predictor Invalidate All on page G4-3796</i>
BPIALLIS	<i>BPIALLIS, Branch Predictor Invalidate All, Inner Shareable on page G4-3797</i>
BPIMVA	<i>BPIMVA, Branch Predictor Invalidate VA on page G4-3798</i>
CCSIDR	<i>CCSIDR, Current Cache Size ID Register on page G4-3799</i>
CLIDR	<i>CLIDR, Cache Level ID Register on page G4-3801</i>
CNTFRQ	<i>CNTFRQ, Counter-timer Frequency register on page G4-4208</i>
CNTHCTL	<i>CNTHCTL, Counter-timer Hyp Control register on page G4-4209</i>
CNTHP_CTL	<i>CNTHP_CTL, Counter-timer Hyp Physical Timer Control register on page G4-4211</i>
CNTHP_CVAL	<i>CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register on page G4-4213</i>
CNTHP_TVAL	<i>CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register on page G4-4214</i>
CNTKCTL	<i>CNTKCTL, Counter-timer Kernel Control register on page G4-4215</i>
CNTP_CTL	<i>CNTP_CTL, Counter-timer Physical Timer Control register on page G4-4217</i>
CNTP_CVAL	<i>CNTP_CVAL, Counter-timer Physical Timer CompareValue register on page G4-4219</i>

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
CNTP_TVAL	<i>CNTP_TVAL</i> , Counter-timer Physical Timer TimerValue register on page G4-4221
CNTPCT	<i>CNTPCT</i> , Counter-timer Physical Count register on page G4-4223
CNTV_CTL	<i>CNTV_CTL</i> , Counter-timer Virtual Timer Control register on page G4-4224
CNTV_CVAL	<i>CNTV_CVAL</i> , Counter-timer Virtual Timer CompareValue register on page G4-4226
CNTV_TVAL	<i>CNTV_TVAL</i> , Counter-timer Virtual Timer TimerValue register on page G4-4227
CNTVCT	<i>CNTVCT</i> , Counter-timer Virtual Count register on page G4-4228
CNTVOFF	<i>CNTVOFF</i> , Counter-timer Virtual Offset register on page G4-4229
CONTEXTIDR	<i>CONTEXTIDR</i> , Context ID Register on page G4-3803
CP15DMB	<i>CP15DMB</i> , CP15 Data Memory Barrier operation on page G4-3805
CP15DSB	<i>CP15DSB</i> , CP15 Data Synchronization Barrier operation on page G4-3806
CP15ISB	<i>CP15ISB</i> , CP15 Instruction Synchronization Barrier operation on page G4-3807
CPACR	<i>CPACR</i> , Architectural Feature Access Control Register on page G4-3808
CPSR	<i>CPSR</i> , Current Program Status Register on page G4-3810
CSSELR	<i>CSSELR</i> , Cache Size Selection Register on page G4-3813
CTR	<i>CTR</i> , Cache Type Register on page G4-3815
DACR	<i>DACR</i> , Domain Access Control Register on page G4-3817
DBGAUTHSTATUS	<i>DBGAUTHSTATUS</i> , Debug Authentication Status register on page G4-4101
DBGBCR<n>	<i>DBGBCR&lt;n&gt;</i> , Debug Breakpoint Control Registers, $n = 0 - 15$ on page G4-4103
DBGBVR<n>	<i>DBGBVR&lt;n&gt;</i> , Debug Breakpoint Value Registers, $n = 0 - 15$ on page G4-4106
DBGBXVR<n>	<i>DBGBXVR&lt;n&gt;</i> , Debug Breakpoint Extended Value Registers, $n = 0 - 15$ on page G4-4108
DBGCLAIMCLR	<i>DBGCLAIMCLR</i> , Debug Claim Tag Clear register on page G4-4110
DBGCLAIMSET	<i>DBGCLAIMSET</i> , Debug Claim Tag Set register on page G4-4112
DBGDCCINT	<i>DBGDCCINT</i> , DCC Interrupt Enable Register on page G4-4114
DBGDEVID	<i>DBGDEVID</i> , Debug Device ID register 0 on page G4-4116
DBGDEVID1	<i>DBGDEVID1</i> , Debug Device ID register 1 on page G4-4118
DBGDEVID2	<i>DBGDEVID2</i> , Debug Device ID register 2 on page G4-4119
DBGDIDR	<i>DBGDIDR</i> , Debug ID Register on page G4-4120
DBGDRAR	<i>DBGDRAR</i> , Debug ROM Address Register on page G4-4122
DBGDSAR	<i>DBGDSAR</i> , Debug Self Address Register on page G4-4124
DBGDSCRext	<i>DBGDSCRext</i> , Debug Status and Control Register, External View on page G4-4126
DBGDSCRint	<i>DBGDSCRint</i> , Debug Status and Control Register, Internal View on page G4-4130
DBGDTRRext	<i>DBGDTRRext</i> , Debug Data Transfer Register, Receive, External View on page G4-4132

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
DBGDTRRXint	<i>DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View</i> on page G4-4134
DBGDTRTXext	<i>DBGDTRTXext, Debug Data Transfer Register, Transmit, External View</i> on page G4-4136
DBGDTRTXint	<i>DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View</i> on page G4-4138
DBGOSDLR	<i>DBGOSDLR, Debug OS Double Lock Register</i> on page G4-4140
DBGOSECCR	<i>DBGOSECCR, Debug OS Lock Exception Catch Control Register</i> on page G4-4141
DBGOSLAR	<i>DBGOSLAR, Debug OS Lock Access Register</i> on page G4-4142
DBGOSLSR	<i>DBGOSLSR, Debug OS Lock Status Register</i> on page G4-4143
DBGPRCR	<i>DBGPRCR, Debug Power Control Register</i> on page G4-4145
DBGVCR	<i>DBGVCR, Debug Vector Catch Register</i> on page G4-4147
DBGWCR<n>	<i>DBGWCR&lt;n&gt;, Debug Watchpoint Control Registers, n = 0 - 15</i> on page G4-4153
DBGWFAR	<i>DBGWFAR, Debug Watchpoint Fault Address Register</i> on page G4-4156
DBGWVR<n>	<i>DBGWVR&lt;n&gt;, Debug Watchpoint Value Registers, n = 0 - 15</i> on page G4-4157
DCCIMVAC	<i>DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC</i> on page G4-3819
DCCISW	<i>DCCISW, Data Cache line Clean and Invalidate by Set/Way</i> on page G4-3820
DCCMVAC	<i>DCCMVAC, Data Cache line Clean by VA to PoC</i> on page G4-3822
DCCMVAU	<i>DCCMVAU, Data Cache line Clean by VA to PoU</i> on page G4-3823
DCCSW	<i>DCCSW, Data Cache line Clean by Set/Way</i> on page G4-3824
DCIMVAC	<i>DCIMVAC, Data Cache line Invalidate by VA to PoC</i> on page G4-3826
DCISW	<i>DCISW, Data Cache line Invalidate by Set/Way</i> on page G4-3827
DFAR	<i>DFAR, Data Fault Address Register</i> on page G4-3829
DFSR	<i>DFSR, Data Fault Status Register</i> on page G4-3831
DLR	<i>DLR, Debug Link Register</i> on page G4-4158
DSPSR	<i>DSPSR, Debug Saved Program Status Register</i> on page G4-4159
DTLBIALL	<i>DTLBIALL, Data TLB Invalidate All entries</i> on page G4-3836
DTLBIASID	<i>DTLBIASID, Data TLB Invalidate by ASID match</i> on page G4-3837
DTLBIMVA	<i>DTLBIMVA, Data TLB Invalidate entry by VA</i> on page G4-3838
ELR_hyp	<i>ELR_hyp, Exception Link Register (Hyp mode)</i> on page G4-3839
FCSEIDR	<i>FCSEIDR, FCSE Process ID register</i> on page G4-3840
FPEXC	<i>FPEXC, Floating-Point Exception Control register</i> on page G4-3841
FPSCR	<i>FPSCR, Floating-Point Status and Control Register</i> on page G4-3845
FPSID	<i>FPSID, Floating-Point System ID register</i> on page G4-3850
HACR	<i>HACR, Hyp Auxiliary Configuration Register</i> on page G4-3852

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
HACTLR	<i>HACTLR, Hyp Auxiliary Control Register on page G4-3853</i>
HADFSR	<i>HADFSR, Hyp Auxiliary Data Fault Status Register on page G4-3854</i>
HAIFSR	<i>HAIFSR, Hyp Auxiliary Instruction Fault Status Register on page G4-3855</i>
HAMAIR0	<i>HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0 on page G4-3856</i>
HAMAIR1	<i>HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1 on page G4-3857</i>
HCPTR	<i>HCPTR, Hyp Architectural Feature Trap Register on page G4-3858</i>
HCR	<i>HCR, Hyp Configuration Register on page G4-3861</i>
HCR2	<i>HCR2, Hyp Configuration Register 2 on page G4-3867</i>
HDCR	<i>HDCR, Hyp Debug Control Register on page G4-4163</i>
HDFAR	<i>HDFAR, Hyp Data Fault Address Register on page G4-3869</i>
HIFAR	<i>HIFAR, Hyp Instruction Fault Address Register on page G4-3870</i>
HMAIR0	<i>HMAIR0, Hyp Memory Attribute Indirection Register 0 on page G4-3871</i>
HMAIR1	<i>HMAIR1, Hyp Memory Attribute Indirection Register 1 on page G4-3874</i>
HPFAR	<i>HPFAR, Hyp IPA Fault Address Register on page G4-3877</i>
HRMR	<i>HRMR, Hyp Reset Management Register on page G4-3878</i>
HSCTLR	<i>HSCTLR, Hyp System Control Register on page G4-3880</i>
HSR	<i>HSR, Hyp Syndrome Register on page G4-3885</i>
HSTR	<i>HSTR, Hyp System Trap Register on page G4-3900</i>
HTCR	<i>HTCR, Hyp Translation Control Register on page G4-3902</i>
HTPIDR	<i>HTPIDR, Hyp Thread Pointer / ID Register on page G4-3904</i>
HTTBR	<i>HTTBR, Hyp Translation Table Base Register on page G4-3905</i>
HVBAR	<i>HVBAR, Hyp Vector Base Address Register on page G4-3907</i>
ICC_AP0R0	<i>ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0) on page G4-4230</i>
ICC_AP0R1	<i>ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1) on page G4-4232</i>
ICC_AP0R2	<i>ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2) on page G4-4234</i>
ICC_AP0R3	<i>ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3) on page G4-4236</i>
ICC_APIR0	<i>ICC_APIR0, Interrupt Controller Active Priorities Register (1,0) on page G4-4238</i>
ICC_APIR1	<i>ICC_APIR1, Interrupt Controller Active Priorities Register (1,1) on page G4-4240</i>
ICC_APIR2	<i>ICC_APIR2, Interrupt Controller Active Priorities Register (1,2) on page G4-4242</i>
ICC_APIR3	<i>ICC_APIR3, Interrupt Controller Active Priorities Register (1,3) on page G4-4244</i>
ICC_ASGI1R	<i>ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register on page G4-4246</i>
ICC_BPR0	<i>ICC_BPR0, Interrupt Controller Binary Point Register 0 on page G4-4248</i>

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
ICC_BPR1	<i>ICC_BPR1, Interrupt Controller Binary Point Register 1 on page G4-4250</i>
ICC_CTLR	<i>ICC_CTLR, Interrupt Controller Control Register on page G4-4252</i>
ICC_DIR	<i>ICC_DIR, Interrupt Controller Deactivate Interrupt Register on page G4-4255</i>
ICC_EOIR0	<i>ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0 on page G4-4256</i>
ICC_EOIR1	<i>ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1 on page G4-4258</i>
ICC_HPPIR0	<i>ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0 on page G4-4260</i>
ICC_HPPIR1	<i>ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1 on page G4-4262</i>
ICC_HSRE	<i>ICC_HSRE, Interrupt Controller Hyp System Register Enable register on page G4-4263</i>
ICC_IAR0	<i>ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0 on page G4-4265</i>
ICC_IAR1	<i>ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1 on page G4-4267</i>
ICC_IGRPEN0	<i>ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register on page G4-4268</i>
ICC_IGRPEN1	<i>ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register on page G4-4270</i>
ICC_MCTLR	<i>ICC_MCTLR, Interrupt Controller Monitor Control Register on page G4-4271</i>
ICC_MGRPEN1	<i>ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register on page G4-4274</i>
ICC_MSRE	<i>ICC_MSRE, Interrupt Controller Monitor System Register Enable register on page G4-4276</i>
ICC_PMR	<i>ICC_PMR, Interrupt Controller Interrupt Priority Mask Register on page G4-4278</i>
ICC_RPR	<i>ICC_RPR, Interrupt Controller Running Priority Register on page G4-4280</i>
ICC_SEIEN	<i>ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register on page G4-4281</i>
ICC_SGI0R	<i>ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register on page G4-4282</i>
ICC_SGI1R	<i>ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register on page G4-4284</i>
ICC_SRE	<i>ICC_SRE, Interrupt Controller System Register Enable register on page G4-4286</i>
ICH_AP0R0	<i>ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0) on page G4-4288</i>
ICH_AP0R1	<i>ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1) on page G4-4290</i>
ICH_AP0R2	<i>ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2) on page G4-4292</i>
ICH_AP0R3	<i>ICH_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3) on page G4-4294</i>
ICH_AP1R0	<i>ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0) on page G4-4296</i>
ICH_AP1R1	<i>ICH_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1) on page G4-4298</i>
ICH_AP1R2	<i>ICH_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2) on page G4-4300</i>
ICH_AP1R3	<i>ICH_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3) on page G4-4302</i>
ICH_EISR	<i>ICH_EISR, Interrupt Controller End of Interrupt Status Register on page G4-4304</i>
ICH_ELSR	<i>ICH_ELSR, Interrupt Controller Empty List Register Status Register on page G4-4306</i>
ICH_HCR	<i>ICH_HCR, Interrupt Controller Hyp Control Register on page G4-4308</i>

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
ICH_LRC<n>	<i>ICH_LRC&lt;n&gt;</i> , Interrupt Controller List Registers, <i>n</i> = 0 - 15 on page G4-4311
ICH_LR<n>	<i>ICH_LR&lt;n&gt;</i> , Interrupt Controller List Registers, <i>n</i> = 0 - 15 on page G4-4313
ICH_MISR	<i>ICH_MISR</i> , Interrupt Controller Maintenance Interrupt State Register on page G4-4314
ICH_VMCR	<i>ICH_VMCR</i> , Interrupt Controller Virtual Machine Control Register on page G4-4316
ICH_VSEIR	<i>ICH_VSEIR</i> , Interrupt Controller Virtual System Error Interrupt Register on page G4-4318
ICH_VTR	<i>ICH_VTR</i> , Interrupt Controller VGIC Type Register on page G4-4319
ICIALLU	<i>ICIALLU</i> , Instruction Cache Invalidate All to PoU on page G4-3908
ICIALLUIS	<i>ICIALLUIS</i> , Instruction Cache Invalidate All to PoU, Inner Shareable on page G4-3909
ICIMVAU	<i>ICIMVAU</i> , Instruction Cache line Invalidate by VA to PoU on page G4-3910
ID_AFR0	<i>ID_AFR0</i> , Auxiliary Feature Register 0 on page G4-3911
ID_DFR0	<i>ID_DFR0</i> , Debug Feature Register 0 on page G4-3912
ID_ISAR0	<i>ID_ISAR0</i> , Instruction Set Attribute Register 0 on page G4-3914
ID_ISAR1	<i>ID_ISAR1</i> , Instruction Set Attribute Register 1 on page G4-3916
ID_ISAR2	<i>ID_ISAR2</i> , Instruction Set Attribute Register 2 on page G4-3919
ID_ISAR3	<i>ID_ISAR3</i> , Instruction Set Attribute Register 3 on page G4-3922
ID_ISAR4	<i>ID_ISAR4</i> , Instruction Set Attribute Register 4 on page G4-3925
ID_ISAR5	<i>ID_ISAR5</i> , Instruction Set Attribute Register 5 on page G4-3928
ID_MMFR0	<i>ID_MMFR0</i> , Memory Model Feature Register 0 on page G4-3930
ID_MMFR1	<i>ID_MMFR1</i> , Memory Model Feature Register 1 on page G4-3933
ID_MMFR2	<i>ID_MMFR2</i> , Memory Model Feature Register 2 on page G4-3937
ID_MMFR3	<i>ID_MMFR3</i> , Memory Model Feature Register 3 on page G4-3940
ID_PFR0	<i>ID_PFR0</i> , Processor Feature Register 0 on page G4-3943
ID_PFR1	<i>ID_PFR1</i> , Processor Feature Register 1 on page G4-3945
IFAR	<i>IFAR</i> , Instruction Fault Address Register on page G4-3948
IFSR	<i>IFSR</i> , Instruction Fault Status Register on page G4-3950
ISR	<i>ISR</i> , Interrupt Status Register on page G4-3954
ITLBIALL	<i>ITLBIALL</i> , Instruction TLB Invalidate All entries on page G4-3956
ITLBIASID	<i>ITLBIASID</i> , Instruction TLB Invalidate by ASID match on page G4-3957
ITLBIMVA	<i>ITLBIMVA</i> , Instruction TLB Invalidate entry by VA on page G4-3958
JIDR	<i>JIDR</i> , Jazelle ID Register on page G4-3959
JMCR	<i>JMCR</i> , Jazelle Main Configuration Register on page G4-3960
JOSCR	<i>JOSCR</i> , Jazelle OS Control Register on page G4-3961

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
MAIRO	<i>MAIRO</i> , Memory Attribute Indirection Register 0 on page G4-3962
MAIR1	<i>MAIR1</i> , Memory Attribute Indirection Register 1 on page G4-3965
MIDR	<i>MIDR</i> , Main ID Register on page G4-3968
MPIDR	<i>MPIDR</i> , Multiprocessor Affinity Register on page G4-3970
MVBAR	<i>MVBAR</i> , Monitor Vector Base Address Register on page G4-3972
MVFR0	<i>MVFR0</i> , Media and VFP Feature Register 0 on page G4-3974
MVFR1	<i>MVFR1</i> , Media and VFP Feature Register 1 on page G4-3977
MVFR2	<i>MVFR2</i> , Media and VFP Feature Register 2 on page G4-3980
NMRR	<i>NMRR</i> , Normal Memory Remap Register on page G4-3982
NSACR	<i>NSACR</i> , Non-Secure Access Control Register on page G4-3984
PAR	<i>PAR</i> , Physical Address Register on page G4-3986
PMCCFILTR	<i>PMCCFILTR</i> , Performance Monitors Cycle Count Filter Register on page G4-4170
PMCCNTR	<i>PMCCNTR</i> , Performance Monitors Cycle Count Register on page G4-4172
PMCEID0	<i>PMCEID0</i> , Performance Monitors Common Event Identification register 0 on page G4-4174
PMCEID1	<i>PMCEID1</i> , Performance Monitors Common Event Identification register 1 on page G4-4176
PMCNTENCLR	<i>PMCNTENCLR</i> , Performance Monitors Count Enable Clear register on page G4-4178
PMCNTENSET	<i>PMCNTENSET</i> , Performance Monitors Count Enable Set register on page G4-4180
PMCR	<i>PMCR</i> , Performance Monitors Control Register on page G4-4182
PMEVCNTR<n>	<i>PMEVCNTR&lt;n&gt;</i> , Performance Monitors Event Count Registers, $n = 0 - 30$ on page G4-4185
PMEVTYPER<n>	<i>PMEVTYPER&lt;n&gt;</i> , Performance Monitors Event Type Registers, $n = 0 - 30$ on page G4-4187
PMINTENCLR	<i>PMINTENCLR</i> , Performance Monitors Interrupt Enable Clear register on page G4-4190
PMINTENSET	<i>PMINTENSET</i> , Performance Monitors Interrupt Enable Set register on page G4-4192
PMOVSr	<i>PMOVSr</i> , Performance Monitors Overflow Flag Status Register on page G4-4194
PMOVSSET	<i>PMOVSSET</i> , Performance Monitors Overflow Flag Status Set register on page G4-4196
PMSELR	<i>PMSELR</i> , Performance Monitors Event Counter Selection Register on page G4-4198
PMSWINC	<i>PMSWINC</i> , Performance Monitors Software Increment register on page G4-4200
PMUSERENR	<i>PMUSERENR</i> , Performance Monitors User Enable Register on page G4-4202
PMXEVNTR	<i>PMXEVNTR</i> , Performance Monitors Selected Event Count Register on page G4-4204
PMXEVTYPER	<i>PMXEVTYPER</i> , Performance Monitors Selected Event Type Register on page G4-4206
PRRR	<i>PRRR</i> , Primary Region Remap Register on page G4-3992
REVIDR	<i>REVIDR</i> , Revision ID Register on page G4-3995
RMR (at EL1)	<i>RMR (at EL1)</i> , Reset Management Register on page G4-3996

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
RMR (at EL3)	<i>RMR (at EL3), Reset Management Register</i> on page G4-3998
RVBAR	<i>RVBAR, Reset Vector Base Address Register</i> on page G4-4000
SCR	<i>SCR, Secure Configuration Register</i> on page G4-4001
SCTLR	<i>SCTLR, System Control Register</i> on page G4-4005
SDCR	<i>SDCR, Secure Debug Configuration Register</i> on page G4-4166
SDER	<i>SDER, Secure Debug Enable Register</i> on page G4-4168
SPSR	<i>SPSR, Saved Program Status Register</i> on page G4-4012
SPSR_abt	<i>SPSR_abt, Saved Program Status Register (Abort mode)</i> on page G4-4015
SPSR_fiq	<i>SPSR_fiq, Saved Program Status Register (FIQ mode)</i> on page G4-4019
SPSR_hyp	<i>SPSR_hyp, Saved Program Status Register (Hyp mode)</i> on page G4-4023
SPSR_irq	<i>SPSR_irq, Saved Program Status Register (IRQ mode)</i> on page G4-4027
SPSR_mon	<i>SPSR_mon, Saved Program Status Register (Monitor mode)</i> on page G4-4031
SPSR_svc	<i>SPSR_svc, Saved Program Status Register (Sup. Call mode)</i> on page G4-4035
SPSR_und	<i>SPSR_und, Saved Program Status Register (Undefined mode)</i> on page G4-4039
TCMTR	<i>TCMTR, TCM Type Register</i> on page G4-4043
TEECR	<i>TEECR, T32EE Configuration Register</i> on page G4-4045
TEEHBR	<i>TEEHBR, T32EE Handler Base Register</i> on page G4-4047
TLBIALL	<i>TLBIALL, TLB Invalidate All entries</i> on page G4-4048
TLBIALLH	<i>TLBIALLH, TLB Invalidate All entries, Hyp mode</i> on page G4-4049
TLBIALLHIS	<i>TLBIALLHIS, TLB Invalidate All entries, Hyp mode, Inner Shareable</i> on page G4-4050
TLBIALLIS	<i>TLBIALLIS, TLB Invalidate All entries, Inner Shareable</i> on page G4-4051
TLBIALLNSNH	<i>TLBIALLNSNH, TLB Invalidate All entries, Non-Secure Non-Hyp</i> on page G4-4052
TLBIALLNSNHIS	<i>TLBIALLNSNHIS, TLB Invalidate All entries, Non-Secure Non-Hyp, Inner Shareable</i> on page G4-4053
TLBIASID	<i>TLBIASID, TLB Invalidate entry by ASID match</i> on page G4-4054
TLBIASIDIS	<i>TLBIASIDIS, TLB Invalidate entry by ASID match, Inner Shareable</i> on page G4-4055
TLBIIPAS2	<i>TLBIIPAS2, TLB Invalidate entry by Intermediate Physical Address, Stage 2</i> on page G4-4056
TLBIIPAS2IS	<i>TLBIIPAS2IS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Inner Shareable</i> on page G4-4057
TLBIIPAS2L	<i>TLBIIPAS2L, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level</i> on page G4-4058
TLBIIPAS2LIS	<i>TLBIIPAS2LIS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level, Inner Shareable</i> on page G4-4059
TLBIMVA	<i>TLBIMVA, TLB Invalidate entry by VA</i> on page G4-4060
TLBIMVAA	<i>TLBIMVAA, TLB Invalidate entry by VA, All ASID</i> on page G4-4061

**Table J-17 Alphabetical index of AArch32 Registers (continued)**

<b>Register</b>	<b>Description, see</b>
TLBIMVAAIS	<i>TLBIMVAAIS, TLB Invalidate entry by VA, All ASID, Inner Shareable on page G4-4062</i>
TLBIMVAAL	<i>TLBIMVAAL, TLB Invalidate entry by VA, All ASID, Last level on page G4-4063</i>
TLBIMVAALIS	<i>TLBIMVAALIS, TLB Invalidate entry by VA, All ASID, Last level, Inner Shareable on page G4-4064</i>
TLBIMVAH	<i>TLBIMVAH, TLB Invalidate entry by VA, Hyp mode on page G4-4065</i>
TLBIMVAHIS	<i>TLBIMVAHIS, TLB Invalidate entry by VA, Hyp mode, Inner Shareable on page G4-4066</i>
TLBIMVAIS	<i>TLBIMVAIS, TLB Invalidate entry by VA, Inner Shareable on page G4-4068</i>
TLBIMVAL	<i>TLBIMVAL, TLB Invalidate entry by VA, Last level on page G4-4069</i>

TLBIMVALIS	<i>TLBIMVALIS, TLB Invalidate entry by VA, Last level, Inner Shareable on page G4-4074</i>
TLBTR	<i>TLBTR, TLB Type Register on page G4-4075</i>
TPIDRPRW	<i>TPIDRPRW, Thread Pointer / ID Register, Privileged Read-Write on page G4-4076</i>
TPIDRURO	<i>TPIDRURO, Thread Pointer / ID Register, Unprivileged Read-Only on page G4-4077</i>
TPIDRURW	<i>TPIDRURW, Thread Pointer / ID Register, Unprivileged Read-Write on page G4-4078</i>
TTBCR	<i>TTBCR, Translation Table Base Control Register on page G4-4079</i>
TTBR0	<i>TTBR0, Translation Table Base Register 0 on page G4-4084</i>
TTBR1	<i>TTBR1, Translation Table Base Register 1 on page G4-4088</i>
VBAR	<i>VBAR, Vector Base Address Register on page G4-4091</i>
VMPIDR	<i>VMPIDR, Virtualization Multiprocessor ID Register on page G4-4093</i>
VPIDR	<i>VPIDR, Virtualization Processor ID Register on page G4-4095</i>
VTCR	<i>VTCR, Virtualization Translation Control Register on page G4-4097</i>
VTTBR	<i>VTTBR, Virtualization Translation Table Base Register on page G4-4099</i>

## J.5 Functional index of AArch32 registers and system instructions

This section is an index of the AArch32 registers and system instructions, divided by functional group.

### J.5.1 Special-purpose registers

This section is an index to the registers in the Processor state and Special-purpose functional groups.

**Table J-18 Special-purpose registers**

Register	Description, see
DLR	<i>DLR, Debug Link Register</i> on page G4-4158
DSPSR	<i>DSPSR, Debug Saved Program Status Register</i> on page G4-4159
ELR_hyp	<i>ELR_hyp, Exception Link Register (Hyp mode)</i> on page G4-3839
FPSCR	<i>FPSCR, Floating-Point Status and Control Register</i> on page G4-3845
SPSR_abt	<i>SPSR_abt, Saved Program Status Register (Abort mode)</i> on page G4-4015
SPSR_fiq	<i>SPSR_fiq, Saved Program Status Register (FIQ mode)</i> on page G4-4019
SPSR_hyp	<i>SPSR_hyp, Saved Program Status Register (Hyp mode)</i> on page G4-4023
SPSR_irq	<i>SPSR_irq, Saved Program Status Register (IRQ mode)</i> on page G4-4027
SPSR_mon	<i>SPSR_mon, Saved Program Status Register (Monitor mode)</i> on page G4-4031
SPSR_svc	<i>SPSR_svc, Saved Program Status Register (Sup. Call mode)</i> on page G4-4035
SPSR_und	<i>SPSR_und, Saved Program Status Register (Undefined mode)</i> on page G4-4039

### J.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control functional group.

**Table J-19 VMSA-specific registers**

Register	Description, see
AMAIRO	<i>AMAIRO, Auxiliary Memory Attribute Indirection Register 0</i> on page G4-3780
AMAIR1	<i>AMAIR1, Auxiliary Memory Attribute Indirection Register 1</i> on page G4-3782
CONTEXTIDR	<i>CONTEXTIDR, Context ID Register</i> on page G4-3803
DACR	<i>DACR, Domain Access Control Register</i> on page G4-3817
HAMAIRO	<i>HAMAIRO, Hyp Auxiliary Memory Attribute Indirection Register 0</i> on page G4-3856
HMAIR1	<i>HMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1</i> on page G4-3857
HMAIRO	<i>HMAIRO, Hyp Memory Attribute Indirection Register 0</i> on page G4-3871
HMAIR1	<i>HMAIR1, Hyp Memory Attribute Indirection Register 1</i> on page G4-3874
HTCR	<i>HTCR, Hyp Translation Control Register</i> on page G4-3902
HTTBR	<i>HTTBR, Hyp Translation Table Base Register</i> on page G4-3905
MAIRO	<i>MAIRO, Memory Attribute Indirection Register 0</i> on page G4-3962
MAIR1	<i>MAIR1, Memory Attribute Indirection Register 1</i> on page G4-3965

**Table J-19 VMSA-specific registers (continued)**

Register	Description, see
NMRR	<i>NMRR, Normal Memory Remap Register on page G4-3982</i>
PRRR	<i>PRRR, Primary Region Remap Register on page G4-3992</i>
TTBCR	<i>TTBCR, Translation Table Base Control Register on page G4-4079</i>
TTBR0	<i>TTBR0, Translation Table Base Register 0 on page G4-4084</i>
TTBR1	<i>TTBR1, Translation Table Base Register 1 on page G4-4088</i>
VTCT	<i>VTCT, Virtualization Translation Control Register on page G4-4097</i>
VTCTBR	<i>VTCTBR, Virtualization Translation Table Base Register on page G4-4099</i>

### J.5.3 ID registers

This section is an index to the registers in the Identification functional group.

**Table J-20 ID registers**

Register	Description, see
AIDR	<i>AIDR, Auxiliary ID Register on page G4-3777</i>
CCSIDR	<i>CCSIDR, Current Cache Size ID Register on page G4-3799</i>
CLIDR	<i>CLIDR, Cache Level ID Register on page G4-3801</i>
CSSELR	<i>CSSELR, Cache Size Selection Register on page G4-3813</i>
CTR	<i>CTR, Cache Type Register on page G4-3815</i>
FPSID	<i>FPSID, Floating-Point System ID register on page G4-3850</i>
ID_AFR0	<i>ID_AFR0, Auxiliary Feature Register 0 on page G4-3911</i>
ID_DFR0	<i>ID_DFR0, Debug Feature Register 0 on page G4-3912</i>
ID_ISAR0	<i>ID_ISAR0, Instruction Set Attribute Register 0 on page G4-3914</i>
ID_ISAR1	<i>ID_ISAR1, Instruction Set Attribute Register 1 on page G4-3916</i>
ID_ISAR2	<i>ID_ISAR2, Instruction Set Attribute Register 2 on page G4-3919</i>
ID_ISAR3	<i>ID_ISAR3, Instruction Set Attribute Register 3 on page G4-3922</i>
ID_ISAR4	<i>ID_ISAR4, Instruction Set Attribute Register 4 on page G4-3925</i>
ID_ISAR5	<i>ID_ISAR5, Instruction Set Attribute Register 5 on page G4-3928</i>
ID_MMFR0	<i>ID_MMFR0, Memory Model Feature Register 0 on page G4-3930</i>
ID_MMFR1	<i>ID_MMFR1, Memory Model Feature Register 1 on page G4-3933</i>
ID_MMFR2	<i>ID_MMFR2, Memory Model Feature Register 2 on page G4-3937</i>
ID_MMFR3	<i>ID_MMFR3, Memory Model Feature Register 3 on page G4-3940</i>
ID_PFR0	<i>ID_PFR0, Processor Feature Register 0 on page G4-3943</i>
ID_PFR1	<i>ID_PFR1, Processor Feature Register 1 on page G4-3945</i>

**Table J-20 ID registers (continued)**

Register	Description, see
MIDR	<i>MIDR, Main ID Register</i> on page G4-3968
MPIDR	<i>MPIDR, Multiprocessor Affinity Register</i> on page G4-3970
MVFR0	<i>MVFR0, Media and VFP Feature Register 0</i> on page G4-3974
MVFR1	<i>MVFR1, Media and VFP Feature Register 1</i> on page G4-3977
MVFR2	<i>MVFR2, Media and VFP Feature Register 2</i> on page G4-3980
REVIDR	<i>REVIDR, Revision ID Register</i> on page G4-3995
TCMTR	<i>TCMTR, TCM Type Register</i> on page G4-4043
TLBTR	<i>TLBTR, TLB Type Register</i> on page G4-4075
VMPIDR	<i>VMPIDR, Virtualization Multiprocessor ID Register</i> on page G4-4093
VPIDR	<i>VPIDR, Virtualization Processor ID Register</i> on page G4-4095

#### J.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors functional group.

**Table J-21 Performance monitors registers**

Register	Description, see
PMCCFILTR	<i>PMCCFILTR, Performance Monitors Cycle Count Filter Register</i> on page G4-4170
PMCCNTR	<i>PMCCNTR, Performance Monitors Cycle Count Register</i> on page G4-4172
PMCEID0	<i>PMCEID0, Performance Monitors Common Event Identification register 0</i> on page G4-4174
PMCEID1	<i>PMCEID1, Performance Monitors Common Event Identification register 1</i> on page G4-4176
PMCNTENCLR	<i>PMCNTENCLR, Performance Monitors Count Enable Clear register</i> on page G4-4178
PMCNTENSET	<i>PMCNTENSET, Performance Monitors Count Enable Set register</i> on page G4-4180
PMCR	<i>PMCR, Performance Monitors Control Register</i> on page G4-4182
PMEVCNTR<n>	<i>PMEVCNTR&lt;n&gt;, Performance Monitors Event Count Registers, n = 0 - 30</i> on page G4-4185
PMEVTYPER<n>	<i>PMEVTYPER&lt;n&gt;, Performance Monitors Event Type Registers, n = 0 - 30</i> on page G4-4187
PMINTENCLR	<i>PMINTENCLR, Performance Monitors Interrupt Enable Clear register</i> on page G4-4190
PMINTENSET	<i>PMINTENSET, Performance Monitors Interrupt Enable Set register</i> on page G4-4192
PMOVSRR	<i>PMOVSRR, Performance Monitors Overflow Flag Status Register</i> on page G4-4194
PMOVSSET	<i>PMOVSSET, Performance Monitors Overflow Flag Status Set register</i> on page G4-4196
PMSELR	<i>PMSELR, Performance Monitors Event Counter Selection Register</i> on page G4-4198
PMSWINC	<i>PMSWINC, Performance Monitors Software Increment register</i> on page G4-4200

**Table J-21 Performance monitors registers (continued)**

Register	Description, see
PMUSERENR	<i>PMUSERENR, Performance Monitors User Enable Register on page G4-4202</i>
PMXEVCNTR	<i>PMXEVCNTR, Performance Monitors Selected Event Count Register on page G4-4204</i>
PMXEVTYPER	<i>PMXEVTYPER, Performance Monitors Selected Event Type Register on page G4-4206</i>

### J.5.5 Debug registers

This section is an index to the registers in the Debug functional group.

**Table J-22 Debug registers**

Register	Description, see
DBGAUTHSTATUS	<i>DBGAUTHSTATUS, Debug Authentication Status register on page G4-4101</i>
DBGBCR<n>	<i>DBGBCR&lt;n&gt;, Debug Breakpoint Control Registers, n = 0 - 15 on page G4-4103</i>
DBGBVR<n>	<i>DBGBVR&lt;n&gt;, Debug Breakpoint Value Registers, n = 0 - 15 on page G4-4106</i>
DBGBXVR<n>	<i>DBGBXVR&lt;n&gt;, Debug Breakpoint Extended Value Registers, n = 0 - 15 on page G4-4108</i>
DBGCLAIMCLR	<i>DBGCLAIMCLR, Debug Claim Tag Clear register on page G4-4110</i>
DBGCLAIMSET	<i>DBGCLAIMSET, Debug Claim Tag Set register on page G4-4112</i>
DBGDCCINT	<i>DBGDCCINT, DCC Interrupt Enable Register on page G4-4114</i>
DBGDEVID	<i>DBGDEVID, Debug Device ID register 0 on page G4-4116</i>
DBGDEVID1	<i>DBGDEVID1, Debug Device ID register 1 on page G4-4118</i>
DBGDEVID2	<i>DBGDEVID2, Debug Device ID register 2 on page G4-4119</i>
DBGDIDR	<i>DBGDIDR, Debug ID Register on page G4-4120</i>
DBGDRAR	<i>DBGDRAR, Debug ROM Address Register on page G4-4122</i>
DBGDSAR	<i>DBGDSAR, Debug Self Address Register on page G4-4124</i>
DBGDSCRext	<i>DBGDSCRext, Debug Status and Control Register, External View on page G4-4126</i>
DBGDSCRint	<i>DBGDSCRint, Debug Status and Control Register, Internal View on page G4-4130</i>
DBGDTRRXext	<i>DBGDTRRXext, Debug Data Transfer Register, Receive, External View on page G4-4132</i>
DBGDTRRXint	<i>DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View on page G4-4134</i>
DBGDTRTXext	<i>DBGDTRTXext, Debug Data Transfer Register, Transmit, External View on page G4-4136</i>
DBGDTRTXint	<i>DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View on page G4-4138</i>
DBGOSDLR	<i>DBGOSDLR, Debug OS Double Lock Register on page G4-4140</i>
DBGOSECCR	<i>DBGOSECCR, Debug OS Lock Exception Catch Control Register on page G4-4141</i>
DBGOSLAR	<i>DBGOSLAR, Debug OS Lock Access Register on page G4-4142</i>
DBGOSLSR	<i>DBGOSLSR, Debug OS Lock Status Register on page G4-4143</i>
DBGPRCR	<i>DBGPRCR, Debug Power Control Register on page G4-4145</i>

**Table J-22 Debug registers (continued)**

Register	Description, see
DBGVCR	<i>DBGVCR, Debug Vector Catch Register</i> on page G4-4147
DBGWCR<n>	<i>DBGWCR&lt;n&gt;, Debug Watchpoint Control Registers, n = 0 - 15</i> on page G4-4153
DBGWFAR	<i>DBGWFAR, Debug Watchpoint Fault Address Register</i> on page G4-4156
DBGWVR<n>	<i>DBGWVR&lt;n&gt;, Debug Watchpoint Value Registers, n = 0 - 15</i> on page G4-4157
DLR	<i>DLR, Debug Link Register</i> on page G4-4158
DSPSR	<i>DSPSR, Debug Saved Program Status Register</i> on page G4-4159
HDCCR	<i>HDCCR, Hyp Debug Control Register</i> on page G4-4163
SDCR	<i>SDCR, Secure Debug Configuration Register</i> on page G4-4166
SDER	<i>SDER, Secure Debug Enable Register</i> on page G4-4168

### J.5.6 Generic timer registers

This section is an index to the registers in the Generic Timer functional group.

**Table J-23 Generic timer registers**

Register	Description, see
CNTFRQ	<i>CNTFRQ, Counter-timer Frequency register</i> on page G4-4208
CNTHCTL	<i>CNTHCTL, Counter-timer Hyp Control register</i> on page G4-4209
CNTHP_CTL	<i>CNTHP_CTL, Counter-timer Hyp Physical Timer Control register</i> on page G4-4211
CNTHP_CVAL	<i>CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register</i> on page G4-4213
CNTHP_TVAL	<i>CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register</i> on page G4-4214
CNTKCTL	<i>CNTKCTL, Counter-timer Kernel Control register</i> on page G4-4215
CNTP_CTL	<i>CNTP_CTL, Counter-timer Physical Timer Control register</i> on page G4-4217
CNTP_CVAL	<i>CNTP_CVAL, Counter-timer Physical Timer CompareValue register</i> on page G4-4219
CNTP_TVAL	<i>CNTP_TVAL, Counter-timer Physical Timer TimerValue register</i> on page G4-4221
CNTPCT	<i>CNTPCT, Counter-timer Physical Count register</i> on page G4-4223
CNTV_CTL	<i>CNTV_CTL, Counter-timer Virtual Timer Control register</i> on page G4-4224
CNTV_CVAL	<i>CNTV_CVAL, Counter-timer Virtual Timer CompareValue register</i> on page G4-4226
CNTV_TVAL	<i>CNTV_TVAL, Counter-timer Virtual Timer TimerValue register</i> on page G4-4227
CNTVCT	<i>CNTVCT, Counter-timer Virtual Count register</i> on page G4-4228
CNTVOFF	<i>CNTVOFF, Counter-timer Virtual Offset register</i> on page G4-4229

## J.5.7 Generic Interrupt Controller CPU interface registers

This section is an index to the registers in the GIC functional group.

**Table J-24 Generic Interrupt Controller CPU interface registers**

Register	Description, see
ICC_AP0R0	<i>ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0) on page G4-4230</i>
ICC_AP0R1	<i>ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1) on page G4-4232</i>
ICC_AP0R2	<i>ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2) on page G4-4234</i>
ICC_AP0R3	<i>ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3) on page G4-4236</i>
ICC_AP1R0	<i>ICC_AP1R0, Interrupt Controller Active Priorities Register (1,0) on page G4-4238</i>
ICC_AP1R1	<i>ICC_AP1R1, Interrupt Controller Active Priorities Register (1,1) on page G4-4240</i>
ICC_AP1R2	<i>ICC_AP1R2, Interrupt Controller Active Priorities Register (1,2) on page G4-4242</i>
ICC_AP1R3	<i>ICC_AP1R3, Interrupt Controller Active Priorities Register (1,3) on page G4-4244</i>
ICC_ASGI1R	<i>ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register on page G4-4246</i>
ICC_BPR0	<i>ICC_BPR0, Interrupt Controller Binary Point Register 0 on page G4-4248</i>
ICC_BPR1	<i>ICC_BPR1, Interrupt Controller Binary Point Register 1 on page G4-4250</i>
ICC_CTLR	<i>ICC_CTLR, Interrupt Controller Control Register on page G4-4252</i>
ICC_DIR	<i>ICC_DIR, Interrupt Controller Deactivate Interrupt Register on page G4-4255</i>
ICC_EOIR0	<i>ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0 on page G4-4256</i>
ICC_EOIR1	<i>ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1 on page G4-4258</i>
ICC_HPPIR0	<i>ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0 on page G4-4260</i>
ICC_HPPIR1	<i>ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1 on page G4-4262</i>
ICC_HSRE	<i>ICC_HSRE, Interrupt Controller Hyp System Register Enable register on page G4-4263</i>
ICC_IAR0	<i>ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0 on page G4-4265</i>
ICC_IAR1	<i>ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1 on page G4-4267</i>
ICC_IGRPEN0	<i>ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register on page G4-4268</i>
ICC_IGRPEN1	<i>ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register on page G4-4270</i>
ICC_MCTLR	<i>ICC_MCTLR, Interrupt Controller Monitor Control Register on page G4-4271</i>
ICC_MGRPEN1	<i>ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register on page G4-4274</i>
ICC_MSRE	<i>ICC_MSRE, Interrupt Controller Monitor System Register Enable register on page G4-4276</i>
ICC_PMR	<i>ICC_PMR, Interrupt Controller Interrupt Priority Mask Register on page G4-4278</i>
ICC_RPR	<i>ICC_RPR, Interrupt Controller Running Priority Register on page G4-4280</i>
ICC_SEIEN	<i>ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register on page G4-4281</i>
ICC_SGI0R	<i>ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register on page G4-4282</i>
ICC_SGI1R	<i>ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register on page G4-4284</i>

**Table J-24 Generic Interrupt Controller CPU interface registers (continued)**

Register	Description, see
ICC_SRE	<i>ICC_SRE, Interrupt Controller System Register Enable register on page G4-4286</i>
ICH_AP0R0	<i>ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0) on page G4-4288</i>
ICH_AP0R1	<i>ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1) on page G4-4290</i>
ICH_AP0R2	<i>ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2) on page G4-4292</i>
ICH_AP0R3	<i>ICH_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3) on page G4-4294</i>
ICH_AP1R0	<i>ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0) on page G4-4296</i>
ICH_AP1R1	<i>ICH_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1) on page G4-4298</i>
ICH_AP1R2	<i>ICH_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2) on page G4-4300</i>
ICH_AP1R3	<i>ICH_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3) on page G4-4302</i>
ICH_EISR	<i>ICH_EISR, Interrupt Controller End of Interrupt Status Register on page G4-4304</i>
ICH_ELSR	<i>ICH_ELSR, Interrupt Controller Empty List Register Status Register on page G4-4306</i>
ICH_HCR	<i>ICH_HCR, Interrupt Controller Hyp Control Register on page G4-4308</i>
ICH_LRC<n>	<i>ICH_LRC&lt;n&gt;, Interrupt Controller List Registers, n = 0 - 15 on page G4-4311</i>
ICH_LR<n>	<i>ICH_LR&lt;n&gt;, Interrupt Controller List Registers, n = 0 - 15 on page G4-4313</i>
ICH_MISR	<i>ICH_MISR, Interrupt Controller Maintenance Interrupt State Register on page G4-4314</i>
ICH_VMCR	<i>ICH_VMCR, Interrupt Controller Virtual Machine Control Register on page G4-4316</i>
ICH_VSEIR	<i>ICH_VSEIR, Interrupt Controller Virtual System Error Interrupt Register on page G4-4318</i>
ICH_VTR	<i>ICH_VTR, Interrupt Controller VGIC Type Register on page G4-4319</i>

### J.5.8 Cache maintenance system instructions

This section is an index to the system instructions in the Cache maintenance functional group.

**Table J-25 Cache maintenance system instructions**

Register	Description, see
BPIALL	<i>BPIALL, Branch Predictor Invalidate All on page G4-3796</i>
BPIALLIS	<i>BPIALLIS, Branch Predictor Invalidate All, Inner Shareable on page G4-3797</i>
BPIMVA	<i>BPIMVA, Branch Predictor Invalidate VA on page G4-3798</i>
DCCIMVAC	<i>DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC on page G4-3819</i>
DCCISW	<i>DCCISW, Data Cache line Clean and Invalidate by Set/Way on page G4-3820</i>
DCCMVAC	<i>DCCMVAC, Data Cache line Clean by VA to PoC on page G4-3822</i>
DCCMVAU	<i>DCCMVAU, Data Cache line Clean by VA to PoU on page G4-3823</i>
DCCSW	<i>DCCSW, Data Cache line Clean by Set/Way on page G4-3824</i>
DCIMVAC	<i>DCIMVAC, Data Cache line Invalidate by VA to PoC on page G4-3826</i>

**Table J-25 Cache maintenance system instructions (continued)**

Register	Description, see
DCISW	<i>DCISW, Data Cache line Invalidate by Set/Way</i> on page G4-3827
ICIALLU	<i>ICIALLU, Instruction Cache Invalidate All to PoU</i> on page G4-3908
ICIALLUIS	<i>ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable</i> on page G4-3909
ICIMVAU	<i>ICIMVAU, Instruction Cache line Invalidate by VA to PoU</i> on page G4-3910

### J.5.9 Address translation system instructions

This section is an index to the system instructions in the Address translation functional group.

**Table J-26 Address translation system instructions**

Register	Description, see
ATS12NSOPR	<i>ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read</i> on page G4-3786
ATS12NSOPW	<i>ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write</i> on page G4-3787
ATS12NSOUR	<i>ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read</i> on page G4-3788
ATS12NSOUW	<i>ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write</i> on page G4-3789
ATS1CPR	<i>ATS1CPR, Address Translate Stage 1 Current state PL1 Read</i> on page G4-3790
ATS1CPW	<i>ATS1CPW, Address Translate Stage 1 Current state PL1 Write</i> on page G4-3791
ATS1CUR	<i>ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read</i> on page G4-3792
ATS1CUW	<i>ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write</i> on page G4-3793
ATS1HR	<i>ATS1HR, Address Translate Stage 1 Hyp mode Read</i> on page G4-3794
ATS1HW	<i>ATS1HW, Address Translate Stage 1 Hyp mode Write</i> on page G4-3795

### J.5.10 TLB maintenance system instructions

This section is an index to the system instructions in the TLB maintenance functional group.

**Table J-27 TLB maintenance system instructions**

Register	Description, see
DTLBIALL	<i>DTLBIALL, Data TLB Invalidate All entries</i> on page G4-3836
DTLBIASID	<i>DTLBIASID, Data TLB Invalidate by ASID match</i> on page G4-3837
DTLBIMVA	<i>DTLBIMVA, Data TLB Invalidate entry by VA</i> on page G4-3838
ITLBIALL	<i>ITLBIALL, Instruction TLB Invalidate All entries</i> on page G4-3956
ITLBIASID	<i>ITLBIASID, Instruction TLB Invalidate by ASID match</i> on page G4-3957
ITLBIMVA	<i>ITLBIMVA, Instruction TLB Invalidate entry by VA</i> on page G4-3958

**Table J-27 TLB maintenance system instructions (continued)**

<b>Register</b>	<b>Description, see</b>
TLBIALL	<i>TLBIALL, TLB Invalidate All entries on page G4-4048</i>
TLBIALLH	<i>TLBIALLH, TLB Invalidate All entries, Hyp mode on page G4-4049</i>
TLBIALLHIS	<i>TLBIALLHIS, TLB Invalidate All entries, Hyp mode, Inner Shareable on page G4-4050</i>
TLBIALLIS	<i>TLBIALLIS, TLB Invalidate All entries, Inner Shareable on page G4-4051</i>
TLBIALLNSNH	<i>TLBIALLNSNH, TLB Invalidate All entries, Non-Secure Non-Hyp on page G4-4052</i>
TLBIALLNSNHIS	<i>TLBIALLNSNHIS, TLB Invalidate All entries, Non-Secure Non-Hyp, Inner Shareable on page G4-4053</i>
TLBIASID	<i>TLBIASID, TLB Invalidate entry by ASID match on page G4-4054</i>
TLBIASIDIS	<i>TLBIASIDIS, TLB Invalidate entry by ASID match, Inner Shareable on page G4-4055</i>
TLBIIPAS2	<i>TLBIIPAS2, TLB Invalidate entry by Intermediate Physical Address, Stage 2 on page G4-4056</i>
TLBIIPAS2IS	<i>TLBIIPAS2IS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Inner Shareable on page G4-4057</i>
TLBIIPAS2L	<i>TLBIIPAS2L, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level on page G4-4058</i>
TLBIIPAS2LIS	<i>TLBIIPAS2LIS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level, Inner Shareable on page G4-4059</i>
TLBIMVA	<i>TLBIMVA, TLB Invalidate entry by VA on page G4-4060</i>
TLBIMVAA	<i>TLBIMVAA, TLB Invalidate entry by VA, All ASID on page G4-4061</i>
TLBIMVAAIS	<i>TLBIMVAAIS, TLB Invalidate entry by VA, All ASID, Inner Shareable on page G4-4062</i>
TLBIMVAAL	<i>TLBIMVAAL, TLB Invalidate entry by VA, All ASID, Last level on page G4-4063</i>
TLBIMVAALIS	<i>TLBIMVAALIS, TLB Invalidate entry by VA, All ASID, Last level, Inner Shareable on page G4-4064</i>
TLBIMVAH	<i>TLBIMVAH, TLB Invalidate entry by VA, Hyp mode on page G4-4065</i>
TLBIMVAHIS	<i>TLBIMVAHIS, TLB Invalidate entry by VA, Hyp mode, Inner Shareable on page G4-4066</i>
TLBIMVAIS	<i>TLBIMVAIS, TLB Invalidate entry by VA, Inner Shareable on page G4-4068</i>
TLBIMVAL	<i>TLBIMVAL, TLB Invalidate entry by VA, Last level on page G4-4069</i>
TLBIMVALH	<i>TLBIMVALH, TLB Invalidate entry by VA, Last level, Hyp mode on page G4-4070</i>
TLBIMVALHIS	<i>TLBIMVALHIS, TLB Invalidate entry by VA, Last level, Hyp mode, Inner Shareable on page G4-4072</i>
TLBIMVALIS	<i>TLBIMVALIS, TLB Invalidate entry by VA, Last level, Inner Shareable on page G4-4074</i>

## J.5.11 Legacy feature registers and system instructions

This section is an index to the registers and system instructions in the Legacy feature functional group.

**Table J-28 Legacy feature registers and system instructions**

Register	Description, see
CP15DMB	<i>CP15DMB, CP15 Data Memory Barrier operation on page G4-3805</i>
CP15DSB	<i>CP15DSB, CP15 Data Synchronization Barrier operation on page G4-3806</i>
CP15ISB	<i>CP15ISB, CP15 Instruction Synchronization Barrier operation on page G4-3807</i>
FCSEIDR	<i>FCSEIDR, FCSE Process ID register on page G4-3840</i>
JIDR	<i>JIDR, Jazelle ID Register on page G4-3959</i>
JMCR	<i>JMCR, Jazelle Main Configuration Register on page G4-3960</i>
JOSCR	<i>JOSCR, Jazelle OS Control Register on page G4-3961</i>
TEECR	<i>TEECR, T32EE Configuration Register on page G4-4045</i>
TEEHBR	<i>TEEHBR, T32EE Handler Base Register on page G4-4047</i>

## J.5.12 Base system registers

This section is an index to the registers that are not a part of any of the other functional groups in this index.

**Table J-29 Base system registers**

Register	Description, see
ACTLR	<i>ACTLR, Auxiliary Control Register on page G4-3773</i>
ADFSR	<i>ADFSR, Auxiliary Data Fault Status Register on page G4-3775</i>
AIFSR	<i>AIFSR, Auxiliary Instruction Fault Status Register on page G4-3778</i>
APSR	<i>APSR, Application Program Status Register on page G4-3784</i>
CPACR	<i>CPACR, Architectural Feature Access Control Register on page G4-3808</i>
CPSR	<i>CPSR, Current Program Status Register on page G4-3810</i>
DFAR	<i>DFAR, Data Fault Address Register on page G4-3829</i>
DFSR	<i>DFSR, Data Fault Status Register on page G4-3831</i>
FPEXC	<i>FPEXC, Floating-Point Exception Control register on page G4-3841</i>
HACR	<i>HACR, Hyp Auxiliary Configuration Register on page G4-3852</i>
HACTLR	<i>HACTLR, Hyp Auxiliary Control Register on page G4-3853</i>
HADFSR	<i>HADFSR, Hyp Auxiliary Data Fault Status Register on page G4-3854</i>
HAIFSR	<i>HAIFSR, Hyp Auxiliary Instruction Fault Status Register on page G4-3855</i>
HCPTR	<i>HCPTR, Hyp Architectural Feature Trap Register on page G4-3858</i>
HCR	<i>HCR, Hyp Configuration Register on page G4-3861</i>
HCR2	<i>HCR2, Hyp Configuration Register 2 on page G4-3867</i>

**Table J-29 Base system registers (continued)**

<b>Register</b>	<b>Description, see</b>
HDFAR	<i>HDFAR, Hyp Data Fault Address Register on page G4-3869</i>
HIFAR	<i>HIFAR, Hyp Instruction Fault Address Register on page G4-3870</i>
HPFAR	<i>HPFAR, Hyp IPA Fault Address Register on page G4-3877</i>
HRMR	<i>HRMR, Hyp Reset Management Register on page G4-3878</i>
HSCTLR	<i>HSCTLR, Hyp System Control Register on page G4-3880</i>
HSR	<i>HSR, Hyp Syndrome Register on page G4-3885</i>
HSTR	<i>HSTR, Hyp System Trap Register on page G4-3900</i>
HTPIDR	<i>HTPIDR, Hyp Thread Pointer / ID Register on page G4-3904</i>
HVBAR	<i>HVBAR, Hyp Vector Base Address Register on page G4-3907</i>
IFAR	<i>IFAR, Instruction Fault Address Register on page G4-3948</i>
IFSR	<i>IFSR, Instruction Fault Status Register on page G4-3950</i>
ISR	<i>ISR, Interrupt Status Register on page G4-3954</i>
MVBAR	<i>MVBAR, Monitor Vector Base Address Register on page G4-3972</i>
NSACR	<i>NSACR, Non-Secure Access Control Register on page G4-3984</i>
PAR	<i>PAR, Physical Address Register on page G4-3986</i>
RMR (at EL1)	<i>RMR (at EL1), Reset Management Register on page G4-3996</i>
RMR (at EL3)	<i>RMR (at EL3), Reset Management Register on page G4-3998</i>
RVBAR	<i>RVBAR, Reset Vector Base Address Register on page G4-4000</i>
SCR	<i>SCR, Secure Configuration Register on page G4-4001</i>
SCTLR	<i>SCTLR, System Control Register on page G4-4005</i>
SPSR	<i>SPSR, Saved Program Status Register on page G4-4012</i>
TPIDRPRW	<i>TPIDRPRW, Thread Pointer / ID Register, Privileged Read-Write on page G4-4076</i>
TPIDRURO	<i>TPIDRURO, Thread Pointer / ID Register, Unprivileged Read-Only on page G4-4077</i>
TPIDRURW	<i>TPIDRURW, Thread Pointer / ID Register, Unprivileged Read-Write on page G4-4078</i>
VBAR	<i>VBAR, Vector Base Address Register on page G4-4091</i>

## J.6 Alphabetical index of memory-mapped registers

This section is an index of memory-mapped registers in alphabetical order.

**Table J-30 Alphabetical index of Memory-Mapped Registers**

Register	Description, see
ASICCTL	<i>ASICCTL</i> , CTI External Multiplexer Control register on page H9-4554
CNTACR<n>	<i>CNTACR&lt;n&gt;</i> , Counter-timer Access Control Registers, $n = 0 - 7$ on page I1-4648
CNTCR	<i>CNTCR</i> , Counter Control Register on page I1-4650
CNTCV	<i>CNTCV</i> , Counter Count Value register on page I1-4652
CNTELOACR	<i>CNTELOACR</i> , Counter-timer EL0 Access Control Register on page I1-4653
CNTFID0	<i>CNTFID0</i> , Counter Frequency ID on page I1-4655
CNTFID<n>	<i>CNTFID&lt;n&gt;</i> , Counter Frequency IDs, $n = 1 - 23$ on page I1-4656
CNTFRQ	<i>CNTFRQ</i> , Counter-timer Frequency on page I1-4657
CNTNSAR	<i>CNTNSAR</i> , Counter-timer Non-secure Access Register on page I1-4658
CNTP_CTL	<i>CNTP_CTL</i> , Counter-timer Physical Timer Control on page I1-4660
CNTP_CVAL	<i>CNTP_CVAL</i> , Counter-timer Physical Timer CompareValue on page I1-4662
CNTP_TVAL	<i>CNTP_TVAL</i> , Counter-timer Physical Timer TimerValue on page I1-4663
CNTPCT	<i>CNTPCT</i> , Counter-timer Physical Count on page I1-4664
CNTSR	<i>CNTSR</i> , Counter Status Register on page I1-4665
CNTTIDR	<i>CNTTIDR</i> , Counter-timer Timer ID Register on page I1-4667
CNTV_CTL	<i>CNTV_CTL</i> , Counter-timer Virtual Timer Control on page I1-4669
CNTV_CVAL	<i>CNTV_CVAL</i> , Counter-timer Virtual Timer CompareValue on page I1-4671
CNTV_TVAL	<i>CNTV_TVAL</i> , Counter-timer Virtual Timer TimerValue on page I1-4673
CNTVCT	<i>CNTVCT</i> , Counter-timer Virtual Count on page I1-4674
CNTVOFF	<i>CNTVOFF</i> , Counter-timer Virtual Offset on page I1-4675
CNTVOFF<n>	<i>CNTVOFF&lt;n&gt;</i> , Counter-timer Virtual Offsets, $n = 0 - 7$ on page I1-4676
CounterID<n>	<i>CounterID&lt;n&gt;</i> , Counter ID registers, $n = 0 - 11$ on page I1-4677
CTIAPPCLEAR	<i>CTIAPPCLEAR</i> , CTI Application Trigger Clear register on page H9-4555
CTIAPPULSE	<i>CTIAPPULSE</i> , CTI Application Pulse register on page H9-4556
CTIAPPSET	<i>CTIAPPSET</i> , CTI Application Trigger Set register on page H9-4557
CTIAUTHSTATUS	<i>CTIAUTHSTATUS</i> , CTI Authentication Status register on page H9-4558
CTICHINSTATUS	<i>CTICHINSTATUS</i> , CTI Channel In Status register on page H9-4560
CTICHOUTSTATUS	<i>CTICHOUTSTATUS</i> , CTI Channel Out Status register on page H9-4561
CTICIDR0	<i>CTICIDR0</i> , CTI Component Identification Register 0 on page H9-4562
CTICIDR1	<i>CTICIDR1</i> , CTI Component Identification Register 1 on page H9-4563

**Table J-30 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
CTICIDR2	<i>CTICIDR2, CTI Component Identification Register 2</i> on page H9-4564
CTICIDR3	<i>CTICIDR3, CTI Component Identification Register 3</i> on page H9-4565
CTICLAIMCLR	<i>CTICLAIMCLR, CTI Claim Tag Clear register</i> on page H9-4566
CTICLAIMSET	<i>CTICLAIMSET, CTI Claim Tag Set register</i> on page H9-4567
CTICONTROL	<i>CTICONTROL, CTI Control register</i> on page H9-4568
CTIDEVAFF0	<i>CTIDEVAFF0, CTI Device Affinity register 0</i> on page H9-4569
CTIDEVAFF1	<i>CTIDEVAFF1, CTI Device Affinity register 1</i> on page H9-4570
CTIDEVARCH	<i>CTIDEVARCH, CTI Device Architecture register</i> on page H9-4571
CTIDEVID	<i>CTIDEVID, CTI Device ID register 0</i> on page H9-4573
CTIDEVID1	<i>CTIDEVID1, CTI Device ID register 1</i> on page H9-4575
CTIDEVID2	<i>CTIDEVID2, CTI Device ID register 2</i> on page H9-4576
CTIDEVTYPE	<i>CTIDEVTYPE, CTI Device Type register</i> on page H9-4577
CTIGATE	<i>CTIGATE, CTI Channel Gate Enable register</i> on page H9-4578
CTIINEN<n>	<i>CTIINEN&lt;n&gt;, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31</i> on page H9-4579
CTIINTACK	<i>CTIINTACK, CTI Output Trigger Acknowledge register</i> on page H9-4580
CTIITCTRL	<i>CTIITCTRL, CTI Integration mode Control register</i> on page H9-4582
CTILAR	<i>CTILAR, CTI Lock Access Register</i> on page H9-4583
CTILSR	<i>CTILSR, CTI Lock Status Register</i> on page H9-4584
CTIOUTEN<n>	<i>CTIOUTEN&lt;n&gt;, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31</i> on page H9-4586
CTIPIDR0	<i>CTIPIDR0, CTI Peripheral Identification Register 0</i> on page H9-4587
CTIPIDR1	<i>CTIPIDR1, CTI Peripheral Identification Register 1</i> on page H9-4588
CTIPIDR2	<i>CTIPIDR2, CTI Peripheral Identification Register 2</i> on page H9-4589
CTIPIDR3	<i>CTIPIDR3, CTI Peripheral Identification Register 3</i> on page H9-4590
CTIPIDR4	<i>CTIPIDR4, CTI Peripheral Identification Register 4</i> on page H9-4591
CTITRIGINSTATUS	<i>CTITRIGINSTATUS, CTI Trigger In Status register</i> on page H9-4592
CTITRIGOUTSTATUS	<i>CTITRIGOUTSTATUS, CTI Trigger Out Status register</i> on page H9-4593
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1, Debug Authentication Status register</i> on page H9-4469
DBGBCR<n>_EL1	<i>DBGBCR&lt;n&gt;_EL1, Debug Breakpoint Control Registers, n = 0 - 15</i> on page H9-4471
DBGBVR<n>_EL1	<i>DBGBVR&lt;n&gt;_EL1, Debug Breakpoint Value Registers, n = 0 - 15</i> on page H9-4474
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1, Debug Claim Tag Clear register</i> on page H9-4477
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1, Debug Claim Tag Set register</i> on page H9-4478
DBGDTRRX_EL0	<i>DBGDTRRX_EL0, Debug Data Transfer Register, Receive</i> on page H9-4479

**Table J-30 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
DBGDTRTX_EL0	<i>DBGDTRTX_EL0, Debug Data Transfer Register, Transmit on page H9-4480</i>
DBGWCR<n>_EL1	<i>DBGWCR&lt;n&gt;_EL1, Debug Watchpoint Control Registers, n = 0 - 15 on page H9-4481</i>
DBGWVR<n>_EL1	<i>DBGWVR&lt;n&gt;_EL1, Debug Watchpoint Value Registers, n = 0 - 15 on page H9-4484</i>
EDACR	<i>EDACR, External Debug Auxiliary Control Register on page H9-4486</i>
EDCIDR0	<i>EDCIDR0, External Debug Component Identification Register 0 on page H9-4487</i>
EDCIDR1	<i>EDCIDR1, External Debug Component Identification Register 1 on page H9-4488</i>
EDCIDR2	<i>EDCIDR2, External Debug Component Identification Register 2 on page H9-4489</i>
EDCIDR3	<i>EDCIDR3, External Debug Component Identification Register 3 on page H9-4490</i>
EDCIDSR	<i>EDCIDSR, External Debug Context ID Sample Register on page H9-4491</i>
EDDEVAFF0	<i>EDDEVAFF0, External Debug Device Affinity register 0 on page H9-4492</i>
EDDEVAFF1	<i>EDDEVAFF1, External Debug Device Affinity register 1 on page H9-4493</i>
EDDEVARCH	<i>EDDEVARCH, External Debug Device Architecture register on page H9-4494</i>
EDDEVID	<i>EDDEVID, External Debug Device ID register 0 on page H9-4496</i>
EDDEVID1	<i>EDDEVID1, External Debug Device ID register 1 on page H9-4498</i>
EDDEVID2	<i>EDDEVID2, External Debug Device ID register 2 on page H9-4499</i>
EDDEVTYPE	<i>EDDEVTYPE, External Debug Device Type register on page H9-4500</i>
EDECCECR	<i>EDECCECR, External Debug Exception Catch Control Register on page H9-4501</i>
EDECRCR	<i>EDECRCR, External Debug Execution Control Register on page H9-4503</i>
EDESRCR	<i>EDESRCR, External Debug Event Status Register on page H9-4505</i>
EDITCTRL	<i>EDITCTRL, External Debug Integration mode Control register on page H9-4507</i>
EDITRCR	<i>EDITRCR, External Debug Instruction Transfer Register on page H9-4508</i>
EDLRCR	<i>EDLRCR, External Debug Lock Access Register on page H9-4510</i>
EDLSRCR	<i>EDLSRCR, External Debug Lock Status Register on page H9-4511</i>
EDPCSCR	<i>EDPCSCR, External Debug Program Counter Sample Register on page H9-4513</i>
EDPIDR0	<i>EDPIDR0, External Debug Peripheral Identification Register 0 on page H9-4515</i>
EDPIDR1	<i>EDPIDR1, External Debug Peripheral Identification Register 1 on page H9-4516</i>
EDPIDR2	<i>EDPIDR2, External Debug Peripheral Identification Register 2 on page H9-4517</i>
EDPIDR3	<i>EDPIDR3, External Debug Peripheral Identification Register 3 on page H9-4518</i>
EDPIDR4	<i>EDPIDR4, External Debug Peripheral Identification Register 4 on page H9-4519</i>
EDPRRCR	<i>EDPRRCR, External Debug Power/Reset Control Register on page H9-4520</i>
EDPRSRCR	<i>EDPRSRCR, External Debug Processor Status Register on page H9-4523</i>
EDRCRCR	<i>EDRCRCR, External Debug Reserve Control Register on page H9-4529</i>

**Table J-30 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
EDSCR	<i>EDSCR, External Debug Status and Control Register</i> on page H9-4531
EDVIDSR	<i>EDVIDSR, External Debug Virtual Context Sample Register</i> on page H9-4535
EDWAR	<i>EDWAR, External Debug Watchpoint Address Register</i> on page H9-4537
ID_AA64DFR0_EL1	<i>ID_AA64DFR0_EL1, Debug Feature Register 0</i> on page H9-4538
ID_AA64DFR1_EL1	<i>ID_AA64DFR1_EL1, Debug Feature Register 1</i> on page H9-4540
ID_AA64ISAR0_EL1	<i>ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0</i> on page H9-4541
ID_AA64ISAR1_EL1	<i>ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1</i> on page H9-4543
ID_AA64MMFR0_EL1	<i>ID_AA64MMFR0_EL1, Memory Model Feature Register 0</i> on page H9-4544
ID_AA64MMFR1_EL1	<i>ID_AA64MMFR1_EL1, Memory Model Feature Register 1</i> on page H9-4547
ID_AA64PFR0_EL1	<i>ID_AA64PFR0_EL1, Processor Feature Register 0</i> on page H9-4548
ID_AA64PFR1_EL1	<i>ID_AA64PFR1_EL1, Processor Feature Register 1</i> on page H9-4550
MIDR_EL1	<i>MIDR_EL1, Main ID Register</i> on page H9-4551
OSLAR_EL1	<i>OSLAR_EL1, OS Lock Access Register</i> on page H9-4553
PMAUTHSTATUS	<i>PMAUTHSTATUS, Performance Monitors Authentication Status register</i> on page I1-4599
PMCCFILTR_EL0	<i>PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register</i> on page I1-4601
PMCCNTR_EL0	<i>PMCCNTR_EL0, Performance Monitors Cycle Counter</i> on page I1-4603
PMCEID0_EL0	<i>PMCEID0_EL0, Performance Monitors Common Event Identification register 0</i> on page I1-4604
PMCEID1_EL0	<i>PMCEID1_EL0, Performance Monitors Common Event Identification register 1</i> on page I1-4606
PMCFGR	<i>PMCFGR, Performance Monitors Configuration Register</i> on page I1-4608
PMCIDR0	<i>PMCIDR0, Performance Monitors Component Identification Register 0</i> on page I1-4610
PMCIDR1	<i>PMCIDR1, Performance Monitors Component Identification Register 1</i> on page I1-4611
PMCIDR2	<i>PMCIDR2, Performance Monitors Component Identification Register 2</i> on page I1-4612
PMCIDR3	<i>PMCIDR3, Performance Monitors Component Identification Register 3</i> on page I1-4613
PMCNTENCLR_EL0	<i>PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register</i> on page I1-4614
PMCNTENSET_EL0	<i>PMCNTENSET_EL0, Performance Monitors Count Enable Set register</i> on page I1-4616
PMCR_EL0	<i>PMCR_EL0, Performance Monitors Control Register</i> on page I1-4618
PMDEVAFF0	<i>PMDEVAFF0, Performance Monitors Device Affinity register 0</i> on page I1-4620
PMDEVAFF1	<i>PMDEVAFF1, Performance Monitors Device Affinity register 1</i> on page I1-4621
PMDEVARCH	<i>PMDEVARCH, Performance Monitors Device Architecture register</i> on page I1-4622
PMDEVTYPE	<i>PMDEVTYPE, Performance Monitors Device Type register</i> on page I1-4624
PMEVCNTR<n>_EL0	<i>PMEVCNTR&lt;n&gt;_EL0, Performance Monitors Event Count Registers, n = 0 - 30</i> on page I1-4625
PMEVTYPER<n>_EL0	<i>PMEVTYPER&lt;n&gt;_EL0, Performance Monitors Event Type Registers, n = 0 - 30</i> on page I1-4626

**Table J-30 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
PMINTENCLR_EL1	<i>PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register on page I1-4628</i>
PMINTENSET_EL1	<i>PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register on page I1-4630</i>
PMITCTRL	<i>PMITCTRL, Performance Monitors Integration mode Control register on page I1-4632</i>
PMLAR	<i>PMLAR, Performance Monitors Lock Access Register on page I1-4633</i>
PMLSR	<i>PMLSR, Performance Monitors Lock Status Register on page I1-4634</i>
PMOVSCLR_EL0	<i>PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register on page I1-4636</i>
PMOVSSET_EL0	<i>PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register on page I1-4638</i>
PMPIDR0	<i>PMPIDR0, Performance Monitors Peripheral Identification Register 0 on page I1-4640</i>
PMPIDR1	<i>PMPIDR1, Performance Monitors Peripheral Identification Register 1 on page I1-4641</i>
PMPIDR2	<i>PMPIDR2, Performance Monitors Peripheral Identification Register 2 on page I1-4642</i>
PMPIDR3	<i>PMPIDR3, Performance Monitors Peripheral Identification Register 3 on page I1-4643</i>
PMPIDR4	<i>PMPIDR4, Performance Monitors Peripheral Identification Register 4 on page I1-4644</i>
PMSWINC_EL0	<i>PMSWINC_EL0, Performance Monitors Software Increment register on page I1-4645</i>

## J.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group.

### J.7.1 ID registers

This section is an index to the registers in the Identification functional group.

**Table J-31 ID registers**

Register	Description, see
ID_AA64DFR0_EL1	<i>ID_AA64DFR0_EL1, Debug Feature Register 0</i> on page H9-4538
ID_AA64DFR1_EL1	<i>ID_AA64DFR1_EL1, Debug Feature Register 1</i> on page H9-4540
ID_AA64ISAR0_EL1	<i>ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0</i> on page H9-4541
ID_AA64ISAR1_EL1	<i>ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1</i> on page H9-4543
ID_AA64MMFR0_EL1	<i>ID_AA64MMFR0_EL1, Memory Model Feature Register 0</i> on page H9-4544
ID_AA64MMFR1_EL1	<i>ID_AA64MMFR1_EL1, Memory Model Feature Register 1</i> on page H9-4547
ID_AA64PFR0_EL1	<i>ID_AA64PFR0_EL1, Processor Feature Register 0</i> on page H9-4548
ID_AA64PFR1_EL1	<i>ID_AA64PFR1_EL1, Processor Feature Register 1</i> on page H9-4550
MIDR_EL1	<i>MIDR_EL1, Main ID Register</i> on page H9-4551

### J.7.2 Performance monitors registers

This section is an index to the registers in the Performance Monitors functional group.

**Table J-32 Performance monitors registers**

Register	Description, see
PMAUTHSTATUS	<i>PMAUTHSTATUS, Performance Monitors Authentication Status register</i> on page I1-4599
PMCCFILTR_EL0	<i>PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register</i> on page I1-4601
PMCCNTR_EL0	<i>PMCCNTR_EL0, Performance Monitors Cycle Counter</i> on page I1-4603
PMCEID0_EL0	<i>PMCEID0_EL0, Performance Monitors Common Event Identification register 0</i> on page I1-4604
PMCEID1_EL0	<i>PMCEID1_EL0, Performance Monitors Common Event Identification register 1</i> on page I1-4606
PMCFGR	<i>PMCFGR, Performance Monitors Configuration Register</i> on page I1-4608
PMCIDR0	<i>PMCIDR0, Performance Monitors Component Identification Register 0</i> on page I1-4610
PMCIDR1	<i>PMCIDR1, Performance Monitors Component Identification Register 1</i> on page I1-4611
PMCIDR2	<i>PMCIDR2, Performance Monitors Component Identification Register 2</i> on page I1-4612
PMCIDR3	<i>PMCIDR3, Performance Monitors Component Identification Register 3</i> on page I1-4613
PMCNTENCLR_EL0	<i>PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register</i> on page I1-4614
PMCNTENSET_EL0	<i>PMCNTENSET_EL0, Performance Monitors Count Enable Set register</i> on page I1-4616
PMCR_EL0	<i>PMCR_EL0, Performance Monitors Control Register</i> on page I1-4618
PMDEVAFF0	<i>PMDEVAFF0, Performance Monitors Device Affinity register 0</i> on page I1-4620

**Table J-32 Performance monitors registers (continued)**

Register	Description, see
PMDEVAFF1	<i>PMDEVAFF1, Performance Monitors Device Affinity register 1</i> on page I1-4621
PMDEVARCH	<i>PMDEVARCH, Performance Monitors Device Architecture register</i> on page I1-4622
PMDEVTYPE	<i>PMDEVTYPE, Performance Monitors Device Type register</i> on page I1-4624
PMEVCNTR<n>_EL0	<i>PMEVCNTR&lt;n&gt;_EL0, Performance Monitors Event Count Registers, n = 0 - 30</i> on page I1-4625
PMEVTYPER<n>_EL0	<i>PMEVTYPER&lt;n&gt;_EL0, Performance Monitors Event Type Registers, n = 0 - 30</i> on page I1-4626
PMINTENCLR_EL1	<i>PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register</i> on page I1-4628
PMINTENSET_EL1	<i>PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register</i> on page I1-4630
PMITCTRL	<i>PMITCTRL, Performance Monitors Integration mode Control register</i> on page I1-4632
PMLAR	<i>PMLAR, Performance Monitors Lock Access Register</i> on page I1-4633
PMSLR	<i>PMSLR, Performance Monitors Lock Status Register</i> on page I1-4634
PMOVSCLR_EL0	<i>PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register</i> on page I1-4636
PMOVSSET_EL0	<i>PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register</i> on page I1-4638
PMPIDR0	<i>PMPIDR0, Performance Monitors Peripheral Identification Register 0</i> on page I1-4640
PMPIDR1	<i>PMPIDR1, Performance Monitors Peripheral Identification Register 1</i> on page I1-4641
PMPIDR2	<i>PMPIDR2, Performance Monitors Peripheral Identification Register 2</i> on page I1-4642
PMPIDR3	<i>PMPIDR3, Performance Monitors Peripheral Identification Register 3</i> on page I1-4643
PMPIDR4	<i>PMPIDR4, Performance Monitors Peripheral Identification Register 4</i> on page I1-4644
PMSWINC_EL0	<i>PMSWINC_EL0, Performance Monitors Software Increment register</i> on page I1-4645

### J.7.3 Debug registers

This section is an index to the registers in the Debug functional group.

**Table J-33 Debug registers**

Register	Description, see
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1, Debug Authentication Status register</i> on page H9-4469
DBGBCR<n>_EL1	<i>DBGBCR&lt;n&gt;_EL1, Debug Breakpoint Control Registers, n = 0 - 15</i> on page H9-4471
DBGBVR<n>_EL1	<i>DBGBVR&lt;n&gt;_EL1, Debug Breakpoint Value Registers, n = 0 - 15</i> on page H9-4474
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1, Debug Claim Tag Clear register</i> on page H9-4477
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1, Debug Claim Tag Set register</i> on page H9-4478
DBGDTRRX_EL0	<i>DBGDTRRX_EL0, Debug Data Transfer Register, Receive</i> on page H9-4479
DBGDTRTX_EL0	<i>DBGDTRTX_EL0, Debug Data Transfer Register, Transmit</i> on page H9-4480
DBGWCR<n>_EL1	<i>DBGWCR&lt;n&gt;_EL1, Debug Watchpoint Control Registers, n = 0 - 15</i> on page H9-4481
DBGWVR<n>_EL1	<i>DBGWVR&lt;n&gt;_EL1, Debug Watchpoint Value Registers, n = 0 - 15</i> on page H9-4484

**Table J-33 Debug registers (continued)**

<b>Register</b>	<b>Description, see</b>
EDACR	<i>EDACR, External Debug Auxiliary Control Register on page H9-4486</i>
EDCIDR0	<i>EDCIDR0, External Debug Component Identification Register 0 on page H9-4487</i>
EDCIDR1	<i>EDCIDR1, External Debug Component Identification Register 1 on page H9-4488</i>
EDCIDR2	<i>EDCIDR2, External Debug Component Identification Register 2 on page H9-4489</i>
EDCIDR3	<i>EDCIDR3, External Debug Component Identification Register 3 on page H9-4490</i>
EDCISR	<i>EDCISR, External Debug Context ID Sample Register on page H9-4491</i>
EDDEVAFF0	<i>EDDEVAFF0, External Debug Device Affinity register 0 on page H9-4492</i>
EDDEVAFF1	<i>EDDEVAFF1, External Debug Device Affinity register 1 on page H9-4493</i>
EDDEVARCH	<i>EDDEVARCH, External Debug Device Architecture register on page H9-4494</i>
EDDEVID	<i>EDDEVID, External Debug Device ID register 0 on page H9-4496</i>
EDDEVID1	<i>EDDEVID1, External Debug Device ID register 1 on page H9-4498</i>
EDDEVID2	<i>EDDEVID2, External Debug Device ID register 2 on page H9-4499</i>
EDDEVTYPE	<i>EDDEVTYPE, External Debug Device Type register on page H9-4500</i>
EDECCR	<i>EDECCR, External Debug Exception Catch Control Register on page H9-4501</i>
EDECR	<i>EDECR, External Debug Execution Control Register on page H9-4503</i>
EDESR	<i>EDESR, External Debug Event Status Register on page H9-4505</i>
EDITCTRL	<i>EDITCTRL, External Debug Integration mode Control register on page H9-4507</i>
EDITR	<i>EDITR, External Debug Instruction Transfer Register on page H9-4508</i>

# Glossary

---

## Note

---

The update of the Glossary from ARMv7 to ARMv8 has been started but remains work-in-progress.

---

- A32 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.
- A32 instructions were previously called ARM instructions, and A32 state was previously called ARM state.
- See also* [A64 instruction](#), [T32 instruction](#)
- A64 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.
- See also* [A32 instruction](#), [T32 instruction](#)
- AArch32** The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets
- See also* [AArch64](#), [A32 instruction](#), [T32 instruction](#).
- AArch64** The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.
- See also* [AArch32](#), [A64 instruction](#).
- Abort** An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.
- Addressing mode** Means a method for generating the memory address used by a load/store instruction.

- Advanced SIMD** A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.
- Aligned** A data item stored at an address that is divisible by the highest power of 2 that divides into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.
- An aligned access is one where the address of the access is aligned to the size of each element of the access.
- Architecturally executed** An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.
- In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.
- See also [Condition code check](#).
- ARM core registers** Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:
- The thirteen general-purpose registers, R0-R12, that software can use for processing.
  - SP, the *stack pointer*, that can also be referred to as R13.
  - LR, the *link register*, that can also be referred to as R14.
  - PC, the *program counter*, that can also be referred to as R15.
- See also [General-purpose registers](#).
- ARM instruction** See [A32 instruction](#).
- Associativity** See [Cache associativity](#).
- Atomicity** Describes either single-copy atomicity or multi-copy atomicity. [Atomicity in the ARM architecture on page B2-79](#) defines these forms of atomicity for the ARM architecture.
- See also [Multi-copy atomicity](#), [Single-copy atomicity](#).
- Banked register** A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.
- Base register** A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.
- Base register writeback** Describes writing back a modified value to the base register used in an address calculation.
- Big-endian memory** Means that, for example:
- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
  - A byte at a halfword-aligned address is the most significant byte in the halfword at that address.
- Blocking** Describes an operation that does not permit following instructions to be executed before the operation completes.
- A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

**Branch prediction**

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also [Prefetching](#).

**Breakpoint**

A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

**Byte**

An 8-bit data item.

**Cache associativity**

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

**Cache level**

The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information see [Terms used in describing the maintenance instructions on page D4-1680](#).

**Cache line**

The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

**Cache lockdown**

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

**Cache miss**

A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

**Cache sets**

Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

**Cache way**

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

**Coherence order**

See [Coherent](#).

**Coherent**

Data accesses from a set of observers to a memory location are coherent if accesses to that memory location by the members of the set of observers are consistent with there being a single total order of all writes to that memory location by all members of the set of observers. This single total order of all writes to that memory location is the *coherence order* for that location.

**Condition code check**

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of the [ITSTATE](#) register determines whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

**Condition code field**

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

**Condition flags**

The N, Z, C, and V bits of PSTATE, or of the APSR, CPSR, SPSR, or FPSCR. See the register descriptions for more information.

See also [Condition code check](#), [PSTATE](#).

**Conditional execution**

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

See also [Condition code check](#).

**CONSTRAINED UNPREDICTABLE**

Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

See also [UNPREDICTABLE](#).

**Context switch** The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

**Context synchronization operation**

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

The architecture requires a context synchronization operation to guarantee visibility of any change to a system control register.

**Digital signal processing (DSP)**

Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

**Direct Memory Access (DMA)**

An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

**DMA** See [Direct Memory Access \(DMA\)](#).

**DNM** See [Do-Not-Modify \(DNM\)](#).

**Domain** In the ARM architecture, *domain* is used in the following contexts.

**Shareability domain** Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

**Power domain** Defines a block of logic with a single, common, power supply.

**Memory regions domain**

When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register (DACR)*. ARM deprecates any use of memory regions domains.

**Do-Not-Modify (DNM)**

Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

**Double-precision value**

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the IEEE 754 standard.

**Deprecated**

Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also [OPTIONAL](#).

**Doubleword**

A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

- Doubleword-aligned**  
Means that the address is divisible by 8.
- DSP**  
*See* [Digital signal processing \(DSP\)](#).
- Endianness**  
An aspect of the system memory mapping.  
*See also* [Big-endian memory](#) and [Little-endian memory](#).
- Exception**  
Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.
- Exception vector**  
A fixed address that contains the address of the first instruction of the corresponding exception handler.
- Execution stream**  
The stream of instructions that would have been executed by sequential execution of the program.
- Explicit access**  
A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.
- External abort**  
An abort that is generated by the external memory system.
- Fast Context Switch Extension (FCSE)**  
Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:
- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
  - Obsolete from the introduction of the Multiprocessing Extensions.
- FCSE**  
*See* [Fast Context Switch Extension \(FCSE\)](#).
- Flat address mapping**  
Is where the physical address for every access is equal to its virtual address.
- Flush-to-zero mode**  
A special processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.
- General-purpose registers**  
The registers that the base instructions use for processing:
- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.
 

———— **Note** —————

Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

—————
  - In AArch64 state the general-purpose registers are:
    - W0-W30 when accessed as 32-bit registers.
    - X0-X30 when accessed as 64-bit registers.
- See also* [High registers](#), [Low registers](#).
- Halfword**  
A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.
- Halfword-aligned**  
Means that the address is divisible by 2.

<b>High registers</b>	InAArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.
	<p>———— <b>Note</b> —————</p> <ul style="list-style-type: none"> <li>• In some contexts, <i>high registers</i> refers to R8-R15, meaning R8-R14 and the PC.</li> </ul> <p>—————</p>
	<i>See also</i> <a href="#">General-purpose registers</a> , <a href="#">Low registers</a> .
<b>High vectors</b>	An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.
<b>Immediate and offset fields</b>	Are unsigned unless otherwise stated.
<b>Immediate value</b>	A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.
<b>IMP</b>	An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.
<b>IMPLEMENTATION DEFINED</b>	Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations. In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.
<b>Index register</b>	A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.
<b>Inline literals</b>	These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.
<b>Intermediate Physical Address (IPA)</b>	An implementation of virtualization, the address to which an Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.  <i>See also</i> <a href="#">Physical address (PA)</a> , <a href="#">Virtual address (VA)</a> .
<b>Interworking</b>	A method of working that permits branches between software using the A32 and T32 instruction sets.
<b>IPA</b>	<i>See</i> <a href="#">Intermediate Physical Address (IPA)</a> .
<b>Level</b>	<i>See</i> <a href="#">Cache level</a> .
<b>Level of coherence (LoC)</b>	The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information see <a href="#">Terms used in describing the maintenance instructions on page D4-1680</a> .  <i>See also</i> <a href="#">Cache level</a> , <a href="#">Point of coherency (PoC)</a> .
<b>Level of unification, Inner Shareable (LoUIS)</b>	The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information see <a href="#">Terms used in describing the maintenance instructions on page D4-1680</a> .  <i>See also</i> <a href="#">Cache level</a> , <a href="#">Point of unification (PoU)</a> .
<b>Level of unification, uniprocessor (LoUU)</b>	For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information see <a href="#">Terms used in describing the maintenance instructions on page D4-1680</a> .  <i>See also</i> <a href="#">Cache level</a> , <a href="#">Point of unification (PoU)</a> .
<b>Line</b>	<i>See</i> <a href="#">Cache line</a> .

**Little-endian memory**

Means that:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

**Load/Store architecture**

An architecture where data-processing operations only operate on register contents, not directly on memory contents.

**LoC**

See [Level of coherence \(LoC\)](#).

**LoUIS**

See [Level of unification, Inner Shareable \(LoUIS\)](#).

**LoUU**

See [Level of unification, uniprocessor \(LoUU\)](#).

**Lockdown**

See [Cache lockdown](#).

**Low registers**

InAArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also [General-purpose registers](#). [High registers](#).

**Memory barrier**

See [Memory barriers on page B2-85](#)

**Memory coherency**

The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

**Memory Management Unit (MMU)**

Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

**Memory Protection Unit (MPU)**

A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

**Miss**

See [Cache miss](#).

**MMU**

See [Memory Management Unit \(MMU\)](#).

**MPU**

See [Memory Protection Unit \(MPU\)](#).

**Multi-copy atomicity**

The form of atomicity described in [Requirements for multi-copy atomicity on page B2-80](#).

See also [Atomicity](#), [Single-copy atomicity](#).

**NaN**

Special floating-point values that can be used when neither a numeric value nor an infinity is appropriate. NaNs can be *quiet* NaNs that propagate through most floating-point operations, or *signaling* NaNs that cause Invalid Operation floating-point exceptions when used. For more information, see the IEEE 754 standard.

**Natural eviction**

A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as a cache maintenance operation. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

**Observer**

A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

**Obsolete**

Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

**Offset addressing**

Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

**OPTIONAL**

When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a feature to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.  
A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.
- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

**Note:** Do not confuse these ARM-specific uses of OPTIONAL with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the `SCTLR.IE` bit indicates the implemented option.

See also [Deprecated](#).

**PA**

See [Physical address \(PA\)](#).

**PE**

See [Processing element \(PE\)](#).

**Physical address (PA)**

An address that identifies a location in the physical memory map.

See also [Intermediate Physical Address \(IPA\)](#), [Virtual address \(VA\)](#).

**PoC**

See [Point of coherency \(PoC\)](#).

**PoU**

See [Point of unification \(PoU\)](#).

**Point of coherency (PoC)**

For a particular MVA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information see [Terms used in describing the maintenance instructions on page D4-1680](#).

**Point of unification (PoU)**

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information see [Terms used in describing the maintenance instructions on page D4-1680](#).

**Post-indexed addressing**

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

**Prefetching**

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

**Note**, in particular, that the Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

**Pre-indexed addressing**

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

**Processing element (PE)**

The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

**Protection region**

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

**Protection Unit** See [Memory Protection Unit \(MPU\)](#).

**Pseudo-instruction**

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

**PSTATE**

An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also [Condition flags](#).

**Quadword**

A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

**Quadword-aligned**

Means that the address is divisible by 16.

**Quiet NaN**

A NaN that propagates unchanged through most floating-point operations.

**RAO**

See [Read-As-One \(RAO\)](#)

**RAZ**

See [Read-As-Zero \(RAZ\)](#).

**RAO/SBOP**

In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In ARMv8, RES1 replaces this description.

See also [UNK/SBOP](#), [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

**RAO/WI**

Read-As-One, Writes Ignored.

Hardware must implement the field as read as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [Read-As-One \(RAO\)](#).

**RAZ/SBZP**

In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In ARMv8, RES0 replaces this description.

See also [UNK/SBZP](#), [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

**RAZ/WI**

Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [Read-As-Zero \(RAZ\)](#).

**Read-allocate cache**

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

**Read-As-One (RAO)**

Hardware must implement the field as reading as all 1s.

Software can rely on the field reading as all 1s.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

**Read-As-Zero (RAZ)**

Hardware must implement the field as reading as all 0s.

Software can rely on the field reading as all 0s.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

**Read, modify, write**

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

**RES0**

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

This definition of RES0 applies only to a bit or field that is RES0 in all contexts. In the ARM architecture a small number of fields are RES0 in one context, and have different behavior in another context. An extended definition of RES0 applies to these bits, see [Fixed values in instruction and register descriptions on page C4-230](#).

In body text, the term RES0 is shown in SMALL CAPITALS.

See also [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), UNKNOWN.

**RES1**

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

This definition of RES1 applies only to a bit or field that is RES1 in all contexts. In the ARM architecture a small number of fields are RES1 in one context, and have different behavior in another context. An extended definition of RES1 applies to these bits, see [Fixed values in instruction and register descriptions on page C4-230](#).

In body text, the term RES1 is shown in SMALL CAPITALS.

See also [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), UNKNOWN.

**Reserved**

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW register, RES0.
  - In an RO register, UNK.
  - In a WO register, RES0.

**RISC**

Reduced Instruction Set Computer.

**Rounding error**

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

**Rounding mode**

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format.

**Round to Nearest (RN) mode**

Means that the rounded result is the nearest representable number to the unrounded result.

**Round towards Plus Infinity (RP) mode**

Means that the rounded result is the nearest representable number that is greater than or equal to the exact result.

**Round towards Minus Infinity (RM) mode**

Means that the rounded result is the nearest representable number that is less than or equal to the exact result.

**Round towards Zero (RZ) mode**

Means that results are rounded to the nearest representable number that is no greater in magnitude than the unrounded result.

**Saturated arithmetic**

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from  $+2^{31}-1$  to  $-2^{31}$  or vice versa.

**SBO** See [Should-Be-One \(SBO\)](#).

**SBOP** See [Should-Be-One-or-Preserved \(SBOP\)](#).

**SBZ** See [Should-Be-Zero \(SBZ\)](#).

**SBZP** See [Should-Be-Zero-or-Preserved \(SBZP\)](#).

**Security hole**

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE. The ARM architecture forbids security holes.

**Self-modifying code**

Code that writes one or more instructions to memory and then executes them. When using self-modifying code you must use cache maintenance and barrier instructions to ensure synchronization. For more information see [Caches and memory hierarchy](#) on page B2-70.

**Set** See [Cache sets](#).

**Should-Be-One (SBO)**

Hardware must ignore writes to the field.

Software should write the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

**Should-Be-One-or-Preserved (SBOP)**

From the introduction of the ARMv7 Large Physical Address Extension the definition of SBOP is modified for register bits that are SBOP in some but not all contexts. For more information see [Meaning of fixed bit values in register diagrams](#) on page G3-3711. The generic definition of SBOP given here applies only to bits that are not affected by this modification.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it should preserve the value of the field by writing the value that it previously read from the field. Otherwise, it should write the field as all 1s.

If software writes a value to the field that is not a value previously read for the field and is not all 1s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

**Should-Be-Zero (SBZ)**

Hardware must ignore writes to the field.

Software should write the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

### Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the ARMv7 Large Physical Address Extension, the definition of SBZP is modified for register bits that are SBZP in some but not all contexts. For more information see [Meaning of fixed bit values in register diagrams on page G3-3711](#). The generic definition of SBZP given here applies only to bits that are not affected by this modification.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 0s.

If software writes a value to the field that is not a value previously read for the field and is not all 0s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

**Signaling NaNs** Cause an Invalid Operation exception whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

### Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

### SIMD

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in [Parallel addition and subtraction instructions on page F1-2389](#).
- The Advanced SIMD instructions summarized in [Advanced SIMD and floating-point instructions on page E1-2303](#), when operating on vectors.

#### ———— Note —————

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

### Simple sequential execution

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

### Single-copy atomicity

The form of atomicity described in [Single-copy atomicity on page B2-79](#).

See also [Atomicity](#), [Multi-copy atomicity](#).

### Single-precision value

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the IEEE 754 standard.

### Spatial locality

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

### SUBARCHITECTURE DEFINED

Means that the behavior is expected to be specified by a subarchitecture definition. This definition might be shared by multiple implementations, but it must not be relied on by architecturally-portable software.

Subarchitecture definitions are used for:

- The interface between an ARMv7 VFP Extension implementation and its support code.
- The interface between an ARMv7 implementation of the Jazelle extension and an Enabled JVM.

In body text, the term SUBARCHITECTURE DEFINED is shown in SMALL CAPITALS.

**T32 instruction** One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions, and T32 state was previously called Thumb state.

See also [A32 instruction](#), [A64 instruction](#)

### Temporal locality

The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

### Thumb instruction

See [T32 instruction](#).

### TLB

See [Translation Lookaside Buffer \(TLB\)](#).

### TLB lockdown

A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

### Translation Lookaside Buffer (TLB)

A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

### Translation table

A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

### Translation table walk

The process of doing a full translation table lookup. It is performed automatically by hardware.

### Trap enable bits

In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

### Unaligned

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

### Unaligned memory accesses

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

### Unallocated

Except where otherwise stated, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as UNDEFINED, UNPREDICTABLE, or an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

### UNDEFINED

Indicates an instruction that generates an Undefined Instruction exception.

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also [Undefined Instruction exception on page G1-3476](#).

### Unified cache

Is a cache used for both processing instruction fetches and processing data loads and stores.

### Unindexed addressing

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0. The LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

### UNK

An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

### UNK/SBOP

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

*See also* [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

**UNK/SBZP**

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

*See also* [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

**UNKNOWN**

An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

*See also* [UNK](#).

**UNPREDICTABLE**

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution in a Non-secure EL1 or EL0 mode of an instruction that is UNPREDICTABLE can be implemented as generating a Hyp Trap exception, provided that at least one instruction that is not UNPREDICTABLE causes a Hyp Trap exception.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

*See also* [CONSTRAINED UNPREDICTABLE](#).

**VA**

*See* [Virtual address \(VA\)](#).

**VFP**

In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

**Virtual address (VA)**

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

*See also* [Intermediate Physical Address \(IPA\)](#), [Physical address \(PA\)](#).

**Watchpoint**

A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

**Way**

*See* [Cache way](#).

**Word**

A 32-bit data item. Words are normally word-aligned in ARM systems.

**Word-aligned**

Means that the address is divisible by 4.

**Write-allocate cache**

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

**Write-back cache**

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

**Write-through cache**

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

**Write buffer**

A block of high-speed memory that optimizes stores to main memory.
